Date

November 19, 2014

Welcome to wxWidgets, a stable and powerful open source framework for developing native cross-platform GUI applications in C++!

If you are new to wxWidgets, please start with the introduction and follow with the programming guides, with maybe a look at the samples as you go. If you are already familiar with wxWidgets, please read about the changes in the latest version compared to 2.8 series. And you can also follow the links in the reference section or jump directly to the `alphabetical list of classes` to find out more about the topic you are interested in.

1.1 User Manual

- Introduction
- Programming Guides
- Library List
- Overview of Available Classes
- Changes Since wxWidgets 2.8

1.2 Reference

- Class List by Category
- Functions and Macros by Category
- Constants

1.3 Other Information

- Samples Overview
- Utilities Overview
- Translations to Other Languages
- Cross-Platform Development Tips
- Copyrights and Licenses

Chapter 2

Overview of Available Classes

This page contains a summarized listing of classes, please see the Class List by Category page for a full listing by category or the `full list of classes` in alphabetical order.

For a more visual approach, see the screenshots page.

2.1 Basic Windows

The following are the most important window classes

- wxWindow: base class for all windows and controls
- wxControl: base class (mostly) for native controls/widgets
- wxPanel: window which can smartly manage child windows
- wxScrolledWindow: Window with automatically managed scrollbars (see wxScrolled)
- wxTopLevelWindow: Any top level window, dialog or frame

2.2 Window Layout

There are two different systems for laying out windows (and dialogs in particular). One is based upon so-called sizers and it requires less typing, thinking and calculating and will in almost all cases produce dialogs looking equally well on all platforms, the other is based on so-called constraints and is deprecated, though still available.

Related Overviews: Sizers Overview

These are the classes relevant to sizer-based layout:

- wxSizer: Abstract base class
- wxBoxSizer: A sizer for laying out windows in a row or column
- wxGridSizer: A sizer for laying out windows in a grid with all fields having the same size
- wxFlexGridSizer: A sizer for laying out windows in a flexible grid
- wxGridBagSizer: Another grid sizer that lets you specify the cell an item is in, and items can span rows and/or columns.
- wxStaticBoxSizer: Same as wxBoxSizer, but with a surrounding static box
- wxWrapSizer: A sizer which wraps its child controls as size permits

Other layout classes:

- wxLayoutAlgorithm: An alternative window layout facility

2.3 Managed Windows

There are several types of window that are directly controlled by the window manager (such as MS Windows, or the Motif Window Manager). Frames and dialogs are similar in wxWidgets, but only dialogs may be modal.

Related Overviews: Common Dialogs

- wxDialog: Dialog box
- wxFrame: Normal frame
- wxMDIChildFrame: MDI child frame
- wxMDIParentFrame: MDI parent frame
- wxMiniFrame: A frame with a small title bar
- wxPopupWindow: A toplevel window without decorations, e.g. for a combobox pop-up
- wxPropertySheetDialog: Property sheet dialog
- wxSplashScreen: Splash screen class
- wxTipWindow: Shows text in a small window
- wxWizard: A wizard dialog

2.4 Menus

- wxMenu: Displays a series of menu items for selection
- wxMenuBar: Contains a series of menus for use with a frame
- wxMenuItem: Represents a single menu item

2.5 Controls

Typically, these are small windows which provide interaction with the user. Controls that are not static can have wxValidator associated with them.

- wxAnimationCtrl: A control to display an animation
- wxControl: The base class for controls
- wxBitmapButton: Push button control, displaying a bitmap
- wxBitmapComboBox: A combobox with bitmaps next to text items
- wxBitmapToggleButton: A toggle button with bitmaps.
- wxButton: Push button control, displaying text
- wxCalendarCtrl: Control showing an entire calendar month
- wxCheckBox: Checkbox control

- wxCheckListBox: A listbox with a checkbox to the left of each item
- wxChoice: Choice control (a combobox without the editable area)
- wxCollapsiblePane: A panel which can be shown/hidden by the user
- wxComboBox: A choice with an editable area
- wxComboCtrl: A combobox with application defined popup
- wxDataViewCtrl: A control to display tabular or tree like data
- wxDataViewTreeCtrl: A specialized wxDataViewCtrl with a wxTreeCtrl-like API
- wxDataViewListCtrl: A specialized wxDataViewCtrl for displaying and editing simple tables.
- wxEditableListBox: A listbox with editable items.
- wxFileCtrl: A control for selecting a file. Useful for custom file dialogs.
- wxGauge: A control to represent a varying quantity, such as time remaining
- wxGenericDirCtrl: A control for displaying a directory tree
- wxGrid: A control to display spread-sheet like data in tabular form
- wxHeaderCtrl: a small control to display the top header of tabular data
- wxHtmlListBox: An abstract class for creating listboxes showing HTML content
- wxHyperlinkCtrl: A static text which opens an URL when clicked
- wxListBox: A list of strings for single or multiple selection
- wxListCtrl: A control for displaying lists of strings and/or icons, plus a multicolumn report view
- wxListView: A simpler interface (façade) for wxListCtrl in report mode
- wxNotebook: A notebook class
- wxOwnerDrawnComboBox: A combobox with owner-drawn list items
- wxPropertyGrid: A complex control to display hierachical, editable information
- wxRadioBox: A group of radio buttons
- wxRadioButton: A round button to be used with others in a mutually exclusive way
- wxRearrangeCtrl: A control allowing the user to rearrange a list of items.
- wxRichTextCtrl: Generic rich text editing control
- wxSimpleHtmlListBox: A listbox showing HTML content
- wxStaticBox: A static, or group box for visually grouping related controls
- wxScrollBar: Scrollbar control
- wxSearchCtrl: A text input control used to initiate a search
- wxSpinButton: A spin or 'up-down' control
- wxSpinCtrl: A spin control - i.e. spin button and text control displaying an integer
- wxSpinCtrlDouble: A spin control - i.e. spin button and text control displaying a real number
- wxStaticText: One or more lines of non-editable text
- wxTextCtrl: Single or multiline text editing control
- wxToggleButton: A button which stays pressed when clicked by user.

- wxTreeCtrl: Tree (hierarchy) control
- wxTreeListCtrl: Multi-column tree control with simple interface
- wxStaticBitmap: A control to display a bitmap
- wxStyledTextCtrl: A wxWidgets implementation of the Scintilla source code editing component for plain text editing.
- wxSlider: A slider that can be dragged by the user
- wxVListBox: A listbox supporting variable height rows

2.6 Validators

These are the window validators, used for filtering and validating user input.

Related Overviews: wxValidator Overview

- wxValidator: Base validator class
- wxTextValidator: Text control validator class
- wxGenericValidator: Generic control validator class
- wxIntegerValidator: Text control validator class for integer numbers
- wxFloatingPointValidator: Text control validator class for floating point numbers

2.7 Picker Controls

These controls provide the user with the possibility to choose something (file or directory, font or colour, ...) directly from the window containing them.

- wxColourPickerCtrl: A control which allows the user to choose a colour
- wxDirPickerCtrl: A control which allows the user to choose a directory
- wxFilePickerCtrl: A control which allows the user to choose a file
- wxFontPickerCtrl: A control which allows the user to choose a font
- wxDatePickerCtrl: Small date picker control

2.8 Miscellaneous Windows

The following are a variety of classes that are derived from wxWindow.

- wxCollapsiblePane: A panel which can be shown/hidden by the user
- wxPanel: A window whose colour changes according to current user settings
- wxScrolledWindow: Window with automatically managed scrollbars (see wxScrolled)
- wxHScrolledWindow: As wxScrolledWindow but supports columns of variable widths
- wxVScrolledWindow: As wxScrolledWindow but supports rows of variable heights
- wxHVScrolledWindow: As wxScrolledWindow but supports scroll units of variable sizes.

- wxGrid: A grid (table) window
- wxInfoBar: An information bar usually shown on top of the main window.
- wxRichToolTip: A customizable tooltip.
- wxSplitterWindow: Window which can be split vertically or horizontally
- wxStatusBar: Implements the status bar on a frame
- wxToolBar: Toolbar class
- wxNotebook: Notebook class
- wxListbook: Similar to notebook but using list control
- wxChoicebook: Similar to notebook but using choice control
- wxTreebook: Similar to notebook but using tree control
- wxSashWindow: Window with four optional sashes that can be dragged
- wxSashLayoutWindow: Window that can be involved in an IDE-like layout arrangement
- wxSimplebook: Another book control but one allowing only the program, not the user, to change its current page.
- wxWizardPage: A base class for the page in wizard dialog.
- wxWizardPageSimple: A page in wizard dialog.
- wxCustomBackgroundWindow: A window allowing to set a custom bitmap.

2.9 Window Docking (wxAUI)

wxAUI is a set classes for writing a customizable application interface with built-in docking, floatable panes and a flexible MDI-like interface.

Related Overviews: wxAUI Overview

- wxAuiManager: The central class for managing the interface
- wxAuiNotebook: A replacement notebook class with extra features
- wxAuiPaneInfo: Describes a single pane
- wxAuiDockArt: Art and metrics provider for customizing the docking user interface
- wxAuiTabArt: Art and metrics provider for customizing the notebook user interface

2.10 Common Dialogs

Common dialogs are ready-made dialog classes which are frequently used in an application.

Related Overviews: Common Dialogs

- wxDialog: Base class for common dialogs
- wxColourDialog: Colour chooser dialog
- wxDirDialog: Directory selector dialog
- wxFileDialog: File selector dialog

- wxFindReplaceDialog: Text search/replace dialog
- wxFontDialog: Font chooser dialog
- wxMessageDialog: Simple message box dialog
- wxMultiChoiceDialog: Dialog to get one or more selections from a list
- wxPageSetupDialog: Standard page setup dialog
- wxPasswordEntryDialog: Dialog to get a password from the user
- wxPrintDialog: Standard print dialog
- wxProgressDialog: Progress indication dialog
- wxRearrangeDialog: Dialog allowing the user to rearrange a list of items.
- wxRichTextFormattingDialog: A dialog for formatting the content of a wxRichTextCtrl
- wxRichMessageDialog: Nicer message box dialog
- wxSingleChoiceDialog: Dialog to get a single selection from a list and return the string
- wxSymbolPickerDialog: Symbol selector dialog
- wxTextEntryDialog: Dialog to get a single line of text from the user
- wxWizard: A wizard dialog.

2.11 HTML

wxWidgets provides a set of classes to display text in HTML format. These classes include a help system based on the HTML widget.

- wxHtmlHelpController: HTML help controller class
- wxHtmlWindow: HTML window class
- wxHtmlEasyPrinting: Simple class for printing HTML
- wxHtmlPrintout: Generic HTML wxPrintout class
- wxHtmlParser: Generic HTML parser class
- wxHtmlTagHandler: HTML tag handler, pluginable into wxHtmlParser
- wxHtmlWinParser: HTML parser class for wxHtmlWindow
- wxHtmlWinTagHandler: HTML tag handler, pluginable into wxHtmlWinParser

2.12 Device Contexts

Device contexts are surfaces that may be drawn on, and provide an abstraction that allows parameterisation of your drawing code by passing different device contexts.

Related Overviews: Device Contexts

- wxAutoBufferedPaintDC: A helper device context for double buffered drawing inside **OnPaint()**.
- wxBufferedDC: A helper device context for double buffered drawing.
- wxBufferedPaintDC: A helper device context for double buffered drawing inside **OnPaint()**.

- wxClientDC: A device context to access the client area outside **OnPaint()** events
- wxPaintDC: A device context to access the client area inside **OnPaint()** events
- wxWindowDC: A device context to access the non-client area
- wxScreenDC: A device context to access the entire screen
- wxDC: The device context base class
- wxMemoryDC: A device context for drawing into bitmaps
- wxMetafileDC: A device context for drawing into metafiles
- wxMirrorDC: A proxy device context allowing for simple mirroring.
- wxPostScriptDC: A device context for drawing into PostScript files
- wxPrinterDC: A device context for drawing to printers

2.13 Graphics Context classes

These classes are related to drawing using a new vector based drawing API and are based on the modern drawing backend GDI+, CoreGraphics and Cairo.

- wxGraphicsRenderer: Represents a drawing engine.
- wxGraphicsContext: Represents a graphics context currently being drawn on.
- wxGraphicsBrush: Brush for drawing into a wxGraphicsContext
- wxGraphicsPen: Pen for drawing into a wxGraphicsContext
- wxGraphicsFont: Font for drawing text on a wxGraphicsContext
- wxGraphicsMatrix: Represents an affine matrix for drawing transformation
- wxGraphicsPath: Represents a path for drawing

2.14 Graphics Device Interface

These classes are related to drawing on device contexts and windows.

- wxColour: Represents the red, blue and green elements of a colour
- wxDCClipper: Wraps the operations of setting and destroying the clipping region
- wxBrush: Used for filling areas on a device context
- wxBrushList: The list of previously-created brushes
- wxFont: Represents fonts
- wxFontList: The list of previously-created fonts
- wxPen: Used for drawing lines on a device context
- wxPenList: The list of previously-created pens
- wxPalette: Represents a table of indices into RGB values
- wxRegion: Represents a simple or complex region on a window or device context
- wxRendererNative: Abstracts high-level drawing primitives

2.15 Image and bitmap classes

These classes represent images and bitmap in various formats and ways to access and create them.

Related Overviews: Bitmaps and Icons

- wxAnimation: Represents an animation
- wxBitmap: Represents a platform dependent bitmap
- wxBitmapHandler: Class for loading a saving a wxBitmap in a specific format
- wxCursor: A small, transparent bitmap representing the cursor
- wxIcon: A small, transparent bitmap for assigning to frames and drawing on device contexts
- wxImage: A platform-independent image class
- wxImageHandler: Class for loading a saving a wxImage in a specific format
- wxImageList: A list of images, used with some controls
- wxMask: Represents a mask to be used with a bitmap for transparent drawing
- wxMemoryDC: A device context for drawing into bitmaps
- wxPixelData: Class template for direct access to wxBitmap's and wxImage's internal data

2.16 Events

An event object contains information about a specific event. Event handlers (usually member functions) have a single, event argument.

Related Overviews: Events and Event Handling

- wxActivateEvent: A window or application activation event
- wxCalendarEvent: Used with wxCalendarCtrl
- wxCalculateLayoutEvent: Used to calculate window layout
- wxChildFocusEvent: A child window focus event
- wxClipboardTextEvent: A clipboard copy/cut/paste treebook event event
- wxCloseEvent: A close window or end session event
- wxCommandEvent: An event from a variety of standard controls
- wxContextMenuEvent: An event generated when the user issues a context menu command
- wxDateEvent: Used with wxDatePickerCtrl
- wxDialUpEvent: Event send by wxDialUpManager
- wxDropFilesEvent: A drop files event
- wxEraseEvent: An erase background event
- wxEvent: The event base class
- wxFindDialogEvent: Event sent by wxFindReplaceDialog
- wxFocusEvent: A window focus event
- wxKeyEvent: A keypress event

- wxIconizeEvent: An iconize/restore event
- wxIdleEvent: An idle event
- wxInitDialogEvent: A dialog initialisation event
- wxJoystickEvent: A joystick event
- wxKeyboardState: State of the keyboard modifiers.
- wxListEvent: A list control event
- wxMaximizeEvent: A maximize event
- wxMenuEvent: A menu event
- wxMouseCaptureChangedEvent: A mouse capture changed event
- wxMouseCaptureLostEvent: A mouse capture lost event
- wxMouseEvent: A mouse event
- wxMouseState: State of the mouse
- wxMoveEvent: A move event
- wxNavigationKeyEvent: An event set by navigation keys such as tab
- wxNotebookEvent: A notebook control event
- wxNotifyEvent: A notification event, which can be vetoed
- wxPaintEvent: A paint event
- wxProcessEvent: A process ending event
- wxQueryLayoutInfoEvent: Used to query layout information
- wxRichTextEvent: A rich text editing event
- wxScrollEvent: A scroll event from sliders, stand-alone scrollbars and spin buttons
- wxScrollWinEvent: A scroll event from scrolled windows
- wxSizeEvent: A size event
- wxSocketEvent: A socket event
- wxSpinEvent: An event from wxSpinButton
- wxSplitterEvent: An event from wxSplitterWindow
- wxSysColourChangedEvent: A system colour change event
- wxTimerEvent: A timer expiration event
- wxTreebookEvent: A treebook control event
- wxTreeEvent: A tree control event
- wxUpdateUIEvent: A user interface update event
- wxWindowCreateEvent: A window creation event
- wxWindowDestroyEvent: A window destruction event
- wxWizardEvent: A wizard event

2.17 Application and Process Management

- wxApp: Application class
- wxCmdLineParser: Command line parser class
- wxDynamicLibrary: Class to work with shared libraries.
- wxProcess: Process class

2.18 Printing Framework

A printing and previewing framework is implemented to make it relatively straightforward to provide document printing facilities.

Related Overviews: Printing Framework Overview

- wxPreviewFrame: Frame for displaying a print preview
- wxPreviewCanvas: Canvas for displaying a print preview
- wxPreviewControlBar: Standard control bar for a print preview
- wxPrintDialog: Standard print dialog
- wxPageSetupDialog: Standard page setup dialog
- wxPrinter: Class representing the printer
- wxPrinterDC: Printer device context
- wxPrintout: Class representing a particular printout
- wxPrintPreview: Class representing a print preview
- wxPrintData: Represents information about the document being printed
- wxPrintDialogData: Represents information about the print dialog
- wxPageSetupDialogData: Represents information about the page setup dialog

2.19 Document/View Framework

wxWidgets supports a document/view framework which provides housekeeping for a document-centric application.

Related Overviews: Document/View Framework

- wxCommand: Base class for undo/redo actions
- wxCommandProcessor: Maintains the undo/redo stack
- wxDocument: Represents a document
- wxView: Represents a view
- wxDocTemplate: Manages the relationship between a document class and a view class
- wxDocManager: Manages the documents and views in an application
- wxDocChildFrame: A child frame for showing a document view
- wxDocParentFrame: A parent frame to contain views
- wxDocMDIChildFrame: An MDI child frame for showing a document view
- wxDocMDIParentFrame: An MDI parent frame to contain views
- wxFileHistory: Maintains a list of the most recently visited files

2.20 Clipboard and Drag & Drop

Related Overviews: Drag and Drop Overview

- wxDataObject: Data object class
- wxDataFormat: Represents a data format
- wxTextDataObject: Text data object class
- wxFileDataObject: File data object class
- wxBitmapDataObject: Bitmap data object class
- wxURLDataObject: URL data object class
- wxCustomDataObject: Custom data object class
- wxClipboard: Clipboard class
- wxDropTarget: Drop target class
- wxFileDropTarget: File drop target class
- wxTextDropTarget: Text drop target class
- wxDropSource: Drop source class

2.21 Virtual File System

wxWidgets provides a set of classes that implement an extensible virtual file system, used internally by the HTML classes.

- wxFSFile: Represents a file in the virtual file system
- wxFileSystem: Main interface for the virtual file system
- wxFileSystemHandler: Class used to announce file system type

2.22 Threading

wxWidgets provides a set of classes to make use of the native thread capabilities of the various platforms.

Related Overviews: Multithreading Overview

- wxThread: Thread class
- wxThreadHelper: Manages background threads easily
- wxMutex: Mutex class
- wxMutexLocker: Mutex locker utility class
- wxCriticalSection: Critical section class
- wxCriticalSectionLocker: Critical section locker utility class
- wxCondition: Condition class
- wxSemaphore: Semaphore class

2.23 Runtime Type Information (RTTI)

wxWidgets supports runtime manipulation of class information, and dynamic creation of objects given class names.

Related Overviews: Runtime Type Information (RTTI)

See also

RTTI Functions and Macros

- wxClassInfo: Holds runtime class information
- wxObject: Root class for classes with runtime information

2.24 Debugging

wxWidgets supports some aspects of debugging an application through classes, functions and macros.

Related Overviews: Debugging

See also

Debugging Functions and Macros

- wxDebugContext: Provides memory-checking facilities
- wxDebugReport: Base class for creating debug reports in case of a program crash.
- wxDebugReportCompress: Class for creating compressed debug reports.
- wxDebugReportUpload: Class for uploading compressed debug reports via HTTP.
- wxDebugReportPreview: Abstract base class for previewing the contents of a debug report.
- wxDebugReportPreviewStd: Standard implementation of wxDebugReportPreview.

2.25 Logging

wxWidgets provides several classes and functions for message logging.

Related overview: Logging Overview

See also

Logging Functions and Macros

- wxLog: The base log class
- wxLogStderr: Log messages to a C STDIO stream
- wxLogStream: Log messages to a C++ iostream
- wxLogTextCtrl: Log messages to a wxTextCtrl
- wxLogWindow: Log messages to a log frame
- wxLogGui: Default log target for GUI programs
- wxLogNull: Temporarily suppress message logging
- wxLogChain: Allows to chain two log targets
- wxLogInterposer: Allows to filter the log messages
- wxLogInterposerTemp: Allows to filter the log messages
- wxStreamToTextRedirector: Allows to redirect output sent to `cout` to a wxTextCtrl

2.26 Data Structures

These are the data structure classes supported by wxWidgets.

- wxAny: A class for storing arbitrary types that may change at run-time
- wxCmdLineParser: Command line parser class
- wxDateSpan: A logical time interval.
- wxDateTime: A class for date/time manipulations
- wxLongLong: A portable 64 bit integer type
- wxObject: The root class for most wxWidgets classes
- wxPathList: A class to help search multiple paths
- wxPoint: Representation of a point
- wxRect: A class representing a rectangle
- wxRegEx: Regular expression support
- wxRegion: A class representing a region
- wxString: A string class
- wxStringTokenizer: A class for interpreting a string as a list of tokens or words
- wxRealPoint: Representation of a point using floating point numbers
- wxSize: Representation of a size
- wxTimeSpan: A time interval.
- wxURI: Represents a Uniform Resource Identifier
- wxVariant: A class for storing arbitrary types that may change at run-time

2.27 Text Conversion

These classes define objects for performing conversions between different multibyte and Unicode encodings and wide character strings.

- wxMBConv: Base class for all converters, defines the API implemented by all the other converter classes.
- wxMBConvUTF7: Converter for UTF-7
- wxMBConvUTF8: Converter for UTF-8
- wxMBConvUTF16: Converter for UTF-16
- wxMBConvUTF32: Converter for UTF-32
- wxCSConv: Converter for any system-supported encoding which can be specified by name.

Related Overviews: wxMBConv Overview

2.28 Containers

These are classes, templates and class macros are used by wxWidgets. Most of these classes provide a subset or almost complete STL API.

Related Overviews: Container Classes

- wxArray<T>: A type-safe dynamic array implementation (macro based)
- wxArrayString: An efficient container for storing wxString objects
- wxHashMap<T>: A type-safe hash map implementation (macro based)
- wxHashSet<T>: A type-safe hash set implementation(macro based)
- wxHashTable: A simple hash table implementation (deprecated, use wxHashMap)
- wxList<T>: A type-safe linked list implementation (macro based)
- wxVector<T>: Template base vector implementation identical to std::vector

2.29 Smart Pointers

wxWidgets provides a few smart pointer class templates.

- wxObjectDataPtr<T>: A shared pointer (using intrusive reference counting)
- wxScopedPtr<T>: A scoped pointer
- wxSharedPtr<T>: A shared pointer (using non-intrusive reference counting)
- wxWeakRef<T>: A weak reference

2.30 File Handling

wxWidgets has several small classes to work with disk files and directories.

Related overview: File Classes and Functions

- wxFileName: Operations with the file name and attributes
- wxDir: Class for enumerating files/subdirectories.
- wxDirTraverser: Class used together with wxDir for recursively enumerating the files/subdirectories
- wxFile: Low-level file input/output class.
- wxFFile: Another low-level file input/output class.
- wxTempFile: Class to safely replace an existing file
- wxTextFile: Class for working with text files as with arrays of lines
- wxStandardPaths: Paths for standard directories
- wxPathList: A class to help search multiple paths
- wxFileSystemWatcher: Class providing notifications of file system changes

2.31 Streams

wxWidgets has its own set of stream classes as an alternative to the standard stream libraries and to provide enhanced functionality.

Related overview: Stream Classes Overview

- wxStreamBase: Stream base class
- wxStreamBuffer: Stream buffer class
- wxInputStream: Input stream class
- wxOutputStream: Output stream class
- wxCountingOutputStream: Stream class for querying what size a stream would have.
- wxFilterInputStream: Filtered input stream class
- wxFilterOutputStream: Filtered output stream class
- wxBufferedInputStream: Buffered input stream class
- wxBufferedOutputStream: Buffered output stream class
- wxMemoryInputStream: Memory input stream class
- wxMemoryOutputStream: Memory output stream class
- wxDataInputStream: Platform-independent binary data input stream class
- wxDataOutputStream: Platform-independent binary data output stream class
- wxTextInputStream: Platform-independent text data input stream class
- wxTextOutputStream: Platform-independent text data output stream class
- wxFileInputStream: File input stream class
- wxFileOutputStream: File output stream class
- wxFFileInputStream: Another file input stream class
- wxFFileOutputStream: Another file output stream class
- wxTempFileOutputStream: Stream to safely replace an existing file
- wxStringInputStream: String input stream class
- wxStringOutputStream: String output stream class
- wxZlibInputStream: Zlib and gzip (compression) input stream class
- wxZlibOutputStream: Zlib and gzip (compression) output stream class
- wxZipInputStream: Input stream for reading from ZIP archives
- wxZipOutputStream: Output stream for writing from ZIP archives
- wxTarInputStream: Input stream for reading from tar archives
- wxTarOutputStream: Output stream for writing from tar archives
- wxSocketInputStream: Socket input stream class
- wxSocketOutputStream: Socket output stream class

2.32 XML

- wxXmlDocument: A class to parse XML files
- wxXmlNode: A class which represents XML nodes
- wxXmlAttribute: A class which represent an XML attribute

2.33 Archive

- wxArchiveInputStream
- wxArchiveOutputStream
- wxArchiveEntry

2.34 XML Based Resource System (XRC)

Resources allow your application to create controls and other user interface elements from specifications stored in an XML format.

Related overview: XML Based Resource System (XRC)

- wxXmlResource: The main class for working with resources
- wxXmlResourceHandler: The base class for XML resource handlers

2.35 Networking

wxWidgets provides its own classes for socket based networking.

- wxDialUpManager: Provides functions to check the status of network connection and to establish one
- wxIPV4address: Represents an Internet address
- wxIPaddress: Represents an Internet address
- wxSocketBase: Represents a socket base object
- wxSocketClient: Represents a socket client
- wxSocketServer: Represents a socket server
- wxSocketEvent: A socket event
- wxFTP: FTP protocol class
- wxHTTP: HTTP protocol class
- wxURL: Represents a Universal Resource Locator

2.36 Interprocess Communication

wxWidgets provides simple interprocess communications facilities based on Windows DDE, but available on most platforms using TCP.

Related overview: Interprocess Communication

- wxClient, wxDDEClient: Represents a client
- wxConnection, wxDDEConnection: Represents the connection between a client and a server
- wxServer, wxDDEServer: Represents a server

2.37 Help

- wxHelpController: Family of classes for controlling help windows
- wxHtmlHelpController: HTML help controller class
- wxContextHelp: Class to put application into context-sensitive help mode
- wxContextHelpButton: Button class for putting application into context-sensitive help mode
- wxHelpProvider: Abstract class for context-sensitive help provision
- wxSimpleHelpProvider: Class for simple context-sensitive help provision
- wxHelpControllerHelpProvider: Class for context-sensitive help provision via a help controller
- wxToolTip: Class implementing tooltips

2.38 Multimedia

- wxMediaCtrl: Display multimedia contents.

2.39 OpenGL

- wxGLCanvas: Canvas that you can render OpenGL calls to.
- wxGLContext: Class to ease sharing of OpenGL data resources.

2.40 Miscellaneous

- wxCaret: A caret (cursor) object
- wxConfigBase: Classes for reading/writing the configuration settings
- wxTimer: Timer class
- wxStopWatch: Stop watch class
- wxMimeTypesManager: MIME-types manager class
- wxSystemSettings: System settings class for obtaining various global parameters
- wxSystemOptions: System options class for run-time configuration

- wxAcceleratorTable: Accelerator table
- wxAutomationObject: OLE automation class
- wxFontMapper: Font mapping, finding suitable font for given encoding
- wxEncodingConverter: Encoding conversions
- wxCalendarDateAttr: Used with wxCalendarCtrl
- wxQuantize: Class to perform quantization, or colour reduction
- wxSingleInstanceChecker: Check that only single program instance is running

Chapter 3

Constants

This chapter describes the constants defined by wxWidgets.

- Standard Event Identifiers
- Stock Items
- Preprocessor Symbols
- wxUSE Preprocessor Symbols

3.1 Standard Event Identifiers

wxWidgets defines a special identifier value `wxID_ANY` which is used in the following two situations:

- when creating a new window you may specify `wxID_ANY` to let wxWidgets assign an unused identifier to it automatically
- when installing an event handler using either the event table macros or wxEvtHandler::Connect, you may use it to indicate that you want to handle the events coming from any control, regardless of its identifier

Another standard special identifier value is `wxID_NONE`: this is a value which is not matched by any other id.

wxWidgets also defines a few standard command identifiers which may be used by the user code and also are sometimes used by wxWidgets itself. These reserved identifiers are all in the range between `wxID_LOWEST` and `wxID_HIGHEST` and, accordingly, the user code should avoid defining its own constants in this range (e.g. by using wxNewId()).

Refer to the list of stock items for the subset of standard IDs which are stock IDs as well.

3.2 Stock Items

The following is the list of the window IDs for which stock buttons and menu items are created.

See the wxButton constructor and the wxMenuItem constructor for classes which automatically add stock bitmaps when using stock IDs.

Also note that you can retrieve stock bitmaps using wxArtProvider.

Stock ID	GTK icon	Stock label

wxID_ABOUT		&About
wxID_ADD		Add
wxID_APPLY		&Apply
wxID_BACKWARD		&Back
wxID_BOLD		&Bold
wxID_BOTTOM		&Bottom
wxID_CANCEL		&Cancel
wxID_CDROM		&CD-Rom
wxID_CLEAR		&Clear
wxID_CLOSE		&Close
wxID_CONVERT		&Convert
wxID_COPY		&Copy
wxID_CUT		Cu&t
wxID_DELETE		&Delete
wxID_DOWN		&Down
wxID_EDIT		&Edit
wxID_EXECUTE		&Execute
wxID_EXIT		&Quit
wxID_FILE		&File
wxID_FIND		&Find
wxID_FIRST		&First
wxID_FLOPPY		&Floppy
wxID_FORWARD		&Forward
wxID_HARDDISK		&Harddisk
wxID_HELP		&Help
wxID_HOME		&Home
wxID_INDENT		Indent
wxID_INDEX		&Index
wxID_INFO		&Info
wxID_ITALIC		&Italic
wxID_JUMP_TO		&Jump to
wxID_JUSTIFY_CENTER		Centered
wxID_JUSTIFY_FILL		Justified
wxID_JUSTIFY_LEFT		Align Left
wxID_JUSTIFY_RIGHT		Align Right
wxID_LAST		&Last
wxID_NETWORK		&Network
wxID_NEW		&New
wxID_NO		&No
wxID_OK		&OK
wxID_OPEN		&Open...
wxID_PASTE		&Paste
wxID_PREFERENCES		&Preferences
wxID_PREVIEW		Print previe&w
wxID_PRINT		&Print...
wxID_PROPERTIES		&Properties
wxID_REDO		&Redo

wxID_REFRESH		Refresh
wxID_REMOVE		Remove
wxID_REPLACE		Rep&lace
wxID_REVERT_TO_SAVED		Revert to Saved
wxID_SAVE		&Save
wxID_SAVEAS		Save &As...
wxID_SELECTALL		Select &All
wxID_SELECT_COLOR		&Color
wxID_SELECT_FONT		&Font
wxID_SORT_ASCENDING		&Ascending
wxID_SORT_DESCENDING		&Descending
wxID_SPELL_CHECK		&Spell Check
wxID_STOP		&Stop
wxID_STRIKETHROUGH		&Strikethrough
wxID_TOP		&Top
wxID_UNDELETE		Undelete
wxID_UNDERLINE		&Underline
wxID_UNDO		&Undo
wxID_UNINDENT		&Unindent
wxID_UP		&Up
wxID_YES		&Yes
wxID_ZOOM_100		&Actual Size
wxID_ZOOM_FIT		Zoom to &Fit
wxID_ZOOM_IN		Zoom &In
wxID_ZOOM_OUT		Zoom &Out

Note that some of the IDs listed above also have a stock accelerator and an associated help string.

3.3 Preprocessor Symbols

These are preprocessor symbols used in the wxWidgets source, grouped by category (and sorted by alphabetical order inside each category).

All of these macros except for the `wxUSE_XXX` variety is defined if the corresponding condition is true and undefined if it isn't, so they should be always tested using #ifdef and not #if.

3.3.1 GUI system

__WXBASE__	Only wxBase, no GUI features (same as wxUSE_GUI == 0)
__WXDFB__	wxUniversal using DirectFB
__WXWINCE__	Windows CE
__WXGTK__	GTK+
__WXGTK12__	GTK+ 1.2 or higher
__WXGTK20__	GTK+ 2.0 or higher
__WXGTK24__	GTK+ 2.4 or higher
__WXGTK26__	GTK+ 2.6 or higher
__WXGTK210__	GTK+ 2.10 or higher
__WXMAC__	old define, same as __WXOSX__
__WXMOTIF__	Motif
__WXMOTIF20__	Motif 2.0 or higher
__WXMSW__	GUI using Windows Controls. Notice that for compatibility reasons, this symbol is defined for console applications under Windows as well, but it should only be used in the GUI code while __WINDOWS__ should be used for the platform tests.
__WXOSX__	OS X GUI using any Apple widget framework (Carbon, AppKit or UIKit)
__WXOSX_IPHONE__	OS X iPhone (UIKit)
__WXOSX_CARBON__	Mac OS X using Carbon
__WXOSX_COCOA__	Mac OS X using Cocoa (AppKit)
__WXOSX_MAC__	Mac OS X (Carbon or Cocoa)
__WXPM__	OS/2 native Presentation Manager (not used any longer).
__WXSTUBS__	Stubbed version ('template' wxWin implementation)
__WXXT__	Xt; mutually exclusive with WX_MOTIF, not implemented in wxWidgets 2.x
__WXX11__	wxX11 (__WXUNIVERSAL__ will be also defined)
__WXWINE__	WINE (i.e. WIN32 on Unix)
__WXUNIVERSAL__	wxUniversal port, always defined in addition to one of the symbols above so this should be tested first.
__X__	any X11-based GUI toolkit except GTK+

There are two wxWidgets ports to Mac OS X. One of them, wxOSX is the successor of the venerable wxMac, it currently exists in three versions: Carbon and Cocoa for the desktop and a very early iPhone port. And there is the Cocoa port named wxCocoa which has not been updated very actively since beginning 2008. To summarize:

- If you want to test for wxOSX on the desktop, use __WXOSX_MAC__.
- If you want to test for wxOSX on the iPhone, use __WXOSX_IPHONE__.
- If you want to test for a particular GUI Mac port under OS X, use __WXOSX_CARBON__ or __WXOSX_COCOA__.
- If you want to test for any port under Mac OS X, including, for example, wxGTK and also wxBase, use __DARWIN__ (see below).

The convention is to use the __WX prefix for these symbols, although this has not always been followed.

3.3.2 Operating Systems

__APPLE__	any Mac OS version
__AIX__	AIX
__BSD__	Any ∗BSD system
__CYGWIN__	Cygwin: Unix on Win32
__DARWIN__	Mac OS X (with BSD C library), using any port (see also __WXOSX__)
__DATA_GENERAL__	DG-UX
__FREEBSD__	FreeBSD
__HPUX__	HP-UX (Unix)
__GNU__	GNU Hurd
__LINUX__	Linux
__MACH__	Mach-O Architecture (Mac OS X only builds)
__OSF__	OSF/1
__QNX__	QNX Neutrino RTOS
__SGI__	IRIX
__SOLARIS__	Solaris
__SUN__	Any Sun
__SUNOS__	Sun OS
__SVR4__	SystemV R4
__SYSV__	SystemV generic
__ULTRIX__	Ultrix
__UNIX__	any Unix
__UNIX_LIKE__	Unix, BeOS or VMS
__VMS__	VMS
__WINDOWS__	Any Windows platform, using any port (see also __WXMSW__)
__WIN16__	Win16 API (not supported since wxWidgets 2.6)
__WIN32__	Win32 API
__WIN64__	Win64 (mostly same as Win32 but data type sizes are different)
__WINE__	Wine
_WIN32_WCE	Windows CE version

3.3.3 Hardware Architectures (CPU)

Note that not all of these symbols are always defined, it depends on the compiler used.

__ALPHA__	DEC Alpha architecture
__INTEL__	Intel i386 or compatible
__IA64__	Intel 64 bit architecture
__POWERPC__	Motorola Power PC

3.3.4 Hardware Type

__SMARTPHONE__	Generic mobile devices with phone buttons and a small display
__PDA__	Personal digital assistant, usually with touch screen
__HANDHELD__	Small but powerful computer, usually with a keyboard
__POCKETPC__	Microsoft-powered PocketPC devices with touch-screen
__WINCE_STANDARDSDK__	Microsoft-powered Windows CE devices, for generic Windows CE applications
__WINCE_NET__	Microsoft-powered Windows CE .NET devices (_WIN32_WCE is 400 or greater)

WIN32_PLATFORM_WFSP	Microsoft-powered smartphone

3.3.5 Compilers

__BORLANDC__	Borland C++. The value of the macro corresponds to the compiler version: 500 is 5.0.
__DJGPP__	DJGPP
__DIGITALMARS__	Digital Mars (not used any more).
__EVC4__	Embedded Visual C++ 4 (can be only used for building wxWinCE)
__GNUG__	Gnu C++ on any platform, see also wxCHECK_GCC_VERSION
__GNUWIN32__	Gnu-Win32 compiler, see also wxCHECK_W32API_VERSION
__INTELC__	Intel C++ compiler
__MINGW32__	Either MinGW32 or MinGW-w64 in either 32 or 64 bits
__MINGW32_TOOLCHAIN	MinGW32 only (32 bits only right now)
__MINGW64__	MinGW-w64 in 64 bit builds
__MINGW64_TOOLCHAIN__	MinGW-w64 in either 32 or 64 bit builds
__SUNCC__	Sun CC, see also wxCHECK_SUNCC_VERSION
__SYMANTECC__	Symantec C++ (not used any more).
__VISAGECPP__	IBM Visual Age (OS/2) (not used any more).
__VISUALC__	Microsoft Visual C++, see also wxCHECK_VISUALC_VERSION. The value of this macro corresponds to the compiler version: `1020` for `4.2` (the first supported version), `1100` for `5.0`, `1200` for `6.0` and so on. For convenience, the symbols **VISUALCn** are also defined for each major compiler version from 5 to 12, i.e. you can use tests such as `#ifdef __VISUALC7__` to test for compiler version being precisely 7.
__XLC__	AIX compiler
__WATCOMC__	Watcom C++. The value of this macro corresponds to the compiler version, `1100` is `11.0` and `1200` is OpenWatcom (not used any more).

3.3.6 Feature Tests

Some library features may not be always available even if they were selected by the user. To make it possible to check if this is the case, the library predefines the symbols in the form `wxHAS_FEATURE`. Unlike `wxUSE_FEATURE` symbols which are defined by the library user (directly in `setup.h` or by running configure script) and which must be always defined as either 0 or 1, the `wxHAS` symbols are only defined if the corresponding feature is available and not defined at all otherwise.

Currently the following symbols exist:

wxHAS_3STATE_CHECKBOX	Defined if wxCheckBox supports wxCHK_3STATE flag, i.e. is capable of showing three states and not only the usual two. Currently defined for almost all ports.
wxHAS_ATOMIC_OPS	Defined if wxAtomicInc() and wxAtomicDec() functions have an efficient (CPU-specific) implementation. Notice that the functions themselves are always available but can be prohibitively slow to use when implemented in a generic way, using a critical section.

wxHAS_BITMAPTOGGLEBUTTON	Defined in wx/tglbtn.h if wxBitmapToggleButton class is available in addition to wxToggleButton.
wxHAS_CONFIG_TEMPLATE_RW	Defined if the currently used compiler supports template Read() and Write() methods in wxConfig.
wxHAS_LARGE_FILES	Defined if wxFile supports files more than 4GB in size (notice that you must include wx/filefn.h before testing for this symbol).
wxHAS_LARGE_FFILES	Defined if wxFFile supports files more than 4GB in size (notice that you must include wx/filefn.h before testing for this symbol).
wxHAS_LONG_LONG_T_DIFFERENT_FROM_LONG	Defined if compiler supports a 64 bit integer type (available as wxLongLong_t) and this type is different from long. Notice that, provided wxUSE_LONGLONG is not turned off, some 64 bit type is always available to wxWidgets programs and this symbol only indicates a presence of such primitive type. It is useful to decide whether some function should be overloaded for both long and long long types.
wxHAS_MULTIPLE_FILEDLG_FILTERS	Defined if wxFileDialog supports multiple ('|'-separated) filters.
wxHAS_IMAGES_IN_RESOURCES	Defined if Windows resource files or OS/2 resource files are available on the current platform.
wxHAS_POWER_EVENTS	Defined if wxPowerEvent are ever generated on the current platform.
wxHAS_RADIO_MENU_ITEMS	Defined if the current port supports radio menu items (see wxMenu::AppendRadioItem).
wxHAS_RAW_BITMAP	Defined if direct access to bitmap data using the classes in wx/rawbmp.h is supported.
wxHAS_RAW_KEY_CODES	Defined if raw key codes (see wxKeyEvent::GetRawKeyCode are supported.
wxHAS_REGEX_ADVANCED	Defined if advanced syntax is available in wxRegEx.
wxHAS_TASK_BAR_ICON	Defined if wxTaskBarIcon is available on the current platform.

3.3.7 Library Selection for MSVC

Microsoft Visual C++ users may use the special wx/setup.h file for this compiler in include/msvc subdirectory. This file implicitly links in all the wxWidgets libraries using MSVC-specific pragmas which usually is much more convenient than manually specifying the libraries list in all of the project configurations. However sometimes linking with all the libraries is not desirable, for example because some of them were not built and this is where the symbols in this section can be helpful: defining them allows to not link with the corresponding library. The following symbols are honoured:

- wxNO_ADV_LIB
- wxNO_AUI_LIB
- wxNO_HTML_LIB
- wxNO_MEDIA_LIB
- wxNO_NET_LIB
- wxNO_PROPGRID_LIB
- wxNO_QA_LIB
- wxNO_RICHTEXT_LIB
- wxNO_WEBVIEW_LIB
- wxNO_XML_LIB
- wxNO_REGEX_LIB
- wxNO_EXPAT_LIB
- wxNO_JPEG_LIB
- wxNO_PNG_LIB
- wxNO_TIFF_LIB
- wxNO_ZLIB_LIB

Notice that the base library is always included and the core is always included for the GUI applications (i.e. those which don't define wxUSE_GUI as 0).

If the makefiles have been used to build the libraries from source and the `CFG` variable has been set to specify a different output path for that particular configuration of build then the `wxCFG` preprocessor symbol should be set in the project that uses wxWidgets to the same value as the `CFG` variable in order for the correct `wx/setup.h` file to automatically be included for that configuration.

3.3.8 Miscellaneous

__WXWINDOWS__	always defined in wxWidgets applications, see also wxCHECK_VERSION
wxDEBUG_LEVEL	defined as 1 by default, may be pre-defined as 0 before including wxWidgets headers to disable generation of any code at all for the assertion macros, see Debugging
__WXDEBUG__	defined if wxDEBUG_LEVEL is 1 or more, undefined otherwise
wxUSE_XXX	if defined as 1, feature XXX is active, see the wxUSE Preprocessor Symbols (the symbols of this form are always defined, use #if and not #ifdef to test for them)
WX_PRECOMP	is defined if precompiled headers (PCH) are in use. In this case, `wx/wxprec.h` includes `wx/wx.h` which, in turn, includes a number of wxWidgets headers thus making it unnecessary to include them explicitly. However if this is not defined, you do need to include them and so the usual idiom which allows to support both cases is to first include `wx/wxprec.h` and then, inside `#ifndef WX_PRECOMP`, individual headers you need.}
_UNICODE and UNICODE	both are defined if wxUSE_UNICODE is set to `1`
wxUSE_GUI	this particular feature test macro is defined to 1 when compiling or using the library with the GUI features activated, if it is defined as `0`, only wxBase is available.
wxUSE_BASE	only used by wxWidgets internally (defined as 1 when building wxBase code, either as a standalone library or as part of the monolithic wxWidgets library, defined as 0 when building GUI library only)
wxNO_RTTI	is defined if the compiler RTTI support has been switched off
wxNO_EXCEPTIONS	is defined if the compiler support for C++ exceptions has been switched off
wxNO_THREADS	if this macro is defined, the compilation options don't include compiler flags needed for multithreaded code generation. This implies that wxUSE_THREADS is 0 and also that other (non-wx-based) threading packages cannot be used neither.
WXMAKINGDLL_XXX	used internally and defined when building the library `XXX` as a DLL; when a monolithic wxWidgets build is used only a single `WXMAKINGDLL` symbol is defined
WXUSINGDLL	defined when compiling code which uses wxWidgets as a DLL/shared library

WXBUILDING	defined when building wxWidgets itself, whether as a static or shared library

3.4 wxUSE Preprocessor Symbols

This section documents the wxUSE preprocessor symbols used in the wxWidgets source, grouped by category (and sorted by alphabetical order inside each category).

These symbols are always defined and whether the given feature is active or not depends on their value: if defined as `1`, feature is active, otherwise it is disabled. Because of this these symbols should always be tested using #if and not #ifdef.

3.4.1 Most Important Symbols

This table summarizes some of the global build features affecting the entire library:

wxUSE_STL	Container classes and wxString are implemented using standard classes and provide the same standard API.
wxUSE_STD_STRING	wxString is implemented using std::[w]string and can be constructed from it (but provides wxWidgets-compatible API, in particular is implicitly convertible to `char*` and not std::[w]string).
wxUSE_STD_IOSTREAM	Standard C++ classes are used instead of or in addition to wx stream classes.
wxUSE_UNICODE	Compiled with Unicode support (default in wxWidgets 3.0, non-Unicode build will be deprecated in the future).
wxUSE_UNICODE_WCHAR	wxString uses wchar_t buffer for internal storage (default under MSW).
wxUSE_UNICODE_UTF8	wxString uses UTF-8 for internal storage (default under Unix and Mac systems).
wxUSE_UTF8_LOCALE_ONLY	Library supports running only under UTF-8 (and C) locale. This eliminates the code necessary for conversions from the other locales and reduces the library size; useful for embedded systems.
wxUSE_GUI	Use the GUI classes; if set to 0 only non-GUI classes are available.

3.4.2 Generic Symbols

wxUSE_ABOUTDLG	Use wxAboutDialogInfo class.
wxUSE_ACCEL	Use wxAcceleratorTable/Entry classes and support for them in wxMenu, wxMenuBar.
wxUSE_AFM_FOR_POSTSCRIPT	In wxPostScriptDC class use AFM (adobe font metrics) file for character widths.
wxUSE_ANIMATIONCTRL	Use wxAnimationCtrl class.
wxUSE_ARTPROVIDER_STD	Use standard low quality icons in wxArtProvider.
wxUSE_ARTPROVIDER_TANGO	Use Tango icons in wxArtProvider.
wxUSE_ANY	Use wxAny class.
wxUSE_APPLE_IEEE	IEEE Extended to/from double routines, see wxDataOutputStream.

wxUSE_ARCHIVE_STREAMS	Enable streams for archive formats.
wxUSE_AUI	Use AUI (dockable windows) library.
wxUSE_BASE64	Enables Base64 support.
wxUSE_BITMAPCOMBOBOX	Use wxBitmapComboBox class.
wxUSE_BMPBUTTON	Use wxBitmapButton class.
wxUSE_BUSYINFO	Use wxBusyInfo class.
wxUSE_BUTTON	Use wxButton class.
wxUSE_CALENDARCTRL	Use wxCalendarCtrl class.
wxUSE_CARET	Use wxCaret class.
wxUSE_CHECKBOX	Use wxCheckBox class.
wxUSE_CHECKLISTBOX	Use wxCheckListBox class.
wxUSE_CHOICE	Use wxChoice class.
wxUSE_CHOICEBOOK	Use wxChoicebook class.
wxUSE_CHOICEDLG	Use wxSingleChoiceDialog, or wxMultiChoiceDialog classes.
wxUSE_CLIPBOARD	Use wxClipboard class.
wxUSE_CMDLINE_PARSER	Use wxCmdLineParser class.
wxUSE_COLLPANE	Use wxCollapsiblePane class.
wxUSE_COLOURDLG	Use wxColourDialog class.
wxUSE_COLOURPICKERCTRL	Use wxColourPickerCtrl class.
wxUSE_COMBOBOX	Use wxComboBox class.
wxUSE_COMBOCTRL	Use wxComboCtrl class.
wxUSE_COMPILER_TLS	Can be set to 0 to prevent using compile thread-specific variables support.
wxUSE_CONFIG	Use wxConfig and related classes.
wxUSE_CONFIG_NATIVE	When enabled use native OS configuration instead of the wxFileConfig class.
wxUSE_CONSOLE_EVENTLOOP	Enable event loop in console programs.
wxUSE_CONSTRAINTS	Use wxLayoutConstraints
wxUSE_CONTROLS	If set to 0, no classes deriving from wxControl can be used.
wxUSE_DATAOBJ	Use wxDataObject and related classes.
wxUSE_DATAVIEWCTRL	Use wxDataViewCtrl class.
wxUSE_DATEPICKCTRL	Use wxDatePickerCtrl class.
wxUSE_DATETIME	Use wxDateTime and related classes.
wxUSE_DBGHELP	Predefine as 0 to avoid using wxDbgHelpDLL and related classes.
wxUSE_DC_TRANSFORM_MATRIX	Use wxDC::SetTransformMatrix() and related methods.
wxUSE_DEBUG_CONTEXT	Use wxDebugContext class.
wxUSE_DEBUG_NEW_ALWAYS	See Debugging
wxUSE_DEBUGREPORT	Use wxDebugReport class.
wxUSE_DIALUP_MANAGER	Use wxDialUpManager and related classes.
wxUSE_DIRDLG	Use wxDirDialog class.
wxUSE_DIRPICKERCTRL	Use wxDirPickerCtrl class.
wxUSE_DISPLAY	Use wxDisplay and related classes.
wxUSE_DOC_VIEW_ARCHITECTURE	Use wxDocument and related classes.
wxUSE_DRAG_AND_DROP	Use Drag and drop classes.

wxUSE_DRAGIMAGE	Use wxDragImage class.
wxUSE_DYNAMIC_LOADER	Use wxPluginManager and related classes. Requires wxDynamicLibrary
wxUSE_DYNLIB_CLASS	Use wxDynamicLibrary
wxUSE_EDITABLELISTBOX	Use wxEditableListBox class.
wxUSE_EXCEPTIONS	Use exception handling.
wxUSE_EXPAT	enable XML support using expat parser.
wxUSE_EXTENDED_RTTI	Use extended RTTI, see also Runtime class information (RTTI)
wxUSE_FFILE	Use wxFFile class.
wxUSE_FILE	Use wxFile class.
wxUSE_FILECONFIG	Use wxFileConfig class.
wxUSE_FILECTRL	Use wxFileCtrl class.
wxUSE_FILEDLG	Use wxFileDialog class.
wxUSE_FILEPICKERCTRL	Use wxFilePickerCtrl class.
wxUSE_FILESYSTEM	Use wxFileSystem and related classes.
wxUSE_FINDREPLDLG	Use wxFindReplaceDialog class.
wxUSE_FONTDLG	Use wxFontDialog class.
wxUSE_FONTENUM	Use wxFontEnumerator class.
wxUSE_FONTMAP	Use wxFontMapper class.
wxUSE_FONTPICKERCTRL	Use wxFontPickerCtrl class.
wxUSE_FS_ARCHIVE	Use virtual archive filesystems like wxArchiveFSHandler in wxFileSystem class.
wxUSE_FS_INET	Use virtual HTTP/FTP filesystems like wxInternetFSHandler in wxFileSystem class.
wxUSE_FS_ZIP	Please use wxUSE_FS_ARCHIVE instead.
wxUSE_FSVOLUME	Use wxFSVolume class.
wxUSE_GAUGE	Use wxGauge class.
wxUSE_GENERIC_DRAGIMAGE	Used in wxDragImage sample.
wxUSE_GENERIC_DRAWELLIPSE	See comment in wx/dc.h file.
wxUSE_GENERIC_MDI_AS_NATIVE	This is not a user-settable symbol, it is only used internally in wx/generic/mdig.h.
wxUSE_GEOMETRY	Use common geometry classes
wxUSE_GIF	Use GIF wxImageHandler
wxUSE_GLCANVAS	Enables OpenGL support.
wxUSE_GLOBAL_MEMORY_OPERATORS	Override global operators `new` and `delete` to use wxWidgets memory leak detection
wxUSE_GRAPHICS_CONTEXT	Use wxGraphicsContext and related classes.
wxUSE_GRID	Use wxGrid and related classes.
wxUSE_HELP	Use wxHelpController and related classes.
wxUSE_HTML	Use wxHtmlWindow and related classes.
wxUSE_HYPERLINKCTRL	Use wxHyperlinkCtrl
wxUSE_ICO_CUR	Support Windows ICO and CUR formats.
wxUSE_IFF	Enables the wxImage handler for Amiga IFF images.
wxUSE_IMAGE	Use wxImage and related classes.
wxUSE_IMAGLIST	Use wxImageList class.
wxUSE_INTL	Use wxLocale and related classes.
wxUSE_IOSTREAMH	Use header "iostream.h" instead of "iostream".

wxUSE_IPC	Use interprocess communication classes.
wxUSE_IPV6	Use experimental wxIPV6address and related classes.
wxUSE_JOYSTICK	Use wxJoystick class.
wxUSE_LIBJPEG	Enables JPEG format support (requires libjpeg).
wxUSE_LIBPNG	Enables PNG format support (requires libpng). Also requires wxUSE_ZLIB.
wxUSE_LIBTIFF	Enables TIFF format support (requires libtiff).
wxUSE_LISTBOOK	Use wxListbook class.
wxUSE_LISTBOX	Use wxListBox class.
wxUSE_LISTCTRL	Use wxListCtrl class.
wxUSE_LOG	Use wxLog and related classes.
wxUSE_LOG_DEBUG	Enabled when wxLog used with **WXDEBUG** defined.
wxUSE_LOG_DIALOG	Use wxLogDialog class.
wxUSE_LOGGUI	Use wxLogGui class.
wxUSE_LOGWINDOW	Use wxLogFrame class.
wxUSE_LONGLONG	Use wxLongLong class.
wxUSE_LONGLONG_NATIVE	Use native `long long` type in wxLongLong implementation.
wxUSE_LONGLONG_WX	Use generic wxLongLong implementation.
wxUSE_MARKUP	Provide wxControl::SetLabelMarkup() method.
wxUSE_MDI	Use wxMDIParentFrame, and wxMDIChildFrame
wxUSE_MDI_ARCHITECTURE	Use MDI-based document-view classes.
wxUSE_MEDIACTRL	Use wxMediaCtrl.
wxUSE_MEMORY_TRACING	Use wxWidgets memory leak detection, not recommended if using another memory debugging tool.
wxUSE_MENUS	Use wxMenu and related classes.
wxUSE_METAFILE	Use wxMetaFile and related classes.
wxUSE_MIMETYPE	Use wxFileType class.
wxUSE_MINIFRAME	Use wxMiniFrame class.
wxUSE_MOUSEWHEEL	Support mouse wheel events.
wxUSE_MSGDLG	Use wxMessageDialog class and wxMessageBox function.
wxUSE_NATIVE_STATUSBAR	Use native wxStatusBar class.
wxUSE_NOTEBOOK	Use wxNotebook and related classes.
wxUSE_NUMBERDLG	Use wxNumberEntryDialog class.
wxUSE_ODCOMBOBOX	Use wxOwnerDrawnComboBox class.
wxUSE_ON_FATAL_EXCEPTION	Catch signals in wxApp::OnFatalException method.
wxUSE_OPENGL	Please use wxUSE_GLCANVAS to test for enabled OpenGL support instead.
wxUSE_OWNER_DRAWN	Use interface for owner-drawn GUI elements.
wxUSE_PALETTE	Use wxPalette and related classes.
wxUSE_PCX	Enables wxImage PCX handler.
wxUSE_PNM	Enables wxImage PNM handler.
wxUSE_POPUPWIN	Use wxPopupWindow class.
wxUSE_POSTSCRIPT	Use wxPostScriptPrinter class.
wxUSE_PRINTF_POS_PARAMS	Use wxVsnprintf which supports positional parameters.

wxUSE_PRINTING_ARCHITECTURE	Enable printer classes.
wxUSE_PROGRESSDLG	Enables progress dialog classes.
wxUSE_PROPGRID	Use wxPropertyGrid library.
wxUSE_PROTOCOL	Use wxProtocol and derived classes.
wxUSE_PROTOCOL_FILE	Use wxFileProto class. (requires wxProtocol)
wxUSE_PROTOCOL_FTP	Use wxFTP class. (requires wxProtocol)
wxUSE_PROTOCOL_HTTP	Use wxHTTP class. (requireswxProtocol)
wxUSE_RADIOBOX	Use wxRadioBox class.
wxUSE_RADIOBTN	Use wxRadioButton class.
wxUSE_REGEX	Use wxRegEx class.
wxUSE_RICHTEXT	Use wxRichTextCtrl class.
wxUSE_RICHTEXT_XML_HANDLER	See src/xrc/xh_richtext.cpp file.
wxUSE_SASH	Use wxSashWindow class.
wxUSE_SCROLLBAR	Use wxScrollBar class.
wxUSE_SEARCHCTRL	Use wxSearchCtrl class.
wxUSE_SELECT_DISPATCHER	Use wxSelectDispatcher class.
wxUSE_SLIDER	Use wxSlider class.
wxUSE_SNGLINST_CHECKER	Use wxSingleInstanceChecker class.
wxUSE_SOCKETS	Enables Network address classes.
wxUSE_SOUND	Use wxSound class.
wxUSE_SPINBTN	Use wxSpinButton class.
wxUSE_SPINCTRL	Use wxSpinCtrl class.
wxUSE_SPLASH	Use wxSplashScreen class.
wxUSE_SPLINES	Provide methods for spline drawing in wxDC.
wxUSE_SPLITTER	Use wxSplitterWindow class.
wxUSE_STACKWALKER	Enables wxStackWalker and related classes.
wxUSE_STARTUP_TIPS	Use startup tips, wxTipProvider class.
wxUSE_STATBMP	Use wxStaticBitmap class.
wxUSE_STATBOX	Use wxStaticBox class.
wxUSE_STATLINE	Use wxStaticLine class.
wxUSE_STATTEXT	Use wxStaticText class.
wxUSE_STATUSBAR	Use wxStatusBar class.
wxUSE_STC	Use wxStyledTextCtrl.
wxUSE_STDPATHS	Use wxStandardPaths class.
wxUSE_STOPWATCH	Use wxStopWatch class.
wxUSE_STREAMS	Enable stream classes.
wxUSE_SVG	Use wxSVGFileDC class.
wxUSE_SYSTEM_OPTIONS	Use wxSystemOptions class.
wxUSE_TAB_DIALOG	Use the obsolete wxTabControl class.
wxUSE_TARSTREAM	Enable Tar files support.
wxUSE_TASKBARICON	Use wxTaskBarIcon class.
wxUSE_TEXTBUFFER	Use wxTextBuffer class.
wxUSE_TEXTCTRL	Use wxTextCtrl class.
wxUSE_TEXTDLG	Use wxTextEntryDialog class.
wxUSE_TEXTFILE	Use wxTextFile class.
wxUSE_TGA	Enable wxImage TGA handler.
wxUSE_THREADS	Use wxThread and related classes.

wxUSE_TIMER	Use wxTimer class.
wxUSE_TIPWINDOW	Use wxTipWindow class.
wxUSE_TOGGLEBTN	Use wxToggleButton class.
wxUSE_TOOLBAR	Use wxToolBar class.
wxUSE_TOOLBAR_NATIVE	Use native wxToolBar class.
wxUSE_TOOLBOOK	Use wxToolbook class.
wxUSE_TOOLTIPS	Use wxToolTip class.
wxUSE_TREEBOOK	Use wxTreebook class.
wxUSE_TREECTRL	Use wxTreeCtrl class.
wxUSE_TREELISTCTRL	Use wxTreeListCtrl class.
wxUSE_TTM_WINDOWFROMPOINT	Obsolete, do not use.
wxUSE_URL	Use wxURL class.
wxUSE_URL_NATIVE	Use native support for some operations with wxURL.
wxUSE_VALIDATORS	Use wxValidator class.
wxUSE_VARIANT	Use wxVariant class.
wxUSE_WEBVIEW	Use wxWebView class.
wxUSE_WIZARDDLG	Use wxWizard class.
wxUSE_WXHTML_HELP	Use wxHtmlHelpController and related classes.
wxUSE_XML	Use XML parsing classes.
wxUSE_XPM	Enable XPM reader for wxImage and wxBitmap classes.
wxUSE_XRC	Use XRC XML-based resource system.
wxUSE_ZIPSTREAM	Enable streams for Zip files.
wxUSE_ZLIB	Use wxZlibInput and wxZlibOutputStream classes, required by wxUSE_LIBPNG.

3.4.3 Unix Platform Symbols

wxUSE_EPOLL_DISPATCHER	Use wxEpollDispatcher class. See also wxUSE_SELECT_DISPATCHER.
wxUSE_GSTREAMER	Use GStreamer library in wxMediaCtrl.
wxUSE_LIBMSPACK	Use libmspack library.
wxUSE_LIBSDL	Use SDL for wxSound implementation.
wxUSE_PLUGINS	See also wxUSE_LIBSDL.
wxUSE_UNIX	Enabled on Unix Platform.

3.4.4 wxX11 Symbols

wxUSE_NANOX	Use NanoX.
wxUSE_UNIV_TEXTCTRL	Use wxUniv's implementation of wxTextCtrl class.

3.4.5 wxGTK Symbols

wxUSE_DETECT_SM	Use code to detect X11 session manager.
wxUSE_GTKPRINT	Use GTK+ printing support.
wxUSE_LIBGNOMEVFS	Use GNOME VFS support. Currently has no effect.
wxUSE_LIBHILDON	Use Hildon framework for Nokia 770. Currently has no effect.

3.4.6 wxMac Symbols

wxUSE_MAC_CRITICAL_REGION_MUTEX	See src/osx/carbon/thread.cpp file.

wxUSE_MAC_PTHREADS_MUTEX	See src/osx/carbon/thread.cpp file.
wxUSE_MAC_SEMAPHORE_MUTEX	See src/osx/carbon/thread.cpp file.
wxUSE_WEBKIT	Use wxWebKitCtrl class.

3.4.7 wxMotif Symbols

wxUSE_GADGETS	Use xmCascadeButtonGadgetClass, xmLabelGadgetClass, xmPushButtonGadgetClass and xmToggleButtonGadgetClass classes.
wxUSE_INVISIBLE_RESIZE	See src/motif/dialog.cpp file.

3.4.8 Cocoa Symbols

wxUSE_OBJC_UNIQUIFYING	Enable Objective-C class name uniquifying.

3.4.9 wxMSW Symbols

wxUSE_ACCESSIBILITY	Enable accessibility support
wxUSE_ACTIVEX	Use wxActiveXContainer and related classes.
wxUSE_COMBOCTRL_POPUP_ANIMATION	See wx/msw/combo.h file.
wxUSE_COMCTL32_SAFELY	See src/msw/treectrl.cpp file.
wxUSE_COMMON_DIALOGS	Enable use of windows common dialogs from header commdlg.h; example PRINTDLG.
wxUSE_CRASHREPORT	Use wxCrashReport class.
wxUSE_DATEPICKCTRL_GENERIC	Use generic wxDatePickerCtrl implementation in addition to the native one.
wxUSE_DC_CACHEING	cache temporary wxDC objects.
wxUSE_DDE_FOR_IPC	See wx/ipc.h file.
wxUSE_ENH_METAFILE	Use wxEnhMetaFile.
wxUSE_HOTKEY	Use wxWindow::RegisterHotKey() and wxWindow::UnregisterHotKey
wxUSE_INKEDIT	Use InkEdit library. Related to Tablet PCs.
wxUSE_MS_HTML_HELP	Use wxCHMHelpController class.
wxUSE_NO_MANIFEST	Can be predefined to disable inclusion of the manifest from wxWidgets RC file. See also wxUSE_RC_MANIFEST.
wxUSE_OLE	Enables OLE helper routines.
wxUSE_OLE_AUTOMATION	Enable OLE automation utilities.
wxUSE_OLE_CLIPBOARD	Use OLE clipboard.
wxUSE_PENWINDOWS	See src/msw/penwin.cpp file.
wxUSE_POSTSCRIPT_ARCHITECTURE_IN_MSW	Use PS printing in wxMSW.
wxUSE_PS_PRINTING	See src/msw/dcprint.cpp file.
wxUSE_RC_MANIFEST	Include manifest for common controls library v6 from wxWidgets RC file. This may be needed to be defined explicitly for MSVC 7 (a.k.a. MSVS 2003) only as later versions of MSVC generate this manifest themselves and the manifest generation is enabled by default for the other compilers. See also wxUSE_NO_MANIFEST.

wxUSE_REGKEY	Use wxRegKey class.
wxUSE_RICHEDIT	Enable use of riched32.dll in wxTextCtrl
wxUSE_RICHEDIT2	Enable use of riched20.dll in wxTextCtrl
wxUSE_VC_CRTDBG	See wx/msw/msvcrt.h file.
wxUSE_UXTHEME	Enable support for XP themes.
wxUSE_WIN_METAFILES_ALWAYS	Use wxMetaFile even when wxUSE_ENH_METAFILE=1.
wxUSE_WXDIB	Use wxDIB class.

3.4.10 wxUniversal Symbols

wxUSE_ALL_THEMES	Use all themes in wxUniversal; See wx/univ/theme.h file.
wxUSE_THEME_GTK	Use GTK+ 1-like theme in wxUniversal
wxUSE_THEME_METAL	Use GTK+ 2-like theme in wxUniversal
wxUSE_THEME_MONO	Use simple monochrome theme in wxUniversal
wxUSE_THEME_WIN32	Use Win32-like theme in wxUniversal

Chapter 4

Copyrights and Licenses

4.1 wxWidgets Copyrights and Licenses

- wxWindows Library Licence
- GNU Library General Public License
- The Open Group and DEC License

4.2 Acknowledgements

The following is the list of the core, active developers of wxWidgets which keep it running and have provided an invaluable, extensive and high-quality amount of changes over the many of years of wxWidgets' life:

- Julian Smart
- Vadim Zeitlin
- Robert Roebling
- Robin Dunn
- Stefan Csomor
- Vaclav Slavik
- Paul Cornett
- Wlodzimierz 'ABX' Skiba
- Chris Elliott
- David Elliott
- Kevin Hock
- Stefan Neis

- Michael Wetherell

We would particularly like to thank the following peoples for their contributions to wxWidgets, and the many others who have been involved in the project over the years. Apologies for any unintentional omissions from this alphabetic list:

Yiorgos Adamopoulos, Jamshid Afshar, Alejandro Aguilar-Sierra, AIAI, Patrick Albert, Karsten Ballueder, Mattia Barbon, Michael Bedward, Kai Bendorf, Yura Bidus, Keith Gary Boyce, Chris Breeze, Pete Britton, Ian Brown, C. Buckley, Marco Cavallini, Dmitri Chubraev, Robin Corbet, Cecil Coupe, Andrew Davison, Gilles Depeyrot, Neil Dudman, Hermann Dunkel, Jos van Eijndhoven, Tom Felici, Thomas Fettig, Matthew Flatt, Pasquale Foggia, Josep Fortiana, Todd Fries, Dominic Gallagher, Guillermo Rodriguez Garcia, Wolfram Gloger, Norbert Grotz, Stefan Gunter, Bill Hale, Patrick Halke, Stefan Hammes, Guillaume Helle, Harco de Hilster, Cord Hockemeyer, Markus Holzem, Olaf Klein, Leif Jensen, Bart Jourquin, Guilhem Lavaux, Ron Lee, Jan Lessner, Nicholas Liebmann, Torsten Liermann, Per Lindqvist, Francesco Montorsi, Thomas Runge, Tatu Männistö, Scott Maxwell, Thomas Myers, Oliver Niedung, Ryan Norton, Hernan Otero, Ian Perrigo, Timothy Peters, Giordano Pezzoli, Harri Pasanen, Thomaso Paoletti, Garrett Potts, Marcel Rasche, Dino Scaringella, Jobst Schmalenbach, Arthur Seaton, Paul Shirley, Stein Somers, Petr Smilauer, Neil Smith, Kari Systä, George Tasker, Arthur Tetzlaff-Deas, Jonathan Tonberg, Jyrki Tuomi, Janos Vegh, Andrea Venturoli, David Webster, Otto Wyss, Xiaokun Zhu, Edward Zimmermann.

Many thanks also to AIAI for being willing to release the original version of wxWidgets into the public domain, and to our patient partners.

'Graphplace', the basis for the wxGraphLayout library, is copyright Dr. Jos T.J. van Eijndhoven of Eindhoven University of Technology. The code has been used in wxGraphLayout (not in wxWidgets anymore) with his permission.

We also acknowledge the author of XFIG, the excellent Unix drawing tool, from the source of which we have borrowed some spline drawing code. His copyright is included below.

XFig2.1 is copyright (c) 1985 by Supoj Sutanthavibul. Permission to use, copy, modify, distribute, and sell this software and its documentation for any purpose is hereby granted without fee, provided that the above copyright notice appear in all copies and that both that copyright notice and this permission notice appear in supporting documentation, and that the name of M.I.T. not be used in advertising or publicity pertaining to distribution of the software without specific, written prior permission. M.I.T. makes no representations about the suitability of this software for any purpose. It is provided "as is" without express or implied warranty.

4.3 wxWindows Library Licence

```
                wxWindows Library Licence, Version 3.1
                ======================================

  Copyright (c) 1998-2005 Julian Smart, Robert Roebling et al

  Everyone is permitted to copy and distribute verbatim copies
  of this licence document, but changing it is not allowed.

                       WXWINDOWS LIBRARY LICENCE
     TERMS AND CONDITIONS FOR COPYING, DISTRIBUTION AND MODIFICATION

  This library is free software; you can redistribute it and/or modify it
  under the terms of the GNU Library General Public Licence as published by
  the Free Software Foundation; either version 2 of the Licence, or (at
  your option) any later version.

  This library is distributed in the hope that it will be useful, but
  WITHOUT ANY WARRANTY; without even the implied warranty of
  MERCHANTABILITY or FITNESS FOR A PARTICULAR PURPOSE.  See the GNU Library
  General Public Licence for more details.

  You should have received a copy of the GNU Library General Public Licence
  along with this software, usually in a file named COPYING.LIB.  If not,
  write to the Free Software Foundation, Inc., 51 Franklin Street, Fifth Floor,
  Boston, MA 02110-1301 USA.

  EXCEPTION NOTICE
```

```
  1. As a special exception, the copyright holders of this library give
  permission for additional uses of the text contained in this release of
  the library as licenced under the wxWindows Library Licence, applying
  either version 3.1 of the Licence, or (at your option) any later version of
  the Licence as published by the copyright holders of version
  3.1 of the Licence document.

  2. The exception is that you may use, copy, link, modify and distribute
  under your own terms, binary object code versions of works based
  on the Library.

  3. If you copy code from files distributed under the terms of the GNU
  General Public Licence or the GNU Library General Public Licence into a
  copy of this library, as this licence permits, the exception does not
  apply to the code that you add in this way.  To avoid misleading anyone as
  to the status of such modified files, you must delete this exception
  notice from such code and/or adjust the licensing conditions notice
  accordingly.

  4. If you write modifications of your own for this library, it is your
  choice whether to permit this exception to apply to your modifications.
  If you do not wish that, you must delete the exception notice from such
  code and/or adjust the licensing conditions notice accordingly.
```

4.4 GNU Library General Public License

```
  GNU LIBRARY GENERAL PUBLIC LICENSE
  ==================================
                Version 2, June 1991

 Copyright (C) 1991 Free Software Foundation, Inc.
                    675 Mass Ave, Cambridge, MA 02139, USA
 Everyone is permitted to copy and distribute verbatim copies
 of this license document, but changing it is not allowed.

[This is the first released version of the library GPL.  It is
 numbered 2 because it goes with version 2 of the ordinary GPL.]

                        Preamble

The licenses for most software are designed to take away your
freedom to share and change it.  By contrast, the GNU General
Public Licenses are intended to guarantee your freedom to share
and change free software--to make sure the software is free for
all its users.

This license, the Library General Public License, applies to
some specially designated Free Software Foundation software, and
to any other libraries whose authors decide to use it.  You can
use it for your libraries, too.

When we speak of free software, we are referring to freedom, not
price.  Our General Public Licenses are designed to make sure
that you have the freedom to distribute copies of free software
(and charge for this service if you wish), that you receive
source code or can get it if you want it, that you can change
the software or use pieces of it in new free programs; and that
you know you can do these things.

To protect your rights, we need to make restrictions that forbid
anyone to deny you these rights or to ask you to surrender the
rights. These restrictions translate to certain responsibilities
for you if you distribute copies of the library, or if you
modify it.

For example, if you distribute copies of the library, whether
gratis or for a fee, you must give the recipients all the rights
that we gave you.  You must make sure that they, too, receive or
can get the source code.  If you link a program with the
```

library, you must provide complete object files to the recipients so that they can relink them with the library, after making changes to the library and recompiling it. And you must show them these terms so they know their rights.

Our method of protecting your rights has two steps: (1) copyright the library, and (2) offer you this license which gives you legal permission to copy, distribute and/or modify the library.

Also, for each distributor's protection, we want to make certain that everyone understands that there is no warranty for this free library. If the library is modified by someone else and passed on, we want its recipients to know that what they have is not the original version, so that any problems introduced by others will not reflect on the original authors' reputations.

Finally, any free program is threatened constantly by software patents. We wish to avoid the danger that companies distributing free software will individually obtain patent licenses, thus in effect transforming the program into proprietary software. To prevent this, we have made it clear that any patent must be licensed for everyone's free use or not licensed at all.

Most GNU software, including some libraries, is covered by the ordinary GNU General Public License, which was designed for utility programs. This license, the GNU Library General Public License, applies to certain designated libraries. This license is quite different from the ordinary one; be sure to read it in full, and don't assume that anything in it is the same as in the ordinary license.

The reason we have a separate public license for some libraries is that they blur the distinction we usually make between modifying or adding to a program and simply using it. Linking a program with a library, without changing the library, is in some sense simply using the library, and is analogous to running a utility program or application program. However, in a textual and legal sense, the linked executable is a combined work, a derivative of the original library, and the ordinary General Public License treats it as such.

Because of this blurred distinction, using the ordinary General Public License for libraries did not effectively promote software sharing, because most developers did not use the libraries. We concluded that weaker conditions might promote sharing better.

However, unrestricted linking of non-free programs would deprive the users of those programs of all benefit from the free status of the libraries themselves. This Library General Public License is intended to permit developers of non-free programs to use free libraries, while preserving your freedom as a user of such programs to change the free libraries that are incorporated in them. (We have not seen how to achieve this as regards changes in header files, but we have achieved it as regards changes in the actual functions of the Library.) The hope is that this will lead to faster development of free libraries.

The precise terms and conditions for copying, distribution and modification follow. Pay close attention to the difference between a "work based on the library" and a "work that uses the library". The former contains code derived from the library, while the latter only works together with the library.

Note that it is possible for a library to be covered by the ordinary General Public License rather than by this special one.

GNU LIBRARY GENERAL PUBLIC LICENSE
TERMS AND CONDITIONS FOR COPYING, DISTRIBUTION AND MODIFICATION

0. This License Agreement applies to any software library which

```
contains a notice placed by the copyright holder or other
authorized party saying it may be distributed under the terms of
this Library General Public License (also called "this
License").  Each licensee is addressed as "you".

A "library" means a collection of software functions and/or data
prepared so as to be conveniently linked with application
programs (which use some of those functions and data) to form
executables.

The "Library", below, refers to any such software library or
work which has been distributed under these terms.  A "work
based on the Library" means either the Library or any derivative
work under copyright law: that is to say, a work containing the
Library or a portion of it, either verbatim or with
modifications and/or translated straightforwardly into another
language.  (Hereinafter, translation is included without
limitation in the term "modification".)

"Source code" for a work means the preferred form of the work
for making modifications to it.  For a library, complete source
code means all the source code for all modules it contains, plus
any associated interface definition files, plus the scripts used
to control compilation and installation of the library.

Activities other than copying, distribution and modification are
not covered by this License; they are outside its scope.  The
act of running a program using the Library is not restricted,
and output from such a program is covered only if its contents
constitute a work based on the Library (independent of the use
of the Library in a tool for writing it).  Whether that is true
depends on what the Library does and what the program that uses
the Library does.

1. You may copy and distribute verbatim copies of the Library's
complete source code as you receive it, in any medium, provided
that you conspicuously and appropriately publish on each copy an
appropriate copyright notice and disclaimer of warranty; keep
intact all the notices that refer to this License and to the
absence of any warranty; and distribute a copy of this License
along with the Library.

You may charge a fee for the physical act of transferring a
copy, and you may at your option offer warranty protection in
exchange for a fee.

2. You may modify your copy or copies of the Library or any
portion of it, thus forming a work based on the Library, and
copy and distribute such modifications or work under the terms
of Section 1 above, provided that you also meet all of these
conditions:

    a) The modified work must itself be a software library.

    b) You must cause the files modified to carry prominent notices
    stating that you changed the files and the date of any change.

    c) You must cause the whole of the work to be licensed at no
    charge to all third parties under the terms of this License.

    d) If a facility in the modified Library refers to a function or a
    table of data to be supplied by an application program that uses
    the facility, other than as an argument passed when the facility
    is invoked, then you must make a good faith effort to ensure that,
    in the event an application does not supply such function or
    table, the facility still operates, and performs whatever part of
    its purpose remains meaningful.

    (For example, a function in a library to compute square roots has
    a purpose that is entirely well-defined independent of the
    application.  Therefore, Subsection 2d requires that any
    application-supplied function or table used by this function must
    be optional: if the application does not supply it, the square
```

```
    root function must still compute square roots.)

These requirements apply to the modified work as a whole.  If
identifiable sections of that work are not derived from the
Library, and can be reasonably considered independent and
separate works in themselves, then this License, and its terms,
do not apply to those sections when you distribute them as
separate works.  But when you distribute the same sections as
part of a whole which is a work based on the Library, the
distribution of the whole must be on the terms of this License,
whose permissions for other licensees extend to the entire
whole, and thus to each and every part regardless of who wrote
it.

Thus, it is not the intent of this section to claim rights or
contest your rights to work written entirely by you; rather, the
intent is to exercise the right to control the distribution of
derivative or collective works based on the Library.

In addition, mere aggregation of another work not based on the
Library with the Library (or with a work based on the Library)
on a volume of a storage or distribution medium does not bring
the other work under the scope of this License.

3. You may opt to apply the terms of the ordinary GNU General
Public License instead of this License to a given copy of the
Library.  To do this, you must alter all the notices that refer
to this License, so that they refer to the ordinary GNU General
Public License, version 2, instead of to this License.  (If a
newer version than version 2 of the ordinary GNU General Public
License has appeared, then you can specify that version instead
if you wish.)  Do not make any other change in these notices.

Once this change is made in a given copy, it is irreversible for
that copy, so the ordinary GNU General Public License applies to
all subsequent copies and derivative works made from that copy.

This option is useful when you wish to copy part of the code of
the Library into a program that is not a library.

4. You may copy and distribute the Library (or a portion or
derivative of it, under Section 2) in object code or executable
form under the terms of Sections 1 and 2 above provided that you
accompany it with the complete corresponding machine-readable
source code, which must be distributed under the terms of
Sections 1 and 2 above on a medium customarily used for software
interchange.

If distribution of object code is made by offering access to
copy from a designated place, then offering equivalent access to
copy the source code from the same place satisfies the
requirement to distribute the source code, even though third
parties are not compelled to copy the source along with the
object code.

5. A program that contains no derivative of any portion of the
Library, but is designed to work with the Library by being
compiled or linked with it, is called a "work that uses the
Library".  Such a work, in isolation, is not a derivative work
of the Library, and therefore falls outside the scope of this
License.

However, linking a "work that uses the Library" with the Library
creates an executable that is a derivative of the Library
(because it contains portions of the Library), rather than a
"work that uses the library".  The executable is therefore
covered by this License. Section 6 states terms for distribution
of such executables.

When a "work that uses the Library" uses material from a header
file that is part of the Library, the object code for the work
may be a derivative work of the Library even though the source
code is not. Whether this is true is especially significant if
```

```
the work can be linked without the Library, or if the work is
itself a library.  The threshold for this to be true is not
precisely defined by law.

If such an object file uses only numerical parameters, data
structure layouts and accessors, and small macros and small
inline functions (ten lines or less in length), then the use of
the object file is unrestricted, regardless of whether it is
legally a derivative work.  (Executables containing this object
code plus portions of the Library will still fall under Section
6.)

Otherwise, if the work is a derivative of the Library, you may
distribute the object code for the work under the terms of
Section 6. Any executables containing that work also fall under
Section 6, whether or not they are linked directly with the
Library itself.

6. As an exception to the Sections above, you may also compile
or link a "work that uses the Library" with the Library to
produce a work containing portions of the Library, and
distribute that work under terms of your choice, provided that
the terms permit modification of the work for the customer's own
use and reverse engineering for debugging such modifications.

You must give prominent notice with each copy of the work that
the Library is used in it and that the Library and its use are
covered by this License.  You must supply a copy of this
License.  If the work during execution displays copyright
notices, you must include the copyright notice for the Library
among them, as well as a reference directing the user to the
copy of this License.  Also, you must do one of these things:

    a) Accompany the work with the complete corresponding
    machine-readable source code for the Library including whatever
    changes were used in the work (which must be distributed under
    Sections 1 and 2 above); and, if the work is an executable linked
    with the Library, with the complete machine-readable "work that
    uses the Library", as object code and/or source code, so that the
    user can modify the Library and then relink to produce a modified
    executable containing the modified Library.  (It is understood
    that the user who changes the contents of definitions files in the
    Library will not necessarily be able to recompile the application
    to use the modified definitions.)

    b) Accompany the work with a written offer, valid for at
    least three years, to give the same user the materials
    specified in Subsection 6a, above, for a charge no more
    than the cost of performing this distribution.

    c) If distribution of the work is made by offering access to copy
    from a designated place, offer equivalent access to copy the above
    specified materials from the same place.

    d) Verify that the user has already received a copy of these
    materials or that you have already sent this user a copy.

For an executable, the required form of the "work that uses the
Library" must include any data and utility programs needed for
reproducing the executable from it.  However, as a special
exception, the source code distributed need not include anything
that is normally distributed (in either source or binary form)
with the major components (compiler, kernel, and so on) of the
operating system on which the executable runs, unless that
component itself accompanies the executable.

It may happen that this requirement contradicts the license
restrictions of other proprietary libraries that do not normally
accompany the operating system.  Such a contradiction means you
cannot use both them and the Library together in an executable
that you distribute.

7. You may place library facilities that are a work based on the
```

Library side-by-side in a single library together with other
library facilities not covered by this License, and distribute
such a combined library, provided that the separate distribution
of the work based on the Library and of the other library
facilities is otherwise permitted, and provided that you do
these two things:

    a) Accompany the combined library with a copy of the same work
    based on the Library, uncombined with any other library
    facilities. This must be distributed under the terms of the
    Sections above.

    b) Give prominent notice with the combined library of the fact
    that part of it is a work based on the Library, and explaining
    where to find the accompanying uncombined form of the same work.

8. You may not copy, modify, sublicense, link with, or
distribute the Library except as expressly provided under this
License. Any attempt otherwise to copy, modify, sublicense,
link with, or distribute the Library is void, and will
automatically terminate your rights under this License.
However, parties who have received copies, or rights, from you
under this License will not have their licenses terminated so
long as such parties remain in full compliance.

9. You are not required to accept this License, since you have
not signed it. However, nothing else grants you permission to
modify or distribute the Library or its derivative works. These
actions are prohibited by law if you do not accept this
License. Therefore, by modifying or distributing the Library
(or any work based on the Library), you indicate your acceptance
of this License to do so, and all its terms and conditions for
copying, distributing or modifying the Library or works based on
it.

10. Each time you redistribute the Library (or any work based on
the Library), the recipient automatically receives a license
from the original licensor to copy, distribute, link with or
modify the Library subject to these terms and conditions. You
may not impose any further restrictions on the recipients'
exercise of the rights granted herein. You are not responsible
for enforcing compliance by third parties to this License.

11. If, as a consequence of a court judgment or allegation of
patent infringement or for any other reason (not limited to
patent issues), conditions are imposed on you (whether by court
order, agreement or otherwise) that contradict the conditions of
this License, they do not excuse you from the conditions of this
License. If you cannot distribute so as to satisfy
simultaneously your obligations under this License and any other
pertinent obligations, then as a consequence you may not
distribute the Library at all. For example, if a patent license
would not permit royalty-free redistribution of the Library by
all those who receive copies directly or indirectly through you,
then the only way you could satisfy both it and this License
would be to refrain entirely from distribution of the Library.

If any portion of this section is held invalid or unenforceable
under any particular circumstance, the balance of the section is
intended to apply, and the section as a whole is intended to
apply in other circumstances.

It is not the purpose of this section to induce you to infringe
any patents or other property right claims or to contest
validity of any such claims; this section has the sole purpose
of protecting the integrity of the free software distribution
system which is implemented by public license practices. Many
people have made generous contributions to the wide range of
software distributed through that system in reliance on
consistent application of that system; it is up to the
author/donor to decide if he or she is willing to distribute
software through any other system and a licensee cannot impose
that choice.

This section is intended to make thoroughly clear what is
believed to be a consequence of the rest of this License.

12. If the distribution and/or use of the Library is restricted
in certain countries either by patents or by copyrighted
interfaces, the original copyright holder who places the Library
under this License may add an explicit geographical distribution
limitation excluding those countries, so that distribution is
permitted only in or among countries not thus excluded. In such
case, this License incorporates the limitation as if written in
the body of this License.

13. The Free Software Foundation may publish revised and/or new
versions of the Library General Public License from time to
time. Such new versions will be similar in spirit to the present
version, but may differ in detail to address new problems or
concerns.

Each version is given a distinguishing version number. If the
Library specifies a version number of this License which applies
to it and "any later version", you have the option of following
the terms and conditions either of that version or of any later
version published by the Free Software Foundation. If the
Library does not specify a license version number, you may
choose any version ever published by the Free Software
Foundation.

14. If you wish to incorporate parts of the Library into other
free programs whose distribution conditions are incompatible
with these, write to the author to ask for permission. For
software which is copyrighted by the Free Software Foundation,
write to the Free Software Foundation; we sometimes make
exceptions for this. Our decision will be guided by the two
goals of preserving the free status of all derivatives of our
free software and of promoting the sharing and reuse of software
generally.

NO WARRANTY

15. BECAUSE THE LIBRARY IS LICENSED FREE OF CHARGE, THERE IS NO
WARRANTY FOR THE LIBRARY, TO THE EXTENT PERMITTED BY APPLICABLE LAW.
EXCEPT WHEN OTHERWISE STATED IN WRITING THE COPYRIGHT HOLDERS AND/OR
OTHER PARTIES PROVIDE THE LIBRARY "AS IS" WITHOUT WARRANTY OF ANY KIND,
EITHER EXPRESSED OR IMPLIED, INCLUDING, BUT NOT LIMITED TO, THE
IMPLIED WARRANTIES OF MERCHANTABILITY AND FITNESS FOR A PARTICULAR
PURPOSE. THE ENTIRE RISK AS TO THE QUALITY AND PERFORMANCE OF THE
LIBRARY IS WITH YOU. SHOULD THE LIBRARY PROVE DEFECTIVE, YOU ASSUME
THE COST OF ALL NECESSARY SERVICING, REPAIR OR CORRECTION.

16. IN NO EVENT UNLESS REQUIRED BY APPLICABLE LAW OR AGREED TO IN
WRITING WILL ANY COPYRIGHT HOLDER, OR ANY OTHER PARTY WHO MAY MODIFY
AND/OR REDISTRIBUTE THE LIBRARY AS PERMITTED ABOVE, BE LIABLE TO YOU
FOR DAMAGES, INCLUDING ANY GENERAL, SPECIAL, INCIDENTAL OR CONSEQUENTIAL
DAMAGES ARISING OUT OF THE USE OR INABILITY TO USE THE
LIBRARY (INCLUDING BUT NOT LIMITED TO LOSS OF DATA OR DATA BEING
RENDERED INACCURATE OR LOSSES SUSTAINED BY YOU OR THIRD PARTIES OR A
FAILURE OF THE LIBRARY TO OPERATE WITH ANY OTHER SOFTWARE), EVEN IF
SUCH HOLDER OR OTHER PARTY HAS BEEN ADVISED OF THE POSSIBILITY OF SUCH DAMAGES.

END OF TERMS AND CONDITIONS

Appendix: How to Apply These Terms to Your New Libraries

If you develop a new library, and you want it to be of the
greatest possible use to the public, we recommend making it free
software that everyone can redistribute and change. You can do
so by permitting redistribution under these terms (or,
alternatively, under the terms of the ordinary General Public
License).

To apply these terms, attach the following notices to the
library. It is safest to attach them to the start of each

```
source file to most effectively convey the exclusion of
warranty; and each file should have at least the "copyright"
line and a pointer to where the full notice is found.

    <one line to give the library's name and a brief idea of what it does.>
    Copyright (C) <year>  <name of author>

Chapter 5

Cross-Platform Development Tips

This chapter describes some general tips related to cross-platform development.

5.1 Include Files

The main include file is "wx/wx.h"; this includes the most commonly used modules of wxWidgets.

To save on compilation time, include only those header files relevant to the source file. If you are using **precompiled** headers, you should include the following section before any other includes:

```
// For compilers that support precompilation, includes "wx.h".
#include <wx/wxprec.h>

#ifdef __BORLANDC__
#   pragma hdrstop
#endif

#ifndef WX_PRECOMP
    // Include your minimal set of headers here, or wx.h
#   include <wx/wx.h>
#endif

... now your other include files ...
```

The file "wx/wxprec.h" includes "wx/wx.h". Although this incantation may seem quirky, it is in fact the end result of a lot of experimentation, and several Windows compilers to use precompilation which is largely automatic for compilers with necessary support. Currently it is used for Visual C++ (including embedded Visual C++), Borland C++ and newer versions of GCC. Some compilers might need extra work from the application developer to set the build environment up as necessary for the support.

5.2 Libraries

All ports of wxWidgets can create either a **static** library or a **shared** library.

When a program is linked against a *static* library, the machine code from the object files for any external functions used by the program is copied from the library into the final executable.

Shared libraries are handled with a more advanced form of linking, which makes the executable file smaller. They use the extension ".so" (Shared Object) under Linux and ".dll" (Dynamic Link Library) under Windows.

An executable file linked against a shared library contains only a small table of the functions it requires, instead of the complete machine code from the object files for the external functions. Before the executable file starts running, the machine code for the external functions is copied into memory from the shared library file on disk by the operating system - a process referred to as *dynamic* linking.

Dynamic linking makes executable files smaller and saves disk space, because one copy of a library can be shared between multiple programs. Most operating systems also provide a virtual memory mechanism which allows one copy of a shared library in physical memory to be used by all running programs, saving memory as well as disk space.

Furthermore, shared libraries make it possible to update a library without recompiling the programs which use it (provided the interface to the library does not change).

wxWidgets can also be built in **multilib** and **monolithic** variants. See the Library List for more information on these.

5.3 Configuration

When using project files and makefiles directly to build wxWidgets, options are configurable in the file "wx/XX↩X/setup.h" where XXX is the required platform (such as msw, motif, gtk, mac).

Some settings are a matter of taste, some help with platform-specific problems, and others can be set to minimize the size of the library. Please see the "setup.h" file and "install.txt" files for details on configuration.

When using the "configure" script to configure wxWidgets (on Unix and other platforms where configure is available), the corresponding "setup.h" files are generated automatically along with suitable makefiles.

When using the RPM packages (or DEB or other forms of *binaries*) for installing wxWidgets on Linux, a correct "setup.h" is shipped in the package and this must not be changed.

5.4 Makefiles

On Microsoft Windows, wxWidgets has a different set of makefiles for each compiler, because each compiler's 'make' tool is slightly different. Popular Windows compilers that we cater for, and the corresponding makefile extensions, include: Microsoft Visual C++ (.vc), Borland C++ (.bcc) and MinGW/Cygwin (.gcc). Makefiles are provided for the wxWidgets library itself, samples, demos, and utilities.

On Linux, Mac and OS/2, you use the 'configure' command to generate the necessary makefiles. You should also use this method when building with MinGW/Cygwin on Windows.

We also provide project files for some compilers, such as Microsoft VC++. However, we recommend using makefiles to build the wxWidgets library itself, because makefiles can be more powerful and less manual intervention is required.

On Windows using a compiler other than MinGW/Cygwin, you would build the wxWidgets library from the "build/msw" directory which contains the relevant makefiles.

On Windows using MinGW/Cygwin, and on Unix, OS X and OS/2, you invoke 'configure' (found in the top-level of the wxWidgets source hierarchy), from within a suitable empty directory for containing makefiles, object files and libraries.

For details on using makefiles, configure, and project files, please see "docs/xxx/install.txt" in your distribution, where "xxx" is the platform of interest, such as msw, gtk, x11, mac.

All wxWidgets makefiles are generated using Bakefile http://www.bakefile.org/. wxWidgets also provides (in the "build/bakefiles/wxpresets" folder) the wxWidgets bakefile presets. These files allow you to create bakefiles for your own wxWidgets-based applications very easily.

5.5 Windows Resource Files

wxWidgets application compilation under MS Windows requires at least one extra file: a resource file.

The least that must be defined in the Windows resource file (extension RC) is the following statement:

```
#include "wx/msw/wx.rc"
```

which includes essential internal wxWidgets definitions. The resource script may also contain references to icons, cursors, etc., for example:

```
wxicon icon wx.ico
```

The icon can then be referenced by name when creating a frame icon. See the Microsoft Windows SDK documentation.

Note

Include "wx.rc" *after* any ICON statements so programs that search your executable for icons (such as the Program Manager) find your application icon first.

5.6 Allocating and Deleting wxWidgets Objects

In general, classes derived from wxWindow must dynamically allocated with *new* and deleted with *delete*. If you delete a window, all of its children and descendants will be automatically deleted, so you don't need to delete these descendants explicitly.

When deleting a frame or dialog, use **Destroy** rather than **delete** so that the wxWidgets delayed deletion can take effect. This waits until idle time (when all messages have been processed) to actually delete the window, to avoid problems associated with the GUI sending events to deleted windows.

In general wxWindow-derived objects should always be allocated on the heap as wxWidgets will destroy them itself. The only, but important, exception to this rule are the modal dialogs, i.e. wxDialog objects which are shown using wxDialog::ShowModal() method. They may be allocated on the stack and, indeed, usually are local variables to ensure that they are destroyed on scope exit as wxWidgets does not destroy them unlike with all the other windows. So while it is still possible to allocate modal dialogs on the heap, you should still destroy or delete them explicitly in this case instead of relying on wxWidgets doing it.

If you decide to allocate a C++ array of objects (such as wxBitmap) that may be cleaned up by wxWidgets, make sure you delete the array explicitly before wxWidgets has a chance to do so on exit, since calling *delete* on array members will cause memory problems.

wxColour can be created statically: it is not automatically cleaned up and is unlikely to be shared between other objects; it is lightweight enough for copies to be made.

Beware of deleting objects such as a wxPen or wxBitmap if they are still in use. Windows is particularly sensitive to this, so make sure you make calls like wxDC::SetPen(wxNullPen) or wxDC::SelectObject(wxNullBitmap) before deleting a drawing object that may be in use. Code that doesn't do this will probably work fine on some platforms, and then fail under Windows.

5.7 Architecture Dependency

A problem which sometimes arises from writing multi-platform programs is that the basic C types are not defined the same on all platforms. This holds true for both the length in bits of the standard types (such as int and long) as well as their byte order, which might be little endian (typically on Intel computers) or big endian (typically on some Unix workstations). wxWidgets defines types and macros that make it easy to write architecture independent code. The types are:

wxInt32, wxInt16, wxInt8, wxUint32, wxUint16 = wxWord, wxUint8 = wxByte

where wxInt32 stands for a 32-bit signed integer type etc. You can also check which architecture the program is compiled on using the wxBYTE_ORDER define which is either wxBIG_ENDIAN or wxLITTLE_ENDIAN (in the future maybe wxPDP_ENDIAN as well).

The macros handling bit-swapping with respect to the applications endianness are described in the Byte Order section.

5.8 Conditional Compilation

One of the purposes of wxWidgets is to reduce the need for conditional compilation in source code, which can be messy and confusing to follow. However, sometimes it is necessary to incorporate platform-specific features (such as metafile use under MS Windows). The wxUSE Preprocessor Symbols symbols listed in the file `setup.h` may be used for this purpose, along with any user-supplied ones.

5.9 C++ Issues

The following documents some miscellaneous C++ issues.

5.9.1 Templates

wxWidgets does not use templates (except for some advanced features that are switched off by default) since it is a notoriously unportable feature.

5.9.2 Runtime Type Information (RTTI)

wxWidgets does not use C++ run-time type information since wxWidgets provides its own run-time type information system, implemented using macros.

5.9.3 Precompiled Headers

Some compilers, such as Borland C++ and Microsoft C++, support precompiled headers. This can save a great deal of compiling time. The recommended approach is to precompile `"wx.h"`, using this precompiled header for compiling both wxWidgets itself and any wxWidgets applications. For Windows compilers, two dummy source files are provided (one for normal applications and one for creating DLLs) to allow initial creation of the precompiled header.

However, there are several downsides to using precompiled headers. One is that to take advantage of the facility, you often need to include more header files than would normally be the case. This means that changing a header file will cause more recompilations (in the case of wxWidgets, everything needs to be recompiled since everything includes `"wx.h"`).

A related problem is that for compilers that don't have precompiled headers, including a lot of header files slows down compilation considerably. For this reason, you will find (in the common X and Windows parts of the library) conditional compilation that under Unix, includes a minimal set of headers; and when using Visual C++, includes `"wx.h"`. This should help provide the optimal compilation for each compiler, although it is biased towards the precompiled headers facility available in Microsoft C++.

5.10 File Handling

When building an application which may be used under different environments, one difficulty is coping with documents which may be moved to different directories on other machines. Saving a file which has pointers to full pathnames is going to be inherently unportable.

One approach is to store filenames on their own, with no directory information. The application then searches into a list of standard paths (platform-specific) through the use of wxStandardPaths.

Eventually you may want to use also the wxPathList class.

Nowadays the limitations of DOS 8+3 filenames doesn't apply anymore. Most modern operating systems allow at least 255 characters in the filename; the exact maximum length, as well as the characters allowed in the filenames,

are OS-specific so you should try to avoid extremely long ($>$ 255 chars) filenames and/or filenames with non-ANSI characters.

Another thing you need to keep in mind is that all Windows operating systems are case-insensitive, while Unix operating systems (Linux, Mac, etc) are case-sensitive.

Also, for text files, different OSes use different End Of Lines (EOL). Windows uses CR+LF convention, Linux uses LF only, Mac CR only.

The wxTextFile, wxTextInputStream, wxTextOutputStream classes help to abstract from these differences. Of course, there are also 3rd party utilities such as `dos2unix` and `unix2dos` which do the EOL conversions.

See also the Files and Directories section of the reference manual for the description of miscellaneous file handling functions.

5.11 Reducing Programming Errors

5.11.1 Use ASSERT

It is good practice to use ASSERT statements liberally, that check for conditions that should or should not hold, and print out appropriate error messages.

These can be compiled out of a non-debugging version of wxWidgets and your application. Using ASSERT is an example of 'defensive programming': it can alert you to problems later on.

See wxASSERT() for more info.

5.11.2 Use wxString in Preference to Character Arrays

Using wxString can be much safer and more convenient than using `wxChar*`.

You can reduce the possibility of memory leaks substantially, and it is much more convenient to use the overloaded operators than functions such as `strcmp`. wxString won't add a significant overhead to your program; the overhead is compensated for by easier manipulation (which means less code).

The same goes for other data types: use classes wherever possible.

5.12 GUI Design

- **Use Sizers:** Don't use absolute panel item positioning if you can avoid it. Every platform's native controls have very different sizes. Consider using the Sizers Overview instead.
- **Use wxWidgets Resource Files:** Use `XRC` (wxWidgets resource files) where possible, because they can be easily changed independently of source code. See the XML Based Resource System (XRC) for more info.

5.13 Debugging

5.13.1 Positive Thinking

It is common to blow up the problem in one's imagination, so that it seems to threaten weeks, months or even years of work. The problem you face may seem insurmountable: but almost never is. Once you have been programming for some time, you will be able to remember similar incidents that threw you into the depths of despair. But remember, you always solved the problem, somehow!

Perseverance is often the key, even though a seemingly trivial problem can take an apparently inordinate amount of time to solve. In the end, you will probably wonder why you worried so much. That's not to say it isn't painful at the time. Try not to worry – there are many more important things in life.

5.13.2 Simplify the Problem

Reduce the code exhibiting the problem to the smallest program possible that exhibits the problem. If it is not possible to reduce a large and complex program to a very small program, then try to ensure your code doesn't hide the problem (you may have attempted to minimize the problem in some way: but now you want to expose it).

With luck, you can add a small amount of code that causes the program to go from functioning to non-functioning state. This should give a clue to the problem. In some cases though, such as memory leaks or wrong deallocation, this can still give totally spurious results!

5.13.3 Use a Debugger

This sounds like facetious advice, but it is surprising how often people don't use a debugger. Often it is an overhead to install or learn how to use a debugger, but it really is essential for anything but the most trivial programs.

5.13.4 Use Logging Functions

There is a variety of logging functions that you can use in your program: see Logging.

Using tracing statements may be more convenient than using the debugger in some circumstances (such as when your debugger doesn't support a lot of debugging code, or you wish to print a bunch of variables).

5.13.5 Use the wxWidgets Debugging Facilities

You can use wxDebugContext to check for memory leaks and corrupt memory: in fact in debugging mode, wx↩ Widgets will automatically check for memory leaks at the end of the program if wxWidgets is suitably configured. Depending on the operating system and compiler, more or less specific information about the problem will be logged.

You should also use Debugging macros as part of a "defensive programming" strategy, scattering wxASSERT()s liberally to test for problems in your code as early as possible. Forward thinking will save a surprising amount of time in the long run.

See the Debugging for further information.

Chapter 6

Introduction

6.1 What is wxWidgets?

wxWidgets is an open source C++ framework allowing to write cross-platform GUI applications with native look and feel in C++ and other languages.

wxWidgets was originally developed by Julian Smart at the Artificial Intelligence Applications Institute, University of Edinburgh, for internal use, and was first made publicly available in 1992, with a vastly improved version 2 released in 1999. The last major version of the library is 3 and was released in 2013. Currently wxWidgets is developed and maintained by Julian Smart, Vadim Zeitlin, Stefan Csomor, Robert Roebling, Vaclav Slavik and many others.

More information about wxWidgets is available on its web site at http://www.wxwidgets.org.

6.2 Why choose wxWidgets?

Compared to the other similar libraries, wxWidgets is:

1. The only C++ GUI library built by wrapping native GUI widgets which results in the best user experience on each platform.
2. Written using only the standard C++ and doesn't rely on any custom extensions or preprocessing.
3. Open source and free for use in both open source and commercial projects.

wxWidgets provides a simple, easy to learn, yet very rich API. It is also mature and stable, and the applications written using wxWidgets 2.0 pre-releases almost 20 years ago can still be built today with wxWidgets 3 almost unchanged. wxWidgets has a large, active and friendly community of people, including both the users and developers of the library. It is also available now for more than a dozen other languages, including Python, Perl, Ruby, Lua, Haskell, D, Erlang, PHP, in addition to C++.

It is impossible to sum up everything included in wxWidgets in a few paragraphs, but here are some of the benefits:

- Available on all major desktop platforms.
- Free for any use.
- Source is available and easy to read and modify if necessary.
- Over 100 example programs.
- Extensive documentation (almost 200,000 lines of it).
- Straightforward API.
- Simple but powerful layout system.

- Run-time loadable or compile-time embeddable resources.
- Flexible event system.
- All the usual and quite a few of more rare GUI controls.
- And also all the standard dialogs.
- 2D path-based drawing API with full support for transparency.
- Built-in support for many file formats (BMP, PNG, JPEG, GIF, XPM, PNM, PCX, TGA, ...).
- Printing, help, clipboard, drag-and-drop, document/view, ... support.
- Integration with the native platform HTML rendering engine.
- Dockable windows framework.
- Word processor-like widget.
- Powerful text editing widget with syntax highlighting.
- And much, much more...

6.3 wxWidgets Requirements

wxWidgets first-tier "ports", ie implementations of wxWidgets API, are:

- wxMSW: This is the native port for Microsoft Windows systems (from Windows 95 up to Windows 8.1 with at least Windows XP being recommended), either 32 or 64 bits. The primarily supported compilers are Microsoft Visual C++ (versions 6 up to 2013 are supported, at least 2005 is recommended) and GNU g++ (either from the traditional MinGW, TDM-GCC or MinGW-w64 distributions).

- wxGTK: wxGTK2 and wxGTK3 are the ports using GTK+ library version 2.x and 3.x respectively. They are very similar, with wxGTK2 being, however, more mature. Both ports work on almost any Unix system (Linux, FreeBSD, OpenBSD, NetBSD, Solaris, AIX, ...) and require GTK+ 2.6 or later or GTK+ 3.x. The primary supported compiler is GNU g++.

- wxOSX: wxOSX/Cocoa is the primary port for Apple computers, replacing the older and now deprecated wxOSX/Carbon port. wxOSX supports either PowerPC or Intel Macs running OS X 10.5 or higher and can be compiled in either 32 or 64 bits using Apple Developer Tools (both GNU g++ and clang are supported).

Other platforms (iOS, Windows CE, OS/2), compilers (Borland C++ under Windows, Sun CC, HP-UX aCC, IBM xlC or SGI mipsPro under Unix) and ports (wxOSX/Carbon, wxGTK1, wxX11, wxDFB, wxPM...) are also supported but to a lesser extent. Please see the platform details page for more information.

There are no CPU speed requirements but the faster (and more) CPU(s) you have, the faster the library will compile. You do need to have enough RAM, especially under Windows platforms, to avoid running out of memory during link phase. Depending on the compiler used, you may need at least 4GB to be able to link. Under all platforms it's recommended to have large amounts of free hard disk space. The exact amount needed depends on the port, compiler and build configurations but at least 1GB and possibly more is required.

6.4 Where to get wxWidgets and support for it

The download links can be found at http://www.wxwidgets.org. The primary download location is https://sourceforge.net/downloads/wxwindows/ and there is also an FTP mirror at ftp://ftp.wxwidgets.org/pub/. Additionally, the latest version can always be retrieved from our version control system using either Subversion (http://svn.wxwidgets.org/svn/wx/wxWidgets/) or Git (https://github.com/wxWidgets/wxWidgets).

wxWidgets documentation that you are reading is also available online at http://docs.wxwidgets.org/trunk/ and please also visit our wiki at http://wiki.wxwidgets.org/ for user-contributed contents.

And if you have any questions, you can join wxWidgets community using

- Web-based wxForum.
- Mailing lists.
- #wxwidgets IRC channel.
- Or asking questions with wxwidgets tag on http://stackoverflow.com/

6.5 Platform Details

wxWidgets defines a common API across platforms, but uses the native graphical user interface (GUI) on each platform, so your program will take on the native look and feel that users are familiar with.

Unfortunately native toolkits and hardware do not always support the functionality that the wxWidgets API requires. This chapter collects notes about differences among supported platforms and ports.

6.5.1 wxGTK

wxGTK is a port of wxWidgets using the GTK+ library. It makes use of GTK+'s native widgets wherever possible and uses wxWidgets' generic controls when needed. GTK+ itself has been ported to a number of systems, but so far only the original X11 version is supported. Support for other GTK+ backends is planned, such as the new DirectFB backend.

All work is being done on GTK+ version 2.0 and above. Support for GTK+ 1.2 will be deprecated in a later release.

You will need GTK+ 2.6 or higher which is available from:

http://www.gtk.org

The newer version of GTK+ you use, the more native widgets and features will be utilized. We have gone to great lengths to allow compiling wxWidgets applications with the latest version of GTK+, with the resulting binary working on systems even with a much earlier version of GTK+. You will have to ensure that the application is launched with lazy symbol binding for that.

In order to configure wxWidgets to compile wxGTK you will need use the `-with-gtk` argument to the `configure` script. This is the default for many systems.

GTK+ 1.2 can still be used, albeit discouraged. For that you can pass `-with-gtk=1` to the `configure` script.

Support for GTK+ 3 is available starting with wxWidgets 2.9.4, use `configure` option `-with-gtk=3` to enable it.

For further information, please see the files in `docs/gtk` in the distribution.

6.5.2 wxOSX

wxOSX/Cocoa

wxOSX/Cocoa is the currently recommended port of wxWidgets for the Macintosh OS platform. It requires OS X 10.7 or later and, unlike wxOSX/Carbon, fully supports 64 bit builds.

This is the default port when building wxOSX, but in order to select it explicitly you can use

```
configure --with-osx_cocoa
```

For further information, please see the files in `docs/osx` in the distribution.

wxOSX/Carbon

wxOSX/Carbon is an older port of wxWidgets for the Macintosh OS platform. Currently OS X 10.5 or higher are supported. wxOSX/Carbon can be compiled both using Apple's command line developer tools as well as Apple's Xcode IDE. wxOSX/Carbon supports Intel and PowerPC architectures and can be used to produce "universal binaries" in order create application which can run both architecture. Unfortunately, wxOSX/Carbon does not support any 64-bit architecture since Apple decided not to port its Carbon API entirely to 64-bit.

Note

Carbon has been deprecated by Apple as of OS X 10.5 and will likely be removed entirely in a future OS version. It's recommended you look into switching your app over to wxOSX/Cocoa as soon as possible.

To build wxWidgets using wxOSX/Carbon you need to do

```
configure --with-osx_carbon
```

For further information, please see the files in `docs/osx` in the distribution.

6.5.3 wxX11

wxX11 is a port of wxWidgets using X11 (The X Window System) as the underlying graphics backend. wxX11 draws its widgets using the wxUniversal widget set which is now part of wxWidgets. wxX11 is well-suited for a number of special applications such as those running on systems with few resources (PDAs) or for applications which need to use a special themed look.

In order to configure wxWidgets to compile wxX11 you will need to type:

```
configure --with-x11 --with-universal
```

For further information, please see the files in `docs/x11` in the distribution. There is also a page on the use of wxWidgets for embedded applications on the wxWidgets web site.

6.5.4 wxMotif

wxMotif is a port of wxWidgets for X11 systems using Motif libraries. Motif libraries provide a clean and fast user interface at the expense of the beauty and candy of newer interfaces like GTK.

For further information, please see the files in `docs/motif` in the distribution.

6.5.5 wxMSW

wxMSW is a port of wxWidgets for the Windows platforms (Windows XP and later are supported). wxMSW provides native look and feel for each Windows version. This port can be compiled with several compilers including Microsoft Studio VC++ 2003 or later, Borland 5.5, MinGW32, Cygwin as well as cross-compilation with a Linux-hosted MinGW32 tool chain.

For further information, please see the files in docs/msw in the distribution.

Resources and Application Icon

All applications using wxMSW should have a Windows resource file (.rc extension) and this file should include `include/wx/msw/wx.rc` file which defines resources used by wxWidgets itself.

Among other things, `wx.rc` defines some standard icons, all of which have names starting with the "wx" prefix. This normally ensures that any icons defined in the application's own resource file come before them in alphabetical

order which is important because Explorer (Windows shell) selects the first icon in alphabetical order to use as the application icon which is displayed when viewing its file in the file manager. So if all the icons defined in your application start with "x", "y" or "z", they won't be used by Explorer. To avoid this, ensure that the icon which is meant to be used as the main application icon has a name preceding "wxICON" in alphabetical order.

Themed Borders

Starting with wxWidgets 2.8.5, you can specify the `wxBORDER_THEME` style to have wxWidgets use a themed border. Using the default XP theme, this is a thin 1-pixel blue border, with an extra 1-pixel border in the window client background colour (usually white) to separate the client area's scrollbars from the border.

If you don't specify a border style for a wxTextCtrl in rich edit mode, wxWidgets now gives the control themed borders automatically, where previously they would take the Windows 95-style sunken border. Other native controls such as wxTextCtrl in non-rich edit mode, and wxComboBox already paint themed borders where appropriate. To use themed borders on other windows, such as wxPanel, pass the `wxBORDER_THEME` style, or (apart from wxPanel) pass no border style.

In general, specifying `wxBORDER_THEME` will cause a border of some kind to be used, chosen by the platform and control class. To leave the border decision entirely to wxWidgets, pass `wxBORDER_DEFAULT`. This is not to be confused with specifying `wxBORDER_NONE`, which says that there should definitely be *no* border.

Internal Border Implementation

The way that wxMSW decides whether to apply a themed border is as follows. The theming code calls wxWindow::GetBorder() to obtain a border. If no border style has been passed to the window constructor, GetBorder() calls GetDefaultBorder() for this window. If wxBORDER_THEME was passed to the window constructor, GetBorder() calls GetDefaultBorderForControl().

The implementation of wxWindow::GetDefaultBorder() on wxMSW calls wxWindow::CanApplyThemeBorder() which is a virtual function that tells wxWidgets whether a control can have a theme applied explicitly (some native controls already paint a theme in which case we should not apply it ourselves). Note that wxPanel is an exception to this rule because in many cases we wish to create a window with no border (for example, notebook pages). So wxPanel overrides GetDefaultBorder() in order to call the generic wxWindowBase::GetDefaultBorder(), returning wxBORDER_NONE.

wxWinCE

wxWinCE is the name given to wxMSW when compiled on Windows CE devices; most of wxMSW is common to Win32 and Windows CE but there are some simplifications, enhancements, and differences in behaviour.

For building instructions, see docs/msw/wince in the distribution, also the section about Visual Studio 2005 project files below. The rest of this section documents issues you need to be aware of when programming for Windows CE devices.

General Issues for wxWinCE

Mobile applications generally have fewer features and simpler user interfaces. Simply omit whole sizers, static lines and controls in your dialogs, and use comboboxes instead of listboxes where appropriate. You also need to reduce the amount of spacing used by sizers, for which you can use a macro such as this:

```
#if defined(__WXWINCE__)
    #define wxLARGESMALL(large,small) small
#else
    #define wxLARGESMALL(large,small) large
#endif

// Usage
topsizer->Add( CreateTextSizer( message ), 0, wxALL, wxLARGESMALL(10,0) );
```

There is only ever one instance of a Windows CE application running, and wxWidgets will take care of showing the current instance and shutting down the second instance if necessary.

You can test the return value of wxSystemSettings::GetScreenType() for a qualitative assessment of what kind of display is available, or use wxGetDisplaySize() if you need more information.

You can also use wxGetOsVersion to test for a version of Windows CE at run-time (see the next section). However, because different builds are currently required to target different kinds of device, these values are hard-wired according to the build, and you cannot dynamically adapt the same executable for different major Windows CE platforms. This would require a different approach to the way wxWidgets adapts its behaviour (such as for menubars) to suit the style of device.

See the "Life!" example (demos/life) for an example of an application that has been tailored for PocketPC and Smartphone use.

Note

Don't forget to have this line in your .rc file, as for desktop Windows applications:

```
#include "wx/msw/wx.rc"
```

Testing for WinCE SDKs

Use these preprocessor symbols to test for the different types of devices:

- **SMARTPHONE** Generic mobile devices with phone buttons and a small display
- **PDA** Generic mobile devices with no phone
- **HANDHELDPC** Generic mobile device with a keyboard
- **WXWINCE** Microsoft-powered Windows CE devices, whether PocketPC, Smartphone or Standard SDK
- **WIN32_PLATFORM_WFSP** Microsoft-powered smartphone
- **POCKETPC** Microsoft-powered PocketPC devices with touch-screen
- **WINCE_STANDARDSDK** Microsoft-powered Windows CE devices, for generic Windows CE applications
- **WINCE_NET** Microsoft-powered Windows CE .NET devices (_WIN32_WCE is 400 or greater)

wxGetOsVersion() will return these values:

- **wxWINDOWS_POCKETPC** The application is running under PocketPC.
- **wxWINDOWS_SMARTPHONE** The application is running under Smartphone.
- **wxWINDOWS_CE** The application is running under Windows CE (built with the Standard SDK).

Window sizing in wxWinCE

Top level windows (dialogs, frames) are created always full-screen. Fit() of sizers will not rescale top level windows but instead will scale window content.

If the screen orientation changes, the windows will automatically be resized so no further action needs to be taken (unless you want to change the layout according to the orientation, which you could detect in idle time, for example). When input panel (SIP) is shown, top level windows (frames and dialogs) resize accordingly (see wxTopLevelWindow::HandleSettingChange()).

Closing Top-level Windows in wxWinCE

You won't get a wxCloseEvent when the user clicks on the X in the titlebar on Smartphone and PocketPC; the window is simply hidden instead. However the system may send the event to force the application to close down.

Hibernation in wxWinCE

Smartphone and PocketPC will send a wxEVT_HIBERNATE to the application object in low memory conditions. Your application should release memory and close dialogs, and wake up again when the next wxEVT_ACTIVATE or wxEVT_ACTIVATE_APP message is received. (wxEVT_ACTIVATE_APP is generated whenever a wxEVT_ACTIVATE event is received in Smartphone and PocketPC, since these platforms do not support WM_ACTIVATEAPP.)

Hardware Buttons in wxWinCE

Special hardware buttons are sent to a window via the wxEVT_HOTKEY event under Smartphone and PocketPC. You should first register each required button with wxWindow::RegisterHotKey(), and unregister the button when you're done with it. For example:

```
win->RegisterHotKey(0, wxMOD_WIN, WXK_SPECIAL1);
win->UnregisterHotKey(0);
```

You may have to register the buttons in a wxEVT_ACTIVATE event handler since other applications will grab the buttons.

There is currently no method of finding out the names of the special buttons or how many there are.

Dialogs in wxWinCE

PocketPC dialogs have an OK button on the caption, and so you should generally not repeat an OK button on the dialog. You can add a Cancel button if necessary, but some dialogs simply don't offer you the choice (the guidelines recommend you offer an Undo facility to make up for it). When the user clicks on the OK button, your dialog will receive a wxID_OK event by default. If you wish to change this, call wxDialog::SetAffirmativeId() with the required identifier to be used. Or, override wxDialog::DoOK() (return false to have wxWidgets simply call Close to dismiss the dialog).

Smartphone dialogs do *not* have an OK button on the caption, and are closed using one of the two menu buttons. You need to assign these using wxTopLevelWindow::SetLeftMenu and wxTopLevelWindow::SetRightMenu(), for example:

```
#ifdef __SMARTPHONE__
    SetLeftMenu(wxID_OK);
    SetRightMenu(wxID_CANCEL, _("Cancel"));
#elif defined(__POCKETPC__)
    // No OK/Cancel buttons on PocketPC, OK on caption will close
#else
    topsizer->Add( CreateButtonSizer( wxOK|wxCANCEL ), 0, wxEXPAND |
      wxALL, 10 );
#endif
```

For implementing property sheets (flat tabs), use a wxNotebook with wxNB_FLAT|wxNB_BOTTOM and have the notebook left, top and right sides overlap the dialog by about 3 pixels to eliminate spurious borders. You can do this by using a negative spacing in your sizer Add() call. The cross-platform property sheet dialog wxPropertySheetDialog is provided, to show settings in the correct style on PocketPC and on other platforms.

Notifications (bubble HTML text with optional buttons and links) will also be implemented in the future for PocketPC.

Modeless dialogs probably don't make sense for PocketPC and Smartphone, since frames and dialogs are normally full-screen, and a modeless dialog is normally intended to co-exist with the main application frame.

Menubars and Toolbars in PocketPC

On PocketPC, a frame must always have a menubar, even if it's empty. An empty menubar/toolbar is automatically provided for dialogs, to hide any existing menubar for the duration of the dialog.

Menubars and toolbars are implemented using a combined control, but you can use essentially the usual wxWidgets API; wxWidgets will combine the menubar and toolbar. However, there are some restrictions:

- You must create the frame's primary toolbar with wxFrame::CreateToolBar(), because this uses the special wxToolMenuBar class (derived from wxToolBar) to implement the combined toolbar and menubar. Otherwise,

you can create and manage toolbars using the wxToolBar class as usual, for example to implement an optional formatting toolbar above the menubar as Pocket Word does. But don't assign a wxToolBar to a frame using SetToolBar - you should always use CreateToolBar for the main frame toolbar.

- Deleting and adding tools to wxToolMenuBar after Realize is called is not supported.
- For speed, colours are not remapped to the system colours as they are in wxMSW. Provide the tool bitmaps either with the correct system button background, or with transparency (for example, using XPMs).
- Adding controls to wxToolMenuBar is not supported. However, wxToolBar supports controls.

Unlike in all other ports, a wxDialog has a wxToolBar automatically created for you. You may either leave it blank, or access it with wxDialog::GetToolBar() and add buttons, then calling wxToolBar::Realize(). You cannot set or recreate the toolbar.

Menubars and Toolbars in Smartphone

On Smartphone, there are only two menu buttons, so a menubar is simulated using a nested menu on the right menu button. Any toolbars are simply ignored on Smartphone.

Closing Windows in wxWinCE

The guidelines state that applications should not have a Quit menu item, since the user should not have to know whether an application is in memory or not. The close button on a window does not call the window's close handler; it simply hides the window. However, the guidelines say that the Ctrl+Q accelerator can be used to quit the application, so wxWidgets defines this accelerator by default and if your application handles wxID_EXIT, it will do the right thing.

Context Menus in wxWinCE

To enable context menus in PocketPC, you currently need to call wxWindow::EnableContextMenu(), a wxWinCE-only function. Otherwise the context menu event (wxContextMenuEvent) will never be sent. This API is subject to change.

Context menus are not supported in Smartphone.

Control Differences on wxWinCE

These controls and styles are specific to wxWinCE:

- wxTextCtrl The `wxTE_CAPITALIZE` style causes a CAPEDIT control to be created, which capitalizes the first letter.

These controls are missing from wxWinCE:

- MDI classes MDI is not supported under Windows CE.
- wxMiniFrame Not supported under Windows CE.

Tooltips are not currently supported for controls, since on PocketPC controls with tooltips are distinct controls, and it will be hard to add dynamic tooltip support.

Control borders on PocketPC and Smartphone should normally be specified with `wxBORDER_SIMPLE` instead of `wxBORDER_SUNKEN`. Controls will usually adapt appropriately by virtue of their GetDefaultBorder() function, but if you wish to specify a style explicitly you can use `wxDEFAULT_CONTROL_BORDER` which will give a simple border on PocketPC and Smartphone, and the sunken border on other platforms.

Online Help in wxWinCE

You can use the help controller wxWinceHelpController which controls simple .htm files, usually installed in the Windows directory. See the Windows CE reference for how to format the HTML files.

Installing your PocketPC and Smartphone Applications

To install your application, you need to build a CAB file using the parameters defined in a special .inf file. The CabWiz program in your SDK will compile the CAB file from the .inf file and files that it specifies.

For delivery, you can simply ask the user to copy the CAB file to the device and execute the CAB file using File Explorer. Or, you can write a program for the desktop PC that will find the ActiveSync Application Manager and install the CAB file on the device, which is obviously much easier for the user.

Here are some links that may help.

- A setup builder that takes CABs and builds a setup program is at http://www.eskimo.com/~scottlu/win/index.html.
- Sample installation files can be found in `Windows CE Tools/wce420/POCKET PC 2003/Samples/Win32/AppInst`.
- An installer generator using wxPython can be found at http://ppcquicksoft.iespana.es/ppcquicksoft/myinstall.html.
- Miscellaneous Windows CE resources can be found at http://www.orbworks.com/pcce/resources.html.
- Installer creation instructions with a setup.exe for installing to PPC can be found at http://www.pocketpcdn.com/articles/creatingsetup.html.
- Microsoft instructions are at http://msdn.microsoft.com/library/default.asp?url=/library/en-us/dnppcgen/html/msdn_cabwiz.asp?frame=true
- Troubleshooting WinCE application installations: http://support.microsoft.com/default.aspx?scid=KB;en-us;q181007

You may also check out `demos/life/setup/wince` which contains scripts to create a PocketPC installation for ARM-based devices. In particular, `build.bat` builds the distribution and copies it to a directory called `Deliver`.

wxFileDialog in PocketPC

Allowing the user to access files on memory cards, or on arbitrary parts of the filesystem, is a pain; the standard file dialog only shows folders under My Documents or folders on memory cards (not the system or card root directory, for example). This is a known problem for PocketPC developers.

If you need a file dialog that allows access to all folders, you can use wxGenericFileDialog instead. You will need to include `wx/generic/filedlgg.h`.

Embedded Visual C++ Issues

Run-time type information

If you wish to use runtime type information (RTTI) with eVC++ 4, you need to download an extra library, `ccrtrtti.lib`, and link with it. At the time of writing you can get it from here:

```
http://support.microsoft.com/kb/830482/en-us
```

Otherwise you will get linker errors similar to this:

```
wxwince26d.lib(control.obj) : error LNK2001: unresolved external symbol "const type_info::`vftable'" (??_7type
```

Windows Mobile 5.0 emulator

Note that there is no separate emulator configuration for Windows Mobile 5.0: the emulator runs the ARM code directly.

Visual Studio 2005 project files

Unfortunately, Visual Studio 2005, required to build Windows Mobile 5.0 applications, doesn't do a perfect job of converting the project files from eVC++ format.

When you have converted the wxWidgets workspace, edit the configuration properties for each configuration and in the Librarian, add a relative path

```
..\..\lib
```

to each library path. For example:

```
..\$(PlatformName)\$(ConfigurationName)\wx_mono.lib
```

Then, for a sample you want to compile, edit the configuration properties and make sure

```
..\..\lib\$(PlatformName)\$(ConfigurationName)
```

is in the Linker/General/Additional Library Directories property. Also change the Linker/Input/Additional Dependencies property to something like

```
coredll.lib wx_mono.lib wx_wxjpeg.lib wx_wxpng.lib wx_wxzlib.lib wx_wxexpat.lib commctrl.lib winsock.lib winin
```

since the library names in the wxWidgets workspace were changed by VS 2005.

Alternately, you could edit all the names to be identical to the original eVC++ names, but this will probably be more fiddly.

Remaining Issues

These are some of the remaining problems to be sorted out, and features to be supported.

- **Windows Mobile 5 issues.** It is not possible to get the HMENU for the command bar on Mobile 5, so the menubar functions need to be rewritten to get the individual menus without use of a menubar handle. Also the new Mobile 5 convention of using only two menus (and no bitmap buttons) needs to be considered.
- **Sizer speed.** Particularly for dialogs containing notebooks, layout seems slow. Some analysis is required.
- **Notification boxes.** The balloon-like notification messages, and their icons, should be implemented. This will be quite straightforward.
- **SIP size.** We need to be able to get the area taken up by the SIP (input panel), and the remaining area, by calling SHSipInfo. We also may need to be able to show and hide the SIP programmatically, with SHSip↩ Preference. See also the *Input Dialogs* topic in the *Programming Windows CE* guide for more on this, and how to have dialogs show the SIP automatically using the `WC_SIPREF` control.
- **wxStaticBitmap.** The About box in the "Life!" demo shows a bitmap that is the correct size on the emulator, but too small on a VGA Pocket Loox device.
- **wxStaticLine.** Lines don't show up, and the documentation suggests that missing styles are implemented with `WM_PAINT`.
- **HTML control.** PocketPC has its own HTML control which can be used for showing local pages or navigating the web. We should create a version of wxHtmlWindow that uses this control, or have a separately-named control (wxHtmlCtrl), with a syntax as close as possible to wxHtmlWindow.
- **Tooltip control.** PocketPC uses special TTBUTTON and TTSTATIC controls for adding tooltips, with the tooltip separated from the label with a double tilde. We need to support this using SetToolTip.(Unfortunately it does not seem possible to dynamically remove the tooltip, so an extra style may be required.)
- **Focus.** In the wxPropertySheetDialog demo on Smartphone, it's not possible to navigate between controls. The focus handling in wxWidgets needs investigation. See in particular src/common/containr.cpp, and note that the default OnActivate handler in src/msw/toplevel.cpp sets the focus to the first child of the dialog.

- **OK button.** We should allow the OK button on a dialog to be optional, perhaps by using `wxCLOSE_BOX` to indicate when the OK button should be displayed.
- **Dynamic adaptation.** We should probably be using run-time tests more than preprocessor tests, so that the same WinCE application can run on different versions of the operating system.
- **Modeless dialogs.** When a modeless dialog is hidden with the OK button, it doesn't restore the frame's menubar. See for example the find dialog in the dialogs sample. However, the menubar is restored if pressing Cancel (the window is closed). This reflects the fact that modeless dialogs are not very useful on Windows CE; however, we could perhaps destroy/restore a modeless dialog's menubar on deactivation and activation.
- **Home screen plugins.** Figure out how to make home screen plugins for use with wxWidgets applications (see http://www.codeproject.com/ce/CTodayWindow.asp for inspiration). Although we can't use wxWidgets to create the plugin (too large), we could perhaps write a generic plugin that takes registry information from a given application, with options to display information in a particular way using icons and text from a specified location.
- **Further abstraction.** We should be able to abstract away more of the differences between desktop and mobile applications, in particular for sizer layout.
- **Dialog captions.** The blue, bold captions on dialogs - with optional help button - should be catered for, either by hard-wiring the capability into all dialogs and panels, or by providing a standard component and sizer.

6.5.6 Native Toolkit Documentation

It's sometimes useful to interface directly with the underlying toolkit used by wxWidgets to e.g. use toolkit-specific features. In such case (or when you want to e.g. write a port-specific patch) it can be necessary to use the underlying toolkit API directly:

- wxMSW port uses win32 API: see MSDN docs at http://msdn2.microsoft.com/en-us/library/ms649779.aspx
- wxGTK port uses GTK+ and other lower-level libraries; see
  - GTK+ docs at http://library.gnome.org/devel/gtk/unstable/
  - GDK docs at http://library.gnome.org/devel/gdk/unstable/
  - GLib docs at http://library.gnome.org/devel/glib/unstable/
  - GObject docs at http://library.gnome.org/devel/gobject/unstable/
  - Pango docs at http://library.gnome.org/devel/pango/unstable/
- wxMac port uses the Carbon API: see Carbon docs at http://developer.apple.com/carbon
- wxCocoa port uses the Cocoa API: see Cocoa docs at http://developer.apple.com/cocoa

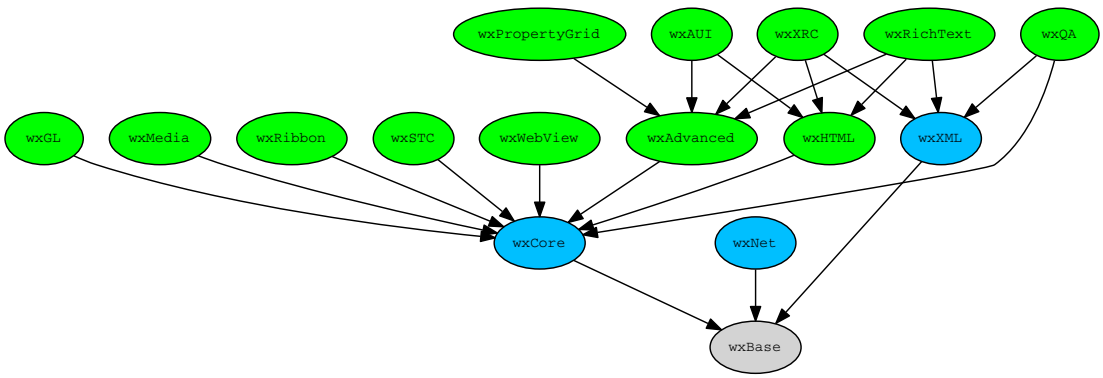
Chapter 7

Library List

wxWidgets can be built either as a single large library (this is called a *monolithic build*) or as several smaller libraries (*multilib build*).

Multilib build is the default.

wxWidgets library is divided into libraries briefly described below. This diagram shows the dependencies between them:



Please note that arrows indicate the "depends from" relation and that all blue libraries depend on the wxBase library (i.e. they are non-GUI libraries), and all green libraries depend on the wxCore library (i.e. they are GUI libraries).

7.1 wxAdvanced

Advanced or rarely used GUI classes:

- wxCalendarCtrl
- wxGrid classes
- wxJoystick
- wxLayoutAlgorithm
- wxSplashScreen
- wxTaskBarIcon

- wxSound
- wxWizard
- wxSashLayoutWindow
- wxSashWindow
- ...others

Requires wxCore and wxBase.

7.2 wxAui

This contains the Advanced User Interface docking library.

Requires wxAdvanced, wxHTML, wxXML, wxCore, wxBase.

7.3 wxBase

Every wxWidgets application must link against this library. It contains mandatory classes that any wxWidgets code depends on (e.g. wxString) and portability classes that abstract differences between platforms. wxBase can be used to develop console mode applications, it does not require any GUI libraries or running X Window System on Unix.

7.4 wxCore

Basic GUI classes such as GDI classes or controls are in this library. All wxWidgets GUI applications must link against this library, only console mode applications don't.

Requires wxBase.

7.5 wxGL

This library contains wxGLCanvas class for integrating OpenGL library with wxWidgets. Unlike all others, this library is **not** part of the monolithic library, it is always built as separate library.

Requires wxCore and wxBase.

7.6 wxHTML

Simple HTML renderer and other wxHTML Overview are contained in this library, as well as wxHtmlHelpController, wxBestHelpController and wxHtmlListBox.

Requires wxCore and wxBase.

7.7 wxMedia

Miscellaneous classes related to multimedia. Currently this library only contains wxMediaCtrl but more classes will be added in the future.

Requires wxCore and wxBase.

7.8 wxNet

Classes for network access:

- wxSocket classes (wxSocketClient, wxSocketServer and related classes)
- wxSocketOutputStream and wxSocketInputStream
- sockets-based IPC classes (wxTCPServer, wxTCPClient and wxTCPConnection)
- wxURL
- wxInternetFSHandler (a wxFileSystem handler)

Requires wxBase.

7.9 wxPropertyGrid

This contains the wxPropertyGrid control.

Requires wxAdvanced, wxCore, wxBase.

7.10 wxQA

This is the library containing extra classes for quality assurance. Currently it only contains wxDebugReport and related classes, but more will be added to it in the future.

Requires wxXML, wxCore, wxBase.

7.11 wxRibbon

This contains the Ribbon User Interface components library.

Requires wxCore, wxBase.

7.12 wxRichText

This contains generic rich text control functionality.

Requires wxAdvanced, wxHTML, wxXML, wxCore, wxBase.

7.13 wxSTC

STC (Styled Text Control) is a wrapper around Scintilla, a syntax-highlighting text editor. See http://www.scintilla.org/ for more info about Scintilla.

Requires wxCore, wxBase.

7.14 wxWebView

The wxWebView library contains the wxWebView control and its associated classes.

Requires wxCore, wxBase.

7.15 wxXML

This library contains simple classes for parsing XML documents.

Requires wxBase.

7.16 wxXRC

This library contains wxXmlResource class that provides access to XML resource files in XRC format.

Requires wxAdvanced, wxHTML, wxXML, wxCore, wxBase.

Chapter 8

Samples Overview

Probably the best way to learn wxWidgets is by reading the source of some 80+ samples provided with it.

Many aspects of wxWidgets programming can be learned from them, but sometimes it is not simple to just choose the right sample to look at. This overview aims at describing what each sample does/demonstrates to make it easier to find the relevant one if a simple grep through all sources didn't help. They also provide some notes about using the samples and what features of wxWidgets are they supposed to test.

There are currently more than 80 different samples as part of wxWidgets: the list in this page is not complete! You should start your tour of wxWidgets with the Minimal Sample which is the wxWidgets version of "Hello, world!". It shows the basic structure of wxWidgets program and is the most commented sample of all - looking at its source code is recommended.

The next most useful sample is Widgets Sample which shows many of wxWidgets controls, such as buttons, text entry zones, list boxes, check boxes, combo boxes etc. It is organized in many different source files, one per each control, which makes it easier to study it, and also allows to change various control styles and call its methods interactively.

Other, more complicated controls, have their own samples. In this category you may find the following samples showing the corresponding controls:

- wxCalendarCtrl: Calendar Sample
- wxListCtrl: List Control Sample
- wxTreeCtrl: wxTreeCtrl Sample
- wxGrid: Grid Sample
- wxDataViewCtrl: wxDataViewCtrl Sample
- wxWebView: wxWebView Sample

Notice that all wxWidgets samples mentioned above can be found in `samples` subdirectory of the library distribution. When a `foobar` sample is mentioned below, its sources can be found in `samples/foobar` directory of your wxWidgets tree. If you installed wxWidgets from a binary package, you might not have this directory. In this case, you may view the samples online at `http://svn.wxwidgets.org/viewvc/wx/wx↩Widgets/trunk/samples/` but you need to download the source distribution in order to be able to build them (highly recommended).

Final advice is to do a search in the entire samples directory if you can't find the sample showing the control you are interested in by name. Most classes contained in wxWidgets occur in at least one of the samples.

Todo Write descriptions for the samples who description started with "This sample demonstrates", they are semi-auto generated.

8.1 Accessibility Sample

This sample shows how you can use the wxAccessible classes in a simple GUI program.

Build Note: You may need to build the wxWidgets library with `wxUSE_ACCESSIBILITY` being set to 1 to be able to make it work, please read comments in `<wx/setup_inc.h>` for more info.

Location: `samples/access` subdirectory of your wxWidgets installation or http://svn.wxwidgets.org/viewvc/wx/wxWidgets/trunk/samples/access

8.2 Animation Sample

This sample shows how you can use wxAnimationCtrl control and shows concept of a platform-dependent animation encapsulated in wxAnimation.

Location: `samples/animate` subdirectory of your wxWidgets installation or http://svn.wxwidgets.org/viewvc/wx/wxWidgets/trunk/samples/animate

8.3 Art Provider Sample

This sample shows how you can customize the look of standard wxWidgets dialogs by replacing default bitmaps/icons with your own versions. It also shows how you can use wxArtProvider to get stock bitmaps for use in your application.

Location: `samples/artprov` subdirectory of your wxWidgets installation or http://svn.wxwidgets.org/viewvc/wx/wxWidgets/trunk/samples/artprov

8.4 Advanced User Interface Sample

This sample demonstrates AUI classes.

Location: `samples/aui` subdirectory of your wxWidgets installation or http://svn.wxwidgets.org/viewvc/wx/wxWidgets/trunk/samples/aui

8.5 Calendar Sample

This sample shows the calendar control in action. It shows how to configure the control (see the different options in the calendar menu) and also how to process the notifications from it.

Location: `samples/calendar` subdirectory of your wxWidgets installation or http://svn.wxwidgets.org/viewvc/wx/wxWidgets/trunk/samples/calendar

8.6 Caret Sample

This sample demonstrates wxCaret.

Location: `samples/caret` subdirectory of your wxWidgets installation or http://svn.wxwidgets.org/viewvc/wx/wxWidgets/trunk/samples/caret

8.7 Collapsible Pane Sample

This sample demonstrates wxCollapsiblePane.

Location: `samples/collpane` subdirectory of your wxWidgets installation or http://svn.wxwidgets.org/viewvc/wx/wxWidgets/trunk/samples/collpane

8.8 Combo Sample

This sample demonstrates wxComboBox, wxComboCtrl and wxOwnerDrawnComboBox etc.

Location: `samples/combo` subdirectory of your wxWidgets installation or http://svn.wxwidgets.org/viewvc/wx/wxWidgets/trunk/samples/combo

8.9 Configuration Sample

This sample demonstrates the wxConfig classes in a platform independent way, i.e. it uses text based files to store a given configuration under Unix and uses the Registry under Windows.

See wxConfig Overview for the descriptions of all features of this class.

Location: `samples/config` subdirectory of your wxWidgets installation or http://svn.wxwidgets.org/viewvc/wx/wxWidgets/trunk/samples/config

8.10 Console Program Sample

This sample demonstrates a console program.

Location: `samples/console` subdirectory of your wxWidgets installation or http://svn.wxwidgets.org/viewvc/wx/wxWidgets/trunk/samples/console

8.11 Controls Sample

The controls sample is the main test program for most simple controls used in wxWidgets. The sample tests their basic functionality, events, placement, modification in terms of colour and font as well as the possibility to change the controls programmatically, such as adding an item to a list box etc. Apart from that, the sample uses a wxNotebook and tests most features of this special control (using bitmap in the tabs, using wxSizer instances and wxLayoutConstraints within notebook pages, advancing pages programmatically and vetoing a page change by intercepting the wxNotebookEvent.

The various controls tested are listed here:

- wxButton
- wxBitmapButton
- wxCheckBox
- wxChoice
- wxComboBox
- wxGauge
- wxStaticBox
- wxListBox
- wxSpinCtrl
- wxSpinButton

- wxStaticText
- wxStaticBitmap
- wxRadioBox
- wxRadioButton
- wxSlider

Location: `samples/controls` subdirectory of your wxWidgets installation or http://svn.wxwidgets.org/viewvc/wx/wxWidgets/trunk/samples/controls

8.12 wxDataViewCtrl Sample

This sample demonstrates wxDataViewCtrl.

Location: `samples/dataview` subdirectory of your wxWidgets installation or http://svn.wxwidgets.org/viewvc/wx/wxWidgets/trunk/samples/dataview

8.13 Clipboard Sample

This sample demonstrates wxClipboard.

Location: `samples/clipboard` subdirectory of your wxWidgets installation or http://svn.wxwidgets.org/viewvc/wx/wxWidgets/trunk/samples/clipboard

8.14 Debug Reporter Sample

This sample shows how to use wxDebugReport class to generate a debug report in case of a program crash or otherwise. On start up, it proposes to either crash itself (by dereferencing a NULL pointer) or generate debug report without doing it. Next it initializes the debug report with standard information adding a custom file to it (just a timestamp) and allows to view the information gathered using wxDebugReportPreview.

For the report processing part of the sample to work you should make available a Web server accepting form uploads, otherwise wxDebugReportUpload will report an error.

Build Note: You may need to build the wxWidgets library with `wxUSE_DEBUGREPORT` and `wxUSE_ON_FATAL_EXCEPTION` being set to 1 to be able to make it work, please read comments in `<wx/setup_inc.h>` for more info.

Location: `samples/debugrpt` subdirectory of your wxWidgets installation or http://svn.wxwidgets.org/viewvc/wx/wxWidgets/trunk/samples/debugrpt

8.15 Dialogs Sample

This sample shows how to use the common dialogs available from wxWidgets. These dialogs are described in detail in the Common Dialogs.

In addition to the dialogs accessible from the sample menus, you can also run it with a `-progress=style` command line option to show a wxProgressDialog with the given style (try 0 for the default style) on program startup, before the main window is shown.

Location: `samples/dialogs` subdirectory of your wxWidgets installation or http://svn.wxwidgets.org/viewvc/wx/wxWidgets/trunk/samples/dialogs

8.16 Dialup Sample

This sample shows the wxDialUpManager class. In the status bar, it displays the information gathered through its interface: in particular, the current connection status (online or offline) and whether the connection is permanent (in which case a string 'LAN' appears in the third status bar field - but note that you may be on a LAN not connected to the Internet, in which case you will not see this) or not.

Using the menu entries, you may also dial or hang up the line if you have a modem attached and (this only makes sense for Windows) list the available connections.

Location: `samples/dialup` subdirectory of your wxWidgets installation or http://svn.wxwidgets.org/viewvc/wx/wxWidgets/trunk/samples/dialup

8.17 Display Sample

This sample demonstrates wxDisplay.

Location: `samples/display` subdirectory of your wxWidgets installation or http://svn.wxwidgets.org/viewvc/wx/wxWidgets/trunk/samples/display

8.18 Drag & Drop Sample

This sample shows both clipboard and drag and drop in action. It is quite non trivial and may be safely used as a basis for implementing the clipboard and drag and drop operations in a real-life program.

When you run the sample, its screen is split in several parts. On the top, there are two listboxes which show the standard derivations of wxDropTarget: wxTextDropTarget and wxFileDropTarget.

The middle of the sample window is taken by the log window which shows what is going on (of course, this only works in debug builds) and may be helpful to see the sequence of steps of data transfer.

Finally, the last part is used for dragging text from it to either one of the listboxes (only one will accept it) or another application. The last functionality available from the main frame is to paste a bitmap from the clipboard (or, in the case of the Windows version, also a metafile) - it will be shown in a new frame.

So far, everything we mentioned was implemented with minimal amount of code using standard wxWidgets classes. The more advanced features are demonstrated if you create a shape frame from the main frame menu. A shape is a geometric object which has a position, size and color. It models some application-specific data in this sample. A shape object supports its own private wxDataFormat which means that you may cut and paste it or drag and drop (between one and the same or different shapes) from one sample instance to another (or the same). However, chances are that no other program supports this format and so shapes can also be rendered as bitmaps which allows them to be pasted/dropped in many other applications (and, under Windows, also as metafiles which are supported by most of Windows programs as well - try Write/Wordpad, for example).

Take a look at DnDShapeDataObject class to see how you may use wxDataObject to achieve this.

Location: `samples/dnd` subdirectory of your wxWidgets installation or http://svn.wxwidgets.org/viewvc/wx/wxWidgets/trunk/samples/dnd

8.19 Document/View Sample

This sample demonstrates Document/View Framework.

Location: `samples/docview` subdirectory of your wxWidgets installation or http://svn.wxwidgets.org/viewvc/wx/wxWidgets/trunk/samples/docview

See also

MDI Sample

8.20 Drag Image Sample

This sample demonstrates wxDragImage.

Location: `samples/dragimag` subdirectory of your wxWidgets installation or `http://svn.wxwidgets.org/viewvc/wx/wxWidgets/trunk/samples/dragimag`

8.21 Drawing Sample

This sample demonstrates the drawing ability of wxDC.

Location: `samples/drawing` subdirectory of your wxWidgets installation or `http://svn.wxwidgets.org/viewvc/wx/wxWidgets/trunk/samples/drawing`

8.22 Erase Event Sample

This sample demonstrates wxEraseEvent.

Location: `samples/erase` subdirectory of your wxWidgets installation or `http://svn.wxwidgets.org/viewvc/wx/wxWidgets/trunk/samples/erase`

8.23 Event Sample

This sample demonstrates various features of the wxWidgets events. It shows how to dynamic events and connecting/disconnecting the event handlers during run time by using wxEvtHandler::Connect() and wxEvtHandler::Disconnect(), and also how to use wxWindow::PushEventHandler() and wxWindow::PopEventHandler().

Location: `samples/event` subdirectory of your wxWidgets installation or `http://svn.wxwidgets.org/viewvc/wx/wxWidgets/trunk/samples/event`

8.24 Exception Sample

This very simple sample shows how to use C++ exceptions in wxWidgets programs, i.e. where to catch the exception which may be thrown by the program code. It doesn't do anything very exciting by itself, you need to study its code to understand what goes on.

Build Note: You need to build the library with `wxUSE_EXCEPTIONS` being set to `1` and compile your code with C++ exceptions support to be able to build this sample.

Location: `samples/except` subdirectory of your wxWidgets installation or `http://svn.wxwidgets.org/viewvc/wx/wxWidgets/trunk/samples/except`

8.25 External Program Execution Sample

The exec sample demonstrates the wxExecute and wxShell functions. Both of them are used to execute the external programs and the sample shows how to do this synchronously (waiting until the program terminates) or asynchronously (notification will come later).

It also shows how to capture the output of the child process in both synchronous and asynchronous cases and how to kill the processes with wxProcess::Kill() and test for their existence with wxProcess::Exists().

Location: `samples/exec` subdirectory of your wxWidgets installation or `http://svn.wxwidgets.org/viewvc/wx/wxWidgets/trunk/samples/exec`

8.26 Flash Sample

The flash sample demonstrates embedding of Adobe Flash into a wxWidgets program. Currently it only works under Windows as it uses the Flash ActiveX control to achieve this but we hope to be able to extend it to also work under other platforms in the future. The sample also currently requires Microsoft Visual C++ compiler as it uses COM support extensions specific to this compiler.

The sample comes with 2 Flash files (SWF), showing a simple Flash animation which can be controlled using the "Play", "Stop" and "Back"/"Forward" buttons in the sample as well as a Flash form which shows how Flash and wxWidgets program can exchange data: calling "GetText" function without arguments returns the text of the text control defined inside Flash and calling "SetText" with an argument sets the control contents to the given string. Finally clicking on the button generates an event which is caught by the C++ program.

8.27 Font Sample

The font sample demonstrates wxFont, wxFontEnumerator and wxFontMapper classes. It allows you to see the fonts available (to wxWidgets) on the computer and shows all characters of the chosen font as well.

Location: `samples/font` subdirectory of your wxWidgets installation or `http://svn.wxwidgets.org/viewvc/wx/wxWidgets/trunk/samples/font`

8.28 Grid Sample

This sample demonstrates wxGrid.

Location: `samples/grid` subdirectory of your wxWidgets installation or `http://svn.wxwidgets.org/viewvc/wx/wxWidgets/trunk/samples/grid`

8.29 Help Sample

This sample demonstrates wxHelpController.

Location: `samples/help` subdirectory of your wxWidgets installation or `http://svn.wxwidgets.org/viewvc/wx/wxWidgets/trunk/samples/help`

8.30 HTML Sample

Eight HTML samples cover all features of the HTML sub-library.

- **Test** demonstrates how to create wxHtmlWindow and also shows most supported HTML tags.
- **Widget** shows how you can embed ordinary controls or windows within an HTML page. It also nicely explains how to write new tag handlers and extend the library to work with unsupported tags.
- **About** may give you an idea how to write good-looking About boxes.

- **Zip** demonstrates use of virtual file systems in wxHTML. The zip archives handler (ships with wxWidgets) allows you to access HTML pages stored in a compressed archive as if they were ordinary files.

- **Virtual** is yet another virtual file systems demo. This one generates pages at run-time. You may find it useful if you need to display some reports in your application.

- **Printing** explains use of wxHtmlEasyPrinting class which serves as as-simple-as-possible interface for printing HTML documents without much work. In fact, only few function calls are sufficient.

- **Help** and **Helpview** are variations on displaying HTML help (compatible with MS HTML Help Workshop). *Help* shows how to embed wxHtmlHelpController in your application while *Helpview* is a simple tool that only pops up the help window and displays help books given at command line.

Location: `samples/html` subdirectory of your wxWidgets installation or `http://svn.wxwidgets.org/viewvc/wx/wxWidgets/trunk/samples/html`

8.31 HTML List Box Sample

This sample demonstrates wxHtmlListBox.

Location: `samples/htlbox` subdirectory of your wxWidgets installation or `http://svn.wxwidgets.org/viewvc/wx/wxWidgets/trunk/samples/htlbox`

8.32 Image Sample

The image sample demonstrates use of the wxImage class and shows how to download images in a variety of formats, currently PNG, GIF, TIFF, JPEG, BMP, PNM and PCX. The top of the sample shows two rectangles, one of which is drawn directly in the window, the other one is drawn into a wxBitmap, converted to a wxImage, saved as a PNG image and then reloaded from the PNG file again so that conversions between wxImage and wxBitmap as well as loading and saving PNG files are tested.

At the bottom of the main frame there is a test for using a monochrome bitmap by drawing into a wxMemoryDC. The bitmap is then drawn specifying the foreground and background colours with wxDC::SetTextForeground() and wxDC::SetTextBackground() (on the left). The bitmap is then converted to a wxImage and the foreground colour (black) is replaced with red using wxImage::Replace().

This sample also contains the code for testing the image rotation and resizing and using raw bitmap access, see the corresponding menu commands.

Location: `samples/image` subdirectory of your wxWidgets installation or `http://svn.wxwidgets.org/viewvc/wx/wxWidgets/trunk/samples/image`

8.33 Internationalization Sample

The not very clearly named internat sample demonstrates the wxWidgets internationalization (i18n for short from now on) features. To be more precise, it only shows localization support, i.e. support for translating the program messages into another language while true i18n would also involve changing the other aspects of the program's behaviour.

More information about this sample can be found in the `readme.txt` file in its directory. Please also see the Internationalization overview.

Location: `samples/internat` subdirectory of your wxWidgets installation or `http://svn.wxwidgets.org/viewvc/wx/wxWidgets/trunk/samples/internat`

8.34 Connection Sample

This sample demonstrates wxConnection.

Location: `samples/ipc` subdirectory of your wxWidgets installation or `http://svn.wxwidgets.org/viewvc/wx/wxWidgets/trunk/samples/ipc`

8.35 Joystick Sample

This sample demonstrates wxJoystick.

Location: `samples/joytest` subdirectory of your wxWidgets installation or `http://svn.wxwidgets.org/viewvc/wx/wxWidgets/trunk/samples/joytest`

8.36 Key Event Sample

This sample demonstrates wxKeyEvent.

This sample can be used to interactively test the events produced by pressing various keyboard keys. It also shows the interaction between accelerators and the normal keyboard events (which are overridden by any defined accelerators) and finally allows to test that not skipping an event in EVT_KEY_DOWN handler suppresses the subsequent EVT_CHAR event.

Location: `samples/keyboard` subdirectory of your wxWidgets installation or `http://svn.wxwidgets.org/viewvc/wx/wxWidgets/trunk/samples/keyboard`

8.37 Layout Sample

The layout sample demonstrates the two different layout systems offered by wxWidgets. When starting the program, you will see a frame with some controls and some graphics. The controls will change their size whenever you resize the entire frame and the exact behaviour of the size changes is determined using the wxLayoutConstraints class. See also the overview and the wxIndividualLayoutConstraint class for further information.

The menu in this sample offers two more tests, one showing how to use a wxBoxSizer in a simple dialog and the other one showing how to use sizers in connection with a wxNotebook class. See also wxSizer.

Location: `samples/layout` subdirectory of your wxWidgets installation or `http://svn.wxwidgets.org/viewvc/wx/wxWidgets/trunk/samples/layout`

8.38 List Control Sample

This sample shows the wxListCtrl control. Different modes supported by the control (list, icons, small icons, report) may be chosen from the menu.

The sample also provides some timings for adding/deleting/sorting a lot of (several thousands) items into the control.

Location: `samples/listctrl` subdirectory of your wxWidgets installation or `http://svn.wxwidgets.org/viewvc/wx/wxWidgets/trunk/samples/listctrl`

8.39 MDI Sample

This sample demonstrates MDI.

See also

Document/View Sample

Location: `samples/mdi` subdirectory of your wxWidgets installation or http://svn.wxwidgets.org/viewvc/wx/wxWidgets/trunk/samples/mdi

8.40 Mediaplayer Sample

This sample demonstrates how to use all the features of wxMediaCtrl and play various types of sound, video, and other files.

It replaces the old `dynamic` sample.

Location: `samples/mediaplayer` subdirectory of your wxWidgets installation or http://svn.wxwidgets.org/viewvc/wx/wxWidgets/trunk/samples/mediaplayer

8.41 Memory Checking Sample

This sample demonstrates memory tracing using wxDebugContext.

Location: `samples/memcheck` subdirectory of your wxWidgets installation or http://svn.wxwidgets.org/viewvc/wx/wxWidgets/trunk/samples/memcheck

Build Note: You may need to build the wxWidgets library with `wxUSE_MEMORY_TRACING` and `wxUSE_DEBUG_CONTEXT` being set to 1 to be able to make it work, please read comments in `<wx/setup_inc.h>` for more info.

8.42 Menu Sample

This sample demonstrates wxMenu classes.

Location: `samples/menu` subdirectory of your wxWidgets installation or http://svn.wxwidgets.org/viewvc/wx/wxWidgets/trunk/samples/menu

8.43 MFC Sample

This sample demonstrates how to mix MFC and wxWidgets code. It pops up an initial wxWidgets frame, with a menu item that allows a new MFC window to be created.

For build instructions please read IMPORTANT NOTES in `mfctest.cpp`.

Availability: only available for the wxMSW port.

Location: `samples/mfc` subdirectory of your wxWidgets installation or http://svn.wxwidgets.org/viewvc/wx/wxWidgets/trunk/samples/mfc

8.44 Minimal Sample

The minimal sample is what most people will know under the term Hello World, i.e. a minimal program that doesn't demonstrate anything apart from what is needed to write a program that will display a "hello" dialog. This is usually a good starting point for learning how to use wxWidgets.

Location: `samples/minimal` subdirectory of your wxWidgets installation or http://svn.wxwidgets.org/viewvc/wx/wxWidgets/trunk/samples/minimal

8.45 Native Windows Dialog Sample

This sample demonstrates native windows dialog.

Availability: only available for the wxMSW port.

Location: `samples/nativdlg` subdirectory of your wxWidgets installation or `http://svn.wxwidgets.org/viewvc/wx/wxWidgets/trunk/samples/nativdlg`

8.46 Notebook Sample

This samples shows wxBookCtrl family of controls. Although initially it was written to demonstrate wxNotebook only, it can now be also used to see wxListbook, wxChoicebook, wxTreebook and wxToolbook in action. Test each of the controls, their orientation, images and pages using commands through the menu.

Location: `samples/notebook` subdirectory of your wxWidgets installation or `http://svn.wxwidgets.org/viewvc/wx/wxWidgets/trunk/samples/notebook`

8.47 OLE Automation Sample

This sample demonstrates OLE automation using wxAutomationObject.

Availability: only available for the wxMSW port.

Location: `samples/oleauto` subdirectory of your wxWidgets installation or `http://svn.wxwidgets.org/viewvc/wx/wxWidgets/trunk/samples/oleauto`

8.48 OpenGL Sample

This sample demonstrates wxGLCanvas.

- **cube** Draws a cube to demonstrate how to write a basic wxWidgets OpenGL program. Arrow keys rotate the cube. Space bar toggles spinning.
- **isosurf** Draws a surface by reading coordinates from a DAT file.
- **penguin** Draws a rotatable penguin by reading data from a DXF file.

Location: `samples/opengl` subdirectory of your wxWidgets installation or `http://svn.wxwidgets.org/viewvc/wx/wxWidgets/trunk/samples/opengl`

8.49 Owner-drawn Sample

This sample demonstrates owner-drawn wxMenuItem, wxCheckList and wxListBox.

Location: `samples/ownerdrw` subdirectory of your wxWidgets installation or `http://svn.wxwidgets.org/viewvc/wx/wxWidgets/trunk/samples/ownerdrw`

8.50 Popup Transient Window Sample

This sample demonstrates wxPopupTransientWindow.

Location: `samples/popup` subdirectory of your wxWidgets installation or `http://svn.wxwidgets.org/viewvc/wx/wxWidgets/trunk/samples/popup`

8.51 Power Management Sample

This sample demonstrates wxWidgets power management.

See also

wxPowerEvent

Location: `samples/power` subdirectory of your wxWidgets installation or http://svn.wxwidgets.org/viewvc/wx/wxWidgets/trunk/samples/power

8.52 Printing Sample

This sample demonstrates printing.

See also

Printing Framework Overview, Printing Under Unix (GTK+)

Build Note: You may need to build the wxWidgets library with `wxUSE_PRINTING_ARCHITECTURE` being set to 1 to be able to make it work, please read comments in `<wx/setup_inc.h>` for more info.

Location: `samples/printing` subdirectory of your wxWidgets installation or http://svn.wxwidgets.org/viewvc/wx/wxWidgets/trunk/samples/printing

8.53 wxPropertyGrid Sample

Sample application has following additional examples of custom properties:

- wxFontDataProperty (edits wxFontData)
- wxPointProperty (edits wxPoint)
- wxSizeProperty (edits wxSize)
- wxAdvImageFileProperty (like wxImageFileProperty, but also has a drop-down for recent image selection)
- wxDirsProperty (edits a wxArrayString consisting of directory strings)
- wxArrayDoubleProperty (edits wxArrayDouble)

This sample demonstrates wxPropertyGrid.

Location: `samples/propgrid` subdirectory of your wxWidgets installation or http://svn.wxwidgets.org/viewvc/wx/wxWidgets/trunk/samples/propgrid

8.54 Registry Sample

This sample demonstrates wxRegKey.

Availability: only available for the wxMSW port.

Location: `samples/regtest` subdirectory of your wxWidgets installation or http://svn.wxwidgets.org/viewvc/wx/wxWidgets/trunk/samples/regtest

8.55 Render Sample

This sample shows how to replace the default wxWidgets renderer and also how to write a shared library (DLL) implementing a renderer and load and unload it during the run-time.

Location: `samples/render` subdirectory of your wxWidgets installation or http://svn.wxwidgets.org/viewvc/wx/wxWidgets/trunk/samples/render

8.56 wxRichTextCtrl Sample

This sample demonstrates wxRichTextCtrl.

Location: `samples/richtext` subdirectory of your wxWidgets installation or http://svn.wxwidgets.org/viewvc/wx/wxWidgets/trunk/samples/richtext

8.57 Sash Sample

This sample demonstrates wxSashWindow classes.

Location: `samples/sashtest` subdirectory of your wxWidgets installation or http://svn.wxwidgets.org/viewvc/wx/wxWidgets/trunk/samples/sashtest

8.58 Scroll Window Sample

This sample demonstrates wxScrolledWindow.

This sample demonstrates use of the wxScrolledWindow class including placing subwindows into it and drawing simple graphics. It uses the SetTargetWindow method and thus the effect of scrolling does not show in the scrolled window itself, but in one of its subwindows.

Additionally, this samples demonstrates how to optimize drawing operations in wxWidgets, in particular using the wxWindow::IsExposed() method with the aim to prevent unnecessary drawing in the window and thus reducing or removing flicker on screen.

Location: `samples/scroll` subdirectory of your wxWidgets installation or http://svn.wxwidgets.org/viewvc/wx/wxWidgets/trunk/samples/scroll

8.59 Shaped Window Sample

This sample demonstrates how to implement a shaped or transparent window, and a window showing/hiding with effect.

See also

wxTopLevelWindow::SetShape(), wxTopLevelWindow::SetTransparent(), wxWindow::ShowWithEffect(), wxWindow::HideWithEffect()

Location: `samples/shaped` subdirectory of your wxWidgets installation or http://svn.wxwidgets.org/viewvc/wx/wxWidgets/trunk/samples/shaped

8.60 Sockets Sample

The sockets sample demonstrates how to use the communication facilities provided by wxSocket. There are two different applications in this sample: a server, which is implemented using a wxSocketServer object, and a client,

which is implemented as a wxSocketClient.

The server binds to the local address, using TCP port number 3000, sets up an event handler to be notified of incoming connection requests (**wxSOCKET_CONNECTION** events), and sits there, waiting for clients (*listening*, in socket parlance). For each accepted connection, a new wxSocketBase object is created. These socket objects are independent from the server that created them, so they set up their own event handler, and then request to be notified of **wxSOCKET_INPUT** (incoming data) or **wxSOCKET_LOST** (connection closed at the remote end) events. In the sample, the event handler is the same for all connections; to find out which socket the event is addressed to, the GetSocket function is used.

Although it might take some time to get used to the event-oriented system upon which wxSocket is built, the benefits are many. See, for example, that the server application, while being single-threaded (and of course without using fork() or ugly select() loops) can handle an arbitrary number of connections.

The client starts up unconnected, so you can use the Connect... option to specify the address of the server you are going to connect to (the TCP port number is hard-coded as 3000). Once connected, a number of tests are possible. Currently, three tests are implemented. They show how to use the basic IO calls in wxSocketBase, such as wxSocketBase::Read(), wxSocketBase::Write(), wxSocketBase::ReadMsg() and wxSocketBase::WriteMsg(), and how to set up the correct IO flags depending on what you are going to do. See the comments in the code for more information. Note that because both clients and connection objects in the server set up an event handler to catch **wxSOCKET_LOST** events, each one is immediately notified if the other end closes the connection.

There is also a URL test which shows how to use the wxURL class to fetch data from a given URL.

The sockets sample is work in progress. Some things to do:

- More tests for basic socket functionality.
- More tests for protocol classes (wxProtocol and its descendants).
- Tests for the recently added (and still in alpha stage) datagram sockets.
- New samples which actually do something useful (suggestions accepted).

Location: `samples/sockets` subdirectory of your wxWidgets installation or `http://svn.wxwidgets.org/viewvc/wx/wxWidgets/trunk/samples/sockets`

8.61 Sound Sample

The `sound` sample shows how to use wxSound for simple audio output (e.g. notifications).

Location: `samples/sound` subdirectory of your wxWidgets installation or `http://svn.wxwidgets.org/viewvc/wx/wxWidgets/trunk/samples/sound`

8.62 Splash Screen Sample

This sample demonstrates wxSplashScreen.

Location: `samples/splash` subdirectory of your wxWidgets installation or `http://svn.wxwidgets.org/viewvc/wx/wxWidgets/trunk/samples/splash`

8.63 Splitter Window Sample

This sample demonstrates wxSplitterWindow.

Location: `samples/splitter` subdirectory of your wxWidgets installation or `http://svn.wxwidgets.org/viewvc/wx/wxWidgets/trunk/samples/splitter`

8.64 Status Bar Sample

This sample shows how to create and use wxStatusBar. Although most of the samples have a statusbar, they usually only create a default one and only do it once.

Here you can see how to recreate the statusbar (with possibly different number of fields) and how to use it to show icons/bitmaps and/or put arbitrary controls into it.

Location: `samples/statbar` subdirectory of your wxWidgets installation or `http://svn.wxwidgets.org/viewvc/wx/wxWidgets/trunk/samples/statbar`

8.65 wxStyledTextCtrl Sample

This sample demonstrates wxStyledTextCtrl.

Location: `samples/stc` subdirectory of your wxWidgets installation or `http://svn.wxwidgets.org/viewvc/wx/wxWidgets/trunk/samples/stc`

8.66 SVG Sample

This sample demonstrates wxSVGFileDC.

Location: `samples/svg` subdirectory of your wxWidgets installation or `http://svn.wxwidgets.org/viewvc/wx/wxWidgets/trunk/samples/svg`

8.67 Tab Order Sample

This sample allows to test keyboard navigation (mostly done using the `TAB` key, hence the sample name) between different controls. It shows the use of wxWindow::MoveBeforeInTabOrder() and MoveAfterInTabOrder() methods to change the default order of the windows in the navigation chain and of wxWindow::Navigate() for moving focus along this chain.

Location: `samples/taborder` subdirectory of your wxWidgets installation or `http://svn.wxwidgets.org/viewvc/wx/wxWidgets/trunk/samples/taborder`

8.68 Task Bar Icon Sample

This sample demonstrates wxTaskBarIcon.

Location: `samples/taskbar` subdirectory of your wxWidgets installation or `http://svn.wxwidgets.org/viewvc/wx/wxWidgets/trunk/samples/taskbar`

8.69 Text Sample

This sample demonstrates four features: firstly the use and many variants of the wxTextCtrl class (single line, multi line, read only, password, ignoring TAB, ignoring ENTER).

Secondly it shows how to intercept a wxKeyEvent in both the raw form using the `EVT_KEY_UP` and `EVT_KEY_DOWN` macros and the higher level from using the `EVT_CHAR` macro. All characters will be logged in a log window at the bottom of the main window. By pressing some of the function keys, you can test some actions in the text ctrl as well as get statistics on the text ctrls, which is useful for testing if these statistics actually are correct.

Thirdly, on platforms which support it, the sample will offer to copy text to the wxClipboard and to paste text from it. The GTK version will use the so called PRIMARY SELECTION, which is the pseudo clipboard under X and best known from pasting text to the XTerm program.

Last but not least: some of the text controls have tooltips and the sample also shows how tooltips can be centrally disabled and their latency controlled.

Location: `samples/text` subdirectory of your wxWidgets installation or http://svn.wxwidgets.org/viewvc/wx/wxWidgets/trunk/samples/text

8.70 Thread Sample

This sample demonstrates use of threads in connection with GUI programs.

There are two fundamentally different ways to use threads in GUI programs and either way has to take care of the fact that the GUI library itself usually is not multi-threading safe, i.e. that it might crash if two threads try to access the GUI class simultaneously.

One way to prevent that is have a normal GUI program in the main thread and some worker threads which work in the background. In order to make communication between the main thread and the worker threads possible, wxWidgets offers the wxQueueEvent function and this sample demonstrates its usage.

The other way is to use a wxMutexGuiEnter and wxMutexGuiLeave functions, but this is not currently shown in the sample.

See also Multithreading Overview and wxThread.

Location: `samples/thread` subdirectory of your wxWidgets installation or http://svn.wxwidgets.org/viewvc/wx/wxWidgets/trunk/samples/thread

8.71 Tool Bar Sample

The toolbar sample shows the wxToolBar class in action.

The following things are demonstrated:

- Creating the toolbar using wxToolBar::AddTool() and wxToolBar::AddControl(): see MyApp::InitToolbar() in the sample.
- Using `EVT_UPDATE_UI` handler for automatically enabling/disabling toolbar buttons without having to explicitly call EnableTool. This is done in MyFrame::OnUpdateCopyAndCut().
- Using wxToolBar::DeleteTool() and wxToolBar::InsertTool() to dynamically update the toolbar.

Some buttons in the main toolbar are check buttons, i.e. they stay checked when pressed. On the platforms which support it, the sample also adds a combobox to the toolbar showing how you can use arbitrary controls and not only buttons in it.

If you toggle another toolbar in the sample (using `Ctrl-A`) you will also see the radio toolbar buttons in action: the first three buttons form a radio group, i.e. checking any of them automatically unchecks the previously checked one.

Location: `samples/toolbar` subdirectory of your wxWidgets installation or http://svn.wxwidgets.org/viewvc/wx/wxWidgets/trunk/samples/toolbar

8.72 wxTreeCtrl Sample

This sample demonstrates using the wxTreeCtrl class. Here you may see how to process various notification messages sent by this control and also when they occur (by looking at the messages in the text control in the bottom part of the frame).

Adding, inserting and deleting items and branches from the tree as well as sorting (in default alphabetical order as well as in custom one) is demonstrated here as well - try the corresponding menu entries.

Location: `samples/treectrl` subdirectory of your wxWidgets installation or http://svn.wxwidgets.org/viewvc/wx/wxWidgets/trunk/samples/treectrl

8.73 Types Sample

This sample demonstrates wxWidgets types.

Todo This sample isn't very didactive; it's more than a set of tests rather than a sample and thus should be rewritten with CppUnit and moved under "tests"

Location: `samples/typetest` subdirectory of your wxWidgets installation or http://svn.wxwidgets.org/viewvc/wx/wxWidgets/trunk/samples/typetest

8.74 wxUIActionSimulator Sample

This sample demonstrates wxUIActionSimulator.

This sample shows some features of wxUIActionSimulator class. When a simulation is run using its menu items, you can see that the button is pressed programmatically and the characters generated by the program appear in the text control.

Location: `samples/uiaction` subdirectory of your wxWidgets installation or http://svn.wxwidgets.org/viewvc/wx/wxWidgets/trunk/samples/uiaction

8.75 Validator Sample

This sample demonstrates wxValidator.

Location: `samples/validate` subdirectory of your wxWidgets installation or http://svn.wxwidgets.org/viewvc/wx/wxWidgets/trunk/samples/validate

8.76 VScrolled Window Sample

This sample demonstrates wxVScrolledWindow.

Location: `samples/vscroll` subdirectory of your wxWidgets installation or http://svn.wxwidgets.org/viewvc/wx/wxWidgets/trunk/samples/vscroll

8.77 wxWebView Sample

The wxWebView sample demonstarates the various capabilities of the wxWebView control. It is set up as a simple single window web browser, but with support for many of the more complex wxWebView features, including browsing through archives.

Location: `samples/webview` subdirectory of your wxWidgets installation or http://svn.wxwidgets.org/viewvc/wx/wxWidgets/trunk/samples/webview

8.78 Widgets Sample

The widgets sample is the main presentation program for most simple and advanced native controls and complex generic widgets provided by wxWidgets. The sample tests their basic functionality, events, placement, modification in terms of colour and font as well as the possibility to change the controls programmatically, such as adding an item to a list box etc. All widgets are categorized for easy browsing.

Location: `samples/widgets` subdirectory of your wxWidgets installation or http://svn.wxwidgets.org/viewvc/wx/wxWidgets/trunk/samples/widgets

8.79 Wizard Sample

This sample shows the so-called wizard dialog (implemented using wxWizard and related classes). It shows almost all features supported:

- Using bitmaps with the wizard and changing them depending on the page shown (notice that wxValidationPage in the sample has a different image from the other ones)
- Using TransferDataFromWindow to verify that the data entered is correct before passing to the next page (done in wxValidationPage which forces the user to check a checkbox before continuing).
- Using more elaborated techniques to allow returning to the previous page, but not continuing to the next one or vice versa (in wxRadioboxPage)
- This (wxRadioboxPage) page also shows how the page may process the *Cancel* button itself instead of relying on the wizard parent to do it.
- Normally, the order of the pages in the wizard is known at compile-time, but sometimes it depends on the user choices: wxCheckboxPage shows how to dynamically decide which page to display next (see also wxWizardPage)

Location: `samples/wizard` subdirectory of your wxWidgets installation or http://svn.wxwidgets.org/viewvc/wx/wxWidgets/trunk/samples/wizard

8.80 wxWrapSizer Sample

This sample demonstrates wxWrapSizer.

Location: `samples/wrapsizer` subdirectory of your wxWidgets installation or http://svn.wxwidgets.org/viewvc/wx/wxWidgets/trunk/samples/wrapsizer

8.81 XRC Sample

This sample shows how to use the various features of the XML Based Resource System (XRC) to create the gui of your program. It starts by loading and showing a frame and other resources. From its menu or toolbar you can then run the following dialogs:

- A non-derived wxDialog
- A derived dialog
- A dialog containing a large number of controls
- An uncentred dialog
- A dialog demonstrating the use of object references and ID ranges

- A dialog that contains a custom class
- A dialog with platform-specific features
- A dialog demonstrating wxArtProvider
- A dialog saying "VARIABLE EXPANSION ISN'T IMPLEMENTED CURRENTLY" :/

Location: `samples/xrc` subdirectory of your wxWidgets installation or `http://svn.wxwidgets.org/viewvc/wx/wxWidgets/trunk/samples/xrc`

Chapter 9

Screenshots of Different Controls

This page contains the screenshots of various controls under the three major platforms: wxMSW in the first column, wxGTK in the second one and wxOSX in the third one.

9.1 Standard Controls

Some common controls:

wxButton wxBitmapButton wxCheckBox wxChoice wxCheckListBox wxComboBox wxGauge wxListBox wxRadio↩ Box wxRadioButton wxScrollBar wxSlider wxSpinButton wxSpinCtrl wxSpinCtrlDouble

9.2 Picker Controls

These controls provide the user with the possibility to choose something (file or directory, font or colour, ...) directly from the window containing them:

wxColourPickerCtrl wxDatePickerCtrl wxFilePickerCtrl wxDirPickerCtrl wxFontPickerCtrl

9.3 Advanced Controls

These controls are considered to be less common and are defined in adv library:

wxAnimationCtrl wxBannerWindow wxBitmapComboBox wxCalendarCtrl wxComboCtrl wxCommandLinkButton wxHyperlinkCtrl wxOwnerDrawnComboBox

9.4 Book Controls

Book controls contain several pages (also called tabs in wxNotebook case) and allow the user to switch between them:

wxChoicebook wxListbook wxNotebook

9.5 Tree and List Controls

Several controls can be used to display items organized in a tree or (multi column) list:

wxDataViewCtrl wxDataViewTreeCtrl wxListCtrl wxPropertyGrid wxSimpleHtmlListBox

9.6 Miscellaneous Other Controls

wxCollapsiblePane wxDirCtrl wxFileCtrl wxRichTextCtrl wxRichToolTip

Chapter 10

Programming Guides

The guides here cover all high level details of a full range of development topics related to building applications with wxWidgets.

10.1 Starting with wxWidgets

- Notes on Using this Reference Manual
- A Quick Guide to Writing Applications
- Hello World Example
- wxPython Overview

10.2 Important wxWidgets Topics

- wxApp Overview
- Unicode Support in wxWidgets
- Internationalization
- Events and Event Handling
- Window Sizing Overview
- Window IDs
- Logging Overview

10.3 Non-GUI Classes

- wxString Overview
- Buffer Classes
- Date and Time
- Container Classes
- File Classes and Functions
- Stream Classes Overview

- Multithreading Overview
- wxConfig Overview
- Persistent Objects Overview
- wxFileSystem Overview
- Regular Expressions
- Archive Formats
- Interprocess Communication

10.4 Drawing Related Classes

- Device Contexts
- Bitmaps and Icons
- wxFont Overview
- Font Encodings
- Printing Framework Overview
- Printing Under Unix (GTK+)

10.5 GUI Classes

- Sizers Overview
- XML Based Resource System (XRC)
- XRC File Format
- Scrolled Windows
- wxDialog Overview
- wxValidator Overview
- wxDataObject Overview
- Drag and Drop Overview

10.6 Individual Controls

- wxHTML Overview
- wxRichTextCtrl Overview
- wxAUI Overview
- wxPropertyGrid Overview
- Common Dialogs
- Toolbar Overview
- wxGrid Overview

- wxTreeCtrl Overview
- wxListCtrl Overview
- wxSplitterWindow Overview
- wxBookCtrl Overview
- wxTipProvider Overview
- Document/View Framework

10.7 Other wxWidgets Programming Overviews

- Backwards Compatibility
- C++ Exceptions
- Runtime Type Information (RTTI)
- Caveats When Not Using C++ RTTI
- Reference Counting
- wxMBConv Overview
- Writing Non-English Applications
- Debugging
- Window Styles
- Window Deletion
- Environment Variables
- Creating a Custom Widget

10.8 Notes on Using this Reference Manual

In the descriptions of the wxWidgets classes and their member functions, note that descriptions of inherited member functions are not duplicated in derived classes unless their behaviour is different.

So in using a class such as wxScrolledWindow, be aware that wxWindow functions may be relevant.

Where not explicitly stated, size and position arguments may usually be given a value of wxDefaultSize and wx↩DefaultPosition, in which case wxWidgets will choose suitable values.

10.9 A Quick Guide to Writing Applications

To set a wxWidgets application going, you will need to derive a wxApp class and override wxApp::OnInit.

An application must have a top-level wxFrame or wxDialog window. Each frame may contain one or more instances of classes such as wxPanel, wxSplitterWindow or other windows and controls.

A frame can have a wxMenuBar, a wxToolBar, a wxStatusBar, and a wxIcon for when the frame is iconized.

A wxPanel is used to place controls (classes derived from wxControl) which are used for user interaction. Examples of controls are wxButton, wxCheckBox, wxChoice, wxListBox, wxRadioBox, and wxSlider.

Instances of wxDialog can also be used for controls and they have the advantage of not requiring a separate frame.

Instead of creating a dialog box and populating it with items, it is possible to choose one of the convenient common dialog classes, such as wxMessageDialog and wxFileDialog.

You never draw directly onto a window - you use a *device context* (DC). wxDC is the base for wxClientDC, wxPaintDC, wxMemoryDC, wxPostScriptDC, wxMemoryDC, wxMetafileDC and wxPrinterDC. If your drawing functions have wxDC as a parameter, you can pass any of these DCs to the function, and thus use the same code to draw to several different devices. You can draw using the member functions of wxDC, such as wxDC::DrawLine and wxDC::DrawText. Control colour on a window (wxColour) with brushes (wxBrush) and pens (wxPen).

To intercept events, you add a DECLARE_EVENT_TABLE macro to the window class declaration, and put a BEGIN_EVENT_TABLE ... END_EVENT_TABLE block in the implementation file. Between these macros, you add event macros which map the event (such as a mouse click) to a member function. These might override predefined event handlers such as for wxKeyEvent and wxMouseEvent.

Most modern applications will have an on-line, hypertext help system; for this, you need wxHelp and the wxHelpController class to control wxHelp.

GUI applications aren't all graphical wizardry. List and hash table needs are catered for by wxList and wxHashMap. You will undoubtedly need some platform-independent Files and Directories, and you may find it handy to maintain and search a list of paths using wxPathList. There's many Miscellaneous of operating system methods and other functions.

Class List by Category

10.10 Hello World Example

This page shows a very simple wxWidgets program that can be used as a skeleton for your own code.

While it does nothing very useful, it introduces a couple of important concepts and explains how to write a working wxWidgets application.

First, you have to include wxWidgets' header files, of course. This can be done on a file by file basis (such as `wx/window.h`) or using one global include (`wx/wx.h`) which includes most of the commonly needed headers (although not all of them as there are simply too many wxWidgets headers to pull in all of them). For the platforms with support for precompiled headers, as indicated by `WX_PRECOMP`, this global header is already included by `wx/wxprec.h` so we only include it for the other ones:

```
// wxWidgets "Hello world" Program

// For compilers that support precompilation, includes "wx/wx.h".
#include <wx/wxprec.h>

#ifndef WX_PRECOMP
    #include <wx/wx.h>
#endif
```

Practically every app should define a new class derived from wxApp. By overriding wxApp's OnInit() virtual method the program can be initialized, e.g. by creating a new main window.

```
class MyApp: public wxApp
{
public:
    virtual bool OnInit();
};
```

The main window is created by deriving a class from wxFrame and giving it a menu and a status bar in its constructor. Also, any class that wishes to respond to any "event" (such as mouse clicks or messages from the menu or a button) must declare an event table using the macro below.

Finally, the way to react to such events must be done in "handlers". In our sample, we react to three menu items, one for our custom menu command and two for the standard "Exit" and "About" commands (any program should normally implement the latter two). Notice that these handlers don't need to be neither virtual nor public.

```
class MyFrame: public wxFrame
{
public:
    MyFrame(const wxString& title, const wxPoint& pos, const
      wxSize& size);

private:
    void OnHello(wxCommandEvent& event);
    void OnExit(wxCommandEvent& event);
    void OnAbout(wxCommandEvent& event);

    wxDECLARE_EVENT_TABLE();
};
```

In order to be able to react to a menu command, it must be given a unique identifier which can be defined as a const variable or an enum element. The latter is often used because typically many such constants will be needed:

```
enum
{
    ID_Hello = 1
};
```

Notice that you don't need to define identifiers for the "About" and "Exit". We then proceed to actually implement an event table in which the events are routed to their respective handler functions in the class MyFrame.

There are predefined macros for routing all common events, ranging from the selection of a list box entry to a resize event when a user resizes a window on the screen. If `wxID_ANY` is given as the ID, the given handler will be invoked for any event of the specified type, so that you could add just one entry in the event table for all menu commands or all button commands etc.

The origin of the event can still be distinguished in the event handler as the (only) parameter in an event handler is a reference to a wxEvent object, which holds various information about the event (such as the ID of and a pointer to the class, which emitted the event).

```
wxBEGIN_EVENT_TABLE(MyFrame, wxFrame)
    EVT_MENU(ID_Hello,   MyFrame::OnHello)
    EVT_MENU(wxID_EXIT,  MyFrame::OnExit)
    EVT_MENU(wxID_ABOUT, MyFrame::OnAbout)
wxEND_EVENT_TABLE()
```

As in all programs there must be a "main" function. Under wxWidgets main is implemented using this macro, which creates an application instance and starts the program.

```
wxIMPLEMENT_APP(MyApp)
```

As mentioned above, wxApp::OnInit() is called upon startup and should be used to initialize the program, maybe showing a "splash screen" and creating the main window (or several). The frame should get a title bar text ("Hello World") and a position and start-up size. One frame can also be declared to be the top window. Returning true indicates a successful initialization.

```
bool MyApp::OnInit()
{
    MyFrame *frame = new MyFrame( "Hello World", wxPoint(50, 50), wxSize(450, 340) );
    frame->Show( true );
    return true;
}
```

In the constructor of the main window (or later on) we create a menu with our menu items as well as a status bar to be shown at the bottom of the main window. Both have to be associated with the frame with respective calls.

```
MyFrame::MyFrame(const wxString& title, const wxPoint& pos, const
      wxSize& size)
        : wxFrame(NULL, wxID_ANY, title, pos, size)
{
    wxMenu *menuFile = new wxMenu;
    menuFile->Append(ID_Hello, "&Hello...\tCtrl-H",
                     "Help string shown in status bar for this menu item");
    menuFile->AppendSeparator();
    menuFile->Append(wxID_EXIT);
```

```
    wxMenu *menuHelp = new wxMenu;
    menuHelp->Append(wxID_ABOUT);

    wxMenuBar *menuBar = new wxMenuBar;
    menuBar->Append( menuFile, "&File" );
    menuBar->Append( menuHelp, "&Help" );

    SetMenuBar( menuBar );

    CreateStatusBar();
    SetStatusText( "Welcome to wxWidgets!" );
}
```

Notice that we don't need to specify the labels for the standard menu items `wxID_ABOUT` and `wxID_EXIT`, they will be given standard (even correctly translated) labels and also standard accelerators correct for the current platform making your program behaviour more native. For this reason you should prefer reusing the standard ids (see Stock Items) if possible.

Here are the standard event handlers implementations. MyFrame::OnExit() closes the main window by calling Close(). The parameter true indicates that other windows have no veto power such as after asking "Do you really want to close?". If there is no other main window left, the application will quit.

```
void MyFrame::OnExit(wxCommandEvent& event)
{
    Close( true );
}
```

MyFrame::OnAbout() will display a small window with some text in it. In this case a typical "About" window with information about the program.

```
void MyFrame::OnAbout(wxCommandEvent& event)
{
    wxMessageBox( "This is a wxWidgets' Hello world sample",
                  "About Hello World", wxOK | wxICON_INFORMATION );
}
```

The implementation of custom menu command handler may perform whatever task your program needs to do, in this case we will simply show a message from it as befits a hello world example:

```
void MyFrame::OnHello(wxCommandEvent& event)
{
    wxLogMessage("Hello world from wxWidgets!");
}
```

Here is the entire program that can be copied and pasted:

```
// wxWidgets "Hello world" Program

// For compilers that support precompilation, includes "wx/wx.h".
#include <wx/wxprec.h>

#ifndef WX_PRECOMP
    #include <wx/wx.h>
#endif

class MyApp: public wxApp
{
public:
    virtual bool OnInit();
};

class MyFrame: public wxFrame
{
public:
    MyFrame(const wxString& title, const wxPoint& pos, const
      wxSize& size);

private:
    void OnHello(wxCommandEvent& event);
    void OnExit(wxCommandEvent& event);
    void OnAbout(wxCommandEvent& event);

    wxDECLARE_EVENT_TABLE();
};
```

```
enum
{
    ID_Hello = 1
};

wxBEGIN_EVENT_TABLE(MyFrame, wxFrame)
    EVT_MENU(ID_Hello,   MyFrame::OnHello)
    EVT_MENU(wxID_EXIT,  MyFrame::OnExit)
    EVT_MENU(wxID_ABOUT, MyFrame::OnAbout)
wxEND_EVENT_TABLE()

wxIMPLEMENT_APP(MyApp);

bool MyApp::OnInit()
{
    MyFrame *frame = new MyFrame( "Hello World", wxPoint(50, 50), wxSize(450, 340) );
    frame->Show( true );
    return true;
}

MyFrame::MyFrame(const wxString& title, const wxPoint& pos, const
      wxSize& size)
        : wxFrame(NULL, wxID_ANY, title, pos, size)
{
    wxMenu *menuFile = new wxMenu;
    menuFile->Append(ID_Hello, "&Hello...\tCtrl-H",
                     "Help string shown in status bar for this menu item");
    menuFile->AppendSeparator();
    menuFile->Append(wxID_EXIT);

    wxMenu *menuHelp = new wxMenu;
    menuHelp->Append(wxID_ABOUT);

    wxMenuBar *menuBar = new wxMenuBar;
    menuBar->Append( menuFile, "&File" );
    menuBar->Append( menuHelp, "&Help" );

    SetMenuBar( menuBar );

    CreateStatusBar();
    SetStatusText( "Welcome to wxWidgets!" );
}

void MyFrame::OnExit(wxCommandEvent& event)
{
    Close( true );
}

void MyFrame::OnAbout(wxCommandEvent& event)
{
    wxMessageBox( "This is a wxWidgets' Hello world sample",
                  "About Hello World", wxOK | wxICON_INFORMATION );
}

void MyFrame::OnHello(wxCommandEvent& event)
{
    wxLogMessage("Hello world from wxWidgets!");
}
```

10.11 wxPython Overview

This topic was written by Robin Dunn, author of the wxPython wrapper.

10.11.1 What is wxPython?

wxPython is a blending of the wxWidgets GUI classes and the Python programming language.

Python

So what is Python? Go to http://www.python.org to learn more, but in a nutshell Python is an interpreted, interactive, object-oriented programming language. It is often compared to Tcl, Perl, Scheme or Java.

Python combines remarkable power with very clear syntax. It has modules, classes, exceptions, very high level dynamic data types, and dynamic typing. There are interfaces to many system calls and libraries, and new built-in

modules are easily written in C or C++. Python is also usable as an extension language for applications that need a programmable interface.

Python is copyrighted but freely usable and distributable, even for commercial use.

wxPython

wxPython is a Python package that can be imported at runtime that includes a collection of Python modules and an extension module (native code). It provides a series of Python classes that mirror (or shadow) many of the wxWidgets GUI classes. This extension module attempts to mirror the class hierarchy of wxWidgets as closely as possible. This means that there is a wxFrame class in wxPython that looks, smells, tastes and acts almost the same as the wxFrame class in the C++ version.

wxPython is very versatile. It can be used to create standalone GUI applications, or in situations where Python is embedded in a C++ application as an internal scripting or macro language.

Currently wxPython is available for Win32 platforms and the GTK toolkit (wxGTK) on most Unix/X-windows platforms. See the wxPython website http://wxPython.org/ for details about getting wxPython working for you.

10.11.2 Why Use wxPython?

So why would you want to use wxPython over just C++ and wxWidgets? Personally I prefer using Python for everything. I only use C++ when I absolutely have to eke more performance out of an algorithm, and even then I usually code it as an extension module and leave the majority of the program in Python.

Another good thing to use wxPython for is quick prototyping of your wxWidgets apps. With C++ you have to continuously go though the edit-compile-link-run cycle, which can be quite time consuming. With Python it is only an edit-run cycle. You can easily build an application in a few hours with Python that would normally take a few days or longer with C++. Converting a wxPython app to a C++/wxWidgets app should be a straight forward task.

10.11.3 Other Python GUIs

There are other GUI solutions out there for Python.

Tkinter

Tkinter is the de facto standard GUI for Python. It is available on nearly every platform that Python and Tcl/TK are. Why Tcl/Tk? Well because Tkinter is just a wrapper around Tcl's GUI toolkit, Tk. This has it's upsides and it's downsides...

The upside is that Tk is a pretty versatile toolkit. It can be made to do a lot of things in a lot of different environments. It is fairly easy to create new widgets and use them interchangeably in your programs.

The downside is Tcl. When using Tkinter you actually have two separate language interpreters running, the Python interpreter and the Tcl interpreter for the GUI. Since the guts of Tcl is mostly about string processing, it is fairly slow as well. (Not too bad on a fast Pentium II, but you really notice the difference on slower machines.)

It wasn't until the latest version of Tcl/Tk that native Look and Feel was possible on non-Motif platforms. This is because Tk usually implements its own widgets (controls) even when there are native controls available.

Tkinter is a pretty low-level toolkit. You have to do a lot of work (verbose program code) to do things that would be much simpler with a higher level of abstraction.

PythonWin

PythonWin is an add-on package for Python for the Win32 platform. It includes wrappers for MFC as well as much of the Win32 API. Because of its foundation, it is very familiar for programmers who have experience with MFC and

the Win32 API. It is obviously not compatible with other platforms and toolkits. PythonWin is organized as separate packages and modules so you can use the pieces you need without having to use the GUI portions.

Others

There are quite a few other GUI modules available for Python, some in active use, some that haven't been updated for ages. Most are simple wrappers around some C or C++ toolkit or another, and most are not cross-platform compatible. See this link for a listing of a few of them.

10.11.4 Using wxPython

I'm not going to try and teach the Python language here. You can do that at the Python Tutorial. I'm also going to assume that you know a bit about wxWidgets already, enough to notice the similarities in the classes used.

Take a look at the following wxPython program. You can find a similar program in the wxPython/demo directory, named DialogUnits.py. If your Python and wxPython are properly installed, you should be able to run it by issuing this command:

```
python DialogUnits.py
```

```
01: ## import all of the wxPython GUI package
02: from wxPython.wx import *
03:
04: ## Create a new frame class, derived from the wxPython Frame.
05: class MyFrame(wxFrame):
06:
07:     def __init__(self, parent, id, title):
08:         # First, call the base class' __init__ method to create the frame
09:         wxFrame.__init__(self, parent, id, title,
10:                          wxPoint(100, 100), wxSize(160, 100))
11:
12:         # Associate some events with methods of this class
13:         EVT_SIZE(self, self.OnSize)
14:         EVT_MOVE(self, self.OnMove)
15:
16:         # Add a panel and some controls to display the size and position
17:         panel = wxPanel(self, -1)
18:         wxStaticText(panel, -1, "Size:",
19:                      wxDLG_PNT(panel, wxPoint(4, 4)),  wxDefaultSize)
20:         wxStaticText(panel, -1, "Pos:",
21:                      wxDLG_PNT(panel, wxPoint(4, 14)), wxDefaultSize)
22:         self.sizeCtrl = wxTextCtrl(panel, -1, "",
23:                                    wxDLG_PNT(panel, wxPoint(24, 4)),
24:                                    wxDLG_SZE(panel, wxSize(36, -1)),
25:                                    wxTE_READONLY)
26:         self.posCtrl = wxTextCtrl(panel, -1, "",
27:                                   wxDLG_PNT(panel, wxPoint(24, 14)),
28:                                   wxDLG_SZE(panel, wxSize(36, -1)),
29:                                   wxTE_READONLY)
30:
31:
32:     # This method is called automatically when the CLOSE event is
33:     # sent to this window
34:     def OnCloseWindow(self, event):
35:         # tell the window to kill itself
36:         self.Destroy()
37:
38:     # This method is called by the system when the window is resized,
39:     # because of the association above.
40:     def OnSize(self, event):
41:         size = event.GetSize()
42:         self.sizeCtrl.SetValue("%s, %s" % (size.width, size.height))
43:
44:         # tell the event system to continue looking for an event handler,
45:         # so the default handler will get called.
46:         event.Skip()
47:
48:     # This method is called by the system when the window is moved,
49:     # because of the association above.
50:     def OnMove(self, event):
51:         pos = event.GetPosition()
52:         self.posCtrl.SetValue("%s, %s" % (pos.x, pos.y))
53:
54:
55: # Every wxWidgets application must have a class derived from wxApp
56: class MyApp(wxApp):
```

```
57:
58:     # wxWidgets calls this method to initialize the application
59:     def OnInit(self):
60:
61:         # Create an instance of our customized Frame class
62:         frame = MyFrame(NULL, -1, "This is a test")
63:         frame.Show(true)
64:
67:
68:         # Return a success flag
69:         return true
70:
71:
72: app = MyApp(0)     # Create an instance of the application class
73: app.MainLoop()     # Tell it to start processing events
74:
```

Things to Notice

At line 2 the wxPython classes, constants, and etc. are imported into the current module's namespace. If you prefer to reduce namespace pollution you can use "`from wxPython import wx`" and then access all the wxPython identifiers through the wx module, for example, "`wx.wxFrame`".

At line 13 the frame's sizing and moving events are connected to methods of the class. These helper functions are intended to be like the event table macros that wxWidgets employs. But since static event tables are impossible with wxPython, we use helpers that are named the same to dynamically build the table. The only real difference is that the first argument to the event helpers is always the window that the event table entry should be added to.

Notice the use of `wxDLG_PNT` and `wxDLG_SZE` in lines 19-29 to convert from dialog units to pixels. These helpers are unique to wxPython since Python can't do method overloading like C++.

There is an `OnCloseWindow` method at line 34 but no call to `EVT_CLOSE` to attach the event to the method. Does it really get called? The answer is, yes it does. This is because many of the standard events are attached to windows that have the associated standard method names. I have tried to follow the lead of the C++ classes in this area to determine what is standard but since that changes from time to time I can make no guarantees, nor will it be fully documented. When in doubt, use an `EVT_***` function.

At lines 17 to 21 notice that there are no saved references to the panel or the static text items that are created. Those of you who know Python might be wondering what happens when Python deletes these objects when they go out of scope. Do they disappear from the GUI? They don't. Remember that in wxPython the Python objects are just shadows of the corresponding C++ objects. Once the C++ windows and controls are attached to their parents, the parents manage them and delete them when necessary. For this reason, most wxPython objects do not need to have a **`del`** method that explicitly causes the C++ object to be deleted. If you ever have the need to forcibly delete a window, use the Destroy() method as shown on line 36.

Just like wxWidgets in C++, wxPython apps need to create a class derived from `wxApp` (line 56) that implements a method named `OnInit`, (line 59.) This method should create the application's main window (line 62) and show it.

And finally, at line 72 an instance of the application class is created. At this point wxPython finishes initializing itself, and calls the `OnInit` method to get things started. (The zero parameter here is a flag for functionality that isn't quite implemented yet. Just ignore it for now.) The call to `MainLoop` at line 73 starts the event loop which continues until the application terminates or all the top level windows are closed.

10.11.5 Classes Implemented in wxPython

The following classes are supported in wxPython. Most provide nearly full implementations of the public interfaces specified in the C++ documentation, others are less so. They will all be brought as close as possible to the C++ spec over time.

- wxAcceleratorEntry
- wxAcceleratorTable
- wxActivateEvent
- wxBitmap

- wxBitmapButton
- wxBitmapDataObject
- wxBMPHandler
- wxBoxSizer
- wxBrush
- wxBusyInfo
- wxBusyCursor
- wxButton
- wxCalculateLayoutEvent
- wxCalendarCtrl
- wxCaret
- wxCheckBox
- wxCheckListBox
- wxChoice
- wxClientDC
- wxClipboard
- wxCloseEvent
- wxColourData
- wxColourDialog
- wxColour
- wxComboBox
- wxCommandEvent
- wxConfigBase
- wxControl
- wxCursor
- wxCustomDataObject
- wxDataFormat
- wxDataObject
- wxDataObjectComposite
- wxDataObjectSimple
- wxDateTime
- wxDateSpan
- wxDC
- wxDialog
- wxDirDialog
- wxDragImage

- wxDropFilesEvent
- wxDropSource
- wxDropTarget
- wxEraseEvent
- wxEvent
- wxEvtHandler
- wxFileConfig
- wxFileDataObject
- wxFileDialog
- wxFileDropTarget
- wxFileSystem
- wxFileSystemHandler
- wxFocusEvent
- wxFontData
- wxFontDialog
- wxFont
- wxFrame
- wxFSFile
- wxGauge
- wxGIFHandler
- wxGLCanvas
- wxHtmlCell
- wxHtmlContainerCell
- wxHtmlDCRenderer
- wxHtmlEasyPrinting
- wxHtmlParser
- wxHtmlTagHandler
- wxHtmlTag
- wxHtmlWinParser
- wxHtmlPrintout
- wxHtmlWinTagHandler
- wxHtmlWindow
- wxIconizeEvent
- wxIcon
- wxIdleEvent
- wxImage

- wxImageHandler
- wxImageList
- wxIndividualLayoutConstraint
- wxInitDialogEvent
- wxInputStream
- wxInternetFSHandler
- wxJoystickEvent
- wxJPEGHandler
- wxKeyEvent
- wxLayoutAlgorithm
- wxLayoutConstraints
- wxListBox

10.11.6 Where to Go for Help

Since wxPython is a blending of multiple technologies, help comes from multiple sources. See http://wxpython.org/ for details on various sources of help, but probably the best source is the wxPython-users mail list. You can view the archive or subscribe by going to http://wxpython.org/maillist.php

Or you can send mail directly to the list using this address: wxpython-users@lists.wxwidgets.org

10.12 wxApp Overview

A wxWidgets application does not have a *main* procedure; the equivalent is the wxApp::OnInit member defined for a class derived from wxApp.

OnInit will usually create a top window as a bare minimum. Unlike in earlier versions of wxWidgets, OnInit does not return a frame. Instead it returns a boolean value which indicates whether processing should continue (true) or not (false).

Note that the program's command line arguments, represented by *argc* and *argv*, are available from within wxApp member functions.

An application closes by destroying all windows. Because all frames must be destroyed for the application to exit, it is advisable to use parent frames wherever possible when creating new frames, so that deleting the top level frame will automatically delete child frames. The alternative is to explicitly delete child frames in the top-level frame's wxCloseEvent handler.

In emergencies the wxExit function can be called to kill the application however normally the application shuts down automatically, see Application Shutdown.

An example of defining an application follows:

```
class DerivedApp : public wxApp
{
public:
    virtual bool OnInit();
};

IMPLEMENT_APP(DerivedApp)

bool DerivedApp::OnInit()
{
    wxFrame *the_frame = new wxFrame(NULL, ID_MYFRAME, argv[0]);
    ...
    the_frame->Show(true);

    return true;
}
```

Note the use of IMPLEMENT_APP(appClass), which allows wxWidgets to dynamically create an instance of the application object at the appropriate point in wxWidgets initialization. Previous versions of wxWidgets used to rely on the creation of a global application object, but this is no longer recommended, because required global initialization may not have been performed at application object construction time.

You can also use DECLARE_APP(appClass) in a header file to declare the wxGetApp function which returns a reference to the application object. Otherwise you can only use the global `wxTheApp` pointer which is of type `wxApp*`.

10.12.1 Application Shutdown

The application normally shuts down when the last of its top level windows is closed. This is normally the expected behaviour and means that it is enough to call wxWindow::Close() in response to the "Exit" menu command if your program has a single top level window. If this behaviour is not desirable wxApp::SetExitOnFrameDelete can be called to change it.

Note that such logic doesn't apply for the windows shown before the program enters the main loop: in other words, you can safely show a dialog from wxApp::OnInit and not be afraid that your application terminates when this dialog

– which is the last top level window for the moment – is closed.

Another aspect of the application shutdown is wxApp::OnExit which is called when the application exits but *before* wxWidgets cleans up its internal structures. You should delete all wxWidgets object that you created by the time OnExit finishes.

In particular, do **not** destroy them from application class' destructor! For example, this code may crash:

```
class MyApp : public wxApp
{
public:
    wxCHMHelpController m_helpCtrl;
    ...
};
```

The reason for that is that `m_helpCtrl` is a member object and is thus destroyed from MyApp destructor. But MyApp object is deleted after wxWidgets structures that wxCHMHelpController depends on were uninitialized! The solution is to destroy HelpCtrl in *OnExit:*

```
class MyApp : public wxApp
{
public:
    wxCHMHelpController *m_helpCtrl;
    ...
};

bool MyApp::OnInit()
{
    ...
    m_helpCtrl = new wxCHMHelpController;
    ...
}

int MyApp::OnExit()
{
    delete m_helpCtrl;
    return 0;
}
```

10.13 Unicode Support in wxWidgets

This section describes how does wxWidgets support Unicode and how can it affect your programs.

Notice that Unicode support has changed radically in wxWidgets 3.0 and a lot of existing material pertaining to the previous versions of the library is not correct any more. Please see Unicode-related Changes for the details of these changes.

You can skip the first two sections if you're already familiar with Unicode and wish to jump directly in the details of its support in the library.

10.13.1 What is Unicode?

Unicode is a standard for character encoding which addresses the shortcomings of the previous standards (e.g. the ASCII standard), by using 8, 16 or 32 bits for encoding each character. This allows enough code points (see below for the definition) sufficient to encode all of the world languages at once. More details about Unicode may be found at `http://www.unicode.org/`.

From a practical point of view, using Unicode is almost a requirement when writing applications for international audience. Moreover, any application reading files which it didn't produce or receiving data from the network from other services should be ready to deal with Unicode.

10.13.2 Unicode Representations and Terminology

When working with Unicode, it's important to define the meaning of some terms.

A ***glyph*** is a particular image (usually part of a font) that represents a character or part of a character. Any character may have one or more glyph associated; e.g. some of the possible glyphs for the capital letter 'A' are:

Unicode assigns each character of almost any existing alphabet/script a number, which is called ***code point***; it's typically indicated in documentation manuals and in the Unicode website as `U+xxxx` where `xxxx` is an hexadecimal number.

Note that typically one character is assigned exactly one code point, but there are exceptions; the so-called *precomposed characters* (see `http://en.wikipedia.org/wiki/Precomposed_character`) or the *ligatures*. In these cases a single "character" may be mapped to more than one code point or vice versa more than one character may be mapped to a single code point.

The Unicode standard divides the space of all possible code points in ***planes***; a plane is a range of 65,536 (1000016) contiguous Unicode code points. Planes are numbered from 0 to 16, where the first one is the *BMP*, or Basic Multilingual Plane. The BMP contains characters for all modern languages, and a large number of special characters. The other planes in fact contain mainly historic scripts, special-purpose characters or are unused.

Code points are represented in computer memory as a sequence of one or more ***code units***, where a code unit is a unit of memory: 8, 16, or 32 bits. More precisely, a code unit is the minimal bit combination that can represent a unit of encoded text for processing or interchange.

The ***UTF*** or Unicode Transformation Formats are algorithms mapping the Unicode code points to code unit sequences. The simplest of them is **UTF-32** where each code unit is composed by 32 bits (4 bytes) and each code point is always represented by a single code unit (fixed length encoding). (Note that even UTF-32 is still not completely trivial as the mapping is different for little and big-endian architectures). UTF-32 is commonly used under Unix systems for internal representation of Unicode strings.

Another very widespread standard is **UTF-16** which is used by Microsoft Windows: it encodes the first (approximately) 64 thousands of Unicode code points (the BMP plane) using 16-bit code units (2 bytes) and uses a pair of 16-bit code units to encode the characters beyond this. These pairs are called *surrogate*. Thus UTF16 uses a variable number of code units to encode each code point.

Finally, the most widespread encoding used for the external Unicode storage (e.g. files and network protocols) is **UTF-8** which is byte-oriented and so avoids the endianness ambiguities of UTF-16 and UTF-32. UTF-8 uses code units of 8 bits (1 byte); code points beyond the usual english alphabet are represented using a variable number of bytes, which makes it less efficient than UTF-32 for internal representation.

As visual aid to understand the differences between the various concepts described so far, look at the different UTF representations of the same code point:

In this particular case UTF8 requires more space than UTF16 (3 bytes instead of 2).

Note that from the C/C++ programmer perspective the situation is further complicated by the fact that the standard type `wchar_t` which is usually used to represent the Unicode ("wide") strings in C/C++ doesn't have the same size on all platforms. It is 4 bytes under Unix systems, corresponding to the tradition of using UTF-32, but only 2 bytes under Windows which is required by compatibility with the OS which uses UTF-16.

Typically when UTF8 is used, code units are stored into `char` types, since `char` are 8bit wide on almost all systems; when using UTF16 typically code units are stored into `wchar_t` types since `wchar_t` is at least 16bits on all systems. This is also the approach used by wxString. See wxString Overview for more info.

See also `http://unicode.org/glossary/` for the official definitions of the terms reported above.

10.13.3 Unicode Support in wxWidgets

Unicode is Always Used by Default

Since wxWidgets 3.0 Unicode support is always enabled and while building the library without it is still possible, it is not recommended any longer and will cease to be supported in the near future. This means that internally only Unicode strings are used and that, under Microsoft Windows, Unicode system API is used which means that wxWidgets programs require the Microsoft Layer for Unicode to run on Windows 95/98/ME.

However, unlike the Unicode build mode of the previous versions of wxWidgets, this support is mostly transparent: you can still continue to work with the **narrow** (i.e. current locale-encoded `char*`) strings even if **wide** (i.e. UT↩

F16-encoded `wchar_t*` or UTF8-encoded `char*`) strings are also supported. Any wxWidgets function accepts arguments of either type as both kinds of strings are implicitly converted to wxString, so both

```
wxMessageBox("Hello, world!");
```

and the somewhat less usual

```
wxMessageBox(L"Salut \u00E0 toi!"); // U+00E0 is "Latin Small Letter a with Grave"
```

work as expected.

Notice that the narrow strings used with wxWidgets are *always* assumed to be in the current locale encoding, so writing

```
wxMessageBox("Salut à toi!");
```

wouldn't work if the encoding used on the user system is incompatible with ISO-8859-1 (or even if the sources were compiled under different locale in the case of gcc). In particular, the most common encoding used under modern Unix systems is UTF-8 and as the string above is not a valid UTF-8 byte sequence, nothing would be displayed at all in this case. Thus it is important to **never use 8-bit (instead of 7-bit) characters directly in the program source** but use wide strings or, alternatively, write:

```
wxMessageBox(wxString::FromUTF8("Salut \xC3\xA0 toi!"));
    // in UTF8 the character U+00E0 is encoded as 0xC3A0
```

In a similar way, wxString provides access to its contents as either `wchar_t` or `char` character buffer. Of course, the latter only works if the string contains data representable in the current locale encoding. This will always be the case if the string had been initially constructed from a narrow string or if it contains only 7-bit ASCII data but otherwise this conversion is not guaranteed to succeed. And as with wxString::FromUTF8() example above, you can always use wxString::ToUTF8() to retrieve the string contents in UTF-8 encoding – this, unlike converting to `char*` using the current locale, never fails.

For more info about how wxString works, please see the wxString Overview.

To summarize, Unicode support in wxWidgets is mostly **transparent** for the application and if you use wxString objects for storing all the character data in your program there is really nothing special to do. However you should be aware of the potential problems covered by the following section.

Choosing Unicode Representation

wxWidgets uses the system `wchar_t` in wxString implementation by default under all systems. Thus, under Microsoft Windows, UCS-2 (simplified version of UTF-16 without support for surrogate characters) is used as `wchar_t` is 2 bytes on this platform. Under Unix systems, including Mac OS X, UCS-4 (also known as UTF-32) is used by default, however it is also possible to build wxWidgets to use UTF-8 internally by passing `-enable-utf8` option to configure.

The interface provided by wxString is the same independently of the format used internally. However different formats have specific advantages and disadvantages. Notably, under Unix, the underlying graphical toolkit (e.g. GTK+) usually uses UTF-8 encoded strings and using the same representations for the strings in wxWidgets allows to avoid conversion from UTF-32 to UTF-8 and vice versa each time a string is shown in the UI or retrieved from it. The overhead of such conversions is usually negligible for small strings but may be important for some programs. If you believe that it would be advantageous to use UTF-8 for the strings in your particular application, you may rebuild wxWidgets to use UTF-8 as explained above (notice that this is currently not supported under Microsoft Windows and arguably doesn't make much sense there as Windows itself uses UTF-16 and not UTF-8) but be sure to be aware of the performance implications (see Performance Implications of Using UTF-8) of using UTF-8 in wxString before doing this!

Generally speaking you should only use non-default UTF-8 build in specific circumstances e.g. building for resource-constrained systems where the overhead of conversions (and also reduced memory usage of UTF-8 compared to UTF-32 for the European languages) can be important. If the environment in which your program is running is under your control – as is quite often the case in such scenarios – consider ensuring that the system always uses UTF-8 locale and use `-enable-utf8only` configure option to disable support for the other locales and consider all strings to be in UTF-8. This further reduces the code size and removes the need for conversions in more cases.

Unicode Related Preprocessor Symbols

wxUSE_UNICODE is defined as 1 now to indicate Unicode support. It can be explicitly set to 0 in setup.h under MSW or you can use --disable-unicode under Unix but doing this is strongly discouraged. By default, wxUSE_UNICODE_WCHAR is also defined as 1, however in UTF-8 build (described in the previous section), it is set to 0 and wxUSE_UNICODE_UTF8, which is usually 0, is set to 1 instead. In the latter case, wxUSE_UTF8_LOCALE_ONLY can also be set to 1 to indicate that all strings are considered to be in UTF-8.

10.13.4 Potential Unicode Pitfalls

The problems can be separated into three broad classes:

Unicode-Related Compilation Errors

Because of the need to support implicit conversions to both char and wchar_t, wxString implementation is rather involved and many of its operators don't return the types which they could be naively expected to return. For example, the operator[] doesn't return neither a char nor a wchar_t but an object of a helper class wxUniChar or wxUniCharRef which is implicitly convertible to either. Usually you don't need to worry about this as the conversions do their work behind the scenes however in some cases it doesn't work. Here are some examples, using a wxString object s and some integer n:

- Writing

  ```
  switch ( s[n] )
  ```

  doesn't work because the argument of the switch statement must be an integer expression so you need to replace s[n] with

  ```
  s[n].GetValue()
  ```

  . You may also force the conversion to char or wchar_t by using an explicit cast but beware that converting the value to char uses the conversion to current locale and may return 0 if it fails. Finally notice that writing

  ```
  (wxChar)s[n]
  ```

  works both with wxWidgets 3.0 and previous library versions and so should be used for writing code which should be compatible with both 2.8 and 3.0.

- Similarly,

  ```
  &s[n]
  ```

  doesn't yield a pointer to char so you may not pass it to functions expecting char* or wchar_t*. Consider using string iterators instead if possible or replace this expression with

  ```
  s.c_str() + n
  ```

  otherwise.

Another class of problems is related to the fact that the value returned by c_str() itself is also not just a pointer to a buffer but a value of helper class wxCStrData which is implicitly convertible to both narrow and wide strings. Again, this mostly will be unnoticeable but can result in some problems:

- You shouldn't pass c_str() result to vararg functions such as standard printf(). Some compilers (notably g++) warn about this but even if they don't, this

  ```
  printf("Hello, %s", s.c_str())
  ```

is not going to work. It can be corrected in one of the following ways:

- Preferred:

```
wxPrintf("Hello, %s", s)
```

(notice the absence of `c_str()`, it is not needed at all with wxWidgets functions)

- Compatible with wxWidgets 2.8:

```
wxPrintf("Hello, %s", s.c_str())
```

- Using an explicit conversion to narrow, multibyte, string:

```
printf("Hello, %s", (const char *)s.mb_str())
```

- Using a cast to force the issue (listed only for completeness):

```
printf("Hello, %s", (const char *)s.c_str())
```

- The result of `c_str()` cannot be cast to `char*` but only to `const char*`. Of course, modifying the string via the pointer returned by this method has never been possible but unfortunately it was occasionally useful to use a `const_cast` here to pass the value to const-incorrect functions. This can be done either using new wxString::char_str() (and matching wchar_str()) method or by writing a double cast:

```
(char *)(const char *)s.c_str()
```

- One of the unfortunate consequences of the possibility to pass wxString to `wxPrintf()` without using `c_str()` is that it is now impossible to pass the elements of unnamed enumerations to `wxPrintf()` and other similar vararg functions, i.e.

```
enum { Red, Green, Blue };
wxPrintf("Red is %d", Red);
```

doesn't compile. The easiest workaround is to give a name to the enum.

Other unexpected compilation errors may arise but they should happen even more rarely than the above-mentioned ones and the solution should usually be quite simple: just use the explicit methods of wxUniChar and wxCStrData classes instead of relying on their implicit conversions if the compiler can't choose among them.

Data Loss due To Unicode Conversion Errors

wxString API provides implicit conversion of the internal Unicode string contents to narrow, char strings. This can be very convenient and is absolutely necessary for backwards compatibility with the existing code using wxWidgets however it is a rather dangerous operation as it can easily give unexpected results if the string contents isn't convertible to the current locale.

To be precise, the conversion will always succeed if the string was created from a narrow string initially. It will also succeed if the current encoding is UTF-8 as all Unicode strings are representable in this encoding. However initializing the string using wxString::FromUTF8() method and then accessing it as a char string via its wxString::c_str() method is a recipe for disaster as the program may work perfectly well during testing on Unix systems using UTF-8 locale but completely fail under Windows where UTF-8 locales are never used because wxString::c_str() would return an empty string.

The simplest way to ensure that this doesn't happen is to avoid conversions to `char*` completely by using wxString throughout your program. However if the program never manipulates 8 bit strings internally, using `char*` pointers is safe as well. So the existing code needs to be reviewed when upgrading to wxWidgets 3.0 and the new code should be used with this in mind and ideally avoiding implicit conversions to `char*`.

Performance Implications of Using UTF-8

As mentioned above, under Unix systems wxString class can use variable-width UTF-8 encoding for internal representation. In this case it can't guarantee constant-time access to N-th element of the string any longer as to find the position of this character in the string we have to examine all the preceding ones. Usually this doesn't matter much because most algorithms used on the strings examine them sequentially anyhow and because wxString implements a cache for iterating over the string by index but it can have serious consequences for algorithms using random access to string elements as they typically acquire O(N^2) time complexity instead of O(N) where N is the length of the string.

Even despite caching the index, indexed access should be replaced with sequential access using string iterators. For example a typical loop:

```
wxString s("hello");
for ( size_t i = 0; i < s.length(); i++ )
{
    wchar_t ch = s[i];

    // do something with it
}
```

should be rewritten as

```
wxString s("hello");
for ( wxString::const_iterator i = s.begin(); i != s.end(); ++i )
{
    wchar_t ch = *i

    // do something with it
}
```

Another, similar, alternative is to use pointer arithmetic:

```
wxString s("hello");
for ( const wchar_t *p = s.wc_str(); *p; p++ )
{
    wchar_t ch = *i

    // do something with it
}
```

however this doesn't work correctly for strings with embedded `NUL` characters and the use of iterators is generally preferred as they provide some run-time checks (at least in debug build) unlike the raw pointers. But if you do use them, it is better to use `wchar_t` pointers rather than `char` ones to avoid the data loss problems due to conversion as discussed in the previous section.

10.13.5 Unicode and the Outside World

Even though wxWidgets always uses Unicode internally, not all the other libraries and programs do and even those that do use Unicode may use a different encoding of it. So you need to be able to convert the data to various representations and the wxString methods wxString::ToAscii(), wxString::ToUTF8() (or its synonym wxString::utf8_str()), wxString::mb_str(), wxString::c_str() and wxString::wc_str() can be used for this.

The first of them should be only used for the string containing 7-bit ASCII characters only, anything else will be replaced by some substitution character. wxString::mb_str() converts the string to the encoding used by the current locale and so can return an empty string if the string contains characters not representable in it as explained in Data Loss due To Unicode Conversion Errors. The same applies to wxString::c_str() if its result is used as a narrow string. Finally, wxString::ToUTF8() and wxString::wc_str() functions never fail and always return a pointer to char string containing the UTF-8 representation of the string or `wchar_t` string.

wxString also provides two convenience functions: wxString::From8BitData() and wxString::To8BitData(). They can be used to create a wxString from arbitrary binary data without supposing that it is in current locale encoding, and then get it back, again, without any conversion or, rather, undoing the conversion used by wxString::From8BitData(). Because of this you should only use wxString::From8BitData() for the strings created using wxString::To8BitData(). Also notice that in spite of the availability of these functions, wxString is not the ideal class for storing arbitrary binary

data as they can take up to 4 times more space than needed (when using `wchar_t` internal representation on the systems where size of wide characters is 4 bytes) and you should consider using wxMemoryBuffer instead.

Final word of caution: most of these functions may return either directly the pointer to internal string buffer or a temporary wxCharBuffer or wxWCharBuffer object. Such objects are implicitly convertible to `char` and `wchar_t` pointers, respectively, and so the result of, for example, wxString::ToUTF8() can always be passed directly to a function taking `const char*`. However code such as

```
const char *p = s.ToUTF8();
...
puts(p); // or call any other function taking const char *
```

does **not** work because the temporary buffer returned by wxString::ToUTF8() is destroyed and `p` is left pointing nowhere. To correct this you should use

```
const wxScopedCharBuffer p(s.ToUTF8());
puts(p);
```

which does work.

Similarly, wxWX2WCbuf can be used for the return type of wxString::wc_str(). But, once again, none of these cryptic types is really needed if you just pass the return value of any of the functions mentioned in this section to another function directly.

10.14 Internationalization

Although internationalization of an application (i18n for short) involves far more than just translating its text messages to another message - date, time and currency formats need changing too, some languages are written left to right and others right to left, character encoding may differ and many other things may need changing too - it is a necessary first step.

wxWidgets provides facilities for message translation with its wxLocale class and is itself fully translated into several languages. Please consult wxWidgets home page for the most up-to-date translations - and if you translate it into one of the languages not done yet, your translations would be gratefully accepted for inclusion into future versions of the library!

The wxWidgets approach to i18n closely follows the GNU gettext package. wxWidgets uses the message catalogs which are binary compatible with gettext catalogs and this allows to use all of the programs in this package to work with them as well as using any of the tools working with message catalogs in this format such as `Poedit`.

Because of this, you will need to use the gettext package to work with the translations during the program development. However no additional libraries are needed during run-time, so you have only the message catalogs to distribute and nothing else.

There are two kinds of message catalogs: source catalogs which are text files with extension .po and binary catalogs which are created from the source ones with *msgfmt* program (part of gettext package) and have the extension .mo. Only the binary files are needed during program execution.

Translating your application involves several steps:

- Translating the strings in the program text using wxGetTranslation or equivalently the `_()` macro.
- Extracting the strings to be translated from the program: this uses the work done in the previous step because `xgettext` program used for string extraction recognises the standard `_()` as well as (using its `-k` option) our wxGetTranslation and extracts all strings inside the calls to these functions. Alternatively, you may use `-a` option to extract all the strings, but it will usually result in many strings being found which don't have to be translated at all. This will create a text message catalog - a .po file.
- Translating the strings extracted in the previous step to other language(s). It involves editing the .po file.
- Compiling the .po file into .mo file to be used by the program.

- Installing the .mo files with your application in the appropriate location for the target system (see Installing translation catalogs).
- Setting the appropriate locale in your program to use the strings for the given language: see wxLocale.

10.14.1 Installing translation catalogs

The .mo files with compiled catalogs must be included with the application. By default, wxFileTranslationsLoader is used to load them from files installed alongside the application (although you could use wxResourceTranslationsLoader or some custom loader too).

The files are expected to be in the resources directory (as returned by wxStandardPaths::GetLocalizedResourcesDir(wxStandardPaths::ResourceCat_Messages). If the message catalogs are not installed in this default location you may explicitly use wxFileTranslationsLoader::AddCatalogLookupPathPrefix() to still allow wxWidgets to find them, but it is recommended to use the default locations when possible.

Depending on the platform, the default location differs. On Windows, it is alongside the executable. On Unix, translations are expected to be in "$prefix/share/locale". On OS X, application bundle's *Resources* subdirectory is used.

In all cases, translations are searched for in subdirectories named using the languages codes from ISO 639. The .mo file(s) should be located either directly in that directory or in LC_MESSAGES subdirectory. On OS X, ".lproj" extension is used for the per-languages Resources subdirectories.

Here's how an app would typically install the files on Unix:

```
/usr/bin/myapp
/usr/share/locale/de/LC_MESSAGES/myapp.mo
/usr/share/locale/fr/LC_MESSAGES/myapp.mo
```

And on OS X:

```
MyApp.app/Contents/MacOS/MyApp
MyApp.app/Contents/Resources/de.lproj/myapp.mo
MyApp.app/Contents/Resources/fr.lproj/myapp.mo
```

And on Windows:

```
C:\Program Files\MyApp\myapp.exe
C:\Program Files\MyApp\de\myapp.mo
C:\Program Files\MyApp\fr\myapp.mo
```

It is of course possible to use the Unix layout everywhere instead.

10.14.2 Translating Menu Accelerators

If you translate the accelerator modifier names (Ctrl, Alt and Shift) in your menu labels, you may find the accelerators no longer work. In your message catalogs, you need to provide individual translations of these modifiers from their lower case names (ctrl, alt, shift) so that the wxWidgets accelerator code can recognise them even when translated. wxWidgets does not provide translations for all of these currently. wxWidgets does not yet handle translated special key names such as Backspace, End, Insert, etc.

See also

- The gettext Manual: http://www.gnu.org/software/gettext/manual/gettext.html
- Writing Non-English Applications - It focuses on handling charsets related problems.
- Internationalization Sample - Shows you how all this looks in practice.

10.15 Events and Event Handling

Like with all the other GUI frameworks, the control of flow in wxWidgets applications is event-based: the program normally performs most of its actions in response to the events generated by the user.

These events can be triggered by using the input devices (such as keyboard, mouse, joystick) directly or, more commonly, by a standard control which synthesizes such input events into higher level events: for example, a wxButton can generate a click event when the user presses the left mouse button on it and then releases it without pressing `Esc` in the meanwhile. There are also events which don't directly correspond to the user actions, such as wxTimerEvent or wxSocketEvent.

But in all cases wxWidgets represents these events in a uniform way and allows you to handle them in the same way wherever they originate from. And while the events are normally generated by wxWidgets itself, you can also do this, which is especially useful when using custom events (see Custom Event Summary).

To be more precise, each event is described by:

- *Event type*: this is simply a value of type wxEventType which uniquely identifies the type of the event. For example, clicking on a button, selecting an item from a list box and pressing a key on the keyboard all generate events with different event types.
- *Event class* carried by the event: each event has some information associated with it and this data is represented by an object of a class derived from wxEvent. Events of different types can use the same event class, for example both button click and listbox selection events use wxCommandEvent class (as do all the other simple control events), but the key press event uses wxKeyEvent as the information associated with it is different.
- *Event source*: wxEvent stores the object which generated the event and, for windows, its identifier (see Window Identifiers). As it is common to have more than one object generating events of the same type (e.g. a typical window contains several buttons, all generating the same button click event), checking the event source object or its id allows to distinguish between them.

10.15.1 Event Handling

There are two principal ways to handle events in wxWidgets. One of them uses *event table* macros and allows you to define the binding between events and their handlers only statically, i.e., during program compilation. The other one uses wxEvtHandler::Bind<>() call and can be used to bind and unbind, the handlers dynamically, i.e. during run-time depending on some conditions. It also allows the direct binding of events to:

- A handler method in another object.
- An ordinary function like a static method or a global function.
- An arbitrary functor like boost::function<>.

The static event tables can only handle events in the object where they are defined so using Bind<>() is more flexible than using the event tables. On the other hand, event tables are more succinct and centralize all event handler bindings in one place. You can either choose a single approach that you find preferable or freely combine both methods in your program in different classes or even in one and the same class, although this is probably sufficiently confusing to be a bad idea.

Also notice that most of the existing wxWidgets tutorials and discussions use the event tables because they historically preceded the apparition of dynamic event handling in wxWidgets. But this absolutely doesn't mean that using the event tables is the preferred way: handling events dynamically is better in several aspects and you should strongly consider doing it if you are just starting with wxWidgets. On the other hand, you still need to know about the event tables if only because you are going to see them in many samples and examples.

So before you make the choice between static event tables and dynamically connecting the event handlers, let us discuss these two ways in more detail. In the next section we provide a short introduction to handling the events using the event tables. Please see Dynamic Event Handling for the discussion of Bind<>().

Event Handling with Event Tables

To use an *event table* you must first decide in which class you wish to handle the events. The only requirement imposed by wxWidgets is that this class must derive from wxEvtHandler and so, considering that wxWindow derives from it, any classes representing windows can handle events. Simple events such as menu commands are usually processed at the level of a top-level window containing the menu, so let's suppose that you need to handle some events in `MyFrame` class deriving from wxFrame.

First define one or more *event handlers*. They are just simple methods of the class that take as a parameter a reference to an object of a wxEvent-derived class and have no return value (any return information is passed via the argument, which is why it is non-const). You also need to insert a macro

```
wxDECLARE_EVENT_TABLE()
```

somewhere in the class declaration. It doesn't matter where it appears but it's customary to put it at the end because the macro changes the access type internally so it's safest if nothing follows it. The full class declaration might look like this:

```
class MyFrame : public wxFrame
{
public:
    MyFrame(...) : wxFrame(...) { }

    ...

protected:
    int m_whatever;

private:
    // Notice that as the event handlers normally are not called from outside
    // the class, they normally are private. In particular they don't need
    // to be public.
    void OnExit(wxCommandEvent& event);
    void OnButton1(wxCommandEvent& event);
    void OnSize(wxSizeEvent& event);

    // it's common to call the event handlers OnSomething() but there is no
    // obligation to do that; this one is an event handler too:
    void DoTest(wxCommandEvent& event);

    wxDECLARE_EVENT_TABLE()
};
```

Next the event table must be defined and, as with any definition, it must be placed in an implementation file. The event table tells wxWidgets how to map events to member functions and in our example it could look like this:

```
wxBEGIN_EVENT_TABLE(MyFrame, wxFrame)
    EVT_MENU(wxID_EXIT, MyFrame::OnExit)
    EVT_MENU(DO_TEST, MyFrame::DoTest)
    EVT_SIZE(MyFrame::OnSize)
    EVT_BUTTON(BUTTON1, MyFrame::OnButton1)
wxEND_EVENT_TABLE()
```

Notice that you must mention a method you want to use for the event handling in the event table definition; just defining it in MyFrame class is *not* enough.

Let us now look at the details of this definition: the first line means that we are defining the event table for My↩ Frame class and that its base class is wxFrame, so events not processed by MyFrame will, by default, be handled by wxFrame. The next four lines define bindings of individual events to their handlers: the first two of them map menu commands from the items with the identifiers specified as the first macro parameter to two different member functions. In the next one, `EVT_SIZE` means that any changes in the size of the frame will result in calling OnSize() method. Note that this macro doesn't need a window identifier, since normally you are only interested in the current window's size events.

The EVT_BUTTON macro demonstrates that the originating event does not have to come from the window class implementing the event table – if the event source is a button within a panel within a frame, this will still work, because event tables are searched up through the hierarchy of windows for the command events. (But only command events, so you can't catch mouse move events in a child control in the parent window in the same way because wxMouseEvent doesn't derive from wxCommandEvent. See below for how you can do it.) In this case, the button's event table will be searched, then the parent panel's, then the frame's.

Finally, you need to implement the event handlers. As mentioned before, all event handlers take a wxEvent-derived argument whose exact class differs according to the type of event and the class of the originating window. For size events, wxSizeEvent is used. For menu commands and most control commands (such as button presses), wxCommandEvent is used. When controls get more complicated, more specific wxCommandEvent-derived event classes providing additional control-specific information can be used, such as wxTreeEvent for events from wxTreeCtrl windows.

In the simplest possible case an event handler may not use the event parameter at all. For example,

```
void MyFrame::OnExit(wxCommandEvent& WXUNUSED(event))
{
    // when the user selects "Exit" from the menu we should close
    Close(true);
}
```

In other cases you may need some information carried by the event argument, as in:

```
void MyFrame::OnSize(wxSizeEvent& event)
{
    wxSize size = event.GetSize();

    ... update the frame using the new size ...
}
```

You will find the details about the event table macros and the corresponding wxEvent-derived classes in the discussion of each control generating these events.

Dynamic Event Handling

See also

Caveats When Not Using C++ RTTI

The possibilities of handling events in this way are rather different. Let us start by looking at the syntax: the first obvious difference is that you need not use wxDECLARE_EVENT_TABLE() nor wxBEGIN_EVENT_TABLE() and the associated macros. Instead, in any place in your code, but usually in the code of the class defining the handler itself (and definitely not in the global scope as with the event tables), call its Bind<>() method like this:

```
MyFrame::MyFrame(...)
{
      Bind(wxEVT_COMMAND_MENU_SELECTED, &MyFrame::OnExit, this, wxID_EXIT);
}
```

Note that this pointer must be specified here.

Now let us describe the semantic differences:

- Event handlers can be bound at any moment. For example, it's possible to do some initialization first and only bind the handlers if and when it succeeds. This can avoid the need to test that the object was properly initialized in the event handlers themselves. With Bind<>() they simply won't be called if it wasn't correctly initialized.
- As a slight extension of the above, the handlers can also be unbound at any time with Unbind<>() (and maybe rebound later). Of course, it's also possible to emulate this behaviour with the classic static (i.e., bound via event tables) handlers by using an internal flag indicating whether the handler is currently enabled and returning from it if it isn't, but using dynamically bind handlers requires less code and is also usually more clear.

- Almost last but very, very far from least is the increased flexibility which allows to bind an event to:
  - A method in another object.
  - An ordinary function like a static method or a global function.
  - An arbitrary functor like boost::function<>.

  This is impossible to do with the event tables because it is not possible to specify these handlers to dispatch the event to, so it necessarily needs to be sent to the same object which generated the event. Not so with Bind<>() which can be used to specify these handlers which will handle the event. To give a quick example, a common question is how to receive the mouse movement events happening when the mouse is in one of the frame children in the frame itself. Doing it in a naive way doesn't work:
  - A `EVT_LEAVE_WINDOW(MyFrame::OnMouseLeave)` line in the frame event table has no effect as mouse move (including entering and leaving) events are not propagated up to the parent window (at least not by default).
  - Putting the same line in a child event table will crash during run-time because the MyFrame method will be called on a wrong object – it's easy to convince oneself that the only object that can be used here is the pointer to the child, as wxWidgets has nothing else. But calling a frame method with the child window pointer instead of the pointer to the frame is, of course, disastrous.

  However writing

  ```
  MyFrame::MyFrame(...)
  {
    m_child->Bind(wxEVT_LEAVE_WINDOW, &MyFrame::OnMouseLeave, this);
  }
  ```

  will work exactly as expected. Note that you can get the object that generated the event – and that is not the same as the frame – via wxEvent::GetEventObject() method of `event` argument passed to the event handler.
- Really last point is the consequence of the previous one: because of increased flexibility of Bind(), it is also safer as it is impossible to accidentally use a method of another class. Instead of run-time crashes you will get compilation errors in this case when using Bind().

Let us now look at more examples of how to use different event handlers using the two overloads of Bind() function: first one for the object methods and the other one for arbitrary functors (callable objects, including simple functions):

In addition to using a method of the object generating the event itself, you can use a method from a completely different object as an event handler:

```
void MyFrameHandler::OnFrameExit( wxCommandEvent & )
{
    // Do something useful.
}

MyFrameHandler myFrameHandler;

MyFrame::MyFrame()
{
      Bind( wxEVT_COMMAND_MENU_SELECTED, &MyFrameHandler::OnFrameExit,
              &myFrameHandler, wxID_EXIT );
}
```

Note that `MyFrameHandler` doesn't need to derive from wxEvtHandler. But keep in mind that then the lifetime of `myFrameHandler` must be greater than that of `MyFrame` object – or at least it needs to be unbound before being destroyed.

To use an ordinary function or a static method as an event handler you would write something like this:

```
void HandleExit( wxCommandEvent & )
{
    // Do something useful
}

MyFrame::MyFrame()
{
    Bind( wxEVT_COMMAND_MENU_SELECTED, &HandleExit, wxID_EXIT );
}
```

And finally you can bind to an arbitrary functor and use it as an event handler:

```
struct MyFunctor
{
    void operator()( wxCommandEvent & )
    {
        // Do something useful
    }
};

MyFunctor myFunctor;

MyFrame::MyFrame()
{
    Bind( wxEVT_COMMAND_MENU_SELECTED, myFunctor, wxID_EXIT );
}
```

A common example of a functor is boost::function<>:

```
using namespace boost;

void MyHandler::OnExit( wxCommandEvent & )
{
    // Do something useful
}

MyHandler myHandler;

MyFrame::MyFrame()
{
    function< void ( wxCommandEvent & ) > exitHandler( bind( &MyHandler::OnExit, &myHandler, _1 ));

    Bind( wxEVT_COMMAND_MENU_SELECTED, exitHandler, wxID_EXIT );
}
```

With the aid of boost::bind<>() you can even use methods or functions which don't quite have the correct signature:

```
void MyHandler::OnExit( int exitCode, wxCommandEvent &, wxString goodByeMessage )
{
    // Do something useful
}

MyHandler myHandler;

MyFrame::MyFrame()
{
    function< void ( wxCommandEvent & ) > exitHandler(
            bind( &MyHandler::OnExit, &myHandler, EXIT_FAILURE, _1, "Bye" ));

    Bind( wxEVT_COMMAND_MENU_SELECTED, exitHandler, wxID_EXIT );
}
```

To summarize, using Bind<>() requires slightly more typing but is much more flexible than using static event tables so don't hesitate to use it when you need this extra power. On the other hand, event tables are still perfectly fine in simple situations where this extra flexibility is not needed.

10.15.2 How Events are Processed

The previous sections explain how to define event handlers but don't address the question of how exactly wxWidgets finds the handler to call for the given event. This section describes the algorithm used in detail. Notice that you may want to run the Event Sample while reading this section and look at its code and the output when the button which can be used to test the event handlers execution order is clicked to understand it better.

When an event is received from the windowing system, wxWidgets calls wxEvtHandler::ProcessEvent() on the first event handler object belonging to the window generating the event. The normal order of event table searching by ProcessEvent() is as follows, with the event processing stopping as soon as a handler is found (unless the handler calls wxEvent::Skip() in which case it doesn't count as having handled the event and the search continues):

1. Before anything else happens, wxApp::FilterEvent() is called. If it returns anything but -1 (default), the event handling stops immediately.

2. If this event handler is disabled via a call to wxEvtHandler::SetEvtHandlerEnabled() the next three steps are skipped and the event handler resumes at step (5).
3. If the object is a wxWindow and has an associated validator, wxValidator gets a chance to process the event.
4. The list of dynamically bound event handlers, i.e., those for which Bind<>() was called, is consulted. Notice that this is done before checking the static event table entries, so if both a dynamic and a static event handler match the same event, the static one is never going to be used unless wxEvent::Skip() is called in the dynamic one. Also note that the dynamically bound handlers are searched in order of their registration during program run-time, i.e. later bound handlers take priority over the previously bound ones.
5. The event table containing all the handlers defined using the event table macros in this class and its base classes is examined. The search in an event table respects the order of the event macros appearance in the source code, i.e. earlier occurring entries take precedence over later occurring ones. Notice that this means that any event handler defined in a base class will be executed at this step.
6. The event is passed to the next event handler, if any, in the event handler chain, i.e., the steps (1) to (4) are done for it. Usually there is no next event handler so the control passes to the next step but see Event Handlers Chain for how the next handler may be defined.
7. If the object is a wxWindow and the event is set to propagate (by default only wxCommandEvent-derived events are set to propagate), then the processing restarts from the step (1) (and excluding the step (7)) for the parent window. If this object is not a window but the next handler exists, the event is passed to its parent if it is a window. This ensures that in a common case of (possibly several) non-window event handlers pushed on top of a window, the event eventually reaches the window parent.
8. Finally, i.e., if the event is still not processed, the wxApp object itself (which derives from wxEvtHandler) gets a last chance to process it.

Please pay close attention to step 6! People often overlook or get confused by this powerful feature of the wxWidgets event processing system. The details of event propagation up the window hierarchy are described in the next section.

Also please notice that there are additional steps in the event handling for the windows-making part of wxWidgets document-view framework, i.e., wxDocParentFrame, wxDocChildFrame and their MDI equivalents wxDocMDIParentFrame and wxDocMDIChildFrame. The parent frame classes modify step (2) above to send the events received by them to wxDocManager object first. This object, in turn, sends the event to the current view and the view itself lets its associated document process the event first. The child frame classes send the event directly to the associated view which still forwards it to its document object. Notice that to avoid remembering the exact order in which the events are processed in the document-view frame, the simplest, and recommended, solution is to only handle the events at the view classes level, and not in the document or document manager classes

How Events Propagate Upwards

As mentioned above, the events of the classes deriving from wxCommandEvent are propagated by default to the parent window if they are not processed in this window itself. But although by default only the command events are propagated like this, other events can be propagated as well because the event handling code uses wxEvent::ShouldPropagate() to check whether an event should be propagated. It is also possible to propagate the event only a limited number of times and not until it is processed (or a top level parent window is reached).

Finally, there is another additional complication (which, in fact, simplifies life of wxWidgets programmers significantly): when propagating the command events up to the parent window, the event propagation stops when it reaches the parent dialog, if any. This means that you don't risk getting unexpected events from the dialog controls (which might be left unprocessed by the dialog itself because it doesn't care about them) when a modal dialog is popped up. The events do propagate beyond the frames, however. The rationale for this choice is that there are only a few frames in a typical application and their parent-child relation are well understood by the programmer while it may be difficult, if not impossible, to track down all the dialogs that may be popped up in a complex program (remember that some are created automatically by wxWidgets). If you need to specify a different behaviour for some reason, you can use `wxWindow::SetExtraStyle(wxWS_EX_BLOCK_EVENTS)` explicitly to prevent the events from being propagated beyond the given window or unset this flag for the dialogs that have it on by default.

Typically events that deal with a window as a window (size, motion, paint, mouse, keyboard, etc.) are sent only to the window. Events that have a higher level of meaning or are generated by the window itself (button click, menu select, tree expand, etc.) are command events and are sent up to the parent to see if it is interested in the event. More precisely, as said above, all event classes **not** deriving from wxCommandEvent (see the wxEvent inheritance map) do **not** propagate upward.

In some cases, it might be desired by the programmer to get a certain number of system events in a parent window, for example all key events sent to, but not used by, the native controls in a dialog. In this case, a special event handler will have to be written that will override ProcessEvent() in order to pass all events (or any selection of them) to the parent window.

Event Handlers Chain

The step 4 of the event propagation algorithm checks for the next handler in the event handler chain. This chain can be formed using wxEvtHandler::SetNextHandler(): (referring to the image, if `A->ProcessEvent` is called and it doesn't handle the event, `B->ProcessEvent` will be called and so on...).

Additionally, in the case of wxWindow you can build a stack (implemented using wxEvtHandler double-linked list) using wxWindow::PushEventHandler(): (referring to the image, if `W->ProcessEvent` is called, it immediately calls `A->ProcessEvent`; if nor `A` nor `B` handle the event, then the wxWindow itself is used – i.e. the dynamically bind event handlers and static event table entries of wxWindow are looked as the last possibility, after all pushed event handlers were tested).

By default the chain is empty, i.e. there is no next handler.

10.15.3 Custom Event Summary

General approach

As each event is uniquely defined by its event type, defining a custom event starts with defining a new event type for it. This is done using wxDEFINE_EVENT() macro. As an event type is a variable, it can also be declared using wxDECLARE_EVENT() if necessary.

The next thing to do is to decide whether you need to define a custom event class for events of this type or if you can reuse an existing class, typically either wxEvent (which doesn't provide any extra information) or wxCommandEvent (which contains several extra fields and also propagates upwards by default). Both strategies are described in details below. See also the Event Sample for a complete example of code defining and working with the custom event types.

Finally, you will need to generate and post your custom events. Generation is as simple as instancing your custom event class and initializing its internal fields. For posting events to a certain event handler there are two possibilities: using wxEvtHandler::AddPendingEvent or using wxEvtHandler::QueueEvent. Basically you will need to use the latter when doing inter-thread communication; when you use only the main thread you can also safely use the former. Last, note that there are also two simple global wrapper functions associated to the two wxEvtHandler mentioned functions: wxPostEvent() and wxQueueEvent().

Using Existing Event Classes

If you just want to use a wxCommandEvent with a new event type, use one of the generic event table macros listed below, without having to define a new event class yourself.

Example:

```
// this is typically in a header: it just declares MY_EVENT event type
wxDECLARE_EVENT(MY_EVENT, wxCommandEvent);

// this is a definition so can't be in a header
wxDEFINE_EVENT(MY_EVENT, wxCommandEvent);

// example of code handling the event with event tables
wxBEGIN_EVENT_TABLE(MyFrame, wxFrame)
    EVT_MENU     (wxID_EXIT, MyFrame::OnExit)
```

```
    ...
    EVT_COMMAND (ID_MY_WINDOW, MY_EVENT, MyFrame::OnMyEvent)
wxEND_EVENT_TABLE()

void MyFrame::OnMyEvent(wxCommandEvent& event)
{
    // do something
    wxString text = event.GetString();
}

// example of code handling the event with Bind<>():
MyFrame::MyFrame()
{
    Bind(MY_EVENT, &MyFrame::OnMyEvent, this, ID_MY_WINDOW);
}

// example of code generating the event
void MyWindow::SendEvent()
{
    wxCommandEvent event(MY_EVENT, GetId());
    event.SetEventObject(this);

    // Give it some contents
    event.SetString("Hello");

    // Do send it
    ProcessWindowEvent(event);
}
```

Defining Your Own Event Class

Under certain circumstances, you must define your own event class e.g., for sending more complex data from one place to another. Apart from defining your event class, you also need to define your own event table macro if you want to use event tables for handling events of this type.

Here is an example:

```
// define a new event class
class MyPlotEvent: public wxEvent
{
public:
    MyPlotEvent(wxEventType eventType, int winid, const wxPoint& pos)
        : wxEvent(winid, eventType),
          m_pos(pos)
    {
    }

    // accessors
    wxPoint GetPoint() const { return m_pos; }

    // implement the base class pure virtual
    virtual wxEvent *Clone() const { return new MyPlotEvent(*this); }

private:
    const wxPoint m_pos;
};

// we define a single MY_PLOT_CLICKED event type associated with the class
// above but typically you are going to have more than one event type, e.g. you
// could also have MY_PLOT_ZOOMED or MY_PLOT_PANNED &c -- in which case you
// would just add more similar lines here
wxDEFINE_EVENT(MY_PLOT_CLICKED, MyPlotEvent);

// if you want to support old compilers you need to use some ugly macros:
typedef void (wxEvtHandler::*MyPlotEventFunction)(MyPlotEvent&);
#define MyPlotEventHandler(func) wxEVENT_HANDLER_CAST(MyPlotEventFunction, func)

// if your code is only built using reasonably modern compilers, you could just
// do this instead:
#define MyPlotEventHandler(func) (&func)

// finally define a macro for creating the event table entries for the new
// event type
//
// remember that you don't need this at all if you only use Bind<>() and that
// you can replace MyPlotEventHandler(func) with just &func unless you use a
// really old compiler
#define MY_EVT_PLOT_CLICK(id, func) \
    wx__DECLARE_EVT1(MY_PLOT_CLICKED, id, MyPlotEventHandler(func))
```

```
// example of code handling the event (you will use one of these methods, not
// both, of course):
wxBEGIN_EVENT_TABLE(MyFrame, wxFrame)
    EVT_PLOT(ID_MY_WINDOW, MyFrame::OnPlot)
wxEND_EVENT_TABLE()

MyFrame::MyFrame()
{
    Bind(MY_PLOT_CLICKED, &MyFrame::OnPlot, this, ID_MY_WINDOW);
}

void MyFrame::OnPlot(MyPlotEvent& event)
{
    ... do something with event.GetPoint() ...
}

// example of code generating the event:
void MyWindow::SendEvent()
{
    MyPlotEvent event(MY_PLOT_CLICKED, GetId(), wxPoint(...));
    event.SetEventObject(this);
    ProcessWindowEvent(event);
}
```

10.15.4 Miscellaneous Notes

Event Handlers vs Virtual Methods

It may be noted that wxWidgets' event processing system implements something close to virtual methods in normal C++ in spirit: both of these mechanisms allow you to alter the behaviour of the base class by defining the event handling functions in the derived classes.

There is however an important difference between the two mechanisms when you want to invoke the default behaviour, as implemented by the base class, from a derived class handler. With the virtual functions, you need to call the base class function directly and you can do it either in the beginning of the derived class handler function (to post-process the event) or at its end (to pre-process the event). With the event handlers, you only have the option of pre-processing the events and in order to still let the default behaviour happen you must call wxEvent::Skip() and *not* call the base class event handler directly. In fact, the event handler probably doesn't even exist in the base class as the default behaviour is often implemented in platform-specific code by the underlying toolkit or OS itself. But even if it does exist at wxWidgets level, it should never be called directly as the event handlers are not part of wxWidgets API and should never be called directly.

User Generated Events vs Programmatically Generated Events

While generically wxEvents can be generated both by user actions (e.g., resize of a wxWindow) and by calls to functions (e.g., wxWindow::SetSize), wxWidgets controls normally send wxCommandEvent-derived events only for the user-generated events. The only **exceptions** to this rule are:

- wxNotebook::AddPage: No event-free alternatives
- wxNotebook::AdvanceSelection: No event-free alternatives
- wxNotebook::DeletePage: No event-free alternatives
- wxNotebook::SetSelection: Use wxNotebook::ChangeSelection instead, as wxNotebook::SetSelection is deprecated
- wxTreeCtrl::Delete: No event-free alternatives
- wxTreeCtrl::DeleteAllItems: No event-free alternatives
- wxTreeCtrl::EditLabel: No event-free alternatives
- All wxTextCtrl methods

wxTextCtrl::ChangeValue can be used instead of wxTextCtrl::SetValue but the other functions, such as wxTextCtrl::Replace or wxTextCtrl::WriteText don't have event-free equivalents.

Pluggable Event Handlers

TODO: Probably deprecated, Bind() provides a better way to do this

In fact, you don't have to derive a new class from a window class if you don't want to. You can derive a new class from wxEvtHandler instead, defining the appropriate event table, and then call wxWindow::SetEventHandler (or, preferably, wxWindow::PushEventHandler) to make this event handler the object that responds to events. This way, you can avoid a lot of class derivation, and use instances of the same event handler class (but different objects as the same event handler object shouldn't be used more than once) to handle events from instances of different widget classes.

If you ever have to call a window's event handler manually, use the GetEventHandler function to retrieve the window's event handler and use that to call the member function. By default, GetEventHandler returns a pointer to the window itself unless an application has redirected event handling using SetEventHandler or PushEventHandler.

One use of PushEventHandler is to temporarily or permanently change the behaviour of the GUI. For example, you might want to invoke a dialog editor in your application that changes aspects of dialog boxes. You can grab all the input for an existing dialog box, and edit it 'in situ', before restoring its behaviour to normal. So even if the application has derived new classes to customize behaviour, your utility can indulge in a spot of body-snatching. It could be a useful technique for on-line tutorials, too, where you take a user through a serious of steps and don't want them to diverge from the lesson. Here, you can examine the events coming from buttons and windows, and if acceptable, pass them through to the original event handler. Use PushEventHandler/PopEventHandler to form a chain of event handlers, where each handler processes a different range of events independently from the other handlers.

Window Identifiers

Window identifiers are integers, and are used to uniquely determine window identity in the event system (though you can use it for other purposes). In fact, identifiers do not need to be unique across your entire application as long they are unique within the particular context you're interested in, such as a frame and its children. You may use the `wxID_OK` identifier, for example, on any number of dialogs as long as you don't have several within the same dialog.

If you pass `wxID_ANY` to a window constructor, an identifier will be generated for you automatically by wxWidgets. This is useful when you don't care about the exact identifier either because you're not going to process the events from the control being created or because you process the events from all controls in one place (in which case you should specify `wxID_ANY` in the event table or wxEvtHandler::Bind call as well). The automatically generated identifiers are always negative and so will never conflict with the user-specified identifiers which must be always positive.

See Standard Event Identifiers for the list of standard identifiers available. You can use wxID_HIGHEST to determine the number above which it is safe to define your own identifiers. Or, you can use identifiers below wxID_LOWEST. Finally, you can allocate identifiers dynamically using wxNewId() function too. If you use wxNewId() consistently in your application, you can be sure that your identifiers don't conflict accidentally.

Generic Event Table Macros

EVT_CUSTOM(event, id, func)	Allows you to add a custom event table entry by specifying the event identifier (such as wxEVT_SIZE), the window identifier, and a member function to call.
EVT_CUSTOM_RANGE(event, id1, id2, func)	The same as EVT_CUSTOM, but responds to a range of window identifiers.
EVT_COMMAND(id, event, func)	The same as EVT_CUSTOM, but expects a member function with a wxCommandEvent argument.
EVT_COMMAND_RANGE(id1, id2, event, func)	The same as EVT_CUSTOM_RANGE, but expects a member function with a wxCommandEvent argument.

EVT_NOTIFY(event, id, func)	The same as EVT_CUSTOM, but expects a member function with a wxNotifyEvent argument.
EVT_NOTIFY_RANGE(event, id1, id2, func)	The same as EVT_CUSTOM_RANGE, but expects a member function with a wxNotifyEvent argument.

List of wxWidgets Events

For the full list of event classes, please see the event classes group page.

10.16 Window Sizing Overview

It can sometimes be confusing to keep track of the various size-related attributes of a wxWindow, how they relate to each other, and how they interact with sizers.

This document will attempt to clear the fog a little, and give some simple explanations of things.

10.16.1 Glossary

- **"Size"**: this is the current size of the window and it can be explicitly set or fetched with the wxWindow::SetSize() or wxWindow::GetSize() methods. This size value is the size that the widget is currently using on screen and is the way to change the size of something that is not being managed by a sizer.

- **"Client Size"**: the client size represents the widget's area inside of any borders belonging to the widget and is the area that can be drawn upon in a `EVT_PAINT` event. For wxFrame, the client size also excludes the frame menu, tool and status bars, if any. If a window doesn't have any border (and is not a wxFrame with some bars) then its client size is the same as its size.

- **"Best Size"**: the best size of a widget depends on what kind of widget it is, and usually also on the contents of the widget. For example a wxListBox's best size will be calculated based on how many items it has, up to a certain limit, or a wxButton's best size will be calculated based on its label size, but normally won't be smaller than the platform default button size (unless a style flag overrides that). There is a special virtual method in the C++ window classes called wxWindow::DoGetBestSize() that a class can override if it wants to calculate its own best size based on its content, however notice that usually it is more convenient to override DoGetBestClientSize(), see below.

- **"Best Client Size"**: this is simply the client size corresponding to the best window size. When the fitting size for the given contents is computed, it will usually be the client size and the size of the borders needs to be added to obtain the full best size. For this reason, it's preferable to override DoGetBestClientSize() and let DoGetBestSize() compute the full best size.

- **"Minimal Size"**: the minimal size of a widget is a size that is normally explicitly set by the programmer either with the wxWindow::SetMinSize() method or with the wxWindow::SetSizeHints() method. Most controls will also set the minimal size to the size given in the control's constructor if a non-default value is passed. Top-level windows such as wxFrame will not allow the user to resize the frame below the minimal size.

- **"Maximum Size"**: just like for the minimal size, the maximum size is normally explicitly set by the programmer with the wxWindow::SetMaxSize() method or with wxWindow::SetSizeHints(). Top-level windows such as wxFrame will not allow the user to resize the frame above the maximum size.

- **"Initial Size"**: the initial size of a widget is the size given to the constructor of the widget, if any. As mentioned above most controls will also set this size value as the control's minimal size. If the size passed to the constructor is the default wxDefaultSize, or if the size is not fully specified (such as wxSize(150,-1)) then most controls will fill in the missing size components using the best size and will set the initial size of the control to the resulting size.

- **"Virtual Size"**: the virtual size is the size of the potentially viewable area of the widget. The virtual size of a widget may be larger than its actual size and in this case scrollbars will appear to the let the user 'explore' the full contents of the widget. See wxScrolled for more info.

10.16.2 Functions related to sizing

- wxWindow::GetEffectiveMinSize(): returns a blending of the widget's minimal size and best size, giving precedence to the minimal size. For example, if a widget's min size is set to (150, -1) and the best size is (80, 22) then the best fitting size is (150, 22). If the min size is (50, 20) then the best fitting size is (50, 20). This method is what is called by the sizers when determining what the requirements of each item in the sizer is, and is used for calculating the overall minimum needs of the sizer.

- wxWindow::SetInitialSize(): this is a little different than the typical size setters. Rather than just setting an "initial size" attribute it actually sets the minimal size to the value passed in, blends that value with the best size, and then sets the size of the widget to be the result. So you can consider this method to be a "Smart SetSize". This method is what is called by the constructor of most controls to set the minimal size and the initial size of the control.

- wxWindow::Fit(): this method sets the size of a window to fit around its children. If it has no children then nothing is done, if it does have children then the size of the window is set to the window's best size.

- wxSizer::Fit(): this sets the size of the window to be large enough to accommodate the minimum size needed by the sizer, (along with a few other constraints...). If the sizer is the one that is assigned to the window then this should be equivalent to wxWindow::Fit().

- wxSizer::Layout(): recalculates the minimum space needed by each item in the sizer, and then lays out the items within the space currently allotted to the sizer.

- wxWindow::Layout(): if the window has a sizer then it sets the space given to the sizer to the current size of the window, which results in a call to wxSizer::Layout(). If the window has layout constraints instead of a sizer then the constraints algorithm is run. The `Layout()` method is what is called by the default `EVT_SIZE` handler for container windows.

10.17 Window IDs

Various controls and other parts of wxWidgets need an ID.

Sometimes the ID may be directly provided by the user or have a predefined value, such as `wxID_OPEN`. Often, however, the value of the ID is unimportant and is created automatically by calling wxWindow::NewControlId or by passing `wxID_ANY` as the ID of an object.

There are two ways to generate an ID. One way is to start at a negative number, and for each new ID, return the next smallest number. This is fine for systems that can use the full range of negative numbers for IDs, as this provides more than enough IDs and it would take a very very long time to run out and wrap around. However, some systems cannot use the full range of the ID value. Windows, for example, can only use 16 bit IDs, and only has about 32000 possible automatic IDs that can be generated by wxWindow::NewControlId. If the program runs long enough, depending on the program itself, using this first method would cause the IDs to wrap around into the positive ID range and cause possible clashes with any directly specified ID values.

The other way is to keep track of the IDs returned by wxWindow::NewControlId and don't return them again until the ID is completely free and not being used by any other objects. This will make sure that the ID values do not clash with one another. This is accomplished by keeping a reference count for each of the IDs that can possibly be returned by wxWindow::NewControlId. Other IDs are not reference counted.

wxIdManager, wxWindow::NewControlId(), wxWindow::UnreserveControlId()

10.17.1 Data Types

A wxWindowID is just the integer type for a window ID. It should be used almost everywhere. To help keep track of the count for the automatically generated IDs, a new type, wxWindowIDRef exists, that can take the place of wxWindowID where needed. When an ID is first created, it is marked as reserved. When assigning it to a wxWindowIDRef, the usage count of the ID is increased, or set to 1 if it is currently reserved. Assigning the same ID to several wxWindowIDRefs will keep track of the count. As the wxWindowIDRef gets destroyed or its value changes, it will decrease the count of the used ID. When there are no more wxWindowIDRef types with the created ID, the ID is considered free and can then be used again by wxWindow::NewControlId.

If a created ID is not assigned to a wxWindowIDRef, then it remains reserved until it is unreserved manually with wxWindow::UnreserveControlId. However, if it is assigned to a wxWindowIDRef, then it will be unreserved automatically and will be considered free when the count is 0, and should NOT be manually unreserved.

wxWindowIDRef can store both automatic IDs from wxWindow::NewControlId and normal IDs. Reference counting is only done for the automatic IDs. Also, wxWindowIDRef has conversion operators that allow it to be treated just like a wxWindowID.

10.17.2 Using wxWindowIDRef

A wxWindowIDRef should be used in place of a wxWindowID where you want to make sure the ID is not created again by wxWindow::NewControlId at least until the wxWindowIDRef is destroyed, usually when the associated object is destroyed. This is done already for windows, menu items, and tool bar items. It should only be used in the main thread, as it is not thread safe.

10.18 Logging Overview

This is a general overview of logging classes provided by wxWidgets.

The word logging here has a broad sense, including all of the program output, not only non-interactive messages. The logging facilities included in wxWidgets provide the base wxLog class which defines the standard interface for a *log* target as well as several standard implementations of it and a family of functions to use with them.

First of all, no knowledge of wxLog classes is needed to use them. For this, you should only know about wxLogXXX() functions. All of them have the same syntax as *printf()* or *vprintf()* , i.e. they take the format string as the first argument and respectively a variable number of arguments or a variable argument list pointer. Here are all of them:

- wxLogFatalError() which is like wxLogError(), but also terminates the program with the exit code 3 (using *abort()* standard function). Unlike for all the other logging functions, this function can't be overridden by a log target.
- wxLogError() is the function to use for error messages, i.e. the messages that must be shown to the user. The default processing is to pop up a message box to inform the user about it.
- wxLogWarning() for warnings. They are also normally shown to the user, but don't interrupt the program work.
- wxLogMessage() is for all normal, informational messages. They also appear in a message box by default (but it can be changed, see below).
- wxLogVerbose() is for verbose output. Normally, it is suppressed, but might be activated if the user wishes to know more details about the program progress (another, but possibly confusing name for the same function is wxLogInfo).
- wxLogStatus() is for status messages. They will go into the status bar of the active or specified (as the first argument) wxFrame if it has one.
- wxLogSysError() is mostly used by wxWidgets itself, but might be handy for logging errors after system call (API function) failure. It logs the specified message text as well as the last system error code (*errno* or Windows' *GetLastError()* depending on the platform) and the corresponding error message. The second form of this function takes the error code explicitly as the first argument.

- wxLogDebug() is **the** right function for debug output. It only does anything at all in the debug mode (when the preprocessor symbol **WXDEBUG** is defined) and expands to nothing in release mode (otherwise). Note that under Windows, you must either run the program under debugger or use a 3rd party program such as DebugView (http://technet.microsoft.com/en-us/sysinternals/bb896647.aspx) to actually see the debug output.
- wxLogTrace() as wxLogDebug() only does something in debug build. The reason for making it a separate function from it is that usually there are a lot of trace messages, so it might make sense to separate them from other debug messages which would be flooded in them. Moreover, the second version of this function takes a trace mask as the first argument which allows to further restrict the amount of messages generated.

See also

Logging Functions and Macros

The usage of these functions should be fairly straightforward, however it may be asked why not use the other logging facilities, such as C standard stdio functions or C++ streams. The short answer is that they're all very good generic mechanisms, but are not really adapted for wxWidgets, while the log classes are. Some of advantages in using wxWidgets log functions are:

- **Portability:** It is a common practice to use *printf()* statements or cout/cerr C++ streams for writing out some (debug or otherwise) information. Although it works just fine under Unix, these messages go strictly nowhere under Windows where the stdout of GUI programs is not assigned to anything. Thus, you might view wxLogMessage() as a simple substitute for *printf()*. You can also redirect the *wxLogXXX* calls to *cout* by just writing:

```
wxLog* logger = new wxLogStream(&cout);
wxLog::SetActiveTarget(logger);
```

  Finally, there is also a possibility to redirect the output sent to *cout* to a wxTextCtrl by using the wxStreamToTextRedirector class.
- **Flexibility:** The output of wxLog functions can be redirected or suppressed entirely based on their importance, which is either impossible or difficult to do with traditional methods. For example, only error messages, or only error messages and warnings might be logged, filtering out all informational messages.
- **Completeness:** Usually, an error message should be presented to the user when some operation fails. Let's take a quite simple but common case of a file error: suppose that you're writing your data file on disk and there is not enough space. The actual error might have been detected inside wxWidgets code (say, in wxFile::Write), so the calling function doesn't really know the exact reason of the failure, it only knows that the data file couldn't be written to the disk. However, as wxWidgets uses wxLogError() in this situation, the exact error code (and the corresponding error message) will be given to the user together with "high level" message about data file writing error.

10.18.1 Log Messages Selection

By default, most log messages are enabled. In particular, this means that errors logged by wxWidgets code itself (e.g. when it fails to perform some operation, for instance wxFile::Open() logs an error when it fails to open a file) will be processed and shown to the user. To disable the logging entirely you can use wxLog::EnableLogging() method or, more usually, wxLogNull class which temporarily disables logging and restores it back to the original setting when it is destroyed.

To limit logging to important messages only, you may use wxLog::SetLogLevel() with e.g. wxLOG_Warning value – this will completely disable all logging messages with the severity less than warnings, so wxLogMessage() output won't be shown to the user any more.

Moreover, the log level can be set separately for different log components. Before showing how this can be useful, let us explain what log components are: they are simply arbitrary strings identifying the component, or module, which generated the message. They are hierarchical in the sense that "foo/bar/baz" component is supposed to be a child of "foo". And all components are children of the unnamed root component.

By default, all messages logged by wxWidgets originate from "wx" component or one of its subcomponents such as "wx/net/ftp", while the messages logged by your own code are assigned empty log component. To change this, you need to define `wxLOG_COMPONENT` to a string uniquely identifying each component, e.g. you could give it the value "MyProgram" by default and re-define it as "MyProgram/DB" in the module working with the database and "MyProgram/DB/Trans" in its part managing the transactions. Then you could use wxLog::SetComponentLevel() in the following ways:

```
// disable all database error messages, everybody knows databases never
// fail anyhow
wxLog::SetComponentLevel("MyProgram/DB",
      wxLOG_FatalError);

// but enable tracing for the transactions as somehow our changes don't
// get committed sometimes
wxLog::SetComponentLevel("MyProgram/DB/Trans",
      wxLOG_Trace);

// also enable tracing messages from wxWidgets dynamic module loading
// mechanism
wxLog::SetComponentLevel("wx/base/module", wxLOG_Trace);
```

Notice that the log level set explicitly for the transactions code overrides the log level of the parent component but that all other database code subcomponents inherit its setting by default and so won't generate any log messages at all.

10.18.2 Log Targets

After having enumerated all the functions which are normally used to log the messages, and why would you want to use them, we now describe how all this works.

wxWidgets has the notion of a *log target*: it is just a class deriving from wxLog. As such, it implements the virtual functions of the base class which are called when a message is logged. Only one log target is *active* at any moment, this is the one used by wxLogXXX() functions. The normal usage of a log object (i.e. object of a class derived from wxLog) is to install it as the active target with a call to *SetActiveTarget()* and it will be used automatically by all subsequent calls to wxLogXXX() functions.

To create a new log target class you only need to derive it from wxLog and override one or several of wxLog::DoLogRecord(), wxLog::DoLogTextAtLevel() and wxLog::DoLogText() in it. The first one is the most flexible and allows you to change the formatting of the messages, dynamically filter and redirect them and so on – all log messages, except for those generated by wxLogFatalError(), pass by this function. wxLog::DoLogTextAtLevel() should be overridden if you simply want to redirect the log messages somewhere else, without changing their formatting. Finally, it is enough to override wxLog::DoLogText() if you only want to redirect the log messages and the destination doesn't depend on the message log level.

There are some predefined classes deriving from wxLog and which might be helpful to see how you can create a new log target class and, of course, may also be used without any change. There are:

- wxLogStderr: This class logs messages to a `FILE *`, using stderr by default as its name suggests.
- wxLogStream: This class has the same functionality as wxLogStderr, but uses *ostream* and cerr instead of `FILE *` and stderr.
- wxLogGui: This is the standard log target for wxWidgets applications (it is used by default if you don't do anything) and provides the most reasonable handling of all types of messages for given platform.
- wxLogWindow: This log target provides a "log console" which collects all messages generated by the application and also passes them to the previous active log target. The log window frame has a menu allowing user to clear the log, close it completely or save all messages to file.
- wxLogBuffer: This target collects all the logged messages in an internal buffer allowing to show them later to the user all at once.
- wxLogNull: The last log class is quite particular: it doesn't do anything. The objects of this class may be instantiated to (temporarily) suppress output of *wxLogXXX()* functions. As an example, trying to open a non-existing file will usually provoke an error message, but if for some reasons it is unwanted, just use this construction:

```
wxFile file;

// wxFile.Open() normally complains if file can't be opened, we don't want it
{
    wxLogNull logNo;
    if ( !file.Open("bar") )
    {
        // ... process error ourselves ...
    }
} // ~wxLogNull called, old log sink restored

wxLogMessage("..."); // ok
```

See also

Logging Classes

The log targets can also be combined: for example you may wish to redirect the messages somewhere else (for example, to a log file) but also process them as normally. For this the wxLogChain, wxLogInterposer, and wxLogInterposerTemp can be used.

10.18.3 Logging in Multi-Threaded Applications

Starting with wxWidgets 2.9.1, logging functions can be safely called from any thread. Messages logged from threads other than the main one will be buffered until wxLog::Flush() is called in the main thread (which usually happens during idle time, i.e. after processing all pending events) and will be really output only then. Notice that the default GUI logger already only output the messages when it is flushed, so by default messages from the other threads will be shown more or less at the same moment as usual. However if you define a custom log target, messages may be logged out of order, e.g. messages from the main thread with later timestamp may appear before messages with earlier timestamp logged from other threads. wxLog does however guarantee that messages logged by each thread will appear in order in which they were logged.

Also notice that wxLog::EnableLogging() and wxLogNull class which uses it only affect the current thread, i.e. logging messages may still be generated by the other threads after a call to `EnableLogging(false)`.

10.18.4 Logging Customization

To completely change the logging behaviour you may define a custom log target. For example, you could define a class inheriting from wxLog which shows all the log messages in some part of your main application window reserved for the message output without interrupting the user work flow with modal message boxes.

To use your custom log target you may either call wxLog::SetActiveTarget() with your custom log object or create a wxAppTraits-derived class and override wxAppTraits::CreateLogTarget() virtual method in it and also override wxApp::CreateTraits() to return an instance of your custom traits object. Notice that in the latter case you should be prepared for logging messages early during the program startup and also during program shutdown so you shouldn't rely on existence of the main application window, for example. You can however safely assume that GUI is (already/still) available when your log target as used as wxWidgets automatically switches to using wxLogStderr if it isn't.

There are several methods which may be overridden in the derived class to customize log messages handling: wxLog::DoLogRecord(), wxLog::DoLogTextAtLevel() and wxLog::DoLogText().

The last method is the simplest one: you should override it if you simply want to redirect the log output elsewhere, without taking into account the level of the message. If you do want to handle messages of different levels differently, then you should override wxLog::DoLogTextAtLevel().

Additionally, you can customize the way full log messages are constructed from the components (such as time stamp, source file information, logging thread ID and so on). This task is performed by wxLogFormatter class so you need to derive a custom class from it and override its Format() method to build the log messages in desired way. Notice that if you just need to modify (or suppress) the time stamp display, overriding FormatTime() is enough.

Finally, if even more control over the output format is needed, then DoLogRecord() can be overridden as it allows to construct custom messages depending on the log level or even do completely different things depending on the

message severity (for example, throw away all messages except warnings and errors, show warnings on the screen and forward the error messages to the user's (or programmer's) cell phone – maybe depending on whether the timestamp tells us if it is day or night in the current time zone).

The *dialog* sample illustrates this approach by defining a custom log target customizing the dialog used by wxLogGui for the single messages.

10.18.5 Using Trace Masks

Notice that the use of log trace masks is hardly necessary any longer in current wxWidgets version as the same effect can be achieved by using different log components for different log statements of any level. Please see Log Messages Selection for more information about the log components.

The functions below allow some limited customization of wxLog behaviour without writing a new log target class (which, aside from being a matter of several minutes, allows you to do anything you want). The verbose messages are the trace messages which are not disabled in the release mode and are generated by wxLogVerbose(). They are not normally shown to the user because they present little interest, but may be activated, for example, in order to help the user find some program problem.

As for the (real) trace messages, their handling depends on the currently enabled trace masks: if wxLog::AddTraceMask() was called for the mask of the given message, it will be logged, otherwise nothing happens.

For example,

```
wxLogTrace( wxTRACE_OleCalls, "IFoo::Bar() called" );
```

will log the message if it was preceded by:

```
wxLog::AddTraceMask( wxTRACE_OleCalls );
```

The standard trace masks are given in wxLogTrace() documentation.

10.19 wxString Overview

wxString is a class which represents a Unicode string of arbitrary length and containing arbitrary Unicode characters.

This class has all the standard operations you can expect to find in a string class: dynamic memory management (string extends to accommodate new characters), construction from other strings, compatibility with C strings and wide character C strings, assignment operators, access to individual characters, string concatenation and comparison, substring extraction, case conversion, trimming and padding (with spaces), searching and replacing and both C-like `printf` (wxString::Printf) and stream-like insertion functions as well as much more - see wxString for a list of all functions.

The wxString class has been completely rewritten for wxWidgets 3.0 but much work has been done to make existing code using ANSI string literals work as it did in previous versions.

10.19.1 Internal wxString Encoding

Since wxWidgets 3.0 wxString may use any of `UTF-16` (under Windows, using the native 16 bit `wchar_t`), `UTF-32` (under Unix, using the native 32 bit `wchar_t`) or `UTF-8` (under both Windows and Unix) to store its content. By default, `wchar_t` is used under all platforms, but wxWidgets can be compiled with `wxUSE_UNICODE_UTF8=1` to use UTF-8.

For simplicity of implementation, wxString uses *per code unit indexing* instead of *per code point indexing* when using UTF-16, i.e. in the default `wxUSE_UNICODE_WCHAR==1` build under Windows and doesn't know anything about surrogate pairs. In other words it always considers code points to be composed by 1 code unit, while this is really true only for characters in the *BMP* (Basic Multilingual Plane), as explained in more details in the Unicode Representations and Terminology section. Thus when iterating over a UTF-16 string stored in a wxString under

Windows, the user code has to take care of *surrogate pairs* himself. (Note however that Windows itself has built-in support for surrogate pairs in UTF-16, such as for drawing strings on screen.)

Remarks

Note that while the behaviour of wxString when `wxUSE_UNICODE_WCHAR==1` resembles UCS-2 encoding, it's not completely correct to refer to wxString as UCS-2 encoded since you can encode code points outside the *BMP* in a wxString as two code units (i.e. as a surrogate pair; as already mentioned however wxString will "see" them as two different code points)

In `wxUSE_UNICODE_UTF8==1` case, wxString handles UTF-8 multi-bytes sequences just fine also for characters outside the BMP (it implements *per code point indexing*), so that you can use UTF-8 in a completely transparent way:

Example:

```
// first test, using exotic characters outside of the Unicode BMP:

wxString test = wxString::FromUTF8("\xF0\x90\x8C\x80");
    // U+10300 is "OLD ITALIC LETTER A" and is part of Unicode Plane 1
    // in UTF8 it's encoded as 0xF0 0x90 0x8C 0x80

// it's a single Unicode code-point encoded as:
// - a UTF16 surrogate pair under Windows
// - a UTF8 multiple-bytes sequence under Linux
// (without considering the final NULL)

wxPrintf("wxString reports a length of %d character(s)", test.length());
    // prints "wxString reports a length of 1 character(s)" on Linux
    // prints "wxString reports a length of 2 character(s)" on Windows
    // since wxString on Windows doesn't have surrogate pairs support!

// second test, this time using characters part of the Unicode BMP:

wxString test2 = wxString::FromUTF8("\x41\xC3\xA0\xE2\x82\xAC");
    // this is the UTF8 encoding of capital letter A followed by
    // 'small case letter a with grave' followed by the 'euro sign'

// they are 3 Unicode code-points encoded as:
// - 3 UTF16 code units under Windows
// - 6 UTF8 code units under Linux
// (without considering the final NULL)

wxPrintf("wxString reports a length of %d character(s)", test2.length());
    // prints "wxString reports a length of 3 character(s)" on Linux
    // prints "wxString reports a length of 3 character(s)" on Windows
```

To better explain what stated above, consider the second string of the example above; it's composed by 3 characters and the final `NULL`:

As you can see, UTF16 encoding is straightforward (for characters in the *BMP*) and in this example the UTF16-encoded wxString takes 8 bytes. UTF8 encoding is more elaborated and in this example takes 7 bytes.

In general, for strings containing many latin characters UTF8 provides a big advantage with regards to the memory footprint respect UTF16, but requires some more processing for common operations like e.g. length calculation.

Finally, note that the type used by wxString to store Unicode code units (`wchar_t` or `char`) is always `typedef-ined` to be wxStringCharType.

10.19.2 Using wxString to store binary data

wxString can be used to store binary data (even if it contains `NULs`) using the functions wxString::To8BitData and wxString::From8BitData.

Beware that even if `NUL` character is allowed, in the current string implementation some methods might not work correctly with them.

Note however that other classes like wxMemoryBuffer are more suited to this task. For handling binary data you may also want to look at the wxStreamBuffer, wxMemoryOutputStream, wxMemoryInputStream classes.

10.19.3 Comparison to Other String Classes

The advantages of using a special string class instead of working directly with C strings are so obvious that there is a huge number of such classes available. The most important advantage is the need to always remember to allocate/free memory for C strings; working with fixed size buffers almost inevitably leads to buffer overflows. At last, C++ has a standard string class (`std::string`). So why the need for wxString? There are several advantages:

- **Efficiency:** Since wxWidgets 3.0 wxString uses `std::string` (in UTF8 mode under Linux, Unix and OS X) or `std::wstring` (in UTF16 mode under Windows) internally by default to store its contents. wxString will therefore inherit the performance characteristics from `std::string`.
- **Compatibility:** This class tries to combine almost full compatibility with the old wxWidgets 1.xx wxString class, some reminiscence of MFC's CString class and 90% of the functionality of `std::string` class.
- **Rich set of functions:** Some of the functions present in wxString are very useful but don't exist in most of other string classes: for example, wxString::AfterFirst, wxString::BeforeLast, wxString::Printf. Of course, all the standard string operations are supported as well.
- **wxString is Unicode friendly:** it allows to easily convert to and from ANSI and Unicode strings (see Unicode Support in wxWidgets for more details) and maps to `std::wstring` transparently.
- **Used by wxWidgets:** And, of course, this class is used everywhere inside wxWidgets so there is no performance loss which would result from conversions of objects of any other string class (including `std::string`) to wxString internally by wxWidgets.

However, there are several problems as well. The most important one is probably that there are often several functions to do exactly the same thing: for example, to get the length of the string either one of wxString::length(), wxString::Len() or wxString::Length() may be used. The first function, as almost all the other functions in lowercase, is `std::string` compatible. The second one is the "native" wxString version and the last one is the wxWidgets 1.xx way.

So which is better to use? The usage of the `std::string` compatible functions is strongly advised! It will both make your code more familiar to other C++ programmers (who are supposed to have knowledge of `std::string` but not of wxString), let you reuse the same code in both wxWidgets and other programs (by just typedefing wxString as `std::string` when used outside wxWidgets) and by staying compatible with future versions of wxWidgets which will probably start using `std::string` sooner or later too.

In the situations where there is no corresponding `std::string` function, please try to use the new wxString methods and not the old wxWidgets 1.xx variants which are deprecated and may disappear in future versions.

10.19.4 Advice About Using wxString

Implicit conversions

Probably the main trap with using this class is the implicit conversion operator to `const char*`. It is advised that you use wxString::c_str() instead to clearly indicate when the conversion is done. Specifically, the danger of this implicit conversion may be seen in the following code fragment:

```
// this function converts the input string to uppercase,
// output it to the screen and returns the result
const char *SayHELLO(const wxString& input)
{
    wxString output = input.Upper();
    printf("Hello, %s!\n", output);
    return output;
}
```

There are two nasty bugs in these three lines. The first is in the call to the `printf()` function. Although the implicit conversion to C strings is applied automatically by the compiler in the case of

```
puts(output);
```

because the argument of `puts()` is known to be of the type `const char*`, this is **not** done for `printf()` which is a function with variable number of arguments (and whose arguments are of unknown types). So this call may do any number of things (including displaying the correct string on screen), although the most likely result is a program crash. The solution is to use wxString::c_str(). Just replace this line with this:

```
printf("Hello, %s!\n", output.c_str());
```

The second bug is that returning `output` doesn't work. The implicit cast is used again, so the code compiles, but as it returns a pointer to a buffer belonging to a local variable which is deleted as soon as the function exits, its contents are completely arbitrary. The solution to this problem is also easy, just make the function return wxString instead of a C string.

This leads us to the following general advice: all functions taking string arguments should take `const wx↩String&` (this makes assignment to the strings inside the function faster) and all functions returning strings should return wxString - this makes it safe to return local variables.

Finally note that wxString uses the current locale encoding to convert any C string literal to Unicode. The same is done for converting to and from `std::string` and for the return value of c_str(). For this conversion, the *wxConvLibc* class instance is used. See wxCSConv and wxMBConv.

Iterating wxString Characters

As previously described, when `wxUSE_UNICODE_UTF8==1`, wxString internally uses the variable-length UTF8 encoding. Accessing a UTF-8 string by index can be very **inefficient** because a single character is represented by a variable number of bytes so that the entire string has to be parsed in order to find the character. Since iterating over a string by index is a common programming technique and was also possible and encouraged by wxString using the access operator[]() wxString implements caching of the last used index so that iterating over a string is a linear operation even in UTF-8 mode.

It is nonetheless recommended to use **iterators** (instead of index based access) like this:

```
wxString s = "hello";
wxString::const_iterator i;
for (i = s.begin(); i != s.end(); ++i)
{
    wxUniChar uni_ch = *i;
    // do something with it
}
```

10.19.5 String Related Functions and Classes

As most programs use character strings, the standard C library provides quite a few functions to work with them. Unfortunately, some of them have rather counter-intuitive behaviour (like `strncpy()` which doesn't always terminate the resulting string with a NULL) and are in general not very safe (passing NULL to them will probably lead to program crash). Moreover, some very useful functions are not standard at all. This is why in addition to all wxString functions, there are also a few global string functions which try to correct these problems: wxIsEmpty() verifies whether the string is empty (returning true for NULL pointers), wxStrlen() also handles NULL correctly and returns 0 for them and wxStricmp() is just a platform-independent version of case-insensitive string comparison function known either as `stricmp()` or `strcasecmp()` on different platforms.

The `<wx/string.h>` header also defines wxSnprintf() and wxVsnprintf() functions which should be used instead of the inherently dangerous standard `sprintf()` and which use `snprintf()` instead which does buffer size checks whenever possible. Of course, you may also use wxString::Printf which is also safe.

There is another class which might be useful when working with wxString: wxStringTokenizer. It is helpful when a string must be broken into tokens and replaces the standard C library `strtok()` function.

And the very last string-related class is wxArrayString: it is just a version of the "template" dynamic array class which is specialized to work with strings. Please note that this class is specially optimized (using its knowledge of the internal structure of wxString) for storing strings and so it is vastly better from a performance point of view than a wxObjectArray of wxStrings.

10.19.6 Tuning wxString for Your Application

Note

This section is strictly about performance issues and is absolutely not necessary to read for using wxString class. Please skip it unless you feel familiar with profilers and relative tools.

For the performance reasons wxString doesn't allocate exactly the amount of memory needed for each string. Instead, it adds a small amount of space to each allocated block which allows it to not reallocate memory (a relatively expensive operation) too often as when, for example, a string is constructed by subsequently adding one character at a time to it, as for example in:

```
// delete all vowels from the string
wxString DeleteAllVowels(const wxString& original)
{
    wxString vowels( "aeuioAEIOU" );
    wxString result;
    wxString::const_iterator i;
    for ( i = original.begin(); i != original.end(); ++i )
    {
        if (vowels.Find( *i ) == wxNOT_FOUND)
            result += *i;
    }

    return result;
}
```

This is quite a common situation and not allocating extra memory at all would lead to very bad performance in this case because there would be as many memory (re)allocations as there are consonants in the original string. Allocating too much extra memory would help to improve the speed in this situation, but due to a great number of wxString objects typically used in a program would also increase the memory consumption too much.

The very best solution in precisely this case would be to use wxString::Alloc() function to preallocate, for example, len bytes from the beginning - this will lead to exactly one memory allocation being performed (because the result is at most as long as the original string).

However, using wxString::Alloc() is tedious and so wxString tries to do its best. The default algorithm assumes that memory allocation is done in granularity of at least 16 bytes (which is the case on almost all of wide-spread platforms) and so nothing is lost if the amount of memory to allocate is rounded up to the next multiple of 16. Like this, no memory is lost and 15 iterations from 16 in the example above won't allocate memory but use the already allocated pool.

The default approach is quite conservative. Allocating more memory may bring important performance benefits for programs using (relatively) few very long strings. The amount of memory allocated is configured by the setting of `EXTRA_ALLOC` in the file string.cpp during compilation (be sure to understand why its default value is what it is before modifying it!). You may try setting it to greater amount (say twice nLen) or to 0 (to see performance degradation which will follow) and analyse the impact of it on your program. If you do it, you will probably find it helpful to also define `WXSTRING_STATISTICS` symbol which tells the wxString class to collect performance statistics and to show them on stderr on program termination. This will show you the average length of strings your program manipulates, their average initial length and also the percent of times when memory wasn't reallocated when string concatenation was done but the already preallocated memory was used (this value should be about 98% for the default allocation policy, if it is less than 90% you should really consider fine tuning wxString for your application).

It goes without saying that a profiler should be used to measure the precise difference the change to `EXTRA_AL↩LOC` makes to your program.

10.19.7 wxString Related Compilation Settings

The main option affecting wxString is `wxUSE_UNICODE` which is now always defined as `1` by default to indicate Unicode support. You may set it to 0 to disable Unicode support in wxString and elsewhere in wxWidgets but this is *strongly* not recommended.

Another option affecting wxWidgets is `wxUSE_UNICODE_WCHAR` which is also 1 by default. You may want to set it to 0 and set `wxUSE_UNICODE_UTF8` to 1 instead to use UTF-8 internally. wxString still provides the same API in

this case, but using UTF-8 has performance implications as explained in Performance Implications of Using UTF-8, so it probably shouldn't be enabled for legacy code which might contain a lot of index-using loops.

See also Most Important Symbols for a few other options affecting wxString.

10.20 Buffer Classes

wxWidgets uses two classes of classes for dealing with buffers in memory.

The first is one for dealing with character buffers, namely wxCharBuffer for char pointer or multi-byte c strings and wxWCharBuffer for wchar_t pointer or wide character c strings.

Secondly, wxWidgets uses, although only rarely currently, wxMemoryBuffer for dealing with raw buffers in memory.

10.20.1 wxXCharBuffer

General Usage

As mentioned, wxCharBuffer and its wide character variant wxWCharBuffer deal with c strings in memory. They have two constructors, one in which you pass the c string you want them to have a copy of, and another where you specify the size of the buffer in memory in characters you want.

wxCharBuffer and its variant only contain the c string as a member, so they can be used safely to c functions with variable arguments such as printf. They also contain standard assignment, character access operators and a copy constructor.

Destruction

It should be noted that on destruction wxCharBuffer and its wide character variant delete the c string that hold onto. If you want to get the pointer to the buffer and don't want wxCharBuffer to delete it on destruction, use the member function release to do so.

10.21 Date and Time

wxWidgets provides a set of powerful classes to work with dates and times.

Some of the supported features of wxDateTime class are:

- Wide range: the range of supported dates goes from about 4714 B.C. to some 480 million years in the future.
- Precision: not using floating point calculations anywhere ensures that the date calculations don't suffer from rounding errors.
- Many features: not only all usual calculations with dates are supported, but also more exotic week and year day calculations, work day testing, standard astronomical functions, conversion to and from strings in either strict or free format.
- Efficiency: objects of wxDateTime are small (8 bytes) and working with them is fast

There are 3 main classes declared in `wx/datetime.h`: except wxDateTime itself which represents an absolute moment in time, there are also two classes - wxTimeSpan and wxDateSpan - which represent the intervals of time.

There are also helper classes which are used together with wxDateTime: wxDateTimeHolidayAuthority which is used to determine whether a given date is a holiday or not and wxDateTimeWorkDays which is a derivation of this class for which (only) Saturdays and Sundays are the holidays. See more about these classes in the discussion of the holidays (see wxDateTime and Holidays).

Finally, in other parts of this manual you may find mentions of wxDate and wxTime classes. Compatibility are obsolete and superseded by wxDateTime.

10.21.1 wxDateTime Characteristics

wxDateTime stores the time as a signed number of milliseconds since the Epoch which is fixed, by convention, to Jan 1, 1970 - however this is not visible to the class users (in particular, dates prior to the Epoch are handled just as well (or as bad) as the dates after it). But it does mean that the best resolution which can be achieved with this class is 1 millisecond.

The size of wxDateTime object is 8 bytes because it is represented as a 64 bit integer. The resulting range of supported dates is thus approximatively 580 million years, but due to the current limitations in the Gregorian calendar support, only dates from Nov 24, 4714BC are supported (this is subject to change if there is sufficient interest in doing it).

Finally, the internal representation is time zone independent (always in GMT) and the time zones only come into play when a date is broken into year/month/day components. See more about timezones below (see Time Zone Considerations).

Currently, the only supported calendar is Gregorian one (which is used even for the dates prior to the historic introduction of this calendar which was first done on Oct 15, 1582 but is, generally speaking, country, and even region, dependent). Future versions will probably have Julian calendar support as well and support for other calendars (Maya, Hebrew, Chinese...) is not ruled out.

10.21.2 wxDateSpan and wxTimeSpan

While there is only one logical way to represent an absolute moment in the time (and hence only one wxDateTime class), there are at least two methods to describe a time interval.

First, there is the direct and self-explaining way implemented by wxTimeSpan: it is just a difference in milliseconds between two moments in time. Adding or subtracting such an interval to wxDateTime is always well-defined and is a fast operation.

But in the daily life other, calendar-dependent time interval specifications are used. For example, 'one month later' is commonly used. However, it is clear that this is not the same as wxTimeSpan of $60*60*24*31$ seconds because 'one month later' Feb 15 is Mar 15 and not Mar 17 or Mar 16 (depending on whether the year is leap or not).

This is why there is another class for representing such intervals called wxDateSpan. It handles these sort of operations in the most natural way possible, but note that manipulating with intervals of this kind is not always well-defined. Consider, for example, Jan 31 + '1 month': this will give Feb 28 (or 29), i.e. the last day of February and not the non-existent Feb 31. Of course, this is what is usually wanted, but you still might be surprised to notice that now subtracting back the same interval from Feb 28 will result in Jan 28 and **not** Jan 31 we started with!

So, unless you plan to implement some kind of natural language parsing in the program, you should probably use wxTimeSpan instead of wxDateSpan (which is also more efficient). However, wxDateSpan may be very useful in situations when you do need to understand what 'in a month' means (of course, it is just `wxDateTime::Now()` + wxDateSpan::Month()).

10.21.3 Date Arithmetics

Many different operations may be performed with the dates, however not all of them make sense. For example, multiplying a date by a number is an invalid operation, even though multiplying either of the time span classes by a number is perfectly valid.

Here is what can be done:

- **Addition:** a wxTimeSpan or wxDateSpan can be added to wxDateTime resulting in a new wxDateTime object and also 2 objects of the same span class can be added together giving another object of the same class.
- **Subtraction:** the same types of operations as above are allowed and, additionally, a difference between two wxDateTime objects can be taken and this will yield wxTimeSpan.
- **Multiplication:** a wxTimeSpan or wxDateSpan object can be multiplied by an integer number resulting in an object of the same type.

- **Unary minus**: a wxTimeSpan or wxDateSpan object may finally be negated giving an interval of the same magnitude but of opposite time direction.

For all these operations there are corresponding global (overloaded) operators and also member functions which are synonyms for them: Add(), Subtract() and Multiply(). Unary minus as well as composite assignment operations (like +=) are only implemented as members and Neg() is the synonym for unary minus.

10.21.4 Time Zone Considerations

Although the time is always stored internally in GMT, you will usually work in the local time zone. Because of this, all wxDateTime constructors and setters which take the broken down date assume that these values are for the local time zone. Thus, `wxDateTime(1, wxDateTime::Jan, 1970)` will not correspond to the wxDateTime Epoch unless you happen to live in the UK. All methods returning the date components (year, month, day, hour, minute, second...) will also return the correct values for the local time zone by default, so, generally, doing the natural things will lead to natural and correct results.

If you only want to do this, you may safely skip the rest of this section. However, if you want to work with different time zones, you should read it to the end.

In this (rare) case, you are still limited to the local time zone when constructing wxDateTime objects, i.e. there is no way to construct a wxDateTime corresponding to the given date in, say, Pacific Standard Time. To do it, you will need to call wxDateTime::ToTimezone or wxDateTime::MakeTimezone methods to adjust the date for the target time zone. There are also special versions of these functions wxDateTime::ToUTC and wxDateTime::MakeUTC for the most common case - when the date should be constructed in UTC.

You also can just retrieve the value for some time zone without converting the object to it first. For this you may pass TimeZone argument to any of the methods which are affected by the time zone (all methods getting date components and the date formatting ones, for example). In particular, the Format() family of methods accepts a TimeZone parameter and this allows to simply print time in any time zone.

To see how to do it, the last issue to address is how to construct a TimeZone object which must be passed to all these methods. First of all, you may construct it manually by specifying the time zone offset in seconds from GMT, but usually you will just use one of the Date and Time and let the conversion constructor do the job.

I.e. you would just write

```
wxDateTime dt(...whatever...);
printf("The time is %s in local time zone", dt.FormatTime().c_str());
printf("The time is %s in GMT", dt.FormatTime(wxDateTime::GMT).c_str());
```

10.21.5 Daylight Saving Time (DST)

DST (a.k.a. 'summer time') handling is always a delicate task which is better left to the operating system which is supposed to be configured by the administrator to behave correctly. Unfortunately, when doing calculations with date outside of the range supported by the standard library, we are forced to deal with these issues ourselves.

Several functions are provided to calculate the beginning and end of DST in the given year and to determine whether it is in effect at the given moment or not, but they should not be considered as absolutely correct because, first of all, they only work more or less correctly for only a handful of countries (any information about other ones appreciated!) and even for them the rules may perfectly well change in the future.

The time zone handling methods (see Time Zone Considerations) use these functions too, so they are subject to the same limitations.

10.21.6 wxDateTime and Holidays

Todo WRITE THIS DOC PARAGRAPH.

10.21.7 Compatibility

The old classes for date/time manipulations ported from wxWidgets version 1.xx are still included but are reimplemented in terms of wxDateTime. However, using them is strongly discouraged because they have a few quirks/bugs and were not 'Y2K' compatible.

10.22 Container Classes

For historical reasons, wxWidgets uses custom container classes internally.

This was unfortunately unavoidable during a long time when the standard library wasn't widely available and can't be easily changed even now that it is for compatibility reasons. If you are building your own version of the library and don't care about compatibility nor slight (less than 5%) size penalty imposed by the use of STL classes, you may choose to use the "STL" build of wxWidgets in which these custom classes are replaced with their standard counterparts and only read the section STL Build explaining how to do it.

Otherwise you will need to know about the custom wxWidgets container classes such as wxList<T> and wxArray<T> if only to use wxWidgets functions that work with them, e.g. wxWindow::GetChildren(), and you should find the information about using these classes below useful.

Notice that we recommend that you use standard classes directly in your own code instead of the container classes provided by wxWidgets in any case as the standard classes are easier to use and may also be safer because of extra run-time checks they may perform as well as more efficient.

Finally notice that recent versions of wxWidgets also provide standard-like classes such as wxVector<T>, wxStack<T> or wxDList which can be used exactly like the std::vector<T>, std::stack<T> and std::list<T*>, respectively, and actually are just typedefs for the corresponding types if wxWidgets is compiled in STL mode. These classes could be useful if you wish to avoid the use of the standard library in your code for some reason.

To summarize, you should use the standard container classes such as std::vector<T> and std::list<T> if possible and wxVector<T> or wxDList<T> if it isn't and only use legacy wxWidgets containers such as wxArray<T> and wxList<T> when you must, i.e. when you use a wxWidgets function taking or returning a container of such type.

See also

Containers

10.22.1 Legacy Classes

The list classes in wxWidgets are doubly-linked lists which may either own the objects they contain (meaning that the list deletes the object when it is removed from the list or the list itself is destroyed) or just store the pointers depending on whether or not you called wxList<T>::DeleteContents() method.

Dynamic arrays resemble C arrays but with two important differences: they provide run-time range checking in debug builds and they automatically expand the allocated memory when there is no more space for new items. They come in two sorts: the "plain" arrays which store either built-in types such as "char", "int" or "bool" or the pointers to arbitrary objects, or "object arrays" which own the object pointers to which they store.

For the same portability reasons, the container classes implementation in wxWidgets don't use templates, but are rather based on C preprocessor i.e. are implemented using the macros: WX_DECLARE_LIST() and WX_DEFINE_LIST() for the linked lists and WX_DECLARE_ARRAY(), WX_DECLARE_OBJARRAY() and WX_DEFINE_OBJARRAY() for the dynamic arrays.

The "DECLARE" macro declares a new container class containing the elements of given type and is needed for all three types of container classes: lists, arrays and objarrays. The "DEFINE" classes must be inserted in your program in a place where the *full* declaration of container element class is in scope (i.e. not just forward declaration), otherwise destructors of the container elements will not be called!

As array classes never delete the items they contain anyhow, there is no WX_DEFINE_ARRAY() macro for them.

Examples of usage of these macros may be found in wxList<T> and wxArray<T> documentation.

Finally, wxWidgets predefines several commonly used container classes. wxList is defined for compatibility with previous versions as a list containing wxObjects and wxStringList as a list of C-style strings (char *), both of these classes are deprecated and should not be used in new programs. The following array classes are defined: wxArrayInt, wxArrayLong, wxArrayPtrVoid and wxArrayString. The first three store elements of corresponding types, but wxArrayString is somewhat special: it is an optimized version of wxArray which uses its knowledge about wxString reference counting schema.

10.22.2 STL Build

To build wxWidgets with the standard containers you need to set wxUSE_STD_CONTAINERS option to 1 in `wx/msw/setup.h` for wxMSW builds or specify `-enable-std_containers` option to configure (which is also implicitly enabled by `-enable-stl` option) in Unix builds.

The standard container build is mostly, but not quite, compatible with the default one. Here are the most important differences:

- wxList::compatibility_iterator must be used instead of wxList::Node* when iterating over the list contents. The compatibility_iterator class has the same semantics as a Node pointer but it is an object and not a pointer, so you need to write

```
for ( wxWindowList::compatibility_iterator it = list.GetFirst();
      it;
      it = it->GetNext() )
    ...
```

  instead of the old

```
for ( wxWindowList::Node *n = list.GetFirst(); n; n = n->GetNext() )
    ...
```

- wxSortedArrayString and wxArrayString are separate classes now and the former doesn't derive from the latter. If you need to convert a sorted array to a normal one, you must copy all the elements. Alternatively, you may avoid the use of wxSortedArrayString by using a normal array and calling its Sort() method when needed.
- WX_DEFINE_ARRAY_INT(bool) cannot be used because of the differences in std::vector<bool> specialization compared with the generic std::vector<> class. Please either use std::vector<bool> directly or use an integer array instead.

10.23 File Classes and Functions

wxWidgets provides some functions and classes to facilitate working with files.

As usual, the accent is put on cross-platform features which explains, for example, the wxTextFile class which may be used to convert between different types of text files (DOS/Unix/Mac).

wxFile may be used for low-level IO. It contains all the usual functions to work with files (opening/closing, reading/writing, seeking, and so on) but compared with using standard C functions, has error checking (in case of an error a message is logged using wxLog facilities) and closes the file automatically in the destructor which may be quite convenient.

wxTempFile is a very small file designed to make replacing the files contents safer - see its documentation for more details.

wxTextFile is a general purpose class for working with small text files on line by line basis. It is especially well suited for working with configuration files and program source files. It can be also used to work with files with "non native" line termination characters and write them as "native" files if needed (in fact, the files may be written in any format).

wxDir is a helper class for enumerating the files or subdirectories of a directory. It may be used to enumerate all files, only files satisfying the given template mask or only non-hidden files.

10.24 Stream Classes Overview

wxWidgets provides its own set of stream classes in order to support platforms not providing standard C++ streams implementation and also to make it possible to provide binary versions of wxWidgets application not depending on any particular standard library version.

The wxWidgets stream classes also provide some functionality not available in the standard library such as support for several compression formats and possibility to work with sockets or text controls (for output only in the latter case).

Nevertheless wxWidgets programs can also use standard stream classes and are encouraged to do so if the above considerations don't apply. Moreover, wxStdInputStream and wxStdOutputStream classes are provided to provide a degree of interoperability between the two and make it possible to use any wxWidgets stream as a standard stream (the converse possibility to use a standard stream as a wxWidgets stream is planned for a future release).

10.24.1 Stream Classes

wxStream classes are divided in two main groups:

- The core: wxStreamBase, wxStreamBuffer, wxInputStream, wxOutputStream, wxFilterInputStream, wxFilterOutputStream
- The "IO" classes: wxSocketInputStream, wxSocketOutputStream, wxFileInputStream, wxFileOutputStream, ...
- Classes for reading text or binary data from a particular stream such as wxTextInputStream, wxTextOutputStream, wxDataInputStream and wxDataOutputStream

wxStreamBase is the base definition of a stream. It defines, for example, the API of OnSysRead(), OnSysWrite(), OnSysSeek() and OnSysTell(). These functions are really implemented by the "IO" classes. wxInputStream and wxOutputStream classes inherit from wxStreamBase and provide specialized methods for input and output.

wxStreamBuffer is a cache manager for wxStreamBase: it manages a stream buffer linked to a stream. One stream can have multiple stream buffers but one stream has always one autoinitialized stream buffer.

wxInputStream is the base class for read-only streams. It implements Read(), SeekI() (I for Input), and all read or IO generic related functions. wxOutputStream does the same thing for write-only streams.

wxFilterInputStream and wxFileterOutputStream are the base class definitions for stream filtering. Stream filtering means a stream which does no syscall but filters data which are passed to it and then pass them to another stream. For example, wxZLibInputStream is an inline stream decompressor.

The "IO" classes implements the specific parts of the stream. This could be nothing in the case of wxMemoryInputStream and wxMemoryOutputStream which base themselves on wxStreamBuffer. This could also be a simple link to the true syscall (for example read(...), write(...)).

10.24.2 Example

Usage is simple. We can take the example of wxFileInputStream and here is some sample code:

```
...
// The constructor initializes the stream buffer and open the file descriptor
// associated to the name of the file.
wxFileInputStream in_stream("the_file_to_be_read");

// Ok, read some bytes ... nb_datas is expressed in bytes.
in_stream.Read(data, nb_datas);
```

```
if (in_stream.LastError() != wxSTREAM_NOERROR) {
    // Oh oh, something bad happens.
    // For a complete list, look into the documentation at wxStreamBase.
}

// You can also inline all like this.
if (in_stream.Read(data, nb_datas).LastError() != wxSTREAM_NOERROR) {
    // Do something.
}

// You can also get the last number of bytes REALLY put into the buffer.
size_t really_read = in_stream.LastRead();

// Ok, moves to the beginning of the stream. SeekI returns the last position
// in the stream counted from the beginning.
off_t old_position = in_stream.SeekI(0, wxFromBeginning);

// What is my current position ?
off_t position = in_stream.TellI();

// wxFileInputStream will close the file descriptor on destruction.
```

10.25 Multithreading Overview

wxWidgets provides a complete set of classes encapsulating objects necessary in multi-threaded (MT) applications: the wxThread class itself and different synchronization objects: mutexes (see wxMutex) and critical sections (see wxCriticalSection) with conditions (see wxCondition).

The thread API in wxWidgets resembles to POSIX1.c threads API (a.k.a. pthreads), although several functions have different names and some features inspired by Win32 thread API are there as well.

These classes hopefully make writing MT programs easier and they also provide some extra error checking (compared to the native - be it Win32 or Posix - thread API), however it is still a non-trivial undertaking especially for large projects. Before starting an MT application (or starting to add MT features to an existing one) it is worth asking oneself if there is no easier and safer way to implement the same functionality. Of course, in some situations threads really make sense (classical example is a server application which launches a new thread for each new client), but in others it might be an overkill. On the other hand, the recent evolution of the computer hardware shows an important trend towards multi-core systems, which are better exploited using multiple threads (e.g. you may want to split a long task among as many threads as many CPU (cores) the system reports; see wxThread::GetCPUCount).

To implement non-blocking operations *without* using multiple threads you have two possible implementation choices:

- use wxIdleEvent (e.g. to perform a long calculation while updating a progress dialog)
- do everything at once but call wxWindow::Update() or wxApp::YieldFor(wxEVT_CATEGORY_UI) periodically to update the screen.

If instead you choose to use threads in your application, please read the following section of this overview.

See also

wxThread, wxThreadHelper, wxMutex, wxCriticalSection, wxCondition, wxSemaphore

10.25.1 Important Notes for Multi-threaded Applications

When writing a multi-threaded application, it is strongly recommended that **no secondary threads call GUI functions**. The design which uses one GUI thread and several worker threads which communicate with the main one using **events** is much more robust and will undoubtedly save you countless problems (example: under Win32 a thread can only access GDI objects such as pens, brushes, device contexts created by itself and not by the other threads).

For communication between secondary threads and the main thread, you may use wxEvtHandler::QueueEvent or its short version wxQueueEvent. These functions have a thread-safe implementation so that they can be used as they are for sending events from one thread to another. However there is no built in method to send messages to the

worker threads and you will need to use the available synchronization classes to implement the solution which suits your needs yourself. In particular, please note that it is not enough to derive your class from wxThread and wxEvtHandler to send messages to it: in fact, this does not work at all. You're instead encouraged to use wxThreadHelper as it greatly simplifies the communication and the sharing of resources.

You should also look at the wxThread docs for important notes about secondary threads and their deletion.

Last, remember that if wxEventLoopBase::YieldFor() is used directly or indirectly (e.g. through wxProgressDialog) in your code, then you may have both re-entrancy problems and also problems caused by the processing of events out of order. To resolve the last problem wxThreadEvent can be used: thanks to its implementation of the wxThreadEvent::GetEventCategory function wxThreadEvent classes in fact do not get processed by wxEventLoopBase::YieldFor() unless you specify the `wxEVT_CATEGORY_THREAD` flag.

See also the Thread Sample for a sample showing some simple interactions between the main and secondary threads.

10.26 wxConfig Overview

Classes: wxConfigBase

This overview briefly describes what the config classes are and what they are for. All the details about how to use them may be found in the description of the wxConfigBase class and the documentation of the file, registry and INI file based implementations mentions all the features/limitations specific to each one of these versions.

The config classes provide a way to store some application configuration information. They were especially designed for this usage and, although may probably be used for many other things as well, should be limited to it. It means that this information should be:

- Typed, i.e. strings or numbers for the moment. You cannot store binary data, for example.
- Small. For instance, it is not recommended to use the Windows registry for amounts of data more than a couple of kilobytes.
- Not performance critical, neither from speed nor from a memory consumption point of view.

On the other hand, the features provided make them very useful for storing all kinds of small to medium volumes of hierarchically-organized, heterogeneous data. In short, this is a place where you can conveniently stuff all your data (numbers and strings) organizing it in a tree where you use the filesystem-like paths to specify the location of a piece of data. In particular, these classes were designed to be as easy to use as possible.

From another point of view, they provide an interface which hides the differences between the Windows registry and the standard Unix text format configuration files. Other (future) implementations of wxConfigBase might also understand GTK resource files or their analogues on the KDE side.

In any case, each implementation of wxConfigBase does its best to make the data look the same way everywhere. Due to limitations of the underlying physical storage, it may not implement 100% of the base class functionality.

There are groups of entries and the entries themselves. Each entry contains either a string or a number (or a boolean value; support for other types of data such as dates or timestamps is planned) and is identified by the full path to it: something like `/MyApp/UserPreferences/Colors/Foreground`.

The previous elements in the path are the group names, and each name may contain an arbitrary number of entries and subgroups.

The path components are *always* separated with a slash, even though some implementations use the backslash internally. Further details (including how to read/write these entries) may be found in the documentation for wxConfigBase.

10.27 Persistent Objects Overview

Persistent objects are simply the objects which automatically save their state when they are destroyed and restore it when they are recreated, even during another program invocation.

Most often, persistent objects are, in fact, persistent windows as it is especially convenient to automatically restore the UI state when the program is restarted but an object of any class can be made persistent. Moreover, persistence is implemented in a non-intrusive way so that the original object class doesn't need to be modified at all in order to add support for saving and restoring its properties.

The persistence framework includes the following components:

- wxPersistenceManager which all persistent objects register themselves with. This class handles actual saving and restoring of persistent data as well as various global aspects of persistence, e.g. it can be used to disable restoring the saved data.
- wxPersistentObject is the base class for all persistent objects or, rather, adaptors for the persistent objects as this class main purpose is to provide the bridge between the original class – which has no special persistence support – and wxPersistenceManager,
- wxPersistentWindow<> which derives from wxPersistentObject and implements some of its methods using wxWindow-specific functionality. Notably, wxPersistenceManager handles the destruction of persistent windows automatically implicitly while it has to be done explicitly for the arbitrary persistent objects.
- wxCreatePersistentObject() function which is used to create the appropriate persistence adapter for the object.

10.27.1 Using Persistent Windows

wxWidgets has built-in support for a (constantly growing) number of controls. Currently the following classes are supported:

- wxTopLevelWindow (and hence wxFrame and wxDialog)
- wxBookCtrlBase (i.e. wxNotebook, wxListbook, wxToolbook and wxChoicebook)
- wxTreebook

To automatically save and restore the properties of the windows of classes listed above you need to:

1. Set a unique name for the window using wxWindow::SetName(): this step is important as the name is used in the configuration file and so must be unique among all windows of the same class.
2. Call wxPersistenceManager::Register() at any moment after creating the window and then wxPersistenceManager::Restore() when the settings may be restored (which can't be always done immediately, e.g. often the window needs to be populated first). If settings can be restored immediately after the window creation, as is often the case for wxTopLevelWindow, for example, then wxPersistenceManager::RegisterAndRestore() can be used to do both at once.
3. If you do not want the settings for the window to be saved (for example the changes to the dialog size are usually not saved if the dialog was cancelled), you need to call wxPersistenceManager::Unregister() manually. Otherwise the settings will be automatically saved when the control itself is destroyed.

Example of using a notebook control which automatically remembers the last open page:

```
wxNotebook *book = new wxNotebook(parent, wxID_ANY);
book->SetName("MyBook"); // do not use the default name
book->AddPage(...);
book->AddPage(...);
book->AddPage(...);
if ( !wxPersistenceManager::RegisterAndRestore(book) )
{
    // nothing was restored, so choose the default page ourselves
    book->SetSelection(0);
}
```

10.27.2 Defining Custom Persistent Windows

User-defined classes can be easily integrated with wxPersistenceManager. To add support for your custom class `MyWidget` you just need to:

1. Define a new `MyPersistentWidget` class inheriting from wxPersistentWindow<MyWidget>.
2. Implement its pure virtual GetKind() method returning a unique string identifying all `MyWidget` objects, typically something like `"widget"`
3. Implement its pure virtual Save() and Restore() methods to actually save and restore the widget settings using wxPersistentObject::SaveValue() and wxPersistentObject::RestoreValue() methods.
4. Define wxCreatePersistentObject() overload taking `MyWidget *` and returning a new `MyPersistentWidget` object.

If you want to add persistence support for a class not deriving from wxWindow, you need to derive `MyPersistentWidget` directly from wxPersistentObject and so implement its pure virtual wxPersistentObject::GetName() method too. Additionally, you must ensure that wxPersistenceManager::SaveAndUnregister() is called when your object is destroyed as this can be only done automatically for windows.

10.28 wxFileSystem Overview

The wxHTML library uses a **virtual** file system mechanism similar to the one used in Midnight Commander, Dos Navigator, FAR or almost any modern file manager.

It allows the user to access data stored in archives as if they were ordinary files. On-the-fly generated files that exist only in memory are also supported.

10.28.1 Classes

Three classes are used in order to provide virtual file systems mechanism:

- The wxFSFile class provides information about opened file (name, input stream, mime type and anchor).
- The wxFileSystem class is the interface. Its main methods are ChangePathTo() and OpenFile(). This class is most often used by the end user.
- The wxFileSystemHandler is the core of virtual file systems mechanism. You can derive your own handler and pass it to the VFS mechanism. You can derive your own handler and pass it to wxFileSystem's AddHandler() method. In the new handler you only need to override the OpenFile() and CanOpen() methods.

10.28.2 Locations

Locations (aka filenames aka addresses) are constructed from four parts:

- **protocol** - handler can recognize if it is able to open a file by checking its protocol. Examples are "http", "file" or "ftp".
- **right location** - is the name of file within the protocol. In "http://www.wxwidgets.org/index.html" the right location is "//www.wxwidgets.org/index.html".
- **anchor** - an anchor is optional and is usually not present. In "index.htm#chapter2" the anchor is "chapter2".
- **left location** - this is usually an empty string. It is used by 'local' protocols such as ZIP. See Combined Protocols paragraph for details.

10.28.3 Combined Protocols

The left location precedes the protocol in the URL string.

It is not used by global protocols like HTTP but it becomes handy when nesting protocols - for example you may want to access files in a ZIP archive: `file:archives/cpp_doc.zip#zip:reference/fopen.htm#syntax` In this example, the protocol is "zip", right location is "reference/fopen.htm", anchor is "syntax" and left location is "file:archives/cpp_doc.zip".

There are **two** protocols used in this example: "zip" and "file".

10.28.4 File Systems Included in wxHTML

The following virtual file system handlers are part of wxWidgets so far:

- **wxArchiveFSHandler:** A handler for archives such as zip and tar. Include file is wx/fs_arc.h. URLs examples: "archive.zip#zip:filename", "archive.tar.gz#gzip:#tar:filename".
- **wxFilterFSHandler:** A handler for compression schemes such as gzip. Header is wx/fs_filter.h. URLs are in the form, e.g.: "document.ps.gz#gzip:".
- **wxInternetFSHandler:** A handler for accessing documents via HTTP or FTP protocols. Include file is wx/fs_inet.h.
- **wxMemoryFSHandler:** This handler allows you to access data stored in memory (such as bitmaps) as if they were regular files. See wxMemoryFSHandler for details. Include file is wx/fs_mem.h. URL is prefixed with memory:, e.g. "memory:myfile.htm"

In addition, wxFileSystem itself can access local files.

10.28.5 Initializing file system handlers

Use wxFileSystem::AddHandler to initialize a handler, for example:

```
#include <wx/fs_mem.h>

...

bool MyApp::OnInit()
{
    wxFileSystem::AddHandler(new wxMemoryFSHandler);
...
}
```

10.29 Regular Expressions

A *regular expression* describes strings of characters.

It's a pattern that matches certain strings and doesn't match others.

See also

wxRegEx

10.29.1 Different Flavors of Regular Expressions

Regular expressions (RE), as defined by POSIX, come in two flavors: *extended regular expressions* (ERE) and *basic regular expressions* (BRE). EREs are roughly those of the traditional *egrep*, while BREs are roughly those of

the traditional *ed*. This implementation adds a third flavor: *advanced regular expressions* (ARE), basically EREs with some significant extensions.

This manual page primarily describes AREs. BREs mostly exist for backward compatibility in some old programs. POSIX EREs are almost an exact subset of AREs. Features of AREs that are not present in EREs will be indicated.

10.29.2 Regular Expression Syntax

These regular expressions are implemented using the package written by Henry Spencer, based on the 1003.2 spec and some (not quite all) of the Perl5 extensions (thanks, Henry!). Much of the description of regular expressions below is copied verbatim from his manual entry.

An ARE is one or more *branches*, separated by "|", matching anything that matches any of the branches.

A branch is zero or more *constraints* or *quantified* atoms, concatenated. It matches a match for the first, followed by a match for the second, etc; an empty branch matches the empty string.

A quantified atom is an *atom* possibly followed by a single *quantifier*. Without a quantifier, it matches a match for the atom. The quantifiers, and what a so-quantified atom matches, are:

`*`	A sequence of 0 or more matches of the atom.
`+`	A sequence of 1 or more matches of the atom.
`?`	A sequence of 0 or 1 matches of the atom.
`{m}`	A sequence of exactly *m* matches of the atom.
`{m,}`	A sequence of *m* or more matches of the atom.
`{m,n}`	A sequence of *m* through *n* (inclusive) matches of the atom; *m* may not exceed *n*.
`*? +? ?? {m}? {m,}? {m,n}?`	*Non-greedy* quantifiers, which match the same possibilities, but prefer the smallest number rather than the largest number of matches (see Matching).

The forms using **{** and **}** are known as *bounds*. The numbers *m* and *n* are unsigned decimal integers with permissible values from 0 to 255 inclusive. An atom is one of:

`(re)`	Where *re* is any regular expression, matches for *re*, with the match captured for possible reporting.
`(?:re)`	As previous, but does no reporting (a "non-capturing" set of parentheses).
`()`	Matches an empty string, captured for possible reporting.
`(?:)`	Matches an empty string, without reporting.
`[chars]`	A *bracket expression*, matching any one of the *chars* (see Bracket Expressions for more details).
`.`	Matches any single character.
`\k`	Where *k* is a non-alphanumeric character, matches that character taken as an ordinary character, e.g. \\ matches a backslash character.
`\c`	Where *c* is alphanumeric (possibly followed by other characters), an *escape* (AREs only), see Escapes below.
`{`	When followed by a character other than a digit, matches the left-brace character "{"; when followed by a digit, it is the beginning of a *bound* (see above).
`x`	Where *x* is a single character with no other significance, matches that character.

A *constraint* matches an empty string when specific conditions are met. A constraint may not be followed by a quantifier. The simple constraints are as follows; some more constraints are described later, under Escapes.

^	Matches at the beginning of a line.
$	Matches at the end of a line.
(?=re)	*Positive* lookahead (AREs only), matches at any point where a substring matching *re* begins.
(?!re)	*Negative* lookahead (AREs only), matches at any point where no substring matching *re* begins.

The lookahead constraints may not contain back references (see later), and all parentheses within them are considered non-capturing. A RE may not end with "\".

10.29.3 Bracket Expressions

A *bracket expression* is a list of characters enclosed in `[]`. It normally matches any single character from the list (but see below). If the list begins with ^, it matches any single character (but see below) *not* from the rest of the list.

If two characters in the list are separated by `-`, this is shorthand for the full *range* of characters between those two (inclusive) in the collating sequence, e.g. `[0-9]` in ASCII matches any decimal digit. Two ranges may not share an endpoint, so e.g. `a-c-e` is illegal. Ranges are very collating-sequence-dependent, and portable programs should avoid relying on them.

To include a literal `]` or `-` in the list, the simplest method is to enclose it in `[.` and `.]` to make it a collating element (see below). Alternatively, make it the first character (following a possible ^), or (AREs only) precede it with `\`. Alternatively, for `-`, make it the last character, or the second endpoint of a range. To use a literal `-` as the first endpoint of a range, make it a collating element or (AREs only) precede it with `\`. With the exception of these, some combinations using `[` (see next paragraphs), and escapes, all other special characters lose their special significance within a bracket expression.

Within a bracket expression, a collating element (a character, a multi-character sequence that collates as if it were a single character, or a collating-sequence name for either) enclosed in `[.` and `.]` stands for the sequence of characters of that collating element.

wxWidgets: Currently no multi-character collating elements are defined. So in `[.X.]`, `X` can either be a single character literal or the name of a character. For example, the following are both identical: `[[.0.]-[.9.]]` and `[[.zero.]-[.nine.]]` and mean the same as `[0-9]`. See Regular Expression Character Names.

Within a bracket expression, a collating element enclosed in `[=` and `=]` is an equivalence class, standing for the sequences of characters of all collating elements equivalent to that one, including itself. An equivalence class may not be an endpoint of a range.

wxWidgets: Currently no equivalence classes are defined, so `[=X=]` stands for just the single character `X`. `X` can either be a single character literal or the name of a character, see Regular Expression Character Names.

Within a bracket expression, the name of a *character* class enclosed in `[:` and `:]` stands for the list of all characters (not all collating elements!) belonging to that class. Standard character classes are:

alpha	A letter.
upper	An upper-case letter.
lower	A lower-case letter.
digit	A decimal digit.
xdigit	A hexadecimal digit.
alnum	An alphanumeric (letter or digit).
print	An alphanumeric (same as alnum).
blank	A space or tab character.
space	A character producing white space in displayed text.
punct	A punctuation character.
graph	A character with a visible representation.
cntrl	A control character.

A character class may not be used as an endpoint of a range.

wxWidgets: In a non-Unicode build, these character classifications depend on the current locale, and correspond to the values return by the ANSI C "is" functions: `isalpha`, `isupper`, etc. In Unicode mode they are based on Unicode classifications, and are not affected by the current locale.

There are two special cases of bracket expressions: the bracket expressions `[[:<:]]` and `[[:>:]]` are constraints, matching empty strings at the beginning and end of a word respectively. A word is defined as a sequence of word characters that is neither preceded nor followed by word characters. A word character is an *alnum* character or an underscore (_). These special bracket expressions are deprecated; users of AREs should use constraint escapes instead (see escapes below).

10.29.4 Escapes

Escapes (AREs only), which begin with a \ followed by an alphanumeric character, come in several varieties: character entry, class shorthands, constraint escapes, and back references. A \ followed by an alphanumeric character but not constituting a valid escape is illegal in AREs. In EREs, there are no escapes: outside a bracket expression, a \ followed by an alphanumeric character merely stands for that character as an ordinary character, and inside a bracket expression, \ is an ordinary character. (The latter is the one actual incompatibility between EREs and AREs.)

Character-entry escapes (AREs only) exist to make it easier to specify non-printing and otherwise inconvenient characters in REs:

`\a`	Alert (bell) character, as in C.
`\b`	Backspace, as in C.
`\B`	Synonym for \ to help reduce backslash doubling in some applications where there are multiple levels of backslash processing.
`\cX`	The character whose low-order 5 bits are the same as those of *X*, and whose other bits are all zero, where *X* is any character.
`\e`	The character whose collating-sequence name is `ESC`, or failing that, the character with octal value 033.
`\f`	Formfeed, as in C.
`\n`	Newline, as in C.
`\r`	Carriage return, as in C.
`\t`	Horizontal tab, as in C.
`\uwxyz`	The Unicode character `U+wxyz` in the local byte ordering, where *wxyz* is exactly four hexadecimal digits.
`\Ustuvwxyz`	Reserved for a somewhat-hypothetical Unicode extension to 32 bits, where *stuvwxyz* is exactly eight hexadecimal digits.
`\v`	Vertical tab, as in C are all available.
`\xhhh`	The single character whose hexadecimal value is *0xhhh*, where *hhh* is any sequence of hexadecimal digits.
`\0`	The character whose value is 0.
`\xy`	The character whose octal value is *0xy*, where *xy* is exactly two octal digits, and is not a *back reference* (see below).
`\xyz`	The character whose octal value is *0xyz*, where *xyz* is exactly three octal digits, and is not a *back reference* (see below).

Hexadecimal digits are 0-9, a-f, and A-F. Octal digits are 0-7.

The character-entry escapes are always taken as ordinary characters. For example, `\135` is `]` in ASCII, but `\135` does not terminate a bracket expression. Beware, however, that some applications (e.g., C compilers) interpret such sequences themselves before the regular-expression package gets to see them, which may require doubling (quadrupling, etc.) the '\'.

Class-shorthand escapes (AREs only) provide shorthands for certain commonly-used character classes:

\d	[[:digit:]]
\s	[[:space:]]
\w	[[:alnum:]_] (note underscore)
\D	[^[:digit:]]
\S	[^[:space:]]
\W	[^[:alnum:]_] (note underscore)

Within bracket expressions, \d, \s, and \w lose their outer brackets, and \D, \S, \W are illegal. So, for example, [a-c\d] is equivalent to [a-c[:digit:]]. Also, [a-c\D], which is equivalent to [a-c^[:digit:]], is illegal.

A constraint escape (AREs only) is a constraint, matching the empty string if specific conditions are met, written as an escape:

\A	Matches only at the beginning of the string, see Matching for how this differs from ^.
\m	Matches only at the beginning of a word.
\M	Matches only at the end of a word.
\y	Matches only at the beginning or end of a word.
\Y	Matches only at a point that is not the beginning or end of a word.
\Z	Matches only at the end of the string, see Matching for how this differs from $.
\m	A *back reference*, where *m* is a non-zero digit. See below.
\mnn	A *back reference*, where *m* is a nonzero digit, and *nn* is some more digits, and the decimal value *mnn* is not greater than the number of closing capturing parentheses seen so far. See below.

A word is defined as in the specification of [[:<:]] and [[:>:]] above. Constraint escapes are illegal within bracket expressions.

A back reference (AREs only) matches the same string matched by the parenthesized subexpression specified by the number. For example, "([bc])\1" matches "bb" or "cc" but not "bc". The subexpression must entirely precede the back reference in the RE.Subexpressions are numbered in the order of their leading parentheses. Non-capturing parentheses do not define subexpressions.

There is an inherent historical ambiguity between octal character-entry escapes and back references, which is resolved by heuristics, as hinted at above. A leading zero always indicates an octal escape. A single non-zero digit, not followed by another digit, is always taken as a back reference. A multi-digit sequence not starting with a zero is taken as a back reference if it comes after a suitable subexpression (i.e. the number is in the legal range for a back reference), and otherwise is taken as octal.

10.29.5 Metasyntax

In addition to the main syntax described above, there are some special forms and miscellaneous syntactic facilities available.

Normally the flavor of RE being used is specified by application-dependent means. However, this can be overridden by a *director*. If an RE of any flavor begins with ***:, the rest of the RE is an ARE. If an RE of any flavor begins with ***=, the rest of the RE is taken to be a literal string, with all characters considered ordinary characters.

An ARE may begin with *embedded options*: a sequence (?xyz) (where *xyz* is one or more alphabetic characters) specifies options affecting the rest of the RE. These supplement, and can override, any options specified by the application. The available option letters are:

b	Rest of RE is a BRE.
c	Case-sensitive matching (usual default).
e	Rest of RE is an ERE.
i	Case-insensitive matching (see Matching, below).
m	Historical synonym for *n*.
n	Newline-sensitive matching (see Matching, below).
p	Partial newline-sensitive matching (see Matching, below).
q	Rest of RE is a literal ("quoted") string, all ordinary characters.
s	Non-newline-sensitive matching (usual default).
t	Tight syntax (usual default; see below).
w	Inverse partial newline-sensitive ("weird") matching (see Matching, below).
x	Expanded syntax (see below).

Embedded options take effect at the `)` terminating the sequence. They are available only at the start of an ARE, and may not be used later within it.

In addition to the usual (*tight*) RE syntax, in which all characters are significant, there is an *expanded* syntax, available in AREs with the embedded x option. In the expanded syntax, white-space characters are ignored and all characters between a `#` and the following newline (or the end of the RE) are ignored, permitting paragraphing and commenting a complex RE. There are three exceptions to that basic rule:

- A white-space character or `#` preceded by `\` is retained.
- White space or `#` within a bracket expression is retained.
- White space and comments are illegal within multi-character symbols like the ARE `(?:` or the BRE `(.`

Expanded-syntax white-space characters are blank, tab, newline, and any character that belongs to the *space* character class.

Finally, in an ARE, outside bracket expressions, the sequence `(?#ttt)` (where *ttt* is any text not containing a `)`) is a comment, completely ignored. Again, this is not allowed between the characters of multi-character symbols like `(?:`. Such comments are more a historical artifact than a useful facility, and their use is deprecated; use the expanded syntax instead.

None of these metasyntax extensions is available if the application (or an initial `***=` director) has specified that the user's input be treated as a literal string rather than as an RE.

10.29.6 Matching

In the event that an RE could match more than one substring of a given string, the RE matches the one starting earliest in the string. If the RE could match more than one substring starting at that point, the choice is determined by it's *preference:* either the longest substring, or the shortest.

Most atoms, and all constraints, have no preference. A parenthesized RE has the same preference (possibly none) as the RE. A quantified atom with quantifier `{m}` or `{m}?` has the same preference (possibly none) as the atom itself. A quantified atom with other normal quantifiers (including `{m,n}` with *m* equal to *n*) prefers longest match. A quantified atom with other non-greedy quantifiers (including `{m,n}?` with *m* equal to *n*) prefers shortest match. A branch has the same preference as the first quantified atom in it which has a preference. An RE consisting of two or more branches connected by the `|` operator prefers longest match.

Subject to the constraints imposed by the rules for matching the whole RE, subexpressions also match the longest or shortest possible substrings, based on their preferences, with subexpressions starting earlier in the RE taking priority over ones starting later. Note that outer subexpressions thus take priority over their component subexpressions.

Note that the quantifiers `{1,1}` and `{1,1}?` can be used to force longest and shortest preference, respectively, on a subexpression or a whole RE.

Match lengths are measured in characters, not collating elements. An empty string is considered longer than no match at all. For example, `bb*` matches the three middle characters of "abbbc", `(week|wee)(night|knights)` matches all ten characters of "weeknights", when `(.*).*` is matched against "abc" the parenthesized subexpression matches all three characters, and when `(a*)*` is matched against "bc" both the whole RE and the parenthesized subexpression match an empty string.

If case-independent matching is specified, the effect is much as if all case distinctions had vanished from the alphabet. When an alphabetic that exists in multiple cases appears as an ordinary character outside a bracket expression, it is effectively transformed into a bracket expression containing both cases, so that `x` becomes [xX]. When it appears inside a bracket expression, all case counterparts of it are added to the bracket expression, so that [x] becomes [xX] and [^x] becomes [^xX].

If newline-sensitive matching is specified, "." and bracket expressions using "^" will never match the newline character (so that matches will never cross newlines unless the RE explicitly arranges it) and "^" and "$" will match the empty string after and before a newline respectively, in addition to matching at beginning and end of string respectively. ARE `\A` and `\Z` continue to match beginning or end of string *only*.

If partial newline-sensitive matching is specified, this affects "." and bracket expressions as with newline-sensitive matching, but not "^" and "$".

If inverse partial newline-sensitive matching is specified, this affects "^" and "$" as with newline-sensitive matching, but not "." and bracket expressions. This isn't very useful but is provided for symmetry.

10.29.7 Limits and Compatibility

No particular limit is imposed on the length of REs. Programs intended to be highly portable should not employ REs longer than 256 bytes, as a POSIX-compliant implementation can refuse to accept such REs.

The only feature of AREs that is actually incompatible with POSIX EREs is that `\` does not lose its special significance inside bracket expressions. All other ARE features use syntax which is illegal or has undefined or unspecified effects in POSIX EREs; the `***` syntax of directors likewise is outside the POSIX syntax for both BREs and EREs.

Many of the ARE extensions are borrowed from Perl, but some have been changed to clean them up, and a few Perl extensions are not present. Incompatibilities of note include `\b`, `\B`, the lack of special treatment for a trailing newline, the addition of complemented bracket expressions to the things affected by newline-sensitive matching, the restrictions on parentheses and back references in lookahead constraints, and the longest/shortest-match (rather than first-match) matching semantics.

The matching rules for REs containing both normal and non-greedy quantifiers have changed since early beta-test versions of this package. The new rules are much simpler and cleaner, but don't work as hard at guessing the user's real intentions.

Henry Spencer's original 1986 *regexp* package, still in widespread use, implemented an early version of today's E↩ REs. There are four incompatibilities between *regexp's* near-EREs (RREs for short) and AREs. In roughly increasing order of significance:

- In AREs, `\` followed by an alphanumeric character is either an escape or an error, while in RREs, it was just another way of writing the alphanumeric. This should not be a problem because there was no reason to write such a sequence in RREs.
- `{` followed by a digit in an ARE is the beginning of a bound, while in RREs, `{` was always an ordinary character. Such sequences should be rare, and will often result in an error because following characters will not look like a valid bound.
- In AREs, `\` remains a special character within [], so a literal `\` within [] must be written as `\\`. `\\` also gives a literal `\` within [] in RREs, but only truly paranoid programmers routinely doubled the backslash.
- AREs report the longest/shortest match for the RE, rather than the first found in a specified search order. This may affect some RREs which were written in the expectation that the first match would be reported. The careful crafting of RREs to optimize the search order for fast matching is obsolete (AREs examine all possible matches in parallel, and their performance is largely insensitive to their complexity) but cases where the search order was exploited to deliberately find a match which was *not* the longest/shortest will need rewriting.

10.29.8 Basic Regular Expressions

BREs differ from EREs in several respects. |, +, and ? are ordinary characters and there is no equivalent for their functionality. The delimiters for bounds are \{ and \}, with { and } by themselves ordinary characters. The parentheses for nested subexpressions are @(and @), with (and) by themselves ordinary characters. ^ is an ordinary character except at the beginning of the RE or the beginning of a parenthesized subexpression, $ is an ordinary character except at the end of the RE or the end of a parenthesized subexpression, and * is an ordinary character if it appears at the beginning of the RE or the beginning of a parenthesized subexpression (after a possible leading ^). Finally, single-digit back references are available, and \< and \> are synonyms for [[:<:]] and [[:>:]] respectively; no other escapes are available.

10.29.9 Regular Expression Character Names

Note that the character names are case sensitive.

10.30 Archive Formats

The archive classes handle archive formats such as zip, tar, rar and cab.

Currently wxZip, wxTar and wxZlib classes are included.

For each archive type, there are the following classes (using zip here as an example):

- wxZipInputStream: Input stream
- wxZipOutputStream: Output stream
- wxZipEntry: Holds meta-data for an entry (e.g. filename, timestamp, etc.)

There are also abstract wxArchive classes that can be used to write code that can handle any of the archive types, see Generic Archive Programming.

Also see wxFileSystem for a higher level interface that can handle archive files in a generic way.

The classes are designed to handle archives on both seekable streams such as disk files, or non-seekable streams such as pipes and sockets (see Archives on Non-Seekable Streams).

10.30.1 Creating an Archive

Call wxArchiveOutputStream::PutNextEntry() to create each new entry in the archive, then write the entry's data. Another call to PutNextEntry() closes the current entry and begins the next. For example:

```
wxFFileOutputStream out(wxT("test.zip"));
wxZipOutputStream zip(out);
wxTextOutputStream txt(zip);
wxString sep(wxFileName::GetPathSeparator());

zip.PutNextEntry(wxT("entry1.txt"));
txt << wxT("Some text for entry1.txt\n");

zip.PutNextEntry(wxT("subdir") + sep + wxT("entry2.txt"));
txt << wxT("Some text for subdir/entry2.txt\n");
```

The name of each entry can be a full path, which makes it possible to store entries in subdirectories.

10.30.2 Extracting an Archive

wxArchiveInputStream::GetNextEntry() returns a pointer to entry object containing the meta-data for the next entry in the archive (and gives away ownership).

Reading from the input stream then returns the entry's data. Eof() becomes true after an attempt has been made to read past the end of the entry's data.

When there are no more entries, GetNextEntry() returns NULL and sets Eof().

```
auto_ptr<wxZipEntry> entry;

wxFFileInputStream in(wxT("test.zip"));
wxZipInputStream zip(in);

while (entry.reset(zip.GetNextEntry()), entry.get() != NULL)
{
    // access meta-data
    wxString name = entry->GetName();
    // read 'zip' to access the entry's data
}
```

10.30.3 Modifying an Archive

To modify an existing archive, write a new copy of the archive to a new file, making any necessary changes along the way and transferring any unchanged entries using wxArchiveOutputStream::CopyEntry().

For archive types which compress entry data, CopyEntry() is likely to be much more efficient than transferring the data using Read() and Write() since it will copy them without decompressing and recompressing them.

In general modifications are not possible without rewriting the archive, though it may be possible in some limited cases. Even then, rewriting the archive is usually a better choice since a failure can be handled without losing the whole archive. wxTempFileOutputStream can be helpful to do this.

For example to delete all entries matching the pattern "*.txt":

```
auto_ptr<wxFFileInputStream> in(new wxFFileInputStream(wxT("test.zip")));
wxTempFileOutputStream out(wxT("test.zip"));

wxZipInputStream inzip(*in);
wxZipOutputStream outzip(out);

auto_ptr<wxZipEntry> entry;

// transfer any meta-data for the archive as a whole (the zip comment
// in the case of zip)
outzip.CopyArchiveMetaData(inzip);

// call CopyEntry for each entry except those matching the pattern
while (entry.reset(inzip.GetNextEntry()), entry.get() != NULL)
    if (!entry->GetName().Matches(wxT("*.txt")))
        if (!outzip.CopyEntry(entry.release(), inzip))
            break;

// close the input stream by releasing the pointer to it, do this
// before closing the output stream so that the file can be replaced
in.reset();

// you can check for success as follows
bool success = inzip.Eof() && outzip.Close() && out.Commit();
```

10.30.4 Looking Up an Archive Entry by Name

Also see wxFileSystem for a higher level interface that is more convenient for accessing archive entries by name.

To open just one entry in an archive, the most efficient way is to simply search for it linearly by calling wxArchiveInputStream::GetNextEntry() until the required entry is found. This works both for archives on seekable and non-seekable streams.

The format of filenames in the archive is likely to be different from the local filename format. For example zips and tars use unix style names, with forward slashes as the path separator, and absolute paths are not allowed. So if on Windows the file "C:\MYDIR\MYFILE.TXT" is stored, then when reading the entry back wxArchiveEntry::GetName() will return "MYDIR\MYFILE.TXT". The conversion into the internal format and back has lost some information.

So to avoid ambiguity when searching for an entry matching a local name, it is better to convert the local name to the archive's internal format and search for that:

```
auto_ptr<wxZipEntry> entry;

// convert the local name we are looking for into the internal format
wxString name = wxZipEntry::GetInternalName(localname);

// open the zip
wxFFileInputStream in(wxT("test.zip"));
wxZipInputStream zip(in);

// call GetNextEntry() until the required internal name is found
do
{
    entry.reset(zip.GetNextEntry());
}
while (entry.get() != NULL && entry->GetInternalName() != name);

if (entry.get() != NULL)
{
    // read the entry's data...
}
```

To access several entries randomly, it is most efficient to transfer the entire catalogue of entries to a container such as a std::map or a wxHashMap then entries looked up by name can be opened using the wxArchiveInputStream::OpenEntry() method.

```
WX_DECLARE_STRING_HASH_MAP(wxZipEntry*, ZipCatalog);
ZipCatalog::iterator it;
wxZipEntry *entry;
ZipCatalog cat;

// open the zip
wxFFileInputStream in(wxT("test.zip"));
wxZipInputStream zip(in);

// load the zip catalog
while ((entry = zip.GetNextEntry()) != NULL)
{
    wxZipEntry*& current = cat[entry->GetInternalName()];
    // some archive formats can have multiple entries with the same name
    // (e.g. tar) though it is an error in the case of zip
    delete current;
    current = entry;
}

// open an entry by name
if ((it = cat.find(wxZipEntry::GetInternalName(localname))) != cat.end())
{
    zip.OpenEntry(*it->second);
    // ... now read entry's data
}
```

To open more than one entry simultaneously you need more than one underlying stream on the same archive:

```
// opening another entry without closing the first requires another
// input stream for the same file
wxFFileInputStream in2(wxT("test.zip"));
wxZipInputStream zip2(in2);
if ((it = cat.find(wxZipEntry::GetInternalName(local2))) != cat.end())
    zip2.OpenEntry(*it->second);
```

10.30.5 Generic Archive Programming

Also see wxFileSystem for a higher level interface that can handle archive files in a generic way.

The specific archive classes, such as the wxZip classes, inherit from the following abstract classes which can be used to write code that can handle any of the archive types:

- wxArchiveInputStream: Input stream
- wxArchiveOutputStream: Output stream
- wxArchiveEntry: Holds the meta-data for an entry (e.g. filename)

In order to able to write generic code it's necessary to be able to create instances of the classes without knowing which archive type is being used.

To allow this there is a class factory for each archive type, derived from wxArchiveClassFactory, that can create the other classes.

For example, given wxArchiveClassFactory* factory, streams and entries can be created like this:

```
// create streams without knowing their type
auto_ptr<wxArchiveInputStream> inarc(factory->NewStream(in));
auto_ptr<wxArchiveOutputStream> outarc(factory->NewStream(out));

// create an empty entry object
auto_ptr<wxArchiveEntry> entry(factory->NewEntry());
```

For the factory itself, the static member wxArchiveClassFactory::Find() can be used to find a class factory that can handle a given file extension or mime type. For example, given *filename:*

```
const wxArchiveClassFactory *factory;
factory = wxArchiveClassFactory::Find(filename,
      wxSTREAM_FILEEXT);

if (factory)
    stream = factory->NewStream(new wxFFileInputStream(filename));
```

Find() does not give away ownership of the returned pointer, so it does not need to be deleted.

There are similar class factories for the filter streams that handle the compression and decompression of a single stream, such as wxGzipInputStream. These can be found using wxFilterClassFactory::Find().

For example, to list the contents of archive *filename:*

```
auto_ptr<wxInputStream> in(new wxFFileInputStream(filename));

if (in->IsOk())
{
    // look for a filter handler, e.g. for '.gz'
    const wxFilterClassFactory *fcf;
    fcf = wxFilterClassFactory::Find(filename,
      wxSTREAM_FILEEXT);
    if (fcf)
    {
        in.reset(fcf->NewStream(in.release()));
        // pop the extension, so if it was '.tar.gz' it is now just '.tar'
        filename = fcf->PopExtension(filename);
    }

    // look for a archive handler, e.g. for '.zip' or '.tar'
    const wxArchiveClassFactory *acf;
    acf = wxArchiveClassFactory::Find(filename,
      wxSTREAM_FILEEXT);
    if (acf)
    {
        auto_ptr<wxArchiveInputStream> arc(acf->NewStream(in.release()));
        auto_ptr<wxArchiveEntry> entry;

        // list the contents of the archive
        while ((entry.reset(arc->GetNextEntry())), entry.get() != NULL)
            std::wcout << entry->GetName().c_str() << "\n";
    }
    else
    {
        wxLogError(wxT("can't handle '%s'"), filename.c_str());
    }
}
```

10.30.6 Archives on Non-Seekable Streams

In general, handling archives on non-seekable streams is done in the same way as for seekable streams, with a few caveats.

The main limitation is that accessing entries randomly using wxArchiveInputStream::OpenEntry() is not possible, the entries can only be accessed sequentially in the order they are stored within the archive.

For each archive type, there will also be other limitations which will depend on the order the entries' meta-data is stored within the archive. These are not too difficult to deal with, and are outlined below.

PutNextEntry and the Entry Size

When writing archives, some archive formats store the entry size before the entry's data (tar has this limitation, zip doesn't). In this case the entry's size must be passed to wxArchiveOutputStream::PutNextEntry() or an error occurs.

This is only an issue on non-seekable streams, since otherwise the archive output stream can seek back and fix up the header once the size of the entry is known.

For generic programming, one way to handle this is to supply the size whenever it is known, and rely on the error message from the output stream when the operation is not supported.

GetNextEntry and the Weak Reference Mechanism

Some archive formats do not store all an entry's meta-data before the entry's data (zip is an example). In this case, when reading from a non-seekable stream, wxArchiveInputStream::GetNextEntry() can only return a partially populated wxArchiveEntry object - not all the fields are set.

The input stream then keeps a weak reference to the entry object and updates it when more meta-data becomes

available. A weak reference being one that does not prevent you from deleting the wxArchiveEntry object - the input stream only attempts to update it if it is still around.

The documentation for each archive entry type gives the details of what meta-data becomes available and when. For generic programming, when the worst case must be assumed, you can rely on all the fields of wxArchiveEntry being fully populated when GetNextEntry() returns, with the following exceptions:

- wxArchiveEntry::GetSize(): Guaranteed to be available after the entry has been read to wxInputStream::Eof(), or wxArchiveInputStream::CloseEntry() has been called.
- wxArchiveEntry::IsReadOnly(): Guaranteed to be available after the end of the archive has been reached, i.e. after GetNextEntry() returns NULL and Eof() is true.

This mechanism allows wxArchiveOutputStream::CopyEntry() to always fully preserve entries' meta-data. No matter what order order the meta-data occurs within the archive, the input stream will always have read it before the output stream must write it.

wxArchiveNotifier

Notifier objects can be used to get a notification whenever an input stream updates a wxArchiveEntry object's data via the weak reference mechanism.

Consider the following code which renames an entry in an archive. This is the usual way to modify an entry's meta-data, simply set the required field before writing it with wxArchiveOutputStream::CopyEntry():

```
auto_ptr<wxArchiveInputStream> arc(factory->NewStream(in));
auto_ptr<wxArchiveOutputStream> outarc(factory->NewStream(out));
auto_ptr<wxArchiveEntry> entry;

outarc->CopyArchiveMetaData(*arc);

while (entry.reset(arc->GetNextEntry()), entry.get() != NULL)
{
    if (entry->GetName() == from)
        entry->SetName(to);
    if (!outarc->CopyEntry(entry.release(), *arc))
        break;
}

bool success = arc->Eof() && outarc->Close();
```

However, for non-seekable streams, this technique cannot be used for fields such as wxArchiveEntry::IsReadOnly(), which are not necessarily set when wxArchiveInputStream::GetNextEntry() returns.

In this case a wxArchiveNotifier can be used:

```
class MyNotifier : public wxArchiveNotifier
{
public:
    void OnEntryUpdated(wxArchiveEntry& entry) { entry.
      SetIsReadOnly(false); }
};
```

The meta-data changes are done in your notifier's wxArchiveNotifier::OnEntryUpdated() method, then wxArchive↩ Entry::SetNotifier() is called before CopyEntry():

```
auto_ptr<wxArchiveInputStream> arc(factory->NewStream(in));
auto_ptr<wxArchiveOutputStream> outarc(factory->NewStream(out));
auto_ptr<wxArchiveEntry> entry;
MyNotifier notifier;

outarc->CopyArchiveMetaData(*arc);

while (entry.reset(arc->GetNextEntry()), entry.get() != NULL)
{
    entry->SetNotifier(notifier);
    if (!outarc->CopyEntry(entry.release(), *arc))
        break;
}

bool success = arc->Eof() && outarc->Close();
```

SetNotifier() calls OnEntryUpdated() immediately, then the input stream calls it again whenever it sets more fields in the entry. Since OnEntryUpdated() will be called at least once, this technique always works even when it is not strictly necessary to use it. For example, changing the entry name can be done this way too and it works on seekable streams as well as non-seekable.

10.31 Interprocess Communication

wxWidgets has a number of different classes to help with interprocess communication and network programming.

This section only discusses one family of classes – the DDE-like protocol – but here's a list of other useful classes:

- wxSocketEvent, wxSocketBase, wxSocketClient, wxSocketServer - Classes for the low-level TCP/IP API.
- wxProtocol, wxURL, wxFTP, wxHTTP - Classes for programming popular Internet protocols.

wxWidgets' DDE-like protocol is a high-level protocol based on Windows DDE. There are two implementations of this DDE-like protocol: one using real DDE running on Windows only, and another using TCP/IP (sockets) that runs on most platforms. Since the API and virtually all of the behaviour is the same apart from the names of the classes, you should find it easy to switch between the two implementations.

Notice that by including <wx/ipc.h> you may define convenient synonyms for the IPC classes: wxServer for either wxDDEServer or wxTCPServer depending on whether DDE-based or socket-based implementation is used and the same thing for wxClient and wxConnection.

By default, the DDE implementation is used under Windows. DDE works within one computer only. If you want to use IPC between different workstations you should define wxUSE_DDE_FOR_IPC as 0 before including this header – this will force using TCP/IP implementation even under Windows.

The following description refers to wxWidgets, but remember that the equivalent wxTCP∗ and wxDDE∗ classes can be used in much the same way.

Three classes are central to the DDE-like API:

- wxClient - This represents the client application, and is used only within a client program.
- wxServer - This represents the server application, and is used only within a server program.
- wxConnection - This represents the connection from the client to the server. Both the client and the server use an instance of this class, one per connection. Most DDE transactions operate on this object.

Messages between applications are usually identified by three variables: connection object, topic name and item name. A data string is a fourth element of some messages. To create a connection (a conversation in Windows parlance), the client application uses wxClient::MakeConnection to send a message to the server object, with a string service name to identify the server and a topic name to identify the topic for the duration of the connection. Under Unix, the service name may be either an integer port identifier in which case an Internet domain socket will be used for the communications or a valid file name (which shouldn't exist and will be deleted afterwards) in which case a Unix domain socket is created.

SECURITY NOTE: Using Internet domain sockets is extremely insecure for IPC as there is absolutely no access control for them, use Unix domain sockets whenever possible!

The server then responds and either vetoes the connection or allows it. If allowed, both the server and client objects create wxConnection objects which persist until the connection is closed. The connection object is then used for sending and receiving subsequent messages between client and server - overriding virtual functions in your class derived from wxConnection allows you to handle the DDE messages.

To create a working server, the programmer must:

- Derive a class from wxConnection, providing handlers for various messages sent to the server side of a wxConnection (e.g. OnExecute, OnRequest, OnPoke). Only the handlers actually required by the application need to be overridden.

- Derive a class from wxServer, overriding OnAcceptConnection to accept or reject a connection on the basis of the topic argument. This member must create and return an instance of the derived connection class if the connection is accepted.
- Create an instance of your server object and call Create to activate it, giving it a service name.

To create a working client, the programmer must:

- Derive a class from wxConnection, providing handlers for various messages sent to the client side of a wxConnection (e.g. OnAdvise). Only the handlers actually required by the application need to be overridden.
- Derive a class from wxClient, overriding OnMakeConnection to create and return an instance of the derived connection class.
- Create an instance of your client object.
- When appropriate, create a new connection using wxClient::MakeConnection, with arguments host name (processed in Unix only, use 'localhost' for local computer), service name, and topic name for this connection. The client object will call OnMakeConnection to create a connection object of the derived class if the connection is successful.
- Use the wxConnection member functions to send messages to the server.

10.31.1 Data Transfer

These are the ways that data can be transferred from one application to another. These are methods of wxConnection.

- **Execute:** the client calls the server with a data string representing a command to be executed. This succeeds or fails, depending on the server's willingness to answer. If the client wants to find the result of the Execute command other than success or failure, it has to explicitly call Request.
- **Request:** the client asks the server for a particular data string associated with a given item string. If the server is unwilling to reply, the return value is NULL. Otherwise, the return value is a string (actually a pointer to the connection buffer, so it should not be deallocated by the application).
- **Poke:** The client sends a data string associated with an item string directly to the server. This succeeds or fails.
- **Advise:** The client asks to be advised of any change in data associated with a particular item. If the server agrees, the server will send an OnAdvise message to the client along with the item and data.

The default data type is wxCF_TEXT (ASCII text), and the default data size is the length of the null-terminated string. Windows-specific data types could also be used on the PC.

10.31.2 Examples

See the sample programs *server* and *client* in the IPC samples directory. Run the server, then the client. This demonstrates using the Execute, Request, and Poke commands from the client, together with an Advise loop: selecting an item in the server list box causes that item to be highlighted in the client list box.

10.31.3 More DDE Details

A wxClient object initiates the client part of a client-server DDE-like (Dynamic Data Exchange) conversation (available in both Windows and Unix).

To create a client which can communicate with a suitable server, you need to derive a class from wxConnection and another from wxClient. The custom wxConnection class will receive communications in a 'conversation' with a

server. and the custom wxServer is required so that a user-overridden wxClient::OnMakeConnection member can return a wxConnection of the required class, when a connection is made.

For example:

```
class MyConnection: public wxConnection
{
public:
    MyConnection(void)::wxConnection() { }
    ~MyConnection(void) { }

    bool OnAdvise(const wxString& topic, const wxString& item, char *data,
                  int size, wxIPCFormat format)
    {
        wxMessageBox(topic, data);
    }
};

class MyClient: public wxClient
{
public:
    MyClient(void) { }

    wxConnectionBase* OnMakeConnection(void)
    {
        return new MyConnection;
    }
};
```

Here, *MyConnection* will respond to OnAdvise messages sent by the server by displaying a message box.

When the client application starts, it must create an instance of the derived wxClient. In the following, command line arguments are used to pass the host name (the name of the machine the server is running on) and the server name (identifying the server process). Calling wxClient::MakeConnection implicitly creates an instance of *MyConnection* if the request for a connection is accepted, and the client then requests an *Advise* loop from the server (an Advise loop is where the server calls the client when data has changed).

```
wxString server = "4242";
wxString hostName;
wxGetHostName(hostName);

// Create a new client
MyClient *client = new MyClient;
connection = (MyConnection *)client->MakeConnection(hostName, server, "IPC TEST");

if (!connection)
{
    wxMessageBox("Failed to make connection to server", "Client Demo Error");
    return NULL;
}

connection->StartAdvise("Item");
```

10.32 Device Contexts

A wxDC is a *device* context onto which graphics and text can be drawn.

The device context is intended to represent a number of output devices in a generic way, with the same API being used throughout.

Some device contexts are created temporarily in order to draw on a window. This is true of wxScreenDC, wxClientDC, wxPaintDC, and wxWindowDC. The following describes the differences between these device contexts and when you should use them.

- **wxScreenDC**. Use this to paint on the screen, as opposed to an individual window.
- **wxClientDC**. Use this to paint on the client area of window (the part without borders and other decorations), but do not use it from within an wxPaintEvent.
- **wxPaintDC**. Use this to paint on the client area of a window, but *only* from within a wxPaintEvent.

- **wxWindowDC**. Use this to paint on the whole area of a window, including decorations. This may not be available on non-Windows platforms.

To use a client, paint or window device context, create an object on the stack with the window as argument, for example:

```
void MyWindow::OnMyCmd(wxCommandEvent& event)
{
    wxClientDC dc(window);
    DrawMyPicture(dc);
}
```

Try to write code so it is parameterised by wxDC - if you do this, the same piece of code may write to a number of different devices, by passing a different device context. This doesn't work for everything (for example not all device contexts support bitmap drawing) but will work most of the time.

See also

Device Contexts

10.33 Bitmaps and Icons

The wxBitmap class encapsulates the concept of a platform-dependent bitmap, either monochrome or colour.

Platform-specific methods for creating a wxBitmap object from an existing file are catered for, and this is an occasion where conditional compilation will sometimes be required.

A bitmap created dynamically or loaded from a file can be selected into a memory device context (instance of wxMemoryDC). This enables the bitmap to be copied to a window or memory device context using wxDC::Blit(), or to be used as a drawing surface.

See wxMemoryDC for an example of drawing onto a bitmap.

All wxWidgets platforms support XPMs for small bitmaps and icons. You may include the XPM inline as below, since it's C code, or you can load it at run-time.

```
#include "sample.xpm"
```

Sometimes you wish to use a .ico resource on Windows, and XPMs on other platforms (for example to take advantage of Windows' support for multiple icon resolutions).

A macro, wxICON(), is available which creates an icon using an XPM on the appropriate platform, or an icon resource on Windows:

```
wxIcon icon(wxICON(sample));

// The above line is equivalent to this:

#if defined(__WXGTK__) || defined(__WXMOTIF__)
    wxIcon icon(sample_xpm);
#endif

#if defined(__WXMSW__)
    wxIcon icon("sample");
#endif
```

There is also a corresponding wxBITMAP() macro which allows to create the bitmaps in much the same way as wxICON() creates icons. It assumes that bitmaps live in resources under Windows and XPM files under all other platforms (for XPMs, the corresponding file must be included before this macro is used, of course, and the name of the bitmap should be the same as the resource name under Windows with _xpm suffix). For example:

```
// an easy and portable way to create a bitmap
wxBitmap bmp(wxBITMAP(bmpname));

// which is roughly equivalent to the following
```

```
#if defined(__WXMSW__)
    wxBitmap bmp("bmpname", wxBITMAP_TYPE_BMP_RESOURCE);
#else // Unix
    wxBitmap bmp(bmpname_xpm, wxBITMAP_TYPE_XPM);
#endif
```

You should always use wxICON() and wxBITMAP() macros because they work for any platform (unlike the code above which doesn't deal with wxMac, wxX11, ...) and are shorter and more clear than versions with many #ifdef blocks. Alternatively, you could use the same XPMs on all platforms and avoid dealing with Windows resource files.

If you'd like to embed bitmaps with alpha transparency in your program, neither XPM nor BMP formats are appropriate as they don't have support for alpha and another format, typically PNG, should be used. wxWidgets provides a similar helper for PNG bitmaps called wxBITMAP_PNG() that can be used to either load PNG files embedded in resources (meaning either Windows resource section of the executable file or OS X "Resource" subdirectory of the application bundle) or arrays containing PNG data included into the program code itself.

See also

Graphics Device Interface (GDI)

10.33.1 Supported Bitmap File Formats

The following lists the formats handled on different platforms. Note that missing or partially-implemented formats are automatically supplemented by using wxImage to load the data, and then converting it to wxBitmap form. Note that using wxImage is the preferred way to load images in wxWidgets, with the exception of resources (XPM-files or native Windows resources).

Writing an image format handler for wxImage is also far easier than writing one for wxBitmap, because wxImage has exactly one format on all platforms whereas wxBitmap can store pixel data very differently, depending on colour depths and platform.

wxBitmap

Under Windows, wxBitmap may load the following formats:

```
@li Windows bitmap resource (wxBITMAP_TYPE_BMP_RESOURCE)
@li Windows bitmap file (wxBITMAP_TYPE_BMP)
@li XPM data and file (wxBITMAP_TYPE_XPM)
@li All formats that are supported by the wxImage class.
```

Under wxGTK, wxBitmap may load the following formats:

```
@li XPM data and file (wxBITMAP_TYPE_XPM)
@li All formats that are supported by the wxImage class.
```

Under wxMotif and wxX11, wxBitmap may load the following formats:

```
@li XBM data and file (wxBITMAP_TYPE_XBM)
@li XPM data and file (wxBITMAP_TYPE_XPM)
@li All formats that are supported by the wxImage class.
```

wxIcon

Under Windows, wxIcon may load the following formats:

```
@li Windows icon resource (wxBITMAP_TYPE_ICO_RESOURCE)
@li Windows icon file (wxBITMAP_TYPE_ICO)
@li XPM data and file (wxBITMAP_TYPE_XPM)
```

Under wxGTK, wxIcon may load the following formats:

```
@li XPM data and file (wxBITMAP_TYPE_XPM)
@li All formats that are supported by the wxImage class.
```

Under wxMotif and wxX11, wxIcon may load the following formats:

```
@li XBM data and file (wxBITMAP_TYPE_XBM)
@li XPM data and file (wxBITMAP_TYPE_XPM)
@li All formats that are supported by the wxImage class.
```

wxCursor

Under Windows, wxCursor may load the following formats:

```
@li Windows cursor resource (wxBITMAP_TYPE_CUR_RESOURCE)
@li Windows cursor file (wxBITMAP_TYPE_CUR)
@li Windows icon file (wxBITMAP_TYPE_ICO)
@li Windows bitmap file (wxBITMAP_TYPE_BMP)
```

Under wxGTK, wxCursor may load the following formats (in addition to stock cursors):

```
@li None (stock cursors only).
```

Under wxMotif and wxX11, wxCursor may load the following formats:

```
@li XBM data and file (wxBITMAP_TYPE_XBM)
```

10.33.2 Bitmap Format Handlers

To provide extensibility, the functionality for loading and saving bitmap formats is not implemented in the wxBitmap class, but in a number of handler classes, derived from wxBitmapHandler. There is a static list of handlers which wxBitmap examines when a file load/save operation is requested.

Some handlers are provided as standard, but if you have special requirements, you may wish to initialise the wxBitmap class with some extra handlers which you write yourself or receive from a third party.

To add a handler object to wxBitmap, your application needs to include the header which implements it, and then call the static function wxBitmap::AddHandler().

Note

Bitmap handlers are not implemented on all platforms, and new ones rarely need to be implemented since wxImage can be used for loading most formats, as noted earlier.

10.34 wxFont Overview

A font is an object which determines the appearance of text, primarily when drawing text to a window or device context.

A font is determined by the following parameters (not all of them have to be specified, of course):

Point size	This is the standard way of referring to text size.
Family	Supported families are: **wxDEFAULT**, **wxDECORATIVE**, **wxROMAN**, **wxSCRIPT**, **wxSWISS**, **wxMODERN**. **wxMODERN** is a fixed pitch font; the others are either fixed or variable pitch.
Style	The value can be **wxNORMAL**, **wxSLANT** or **wxITALIC**.
Weight	The value can be **wxNORMAL**, **wxLIGHT** or **wxBOLD**.
Underlining	The value can be true or false.
Face name	An optional string specifying the actual typeface to be used. If NULL, a default typeface will chosen based on the family.
Encoding	The font encoding (see **wxFONTENCODING_XXX** constants and the Font Encodings for more details)

Specifying a family, rather than a specific typeface name, ensures a degree of portability across platforms because a suitable font will be chosen for the given font family, however it doesn't allow to choose a font precisely as the parameters above don't suffice, in general, to identify all the available fonts and this is where using the native font descriptions may be helpful - see below.

Under Windows, the face name can be one of the installed fonts on the user's system. Since the choice of fonts differs from system to system, either choose standard Windows fonts, or if allowing the user to specify a face name, store the family name with any file that might be transported to a different Windows machine or other platform.

See also

wxFont, wxFontDialog

Note

There is currently a difference between the appearance of fonts on the two platforms, if the mapping mode is anything other than wxMM_TEXT. Under X, font size is always specified in points. Under MS Windows, the unit for text is points but the text is scaled according to the current mapping mode. However, user scaling on a device context will also scale fonts under both environments.

10.34.1 Native Font Information

An alternative way of choosing fonts is to use the native font description. This is the only acceptable solution if the user is allowed to choose the font using the wxFontDialog because the selected font cannot be described using only the family name and so, if only family name is stored permanently, the user would almost surely see a different font in the program later.

Instead, you should store the value returned by wxFont::GetNativeFontInfoDesc and pass it to wxFont::SetNativeFontInfo later to recreate exactly the same font.

Note that the contents of this string depends on the platform and shouldn't be used for any other purpose (in particular, it is not meant to be shown to the user). Also please note that although the native font information is currently implemented for Windows and Unix (GTK+ and Motif) ports only, all the methods are available for all the ports and should be used to make your program work correctly when they are implemented later.

10.35 Font Encodings

wxWidgets has support for multiple font encodings.

By encoding we mean here the mapping between the character codes and the letters. Probably the most well-known encoding is (7 bit) ASCII one which is used almost universally now to represent the letters of the English alphabet and some other common characters. However, it is not enough to represent the letters of foreign alphabets and

here other encodings come into play. Please note that we will only discuss 8-bit fonts here and not Unicode (see Unicode Support in wxWidgets).

Font encoding support is ensured by several classes: wxFont itself, but also wxFontEnumerator and wxFontMapper. wxFont encoding support is reflected by a (new) constructor parameter *encoding* which takes one of the following values (elements of enumeration type `wxFontEncoding`):

wxFONTENCODING_SYSTEM	The default encoding of the underlying operating system (notice that this might be a "foreign" encoding for foreign versions of Windows 9x/NT).
wxFONTENCODING_DEFAULT	The applications default encoding as returned by wxFont::GetDefaultEncoding. On program startup, the applications default encoding is the same as wxFONTENCODING_SYSTEM, but may be changed to make all the fonts created later to use it (by default).
wxFONTENCODING_ISO8859_1..15	ISO8859 family encodings which are usually used by all non-Microsoft operating systems.
wxFONTENCODING_KOI8	Standard Cyrillic encoding for the Internet (but see also wxFONTENCODING_ISO8859_5 and wxFONTENCODING_CP1251).
wxFONTENCODING_CP1250	Microsoft analogue of ISO8859-2
wxFONTENCODING_CP1251	Microsoft analogue of ISO8859-5
wxFONTENCODING_CP1252	Microsoft analogue of ISO8859-1

As you may see, Microsoft's encoding partly mirror the standard ISO8859 ones, but there are (minor) differences even between ISO8859-1 (Latin1, ISO encoding for Western Europe) and CP1251 (WinLatin1, standard code page for English versions of Windows) and there are more of them for other encodings.

The situation is particularly complicated with Cyrillic encodings for which (more than) three incompatible encodings exist: KOI8 (the old standard, widely used on the Internet), ISO8859-5 (ISO standard for Cyrillic) and CP1251 (WinCyrillic).

This abundance of (incompatible) encodings should make it clear that using encodings is less easy than it might seem. The problems arise both from the fact that the standard encodings for the given language (say Russian, which is written in Cyrillic) are different on different platforms and because the fonts in the given encoding might just not be installed (this is especially a problem with Unix, or, in general, non-Win32 systems).

To clarify, the wxFontEnumerator class may be used to enumerate both all available encodings and to find the facename(s) in which the given encoding exists. If you can find the font in the correct encoding with wxFontEnumerator then your troubles are over, but, unfortunately, sometimes this is not enough. For example, there is no standard way (that I know of, please tell me if you do!) to find a font on a Windows system for KOI8 encoding (only for WinCyrillic one which is quite different), so wxFontEnumerator will never return one, even if the user has installed a KOI8 font on his system.

To solve this problem, a wxFontMapper class is provided.

This class stores the mapping between the encodings and the font face names which support them in wxConfigBase object. Of course, it would be fairly useless if it tried to determine these mappings by itself, so, instead, it (optionally) asks the user and remembers his answers so that the next time the program will automatically choose the correct font. All these topics are illustrated by the Font Sample; please refer to it and the documentation of the classes mentioned here for further explanations.

10.36 Printing Framework Overview

The printing framework relies on the application to provide classes whose member functions can respond to particular requests, such as 'print this page' or 'does this page exist in the document?'.

This method allows wxWidgets to take over the housekeeping duties of turning preview pages, calling the print dialog box, creating the printer device context, and so on: the application can concentrate on the rendering of the information onto a device context.

In most cases, the only class you will need to derive from is wxPrintout; all others will be used as-is.

A brief description of each class's role and how they work together follows.

For the special case of printing under Unix, where various different printing backends have to be offered, please have a look at Printing Under Unix (GTK+).

See also

Printing Framework

10.36.1 wxPrintout

A document's printing ability is represented in an application by a derived wxPrintout class. This class prints a page on request, and can be passed to the Print function of a wxPrinter object to actually print the document, or can be passed to a wxPrintPreview object to initiate previewing. The following code (from the printing sample) shows how easy it is to initiate printing, previewing and the print setup dialog, once the wxPrintout functionality has been defined. Notice the use of MyPrintout for both printing and previewing. All the preview user interface functionality is taken care of by wxWidgets. For more details on how MyPrintout is defined, please look at the printout sample code.

```
case WXPRINT_PRINT:
{
    wxPrinter printer;
    MyPrintout printout("My printout");
    printer.Print(this, &printout, true);
    break;
}
case WXPRINT_PREVIEW:
{
    // Pass two printout objects: for preview, and possible printing.
    wxPrintPreview *preview = new wxPrintPreview(new MyPrintout, new MyPrintout
      );
    wxPreviewFrame *frame = new wxPreviewFrame(preview, this,
                                               "Demo Print Preview",
                                               wxPoint(100, 100),
                                               wxSize(600, 650));
    frame->Centre(wxBOTH);
    frame->Initialize();
    frame->Show(true);
    break;
}
```

wxPrintout assembles the printed page and (using your subclass's overrides) writes requested pages to a wxDC that is passed to it. This wxDC could be a wxMemoryDC (for displaying the preview image on-screen), a wxPrinterDC (for printing under MSW and Mac), or a wxPostScriptDC (for printing under GTK or generating PostScript output).

The document/view framework creates a default wxPrintout object for every view, calling wxView::OnDraw() to achieve a prepackaged print/preview facility.

If your window classes have a Draw(wxDC *dc) routine to do screen rendering, your wxPrintout subclass will typically call those routines to create portions of the image on your printout. Your wxPrintout subclass can also make its own calls to its wxDC to draw headers, footers, page numbers, etc.

The scaling of the drawn image typically differs from the screen to the preview and printed images. This class provides a set of routines named FitThisSizeToXXX(), MapScreenSizeToXXX(), and GetLogicalXXXRect, which can be used to set the user scale and origin of the wxPrintout's DC so that your class can easily map your image to the printout without getting into the details of screen and printer PPI and scaling. See the printing sample for examples of how these routines are used.

10.36.2 wxPrinter

Class wxPrinter encapsulates the platform-dependent print function with a common interface. In most cases, you will not need to derive a class from wxPrinter; simply create a wxPrinter object in your Print function as in the example above.

10.36.3 wxPrintPreview

Class wxPrintPreview manages the print preview process. Among other things, it constructs the wxDCs that get passed to your wxPrintout subclass for printing and manages the display of multiple pages, a zoomable preview image, and so forth. In most cases you will use this class as-is, but you can create your own subclass, for example, to change the layout or contents of the preview window.

10.36.4 wxPrinterDC

Class wxPrinterDC is the wxDC that represents the actual printed page under MSW and Mac. During printing, an object of this class will be passed to your derived wxPrintout object to draw upon. The size of the wxPrinterDC will depend on the paper orientation and the resolution of the printer.

There are two important rectangles in printing: the *page rectangle* defines the printable area seen by the application, and under MSW and Mac, it is the printable area specified by the printer. (For PostScript printing, the page rectangle is the entire page.) The inherited function wxDC::GetSize() returns the page size in device pixels. The point (0,0) on the wxPrinterDC represents the top left corner of the page rectangle; that is, the page rect is given by wxRect(0, 0, w, h), where (w,h) are the values returned by GetSize.

The *paper rectangle*, on the other hand, represents the entire paper area including the non-printable border. Thus, the coordinates of the top left corner of the paper rectangle will have small negative values, while the width and height will be somewhat larger than that of the page rectangle. The wxPrinterDC-specific function wxPrinterDC::GetPaperRect() returns the paper rectangle of the given wxPrinterDC.

10.36.5 wxPostScriptDC

Class wxPostScriptDC is the wxDC that represents the actual printed page under GTK and other PostScript printing. During printing, an object of this class will be passed to your derived wxPrintout object to draw upon. The size of the wxPostScriptDC will depend upon the wxPrintData used to construct it.

Unlike a wxPrinterDC, there is no distinction between the page rectangle and the paper rectangle in a wxPostScriptDC; both rectangles are taken to represent the entire sheet of paper.

10.36.6 wxPrintDialog

Class wxPrintDialog puts up the standard print dialog, which allows you to select the page range for printing (as well as many other print settings, which may vary from platform to platform). You provide an object of type wxPrintDialogData to the wxPrintDialog at construction, which is used to populate the dialog.

10.36.7 wxPrintData

Class wxPrintData is a subset of wxPrintDialogData that is used (internally) to initialize a wxPrinterDC or wxPostScriptDC. (In fact, a wxPrintData is a data member of a wxPrintDialogData and a wxPageSetupDialogData). Essentially, wxPrintData contains those bits of information from the two dialogs necessary to configure the wxPrinterDC or wxPostScriptDC (e.g., size, orientation, etc.). You might wish to create a global instance of this object to provide call-to-call persistence to your application's print settings.

10.36.8 wxPrintDialogData

Class wxPrintDialogData contains the settings entered by the user in the print dialog. It contains such things as page range, number of copies, and so forth. In most cases, you won't need to access this information; the framework takes care of asking your wxPrintout derived object for the pages requested by the user.

10.36.9 wxPageSetupDialog

Class wxPageSetupDialog puts up the standard page setup dialog, which allows you to specify the orientation, paper size, and related settings. You provide it with a wxPageSetupDialogData object at initialization, which is used to populate the dialog; when the dialog is dismissed, this object contains the settings chosen by the user, including orientation and/or page margins.

Note that on Macintosh, the native page setup dialog does not contain entries that allow you to change the page margins. You can use the Mac-specific class wxMacPageMarginsDialog (which, like wxPageSetupDialog, takes a wxPageSetupDialogData object in its constructor) to provide this capability; see the printing sample for an example.

10.36.10 wxPageSetupDialogData

Class wxPageSetupDialogData contains settings affecting the page size (paper size), orientation, margins, and so forth. Note that not all platforms populate all fields; for example, the MSW page setup dialog lets you set the page margins while the Mac setup dialog does not.

You will typically create a global instance of each of a wxPrintData and wxPageSetupDialogData at program initiation, which will contain the default settings provided by the system. Each time the user calls up either the wxPrintDialog or the wxPageSetupDialog, you pass these data structures to initialize the dialog values and to be updated by the dialog. The framework then queries these data structures to get information like the printed page range (from the wxPrintDialogData) or the paper size and/or page orientation (from the wxPageSetupDialogData).

10.37 Printing Under Unix (GTK+)

Printing under Unix has always been a cause of problems as Unix does not provide a standard way to display text and graphics on screen and print it to a printer using the same application programming interface - instead, displaying on screen is done via the X11 library while printing has to be done with using PostScript commands.

This was particularly difficult to handle for the case of fonts with the result that only a selected number of application could offer WYSIWYG under Unix. Equally, wxWidgets offered its own printing implementation using PostScript which never really matched the screen display.

Since GTK+ 2.10, support for printing has been added to GTK+ itself and beginning with wxWidgets 2.9, GTK+ printing is used by default (i.e. unless `-without-gtkprint` was explicitly used when configuring the library). Support for GTK+ print is detected dynamically, i.e. during the run-time: if it is found, printing will be done through GTK+, otherwise the application will fall back to the old PostScript printing code. This allows the applications built with wxWidgets to still work on the very old systems using GTK+ earlier than 2.10.

10.38 Sizers Overview

Sizers, as represented by the wxSizer class and its descendants in the wxWidgets class hierarchy, have become the method of choice to define the layout of controls in dialogs in wxWidgets because of their ability to create visually appealing dialogs independent of the platform, taking into account the differences in size and style of the individual controls.

Unlike the original wxWidgets Dialog Editor, editors such as wxDesigner, DialogBlocks, XRCed and wxWorkshop create dialogs based exclusively on sizers, practically forcing the user to create platform independent layouts without compromises.

The next section describes and shows what can be done with sizers. The following sections briefly describe how to program with individual sizer classes.

For information about the wxWidgets resource system, which can describe sizer-based dialogs, see the XML Based Resource System (XRC).

wxSizer, wxBoxSizer, wxStaticBoxSizer, wxGridSizer, wxFlexGridSizer, wxGridBagSizer

10.38.1 The Idea Behind Sizers

The layout algorithm used by sizers in wxWidgets is closely related to layout systems in other GUI toolkits, such as Java's AWT, the GTK toolkit or the Qt toolkit. It is based upon the idea of individual subwindows reporting their minimal required size and their ability to get stretched if the size of the parent window has changed. This will most often mean that the programmer does not set the start-up size of a dialog, the dialog will rather be assigned a sizer and this sizer will be queried about the recommended size. This sizer in turn will query its children (which can be normal windows, empty space or other sizers) so that a hierarchy of sizers can be constructed. Note that wxSizer does not derive from wxWindow and thus does not interfere with tab ordering and requires very few resources compared to a real window on screen.

What makes sizers so well fitted for use in wxWidgets is the fact that every control reports its own minimal size and the algorithm can handle differences in font sizes or different window (dialog item) sizes on different platforms without problems. For example, if the standard font as well as the overall design of Linux/GTK widgets requires more space than on Windows, the initial dialog size will automatically be bigger on Linux/GTK than on Windows.

There are currently five different kinds of sizers available in wxWidgets. Each represents either a certain way to lay out dialog items in a dialog or it fulfills a special task such as wrapping a static box around a dialog item (or another sizer). These sizers will be discussed one by one in the text below. For more detailed information on how to use sizers programmatically, please refer to the section Programming with wxBoxSizer.

10.38.2 Common Features

All sizers are containers, that is, they are used to lay out one dialog item (or several dialog items), which they contain. Such items are sometimes referred to as the children of the sizer. Independent of how the individual sizers lay out their children, all children have certain features in common:

A minimal size: This minimal size is usually identical to the initial size of the controls and may either be set explicitly in the wxSize field of the control constructor or may be calculated by wxWidgets, typically by setting the height and/or the width of the item to -1. Note that only some controls can calculate their size (such as a checkbox) whereas others (such as a listbox) don't have any natural width or height and thus require an explicit size. Some controls can calculate their height, but not their width (e.g. a single line text control):

A border: The border is just empty space and is used to separate dialog items in a dialog. This border can either be all around, or at any combination of sides such as only above and below the control. The thickness of this border must be set explicitly, typically 5 points. The following samples show dialogs with only one dialog item (a button) and a border of 0, 5, and 10 pixels around the button:

An alignment: Often, a dialog item is given more space than its minimal size plus its border. Depending on what flags are used for the respective dialog item, the dialog item can be made to fill out the available space entirely, i.e. it will grow to a size larger than the minimal size, or it will be moved to either the centre of the available space or to either side of the space. The following sample shows a listbox and three buttons in a horizontal box sizer; one button is centred, one is aligned at the top, one is aligned at the bottom:

A stretch factor: If a sizer contains more than one child and it is offered more space than its children and their borders need, the question arises how to distribute the surplus space among the children. For this purpose, a stretch factor may be assigned to each child, where the default value of 0 indicates that the child will not get more space than its requested minimum size. A value of more than zero is interpreted in relation to the sum of all stretch factors in the children of the respective sizer, i.e. if two children get a stretch factor of 1, they will get half the extra space each *independent of whether one control has a minimal sizer inferior to the other or not*. The following sample shows a dialog with three buttons, the first one has a stretch factor of 1 and thus gets stretched, whereas the other two buttons have a stretch factor of zero and keep their initial width:

Within wxDesigner, this stretch factor gets set from the *Option* menu.

10.38.3 Hiding Controls Using Sizers

You can hide controls contained in sizers the same way you would hide any control, using the wxWindow::Show method. However, wxSizer also offers a separate method which can tell the sizer not to consider that control in its size calculations. To hide a window using the sizer, call wxSizer::Show. You must then call Layout on the sizer to force an update.

This is useful when hiding parts of the interface, since you can avoid removing the controls from the sizer and having to add them back later.

Note

This is supported only by wxBoxSizer and wxFlexGridSizer.

wxBoxSizer

wxBoxSizer can lay out its children either vertically or horizontally, depending on what flag is being used in its constructor. When using a vertical sizer, each child can be centered, aligned to the right or aligned to the left. Correspondingly, when using a horizontal sizer, each child can be centered, aligned at the bottom or aligned at the top. The stretch factor described in the last paragraph is used for the main orientation, i.e. when using a horizontal box sizer, the stretch factor determines how much the child can be stretched horizontally. The following sample shows the same dialog as in the last sample, only the box sizer is a vertical box sizer now:

wxStaticBoxSizer

wxStaticBoxSixer is the same as a wxBoxSizer, but surrounded by a static box. Here is a sample:

wxGridSizer

wxGridSizer is a two-dimensional sizer. All children are given the same size, which is the minimal size required by the biggest child, in this case the text control in the left bottom border. Either the number of columns or the number or rows is fixed and the grid sizer will grow in the respectively other orientation if new children are added:

For programming information, see wxGridSizer.

wxFlexGridSizer

Another two-dimensional sizer derived from wxGridSizer. The width of each column and the height of each row are calculated individually according to the minimal requirements from the respectively biggest child. Additionally, columns and rows can be declared to be stretchable if the sizer is assigned a size different from the one it requested. The following sample shows the same dialog as the one above, but using a flex grid sizer:

10.38.4 Programming with wxBoxSizer

The basic idea behind a wxBoxSizer is that windows will most often be laid out in rather simple basic geometry, typically in a row or a column or several hierarchies of either.

As an example, we will construct a dialog that will contain a text field at the top and two buttons at the bottom. This can be seen as a top-hierarchy column with the text at the top and buttons at the bottom and a low-hierarchy row with an OK button to the left and a Cancel button to the right. In many cases (particularly dialogs under Unix and normal frames) the main window will be resizable by the user and this change of size will have to get propagated to its children. In our case, we want the text area to grow with the dialog, whereas the button shall have a fixed size. In addition, there will be a thin border around all controls to make the dialog look nice and - to make matter worse - the buttons shall be centred as the width of the dialog changes.

It is the unique feature of a box sizer, that it can grow in both directions (height and width) but can distribute its growth in the main direction (horizontal for a row) *unevenly* among its children. In our example case, the vertical

sizer is supposed to propagate all its height changes to only the text area, not to the button area. This is determined by the *proportion* parameter when adding a window (or another sizer) to a sizer. It is interpreted as a weight factor, i.e. it can be zero, indicating that the window may not be resized at all, or above zero. If several windows have a value above zero, the value is interpreted relative to the sum of all weight factors of the sizer, so when adding two windows with a value of 1, they will both get resized equally much and each half as much as the sizer owning them. Then what do we do when a column sizer changes its width? This behaviour is controlled by *flags* (the second parameter of the Add() function): Zero or no flag indicates that the window will preserve it is original size, wxGR↩ OW flag (same as wxEXPAND) forces the window to grow with the sizer, and wxSHAPED flag tells the window to change it is size proportionally, preserving original aspect ratio. When wxGROW flag is not used, the item can be aligned within available space. wxALIGN_LEFT, wxALIGN_TOP, wxALIGN_RIGHT, wxALIGN_BOTTOM, wxALIG↩ N_CENTER_HORIZONTAL and wxALIGN_CENTER_VERTICAL do what they say. wxALIGN_CENTRE (same as wxALIGN_CENTER) is defined as (wxALIGN_CENTER_HORIZONTAL | wxALIGN_CENTER_VERTICAL). Default alignment is wxALIGN_LEFT | wxALIGN_TOP.

As mentioned above, any window belonging to a sizer may have a border, and it can be specified which of the four sides may have this border, using the wxTOP, wxLEFT, wxRIGHT and wxBOTTOM constants or wxALL for all directions (and you may also use wxNORTH, wxWEST etc instead). These flags can be used in combination with the alignment flags above as the second parameter of the Add() method using the binary or operator |. The sizer of the border also must be made known, and it is the third parameter in the Add() method. This means, that the entire behaviour of a sizer and its children can be controlled by the three parameters of the Add() method.

```
// We want to get a dialog that is stretchable because it
// has a text ctrl at the top and two buttons at the bottom.

MyDialog::MyDialog(wxFrame *parent, wxWindowID id, const
      wxString &title )
: wxDialog(parent, id, title, wxDefaultPosition,
      wxDefaultSize,
           wxDEFAULT_DIALOG_STYLE | wxRESIZE_BORDER)
{
    wxBoxSizer *topsizer = new wxBoxSizer( wxVERTICAL );

    // create text ctrl with minimal size 100x60
    topsizer->Add(
        new wxTextCtrl( this, -1, "My text.", wxDefaultPosition,
      wxSize(100,60), wxTE_MULTILINE),
        1,            // make vertically stretchable
        wxEXPAND |    // make horizontally stretchable
        wxALL,        //   and make border all around
        10 );         // set border width to 10

    wxBoxSizer *button_sizer = new wxBoxSizer( wxHORIZONTAL );
    button_sizer->Add(
        new wxButton( this, wxID_OK, "OK" ),
        0,            // make horizontally unstretchable
        wxALL,        // make border all around (implicit top alignment)
        10 );         // set border width to 10
    button_sizer->Add(
        new wxButton( this, wxID_CANCEL, "Cancel" ),
        0,            // make horizontally unstretchable
        wxALL,        // make border all around (implicit top alignment)
        10 );         // set border width to 10

    topsizer->Add(
        button_sizer,
        0,                // make vertically unstretchable
        wxALIGN_CENTER ); // no border and centre horizontally

    SetSizerAndFit(topsizer); // use the sizer for layout and size window
                              // accordingly and prevent it from being resized
                              // to smaller size
}
```

Note that the new way of specifying flags to wxSizer is via wxSizerFlags. This class greatly eases the burden of passing flags to a wxSizer.

Here's how you'd do the previous example with wxSizerFlags:

```
// We want to get a dialog that is stretchable because it
// has a text ctrl at the top and two buttons at the bottom.

MyDialog::MyDialog(wxFrame *parent, wxWindowID id, const
      wxString &title )
: wxDialog(parent, id, title, wxDefaultPosition,
      wxDefaultSize,
```

```
            wxDEFAULT_DIALOG_STYLE | wxRESIZE_BORDER)
{
    wxBoxSizer *topsizer = new wxBoxSizer( wxVERTICAL );

    // create text ctrl with minimal size 100x60 that is horizontally and
    // vertically stretchable with a border width of 10
    topsizer->Add(
        new wxTextCtrl( this, -1, "My text.", wxDefaultPosition,
      wxSize(100,60), wxTE_MULTILINE),
        wxSizerFlags(1).Align().Expand().Border(wxALL, 10));

    wxBoxSizer *button_sizer = new wxBoxSizer( wxHORIZONTAL );

    //create two buttons that are horizontally unstretchable,
    // with an all-around border with a width of 10 and implicit top alignment
    button_sizer->Add(
        new wxButton( this, wxID_OK, "OK" ),
        wxSizerFlags(0).Align().Border(wxALL, 10));

    button_sizer->Add(
        new wxButton( this, wxID_CANCEL, "Cancel" ),
        wxSizerFlags(0).Align().Border(wxALL, 10));

    //create a sizer with no border and centered horizontally
    topsizer->Add(
        button_sizer,
        wxSizerFlags(0).Center() );

    SetSizerAndFit(topsizer); // use the sizer for layout and set size and hints
}
```

10.38.5 Other Types of Sizers

wxGridSizer is a sizer which lays out its children in a two-dimensional table with all table fields having the same size, i.e. the width of each field is the width of the widest child, the height of each field is the height of the tallest child.

wxFlexGridSizer is a sizer which lays out its children in a two-dimensional table with all table fields in one row having the same height and all fields in one column having the same width, but all rows or all columns are not necessarily the same height or width as in the wxGridSizer.

wxStaticBoxSizer is a sizer derived from wxBoxSizer but adds a static box around the sizer. Note that this static box has to be created separately.

wxGridBagSizer is a rather special kind of sizer which, unlike the other classes, allows to directly put the elements at the given position in the sizer. Please see its documentation for more details.

10.38.6 CreateButtonSizer

As a convenience, wxDialog::CreateButtonSizer(long flags) can be used to create a standard button sizer in which standard buttons are displayed. The following flags can be passed to this function:

```
wxYES_NO     // Add Yes/No subpanel
wxYES        // return wxID_YES
wxNO         // return wxID_NO
wxNO_DEFAULT // make the wxNO button the default,
             // otherwise wxYES or wxOK button will be default

wxOK     // return wxID_OK
wxCANCEL // return wxID_CANCEL
wxHELP   // return wxID_HELP

wxFORWARD   // return wxID_FORWARD
wxBACKWARD  // return wxID_BACKWARD
wxSETUP     // return wxID_SETUP
wxMORE      // return wxID_MORE
```

10.39 XML Based Resource System (XRC)

The XML-based resource system, known as XRC, allows user interface elements such as dialogs, menu bars and toolbars, to be stored in text files and loaded into the application at run-time.

XRC files can also be compiled into binary XRS files or C++ code (the former makes it possible to store all resources in a single file and the latter is useful when you want to embed the resources into the executable).

There are several advantages to using XRC resources:

- Recompiling and linking an application is not necessary if the resources change.
- If you use a dialog designer that generates C++ code, it can be hard to reintegrate this into existing C++ code. Separation of resources and code is a more elegant solution.
- You can choose between different alternative resource files at run time, if necessary.
- The XRC format uses sizers for flexibility, allowing dialogs to be resizable and highly portable.
- The XRC format is a wxWidgets standard, and can be generated or postprocessed by any program that understands it. As it is based on the XML standard, existing XML editors can be used for simple editing purposes.

XRC was written by Vaclav Slavik.

10.39.1 Getting Started with XRC

Creating an XRC file

You will need to write an XRC file. Though this *can* be done by hand in a text editor, for all but the smallest files it is advisable to use a specialised tool. Examples of these include:

Non-free:

- DialogBlocks http://www.anthemion.co.uk/dialogblocks/, a commercial dialog editor.

Free:

- XRCed http://xrced.sf.net/, a wxPython-based dialog editor that you can find in the wx↩ Python/tools subdirectory of the wxWidgets SVN archive.
- wxFormBuilder http://wxformbuilder.org/, a C++-based form designer that can output C++, XRC or python.
- wxCrafter (free version) http://www.codelite.org/wxcrafter/, a C++-based form designer that can output C++ or XRC.

There's a more complete list at http://www.wxwidgets.org/wiki/index.php/Tools

This small demonstration XRC file contains a simple dialog:

```
<?xml version="1.0" ?>
<resource version="2.3.0.1">
  <object class="wxDialog" name="SimpleDialog">
    <title>Simple dialog</title>
    <object class="wxBoxSizer">
      <orient>wxVERTICAL</orient>
      <object class="sizeritem">
        <object class="wxTextCtrl" name="text"/>
        <option>1</option>
        <flag>wxALL|wxEXPAND</flag>
        <border>10</border>
      </object>
      <object class="sizeritem">
        <object class="wxBoxSizer">
          <object class="sizeritem">
            <object class="wxButton" name="clickme_btn">
              <label>Click</label>
```

```
            </object>
            <flag>wxRIGHT</flag>
            <border>10</border>
          </object>
          <object class="sizeritem">
            <object class="wxButton" name="wxID_OK">
              <label>OK</label>
            </object>
            <flag>wxLEFT</flag>
            <border>10</border>
          </object>
          <orient>wxHORIZONTAL</orient>
        </object>
        <flag>wxALL|wxALIGN_CENTRE</flag>
        <border>10</border>
      </object>
    </object>
  </object>
</resource>
```

You can keep all your XRC elements together in one file, or split them between several.

Loading XRC files

Before you can use XRC in an app, it must first be loaded. This code fragment shows how to load a single XRC file "resource.xrc" from the current working directory, plus all the ∗.xrc files contained in the subdirectory "rc".

```
#include "wx/xrc/xmlres.h"

bool MyApp::OnInit()
{
    ...
    wxXmlResource::Get()->InitAllHandlers();

    wxXmlResource::Get()->Load("resource.xrc");
    wxXmlResource::Get()->LoadAllFiles("rc");
    ...
}
```

It's normal to load any XRC files at the beginning of an app. Though it is possible to unload a file later, it's seldom necessary.

Using an XRC item

The XRC file(s) are now loaded into the app's virtual filesystem. From there, you must do another sort of load when you want to use an individual object. Yes, it's confusingly named, but you first Load() the file, and later load each top-level object when its needed.

This is how you would use the above simple dialog in your code.

```
void MyClass::ShowDialog()
{
    wxDialog dlg;
    if (wxXmlResource::Get()->LoadDialog(&dlg, NULL, "SimpleDialog"))
        dlg.ShowModal();
}
```

See how simple the code is. All the instantiation is done invisibly by the XRC system.

Though you'll most often use wxXmlResource::LoadDialog, there are also equivalents that load a frame, a menu etc; and the generic wxXmlResource::LoadObject. See wxXmlResource for more details.

Accessing XRC child controls

The last section showed how to load top-level windows like dialogs, but what about child windows like the wxTextCtrl named "text" that the dialog contains? You can't 'load' an individual child control in the same way. Instead you use the XRCCTRL macro to get a pointer to the child. To expand the previous code:

```
void MyClass::ShowDialog()
{
    wxDialog dlg;
    if (!wxXmlResource::Get()->LoadDialog(&dlg, NULL, "SimpleDialog"))
        return;

    wxTextCtrl* pText = XRCCTRL(dlg, "text", wxTextCtrl);
```

```
    if (pText)
        pText->ChangeValue("This is a simple dialog");

    dlg.ShowModal();
}
```

XRCCTRL takes a reference to the parent container and uses wxWindow::FindWindow to search inside it for a wxWindow with the supplied name (here "text"). It returns a pointer to that control, cast to the type in the third parameter; so a similar effect could be obtained by writing:

```
pText = (wxTextCtrl*)(dlg.FindWindowByName("text"));
```

XRC and IDs

The ID of a control is often needed, e.g. for use in an event table or with wxEvtHandler::Bind. It can easily be found by passing the name of the control to the XRCID macro:

```
void MyClass::ShowDialog()
{
    wxDialog dlg;
    if (!wxXmlResource::Get()->LoadDialog(&dlg, NULL, "SimpleDialog"))
        return;

    XRCCTRL(dlg, "text", wxTextCtrl)->Bind(wxEVT_COMMAND_TEXT_UPDATED,
        wxTextEventHandler(MyClass::OnTextEntered), this, XRCID("text"));

    XRCCTRL(dlg, "clickme_btn", wxButton)->Bind(wxEVT_COMMAND_BUTTON_CLICKED,
        wxCommandEventHandler(MyClass::OnClickme), this, XRCID("clickme_btn"));

    dlg.ShowModal();
}
```

A few points to note:

- The value of the int returned by XRCID("foo") is guaranteed to be unique within an app.
- However that value isn't predictable, and you shouldn't rely on it being consistent between runs. It certainly won't be the same in different apps.
- Stock Items such as wxID_OK work correctly without requiring XRCID (because, internally, XRCID("wxID_↩ OK") is mapped to wxID_OK).
- Both XRCID and XRCCTRL use the 'name' of the control (as in wxWindow::GetName). This is different from the label that the user sees on e.g. a wxButton.

Subclassing in XRC

You will often want to use subclassed wx controls in your code. There are three ways to do this from XRC:

- Very rarely you might need to create your own wxXmlResourceHandler
- Occasionally wxXmlResource::AttachUnknownControl may be best. See Unknown Objects
- Usually though, the simple 'subclass' keyword will suffice.

Suppose you wanted the wxTextCtrl named "text" to be created as your derived class MyTextCtrl. The only change needed in the XRC file would be in this line:

```
<object class="wxTextCtrl" name="text" subclass="MyTextCtrl"/>
```

The only change in your code would be to use MyTextCtrl in XRCCTRL. However for the subclass to be created successfully, it's important to ensure that it uses wxWidget's RTTI mechanism: see Subclassing for the details.

10.39.2 The XRC sample

A major resource for learning how to use XRC is the XRC Sample. This demonstrates all of the standard uses of XRC, and some of the less common ones. It is strongly suggested that you run it, and look at the well-commented source code to see how it works.

10.39.3 Binary Resource Files

To compile binary resource files, use the command-line `wxrc` utility. It takes one or more file parameters (the input XRC files) and the following switches and options:

- -h (–help): Show a help message.
- -v (–verbose): Show verbose logging information.
- -c (–cpp-code): Write C++ source rather than a XRS file.
- -e (–extra-cpp-code): If used together with -c, generates C++ header file containing class definitions for the windows defined by the XRC file (see special subsection).
- -u (–uncompressed): Do not compress XML files (C++ only).
- -g (–gettext): Output underscore-wrapped strings that poEdit or gettext can scan. Outputs to stdout, or a file if -o is used.
- -n (–function) <name>: Specify C++ function name (use with -c).
- -o (–output) <filename>: Specify the output file, such as resource.xrs or resource.cpp.
- -l (–list-of-handlers) <filename>: Output a list of necessary handlers to this file.

For example:

```
$ wxrc resource.xrc
$ wxrc resource.xrc -o resource.xrs
$ wxrc resource.xrc -v -c -o resource.cpp
```

Note

XRS file is essentially a renamed ZIP archive which means that you can manipulate it with standard ZIP tools. Note that if you are using XRS files, you have to initialize the wxFileSystem archive handler first! It is a simple thing to do:

```
#include <wx/filesys.h>
#include <wx/fs_arc.h>
...
wxFileSystem::AddHandler(new wxArchiveFSHandler);
```

10.39.4 Using Embedded Resources

It is sometimes useful to embed resources in the executable itself instead of loading an external file (e.g. when your app is small and consists only of one exe file). XRC provides means to convert resources into regular C++ file that can be compiled and included in the executable.

Use the `-c` switch to `wxrc` utility to produce C++ file with embedded resources. This file will contain a function called `InitXmlResource` (unless you override this with a command line switch). Use it to load the resource:

```
extern void InitXmlResource(); // defined in generated file
...
wxXmlResource::Get()->InitAllHandlers();
InitXmlResource();
...
```

10.39.5 C++ header file generation

Using the `-e` switch together with `-c`, a C++ header file is written containing class definitions for the GUI windows defined in the XRC file. This code generation can make it easier to use XRC and automate program development. The classes can be used as basis for development, freeing the programmer from dealing with most of the XRC specifics (e.g. `XRCCTRL`).

For each top level window defined in the XRC file a C++ class definition is generated, containing as class members the named widgets of the window. A default constructor for each class is also generated. Inside the constructor all XRC loading is done and all class members representing widgets are initialized.

A simple example will help understand how the scheme works. Suppose you have a XRC file defining a top level window `TestWnd_Base`, which subclasses wxFrame (any other class like `wxDialog` will do also), and has subwidgets wxTextCtrl A and wxButton B.

The XRC file and corresponding class definition in the header file will be something like:

```
<?xml version="1.0"?>
<resource version="2.3.0.1">
    <object class="wxFrame" name="TestWnd_Base">
        <size>-1,-1</size>
        <title>Test</title>
        <object class="wxBoxSizer">
            <orient>wxHORIZONTAL</orient>
            <object class="sizeritem">
                <object class="wxTextCtrl" name="A">
                    <label>Test label</label>
                </object>
            </object>
            <object class="sizeritem">
                <object class="wxButton" name="B">
                    <label>Test button</label>
                </object>
            </object>
        </object>
    </object>
</resource>
```

```
class TestWnd_Base : public wxFrame
{
protected:
    wxTextCtrl* A;
    wxButton* B;

private:
    void InitWidgetsFromXRC()
    {
        wxXmlResource::Get()->LoadObject(this, NULL, "TestWnd", "wxFrame");
        A = XRCCTRL(*this, "A", wxTextCtrl);
        B = XRCCTRL(*this, "B", wxButton);
    }
public:
    TestWnd::TestWnd()
    {
        InitWidgetsFromXRC();
    }
};
```

The generated window class can be used as basis for the full window class. The class members which represent widgets may be accessed by name instead of using `XRCCTRL` every time you wish to reference them (note that they are `protected` class members), though you must still use `XRCID` to refer to widget IDs in the event table.

Example:

```
#include "resource.h"

class TestWnd : public TestWnd_Base
{
public:
    TestWnd()
    {
        // A, B already initialised at this point
        A->SetValue("Updated in TestWnd::TestWnd");
        B->SetValue("Nice :)");
    }
    void OnBPressed(wxEvent& event)
    {
```

```
        Close();
    }
    DECLARE_EVENT_TABLE();
};

BEGIN_EVENT_TABLE(TestWnd,TestWnd_Base)
    EVT_BUTTON(XRCID("B"), TestWnd::OnBPressed)
END_EVENT_TABLE()
```

It is also possible to access the wxSizerItem of a sizer that is part of a resource. This can be done using `XRCSIZERITEM` as shown.

The resource file can have something like this for a sizer item.

```
<object class="spacer" name="area">
  <size>400, 300</size>
</object>
```

The code can then access the sizer item by using `XRCSIZERITEM` and `XRCID` together.

```
wxSizerItem* item = XRCSIZERITEM(*this, "area");
```

10.39.6 Adding New Resource Handlers

Adding a new resource handler is pretty easy.

Typically, to add an handler for the `MyControl` class, you'll want to create the `xh_mycontrol.h` and `xh_mycontrol.cpp` files.

The header needs to contains the `MyControlXmlHandler` class definition:

```
class MyControlXmlHandler : public wxXmlResourceHandler
{
public:
    // Constructor.
    MyControlXmlHandler();

    // Creates the control and returns a pointer to it.
    virtual wxObject *DoCreateResource();

    // Returns true if we know how to create a control for the given node.
    virtual bool CanHandle(wxXmlNode *node);

    // Register with wxWidgets' dynamic class subsystem.
    DECLARE_DYNAMIC_CLASS(MyControlXmlHandler)
};
```

The implementation of your custom XML handler will typically look as:

```
// Register with wxWidgets' dynamic class subsystem.
IMPLEMENT_DYNAMIC_CLASS(MyControlXmlHandler, wxXmlResourceHandler)

MyControlXmlHandler::MyControlXmlHandler()
{
    // this call adds support for all wxWidgets class styles
    // (e.g. wxBORDER_SIMPLE, wxBORDER_SUNKEN, wxWS_EX_* etc etc)
    AddWindowStyles();

    // if MyControl class supports e.g. MYCONTROL_DEFAULT_STYLE
    // you should use:
    //     XRC_ADD_STYLE(MYCONTROL_DEFAULT_STYLE);
}

wxObject *MyControlXmlHandler::DoCreateResource()
{
    // the following macro will init a pointer named "control"
    // with a new instance of the MyControl class, but will NOT
    // Create() it!
    XRC_MAKE_INSTANCE(control, MyControl)

    // this is the point where you'll typically need to do the most
    // important changes: here the control is created and initialized.
    // You'll want to use the wxXmlResourceHandler's getters to
    // do most of your work.
    // If e.g. the MyControl::Create function looks like:
```

```
    //
    // bool MyControl::Create(wxWindow *parent, int id,
    //                        const wxBitmap &first, const wxPoint &posFirst,
    //                        const wxBitmap &second, const wxPoint &posSecond,
    //                        const wxString &theTitle, const wxFont &titleFont,
    //                        const wxPoint &pos, const wxSize &size,
    //                        long style = MYCONTROL_DEFAULT_STYLE,
    //                        const wxString &name = wxT("MyControl"));
    //
    // Then the XRC for your component should look like:
    //
    //    <object class="MyControl" name="some_name">
    //      <first-bitmap>first.xpm</first-bitmap>
    //      <second-bitmap>text.xpm</second-bitmap>
    //      <first-pos>3,3</first-pos>
    //      <second-pos>4,4</second-pos>
    //      <the-title>a title</the-title>
    //      <title-font>
    //        <!-- Standard XRC tags for a font: <size>, <style>, <weight>, etc -->
    //      </title-font>
    //      <!-- XRC also accepts other usual tags for wxWindow-derived classes:
    //           like e.g. <name>, <style>, <size>, <position>, etc -->
    //    </object>
    //
    // And the code to read your custom tags from the XRC file is just:
    control->Create(m_parentAsWindow, GetID(),
                    GetBitmap(wxT("first-bitmap")),
                    GetPosition(wxT("first-pos")),
                    GetBitmap(wxT("second-bitmap")),
                    GetPosition(wxT("second-pos")),
                    GetText(wxT("the-title")),
                    GetFont(wxT("title-font")),
                    GetPosition(), GetSize(), GetStyle(), GetName());

    SetupWindow(control);

    return control;
}

bool MyControlXmlHandler::CanHandle(wxXmlNode *node)
{
    // this function tells XRC system that this handler can parse
    // the <object class="MyControl"> tags
    return IsOfClass(node, wxT("MyControl"));
}
```

You may want to check the wxXmlResourceHandler documentation to see how many built-in getters it contains. It's very easy to retrieve also complex structures out of XRC files using them.

10.40 XRC File Format

This document describes the format of XRC resource files, as used by wxXmlResource.

Formal description in the form of a RELAX NG schema is located in the `misc/schema` subdirectory of the wx↩ Widgets sources.

XRC file is a XML file with all of its elements in the `http://www.wxwidgets.org/wxxrc` namespace. For backward compatibility, `http://www.wxwindows.org/wxxrc` namespace is accepted as well (and treated as identical to `http://www.wxwidgets.org/wxxrc`), but it shouldn't be used in new XRC files.

XRC file contains definitions for one or more *objects* – typically windows. The objects may themselves contain child objects.

Objects defined at the top level, under the root element, can be accessed using wxXmlResource::LoadDialog() and other LoadXXX methods. They must have `name` attribute that is used as LoadXXX's argument (see Object Element for details).

Child objects are not directly accessible via wxXmlResource, they can only be accessed using XRCCTRL().

10.40.1 Resource Root Element

The root element is always `<resource>`. It has one optional attribute, `version`. If set, it specifies version of the file. In absence of `version` attribute, the default is `"0.0.0.0"`.

The version consists of four integers separated by periods. The first three components are major, minor and release number of the wxWidgets release when the change was introduced, the last one is revision number and is 0 for the first incompatible change in given wxWidgets release, 1 for the second and so on. The version changes only if there was an incompatible change introduced; merely adding new kind of objects does not constitute incompatible change.

At the time of writing, the latest version is "2.5.3.0".

Note that even though version attribute is optional, it should always be specified to take advantage of the latest capabilities:

```
<?xml version="1.0"?>
<resource xmlns="http://www.wxwidgets.org/wxxrc" version="2.5.3.0">
    ...
</resource>
```

<resource> may have arbitrary number of object elements as its children; they are referred to as *toplevel* objects in the rest of this document. Unlike objects defined deeper in the hierarchy, toplevel objects *must* have their name attribute set and it must be set to a value unique among root's children.

10.40.2 Defining Objects

Object Element

The <object> element represents a single object (typically a GUI element) and it usually maps directly to a wxWidgets class instance. It has one mandatory attribute, class, and optional name and subclass attributes.

The class attribute must always be present, it tells XRC what wxWidgets object should be created and by which wxXmlResourceHandler.

name is the identifier used to identify the object. This name serves three purposes:

1. It is used by wxXmlResource's various LoadXXX() methods to find the resource by name passed as argument.
2. wxWindow's name (see wxWindow::GetName()) is set to it.
3. Numeric ID of a window or menu item is derived from the name. If the value represents an integer (in decimal notation), it is used for the numeric ID unmodified. If it is one of the wxID_XXX literals defined by wxWidgets (see Stock Items), its respective value is used. Otherwise, the name is transformed into dynamically generated ID. See wxXmlResource::GetXRCID() for more information.

Name attributes must be unique at the top level (where the name is used to load resources) and should be unique among all controls within the same toplevel window (wxDialog, wxFrame).

The subclass attribute optional name of class whose constructor will be called instead of the constructor for "class". See Subclassing for more details.

<object> element may – and almost always do – have children elements. These come in two varieties:

1. Object's properties. A *property* is a value describing part of object's behaviour, for example the "label" property on wxButton defines its label. In the most common form, property is a single element with text content ("\<label\>Cancel\</label\>"), but they may use nested subelements too (e.g. font property). A property can only be listed once in an object's definition.
2. Child objects. Window childs, sizers, sizer items or notebook pages are all examples of child objects. They are represented using nested <object> elements and are can be repeated more than once. The specifics of which object classes are allowed as children are class-specific and are documented below in Supported Controls.

Example:

```
<object class="wxDialog" name="example_dialog">
    <!-- properties: -->
    <title>Non-Derived Dialog Example</title>
    <centered>1</centered>
    <!-- child objects: -->
    <object class="wxBoxSizer">
        <orient>wxVERTICAL</orient>
        <cols>1</cols>
        <rows>0</rows>
        ...
    </object>
</object>
```

Object References

Anywhere an <object> element can be used, <object_ref> may be used instead. <object_ref> is a *reference* to another named (i.e. with the name attribute) <object> element. It has one mandatory attribute, ref, with value containing the name of a named <object> element. When an <object_ref> is encountered, a copy of the referenced <object> element is made in place of <object_ref> occurrence and processed as usual.

For example, the following code:

```
<object class="wxDialog" name="my_dlg">
    ...
</object>
<object_ref name="my_dlg_alias" ref="my_dlg"/>
```

is equivalent to

```
<object class="wxDialog" name="my_dlg">
    ...
</object>
<object class="wxDialog" name="my_dlg_alias">
    ... <!-- same as in my_dlg -->
</object>
```

Additionally, it is possible to override some parts of the referenced object in the <object_ref> pointing to it. This is useful for putting repetitive parts of XRC definitions into a template that can be reused and customized in several places. The two parts are merged as follows:

1. The referred object is used as the initial content.
2. All attributes set on <object_ref> are added to it.
3. All child elements of <object_ref> are scanned. If an element with the same name (and, if specified, the name attribute too) is found in the referred object, they are recursively merged.
4. Child elements in <object_ref> that do not have a match in the referred object are appended to the list of children of the resulting element by default. Optionally, they may have insert_at attribute with two possible values, "begin" or "end". When set to "begin", the element is prepended to the list of children instead of appended.

For example, "my_dlg" in this snippet:

```
<object class="wxDialog" name="template">
    <title>Dummy dialog</title>
    <size>400,400</size>
</object>
<object_ref ref="template" name="my_dlg">
    <title>My dialog</title>
    <centered>1</centered>
</object_ref>
```

is identical to:

```
<object class="wxDialog" name="my_dlg">
    <title>My dialog</title>
    <size>400,400</size>
    <centered>1</centered>
</object>
```

10.40.3 Data Types

There are several property data types that are frequently reused by different properties. Rather than describing their format in the documentation of every property, we list commonly used types in this section and document their format.

Boolean

Boolean values are expressed using either "1" literal (true) or "0" (false).

Floating-point value

Floating point values use POSIX (C locale) formatting – decimal separator is "." regardless of the locale.

Colour

Colour specification can be either any string colour representation accepted by wxColour::Set() or any wxSYS_COLOUR_XXX symbolic name accepted by wxSystemSettings::GetColour(). In particular, the following forms are supported:

- named colours from wxColourDatabase
- HTML-like "#rrggbb" syntax (but not "#rgb")
- CSS-style "rgb(r,g,b)" and "rgba(r,g,b,a)"
- wxSYS_COLOUR_XXX symbolic names

Some examples:

```
<fg>red</fg>
<fg>#ff0000</fg>
<fg>rgb(255,0,0)</fg>
<fg>wxSYS_COLOUR_HIGHLIGHT</fg>
```

Size

Sizes and positions have the form of string with two comma-separated integer components, with optional "d" suffix. Semi-formally:

size := x "," y ["d"]

where x and y are integers. Either of the components (or both) may be "-1" to signify default value. As a shortcut, empty string is equivalent to "-1,-1" (= wxDefaultSize or wxDefaultPosition).

When the "d" suffix is used, integer values are interpreted as dialog units in the parent window.

Examples:

```
42,-1
100,100
100,50d
```

Position

Same as Size.

Dimension

Similarly to sizes, dimensions are expressed as integers with optional "d" suffix. When "d" suffix is used, the integer preceding it is interpreted as dialog units in the parent window.

Text

String properties use several escape sequences that are translated according to the following table:

"_"	"&" (used for accelerators in wxWidgets)
"__"	"_"
"\n"	line break
"\r"	carriage return
"\t"	tab
"\\"	"\"

By default, the text is translated using wxLocale::GetTranslation() before it is used. This can be disabled either globally by not passing wxXRC_USE_LOCALE to wxXmlResource constructor, or by setting the `translate` attribute on the property node to "0":

```
<!-- this is not translated: -->
<label translate="0">_Unix</label>
<!-- but this is: -->
<help>Use Unix-style newlines</help>
```

Note

Even though the "_" character is used instead of "&" for accelerators, it is still possible to use "&". The latter has to be encoded as "&", though, so using "_" is more convenient.

See also

Versions Before 2.5.3.0, Versions Before 2.3.0.1

Non-Translatable Text

Like Text, but the text is never translated and `translate` attribute cannot be used.

String

An unformatted string. Unlike with Text, no escaping or translations are done.

URL

Any URL accepted by wxFileSystem (typically relative to XRC file's location, but can be absolute too). Unlike with Text, no escaping or translations are done.

Bitmap

Bitmap properties contain specification of a single bitmap or icon. In the most basic form, their text value is simply a relative filename (or another wxFileSystem URL) of the bitmap to use. For example:

```
<object class="tool" name="wxID_NEW">
    <tooltip>New</tooltip>
    <bitmap>new.png</bitmap>
</object>
```

The value is interpreted as path relative to the location of XRC file where the reference occurs.

Alternatively, it is possible to specify the bitmap using wxArtProvider IDs. In this case, the property element has no textual value (filename) and instead has the `stock_id` XML attribute that contains stock art ID as accepted by wxArtProvider::GetBitmap(). This can be either custom value (if the app uses app-specific art provider) or one of the predefined wxART_XXX constants.

Optionally, `stock_client` attribute may be specified too and contain one of the predefined wxArtClient values. If it is not specified, the default client ID most appropriate in the context where the bitmap is referenced will be used. In most cases, specifying `stock_client` is not needed.

Examples of stock bitmaps usage:

```
<bitmap stock_id="fixed-width"/>        <!-- custom app-specific art -->
<bitmap stock_id="wxART_FILE_OPEN"/>    <!-- standard art -->
```

If both specifications are provided, then `stock_id` is used if it is recognized by wxArtProvider and the provided bitmap file is used as a fallback.

Style

Style properties (such as window's style or sizer flags) use syntax similar to C++: the style value is OR-combination of individual flags. Symbolic names identical to those used in C++ code are used for the flags. Flags are separated with "|" (whitespace is allowed but not required around it).

The flags that are allowed for a given property are context-dependent.

Examples:

```
<style>wxCAPTION|wxSYSTEM_MENU | wxRESIZE_BORDER</style>
<exstyle>wxDIALOG_EX_CONTEXTHELP</exstyle>
```

Font

XRC uses similar, but more flexible, abstract description of fonts to that used by wxFont class. A font can be described either in terms of its elementary properties, or it can be derived from one of system fonts or the parent window font.

The font property element is a "composite" element: unlike majority of properties, it doesn't have text value but contains several child elements instead. These children are handled in the same way as object properties and can be one of the following "sub-properties":

property	type	description
size	unsigned integer	Pixel size of the font (default: wxNORMAL_FONT's size or `sysfont's` size if the `sysfont` property is used or the current size of the font of the enclosing control if the `inherit` property is used.
style	enum	One of "normal", "italic" or "slant" (default: normal).
weight	enum	One of "normal", "bold" or "light" (default: normal).
family	enum	One of "default", "roman", "script", "decorative", "swiss", "modern" or "teletype" (default: default).

underlined	Boolean	Whether the font should be underlined (default: 0).
face		Comma-separated list of face names; the first one available is used (default: unspecified).
encoding		Charset of the font, unused in Unicode build), as string (default: unspecified).
sysfont		Symbolic name of system standard font(one of wxSYS_*_FONT constants).
inherit	Boolean	If true, the font of the enclosing control is used. If this property and the `sysfont` property are specified the `sysfont` property takes precedence.
relativesize	float	Float, font size relative to chosen system font's or inherited font's size; can only be used when 'sysfont' or 'inherit' is used and when 'size' is not used.

All of them are optional, if they are missing, appropriate wxFont default is used. If the `sysfont` or `inherit` property is used, then the defaults are taken from it instead.

Examples:

```
<font>
    <!-- fixed font: Arial if available, fall back to Helvetica -->
    <face>arial,helvetica</face>
    <size>12</size>
</font>

<font>
    <!-- enlarged, enboldened standard font: -->
    <sysfont>wxSYS_DEFAULT_GUI_FONT</sysfont>
    <weight>bold</weight>
    <relativesize>1.5</relativesize>
</font>
```

Note

You cannot use `inherit` for a font that gets used before the enclosing control is created, e.g. if the control gets the font passed as parameter for its constructor, or if the control is not derived from wxWindow.

Image List

Defines a wxImageList.

The imagelist property element is a "composite" element: unlike majority of properties, it doesn't have text value but contains several child elements instead. These children are handled similarly to object properties and can be one of the following "sub-properties":

property	type	description
mask	Boolean	If masks should be created for all images (default: 1).
size	Size	The size of the images in the list (default: the size of the first bitmap).
bitmap	Bitmap	Adds a new image. Unlike normal object properties, `bitmap` may be used more than once to add multiple images to the list. At least one `bitmap` value is required.

Example:

```
<imagelist>
    <size>32,32</size>
    <bitmap stock_id="wxART_QUESTION"/>
    <bitmap stock_id="wxART_INFORMATION"/>
</imagelist>
```

10.40.4 Controls and Windows

This section describes support wxWindow-derived classes in XRC format.

Standard Properties

The following properties are always (unless stated otherwise in control-specific docs) available for *windows* objects. They are omitted from properties lists below.

property	type	description
pos	Position	Initial position of the window (default: wxDefaultPosition).
size	Size	Initial size of the window (default: wxDefaultSize).
style	Style	Window style for this control. The allowed values depend on what window is being created, consult respective class' constructor documentation for details (default: window-dependent default, usually wxFOO_DEFAULT_STYLE if defined for class wxFoo, 0 if not).
exstyle	Style	Extra style for the window, if any. See wxWindow::SetExtraStyle() (default: not set).
fg	Colour	Foreground colour of the window (default: window's default).
ownfg	Colour	Non-inheritable foreground colour of the window, see wxWindow::SetOwnForegroundColour() (default: none).
bg	Colour	Background colour of the window (default: window's default).
ownbg	Colour	Non-inheritable background colour of the window, see wxWindow::SetOwnBackgroundColour() (default: none).
enabled	Boolean	If set to 0, the control is disabled (default: 1).
focused	Boolean	If set to 1, the control has focus initially (default: 0).
hidden	Boolean	If set to 1, the control is created hidden (default: 0).
tooltip	Text	Tooltip to use for the control (default: not set).

variant	String	Window variant (see wxWindow::SetWindowVariant()), one of "normal", "small", "mini" or "large" (default: "normal") (new since wxWidgets 3.0.2).
font	Font	Font to use for the control (default: window's default).
ownfont	Font	Non-inheritable font to use for the control, see wxWindow::SetOwnFont() (default: none).
help	Text	Context-sensitive help for the control, used by wxHelpProvider (default: not set).

All of these properties are optional.

Supported Controls

This section lists all controls supported by default. For each control, its control-specific properties are listed. If the control can have child objects, it is documented there too; unless said otherwise, XRC elements for these controls cannot have children.

wxAnimationCtrl

property	type	description
animation	URL	Animation file to load into the control (default: none).
inactive-bitmap	Bitmap	Bitmap to use when not playing the animation (default: the default).

wxAuiNotebook

A wxAuiNotebook can have one or more child objects of the `notebookpage` pseudo-class. `notebookpage` objects have the following properties:

property	type	description
label	Text	Page label (default: empty).
bitmap	Bitmap	Bitmap shown alongside the label (default: none).
selected	Boolean	Is the page selected initially (only one page can be selected; default: 0)?

Each `notebookpage` must have exactly one non-toplevel window as its child.

Example:

```
<object class="wxAuiNotebook">
    <style>wxBK_BOTTOM</style>
    <object class="notebookpage">
        <label>Page 1</label>
        <bitmap>bitmap.png</bitmap>
        <object class="wxPanel" name="page_1">
            ...
        </object>
    </object>
</object>
```

Notice that wxAuiNotebook support in XRC is available in wxWidgets 2.9.5 and later only and you need to explicitly register its handler using

```
#include <wx/xrc/xh_auinotbk.h>

AddHandler(new wxAuiNotebookXmlHandler);
```

to use it.

wxAuiToolBar

Building an XRC for wxAuiToolBar is quite similar to wxToolBar. The only significant differences are:

- the use of the class name wxAuiToolBar
- the styles supported are the ones described in the wxAuiToolBar class definition
- the 'space' pseudo-class has two optional, mutually exclusive, integer properties: 'proportion' and 'width'. If 'width' is specified, a space is added using wxAuiToolBar::AddSpacer(); if 'proportion', the value is used in wxAuiToolBar::AddStretchSpacer(). If neither are provided, the default is a stretch-spacer with a proportion of 1.
- there is an additional pseudo-class, 'label', that has a string property. See wxAuiToolBar::AddLabel().

Refer to the section wxToolBar for more details.

Note

The XML Handler should be explicitly registered:

```
#include <wx/xrc/xh_auitoolb.h>

AddHandler(new wxAuiToolBarXmlHandler);
```

Since

3.1.0

wxBannerWindow

property	type	description
direction	wxLEFT|wxRIGHT|wxTOP|wx↩ BOTTOM	The side along which the banner will be positioned (default: wxLEFT).
bitmap	Bitmap	Bitmap to use as the banner background (default: none).
title	Text	Banner title, should be single line (default: none).
message	Text	Possibly multi-line banner message (default: none).
gradient-start	Colour	Starting colour of the gradient used as banner background. (Optional. Can't be used if a valid bitmap is specified. If used, both gradient values must be set.)
gradient-end	Colour	End colour of the gradient used as banner background. (Optional. Can't be used if a valid bitmap is specified. If used, both gradient values must be set.)

wxBitmapButton

property	type	description
default	Boolean	Should this button be the default button in dialog (default: 0)?
bitmap	Bitmap	Bitmap to show on the button (default: none).
selected	Bitmap	Bitmap to show when the button is selected (default: none, same as `bitmap`).
focus	Bitmap	Bitmap to show when the button has focus (default: none, same as `bitmap`).
disabled	Bitmap	Bitmap to show when the button is disabled (default: none, same as `bitmap`).
hover	Bitmap	Bitmap to show when mouse cursor hovers above the bitmap (default: none, same as `bitmap`).

wxBitmapComboBox

property	type	description
selection	integer	Index of the initially selected item or -1 for no selection (default: -1).
value	String	Initial value in the control (doesn't have to be one of @ content values; default: empty).

If both `value` and `selection` are specified and `selection` is not -1, then `selection` takes precedence.

A wxBitmapComboBox can have one or more child objects of the `ownerdrawnitem` pseudo-class. `ownerdrawnitem` objects have the following properties:

property	type	description
text	Text	Item's label (default: empty).
bitmap	Bitmap	Item's bitmap (default: no bitmap).

Example:

```
<object class="wxBitmapComboBox">
    <selection>1</selection>
    <object class="ownerdrawnitem">
        <text>Foo</text>
        <bitmap>foo.png</bitmap>
    </object>
    <object class="ownerdrawnitem">
        <text>Bar</text>
        <bitmap>bar.png</bitmap>
    </object>
</object>
```

wxBitmapToggleButton

property	type	description
bitmap	Bitmap	Label to display on the button (default: none).
checked	Boolean	Should the button be checked/pressed initially (default: 0)?

wxButton

property	type	description
label	Text	Label to display on the button (may be omitted if only the bitmap or stock ID is used).
bitmap	Bitmap	Bitmap to display in the button (optional).
bitmapposition	wxLEFT|wxRIGHT|wxTOP|wxBOTTOM	Position of the bitmap in the button, see wxButton::SetBitmapPosition() (default: wxLEFT).
default	Boolean	Should this button be the default button in dialog (default: 0)?

wxCalendarCtrl

No additional properties.

wxCheckBox

property	type	description
label	Text	Label to use for the checkbox (default: empty).
checked	Boolean	Should the checkbox be checked initially (default: 0)?

wxCheckListBox

property	type	description
content	items	Content of the control; this property has any number of <item> XML elements as its children, with the items text as their text values (default: empty).

The <item> elements have listbox items' labels as their text values. They can also have optional checked XML attribute – if set to "1", the value is initially checked.

Example:

```
<object class="wxCheckListBox">
    <content>
        <item checked="1">Download library</item>
        <item checked="1">Compile samples</item>
        <item checked="1">Skim docs</item>
        <item checked="1">Finish project</item>
        <item>Wash car</item>
    </content>
</object>
```

wxChoice

property	type	description
selection	integer	Index of the initially selected item or -1 for no selection (default: -1).
content	items	Content of the control; this property has any number of <item> XML elements as its children, with the items text as their text values (default: empty).

Example:

```
<object class="wxChoice" name="controls_choice">
    <content>
        <item>See</item>
        <item>Hear</item>
        <item>Feel</item>
```

```
        <item>Smell</item>
        <item>Taste</item>
        <item>The Sixth Sense!</item>
    </content>
</object>
```

wxChoicebook

property	type	description
imagelist	Image List	Image list to use for the images (default: none, built implicitly).

Additionally, a choicebook can have one or more child objects of the `choicebookpage` pseudo-class (similarly to wxNotebook and its `notebookpage`).

`choicebookpage` objects have the following properties:

property	type	description
label	Text	Sheet page's title (default: empty).
bitmap	Bitmap	Bitmap shown alongside the label (default: none, mutually exclusive with `image`).
image	integer	The zero-based index of the image associated with the item into the image list (default: none, mutually exclusive with `bitmap`, only if imagelist was set).
selected	Boolean	Is the page selected initially (only one page can be selected; default: 0)?

Each `choicebookpage` has exactly one non-toplevel window as its child.

wxCommandLinkButton

The wxCommandLinkButton contains a main title-like `label` and an optional `note` for longer description. The main `label` and the `note` can be concatenated into a single string using a new line character between them (notice that the `note` part can have more new lines in it).

property	type	description
label	Text	First line of text on the button, typically the label of an action that will be made when the button is pressed (default: empty).
note	Text	Second line of text describing the action performed when the button is pressed (default: none).

wxCollapsiblePane

property	type	description
label	Text	Label to use for the collapsible section (default: empty).
collapsed	Boolean	Should the pane be collapsed initially (default: 0)?

wxCollapsiblePane may contain single optional child object of the `panewindow` pseudo-class type. `panewindow` itself must contain exactly one child that is a sizer or a non-toplevel window object.

wxColourPickerCtrl

property	type	description
value	Colour	Initial value of the control (default: wxBLACK).

wxComboBox

property	type	description
selection	integer	Index of the initially selected item or -1 for no selection (default: not used).
content	items	Content of the control; this property has any number of `<item>` XML elements as its children, with the items text as their text values (default: empty).
value	String	Initial value in the control (doesn't have to be one of @ content values; default: empty).

If both `value` and `selection` are specified and `selection` is not -1, then `selection` takes precedence.

Example:

```
<object class="wxComboBox" name="controls_combobox">
    <style>wxCB_DROPDOWN</style>
    <value>nedit</value>
    <content>
        <item>vim</item>
        <item>emacs</item>
        <item>notepad.exe</item>
        <item>bbedit</item>
    </content>
</object>
```

wxComboCtrl

property	type	description
value	String	Initial value in the control (default: empty).

wxDatePickerCtrl

No additional properties.

wxDialog

property	type	description
title	Text	Dialog's title (default: empty).
icon	Bitmap	Dialog's icon (default: not used).
centered	Boolean	Whether the dialog should be centered on the screen (default: 0).

wxDialog may have optional children: either exactly one sizer child or any number of non-toplevel window objects. If sizer child is used, it sets size hints too.

wxDirPickerCtrl

property	type	description
value	String	Initial value of the control (default: empty).
message	Text	Message shown to the user in wxDirDialog shown by the control (default: empty).

wxEditableListBox

property	type	description
label	Text	Label shown above the list (default: empty).
content	items	Content of the control; this property has any number of <item> XML elements as its children, with the items text as their text values (default: empty).

Example:

```
<object class="wxEditableListBox" name="controls_listbox">
    <size>250,160</size>
    <label>List of things</label>
    <content>
        <item>Milk</item>
        <item>Pizza</item>
        <item>Bread</item>
        <item>Orange juice</item>
        <item>Paper towels</item>
    </content>
</object>
```

wxFileCtrl

property	type	description
defaultdirectory	String	Sets the current directory displayed in the control (default: empty).
defaultfilename	String	Selects a certain file (default: empty).
wildcard	String	Sets the wildcard, which can contain multiple file types, for example: "BMP files (∗.bmp)|∗.bmp|GIF files (∗.gif)|∗.gif" (default: all files).

wxFilePickerCtrl

property	type	description
value	String	Initial value of the control (default: empty).
message	Text	Message shown to the user in wxDirDialog shown by the control (default: empty).
wildcard	String	Sets the wildcard, which can contain multiple file types, for example: "BMP files (∗.bmp)|∗.bmp|GIF files (∗.gif)|∗.gif" (default: all files).

wxFontPickerCtrl

property	type	description
value	Font	Initial value of the control (default: wxNORMAL_FONT).

wxFrame

property	type	description
title	Text	Frame's title (default: empty).
icon	Bitmap	Frame's icon (default: not used).
centered	Boolean	Whether the frame should be centered on the screen (default: 0).

wxFrame may have optional children: either exactly one sizer child or any number of non-toplevel window objects. If sizer child is used, it sets size hints too.

wxGauge

property	type	description
range	integer	Maximum value of the gauge (default: 100).
value	integer	Initial value of the control (default: 0).
shadow	Dimension	Rendered shadow size (default: none; ignored by most platforms).
bezel	Dimension	Rendered bezel size (default: none; ignored by most platforms).

wxGenericDirCtrl

property	type	description
defaultfolder	String	Initial folder (default: empty).
filter	Text	Filter string, using the same syntax as used by wxFileDialog, e.g. "All files (∗.∗)|∗.∗|JPEG files (∗.jpg)|∗.jpg" (default: empty).
defaultfilter	integer	Zero-based index of default filter (default: 0).

wxGrid

No additional properties.

wxHtmlWindow

property	type	description
url	URL	Page to display in the window (default: none).
htmlcode	Text	HTML markup to display in the window (default: none).
borders	Dimension	Border around HTML content (default: 0).

At most one of `url` and `htmlcode` properties may be specified, they are mutually exclusive. If neither is set, the window is initialized to show empty page.

wxHyperlinkCtrl

property	type	description
label	Text	Label to display on the control (default: empty).
url	URL	URL to open when the link is clicked (default: empty).

wxListBox

property	type	description
selection	integer	Index of the initially selected item or -1 for no selection (default: -1).
content	items	Content of the control; this property has any number of `<item>` XML elements as its children, with the items text as their text values (default: empty).

Example:

```
<object class="wxListBox" name="controls_listbox">
    <size>250,160</size>
    <style>wxLB_SINGLE</style>
    <content>
        <item>Milk</item>
        <item>Pizza</item>
        <item>Bread</item>
        <item>Orange juice</item>
        <item>Paper towels</item>
    </content>
</object>
```

wxListbook

property	type	description
imagelist	Image List	Image list to use for the images (default: none, built implicitly).

Additionally, a listbook can have one or more child objects of the `listbookpage` pseudo-class (similarly to wxNotebook and its `notebookpage`).

`listbookpage` objects have the following properties:

property	type	description
label	Text	Sheet page's title (default: empty).
bitmap	Bitmap	Bitmap shown alongside the label (default: none, mutually exclusive with `image`).
image	integer	The zero-based index of the image associated with the item into the image list (default: none, mutually exclusive with `bitmap`, only if imagelist was set).
selected	Boolean	Is the page selected initially (only one page can be selected; default: 0)?

Each `listbookpage` has exactly one non-toplevel window as its child.

wxListCtrl

property	type	description
imagelist	Image List	The normal (wxIMAGE_LIST_NORMAL) image list (default: none, built implicitly).
imagelist-small	Image List	The small (wxIMAGE_LIST_SMALL) image list (default: none, built implicitly).

A list control can have optional child objects of the listitem class. Report mode list controls (i.e. created with `wxLC_REPORT` style) can in addition have optional listcol child objects.

listcol

The `listcol` class can only be used for wxListCtrl children. It can have the following properties (all of them optional):

property	type	description
align	wxListColumnFormat	The alignment for the item. Can be one of `wxLIST_FORMAT_LEFT`, `wxLIST_FORMAT_RIGHT` or `wxLIST_FORMAT_CENTRE`.
text	Text	The title of the column.
width	integer	The column width.
image	integer	The zero-based index of the image associated with the item in the 'small' image list.

The columns are appended to the control in order of their appearance and may be referenced by 0-based index in the `col` attributes of subsequent `listitem` objects.

listitem

The `listitem` is a child object for the class wxListCtrl. It can have the following properties (all of them optional):

property	type	description
align	wxListColumnFormat	The alignment for the item. Can be one of `wxLIST_FORMAT_LEFT`, `wxLIST_FORMAT_RIGHT` or `wxLIST_FORMAT_CENTRE`.
bg	Colour	The background color for the item.
bitmap	Bitmap	Add a bitmap to the (normal) Image List associated with the wxListCtrl parent and associate it with this item. If the imagelist is not defined it will be created implicitly (default: none, mutually exclusive with `image`).
bitmap-small	Bitmap	Add a bitmap in the 'small' Image List associated with the wxListCtrl parent and associate it with this item. If the 'small' imagelist is not defined it will be created implicitly (default: none, mutually exclusive with `image-small`).
col	integer	The zero-based column index.
image	integer	The zero-based index of the image associated with the item in the (normal) image list (default: none, mutually exclusive with `bitmap`, only if imagelist was set).
image-small	integer	The zero-based index of the image associated with the item in the 'small' image list (default: none, mutually exclusive with `bitmap-small`, only if imagelist-small was set).

data	integer	The client data for the item.
font	Font	The font for the item.
state	Style	The item state. Can be any combination of the following values: • `wxLIST_STATE_FOCUSED`: The item has the focus. • `wxLIST_STATE_SELECTED`: The item is selected.
text	Text	The text label for the item.
textcolour	Colour	The text colour for the item.

Notice that the item position can't be specified here, the items are appended to the list control in order of their appearance.

wxMDIParentFrame

wxMDIParentFrame supports the same properties that wxFrame does.

wxMDIParentFrame may have optional children. When used, the child objects must be of wxMDIChildFrame type.

wxMDIChildFrame

wxMDIChildFrame supports the same properties that wxFrame and wxMDIParentFrame do.

wxMDIChildFrame can only be used as as immediate child of wxMDIParentFrame.

wxMDIChildFrame may have optional children: either exactly one sizer child or any number of non-toplevel window objects. If sizer child is used, it sets size hints too.

wxMenu

property	type	description
label	Text	Menu's label (default: empty, but required for menus other than popup menus).
style	Style	Window style for the menu.
help	Text	Help shown in statusbar when the menu is selected (only for submenus of another wxMenu, default: none).
enabled	Boolean	Is the submenu item enabled (only for submenus of another wxMenu, default: 1)?

Note that unlike most controls, wxMenu does *not* have Standard Properties, with the exception of `style`.

A menu object can have one or more child objects of the wxMenuItem or wxMenu classes or `break` or `separator` pseudo-classes.

The `separator` pseudo-class is used to insert separators into the menu and has neither properties nor children. Likewise, `break` inserts a break (see wxMenu::Break()).

wxMenuItem objects support the following properties:

property	type	description
label	Text	Item's label (may be omitted if stock ID is used).
accel	Non-Translatable Text	Item's accelerator (default: none).
radio	Boolean	Item's kind is wxITEM_RADIO (default: 0)?
checkable	Boolean	Item's kind is wxITEM_CHECK (default: 0)?
bitmap	Bitmap	Bitmap to show with the item (default: none).
bitmap2	Bitmap	Bitmap for the checked state (wxMSW, if checkable; default: none).
help	Text	Help shown in statusbar when the item is selected (default: none).
enabled	Boolean	Is the item enabled (default: 1)?
checked	Boolean	Is the item checked initially (default: 0)?

Example:

```
<object class="wxMenu" name="menu_edit">
  <style>wxMENU_TEAROFF</style>
  <label>_Edit</label>
  <object class="wxMenuItem" name="wxID_FIND">
    <label>_Find...</label>
    <accel>Ctrl-F</accel>
  </object>
  <object class="separator"/>
  <object class="wxMenuItem" name="menu_fuzzy">
    <label>Translation is _fuzzy</label>
    <checkable>1</checkable>
  </object>
  <object class="wxMenu" name="submenu">
    <label>A submenu</label>
    <object class="wxMenuItem" name="foo">...</object>
    ...
  </object>
  <object class="separator" platform="unix"/>
  <object class="wxMenuItem" name="wxID_PREFERENCES" platform="unix">
    <label>_Preferences</label>
  </object>
</object>
```

wxMenuBar

property	type	description
style	Style	Window style for the menu bar.

Note that unlike most controls, wxMenuBar does *not* have Standard Properties, with the exception of `style`.

A menubar can have one or more child objects of the wxMenu class.

wxNotebook

property	type	description
imagelist	Image List	Image list to use for the images (default: none, built implicitly).

A notebook can have one or more child objects of the `notebookpage` pseudo-class.

`notebookpage` objects have the following properties:

property	type	description
label	Text	Page's title (default: empty).
bitmap	Bitmap	Bitmap shown alongside the label (default: none, mutually exclusive with `image`).
image	integer	The zero-based index of the image associated with the item into the image list (default: none, mutually exclusive with `bitmap`, only if imagelist was set).
selected	Boolean	Is the page selected initially (only one page can be selected; default: 0)?

Each `notebookpage` has exactly one non-toplevel window as its child.

Example:

```
<object class="wxNotebook">
    <style>wxBK_BOTTOM</style>
    <object class="notebookpage">
        <label>Page 1</label>
        <object class="wxPanel" name="page_1">
            ...
        </object>
    </object>
    <object class="notebookpage">
        <label>Page 2</label>
        <object class="wxPanel" name="page_2">
            ...
        </object>
    </object>
</object>
```

wxOwnerDrawnComboBox

wxOwnerDrawnComboBox has the same properties as wxComboBox, plus the following additional properties:

property	type	description
buttonsize	Size	Size of the dropdown button (default: default).

wxPanel

No additional properties.

wxPanel may have optional children: either exactly one sizer child or any number of non-toplevel window objects.

wxPropertySheetDialog

property	type	description
title	Text	Dialog's title (default: empty).
icon	Bitmap	Dialog's icon (default: not used).
centered	Boolean	Whether the dialog should be centered on the screen (default: 0).
buttons	Style	Buttons to show, combination of flags accepted by wxPropertySheetDialog::CreateButtons() (default: 0).

A sheet dialog can have one or more child objects of the `propertysheetpage` pseudo-class (similarly to wxNotebook and its `notebookpage`). `propertysheetpage` objects have the following properties:

property	type	description
label	Text	Sheet page's title (default: empty).
bitmap	Bitmap	Bitmap shown alongside the label (default: none).
selected	Boolean	Is the page selected initially (only one page can be selected; default: 0)?

Each `propertysheetpage` has exactly one non-toplevel window as its child.

wxRadioButton

property	type	description
label	Text	Label shown on the radio button (default: empty).
value	Boolean	Initial value of the control (default: 0).

wxRadioBox

property	type	description
label	Text	Label for the whole box (default: empty).
dimension	integer	Specifies the maximum number of rows (if style contains `wxRA_SPECIFY_ROWS`) or columns (if style contains `wxRA_SPECIFY_COLS`) for a two-dimensional radiobox (default: 1).
selection	integer	Index of the initially selected item or -1 for no selection (default: -1).
content	items	Content of the control; this property has any number of `<item>` XML elements as its children, with the items text as their text values (see below; default: empty).

The `<item>` elements have radio buttons' labels as their text values. They can also have some optional XML *attributes* (not properties!):

attribute	type	description
tooltip	String	Tooltip to show over this ratio button (default: none).
helptext	String	Contextual help for this radio button (default: none).
enabled	Boolean	Is the button enabled (default: 1)?
hidden	Boolean	Is the button hidden initially (default: 0)?

Example:

```
<object class="wxRadioBox" name="controls_radiobox">
    <style>wxRA_SPECIFY_COLS</style>
    <label>Radio stations</label>
    <dimension>1</dimension>
    <selection>0</selection>
    <content>
        <item tooltip="Powerful radio station" helptext="This station is for amateurs of hard rock and
       heavy metal">Power 108</item>
        <item tooltip="Disabled radio station" enabled="0">Power 0</item>
        <item tooltip="">WMMS 100.7</item>
        <item tooltip="E=mc^2">Energy 98.3</item>
        <item helptext="Favourite chukcha's radio">CHUM FM</item>
        <item>92FM</item>
```

```
        <item hidden="1">Very quit station</item>
    </content>
</object>
```

wxRibbonBar

property	type	description
art-provider	String	One of `default`, `aui` or `msw` (default: `default`).

A wxRibbonBar may have wxRibbonPage child objects. The `page` pseudo-class may be used instead of `wxRibbonPage` when used as wxRibbonBar children.

Example:

```
<object class="wxRibbonBar" name="ribbonbar">
    <object class="page" name="FilePage">
        <label>First</label>
        <object class="panel">
            <label>File</label>
            <object class="wxRibbonButtonBar">
                <object class="button" name="Open">
                    <bitmap>open.xpm</bitmap>
                    <label>Open</label>
                </object>
            </object>
        </object>
    </object>
    <object class="page" name="ViewPage">
        <label>View</label>
        <object class="panel">
            <label>Zoom</label>
            <object class="wxRibbonGallery">
                <object class="item">
                    <bitmap>zoomin.xpm</bitmap>
                </object>
                <object class="item">
                    <bitmap>zoomout.xpm</bitmap>
                </object>
            </object>
        </object>
    </object>
</object>
```

Notice that wxRibbonBar support in XRC is available in wxWidgets 2.9.5 and later only and you need to explicitly register its handler using

```
#include <wx/xrc/xh_ribbon.h>

AddHandler(new wxRibbonXmlHandler);
```

to use it.

wxRibbonButtonBar

No additional properties.

wxRibbonButtonBar can have child objects of the `button` pseudo-class. `button` objects have the following properties:

property	type	description
hybrid	Boolean	If true, the `wxRIBBON_BUTTON_HYBRID` kind is used (default: false).
disabled	Boolean	Whether the button should be disabled (default: false).
label	Text	Item's label (default: empty).
bitmap	Bitmap	Item's bitmap (default: none).
small-bitmap	Bitmap	Small bitmap (default: none).
disabled-bitmap	Bitmap	Disabled bitmap (default: none).
small-disabled-bitmap	Bitmap	Small disabled bitmap (default: none).
help	Text	Item's help text (default: none).

wxRibbonControl

No additional properties.

Objects of this type *must* be subclassed with the `subclass` attribute.

wxRibbonGallery

No additional properties.

wxRibbonGallery can have child objects of the `item` pseudo-class. `item` objects have the following properties:

property	type	description
bitmap	Bitmap	Item's bitmap (default: none).

wxRibbonPage

property	type	description
label	Text	Label (default: none).
icon	Bitmap	Icon (default: none).

A wxRibbonPage may have children of any type derived from wxRibbonControl. Most commonly, wxRibbonPanel is used. As a special case, the `panel` pseudo-class may be used instead of `wxRibbonPanel` when used as wxRibbonPage children.

wxRibbonPanel

property	type	description
label	Text	Label (default: none).
icon	Bitmap	Icon (default: none).

A wxRibbonPanel may have children of any type derived from wxRibbonControl or a single wxSizer child with non-ribbon windows in it.

wxRichTextCtrl

property	type	description
value	Text	Initial value of the control (default: empty).
maxlength	integer	Maximum length of the text entered (default: unlimited).

Notice that wxRichTextCtrl support in XRC is available in wxWidgets 2.9.5 and later only and you need to explicitly register its handler using

```
#include <wx/xrc/xh_richtext.h>

AddHandler(new wxRichTextCtrl);
```

to use it.

wxScrollBar

property	type	description
value	integer	Initial position of the scrollbar (default: 0).
range	integer	Maximum value of the gauge (default: 10).
thumbsize	integer	Size of the thumb (default: 1).
pagesize	integer	Page size (default: 1).

wxScrolledWindow

property	type	description
scrollrate	Size	Scroll rate in *x* and *y* directions (default: not set; required if the window has a sizer child).

wxScrolledWindow may have optional children: either exactly one sizer child or any number of non-toplevel window objects. If sizer child is used, wxSizer::FitInside() is used (instead of wxSizer::Fit() as usual) and so the children don't determine scrolled window's minimal size, they only affect *virtual* size. Usually, both `scrollrate` and either `size` or `minsize` on containing sizer item should be used in this case.

wxSimpleHtmlListBox

wxSimpleHtmlListBox has same properties as wxListBox. The only difference is that the text contained in `<item>` elements is HTML markup. Note that the markup has to be escaped:

```
<object class="wxSimpleHtmlListBox">
    <content>
        <item>&amp;lt;b&amp;gt;Bold&amp;lt;/b&amp;gt; Milk</item>
    </content>
</object>
```

(X)HTML markup elements cannot be included directly:

```
<object class="wxSimpleHtmlListBox">
    <content>
        <!-- This is incorrect, doesn't work! -->
        <item><b>Bold</b> Milk</item>
    </content>
</object>
```

wxSimplebook

wxSimplebook is similar to wxNotebook but simpler: as it doesn't show any page headers, it doesn't use neither image list nor individual page bitmaps and while it still accepts page labels, they are optional as they are not shown to the user neither.

So `simplebookpage` child elements, that must occur inside this object, only have the following properties:

`choicebookpage` objects have the following properties:

property	type	description
label	Text	Page's label (default: empty).
selected	Boolean	Is the page selected initially (only one page can be selected; default: 0)?

As with all the other book page elements, each `simplebookpage` must have exactly one non-toplevel window as its child.

Since

3.0.2

wxSlider

property	type	description
value	integer	Initial value of the control (default: 0).
min	integer	Minimum allowed value (default: 0).
max	integer	Maximum allowed value (default: 100).
pagesize	integer	Page size; number of steps the slider moves when the user moves pages up or down (default: unset).
linesize	integer	Line size; number of steps the slider moves when the user moves it up or down a line (default: unset).
tickfreq	integer	Tick marks frequency (Windows only; default: unset).
tick	integer	Tick position (Windows only; default: unset).
thumb	integer	Thumb length (Windows only; default: unset).
selmin	integer	Selection start position (Windows only; default: unset).
selmax	integer	Selection end position (Windows only; default: unset).

wxSpinButton

property	type	description
value	integer	Initial value of the control (default: 0).
min	integer	Minimum allowed value (default: 0).
max	integer	Maximum allowed value (default: 100).

wxSpinCtrl

wxSpinCtrl supports the same properties as wxSpinButton and, since wxWidgets 2.9.5, another one:

base	integer	Numeric base, currently can be only 10 or 16 (default: 10).

wxSplitterWindow

property	type	description
orientation	String	Orientation of the splitter, either "vertical" or "horizontal" (default: horizontal).
sashpos	Dimension	Initial position of the sash (default: 0).
minsize	Dimension	Minimum child size (default: not set).
gravity	Floating-point value	Sash gravity, see wxSplitterWindow::SetSashGravity() (default: not set).

wxSplitterWindow must have one or two children that are non-toplevel window objects. If there's only one child, it is used as wxSplitterWindow's only visible child. If there are two children, the first one is used for left/top child and the second one for right/bottom child window.

wxSearchCtrl

property	type	description
value	Text	Initial value of the control (default: empty).

wxStatusBar

property	type	description
fields	integer	Number of status bar fields (default: 1).
widths	String	Comma-separated list of *fields* integers. Each value specifies width of one field; the values are interpreted using the same convention used by wxStatusBar::SetStatusWidths() (default: not set).
styles	String	Comma-separated list of *fields* style values. Each value specifies style of one field and can be one of `wxSB_NORMAL`, `wxSB_FLAT`, `wxSB_RAISED` or `wxSB_SUNKEN` (default: not set).

wxStaticBitmap

property	type	description
bitmap	Bitmap	Bitmap to display (required).

wxStaticBox

property	type	description
label	Text	Static box's label (default: empty).

wxStaticLine

No additional properties.

wxStaticText

property	type	description
label	Text	Label to display (default: empty).
wrap	Dimension	Wrap the text so that each line is at most the given number of pixels, see wxStaticText::Wrap() (default: no wrap).

wxTextCtrl

property	type	description
value	Text	Initial value of the control (default: empty).
maxlength	integer	Maximum length of the text which can be entered by user (default: unlimited).
hint	Text	Hint shown in empty control (new since wxWidgets 3.0.1).

wxTimePickerCtrl

No additional properties.

wxToggleButton

property	type	description
label	Text	Label to display on the button (default: empty).
checked	Boolean	Should the button be checked/pressed initially (default: 0)?

wxToolBar

property	type	description
bitmapsize	Size	Size of toolbar bitmaps (default: not set).
margins	Size	Margins (default: platform default).
packing	integer	Packing, see wxToolBar::SetToolPacking() (default: not set).
separation	integer	Default separator size, see wxToolBar::SetToolSeparation() (default: not set).
dontattachtoframe	Boolean	If set to 0 and the toolbar object is child of a wxFrame, wxFrame::SetToolBar() is called; otherwise, you have to add it to a frame manually. The toolbar is attached by default, you have to set this property to 1 to disable this behaviour (default: 0).

A toolbar can have one or more child objects of any wxControl-derived class or one of three pseudo-classes: `separator`, `space` or `tool`.

The `separator` pseudo-class is used to insert separators into the toolbar and has neither properties nor children. Similarly, the `space` pseudo-class is used for stretchable spaces (see wxToolBar::AddStretchableSpace(), new since wxWidgets 2.9.1).

The `tool` pseudo-class objects specify toolbar buttons and have the following properties:

property	type	description
bitmap	Bitmap	Tool's bitmap (default: empty).
bitmap2	Bitmap	Bitmap for disabled tool (default: derived from `bitmap`).
label	Text	Label to display on the tool (default: no label).
radio	Boolean	Item's kind is wxITEM_RADIO (default: 0)?
toggle	Boolean	Item's kind is wxITEM_CHECK (default: 0)?
dropdown	see below	Item's kind is wxITEM_DROPDOWN (default: 0)? (only available since wxWidgets 2.9.0)
tooltip	Text	Tooltip to use for the tool (default: none).
longhelp	Text	Help text shown in statusbar when the mouse is on the tool (default: none).
disabled	Boolean	Is the tool initially disabled (default: 0)?
checked	Boolean	Is the tool initially checked (default: 0)? (only available since wxWidgets 2.9.3)

The presence of a `dropdown` property indicates that the tool is of type wxITEM_DROPDOWN. It must be either empty or contain exactly one wxMenu child object defining the drop-down button associated menu.

Notice that `radio`, `toggle` and `dropdown` are mutually exclusive.

Children that are not `tool`, `space` or `separator` must be instances of classes derived from wxControl and are added to the toolbar using wxToolBar::AddControl().

Example:

```
<object class="wxToolBar">
    <style>wxTB_FLAT|wxTB_NODIVIDER</style>
    <object class="tool" name="foo">
        <bitmap>foo.png</bitmap>
        <label>Foo</label>
    </object>
    <object class="tool" name="bar">
        <bitmap>bar.png</bitmap>
        <label>Bar</label>
    </object>
    <object class="separator"/>
    <object class="tool" name="view_auto">
        <bitmap>view.png</bitmap>
        <label>View</label>
        <dropdown>
            <object class="wxMenu">
                <object class="wxMenuItem" name="view_as_text">
                    <label>View as text</label>
                </object>
                <object class="wxMenuItem" name="view_as_hex">
                    <label>View as binary</label>
                </object>
            </object>
        </dropdown>
    </object>
    <object class="space"/>
    <object class="wxComboBox">
        <content>
            <item>Just</item>
            <item>a combobox</item>
            <item>in the toolbar</item>
        </content>
    </object>
</object>
```

wxToolbook

property	type	description
imagelist	Image List	Image list to use for the images (default: none, built implicitly).

A toolbook can have one or more child objects of the `toolbookpage` pseudo-class (similarly to wxNotebook and its `notebookpage`).

`toolbookpage` objects have the following properties:

property	type	description
label	Text	Sheet page's title (default: empty).
bitmap	Bitmap	Bitmap shown alongside the label (default: none, mutually exclusive with `image`).
image	integer	The zero-based index of the image associated with the item into the image list (default: none, mutually exclusive with `bitmap`, only if imagelist was set).
selected	Boolean	Is the page selected initially (only one page can be selected; default: 0)?

Each `toolbookpage` has exactly one non-toplevel window as its child.

wxTreeCtrl

property	type	description
imagelist	Image List	Image list to use for the images (default: none).

wxTreebook

property	type	description
imagelist	Image List	Image list to use for the images (default: none, built implicitly).

A treebook can have one or more child objects of the `treebookpage` pseudo-class (similarly to wxNotebook and its `notebookpage`).

`treebookpage` objects have the following properties:

property	type	description
depth	integer	Page's depth in the labels tree (default: 0; see below).
label	Text	Sheet page's title (default: empty).
bitmap	Bitmap	Bitmap shown alongside the label (default: none, mutually exclusive with `image`).
image	integer	The zero-based index of the image associated with the item into the image list (default: none, mutually exclusive with `bitmap`, only if imagelist was set).
selected	Boolean	Is the page selected initially (only one page can be selected; default: 0)?

expanded	Boolean	If set to 1, the page is initially expanded. By default all pages are initially collapsed.

Each `treebookpage` has exactly one non-toplevel window as its child.

The tree of labels is not described using nested `treebookpage` objects, but using the *depth* property. Toplevel pages have depth 0, their child pages have depth 1 and so on. A `treebookpage's` label is inserted as child of the latest preceding page with depth equal to *depth-1*. For example, this XRC markup:

```
<object class="wxTreebook">
  ...
  <object class="treebookpage">
    <depth>0</depth>
    <label>Page 1</label>
    <object class="wxPanel">...</object>
  </object>
  <object class="treebookpage">
    <depth>1</depth>
    <label>Subpage 1A</label>
    <object class="wxPanel">...</object>
  </object>
  <object class="treebookpage">
    <depth>2</depth>
    <label>Subsubpage 1</label>
    <object class="wxPanel">...</object>
  </object>
  <object class="treebookpage">
    <depth>1</depth>
    <label>Subpage 1B</label>
    <object class="wxPanel">...</object>
  </object>
  <object class="treebookpage">
    <depth>2</depth>
    <label>Subsubpage 2</label>
    <object class="wxPanel">...</object>
  </object>
  <object class="treebookpage">
    <depth>0</depth>
    <label>Page 2</label>
    <object class="wxPanel">...</object>
  </object>
</object>
```

corresponds to the following tree of labels:

- Page 1
  - Subpage 1A
    - Subsubpage 1
  - Subpage 1B
    - Subsubpage 2
- Page 2

wxWizard

property	type	description
bitmap	Bitmap	Bitmap to display on the left side of the wizard (default: none).

A wizard object can have one or more child objects of the wxWizardPage or wxWizardPageSimple classes. They both support the following properties (in addition to Standard Properties):

property	type	description
title	Text	Wizard window's title (default: none).
bitmap	Bitmap	Page-specific bitmap (default: none).

wxWizardPage and wxWizardPageSimple nodes may have optional children: either exactly one sizer child or any number of non-toplevel window objects.

wxWizardPageSimple pages are automatically chained together; wxWizardPage pages transitions must be handled programmatically.

10.40.5 Sizers

Sizers are handled slightly differently in XRC resources than they are in wxWindow hierarchy. wxWindow's sizers hierarchy is parallel to the wxWindow children hierarchy: child windows are children of their parent window and the sizer (or sizers) form separate hierarchy attached to the window with wxWindow::SetSizer().

In XRC, the two hierarchies are merged together: sizers are children of other sizers or windows and they can contain child window objects.

If a sizer is child of a window object in the resource, it must be the only child and it will be attached to the parent with wxWindow::SetSizer(). Additionally, if the window doesn't have its size explicitly set, wxSizer::Fit() is used to resize the window. If the parent window is toplevel window, wxSizer::SetSizeHints() is called to set its hints.

A sizer object can have one or more child objects of one of two pseudo-classes: `sizeritem` or `spacer` (see wxStdDialogButtonSizer for an exception). The former specifies an element (another sizer or a window) to include in the sizer, the latter adds empty space to the sizer.

`sizeritem` objects have exactly one child object: either another sizer object, or a window object. `spacer` objects don't have any children, but they have one property:

property	type	description
size	Size	Size of the empty space (default: `wxDefaultSize`).

Both `sizeritem` and `spacer` objects can have any of the following properties:

property	type	description
option	integer	The "option" value for sizers. Used by wxBoxSizer to set proportion of the item in the growable direction (default: 0).
flag	Style	wxSizerItem flags (default: 0).
border	Dimension	Size of the border around the item (directions are specified in flags) (default: 0).
minsize	Size	Minimal size of this item (default: no min size).
ratio	Size	Item ratio, see wxSizer::SetRatio() (default: no ratio).
cellpos	Position	(wxGridBagSizer only) Position, see wxGBSizerItem::SetPos() (required).
cellspan	Size	(wxGridBagSizer only) Span, see wxGBSizerItem::SetSpan() (required).

Example of sizers XRC code:

```
<object class="wxDialog" name="derived_dialog">
    <title>Derived Dialog Example</title>
    <centered>1</centered>
    <!-- this sizer is set to be this dialog's sizer: -->
    <object class="wxFlexGridSizer">
        <cols>1</cols>
        <rows>0</rows>
        <vgap>0</vgap>
        <hgap>0</hgap>
        <growablecols>0:1</growablecols>
        <growablerows>0:1</growablerows>
        <object class="sizeritem">
            <flag>wxALIGN_CENTRE|wxALL</flag>
            <border>5</border>
            <object class="wxButton" name="my_button">
                <label>My Button</label>
```

```
            </object>
        </object>
        <object class="sizeritem">
            <flag>wxALIGN_CENTRE|wxALL</flag>
            <border>5</border>
            <object class="wxBoxSizer">
                <orient>wxHORIZONTAL</orient>
                <object class="sizeritem">
                    <flag>wxALIGN_CENTRE|wxALL</flag>
                    <border>5</border>
                    <object class="wxCheckBox" name="my_checkbox">
                        <label>Enable this text control:</label>
                    </object>
                </object>
                <object class="sizeritem">
                    <flag>wxALIGN_CENTRE|wxALL</flag>
                    <border>5</border>
                    <object class="wxTextCtrl" name="my_textctrl">
                        <size>80,-1</size>
                        <value></value>
                    </object>
                </object>
            </object>
        </object>
        ...
    </object>
</object>
```

The sizer classes that can be used are listed below, together with their class-specific properties. All classes support the following properties:

property	type	description
minsize	Size	Minimal size that this sizer will have, see wxSizer::SetMinSize() (default: no min size).

wxBoxSizer

property	type	description
orient	Style	Sizer orientation, "wxHORIZONTAL" or "wxVERTICAL" (default: wxHORIZONTAL).

wxStaticBoxSizer

property	type	description
orient	Style	Sizer orientation, "wxHORIZONTAL" or "wxVERTICAL" (default: wxHORIZONTAL).
label	Text	Label to be used for the static box around the sizer (default: empty).

wxGridSizer

property	type	description
rows	unsigned integer	Number of rows in the grid (default: 0 - determine automatically).
cols	unsigned integer	Number of columns in the grid (default: 0 - determine automatically).
vgap	Dimension	Vertical gap between children (default: 0).
hgap	Dimension	Horizontal gap between children (default: 0).

wxFlexGridSizer

property	type	description
rows	unsigned integer	Number of rows in the grid (default: 0 - determine automatically).
cols	unsigned integer	Number of columns in the grid (default: 0 - determine automatically).
vgap	Dimension	Vertical gap between children (default: 0).
hgap	Dimension	Horizontal gap between children (default: 0).
flexibledirection	Style	Flexible direction, `wxVERTICAL`, `wxHORIZONTAL` or `wxBOTH` (default). This property is only available since wxWidgets 2.9.5.
nonflexiblegrowmode	Style	Grow mode in the non-flexible direction, `wxFLEX_GROWMODE_NONE`, `wxFLEX_GROWMODE_SPECIFIED` (default) or `wxFLEX_GROWMODE_ALL`. This property is only available since wxWidgets 2.9.5.
growablerows	comma-separated integers list	Comma-separated list of indexes of rows that are growable (none by default). Since wxWidgets 2.9.5 optional proportion can be appended to each number after a colon (:).
growablecols	comma-separated integers list	Comma-separated list of indexes of columns that are growable (none by default). Since wxWidgets 2.9.5 optional proportion can be appended to each number after a colon (:).

wxGridBagSizer

property	type	description
vgap	Dimension	Vertical gap between children (default: 0).
hgap	Dimension	Horizontal gap between children (default: 0).
flexibledirection	Style	Flexible direction, `wxVERTICAL`, `wxHORIZONTAL`, `wxBOTH` (default: `wxBOTH`).
nonflexiblegrowmode	Style	Grow mode in the non-flexible direction, `wxFLEX_GROWMODE_NONE`, `wxFLEX_GROWMODE_SPECIFIED`, `wxFLEX_GROWMODE_ALL` (default: `wxFLEX_GROWMODE_SPECIFIED`).
growablerows	comma-separated integers list	Comma-separated list of indexes of rows that are growable, optionally the proportion can be appended after each number separated by a : (default: none).
growablecols	comma-separated integers list	Comma-separated list of indexes of columns that are growable, optionally the proportion can be appended after each number separated by a : (default: none).

wxWrapSizer

property	type	description
orient	Style	Sizer orientation, "wxHORIZONTAL" or "wxVERTICAL" (default: wxHORIZONTAL).
flag	Style	wxWrapSizer flags (default: 0).

wxStdDialogButtonSizer

Unlike other sizers, wxStdDialogButtonSizer has neither `sizeritem` nor `spacer` children. Instead, it has one or more children of the `button` pseudo-class. `button` objects have no properties and they must always have exactly one child of the `wxButton` class or a class derived from wxButton.

Example:

```
<object class="wxStdDialogButtonSizer">
    <object class="button">
        <object class="wxButton" name="wxID_OK">
            <label>OK</label>
        </object>
    </object>
    <object class="button">
        <object class="wxButton" name="wxID_CANCEL">
            <label>Cancel</label>
        </object>
    </object>
</object>
```

10.40.6 Other Objects

In addition to describing UI elements, XRC files can contain non-windows objects such as bitmaps or icons. This is a concession to Windows developers used to storing them in Win32 resources.

Note that unlike Win32 resources, bitmaps included in XRC files are *not* embedded in the XRC file itself. XRC file only contains a reference to another file with bitmap data.

wxBitmap

Bitmaps are stored in `<object>` element with class set to `wxBitmap`. Such bitmaps can then be loaded using wxXmlResource::LoadBitmap(). The content of the element is exactly same as in the case of bitmap properties, except that toplevel `<object>` is used.

For example, instead of:

```
<bitmap>mybmp.png</bitmap>
<bitmap stock_id="wxART_NEW"/>
```

toplevel wxBitmap resources would look like:

```
<object class="wxBitmap" name="my_bitmap">mybmp.png</object>
<object class="wxBitmap" name="my_new_bitmap" stock_id="wxART_NEW"/>
```

wxIcon

wxIcon resources are identical to wxBitmap ones, except that the class is `wxIcon`.

10.40.7 Platform Specific Content

It is possible to conditionally process parts of XRC files on some platforms only and ignore them on other platforms. *Any* element in XRC file, be it toplevel or arbitrarily nested one, can have the `platform` attribute. When used, `platform` contains |-separated list of platforms that this element should be processed on. It is filtered out and ignored on any other platforms.

Possible elemental values are:

`win`	Windows
`mac`	Mac OS X (or Mac Classic in wxWidgets version supporting it)
`unix`	Any Unix platform *except* OS X

Examples:

```
<label platform="win">Windows</label>
<label platform="unix">Unix</label>
<label platform="mac">Mac OS X</label>
<help platform="mac|unix">Not a Windows machine</help>
```

10.40.8 ID Ranges

Usually you won't care what value the XRCID macro returns for the ID of an object. Sometimes though it is convenient to have a range of IDs that are guaranteed to be consecutive. An example of this would be connecting a group of similar controls to the same event handler.

The following XRC fragment 'declares' an ID range called *foo* and another called *bar*; each with some items.

```
    <object class="wxButton" name="foo[start]">
    <object class="wxButton" name="foo[end]">
    <object class="wxButton" name="foo[2]">
    ...
```

```
    <object class="wxButton" name="bar[0]">
    <object class="wxButton" name="bar[2]">
    <object class="wxButton" name="bar[1]">
    ...
<ids-range name="foo" />
<ids-range name="bar" size="30" start="10000" />
```

For the range foo, no *size* or *start* parameters were given, so the size will be calculated from the number of range items, and IDs allocated by wxWindow::NewControlId (so they'll be negative). Range bar asked for a size of 30, so this will be its minimum size: should it have more items, the range will automatically expand to fit them. It specified a start ID of 10000, so XRCID("bar[0]") will be 10000, XRCID("bar[1]") 10001 etc. Note that if you choose to supply a start value it must be positive, and it's your responsibility to avoid clashes.

For every ID range, the first item can be referenced either as *rangename*[0] or *rangename*[start]. Similarly *rangename*[end] is the last item. Using [start] and [end] is more descriptive in e.g. a Bind() event range or a *for* loop, and they don't have to be altered whenever the number of items changes.

Whether a range has positive or negative IDs, [start] is always a smaller number than [end]; so code like this works as expected:

```
for (int n=XRCID("foo[start]"); n <= XRCID("foo[end]"); ++n)
    ...
```

ID ranges can be seen in action in the *objref* dialog section of the XRC Sample.

Note

- All the items in an ID range must be contained in the same XRC file.
- You can't use an ID range in a situation where static initialisation occurs; in particular, they won't work as expected in an event table. This is because the event table's IDs are set to their integer values before the XRC file is loaded, and aren't subsequently altered when the XRCID value changes.

Since

2.9.2

10.40.9 Extending the XRC Format

The XRC format is designed to be extensible and allows specifying and loading custom controls. The three available mechanisms are described in the rest of this section in the order of increasing complexity.

Subclassing

The simplest way to add custom controls is to set the `subclass` attribute of `<object>` element:

```
<object name="my_value" class="wxTextCtrl" subclass="MyTextCtrl">
  <style>wxTE_MULTILINE</style>
  ...etc., setup wxTextCtrl as usual...
</object>
```

In that case, wxXmlResource will create an instance of the specified subclass (`MyTextCtrl` in the example above) instead of the class (`wxTextCtrl` above) when loading the resource. However, the rest of the object's loading (calling its Create() method, setting its properties, loading any children etc.) will proceed in *exactly* the same way as it would without `subclass` attribute. In other words, this approach is only sufficient when the custom class is just a small modification (e.g. overridden methods or customized events handling) of an already supported classes.

The subclass must satisfy a number of requirements:

1. It must be derived from the class specified in `class` attribute.

2. It must be visible in wxWidget's pseudo-RTTI mechanism, i.e. there must be a DECLARE_DYNAMIC_CLASS() entry for it.

3. It must support two-phase creation. In particular, this means that it has to have default constructor.

4. It cannot provide custom Create() method and must be constructible using base `class'` Create() method (this is because XRC will call Create() of `class`, not `subclass`). In other words, *creation* of the control must not be customized.

Unknown Objects

A more flexible solution is to put a *placeholder* in the XRC file and replace it with custom control after the resource is loaded. This is done by using the `unknown` pseudo-class:

```
<object class="unknown" name="my_placeholder"/>
```

The placeholder is inserted as dummy wxPanel that will hold custom control in it. At runtime, after the resource is loaded and a window created from it (using e.g. wxXmlResource::LoadDialog()), use code must call wxXmlResource::AttachUnknownControl() to insert the desired control into placeholder container.

This method makes it possible to insert controls that are not known to XRC at all, but it's also impossible to configure the control in XRC description in any way. The only properties that can be specified are the standard window properties.

Note

`unknown` class cannot be combined with `subclass` attribute, they are mutually exclusive.

Adding Custom Classes

Finally, XRC allows adding completely new classes in addition to the ones listed in this document. A class for which wxXmlResourceHandler is implemented can be used as first-class object in XRC simply by passing class name as the value of `class` attribute:

```
<object name="my_ctrl" class="MyWidget">
  <my_prop>foo</my_prop>
  ...etc., whatever MyWidget handler accepts...
</object>
```

The only requirements on the class are that

1. the class must derive from wxObject

2. it must support wxWidget's pseudo-RTTI mechanism

Child elements of `<object>` are handled by the custom handler and there are no limitations on them imposed by XRC format.

This is the only mechanism that works for toplevel objects – custom controls are accessible using the type-unsafe wxXmlResource::LoadObject() method.

10.40.10 Packed XRC Files

In addition to plain XRC files, wxXmlResource supports (if wxFileSystem support is compiled in) compressed XRC resources. Compressed resources have either .zip or .xrs extension and are simply ZIP files that contain arbitrary number of XRC files and their dependencies (bitmaps, icons etc.).

10.40.11 Older Format Versions

This section describes differences in older revisions of XRC format (i.e. files with older values of `version` attribute of `<resource>`).

Versions Before 2.5.3.0

Version 2.5.3.0 introduced C-like handling of "\\" in text. In older versions, "\n", "\t" and "\r" escape sequences were replaced with respective characters in the same matter it's done in C, but "\\" was left intact instead of being replaced with single "\", as one would expect. Starting with 2.5.3.0, all of them are handled in C-like manner.

Versions Before 2.3.0.1

Prior to version 2.3.0.1, "$" was used for accelerators instead of "_" or "&". For example,

```
<label>$File</label>
```

was used in place of current version's

```
<label>_File</label>
```

(or "&File").

10.41 Scrolled Windows

Scrollbars come in various guises in wxWidgets.

All windows have the potential to show a vertical scrollbar and/or a horizontal scrollbar: it is a basic capability of a window. However, in practice, not all windows do make use of scrollbars, such as a single-line wxTextCtrl.

Because any class derived from wxWindow may have scrollbars, there are functions to manipulate the scrollbars and event handlers to intercept scroll events. But just because a window generates a scroll event, doesn't mean that the window necessarily handles it and physically scrolls the window. The base class wxWindow in fact doesn't have any default functionality to handle scroll events. If you created a wxWindow object with scrollbars, and then clicked on the scrollbars, nothing at all would happen. This is deliberate, because the *interpretation* of scroll events varies from one window class to another.

wxScrolledWindow (formerly wxCanvas) is an example of a window that adds functionality to make scrolling really work. It assumes that scrolling happens in consistent units, not different-sized jumps, and that page size is represented by the visible portion of the window. It is suited to drawing applications, but perhaps not so suitable for a sophisticated editor in which the amount scrolled may vary according to the size of text on a given line. For this, you would derive from wxWindow and implement scrolling yourself. wxGrid is an example of a class that implements its own scrolling, largely because columns and rows can vary in size.

wxScrollBar

10.41.1 The Scrollbar Model

The function wxWindow::SetScrollbar gives a clue about the way a scrollbar is modeled. This function takes the following arguments:

orientation	Which scrollbar: wxVERTICAL or wxHORIZONTAL.
position	The position of the scrollbar in scroll units.
visible	The size of the visible portion of the scrollbar, in scroll units.
range	The maximum position of the scrollbar.
refresh	Whether the scrollbar should be repainted.

orientation determines whether we're talking about the built-in horizontal or vertical scrollbar.

position is simply the position of the 'thumb' (the bit you drag to scroll around). It is given in scroll units, and so is relative to the total range of the scrollbar.

visible gives the number of scroll units that represents the portion of the window currently visible. Normally, a scrollbar is capable of indicating this visually by showing a different length of thumb.

range is the maximum value of the scrollbar, where zero is the start position. You choose the units that suit you, so if you wanted to display text that has 100 lines, you would set this to 100. Note that this doesn't have to correspond to the number of pixels scrolled - it is up to you how you actually show the contents of the window.

refresh just indicates whether the scrollbar should be repainted immediately or not.

10.41.2 An Example

Let's say you wish to display 50 lines of text, using the same font. The window is sized so that you can only see 16 lines at a time. You would use:

```
SetScrollbar(wxVERTICAL, 0, 16, 50);
```

Note that with the window at this size, the thumb position can never go above 50 minus 16, or 34. You can determine how many lines are currently visible by dividing the current view size by the character height in pixels.

When defining your own scrollbar behaviour, you will always need to recalculate the scrollbar settings when the window size changes. You could therefore put your scrollbar calculations and SetScrollbar call into a function named AdjustScrollbars, which can be called initially and also from your wxSizeEvent handler function.

10.42 wxDialog Overview

Classes: wxDialog, wxDialogLayoutAdapter

A dialog box is similar to a panel, in that it is a window which can be used for placing controls, with the following exceptions:

- A surrounding frame is implicitly created.
- Extra functionality is automatically given to the dialog box, such as tabbing between items (currently Windows only).
- If the dialog box is *modal*, the calling program is blocked until the dialog box is dismissed.

For a set of dialog convenience functions, including file selection, see Dialogs.

See also wxTopLevelWindow and wxWindow for inherited member functions. Validation of data in controls is covered in wxValidator Overview.

10.42.1 Automatic Scrolled Dialogs

As an ever greater variety of mobile hardware comes to market, it becomes more imperative for wxWidgets applications to adapt to these platforms without putting too much burden on the programmer. One area where wxWidgets can help is in adapting dialogs for the lower resolution screens that inevitably accompany a smaller form factor.

wxDialog therefore supplies a global wxDialogLayoutAdapter class that implements automatic scrolling adaptation for most sizer-based custom dialogs.

Many applications should therefore be able to adapt to small displays with little or no work, as far as dialogs are concerned. By default this adaptation is off. To switch scrolling adaptation on globally in your application, call the static function wxDialog::EnableLayoutAdaptation passing true. You can also adjust adaptation on a per-dialog basis by calling wxDialog::SetLayoutAdaptationMode with one of `wxDIALOG_ADAPTATION_MODE_DEFAULT` (use the global setting), `wxDIALOG_ADAPTATION_MODE_ENABLED` or `wxDIALOG_ADAPTATION_MODE_DISABLED`.

The last two modes override the global adaptation setting. With adaptation enabled, if the display size is too small for the dialog, wxWidgets (or rather the standard adapter class wxStandardDialogLayoutAdapter) will make part of the dialog scrolling, leaving standard buttons in a non-scrolling part at the bottom of the dialog. This is done as follows, in wxDialogLayoutAdapter::DoLayoutAdaptation called from within wxDialog::Show or wxDialog::ShowModal:

- If wxDialog::GetContentWindow returns a window derived from wxBookCtrlBase, the pages are made scrollable and no other adaptation is done.
- wxWidgets looks for a wxStdDialogButtonSizer and uses it for the non-scrolling part.
- If that search failed, wxWidgets looks for a horizontal wxBoxSizer with one or more standard buttons, with identifiers such as `wxID_OK` and `wxID_CANCEL`.
- If that search failed too, wxWidgets finds 'loose' standard buttons (in any kind of sizer) and adds them to a wxStdDialogButtonSizer. If no standard buttons were found, the whole dialog content will scroll.
- All the children apart from standard buttons are reparented onto a new wxScrolledWindow object, using the old top-level sizer for the scrolled window and creating a new top-level sizer to lay out the scrolled window and standard button sizer.

Customising Scrolling Adaptation

In addition to switching adaptation on and off globally and per dialog, you can choose how aggressively wxWidgets will search for standard buttons by setting wxDialog::SetLayoutAdaptationLevel. By default, all the steps described above will be performed but by setting the level to 1, for example, you can choose to only look for wxStdDialogButtonSizer.

You can use wxDialog::AddMainButtonId to add identifiers for buttons that should also be treated as standard buttons for the non-scrolling area.

You can derive your own class from wxDialogLayoutAdapter or wxStandardDialogLayoutAdapter and call wxDialog::SetLayoutAdapter, deleting the old object that this function returns. Override the functions CanDoLayoutAdaptation and DoLayoutAdaptation to test for adaptation applicability and perform the adaptation.

You can also override wxDialog::CanDoLayoutAdaptation and wxDialog::DoLayoutAdaptation in a class derived from wxDialog.

Where Scrolling Adaptation May Fail

Because adaptation rearranges your sizer and window hierarchy, it is not fool-proof, and may fail in the following situations:

- The dialog doesn't use sizers.
- The dialog implementation makes assumptions about the window hierarchy, for example getting the parent of a control and casting to the dialog class.
- The dialog does custom painting and/or event handling not handled by the scrolled window. If this problem can be solved globally, you can derive a new adapter class from wxStandardDialogLayoutAdapter and override its CreateScrolledWindow function to return an instance of your own class.

- The dialog has unusual layout, for example a vertical sizer containing a mixture of standard buttons and other controls.
- The dialog makes assumptions about the sizer hierarchy, for example to show or hide children of the top-level sizer. However, the original sizer hierarchy will still hold until Show or ShowModal is called.

You can help make sure that your dialogs will continue to function after adaptation by:

- avoiding the above situations and assumptions;
- using wxStdDialogButtonSizer;
- only making assumptions about hierarchy immediately after the dialog is created;
- using an intermediate sizer under the main sizer, a false top-level sizer that can be relied on to exist for the purposes of manipulating child sizers and windows;
- overriding wxDialog::GetContentWindow to return a book control if your dialog implements pages: wxWidgets will then only make the pages scrollable.

wxPropertySheetDialog and wxWizard

Adaptation for wxPropertySheetDialog is always done by simply making the pages scrollable, since wxDialog::GetContentWindow returns the dialog's book control and this is handled by the standard layout adapter.

wxWizard uses its own CanDoLayoutAdaptation and DoLayoutAdaptation functions rather than the global adapter: again, only the wizard pages are made scrollable.

10.43 wxValidator Overview

The aim of the validator concept is to make dialogs very much easier to write.

A validator is an object that can be plugged into a control (such as a wxTextCtrl), and mediates between C++ data and the control, transferring the data in either direction and validating it. It also is able to intercept events generated by the control, providing filtering behaviour without the need to derive a new control class.

You can use a stock validator, such as wxTextValidator (which does text control data transfer, validation and filtering) and wxGenericValidator (which does data transfer for a range of controls); or you can write your own.

Here is an example of wxTextValidator usage.

```
wxTextCtrl *txt1 = new wxTextCtrl(
    this, -1, wxT(""), wxDefaultPosition, wxDefaultSize, 0,
    wxTextValidator(wxFILTER_ALPHA, &g_data.m_string));
```

In this example, the text validator object provides the following functionality:

- It transfers the value of g_data.m_string (a wxString variable) to the wxTextCtrl when the dialog is initialised.
- It transfers the wxTextCtrl data back to this variable when the dialog is dismissed.
- It filters input characters so that only alphabetic characters are allowed.

The validation and filtering of input is accomplished in two ways. When a character is input, wxTextValidator checks the character against the allowed filter flag (`wxFILTER_ALPHA` in this case). If the character is inappropriate, it is vetoed (does not appear) and a warning beep sounds (unless wxValidator::SetBellOnError(false) has been called). The second type of validation is performed when the dialog is about to be dismissed, so if the default string contained invalid characters already, a dialog box is shown giving the error, and the dialog is not dismissed.

Note that any wxWindow may have a validator; using the `wxWS_EX_VALIDATE_RECURSIVELY` style (see wxWindow extended styles) you can also implement recursive validation.

wxValidator, wxTextValidator, wxGenericValidator, wxIntegerValidator, wxFloatingPointValidator

10.43.1 Anatomy of a Validator

A programmer creating a new validator class should provide the following functionality.

A validator constructor is responsible for allowing the programmer to specify the kind of validation required, and perhaps a pointer to a C++ variable that is used for storing the data for the control. If such a variable address is not supplied by the user, then the validator should store the data internally.

The wxValidator::Validate member function should return true if the data in the control (not the C++ variable) is valid. It should also show an appropriate message if data was not valid.

The wxValidator::TransferToWindow member function should transfer the data from the validator or associated C++ variable to the control.

The wxValidator::TransferFromWindow member function should transfer the data from the control to the validator or associated C++ variable.

There should be a copy constructor, and a wxValidator::Clone function which returns a copy of the validator object. This is important because validators are passed by reference to window constructors, and must therefore be cloned internally.

You can optionally define event handlers for the validator, to implement filtering. These handlers will capture events before the control itself does (see How Events are Processed). For an example implementation, see the `valtext.h` and `valtext.cpp` files in the wxWidgets library.

10.43.2 How Validators Interact with Dialogs

For validators to work correctly, validator functions must be called at the right times during dialog initialisation and dismissal.

When a wxDialog::Show is called (for a modeless dialog) or wxDialog::ShowModal is called (for a modal dialog), the function wxWindow::InitDialog is automatically called. This in turn sends an initialisation event to the dialog. The default handler for the `wxEVT_INIT_DIALOG` event is defined in the wxWindow class to simply call the function wxWindow::TransferDataToWindow. This function finds all the validators in the window's children and calls the wx↩Validator::TransferToWindow function for each. Thus, data is transferred from C++ variables to the dialog just as the dialog is being shown.

Note

If you are using a window or panel instead of a dialog, you will need to call wxWindow::InitDialog explicitly before showing the window.

When the user clicks on a button, for example the OK button, the application should first call wxWindow::Validate, which returns false if any of the child window validators failed to validate the window data. The button handler should return immediately if validation failed. Secondly, the application should call wxWindow::TransferDataFromWindow and return if this failed. It is then safe to end the dialog by calling wxDialog::EndModal (if modal) or wxDialog::Show (if modeless).

In fact, wxDialog contains a default command event handler for the `wxID_OK` button. It goes like this:

```
void wxDialog::OnOK(wxCommandEvent& event)
{
    if ( Validate() && TransferDataFromWindow() )
    {
        if ( IsModal() )
            EndModal(wxID_OK);
        else
        {
            SetReturnCode(wxID_OK);
            this->Show(false);
        }
    }
}
```

So if using validators and a normal OK button, you may not even need to write any code for handling dialog dismissal.

If you load your dialog from a resource file, you will need to iterate through the controls setting validators, since validators can't be specified in a dialog resource.

10.44 wxDataObject Overview

This overview discusses data transfer through clipboard or drag and drop.

In wxWidgets, these two ways to transfer data (either between different applications or inside one and the same) are very similar which allows to implement both of them using almost the same code - or, in other words, if you implement drag and drop support for your application, you get clipboard support for free and vice versa.

At the heart of both clipboard and drag and drop operations lies the wxDataObject class. The objects of this class (or, to be precise, classes derived from it) represent the data which is being carried by the mouse during drag and drop operation or copied to or pasted from the clipboard. wxDataObject is a "smart" piece of data because it knows which formats it supports (see GetFormatCount and GetAllFormats) and knows how to render itself in any of them (see GetDataHere). It can also receive its value from the outside in a format it supports if it implements the SetData method. Please see the documentation of this class for more details.

Both clipboard and drag and drop operations have two sides: the source and target, the data provider and the data receiver. These which may be in the same application and even the same window when, for example, you drag some text from one position to another in a word processor. Let us describe what each of them should do.

See also

Drag and Drop Overview, Clipboard and Drag & Drop, Drag & Drop Sample

10.44.1 The Data Provider (Source)

The data provider is responsible for creating a wxDataObject containing the data to be transferred. Then it should either pass it to the clipboard using wxClipboard::SetData function or to wxDropSource and call wxDropSource::DoDragDrop function.

The only (but important) difference is that the object for the clipboard transfer must always be created on the heap (i.e. using `new`) and it will be freed by the clipboard when it is no longer needed (indeed, it is not known in advance when, if ever, the data will be pasted from the clipboard). On the other hand, the object for drag and drop operation must only exist while wxDropSource::DoDragDrop executes and may be safely deleted afterwards and so can be created either on heap or on stack (i.e. as a local variable).

Another small difference is that in the case of clipboard operation, the application usually knows in advance whether it copies or cuts (i.e. copies and deletes) data - in fact, this usually depends on which menu item the user chose. But for drag and drop it can only know it after wxDropSource::DoDragDrop returns (from its return value).

10.44.2 The Data Receiver (Target)

To receive (paste in usual terminology) data from the clipboard, you should create a wxDataObject derived class which supports the data formats you need and pass it as argument to wxClipboard::GetData. If it returns false, no data in (any of) the supported format(s) is available. If it returns true, the data has been successfully transferred to wxDataObject.

For drag and drop case, the wxDropTarget::OnData virtual function will be called when a data object is dropped, from which the data itself may be requested by calling wxDropTarget::GetData method which fills the data object.

10.45 Drag and Drop Overview

It may be noted that data transfer to and from the clipboard is quite similar to data transfer with drag and drop and the code to implement these two types is almost the same.

In particular, both data transfer mechanisms store data in some kind of wxDataObject and identify its format(s) using the wxDataFormat class.

Note that `wxUSE_DRAG_AND_DROP` must be defined in `setup.h` in order to use drag and drop in wxWidgets.

wxDataObject Overview, Clipboard and Drag & Drop, Drag & Drop Sample

10.45.1 Drop Source Requirements

To be a *"drop source"*, i.e. to provide the data which may be dragged by the user elsewhere, you should implement the following steps:

- **Preparation:** First of all, a data object must be created and initialized with the data you wish to drag. For example:

```
wxTextDataObject my_data("This text will be dragged.");
```

- **Drag start**: To start the dragging process (typically in response to a mouse click) you must call wxDropSource::DoDragDrop like this:

```
wxDropSource dragSource( this );
dragSource.SetData( my_data );
wxDragResult result = dragSource.DoDragDrop( true );
```

- **Dragging:** The call to DoDragDrop() blocks the program until the user releases the mouse button (unless you override the wxDropSource::GiveFeedback function to do something special). When the mouse moves in a window of a program which understands the same drag-and-drop protocol (any program under Windows or any program supporting the XDnD protocol under X Windows), the corresponding wxDropTarget methods are called - see below.

- **Processing the result**: DoDragDrop() returns an *effect* code which is one of the values of `wxDragResult` enum (explained in wxDropTarget page):

```
switch (result)
{
    case wxDragCopy:
        // copy the data
        break;
    case wxDragMove:
        // move the data
        break;
    default:
        // do nothing
        break;
}
```

10.45.2 Drop Target Requirements

To be a *"drop target"*, i.e. to receive the data dropped by the user you should follow the instructions below:

- **Initialization:** For a window to be a drop target, it needs to have an associated wxDropTarget object. Normally, you will call wxWindow::SetDropTarget during window creation associating your drop target with it. You must derive a class from wxDropTarget and override its pure virtual methods. Alternatively, you may derive from wxTextDropTarget or wxFileDropTarget and override their OnDropText() or OnDropFiles() method.

- **Drop:** When the user releases the mouse over a window, wxWidgets asks the associated wxDropTarget object if it accepts the data. For this, a wxDataObject must be associated with the drop target and this data object will be responsible for the format negotiation between the drag source and the drop target. If all goes well, then wxDropTarget::OnData will get called and the wxDataObject belonging to the drop target can get filled with data.

- **The end**: After processing the data, DoDragDrop() returns either wxDragCopy or wxDragMove depending on the state of the keys Ctrl, Shift and Alt at the moment of the drop. There is currently no way for the drop target to change this return code.

10.46 wxHTML Overview

The wxHTML library provides classes for parsing and displaying HTML.

It is not intended to be a high-end HTML browser. If you are looking for something like that try http://www.mozilla.org/.

wxHTML can be used as a generic rich text viewer - for example to display a nice About Box (like those of GNOME apps) or to display the result of database searching. There is a wxFileSystem class which allows you to use your own virtual file systems.

wxHtmlWindow supports tag handlers. This means that you can easily extend wxHtml library with new, unsupported tags. Not only that, you can even use your own application-specific tags!

See src/html/m_*.cpp files for details.

There is a generic wxHtmlParser class, independent of wxHtmlWindow.

10.46.1 wxHTML Quick Start

Displaying HTML

First of all, you must include wx/wxhtml.h.

Class wxHtmlWindow (derived from wxScrolledWindow) is used to display HTML documents.

It has two important methods: wxHtmlWindow::LoadPage and wxHtmlWindow::SetPage. LoadPage loads and displays HTML file while SetPage displays directly the passed **string**. See the example:

```
mywin->LoadPage("test.htm");
mywin->SetPage("htmlbody"
               "h1Error/h1"
               "Some error occurred :-H)"
               "/body/hmtl");
```

Setting up wxHtmlWindow

Because wxHtmlWindow is derived from wxScrolledWindow and not from wxFrame, it doesn't have visible frame. But the user usually wants to see the title of HTML page displayed somewhere and the frame's titlebar is the ideal place for it.

wxHtmlWindow provides 2 methods in order to handle this: wxHtmlWindow::SetRelatedFrame and wxHtmlWindow::SetRelatedStatusBar. See the example:

```
html = new wxHtmlWindow(this);
html->SetRelatedFrame(this, "HTML : %%s");
html->SetRelatedStatusBar(0);
```

The first command associates the HTML object with its parent frame (this points to wxFrame object there) and sets the format of the title. Page title "Hello, world!" will be displayed as "HTML : Hello, world!" in this example.

The second command sets which frame's status bar should be used to display browser's messages (such as "Loading..." or "Done" or hypertext links).

Customizing wxHtmlWindow

You can customize wxHtmlWindow by setting font size, font face and borders (space between border of window and displayed HTML). Related functions:

- wxHtmlWindow::SetFonts
- wxHtmlWindow::SetBorders

- wxHtmlWindow::ReadCustomization
- wxHtmlWindow::WriteCustomization

The last two functions are used to store user customization info wxConfig stuff (for example in the registry under Windows, or in a dotfile under Unix).

10.46.2 HTML Printing

The wxHTML library provides printing facilities with several levels of complexity. The easiest way to print an HTML document is to use the wxHtmlEasyPrinting class.

It lets you print HTML documents with only one command and you don't have to worry about deriving from the wxPrintout class at all. It is only a simple wrapper around the wxHtmlPrintout, normal wxWidgets printout class.

And finally there is the low level class wxHtmlDCRenderer which you can use to render HTML into a rectangular area on any DC. It supports rendering into multiple rectangles with the same width. The most common use of this is placing one rectangle on each page or printing into two columns.

10.46.3 Help Files Format

wxHTML library can be used to show an help manual to the user; in fact, it supports natively (through wxHtmlHelpController) a reduced version of MS HTML Workshop format.

A **book** consists of three files: the header file, the contents file and the index file.

You can make a regular zip archive of these files, plus the HTML and any image files, for wxHTML (or helpview) to read; and the "`.zip`" file can optionally be renamed to "`.htb`".

Header file (.hhp)

The header file must contain these lines (and may contain additional lines which are ignored):

```
Contents file=filename.hhc
Index file=filename.hhk
Title=title of your book
Default topic=default page to be displayed.htm
```

All filenames (including the Default topic) are relative to the location of the "`.hhp`" file.

Note

For localization, in addition the "`.hhp`" file may contain the line

```
Charset=rfc_charset
```

which specifies what charset (e.g. "iso8859_1") was used in contents and index files. Please note that this line is incompatible with MS HTML Help Workshop and it would either silently remove it or complain with some error. See also Writing Non-English Applications.

Contents file (.hhc)

Contents file has HTML syntax and it can be parsed by regular HTML parser. It contains exactly one list (<ul>.... statement):

```
<ul>
    <li><object type="text/sitemap">
            <param name="Name" value="@topic name@">
            <param name="ID" value=@numeric_id@>
            <param name="Local" value="@filename.htm@">
        </object>
```

```
    <li><object type="text/sitemap">
            <param name="Name" value="@topic name@">
            <param name="ID" value=@numeric_id@>
            <param name="Local" value="@filename.htm@">
        </object>
    ...
</ul>
```

You can modify value attributes of param tags. The *topic name* is name of chapter/topic as is displayed in contents, *filename.htm* is the HTML page name (relative to the "`.hhp`" file) and *numeric_id* is optional, it is used only when you use wxHtmlHelpController::Display(int).

Items in the list may be nested - one <li> statement may contain a <ul> sub-statement:

```
<ul>
    <li><object type="text/sitemap">
            <param name="Name" value="Top node">
            <param name="Local" value="top.htm">
        </object>
    <ul>
        <li><object type="text/sitemap">
            <param name="Name" value="subnode in topnode">
            <param name="Local" value="subnode1.htm">
            </object>
        ...
    </ul>
    <li><object type="text/sitemap">
            <param name="Name" value="Another Top">
            <param name="Local" value="top2.htm">
        </object>
    ...
</ul>
```

Index Files (.hhk)

Index files have same format as contents files except that ID params are ignored and sublists are **not** allowed.

10.46.4 Input Filters

The wxHTML library provides a mechanism for reading and displaying files of many different file formats.

wxHtmlWindow::LoadPage can load not only HTML files but any known file. To make a file type known to wxHtml↩ Window you must create a wxHtmlFilter filter and register it using wxHtmlWindow::AddFilter.

10.46.5 Cells and Containers

This article describes mechanism used by wxHtmlWinParser and wxHtmlWindow to parse and display HTML documents.

Cells

You can divide any text (or HTML) into small fragments. Let's call these fragments **cells**. Cell is for example one word, horizontal line, image or any other part of document. Each cell has width and height (except special "magic" cells with zero dimensions - e.g. colour changers or font changers). See wxHtmlCell.

Containers

Container is kind of cell that may contain sub-cells. Its size depends on number and sizes of its sub-cells (and also depends on width of window). See wxHtmlContainerCell, wxHtmlCell::Layout. This image shows the cells and containers:

Using Containers in Tag Handler

wxHtmlWinParser provides a user-friendly way of managing containers. It is based on the idea of opening and closing containers.

Use wxHtmlWinParser::OpenContainer to open new a container *within* an already opened container. This new container is a *sub-container* of the old one. (If you want to create a new container with the same depth level you can call `CloseContainer()`; OpenContainer();.)

Use wxHtmlWinParser::CloseContainer to close the container. This doesn't create a new container with same depth level but it returns "control" to the parent container. See explanation:

There clearly must be same number of calls to OpenContainer as to CloseContainer.

This code creates a new paragraph (container at same depth level) with "Hello, world!":

```
m_WParser->CloseContainer();
c = m_WParser->OpenContainer();

m_WParser->AddText("Hello, ");
m_WParser->AddText("world!");

m_WParser->CloseContainer();
m_WParser->OpenContainer();
```

and here is image of the situation:

You can see that there was an opened container before the code was executed. We closed it, created our own container, then closed our container and opened new container.

The result was that we had *same* depth level after executing. This is general rule that should be followed by tag handlers: leave depth level of containers unmodified (in other words, number of OpenContainer and CloseContainer calls should be same within wxHtmlTagHandler::HandleTag's body).

Notice that it would be usually better to use wxHtmlContainerCell::InsertCell instead of adding text to the parser directly.

10.46.6 Tag Handlers

The wxHTML library provides architecture of pluggable *tag* handlers. Tag handler is class that understands particular HTML tag (or tags) and is able to interpret it.

wxHtmlWinParser has a static table of **modules**. Each module contains one or more tag handlers. Each time a new wxHtmlWinParser object is constructed all modules are scanned and handlers are added to wxHtmlParser's list of available handlers (note: wxHtmlParser's list is non-static).

How it works

Common tag handler's wxHtmlTagHandler::HandleTag method works in four steps:

- Save state of parent parser into local variables
- Change parser state according to tag's params
- Parse text between the tag and paired ending tag (if present)
- Restore original parser state

See wxHtmlWinParser for methods for modifying parser's state. In general you can do things like opening/closing containers, changing colors, fonts etc.

Providing own tag handlers

You should create a new .cpp file and place the following lines into it:

```
#include <mod_templ.h>
#include <forcelink.h>
FORCE_LINK_ME(yourmodulefilenamewithoutcpp)
```

Then you must define handlers and one module.

Tag handlers

The handler is derived from wxHtmlWinTagHandler (or directly from wxHtmlTagHandler).

You can use set of macros to define the handler (see src/html/m_∗.cpp files for details). Handler definition must start with **TAG_HANDLER_BEGIN** macro and end with **TAG_HANDLER_END** macro.

I strongly recommend to have a look at *include/wxhtml/mod_templ.h* file. Otherwise you won't understand the structure of macros.

See macros reference:

- **TAG_HANDLER_BEGIN**(*name*, *tags*): Starts handler definition. *name* is handler identifier (in fact part of class name), *tags* is string containing list of tags supported by this handler (in uppercase). This macro derives new class from wxHtmlWinTagHandler and implements it is wxHtmlTagHandler::GetSupportedTags method. Example: TAG_HANDLER_BEGIN(FONTS, "B,I,U,T")

- **TAG_HANDLER_VARS:** This macro starts block of variables definitions. (Variables are identical to class attributes.) Example:

```
TAG_HANDLER_BEGIN(VARS_ONLY, "CRAZYTAG")
    TAG_HANDLER_VARS
        int my_int_var;
        wxString something_else;
TAG_HANDLER_END(VARS_ONLY)
```

This macro is used only in rare cases.

- **TAG_HANDLER_CONSTR**(*name*): This macro supplies object constructor. *name* is same name as the one from TAG_HANDLER_BEGIN macro. Body of constructor follow after this macro (you must use { and }). Example:

```
TAG_HANDLER_BEGIN(VARS2, "CRAZYTAG")
    TAG_HANDLER_VARS
        int my_int_var;
    TAG_HANDLER_CONSTR(vars2)
        { // !!!!!!
        my_int_var = 666;
        } // !!!!!!
TAG_HANDLER_END(VARS2)
```

Never used in wxHTML :-)

- **TAG_HANDLER_PROC**(*varib*): This is very important macro. It defines wxHtmlTagHandler::HandleTag method. *varib* is name of parameter passed to the method, usually *tag*. Body of method follows after this macro. Note than you must use { and } ! Example:

```
TAG_HANDLER_BEGIN(TITLE, "TITLE")
    TAG_HANDLER_PROC(tag)
        {
        printf("TITLE found...\n");
        }
TAG_HANDLER_END(TITLE)
```

- **TAG_HANDLER_END**(*name*): Ends definition of tag handler *name*.

Tags Modules

You can use set of 3 macros TAGS_MODULE_BEGIN, TAGS_MODULE_ADD and TAGS_MODULE_END to inherit new module from wxHtmlTagsModule and to create instance of it.

See macros reference:

- **TAGS_MODULE_BEGIN**(*modname*): Begins module definition. *modname* is part of class name and must be unique.
- **TAGS_MODULE_ADD**(*name*): Adds the handler to this module. *name* is the identifier from TAG_HANDLER_BEGIN.
- **TAGS_MODULE_END**(*modname*): Ends the definition of module. Example:

```
TAGS_MODULE_BEGIN(Examples)
    TAGS_MODULE_ADD(VARS_ONLY)
    TAGS_MODULE_ADD(VARS2)
    TAGS_MODULE_ADD(TITLE)
TAGS_MODULE_END(Examples)
```

10.46.7 Supported HTML Tags

wxHTML is not full implementation of HTML standard. Instead, it supports most common tags so that it is possible to display *simple* HTML documents with it. (For example it works fine with pages created in Netscape Composer or generated by tex2rtf).

Following tables list all tags known to wxHTML, together with supported parameters.

A tag has general form of `tagname` param_1 param_2 ... param_n where param_i is either `paramname="paramvalue"` or `paramname=paramvalue` - these two are equivalent. Unless stated otherwise, wxHTML is case-insensitive.

Common Parameter Values

We will use these substitutions in tags descriptions:

```
[alignment]     CENTER
                LEFT
                RIGHT
                JUSTIFY

[v_alignment]   TOP
                BOTTOM
                CENTER

[color]         HTML 4.0-compliant colour specification

[fontsize]      -2
                -1
                +0
                +1
                +2
                +3
                +4
                1
                2
                3
                4
                5
                6
                7

[pixels]        integer value that represents dimension in pixels

[percent]       i%
                where i is integer

[url]           an URL

[string]        text string

[coords]        c(1),c(2),c(3),...,c(n)
                where c(i) is integer
```

Supported Styles

wxHTML doesn't really have CSS support but it does support a few simple styles: you can use "text-align", "width", "vertical-align" and "background" with all elements and for SPAN elements a few other styles are additionally recognized:

- color
- font-family
- font-size (only in point units)
- font-style (only "oblique", "italic" and "normal" values are supported)
- font-weight (only "bold" and "normal" values are supported)
- text-decoration (only "underline" value is supported)

10.47 wxRichTextCtrl Overview

wxRichTextCtrl provides a generic implementation of a rich text editor that can handle different character styles, paragraph formatting, and images.

It's aimed at editing 'natural' language text - if you need an editor that supports code editing, wxStyledTextCtrl is a better choice.

Despite its name, it cannot currently read or write RTF (rich text format) files. Instead, it uses its own XML format, and can also read and write plain text. In future we expect to provide RTF or OpenDocument file capabilities. Custom file formats can be supported by creating additional file handlers and registering them with the control.

wxRichTextCtrl is largely compatible with the wxTextCtrl API, but extends it where necessary. The control can be used where the native rich text capabilities of wxTextCtrl are not adequate (this is particularly true on Windows) and where more direct access to the content representation is required. It is difficult and inefficient to read the style information in a wxTextCtrl, whereas this information is readily available in wxRichTextCtrl. Since it's written in pure wxWidgets, any customizations you make to wxRichTextCtrl will be reflected on all platforms.

wxRichTextCtrl supports basic printing via the easy-to-use wxRichTextPrinting class. Creating applications with simple word processing features is simplified with the inclusion of wxRichTextFormattingDialog, a tabbed dialog allowing interactive tailoring of paragraph and character styling. Also provided is the multi-purpose dialog wxRich↩TextStyleOrganiserDialog that can be used for managing style definitions, browsing styles and applying them, or selecting list styles with a renumber option.

There are a few disadvantages to using wxRichTextCtrl. It is not native, so does not behave exactly as a native wxTextCtrl, although common editing conventions are followed. Users may miss the built-in spelling correction on Mac OS X, or any special character input that may be provided by the native control. It would also be a poor choice if intended users rely on screen readers that would be not work well with non-native text input implementation. You might mitigate this by providing the choice between wxTextCtrl and wxRichTextCtrl, with fewer features in the former case.

A good way to understand wxRichTextCtrl's capabilities is to compile and run the sample, samples/richtext, and browse the code.

10.47.1 Related Classes

Major classes: wxRichTextCtrl, wxRichTextBuffer, wxRichTextEvent

Helper classes: wxTextAttr, wxRichTextRange

File handler classes: wxRichTextFileHandler, wxRichTextHTMLHandler, wxRichTextXMLHandler

Style classes: wxRichTextCharacterStyleDefinition, wxRichTextParagraphStyleDefinition, wxRichTextListStyleDefinition, wxRichTextStyleSheet

Additional controls: wxRichTextStyleComboCtrl, wxRichTextStyleListBox, wxRichTextStyleListCtrl

Printing classes: wxRichTextPrinting, wxRichTextPrintout, wxRichTextHeaderFooterData

Dialog classes: wxRichTextStyleOrganiserDialog, wxRichTextFormattingDialog, wxSymbolPickerDialog

10.47.2 Code Example

The following code is an example taken from the sample, and adds text and styles to a rich text control programmatically.

```
wxRichTextCtrl* richTextCtrl = new wxRichTextCtrl(
    splitter, wxID_ANY, wxEmptyString, wxDefaultPosition,
    wxSize(200, 200), wxVSCROLL | wxHSCROLL |
      wxBORDER_NONE | wxWANTS_CHARS);

wxFont textFont = wxFont(12, wxROMAN, wxNORMAL, wxNORMAL);
wxFont boldFont = wxFont(12, wxROMAN, wxNORMAL, wxBOLD);
wxFont italicFont = wxFont(12, wxROMAN, wxITALIC, wxNORMAL);

wxFont font(12, wxROMAN, wxNORMAL, wxNORMAL);

m_richTextCtrl->SetFont(font);

wxRichTextCtrl& r = richTextCtrl;

r.BeginSuppressUndo();

r.BeginParagraphSpacing(0, 20);

r.BeginAlignment(wxTEXT_ALIGNMENT_CENTRE);
r.BeginBold();

r.BeginFontSize(14);
r.WriteText(wxT("Welcome to wxRichTextCtrl, a wxWidgets control for editing and presenting
       styled text and images"));
r.EndFontSize();
r.Newline();

r.BeginItalic();
r.WriteText(wxT("by Julian Smart"));
r.EndItalic();

r.EndBold();

r.Newline();
r.WriteImage(wxBitmap(zebra_xpm));

r.EndAlignment();

r.Newline();
r.Newline();

r.WriteText(wxT("What can you do with this thing? "));
r.WriteImage(wxBitmap(smiley_xpm));
r.WriteText(wxT(" Well, you can change text "));

r.BeginTextColour(wxColour(255, 0, 0));
r.WriteText(wxT("colour, like this red bit."));
r.EndTextColour();

r.BeginTextColour(wxColour(0, 0, 255));
r.WriteText(wxT(" And this blue bit."));
r.EndTextColour();

r.WriteText(wxT(" Naturally you can make things "));
r.BeginBold();
r.WriteText(wxT("bold "));
r.EndBold();
r.BeginItalic();
r.WriteText(wxT("or italic "));
r.EndItalic();
r.BeginUnderline();
r.WriteText(wxT("or underlined."));
r.EndUnderline();
```

```
r.BeginFontSize(14);
r.WriteText(wxT(" Different font sizes on the same line is allowed, too."));
r.EndFontSize();

r.WriteText(wxT(" Next we'll show an indented paragraph."));

r.BeginLeftIndent(60);
r.Newline();

r.WriteText(wxT("Indented paragraph."));
r.EndLeftIndent();

r.Newline();

r.WriteText(wxT("Next, we'll show a first-line indent, achieved using BeginLeftIndent(100,
       -40)."));

r.BeginLeftIndent(100, -40);
r.Newline();

r.WriteText(wxT("It was in January, the most down-trodden month of an Edinburgh winter."));
r.EndLeftIndent();

r.Newline();

r.WriteText(wxT("Numbered bullets are possible, again using subindents:"));

r.BeginNumberedBullet(1, 100, 60);
r.Newline();

r.WriteText(wxT("This is my first item. Note that wxRichTextCtrl doesn't automatically do
       numbering, but this will be added later."));
r.EndNumberedBullet();

r.BeginNumberedBullet(2, 100, 60);
r.Newline();

r.WriteText(wxT("This is my second item."));
r.EndNumberedBullet();

r.Newline();

r.WriteText(wxT("The following paragraph is right-indented:"));

r.BeginRightIndent(200);
r.Newline();

r.WriteText(wxT("It was in January, the most down-trodden month of an Edinburgh winter. An
       attractive woman came into the cafe, which is nothing remarkable."));
r.EndRightIndent();

r.Newline();

wxArrayInt tabs;
tabs.Add(400);
tabs.Add(600);
tabs.Add(800);
tabs.Add(1000);
wxTextAttr attr;
attr.SetFlags(wxTEXT_ATTR_TABS);
attr.SetTabs(tabs);
r.SetDefaultStyle(attr);

r.WriteText(wxT("This line contains tabs:\tFirst tab\tSecond tab\tThird tab"));

r.Newline();
r.WriteText(wxT("Other notable features of wxRichTextCtrl include:"));

r.BeginSymbolBullet(wxT('*'), 100, 60);
r.Newline();
r.WriteText(wxT("Compatibility with wxTextCtrl API"));
r.EndSymbolBullet();

r.WriteText(wxT("Note: this sample content was generated programmatically from within the
       MyFrame constructor in the demo. The images were loaded from inline XPMs. Enjoy wxRichTextCtrl!"));

r.EndSuppressUndo();
```

10.47.3 Starting to Use wxRichTextCtrl

You need to include <wx/richtext/richtextctrl.h> in your source, and link with the appropriate wx↩ Widgets library with `richtext` suffix. Put the rich text library first in your link line to avoid unresolved symbols.

Then you can create a wxRichTextCtrl, with the wxWANT_CHARS style if you want tabs to be processed by the control rather than being used for navigation between controls.

10.47.4 Text Styles

Styling attributes are represented by wxTextAttr, or for more control over attributes such as margins and size, the derived class wxRichTextAttr.

When setting a style, the flags of the attribute object determine which attributes are applied. When querying a style, the passed flags are ignored except (optionally) to determine whether attributes should be retrieved from character content or from the paragraph object.

wxRichTextCtrl takes a layered approach to styles, so that different parts of the content may be responsible for contributing different attributes to the final style you see on the screen.

There are four main notions of style within a control:

- **Basic style**: The fundamental style of a control, onto which any other styles are layered. It provides default attributes, and changing the basic style may immediately change the look of the content depending on what other styles the content uses. Calling wxRichTextCtrl::SetFont changes the font for the basic style. The basic style is set with wxRichTextCtrl::SetBasicStyle.
- **Paragraph style**: Each paragraph has attributes that are set independently from other paragraphs and independently from the content within the paragraph. Normally, these attributes are paragraph-related, such as alignment and indentation, but it is possible to set character attributes too. The paragraph style can be set independently of its content by passing wxRICHTEXT_SETSTYLE_PARAGRAPHS_ONLY to wxRichTextCtrl::SetStyleEx.
- **Character style**: Characters within each paragraph can have attributes. A single character, or a run of characters, can have a particular set of attributes. The character style can be with wxRichTextCtrl::SetStyle or wxRichTextCtrl::SetStyleEx.
- **Default style**: This is the 'current' style that determines the style of content that is subsequently typed, pasted or programmatically inserted. The default style is set with wxRichTextCtrl::SetDefaultStyle.

What you see on the screen is the dynamically *combined* style, found by merging the first three of the above style types (the fourth is only a guide for future content insertion and therefore does not affect the currently displayed content).

To make all this more concrete, here are examples of where you might set these different styles:

- You might set the *basic style* to have a Times Roman font in 12 point, left-aligned, with two millimetres of spacing after each paragraph.
- You might set the *paragraph style* (for one particular paragraph) to be centred.
- You might set the *character style* of one particular word to bold.
- You might set the *default style* to be underlined, for subsequent inserted text.

Naturally you can do any of these things either using your own UI, or programmatically.

The basic wxTextCtrl doesn't make the same distinctions as wxRichTextCtrl regarding attribute storage. So we need finer control when setting and retrieving attributes. wxRichTextCtrl::SetStyleEx takes a *flags* parameter:

- wxRICHTEXT_SETSTYLE_OPTIMIZE specifies that the style should be changed only if the combined attributes are different from the attributes for the current object. This is important when applying styling that has been edited by the user, because he has just edited the *combined* (visible) style, and wxRichTextCtrl wants to leave unchanged attributes associated with their original objects instead of applying them to both paragraph and content objects.

- wxRICHTEXT_SETSTYLE_PARAGRAPHS_ONLY specifies that only paragraph objects within the given range should take on the attributes.
- wxRICHTEXT_SETSTYLE_CHARACTERS_ONLY specifies that only content objects (text or images) within the given range should take on the attributes.
- wxRICHTEXT_SETSTYLE_WITH_UNDO specifies that the operation should be undoable.

It's great to be able to change arbitrary attributes in a wxRichTextCtrl, but it can be unwieldy for the user or programmer to set attributes separately. Word processors have collections of styles that you can tailor or use as-is, and this means that you can set a heading with one click instead of marking text in bold, specifying a large font size, and applying a certain paragraph spacing and alignment for every such heading. Similarly, wxWidgets provides a class called wxRichTextStyleSheet which manages style definitions (wxRichTextParagraphStyleDefinition, wxRichTextListStyleDefinition and wxRichTextCharacterStyleDefinition). Once you have added definitions to a style sheet and associated it with a wxRichTextCtrl, you can apply a named definition to a range of text. The classes wxRichTextStyleComboCtrl and wxRichTextStyleListBox can be used to present the user with a list of styles in a sheet, and apply them to the selected text.

You can reapply a style sheet to the contents of the control, by calling wxRichTextCtrl::ApplyStyleSheet. This is useful if the style definitions have changed, and you want the content to reflect this. It relies on the fact that when you apply a named style, the style definition name is recorded in the content. So ApplyStyleSheet works by finding the paragraph attributes with style names and re-applying the definition's attributes to the paragraph. Currently, this works with paragraph and list style definitions only.

10.47.5 Included Dialogs

wxRichTextCtrl comes with standard dialogs to make it easier to implement text editing functionality.

wxRichTextFormattingDialog can be used for character or paragraph formatting, or a combination of both. It's a wxPropertySheetDialog with the following available tabs: Font, Indents & Spacing, Tabs, Bullets, Style, Borders, Margins, Background, Size, and List Style. You can select which pages will be shown by supplying flags to the dialog constructor. In a character formatting dialog, typically only the Font page will be shown. In a paragraph formatting dialog, you'll show the Indents & Spacing, Tabs and Bullets pages. The Style tab is useful when editing a style definition.

You can customize this dialog by providing your own wxRichTextFormattingDialogFactory object, which tells the formatting dialog how many pages are supported, what their identifiers are, and how to creates the pages.

wxRichTextStyleOrganiserDialog is a multi-purpose dialog that can be used for managing style definitions, browsing styles and applying them, or selecting list styles with a renumber option. See the sample for usage - it is used for the "Manage Styles" and "Bullets and Numbering" menu commands.

wxSymbolPickerDialog lets the user insert a symbol from a specified font. It has no wxRichTextCtrl dependencies besides being included in the rich text library.

10.47.6 How wxRichTextCtrl is Implemented

Data representation is handled by wxRichTextBuffer, and a wxRichTextCtrl always has one such buffer.

The content is represented by a hierarchy of objects, all derived from wxRichTextObject. An object might be an image, a fragment of text, a paragraph, or a further composite object. Objects store a wxRichTextAttr containing style information; a paragraph object can contain both paragraph and character information, but content objects such as text can only store character information. The final style displayed in the control or in a printout is a combination of base style, paragraph style and content (character) style.

The top of the hierarchy is the buffer, a kind of wxRichTextParagraphLayoutBox, containing further wxRichTextParagraph objects, each of which can include text, images and potentially other types of object.

Each object maintains a range (start and end position) measured from the start of the main parent object.

When Layout is called on an object, it is given a size which the object must limit itself to, or one or more flexible directions (vertical or horizontal). So, for example, a centred paragraph is given the page width to play with (minus any

margins), but can extend indefinitely in the vertical direction. The implementation of Layout caches the calculated size and position.

When the buffer is modified, a range is invalidated (marked as requiring layout), so that only the minimum amount of layout is performed.

A paragraph of pure text with the same style contains just one further object, a wxRichTextPlainText object. When styling is applied to part of this object, the object is decomposed into separate objects, one object for each different character style. So each object within a paragraph always has just one wxTextAttr object to denote its character style. Of course, this can lead to fragmentation after a lot of edit operations, potentially leading to several objects with the same style where just one would do. So a Defragment function is called when updating the control's display, to ensure that the minimum number of objects is used.

10.47.7 Nested Objects

wxRichTextCtrl supports nested objects such as text boxes and tables. To achieve compatibility with the existing API, there is the concept of *object focus*. When the user clicks on a nested text box, the object focus is set to that container object so all keyboard input and API functions apply to that container. The application can change the focus using wxRichTextCtrl::SetObjectFocus. Call this function with a `null` parameter to set the focus back to the top-level object.

An event will be sent to the control when the focus changes.

When the user clicks on the control, wxRichTextCtrl determines which container to set as the current object focus by calling the found container's overrided wxRichTextObject::AcceptsFocus function. For example, although a table is a container, it must not itself be the object focus because there is no text editing at the table level. Instead, a cell within the table must accept the focus.

Since with nested objects it is not possible to represent a section with merely a start position and an end position, the class wxRichTextSelection is provided which stores multiple ranges (for non-contiguous selections such as table cells) and a pointer to the container object in question. You can pass wxRichTextSelection to wxRichTextCtrl::SetSelection or get an instance of it from wxRichTextCtrl::GetSelection.

When selecting multiple objects, such as cell tables, the wxRichTextCtrl dragging handler code calls the function wxRichTextObject::HandlesChildSelections to determine whether the children can be individual selections. Currently only table cells can be multiply-selected in this way.

10.47.8 Context Menus and Property Dialogs

There are three ways you can make use of context menus: you can let wxRichTextCtrl handle everything and provide a basic menu; you can set your own context menu using wxRichTextCtrl::SetContextMenu but let wxRichTextCtrl handle showing it and adding property items; or you can override the default context menu behaviour by adding a context menu event handler to your class in the normal way.

If you right-click over a text box in cell in a table, you may want to edit the properties of one of these objects - but which properties will you be editing?

Well, the default behaviour allows up to three property-editing menu items simultaneously - for the object clicked on, the container of that object, and the container's parent (depending on whether any of these objects return true from their wxRichTextObject::CanEditProperties functions). If you supply a context menu, add a property command item using the wxID_RICHTEXT_PROPERTIES1 identifier, so that wxRichTextCtrl can find the position to add command items. The object should tell the control what label to use by returning a string from wxRichTextObject::GetPropertiesMenuLabel.

Since there may be several property-editing commands showing, it is recommended that you don't include the word Properties - just the name of the object, such as Text Box or Table.

10.47.9 Development Roadmap

Bugs

This is an incomplete list of bugs.

- Moving the caret up at the beginning of a line sometimes incorrectly positions the caret.
- As the selection is expanded, the text jumps slightly due to kerning differences between drawing a single text string versus drawing several fragments separately. This could be improved by using wxDC::GetPartialTextExtents to calculate exactly where the separate fragments should be drawn. Note that this problem also applies to separation of text fragments due to difference in their attributes.

Features

This is a list of some of the features that have yet to be implemented. Help with them will be appreciated.

- support for composite objects in some functions where it's not yet implemented, for example ApplyStyleSheet
- Table API enhancements and dialogs; improved table layout especially row spans and fitting
- Conversion from HTML, and a rewrite of the HTML output handler that includes CSS, tables, text boxes, and floating images, in addition to a simplified-HTML mode for wxHTML compatibility
- Open Office input and output
- RTF input and output
- A ruler control
- Standard editing toolbars
- Bitmap bullets
- Justified text, in print/preview at least
- scaling: either everything scaled, or rendering using a custom reference point size and an optional dimension scale

There are also things that could be done to take advantage of the underlying text capabilities of the platform; higher-level text formatting APIs are available on some platforms, such as Mac OS X, and some of translation from high level to low level wxDC API is unnecessary. However this would require additions to the wxWidgets API.

10.48 wxAUI Overview

wxAUI stands for Advanced User Interface.

It aims to give the user a cutting edge interface with floatable windows, and a user-customizable layout. The original wxAUI sources have kindly been made available under the wxWindows licence by Kirix Corp. and they have since then been integrated into wxWidgets and further improved.

Window Docking (wxAUI)

10.48.1 Frame Management

Frame management provides the means to open, move and hide common controls that are needed to interact with the document, and allow these configurations to be saved into different perspectives and loaded at a later time.

10.48.2 Toolbars

Toolbars are a specialized subset of the frame management system and should behave similarly to other docked components. However, they also require additional functionality, such as "spring-loaded" rebar support, "chevron" buttons and end-user customizability.

10.48.3 Modeless Controls

Modeless controls expose a tool palette or set of options that float above the application content while allowing it to be accessed. Usually accessed by the toolbar, these controls disappear when an option is selected, but may also be "torn off" the toolbar into a floating frame of their own.

10.48.4 Look and Feel

Look and feel encompasses the way controls are drawn, both when shown statically as well as when they are being moved. This aspect of user interface design incorporates "special effects" such as transparent window dragging as well as frame animation.

wxAUI adheres to the following principles: Use native floating frames to obtain a native look and feel for all platforms. Use existing wxWidgets code where possible, such as sizer implementation for frame management. Use classes included in wxCore and wxBase only.

10.49 wxPropertyGrid Overview

wxPropertyGrid is a specialized grid for editing properties - in other words name = value pairs.

List of ready-to-use property classes include strings, numbers, flag sets, fonts, colours and many others. It is possible, for example, to categorize properties, set up a complete tree-hierarchy, add more than two columns, and set arbitrary per-property attributes.

As this version of wxPropertyGrid has some backward-incompatible changes from version 1.4, everybody who need to maintain custom property classes should carefully read final section in Changes from wxPropertyGrid 1.4.

10.49.1 Creating and Populating wxPropertyGrid

As seen here, wxPropertyGrid is constructed in the same way as other wxWidgets controls:

```
// Necessary header file
#include <wx/propgrid/propgrid.h>

...

    // Assumes code is in frame/dialog constructor

    // Construct wxPropertyGrid control
    wxPropertyGrid* pg = new wxPropertyGrid(
        this, // parent
        PGID, // id
        wxDefaultPosition, // position
        wxDefaultSize, // size
        // Here are just some of the supported window styles
        wxPG_AUTO_SORT | // Automatic sorting after items added
        wxPG_SPLITTER_AUTO_CENTER | // Automatically center splitter until user
       manually adjusts it
        // Default style
        wxPG_DEFAULT_STYLE );

    // Window style flags are at premium, so some less often needed ones are
    // available as extra window styles (wxPG_EX_xxx) which must be set using
```

```
    // SetExtraStyle member function. wxPG_EX_HELP_AS_TOOLTIPS, for instance,
    // allows displaying help strings as tool tips.
    pg->SetExtraStyle( wxPG_EX_HELP_AS_TOOLTIPS );
```

(for complete list of new window styles, see wxPropertyGrid Window Styles)

wxPropertyGrid is usually populated with lines like this:

```
pg->Append( new wxStringProperty("Label", "Name", "Initial Value") );
```

Naturally, wxStringProperty is a property class. Only the first function argument (label) is mandatory. Second one, name, defaults to label and, third, the initial value, to default value. If constant wxPG_LABEL is used as the name argument, then the label is automatically used as a name as well (this is more efficient than manually defining both as the same). Use of empty name is discouraged and will sometimes result in run-time error. Note that all property class constructors have quite similar constructor argument list.

To demonstrate other common property classes, here's another code snippet:

```
// Add int property
pg->Append( new wxIntProperty("IntProperty", wxPG_LABEL, 12345678) );

// Add float property (value type is actually double)
pg->Append( new wxFloatProperty("FloatProperty", wxPG_LABEL, 12345.678) );

// Add a bool property
pg->Append( new wxBoolProperty("BoolProperty", wxPG_LABEL, false) );

// A string property that can be edited in a separate editor dialog.
pg->Append( new wxLongStringProperty("LongStringProperty",
                                     wxPG_LABEL,
                                     "This is much longer string than the "
                                     "first one. Edit it by clicking the button."));

// String editor with dir selector button.
pg->Append( new wxDirProperty("DirProperty", wxPG_LABEL, ::wxGetUserHome()) );

// wxArrayStringProperty embeds a wxArrayString.
pg->Append( new wxArrayStringProperty("Label of ArrayStringProperty",
                                      "NameOfArrayStringProp"));

// A file selector property.
pg->Append( new wxFileProperty("FileProperty", wxPG_LABEL, wxEmptyString) );

// Extra: set wild card for file property (format same as in wxFileDialog).
pg->SetPropertyAttribute( "FileProperty",
                          wxPG_FILE_WILDCARD,
                          "All files (*.*)|*.*" );
```

Operations on properties are usually done by directly calling wxPGProperty's or wxPropertyGridInterface's member functions. wxPropertyGridInterface is an abstract base class for property containers such as wxPropertyGrid, wxPropertyGridManager, and wxPropertyGridPage. Note however that wxPGProperty's member functions generally do not refresh the grid.

wxPropertyGridInterface's property operation member functions , such as SetPropertyValue() and DisableProperty(), all accept a special wxPGPropArg id argument, using which you can refer to properties either by their pointer (for performance) or by their name (for convenience). For instance:

```
// Add a file selector property.
wxPGProperty* prop = pg->Append( new wxFileProperty("FileProperty",
                                 wxPG_LABEL,
                                 wxEmptyString) );

// Valid: Set wild card by name
pg->SetPropertyAttribute( "FileProperty",
                          wxPG_FILE_WILDCARD,
                          "All files (*.*)|*.*" );

// Also Valid: Set wild card by property pointer
pg->SetPropertyAttribute( prop,
                          wxPG_FILE_WILDCARD,
                          "All files (*.*)|*.*" );
```

Using pointer is faster, since it doesn't require hash map lookup. Anyway, you can always get property pointer (wxPGProperty*) as return value from Append() or Insert(), or by calling wxPropertyGridInterface::GetPropertyByName() or just plain GetProperty().

10.49.2 Categories

wxPropertyGrid has a hierarchic property storage and display model, which allows property categories to hold child properties and even other categories. Other than that, from the programmer's point of view, categories can be treated exactly the same as "other" properties. For example, despite its name, GetPropertyByName() also returns a category by name. Note however that sometimes the label of a property category may be referred as caption (for example, there is wxPropertyGrid::SetCaptionTextColour() method that sets text colour of property category labels).

When category is added at the top (i.e. root) level of the hierarchy, it becomes a *current category*. This means that all other (non-category) properties after it are automatically appended to it. You may add properties to specific categories by using wxPropertyGridInterface::Insert or wxPropertyGridInterface::AppendIn.

Category code sample:

```
// One way to add category (similar to how other properties are added)
pg->Append( new wxPropertyCategory("Main") );

// All these are added to "Main" category
pg->Append( new wxStringProperty("Name") );
pg->Append( new wxIntProperty("Age",wxPG_LABEL,25) );
pg->Append( new wxIntProperty("Height",wxPG_LABEL,180) );
pg->Append( new wxIntProperty("Weight") );

// Another one
pg->Append( new wxPropertyCategory("Attributes") );

// All these are added to "Attributes" category
pg->Append( new wxIntProperty("Intelligence") );
pg->Append( new wxIntProperty("Agility") );
pg->Append( new wxIntProperty("Strength") );
```

10.49.3 Tree-like Property Structure

Basically any property can have children. There are few limitations, however.

Remarks

- Names of properties with non-category, non-root parents are not stored in global hash map. Instead, they can be accessed with strings like "Parent.Child". For instance, in the sample below, child property named "Max. Speed (mph)" can be accessed by global name "Car.Speeds.Max Speed (mph)".
- If you want to property's value to be a string composed of the child property values, you must use wxStringProperty as parent and use magic string "<composed>" as its value.
- Events (eg. change of value) that occur in parent do not propagate to children. Events that occur in children will propagate to parents, but only if they are wxStringProperties with "<composed>" value.

Sample:

```
wxPGProperty* carProp = pg->Append(new wxStringProperty("Car",
                                   wxPG_LABEL,
                                   "<composed>"));

pg->AppendIn(carProp, new wxStringProperty("Model",
                                           wxPG_LABEL,
                                           "Lamborghini Diablo SV"));

pg->AppendIn(carProp, new wxIntProperty("Engine Size (cc)",
                                        wxPG_LABEL,
                                        5707) );

wxPGProperty* speedsProp = pg->AppendIn(carProp,
                                        new wxStringProperty("Speeds",
                                          wxPG_LABEL,
                                          "<composed>"));

pg->AppendIn( speedsProp, new wxIntProperty("Max. Speed (mph)",
                                            wxPG_LABEL,290) );
pg->AppendIn( speedsProp, new wxFloatProperty("0-100 mph (sec)",
                                              wxPG_LABEL,3.9) );
pg->AppendIn( speedsProp, new wxFloatProperty("1/4 mile (sec)",
                                              wxPG_LABEL,8.6) );
```

```
// This is how child property can be referred to by name
pg->SetPropertyValue( "Car.Speeds.Max. Speed (mph)", 300 );

pg->AppendIn(carProp, new wxIntProperty("Price ($)",
                                        wxPG_LABEL,
                                        300000) );

// Displayed value of "Car" property is now very close to this:
// "Lamborghini Diablo SV; 5707 [300; 3.9; 8.6] 300000"
```

10.49.4 wxEnumProperty and wxFlagsProperty

wxEnumProperty is used when you want property's (integer or string) value to be selected from a popup list of choices.

Creating wxEnumProperty is slightly more complex than those described earlier. You have to provide list of constant labels, and optionally relevant values (if label indexes are not sufficient).

Remarks

- Value wxPG_INVALID_VALUE (equals INT_MAX) is not allowed as list item value.

A very simple example:

```
//
// Using wxArrayString
//
wxArrayString arrDiet;
arr.Add("Herbivore");
arr.Add("Carnivore");
arr.Add("Omnivore");

pg->Append( new wxEnumProperty("Diet",
                               wxPG_LABEL,
                               arrDiet) );

//
// Using wxChar* array
//
const wxChar* arrayDiet[] =
{ wxT("Herbivore"), wxT("Carnivore"), wxT("Omnivore"), NULL };

pg->Append( new wxEnumProperty("Diet",
                               wxPG_LABEL,
                               arrayDiet) );
```

Here's extended example using values as well:

```
//
// Using wxArrayString and wxArrayInt
//
wxArrayString arrDiet;
arr.Add("Herbivore");
arr.Add("Carnivore");
arr.Add("Omnivore");

wxArrayInt arrIds;
arrIds.Add(40);
arrIds.Add(45);
arrIds.Add(50);

// Note that the initial value (the last argument) is the actual value,
// not index or anything like that. Thus, our value selects "Omnivore".
pg->Append( new wxEnumProperty("Diet",
                               wxPG_LABEL,
                               arrDiet,
                               arrIds,
                               50));
```

wxPGChoices is a class where wxEnumProperty, and other properties which require storage for list of items, actually stores strings and values. It is used to facilitate reference counting, and therefore recommended way of adding items when multiple properties share the same set.

You can use wxPGChoices directly as well, filling it and then passing it to the constructor. In fact, if you wish to display bitmaps next to labels, your best choice is to use this approach.

```
wxPGChoices chs;
chs.Add("Herbivore", 40);
chs.Add("Carnivore", 45);
chs.Add("Omnivore", 50);

// Let's add an item with bitmap, too
chs.Add("None of the above", wxBitmap(), 60);

pg->Append( new wxEnumProperty("Primary Diet",
                               wxPG_LABEL,
                               chs) );

// Add same choices to another property as well - this is efficient due
// to reference counting
pg->Append( new wxEnumProperty("Secondary Diet",
                               wxPG_LABEL,
                               chs) );
```

You can later change choices of property by using wxPGProperty::AddChoice(), wxPGProperty::InsertChoice(), wxPGProperty::DeleteChoice(), and wxPGProperty::SetChoices().

wxEditEnumProperty works exactly like wxEnumProperty, except is uses non-read-only combo box as default editor, and value is stored as string when it is not any of the choices.

wxFlagsProperty has similar construction:

```
const wxChar* flags_prop_labels[] = { wxT("wxICONIZE"),
    wxT("wxCAPTION"), wxT("wxMINIMIZE_BOX"), wxT("wxMAXIMIZE_BOX"), NULL };

// this value array would be optional if values matched string indexes
long flags_prop_values[] = { wxICONIZE, wxCAPTION,
      wxMINIMIZE_BOX,
    wxMAXIMIZE_BOX };

pg->Append( new wxFlagsProperty("Window Style",
                                wxPG_LABEL,
                                flags_prop_labels,
                                flags_prop_values,
                                wxDEFAULT_FRAME_STYLE) );
```

wxFlagsProperty can use wxPGChoices just the same way as wxEnumProperty **Note:** When changing "choices" (ie. flag labels) of wxFlagsProperty, you will need to use wxPGProperty::SetChoices() to replace all choices at once - otherwise implicit child properties will not get updated properly.

10.49.5 Specialized Properties

This section describes the use of less often needed property classes. To use them, you have to include <wx/propgrid/advprops.h>.

```
// Necessary extra header file
#include <wx/propgrid/advprops.h>

...

    // Date property.
    pg->Append( new wxDateProperty("MyDateProperty",
                                   wxPG_LABEL,
                                   wxDateTime::Now()) );

    // Image file property. Wild card is auto-generated from available
    // image handlers, so it is not set this time.
    pg->Append( new wxImageFileProperty("Label of ImageFileProperty",
                                        "NameOfImageFileProp") );

    // Font property has sub-properties. Note that we give window's font as
    // initial value.
    pg->Append( new wxFontProperty("Font",
                                   wxPG_LABEL,
                                   GetFont()) );

    // Colour property with arbitrary colour.
    pg->Append( new wxColourProperty("My Colour 1",
```

```
                                    wxPG_LABEL,
                                    wxColour(242,109,0) ) );

    // System colour property.
    pg->Append( new wxSystemColourProperty("My SysColour 1",
                                           wxPG_LABEL,
                                           wxSystemSettings::GetColour(
      wxSYS_COLOUR_WINDOW)) );

    // System colour property with custom colour.
    pg->Append( new wxSystemColourProperty("My SysColour 2",
                                           wxPG_LABEL,
                                           wxColour(0,200,160) ) );

    // Cursor property
    pg->Append( new wxCursorProperty("My Cursor",
                                     wxPG_LABEL,
                                     wxCURSOR_ARROW));
```

10.49.6 Processing Property Values

Properties store their values internally as wxVariant, but is also possible to obtain them as wxAny, using implicit conversion. You can get property values with wxPGProperty::GetValue() and wxPropertyGridInterface::GetProperty↩Value().

Below is a code example which handles wxEVT_PG_CHANGED event:

```
void MyWindowClass::OnPropertyGridChanged(wxPropertyGridEvent& event)
{
    wxPGProperty* property = event.GetProperty();

    // Do nothing if event did not have associated property
    if ( !property )
        return;

    // GetValue() returns wxVariant, but it is converted transparently to
    // wxAny
    wxAny value = property->GetValue();

    // Also, handle the case where property value is unspecified
    if ( value.IsNull() )
        return;

    // Handle changes in values, as needed
    if ( property->GetName() == "MyStringProperty" )
        OnMyStringPropertyChanged(value.As<wxString>());
    else if ( property->GetName() == "MyColourProperty" )
        OnMyColourPropertyChanged(value.As<wxColour>());
}
```

You can get a string-representation of property's value using wxPGProperty::GetValueAsString() or wxProperty↩GridInterface::GetPropertyValueAsString(). This particular function is very safe to use with any kind of property.

Note

There is a one case in which you may want to take extra care when dealing with raw wxVariant values. That is, integer-type properties, such as wxIntProperty and wxUIntProperty, store value internally as wx(U)LongLong when number doesn't fit into standard long type. Using << operator to get wx(U)LongLong from wxVariant is customized to work quite safely with various types of variant data. However, you can also bypass this problem by using wxAny in your code instead of wxVariant.

Note that in some cases property value can be Null variant, which means that property value is unspecified. This usually occurs only when wxPG_EX_AUTO_UNSPECIFIED_VALUES extra window style is defined or when you manually set property value to Null (or unspecified).

10.49.7 Iterating through a property container

You can use somewhat STL'ish iterator classes to iterate through the grid. Here is a simple example of forward iterating through all individual properties (not categories nor private child properties that are normally 'transparent' to application code):

```
wxPropertyGridIterator it;

for ( it = pg->GetIterator();
      !it.AtEnd();
      it++ )
{
    wxPGProperty* p = *it;
    // Do something with the property
}
```

As expected there is also a const iterator:

```
wxPropertyGridConstIterator it;

for ( it = pg->GetIterator();
      !it.AtEnd();
      it++ )
{
    const wxPGProperty* p = *it;
    // Do something with the property
}
```

You can give some arguments to GetIterator to determine which properties get automatically filtered out. For complete list of options, see wxPropertyGridIterator Flags. GetIterator() also accepts other arguments. See wxPropertyGridInterface::GetIterator() for details.

This example reverse-iterates through all visible items:

```
wxPropertyGridIterator it;

for ( it = pg->GetIterator(wxPG_ITERATE_VISIBLE,
      wxBOTTOM);
      !it.AtEnd();
      it-- )
{
    wxPGProperty* p = *it;
    // Do something with the property
}
```

GetIterator() only works with wxPropertyGrid and the individual pages of wxPropertyGridManager. In order to iterate through an arbitrary property container (such as entire wxPropertyGridManager), you need to use wxPropertyGridInterface::GetVIterator(). Note however that this virtual iterator is limited to forward iteration.

```
wxPGVIterator it;

for ( it = manager->GetVIterator(wxPG_ITERATE_ALL);
      !it.AtEnd();
      it.Next() )
{
    wxPGProperty* p = it.GetProperty();
    // Do something with the property
}
```

10.49.8 Populating wxPropertyGrid Automatically

Populating from List of wxVariants

Example of populating an empty wxPropertyGrid from a values stored in an arbitrary list of wxVariants.

```
// This is a static method that initializes *all* built-in type handlers
// available, including those for wxColour and wxFont. Refers to *all*
// included properties, so when compiling with static library, this
// method may increase the executable size noticeably.
pg->InitAllTypeHandlers();

// Get contents of the grid as a wxVariant list
wxVariant all_values = pg->GetPropertyValues();

// Populate the list with values. If a property with appropriate
// name is not found, it is created according to the type of variant.
pg->SetPropertyValues( my_list_variant );
```

Loading Population from a Text-based Storage

Class wxPropertyGridPopulator may be helpful when writing code that loads properties from a text-source. In fact, the wxPropertyGrid xrc-handler (which may not be currently included in wxWidgets, but probably will be in near future) uses it.

Saving and Restoring User-Editable State

You can use wxPropertyGridInterface::SaveEditableState() and wxPropertyGridInterface::RestoreEditableState() to save and restore user-editable state (selected property, expanded/collapsed properties, selected page, scrolled position, and splitter positions).

10.49.9 Event Handling

Probably the most important event is the Changed event which occurs when value of any property is changed by the user. Use EVT_PG_CHANGED(id,func) in your event table to use it.

For complete list of event types, see wxPropertyGrid class reference.

However, one type of event that might need focused attention is EVT_PG_CHANGING, which occurs just prior property value is being changed by user. You can acquire pending value using wxPropertyGridEvent::GetValue(), and if it is not acceptable, call wxPropertyGridEvent::Veto() to prevent the value change from taking place.

```
void MyForm::OnPropertyGridChanging( wxPropertyGridEvent& event )
{
    wxPGProperty* property = event.GetProperty();

    if ( property == m_pWatchThisProperty )
    {
        // GetValue() returns the pending value, but is only
        // supported by wxEVT_PG_CHANGING.
        if ( event.GetValue().GetString() == g_pThisTextIsNotAllowed )
        {
            event.Veto();
            return;
        }
    }
}
```

Remarks

On Child Property Event Handling

- For properties which have private, implicit children (wxFontProperty and wxFlagsProperty), events occur for the main parent property only. For other properties events occur for the children themselves. See Tree-like Property Structure.
- When property's child gets changed, you can use wxPropertyGridEvent::GetMainParent() to obtain its topmost non-category parent (useful, if you have deeply nested properties).

10.49.10 Help String, Hint and Tool Tips

For each property you can specify two different types of help text. First, you can use wxPropertyGridInterface::SetPropertyHelpString() or wxPGProperty::SetHelpString() to set property's help text. Second, you can use wxPGProperty::SetAttribute() to set property's "Hint" attribute.

Difference between hint and help string is that the hint is shown in an empty property value cell, while help string is shown either in the description text box, as a tool tip, or on the status bar, whichever of these is available.

To enable display of help string as tool tips, you must explicitly use the wxPG_EX_HELP_AS_TOOLTIPS extra window style.

10.49.11 Validating Property Values

There are various ways to make sure user enters only correct values. First, you can use wxValidators similar to as you would with ordinary controls. Use wxPropertyGridInterface::SetPropertyValidator() to assign wxValidator to property.

Second, you can subclass a property and override wxPGProperty::ValidateValue(), or handle wxEVT_PG_CHANGING for the same effect. Both of these ways do not actually prevent user from temporarily entering invalid text, but they do give you an opportunity to warn the user and block changed value from being committed in a property.

Various validation failure options can be controlled globally with wxPropertyGrid::SetValidationFailureBehavior(), or on an event basis by calling wxEvent::SetValidationFailureBehavior(). Here's a code snippet of how to handle wxEVT_PG_CHANGING, and to set custom failure behaviour and message.

```
void MyFrame::OnPropertyGridChanging(wxPropertyGridEvent& event)
{
    wxPGProperty* property = event.GetProperty();

    // You must use wxPropertyGridEvent::GetValue() to access
    // the value to be validated.
    wxVariant pendingValue = event.GetValue();

    if ( property->GetName() == "Font" )
    {
        // Make sure value is not unspecified
        if ( !pendingValue.IsNull() )
        {
            wxFont font;
            font << pendingValue;

            // Let's just allow Arial font
            if ( font.GetFaceName() != "Arial" )
            {
                event.Veto();
                event.SetValidationFailureBehavior(wxPG_VFB_STAY_IN_PROPERTY |
                                                   wxPG_VFB_BEEP |
                                                   wxPG_VFB_SHOW_MESSAGEBOX);
            }
        }
    }
}
```

10.49.12 Customizing Individual Cell Appearance

You can control text colour, background colour, and attached image of each cell in the property grid. Use wxPropertyGridInterface::SetPropertyCell() or wxPGProperty::SetCell() for this purpose.

In addition, it is possible to control these characteristics for wxPGChoices list items. See wxPGChoices class reference for more info.

10.49.13 Customizing Keyboard Handling

There is probably one preference for keyboard handling for every developer out there, and as a conveniency control wxPropertyGrid tries to cater for that. By the default arrow keys are used for navigating between properties, and TAB key is used to move focus between the property editor and the first column. When the focus is in the editor, arrow keys usually no longer work for navigation since they are consumed by the editor.

There are mainly two functions which you can use this customize things, wxPropertyGrid::AddActionTrigger() and wxPropertyGrid::DedicateKey(). First one can be used to set a navigation event to occur on a specific key press and the second is used to divert a key from property editors, making it possible for the grid to use keys normally consumed by the focused editors.

For example, let's say you want to have an ENTER-based editing scheme. That is, editor is focused on ENTER press and the next property is selected when the user finishes editing and presses ENTER again. Code like this would accomplish the task:

```
// Have property editor focus on Enter
propgrid->AddActionTrigger( wxPG_ACTION_EDIT, WXK_RETURN );
```

```
// Have Enter work as action trigger even when editor is focused
propgrid->DedicateKey( WXK_RETURN );

// Let Enter also navigate to the next property
propgrid->AddActionTrigger( wxPG_ACTION_NEXT_PROPERTY,
      WXK_RETURN );
```

wxPG_ACTION_EDIT is prioritized above wxPG_ACTION_NEXT_PROPERTY so that the above code can work without conflicts. For a complete list of available actions, see wxPropertyGrid Action Identifiers.

Here's another trick. Normally the up and down cursor keys are consumed by the focused wxTextCtrl editor and as such can't be used for navigating between properties when that editor is focused. However, using DedicateKey() we can change this so that instead of the cursor keys moving the caret inside the wxTextCtrl, they navigate between adjacent properties. As such:

```
propgrid->DedicateKey(WXK_UP);
propgrid->DedicateKey(WXK_DOWN);
```

10.49.14 Customizing Properties (without sub-classing)

In this section are presented miscellaneous ways to have custom appearance and behaviour for your properties without all the necessary hassle of sub-classing a property class etc.

Setting Value Image

Every property can have a small value image placed in front of the actual value text. Built-in example of this can be seen with wxColourProperty and wxImageFileProperty, but for others it can be set using wxPropertyGrid::SetPropertyImage method.

Setting Property's Editor Control(s)

You can set editor control (or controls, in case of a control and button), of any property using wxPropertyGrid::SetPropertyEditor. Editors are passed as wxPGEditor_EditorName, and valid built-in EditorNames are TextCtrl, Choice, ComboBox, CheckBox, TextCtrlAndButton, ChoiceAndButton, SpinCtrl, and DatePickerCtrl. Two last mentioned ones require call to static member function wxPropertyGrid::RegisterAdditionalEditors().

Following example changes wxColourProperty's editor from default Choice to TextCtrlAndButton. wxColourProperty has its internal event handling set up so that button click events of the button will be used to trigger colour selection dialog.

```
wxPGProperty* colProp = new wxColourProperty("Text Colour");
pg->Append(colProp);
pg->SetPropertyEditor(colProp, wxPGEditor_TextCtrlAndButton);
```

Naturally, creating and setting custom editor classes is a possibility as well. For more information, see wxPGEditor class reference.

Property Attributes Recognized by Editors

SpinCtrl editor can make use of property's "Min", "Max", "Step" and "Wrap" attributes.

Adding Multiple Buttons Next to an Editor

See wxPGMultiButton class reference.

Handling Events Passed from Properties

wxEVT_COMMAND_BUTTON_CLICKED (corresponds to event table macro EVT_BUTTON): Occurs when editor button click is not handled by the property itself (as is the case, for example, if you set property's editor to TextCtrl↩ AndButton from the original TextCtrl).

Property Attributes

Miscellaneous values, often specific to a property type, can be set using wxPropertyGridInterface::SetProperty↩ Attribute() and wxPropertyGridInterface::SetPropertyAttributeAll() methods.

Attribute names are strings and values wxVariant. Arbitrary names are allowed in order to store values that are relevant to application only and not property grid. Constant equivalents of all attribute string names are provided. Some of them are defined as cached strings, so using these constants can provide for smaller binary size.

For complete list of attributes, see wxPropertyGrid Property Attribute Identifiers.

10.49.15 Using wxPropertyGridManager

wxPropertyGridManager is an efficient multi-page version of wxPropertyGrid, which can optionally have tool bar for mode and page selection, and a help text box. For more information, see wxPropertyGridManager class reference.

wxPropertyGridPage

wxPropertyGridPage is holder of properties for one page in manager. It is derived from wxEvtHandler, so you can subclass it to process page-specific property grid events. Hand over your page instance in wxPropertyGrid↩ Manager::AddPage().

Please note that the wxPropertyGridPage itself only sports subset of wxPropertyGrid API (but unlike manager, this include item iteration). Naturally it inherits from wxPropertyGridInterface.

For more information, see wxPropertyGridPage class reference.

10.49.16 Sub-classing wxPropertyGrid and wxPropertyGridManager

Few things to note:

- Only a small percentage of member functions are virtual. If you need more, just e-mail to wx-dev mailing list.
- Data manipulation is done in wxPropertyGridPageState class. So, instead of overriding wxPropertyGrid::↩ Insert(), you'll probably want to override wxPropertyGridPageState::DoInsert(). See header file for details.
- Override wxPropertyGrid::CreateState() to instantiate your derivate wxPropertyGridPageState. For wx↩ PropertyGridManager, you'll need to subclass wxPropertyGridPage instead (since it is derived from wx↩ PropertyGridPageState), and hand over instances in wxPropertyGridManager::AddPage() calls.
- You can use a derivate wxPropertyGrid with manager by overriding wxPropertyGridManager::Create↩ PropertyGrid() member function.

10.49.17 Miscellaneous Topics

Property Name Scope

All properties which parent is category or root can be accessed directly by their base name (ie. name given for property in its constructor). Other properties can be accessed via "ParentsName.BaseName" notation, Naturally, all property names should be unique.

Non-unique Labels

It is possible to have properties with identical label under same parent. However, care must be taken to ensure that each property still has unique (base) name.

wxBoolProperty

There are few points about wxBoolProperty that require further discussion:

- wxBoolProperty can be shown as either normal combo box or as a check box. Property attribute wxPG_BOOL_USE_CHECKBOX is used to change this. For example, if you have a wxFlagsProperty, you can set its all items to use check box using the following:

  ```
  pg->SetPropertyAttribute("MyFlagsProperty",
        wxPG_BOOL_USE_CHECKBOX, true, wxPG_RECURSE);
  ```

  Following will set all individual bool properties in your control to use check box:

```
pg->SetPropertyAttributeAll(wxPG_BOOL_USE_CHECKBOX, true);
```

- Default item names for wxBoolProperty are ["False", "True"]. This can be changed using static function wxPropertyGrid::SetBoolChoices(trueChoice, falseChoice).

Updates from wxTextCtrl Based Editor

Changes from wxTextCtrl based property editors are committed (ie. wxEVT_PG_CHANGED is sent etc.) *only* when (1) user presser enter, (2) user moves to edit another property, or (3) when focus leaves the grid.

Because of this, you may find it useful, in some apps, to call wxPropertyGrid::CommitChangesFromEditor() just before you need to do any computations based on property grid values. Note that CommitChangesFromEditor() will dispatch wxEVT_PG_CHANGED with ProcessEvent, so any of your event handlers will be called immediately.

Centering the Splitter

If you need to center the splitter, but only once when the program starts, then do **not** use the wxPG_SPLITTER_AUTO_CENTER window style, but the wxPropertyGrid::CenterSplitter() method. **However, be sure to call it after the sizer setup and SetSize calls!** (ie. usually at the end of the frame/dialog constructor)

Splitter centering behaviour can be customized using wxPropertyGridInterface::SetColumnProportion(). Usually it is used to set non-equal column proportions, which in essence stops the splitter(s) from being 'centered' as such, and instead just auto-resized.

Setting Splitter Position When Creating Property Grid

Splitter position cannot exceed grid size, and therefore setting it during form creation may fail as initial grid size is often smaller than desired splitter position, especially when sizers are being used.

wxColourProperty and wxSystemColourProperty

Through sub-classing, these two property classes provide substantial customization features. Subclass wxSystemColourProperty if you want to use wxColourPropertyValue (which features colour type in addition to wxColour), and wxColourProperty if plain wxColour is enough.

Override wxSystemColourProperty::ColourToString() to redefine how colours are printed as strings.

Override wxSystemColourProperty::GetCustomColourIndex() to redefine location of the item that triggers colour picker dialog (default is last).

Override wxSystemColourProperty::GetColour() to determine which colour matches which choice entry.

10.49.18 Property Class Descriptions

See Supplied Ready-to-use Property Classes

10.49.19 Changes from wxPropertyGrid 1.4

Version of wxPropertyGrid bundled with wxWidgets 2.9+ has various backward- incompatible changes from version 1.4, which had a stable API and will remain as the last separate branch.

Note that in general any behaviour-breaking changes should not compile or run without warnings or errors.

General Changes

- Tab-traversal can no longer be used to travel between properties. Now it only causes focus to move from main grid to editor of selected property. Arrow keys are now your primary means of navigating between properties, with keyboard. This change allowed fixing broken tab traversal on wxGTK (which is open issue in wxPropertyGrid 1.4).
- wxPG_EX_UNFOCUS_ON_ENTER style is removed and is now default behaviour. That is, when enter is pressed, editing is considered done and focus moves back to the property grid from the editor control.
- A few member functions were removed from wxPropertyGridInterface. Please use wxPGProperty's counterparts from now on.
- wxPGChoices now has proper Copy-On-Write behaviour.
- wxPGChoices::SetExclusive() was renamed to AllocExclusive().
- wxPGProperty::SetPropertyChoicesExclusive() was removed. Instead, use GetChoices().AllocExclusive().
- wxPGProperty::ClearModifiedStatus() is removed. Please use SetModifiedStatus() instead.
- wxPropertyGridInterface::GetExpandedProperties() is removed. You should now use wxPropertyGrid↩ Interface::GetEditableState() instead.
- wxPG_EX_DISABLE_TLP_TRACKING is now enabled by default. To get the old behaviour (recommended if you don't use a system that reparents the grid on its own), use the wxPG_EX_ENABLE_TLP_TRACKING extra style.
- Extended window style wxPG_EX_LEGACY_VALIDATORS was removed.
- Default property validation failure behaviour has been changed to (wxPG_VFB_MARK_CELL | wxPG_VF↩ B_SHOW_MESSAGEBOX), which means that the cell is marked red and wxMessageBox is shown. This is more user-friendly than the old behaviour, which simply beeped and prevented leaving the property editor until a valid value was entered.
- wxPropertyGridManager now has same Get/SetSelection() semantics as wxPropertyGrid.
- Various wxPropertyGridManager page-related functions now return pointer to the page object instead of index.
- wxArrayEditorDialog used by wxArrayStringProperty and some sample properties has been renamed to wx↩ PGArrayEditorDialog. Also, it now uses wxEditableListBox for editing.
- Instead of calling wxPropertyGrid::SetButtonShortcut(), use wxPropertyGrid::SetActionTrigger(wxPG_ACT↩ ION_PRESS_BUTTON).
- wxPGProperty::GetCell() now returns a reference. AcquireCell() was removed.
- wxPGMultiButton::FinalizePosition() has been renamed to Finalize(), and it has slightly different argument list.
- wxPropertyGridEvent::HasProperty() is removed. You can use GetProperty() as immediate replacement when checking if event has a property.

- "InlineHelp" property has been replaced with "Hint".
- wxPropertyGrid::CanClose() has been removed. Call wxPropertyGridInterface::EditorValidate() instead.
- wxPGProperty::SetFlag() has been moved to private API. This was done to underline the fact that it was not the preferred method to change a property's state since it never had any desired side-effects. ChangeFlag() still exists for those who really need to achieve the same effect.
- wxArrayStringProperty default delimiter is now comma (','), and it can be changed by setting the new "↩ Delimiter" attribute.

Property and Editor Sub-classing Changes

- Confusing custom property macros have been eliminated.
- Implement wxPGProperty::ValueToString() instead of GetValueAsString().
- wxPGProperty::ChildChanged() must now return the modified value of whole property instead of writing it back into 'thisValue' argument.
- Removed wxPropertyGrid::PrepareValueForDialogEditing(). Use wxPropertyGrid::GetPendingEditedValue() instead.
- wxPGProperty::GetChoiceInfo() is removed, as all properties now carry wxPGChoices instance (protected wxPGProperty::m_choices).
- Connect() should no longer be called in implementations of wxPGEditor::CreateControls(). wxProperty↩ Grid automatically passes all events from editor to wxPGEditor::OnEvent() and wxPGProperty::OnEvent(), as appropriate.
- wxPython: Previously some of the reimplemented member functions needed a 'Py' prefix. This is no longer necessary. For instance, if you previously implemented PyStringToValue() for your custom property, you should now just implement StringToValue().

10.50 Common Dialogs

Common dialog classes and functions encapsulate commonly-needed dialog box requirements.

They are all 'modal', grabbing the flow of control until the user dismisses the dialog, to make them easy to use within an application.

Some dialogs have both platform-dependent and platform-independent implementations, so that if underlying windowing systems do not provide the required functionality, the generic classes and functions can stand in. For example, under MS Windows, wxColourDialog uses the standard colour selector. There is also an equivalent called wxGenericColourDialog for other platforms, and a macro defines wxColourDialog to be the same as wxGeneric↩ ColourDialog on non-MS Windows platforms. However, under MS Windows, the generic dialog can also be used, for testing or other purposes.

See also

Common Dialogs

10.50.1 wxColourDialog Overview

Classes: wxColourDialog, wxColourData

The wxColourDialog presents a colour selector to the user, and returns with colour information.

The MS Windows Colour Selector

Under Windows, the native colour selector common dialog is used. This presents a dialog box with three main regions: at the top left, a palette of 48 commonly-used colours is shown. Under this, there is a palette of 16 'custom colours' which can be set by the application if desired. Additionally, the user may open up the dialog box to show a right-hand panel containing controls to select a precise colour, and add it to the custom colour palette.

The Generic Colour Selector

Under non-MS Windows platforms, the colour selector is a simulation of most of the features of the MS Windows selector. Two palettes of 48 standard and 16 custom colours are presented, with the right-hand area containing three sliders for the user to select a colour from red, green and blue components. This colour may be added to the custom colour palette, and will replace either the currently selected custom colour, or the first one in the palette if none is selected. The RGB colour sliders are not optional in the generic colour selector. The generic colour selector is also available under MS Windows; use the name wxGenericColourDialog.

Example

In the samples/dialogs directory, there is an example of using the wxColourDialog class. Here is an excerpt, which sets various parameters of a wxColourData object, including a grey scale for the custom colours. If the user did not cancel the dialog, the application retrieves the selected colour and uses it to set the background of a window.

```
wxColourData data;
data.SetChooseFull(true);
for (int i = 0; i < 16; i++)
{
    wxColour colour(i*16, i*16, i*16);
    data.SetCustomColour(i, colour);
}

wxColourDialog dialog(this, &data);
if (dialog.ShowModal() == wxID_OK)
{
    wxColourData retData = dialog.GetColourData();
    wxColour col = retData.GetColour();
    wxBrush brush(col, wxSOLID);
    myWindow->SetBackground(brush);
    myWindow->Clear();
    myWindow->Refresh();
}
```

10.50.2 wxFontDialog Overview

Classes: wxFontDialog, wxFontData

The wxFontDialog presents a font selector to the user, and returns with font and colour information.

The MS Windows Font Selector

Under Windows, the native font selector common dialog is used. This presents a dialog box with controls for font name, point size, style, weight, underlining, strikeout and text foreground colour. A sample of the font is shown on a white area of the dialog box. Note that in the translation from full MS Windows fonts to wxWidgets font conventions, strikeout is ignored and a font family (such as Swiss or Modern) is deduced from the actual font name (such as Arial or Courier).

The Generic Font Selector

Under non-MS Windows platforms, the font selector is simpler. Controls for font family, point size, style, weight, underlining and text foreground colour are provided, and a sample is shown upon a white background. The generic font selector is also available under MS Windows; use the name wxGenericFontDialog.

Example

In the samples/dialogs directory, there is an example of using the wxFontDialog class. The application uses the returned font and colour for drawing text on a canvas. Here is an excerpt:

```
wxFontData data;
data.SetInitialFont(canvasFont);
data.SetColour(canvasTextColour);

wxFontDialog dialog(this, &data);
if (dialog.ShowModal() == wxID_OK)
{
    wxFontData retData = dialog.GetFontData();
    canvasFont = retData.GetChosenFont();
    canvasTextColour = retData.GetColour();
    myWindow->Refresh();
}
```

10.50.3 wxPrintDialog Overview

Classes: wxPrintDialog, wxPrintData

This class represents the print and print setup common dialogs. You may obtain a wxPrinterDC device context from a successfully dismissed print dialog.

The samples/printing example shows how to use it: see Printing Framework Overview for an excerpt from this example.

10.50.4 wxFileDialog Overview

Classes: wxFileDialog

Pops up a file selector box. On Windows and GTK 2.4+, this is the common file selector dialog. In X, this is a file selector box with somewhat less functionality. The path and filename are distinct elements of a full file pathname.

If path is "", the current directory will be used. If filename is "", no default filename will be supplied. The wildcard determines what files are displayed in the file selector, and file extension supplies a type extension for the required filename. Flags may be a combination of wxFD_OPEN, wxFD_SAVE, wxFD_OVERWRITE_PROMPT, wxFD_HIDE_READONLY, wxFD_FILE_MUST_EXIST, wxFD_MULTIPLE, wxFD_CHANGE_DIR or 0.

Both the X and Windows versions implement a wildcard filter. Typing a filename containing wildcards (*, ?) in the filename text item, and clicking on Ok, will result in only those files matching the pattern being displayed. In the X version, supplying no default name will result in the wildcard filter being inserted in the filename text item; the filter is ignored if a default name is supplied.

The wildcard may be a specification for multiple types of file with a description for each, such as:

```
"BMP files (*.bmp)|*.bmp|GIF files (*.gif)|*.gif"
```

10.50.5 wxDirDialog Overview

Classes: wxDirDialog

This dialog shows a directory selector dialog, allowing the user to select a single directory.

10.50.6 wxTextEntryDialog Overview

Classes: wxTextEntryDialog

This is a dialog with a text entry field. The value that the user entered is obtained using wxTextEntryDialog::GetValue().

10.50.7 wxPasswordEntryDialog Overview

Classes: wxPasswordEntryDialog

This is a dialog with a password entry field. The value that the user entered is obtained using wxTextEntryDialog::GetValue().

10.50.8 wxMessageDialog Overview

Classes: wxMessageDialog

This dialog shows a message, plus buttons that can be chosen from OK, Cancel, Yes, and No. Under Windows, an optional icon can be shown, such as an exclamation mark or question mark.

The return value of wxMessageDialog::ShowModal() indicates which button the user pressed.

10.50.9 wxSingleChoiceDialog Overview

Classes: wxSingleChoiceDialog

This dialog shows a list of choices, plus OK and (optionally) Cancel. The user can select one of them. The selection can be obtained from the dialog as an index, a string or client data.

10.50.10 wxMultiChoiceDialog Overview

Classes: wxMultiChoiceDialog

This dialog shows a list of choices, plus OK and (optionally) Cancel. The user can select one or more of them.

10.51 Toolbar Overview

The toolbar family of classes allows an application to use toolbars in a variety of configurations and styles.

The toolbar is a popular user interface component and contains a set of bitmap buttons or toggles. A toolbar gives faster access to an application's facilities than menus, which have to be popped up and selected rather laboriously.

Instead of supplying one toolbar class with a number of different implementations depending on platform, wxWidgets separates out the classes. This is because there are a number of different toolbar styles that you may wish to use simultaneously, and also, future toolbar implementations will emerge which cannot all be shoe-horned into the one class.

For each platform, the symbol wxToolBar is defined to be one of the specific toolbar classes.

The following is a summary of the toolbar classes and their differences:

- wxToolBarBase: This is a base class with pure virtual functions, and should not be used directly.
- wxToolBarSimple: A simple toolbar class written entirely with generic wxWidgets functionality. A simple 3D effect for buttons is possible, but it is not consistent with the Windows look and feel. This toolbar can scroll, and you can have arbitrary numbers of rows and columns.
- wxToolBarMSW: This class implements an old-style Windows toolbar, only on Windows. There are small, three-dimensional buttons, which do not (currently) reflect the current Windows colour settings: the buttons are grey. This is the default wxToolBar on 16-bit windows.
- wxToolBar95: Uses the native Windows 95 toolbar class. It dynamically adjusts it's background and button colours according to user colour settings. CreateTools must be called after the tools have been added. No absolute positioning is supported but you can specify the number of rows, and add tool separators with `AddSeparator`. Tooltips are supported. `OnRightClick` is not supported. This is the default wxToolBar on

Windows 95, Windows NT 4 and above. With the style wxTB_FLAT, the flat toolbar look is used, with a border that is highlighted when the cursor moves over the buttons.

A toolbar might appear as a single row of images under the menubar, or it might be in a separate frame layout in several rows and columns. The class handles the layout of the images, unless explicit positioning is requested.

A tool is a bitmap which can either be a button (there is no 'state', it just generates an event when clicked) or it can be a toggle. If a toggle, a second bitmap can be provided to depict the 'on' state; if the second bitmap is omitted, either the inverse of the first bitmap will be used (for monochrome displays) or a thick border is drawn around the bitmap (for colour displays where inverting will not have the desired result).

The Windows-specific toolbar classes expect 16-colour bitmaps that are 16 pixels wide and 15 pixels high. If you want to use a different size, call `SetToolBitmapSize` as the demo shows, before adding tools to the button bar. Don't supply more than one bitmap for each tool, because the toolbar generates all three images (normal, depressed, and checked) from the single bitmap you give it.

10.51.1 Using the Toolbar Library

Include `"wx/toolbar.h"`, or if using a class directly, one of:

- `"wx/msw/tbarmsw.h"` for wxToolBarMSW
- `"wx/msw/tbar95.h"` for wxToolBar95
- `"wx/tbarsmpl.h"` for wxToolBarSimple

An example of using a toolbar is given in the "toolbar" sample.

10.52 wxGrid Overview

wxGrid and its related classes are used for displaying and editing tabular data.

wxGrid supports custom attributes for the table cells, allowing to completely customize its appearance and uses a separate grid table (wxGridTableBase-derived) class for the data management meaning that it can be used to display arbitrary amounts of data.

10.52.1 Getting Started

For simple applications you need only refer to the wxGrid class in your code. This example shows how you might create a grid in a frame or dialog constructor and illustrates some of the formatting functions.

```
// Create a wxGrid object

grid = new wxGrid( this,
                   -1,
                   wxPoint( 0, 0 ),
                   wxSize( 400, 300 ) );

// Then we call CreateGrid to set the dimensions of the grid
// (100 rows and 10 columns in this example)
grid->CreateGrid( 100, 10 );

// We can set the sizes of individual rows and columns
// in pixels
grid->SetRowSize( 0, 60 );
grid->SetColSize( 0, 120 );

// And set grid cell contents as strings
grid->SetCellValue( 0, 0, "wxGrid is good" );

// We can specify that some cells are read->only
grid->SetCellValue( 0, 3, "This is read->only" );
grid->SetReadOnly( 0, 3 );
```

```
// Colours can be specified for grid cell contents
grid->SetCellValue(3, 3, "green on grey");
grid->SetCellTextColour(3, 3, *wxGREEN);
grid->SetCellBackgroundColour(3, 3, *wxLIGHT_GREY);

// We can specify the some cells will store numeric
// values rather than strings. Here we set grid column 5
// to hold floating point values displayed with width of 6
// and precision of 2
grid->SetColFormatFloat(5, 6, 2);
grid->SetCellValue(0, 6, "3.1415");
```

Here is a list of classes related to wxGrid:

- wxGrid: The main grid control class itself.
- wxGridTableBase: The base class for grid data provider.
- wxGridStringTable: Simple wxGridTableBase implementation supporting only string data items and storing them all in memory (hence suitable for not too large grids only).
- wxGridCellAttr: A cell attribute, allowing to customize its appearance as well as the renderer and editor used for displaying and editing it.
- wxGridCellAttrProvider: The object responsible for storing and retrieving the cell attributes.
- wxGridColLabelWindow: The window showing the grid columns labels.
- wxGridRowLabelWindow: The window showing the grid rows labels.
- wxGridCornerLabelWindow: The window used in the upper left grid corner.
- wxGridWindow: The window representing the main part of the grid.
- wxGridCellRenderer: Base class for objects used to display a cell value.
- wxGridCellStringRenderer: Renderer showing the cell as a text string.
- wxGridCellNumberRenderer: Renderer showing the cell as an integer number.
- wxGridCellFloatRenderer: Renderer showing the cell as a floating point number.
- wxGridCellBoolRenderer: Renderer showing the cell as checked or unchecked box.
- wxGridCellEditor: Base class for objects used to edit the cell value.
- wxGridCellStringEditor: Editor for cells containing text strings.
- wxGridCellNumberEditor: Editor for cells containing integer numbers.
- wxGridCellFloatEditor: Editor for cells containing floating point numbers.
- wxGridCellBoolEditor: Editor for boolean-valued cells.
- wxGridCellChoiceEditor: Editor allowing to choose one of the predefined strings (and possibly enter new one).
- wxGridEvent: The event sent by most of wxGrid actions.
- wxGridSizeEvent: The special event sent when a grid column or row is resized.
- wxGridRangeSelectEvent: The special event sent when a range of cells is selected in the grid.
- wxGridEditorCreatedEvent: The special event sent when a cell editor is created.
- wxGridSelection: The object efficiently representing the grid selection.
- wxGridTypeRegistry: Contains information about the data types supported by the grid.

10.52.2 Column and Row Sizes

NB: This section will discuss the resizing of wxGrid rows only to avoid repetitions but everything in it also applies to grid columns, just replace `Row` in the method names with `Col`.

Initially all wxGrid rows have the same height, which can be modified for all of them at once using wxGrid::SetDefaultRowSize(). However, unlike simpler controls such as wxListBox or wxListCtrl, wxGrid also allows its rows to be individually resized to have their own height using wxGrid::SetRowSize() (as a special case, a row may be hidden entirely by setting its size to 0, which is done by a helper wxGrid::HideRow() method). It is also possible to resize a row to fit its contents with wxGrid::AutoSizeRow() or do it for all rows at once with wxGrid::AutoSizeRows().

Additionally, by default the user can also drag the row separator lines to resize the rows interactively. This can be forbidden completely by calling wxGrid::DisableDragRowSize() or just for the individual rows using wxGrid::DisableRowResize().

If you do allow the user to resize the grid rows, it may be a good idea to save their heights and restore it when the grid is recreated the next time (possibly during a next program execution): the functions wxGrid::GetRowSizes() and wxGrid::SetRowSizes() can help with this, you will just need to serialize wxGridSizesInfo structure returned by the former in some way and deserialize it back before calling the latter.

10.53 wxTreeCtrl Overview

The tree control displays its items in a tree like structure.

Each item has its own (optional) icon and a label. An item may be either collapsed (meaning that its children are not visible) or expanded (meaning that its children are shown). Each item in the tree is identified by its `itemId` which is of opaque data type wxTreeItemId. You can test whether an item is valid by calling wxTreeItemId::IsOk.

See also

wxTreeCtrl, wxImageList

The items text and image may be retrieved and changed with (Get|Set)ItemText and (Get|Set)ItemImage. In fact, an item may even have two images associated with it: the normal one and another one for selected state which is set/retrieved with (Get|Set)ItemSelectedImage functions, but this functionality might be unavailable on some platforms.

Tree items have several attributes: an item may be selected or not, visible or not, bold or not. It may also be expanded or collapsed. All these attributes may be retrieved with the corresponding functions: IsSelected, IsVisible, IsBold and IsExpanded. Only one item at a time may be selected, selecting another one (with SelectItem) automatically unselects the previously selected one.

In addition to its icon and label, a user-specific data structure may be associated with all tree items. If you wish to do it, you should derive a class from wxTreeItemData which is a very simple class having only one function GetId() which returns the id of the item this data is associated with. This data will be freed by the control itself when the associated item is deleted (all items are deleted when the control is destroyed), so you shouldn't delete it yourself (if you do it, you should call SetItemData(NULL) to prevent the tree from deleting the pointer second time). The associated data may be retrieved with GetItemData() function.

Working with trees is relatively straightforward if all the items are added to the tree at the moment of its creation. However, for large trees it may be very inefficient. To improve the performance you may want to delay adding the items to the tree until the branch containing the items is expanded: so, in the beginning, only the root item is created (with AddRoot). Other items are added when EVT_TREE_ITEM_EXPANDING event is received: then all items lying immediately under the item being expanded should be added, but, of course, only when this event is received for the first time for this item - otherwise, the items would be added twice if the user expands/collapses/re-expands the branch.

The tree control provides functions for enumerating its items. There are 3 groups of enumeration functions: for the children of a given item, for the sibling of the given item and for the visible items (those which are currently shown to the user: an item may be invisible either because its branch is collapsed or because it is scrolled out of view). Child enumeration functions require the caller to give them a *cookie* parameter: it is a number which is opaque to

the caller but is used by the tree control itself to allow multiple enumerations to run simultaneously (this is explicitly allowed). The only thing to remember is that the *cookie* passed to GetFirstChild and to GetNextChild should be the same variable (and that nothing should be done with it by the user code).

Among other features of the tree control are: item sorting with SortChildren which uses the user-defined comparison function OnCompareItems (by default the comparison is the alphabetic comparison of tree labels), hit testing (determining to which portion of the control the given point belongs, useful for implementing drag-and-drop in the tree) with HitTest and editing of the tree item labels in place (see EditLabel).

Finally, the tree control has a keyboard interface: the cursor navigation (arrow) keys may be used to change the current selection. HOME and END are used to go to the first/last sibling of the current item. '+', '-' and '∗' expand, collapse and toggle the current branch. Note, however, that DEL and INS keys do nothing by default, but it is common to associate them with deleting an item from a tree and inserting a new one into it.

10.54 wxListCtrl Overview

Todo The wxListCtrl topic overview still needs to be written, sorry.

See also

wxListCtrl, wxImageList, wxListItem

10.55 wxSplitterWindow Overview

See also

wxSplitterWindow

10.55.1 Appearance

The following screenshot shows the appearance of a splitter window with a horizontal split.

The style wxSP_3D has been used to show a 3D border and 3D sash.

10.55.2 Example

The following fragment shows how to create a splitter window, creating two subwindows and hiding one of them.

```
splitter = new wxSplitterWindow(this, -1, wxPoint(0, 0),
                                wxSize(400, 400), wxSP_3D);

leftWindow = new MyWindow(splitter);
leftWindow->SetScrollbars(20, 20, 50, 50);

rightWindow = new MyWindow(splitter);
rightWindow->SetScrollbars(20, 20, 50, 50);
rightWindow->Show(false);

splitter->Initialize(leftWindow);

// Set this to prevent unsplitting
// splitter->SetMinimumPaneSize(20);
```

The next fragment shows how the splitter window can be manipulated after creation.

```
void MyFrame::OnSplitVertical(wxCommandEvent& event)
{
    if ( splitter->IsSplit() )
        splitter->Unsplit();
    leftWindow->Show(true);
    rightWindow->Show(true);
```

```
    splitter->SplitVertically( leftWindow, rightWindow );
}

void MyFrame::OnSplitHorizontal(wxCommandEvent& event)
{
    if ( splitter->IsSplit() )
        splitter->Unsplit();
    leftWindow->Show(true);
    rightWindow->Show(true);
    splitter->SplitHorizontally( leftWindow, rightWindow );
}

void MyFrame::OnUnsplit(wxCommandEvent& event)
{
    if ( splitter->IsSplit() )
        splitter->Unsplit();
}
```

10.56 wxBookCtrl Overview

A book control is a convenient way of displaying multiple pages of information, displayed one page at a time.

wxWidgets has five variants of this control:

- wxChoicebook: controlled by a wxChoice
- wxListbook: controlled by a wxListCtrl
- wxNotebook: uses a row of tabs
- wxSimplebook: doesn't allow the user to change the page at all.
- wxTreebook: controlled by a wxTreeCtrl
- wxToolbook: controlled by a wxToolBar

See the Notebook Sample for an example of wxBookCtrl usage.

Notice that wxSimplebook is special in that it only allows the program to change the selection, thus it's usually used in slightly different circumstances than the other variants.

See also

Book Controls

10.56.1 Best Book

wxBookCtrl is mapped to the class best suited for a given platform. Currently it provides wxChoicebook for smartphones equipped with WinCE, and wxNotebook for all other platforms. The mapping consists of:

wxBookCtrl	wxChoicebook or wxNotebook
wxEVT_COMMAND_BOOKCTRL_PAGE_CHANGED	wxEVT_COMMAND_CHOICEBOOK_PAGE_CHANGED or wxEVT_COMMAND_NOTEBOOK_PAGE_CHANGED
wxEVT_COMMAND_BOOKCTRL_PAGE_CHANGING	wxEVT_COMMAND_CHOICEBOOK_PAGE_CHANGING or wxEVT_COMMAND_NOTEBOOK_PAGE_CHANGING

EVT_BOOKCTRL_PAGE_CHANGED(id, fn)	EVT_CHOICEBOOK_PAGE_CHANGED(id, fn) or EVT_NOTEBOOK_PAGE_CHANGED(id, fn)
EVT_BOOKCTRL_PAGE_CHANGING(id, fn)	EVT_CHOICEBOOK_PAGE_CHANGING(id, fn) or EVT_NOTEBOOK_PAGE_CHANGING(id, fn)

For orientation of the book controller, use following flags in style:

- **wxBK_TOP:** controller above pages
- **wxBK_BOTTOM:** controller below pages
- **wxBK_LEFT:** controller on the left
- **wxBK_RIGHT:** controller on the right
- **wxBK_DEFAULT:** native controller placement

10.57 wxTipProvider Overview

Many "modern" Windows programs have a feature (some would say annoyance) of presenting the user tips at program startup.

While this is probably useless to the advanced users of the program, the experience shows that the tips may be quite helpful for the novices and so more and more programs now do this. For a wxWidgets programmer, implementing this feature is extremely easy. To show a tip, it is enough to just call wxShowTip function like this:

```
if ( ...show tips at startup?... )
{
    wxTipProvider *tipProvider = wxCreateFileTipProvider("tips.txt", 0)
      ;
    wxShowTip(windowParent, tipProvider);
    delete tipProvider;
}
```

Of course, you need to get the text of the tips from somewhere - in the example above, the text is supposed to be in the file tips.txt from where it is read by the *tip provider*. The tip provider is just an object of a class deriving from wxTipProvider. It has to implement one pure virtual function of the base class: GetTip. In the case of the tip provider created by wxCreateFileTipProvider, the tips are just the lines of the text file.

If you want to implement your own tip provider (for example, if you wish to hardcode the tips inside your program), you just have to derive another class from wxTipProvider and pass a pointer to the object of this class to wxShowTip - then you don't need wxCreateFileTipProvider at all.

You will probably want to save somewhere the index of the tip last shown - so that the program doesn't always show the same tip on startup. As you also need to remember whether to show tips or not (you shouldn't do it if the user unchecked "Show tips on startup" checkbox in the dialog), you will probably want to store both the index of the last shown tip (as returned by wxTipProvider::GetCurrentTip and the flag telling whether to show the tips at startup at all.

In a tips.txt file, lines that begin with a # character are considered comments and are automatically skipped. Blank lines and lines only having spaces are also skipped.

You can easily add runtime-translation capacity by placing each line of the tips.txt file inside the usual translation macro. For example, your tips.txt file would look like this:

```
_("This is my first tip")
_("This is my second tip")
```

Now add your tips.txt file into the list of files that gettext searches for translatable strings. The tips will thus get included into your generated .po file catalog and be translated at runtime along with the rest of your application's translatable strings.

Note

Each line in the tips.txt file needs to strictly begin with exactly the 3 characters of underscore-parenthesis-doublequote, and end with doublequote-parenthesis, as shown above. Also, remember to escape any double-quote characters within the tip string with a backslash-doublequote.

See the dialogs program in your samples folder for a working example inside a program.

10.58 Document/View Framework

The document/view framework is found in most application frameworks, because it can dramatically simplify the code required to build many kinds of application.

The idea is that you can model your application primarily in terms of *documents* to store data and provide interface-independent operations upon it, and *views* to visualise and manipulate the data. Documents know how to do input and output given stream objects, and views are responsible for taking input from physical windows and performing the manipulation on the document data.

If a document's data changes, all views should be updated to reflect the change. The framework can provide many user-interface elements based on this model.

Once you have defined your own classes and the relationships between them, the framework takes care of popping up file selectors, opening and closing files, asking the user to save modifications, routing menu commands to appropriate (possibly default) code, even some default print/preview functionality and support for command undo/redo.

The framework is highly modular, allowing overriding and replacement of functionality and objects to achieve more than the default behaviour.

These are the overall steps involved in creating an application based on the document/view framework:

- Define your own document and view classes, overriding a minimal set of member functions e.g. for input/output, drawing and initialization.
- Define any subwindows (such as a scrolled window) that are needed for the view(s). You may need to route some events to views or documents, for example, "OnPaint" needs to be routed to wxView::OnDraw.
- Decide what style of interface you will use: Microsoft's MDI (multiple document child frames surrounded by an overall frame), SDI (a separate, unconstrained frame for each document), or single-window (one document open at a time, as in Windows Write).
- Use the appropriate wxDocParentFrame and wxDocChildFrame classes. Construct an instance of wxDocParentFrame in your wxApp::OnInit, and a wxDocChildFrame (if not single-window) when you initialize a view. Create menus using standard menu ids (such as wxID_OPEN, wxID_PRINT).
- Construct a single wxDocManager instance at the beginning of your wxApp::OnInit, and then as many wxDocTemplate instances as necessary to define relationships between documents and views. For a simple application, there will be just one wxDocTemplate.

If you wish to implement Undo/Redo, you need to derive your own class(es) from wxCommand and use wxCommandProcessor::Submit instead of directly executing code. The framework will take care of calling Undo and Do functions as appropriate, so long as the wxID_UNDO and wxID_REDO menu items are defined in the view menu.

Here are a few examples of the tailoring you can do to go beyond the default framework behaviour:

- Override wxDocument::OnCreateCommandProcessor to define a different Do/Undo strategy, or a command history editor.
- Override wxView::OnCreatePrintout to create an instance of a derived wxPrintout class, to provide multi-page document facilities.
- Override wxDocManager::SelectDocumentPath to provide a different file selector.

- Limit the maximum number of open documents and the maximum number of undo commands.

Note that to activate framework functionality, you need to use some or all of the wxWidgets Predefined Command Identifiers in your menus.

wxPerl Note: The document/view framework is available in wxPerl. To use it, you will need the following statements in your application code:

```
1 use Wx::DocView;
2 use Wx ':docview';   # import constants (optional)
```

Document/View Framework,

10.58.1 wxDocument Overview

The wxDocument class can be used to model an application's file-based data. It is part of the document/view framework supported by wxWidgets, and cooperates with the wxView, wxDocTemplate and wxDocManager classes. Using this framework can save a lot of routine user-interface programming, since a range of menu commands – such as open, save, save as – are supported automatically.

The programmer just needs to define a minimal set of classes and member functions for the framework to call when necessary. Data, and the means to view and edit the data, are explicitly separated out in this model, and the concept of multiple *views* onto the same data is supported.

Note that the document/view model will suit many but not all styles of application. For example, it would be overkill for a simple file conversion utility, where there may be no call for *views* on *documents* or the ability to open, edit and save files. But probably the majority of applications are document-based.

See the example application in `samples/docview`. To use the abstract wxDocument class, you need to derive a new class and override at least the member functions SaveObject and LoadObject. SaveObject and LoadObject will be called by the framework when the document needs to be saved or loaded.

Use the macros DECLARE_DYNAMIC_CLASS and IMPLEMENT_DYNAMIC_CLASS in order to allow the framework to create document objects on demand. When you create a wxDocTemplate object on application initialization, you should pass CLASSINFO(YourDocumentClass) to the wxDocTemplate constructor so that it knows how to create an instance of this class.

If you do not wish to use the wxWidgets method of creating document objects dynamically, you must override wxDocTemplate::CreateDocument to return an instance of the appropriate class.

10.58.2 wxView Overview

The wxView class can be used to model the viewing and editing component of an application's file-based data. It is part of the document/view framework supported by wxWidgets, and cooperates with the wxDocument, wxDoc↩ Template and wxDocManager classes.

See the example application in `samples/docview`.

To use the abstract wxView class, you need to derive a new class and override at least the member functions On↩ Create, OnDraw, OnUpdate and OnClose. You will probably want to respond to menu commands from the frame containing the view.

Use the macros DECLARE_DYNAMIC_CLASS and IMPLEMENT_DYNAMIC_CLASS in order to allow the framework to create view objects on demand. When you create a wxDocTemplate object on application initialization, you should pass CLASSINFO(YourViewClass) to the wxDocTemplate constructor so that it knows how to create an instance of this class.

If you do not wish to use the wxWidgets method of creating view objects dynamically, you must override wxDoc↩ Template::CreateView to return an instance of the appropriate class.

10.58.3 wxDocTemplate Overview

The wxDocTemplate class is used to model the relationship between a document class and a view class. The application creates a document template object for each document/view pair. The list of document templates managed by the wxDocManager instance is used to create documents and views. Each document template knows what file filters and default extension are appropriate for a document/view combination, and how to create a document or view.

For example, you might write a small doodling application that can load and save lists of line segments. If you had two views of the data – graphical, and a list of the segments – then you would create one document class DoodleDocument, and two view classes (DoodleGraphicView and DoodleListView). You would also need two document templates, one for the graphical view and another for the list view. You would pass the same document class and default file extension to both document templates, but each would be passed a different view class. When the user clicks on the Open menu item, the file selector is displayed with a list of possible file filters – one for each wxDocTemplate. Selecting the filter selects the wxDocTemplate, and when a file is selected, that template will be used for creating a document and view.

For the case where an application has one document type and one view type, a single document template is constructed, and dialogs will be appropriately simplified.

wxDocTemplate is part of the document/view framework supported by wxWidgets, and cooperates with the wxView, wxDocument and wxDocManager classes.

See the example application in `samples/docview`.

To use the wxDocTemplate class, you do not need to derive a new class. Just pass relevant information to the constructor including CLASSINFO(YourDocumentClass) and CLASSINFO(YourViewClass) to allow dynamic instance creation.

If you do not wish to use the wxWidgets method of creating document objects dynamically, you must override wxDocTemplate::CreateDocument and wxDocTemplate::CreateView to return instances of the appropriate class.

Note

The document template has nothing to do with the C++ template construct.

10.58.4 wxDocManager Overview

The wxDocManager class is part of the document/view framework supported by wxWidgets, and cooperates with the wxView, wxDocument and wxDocTemplate classes.

A wxDocManager instance coordinates documents, views and document templates. It keeps a list of document and template instances, and much functionality is routed through this object, such as providing selection and file dialogs. The application can use this class 'as is' or derive a class and override some members to extend or change the functionality.

Create an instance of this class near the beginning of your application initialization, before any documents, views or templates are manipulated.

There may be multiple wxDocManager instances in an application. See the example application in `samples/docview`.

10.58.5 Event Propagation in Document/View framework

While wxDocument, wxDocManager and wxView are abstract objects, with which the user can't interact directly, all of them derive from wxEvtHandler class and can handle events arising in the windows showing the document with which the user does interact. This is implemented by adding additional steps to the event handling process described in How Events are Processed, so the full list of the handlers searched for an event occurring directly in wxDocChildFrame is:

1. wxDocument opened in this frame.

2. wxView shown in this frame.
3. wxDocManager associated with the parent wxDocParentFrame.
4. wxDocChildFrame itself.
5. wxDocParentFrame, as per the usual event bubbling up to parent rules.
6. wxApp, again as the usual fallback for all events.

This is mostly useful to define handlers for some menu commands directly in wxDocument or wxView and is also used by the framework itself to define the handlers for several standard commands, such as wxID_NEW or wx↩ ID_SAVE, in wxDocManager itself. Notice that due to the order of the event handler search detailed above, the handling of these commands can *not* be overridden at wxDocParentFrame level but must be done at the level of wxDocManager itself.

10.58.6 wxCommand Overview

wxCommand is a base class for modelling an application command, which is an action usually performed by selecting a menu item, pressing a toolbar button or any other means provided by the application to change the data or view.

Instead of the application functionality being scattered around switch statements and functions in a way that may be hard to read and maintain, the functionality for a command is explicitly represented as an object which can be manipulated by a framework or application.

When a user interface event occurs, the application *submits* a command to a wxCommandProcessor object to execute and store.

The wxWidgets document/view framework handles Undo and Redo by use of wxCommand and wxCommand↩ Processor objects. You might find further uses for wxCommand, such as implementing a macro facility that stores, loads and replays commands.

An application can derive a new class for every command, or, more likely, use one class parameterized with an integer or string command identifier.

10.58.7 wxCommandProcessor Overview

wxCommandProcessor is a class that maintains a history of wxCommand instances, with undo/redo functionality built-in. Derive a new class from this if you want different behaviour.

10.58.8 wxFileHistory Overview

wxFileHistory encapsulates functionality to record the last few files visited, and to allow the user to quickly load these files using the list appended to the File menu. Although wxFileHistory is used by wxDocManager, it can be used independently. You may wish to derive from it to allow different behaviour, such as popping up a scrolling list of files.

By calling wxFileHistory::UseMenu() you can associate a file menu with the file history. The menu will then be used for appending filenames that are added to the history.

Please notice that currently if the history already contained filenames when UseMenu() is called (e.g. when initializing a second MDI child frame), the menu is not automatically initialized with the existing filenames in the history and so you need to call wxFileHistory::AddFilesToMenu() after UseMenu() explicitly in order to initialize the menu with the existing list of MRU files (otherwise an assertion failure is raised in debug builds).

The filenames are appended using menu identifiers in the range `wxID_FILE1` to `wxID_FILE9`.

In order to respond to a file load command from one of these identifiers, you need to handle them using an event handler, for example:

```
BEGIN_EVENT_TABLE(wxDocParentFrame, wxFrame)
    EVT_MENU(wxID_EXIT, wxDocParentFrame::OnExit)
    EVT_MENU_RANGE(wxID_FILE1, wxID_FILE9, wxDocParentFrame::OnMRUFile)
END_EVENT_TABLE()

void wxDocParentFrame::OnExit(wxCommandEvent& WXUNUSED(event))
{
    Close();
}

void wxDocParentFrame::OnMRUFile(wxCommandEvent& event)
{
    wxString f(m_docManager->GetHistoryFile(event.GetId() -
      wxID_FILE1));
    if (!f.empty())
        (void)m_docManager-CreateDocument(f, wxDOC_SILENT);
}
```

10.58.9 Predefined Command Identifiers

To allow communication between the application's menus and the document/view framework, several command identifiers are predefined for you to use in menus.

```
wxID_OPEN (5000)
wxID_CLOSE (5001)
wxID_NEW (5002)
wxID_SAVE (5003)
wxID_SAVEAS (5004)
wxID_REVERT (5005)
wxID_EXIT (5006)
wxID_UNDO (5007)
wxID_REDO (5008)
wxID_HELP (5009)
wxID_PRINT (5010)
wxID_PRINT_SETUP (5011)
wxID_PREVIEW (5012)
```

10.59 Backwards Compatibility

Many of the GUIs and platforms supported by wxWidgets are continuously evolving, and some of the new platforms wxWidgets now supports were quite unimaginable even a few years ago.

In this environment wxWidgets must also evolve in order to support these new features and platforms.

However the goal of wxWidgets is not only to provide a consistent programming interface across many platforms, but also to provide an interface that is reasonably stable over time, to help protect its users from some of the uncertainty of the future.

10.59.1 The Version Numbering Scheme

wxWidgets version numbers can have up to four components, with trailing zeros sometimes omitted:

```
major.minor.release.sub-release
```

A stable release of wxWidgets will have an even number for *minor*, e.g. 2.6.0. Stable, in this context, means that the API is not changing. In truth, some changes are permitted, but only those that are backward compatible. For example, you can expect later 2.6.x releases, such as 2.6.1 and 2.6.2 to be backward compatible with their predecessor.

When it becomes necessary to make changes which are not wholly backward compatible, the stable branch is forked, creating a new development branch of wxWidgets. This development branch will have an odd number for *minor*, for example 2.7.x. Releases from this branch are known as development snapshots.

The stable branch and the development branch will then be developed in parallel for some time. When it is no longer useful to continue developing the stable branch, the development branch is renamed and becomes a new stable

branch, for example: 2.8.0. And the process begins again. This is how the tension between keeping the interface stable, and allowing the library to evolve is managed.

You can expect the versions with the same major and even minor version number to be compatible, but between minor versions there will be incompatibilities. Compatibility is not broken gratuitously however, so many applications will require no changes or only small changes to work with the new version.

10.59.2 Source Level Compatibility

Later releases from a stable branch are backward compatible with earlier releases from the same branch at the source level. This means that, for example, if you develop your application using wxWidgets 2.8.0 then it should also compile fine with all later 2.8.x versions.

The converse is also true providing you avoid any new features not present in the earlier version. For example if you develop using 2.6.1 your program will compile fine with wxWidgets 2.8.0 providing you don't use any 2.8.1 specific features.

For some platforms binary compatibility is also supported, see Library Binary Compatibility below.

Between minor versions, for example between 2.4.x, 2.6.x and 2.8.x, there will be some incompatibilities. Wherever possible the old way of doing something is kept alongside the new for a time wrapped inside:

```
#if WXWIN_COMPATIBILITY_2_6
    // deprecated feature
    ...
#endif
```

By default the `WXWIN_COMPATIBILITY_X_X` macro is set to 1 for the previous stable branch, for example in 2.8.x, `WXWIN_COMPATIBILITY_2_6` = 1. For the next earlier stable branch the default is 0, so `WXWIN_COMPATIBILITY_2_4` = 0 for 2.8.x. Earlier than that, obsolete features are removed.

These macros can be changed in `setup.h`. Or on UNIX-like systems you can set them using the `-disable-compat26` and `-enable-compat24` options to configure.

They can be useful in two ways:

- Changing `WXWIN_COMPATIBILITY_2_6` to 0 can be useful to find uses of deprecated features in your program that should eventually be removed.
- Changing `WXWIN_COMPATIBILITY_2_4` to 1 can be useful to compile a program developed using 2.4.x that no longer compiles with 2.8.x.

A program requiring one of these macros to be 1 will become incompatible with some future version of wxWidgets, and you should consider updating it.

10.59.3 Library Binary Compatibility

For some platforms, releases from a stable branch are not only source level compatible but can also be binary compatible.

Binary compatibility makes it possible to get the maximum benefit from using shared libraries, also known as dynamic link libraries (DLLs) on Windows or dynamic shared libraries on OS X.

For example, suppose several applications are installed on a system requiring wxWidgets 2.6.0, 2.6.1 and 2.6.2. Since 2.6.2 is backward compatible with the earlier versions, it should be enough to install just wxWidgets 2.6.2 shared libraries, and all the applications should be able to use them. If binary compatibility is not supported, then all the required versions 2.6.0, 2.6.1 and 2.6.2 must be installed side by side.

Achieving this, without the user being required to have the source code and recompile everything, places many extra constraints on the changes that can be made within the stable branch. So it is not supported for all platforms, and not for all versions of wxWidgets. To date it has mainly been supported by wxGTK for UNIX-like platforms.

Another practical consideration is that for binary compatibility to work, all the applications and libraries must have been compiled with compilers that are capable of producing compatible code; that is, they must use the same ABI (Application Binary Interface). Unfortunately most different C++ compilers do not produce code compatible with each other, and often even different versions of the same compiler are not compatible.

10.59.4 Application Binary Compatibility

The most important aspect of binary compatibility is that applications compiled with one version of wxWidgets, e.g. 2.6.1, continue to work with shared libraries of a later binary compatible version, for example 2.6.2. The converse can also be useful however. That is, it can be useful for a developer using a later version, e.g. 2.6.2 to be able to create binary application packages that will work with all binary compatible versions of the shared library starting with, for example 2.6.0.

To do this the developer must, of course, avoid any features not available in the earlier versions. However this is not necessarily enough; in some cases an application compiled with a later version may depend on it even though the same code would compile fine against an earlier version.

To help with this, a preprocessor symbol `wxABI_VERSION` can be defined during the compilation of the application (this would usually be done in the application's makefile or project settings). It should be set to the lowest version that is being targeted, as a number with two decimal digits for each component, for example `wxABI_VERSIO↩N=20600` for 2.6.0.

Setting `wxABI_VERSION` should prevent the application from implicitly depending on a later version of wxWidgets, and also disables any new features in the API, giving a compile time check that the source is compatible with the versions of wxWidgets being targeted.

Uses of `wxABI_VERSION` are stripped out of the wxWidgets sources when each new development branch is created. Therefore it is only useful to help achieve compatibility with earlier versions with the same major and even minor version numbers. It won't, for example, help you write code compatible with 2.6.x using wxWidgets 2.8.x.

10.60 C++ Exceptions

wxWidgets had been started long before the exceptions were introduced in C++ so it is not very surprising that it is not built around using them as some more modern C++ libraries are.

For instance, the library doesn't throw exceptions to signal about the errors. Moreover, up to (and including) the version 2.4 of wxWidgets, even using the exceptions in the user code was dangerous because the library code wasn't exception-safe and so an exception propagating through it could result in memory and/or resource leaks, and also not very convenient.

However the recent wxWidgets versions are exception-friendly. This means that while the library still doesn't use the exceptions by itself, it should be now safe to use the exceptions in the user code and the library tries to help you with this.

10.60.1 Strategies for Exception Handling

There are several choice for using the exceptions in wxWidgets programs. First of all, you may not use them at all. As stated above, the library doesn't throw any exceptions by itself and so you don't have to worry about exceptions at all unless your own code throws them. This is, of course, the simplest solution but may be not the best one to deal with all possible errors.

The next simplest strategy is to only use exceptions inside non-GUI code, i.e. never let unhandled exceptions escape the event handler in which it happened. In this case using exceptions in wxWidgets programs is not different from using them in any other C++ program.

Things get more interesting if you decide to let (at least some) exceptions escape from the event handler in which they occurred. Such exceptions will be caught by wxWidgets and the special wxApp::OnExceptionInMainLoop() method will be called from the `catch` clause. This allows you to decide in a single place what to do about such

exceptions: you may want to handle the exception somehow or terminate the program. In this sense, OnExceptionInMainLoop() is equivalent to putting a `try/catch` block around the entire `main()` function body in the traditional console programs. However notice that, as its name indicates, this method won't help you with the exceptions thrown before the main loop is started or after it is over, so you may still want to have `try/catch` in your overridden wxApp::OnInit() and wxApp::OnExit() methods too, otherwise wxApp::OnUnhandledException() will be called.

Finally, notice that even if you decide to not let any exceptions escape in this way, this still may happen unexpectedly in a program using exceptions as a result of a bug. So consider always overriding OnExceptionInMainLoop() in your wxApp-derived class if you use exceptions in your program, whether you expect it to be called or not. In the latter case you may simple re-throw the exception and let it bubble up to OnUnhandledException() as well.

To summarize, when you use exceptions in your code, you may handle them in the following places, in order of priority:

1. In a `try/catch` block inside an event handler.
2. In wxApp::OnExceptionInMainLoop().
3. In wxApp::OnUnhandledException().

In the first two cases you may decide whether you want to handle the exception and continue execution or to exit the program. In the last one the program is about to exit already so you can just try to save any unsaved data and notify the user about the problem (while being careful not to throw any more exceptions as otherwise `std::terminate()` will be called).

10.60.2 Handling Exception Inside wxYield()

In some, relatively rare cases, using wxApp::OnExceptionInMainLoop() may not be sufficiently flexible. The most common example is using automated GUI tests, when test failures are signaled by throwing an exception and these exceptions can't be caught in a single central method because their handling depends on the test logic, e.g. sometimes an exception is expected while at other times it is an actual error. Typically this results in writing code like the following:

```
void TestNewDocument()
{
    wxUIActionSimulator ui;
    ui.Char('n', wxMOD_CONTROL); // simulate creating a new file

    // Let wxWidgets dispatch Ctrl+N event, invoke the handler and create the
    // new document.
    try {
        wxYield();
    } catch ( ... ) {
        // Handle exceptions as failure in the new document creation test.
    }
}
```

Unfortunately, by default this example only works when using a C++11 compiler because the exception can't be safely propagated back to the code handling it in `TestNewDocument()` through the system event dispatch functions which are not compatible with C++ exceptions and needs to be stored by wxWidgets when it is first caught and rethrown later, when it is safe to do it. And such storing and rethrowing of exceptions is only possible in C++11, so while everything just works if you do use C++11, there is an extra step if you are using C++98: In this case you need to override wxApp::StoreCurrentException() and wxApp::RethrowStoredException() to help wxWidgets to do this, please see the documentation of these functions for more details.

10.60.3 Technicalities

To use any kind of exception support in the library you need to build it with `wxUSE_EXCEPTIONS` set to 1. It is turned on by default but you may wish to check `include/wx/msw/setup.h` file under Windows or run `configure` with explicit `-enable-exceptions` argument under Unix.

On the other hand, if you do not plan to use exceptions, setting this flag to 0 or using `-disable-exceptions` could result in a leaner and slightly faster library.

As for any other library feature, there is a sample (`except`) showing how to use it. Please look at its sources for further information.

10.61 Runtime Type Information (RTTI)

One of the failings of C++ used to be that no runtime information was provided about a class and its position in the inheritance hierarchy.

Another, which still persists, is that instances of a class cannot be created just by knowing the name of a class, which makes facilities such as persistent storage hard to implement.

Most C++ GUI frameworks overcome these limitations by means of a set of macros and functions and wxWidgets is no exception. As it originated before the addition of RTTI to the C++ standard and as support for it is still missing from some (albeit old) compilers, wxWidgets doesn't (yet) use it, but provides its own macro-based RTTI system.

In the future, the standard C++ RTTI will be used though and you're encouraged to use whenever possible the wxDynamicCast macro which, for the implementations that support it, is defined just as dynamic_cast and uses wxWidgets RTTI for all the others. This macro is limited to wxWidgets classes only and only works with pointers (unlike the real dynamic_cast which also accepts references).

Each class that you wish to be known to the type system should have a macro such as DECLARE_DYNAMIC_CL↩ ASS just inside the class declaration. The macro IMPLEMENT_DYNAMIC_CLASS should be in the implementation file. Note that these are entirely optional; use them if you wish to check object types, or create instances of classes using the class name. However, it is good to get into the habit of adding these macros for all classes.

Variations on these macros are used for multiple inheritance, and abstract classes that cannot be instantiated dynamically or otherwise.

DECLARE_DYNAMIC_CLASS inserts a static wxClassInfo declaration into the class, initialized by IMPLEMEN↩ T_DYNAMIC_CLASS. When initialized, the wxClassInfo object inserts itself into a linked list (accessed through wxClassInfo::first and wxClassInfo::next pointers). The linked list is fully created by the time all global initialisation is done.

IMPLEMENT_DYNAMIC_CLASS is a macro that not only initialises the static wxClassInfo member, but defines a global function capable of creating a dynamic object of the class in question. A pointer to this function is stored in wxClassInfo, and is used when an object should be created dynamically.

wxObject::IsKindOf uses the linked list of wxClassInfo. It takes a wxClassInfo argument, so use CLASSINFO(class↩ Name) to return an appropriate wxClassInfo pointer to use in this function.

The function wxCreateDynamicObject can be used to construct a new object of a given type, by supplying a string name. If you have a pointer to the wxClassInfo object instead, then you can simply call wxClassInfo::CreateObject.

See also

wxObject

10.61.1 wxClassInfo

This class stores meta-information about classes. An application may use macros such as DECLARE_DYNAMI↩ C_CLASS and IMPLEMENT_DYNAMIC_CLASS to record runtime information about a class, including:

- Its position in the inheritance hierarchy.
- The base class name(s) (up to two base classes are permitted).
- A string representation of the class name.
- A function that can be called to construct an instance of this class.

The DECLARE_... macros declare a static wxClassInfo variable in a class, which is initialized by macros of the form IMPLEMENT_... in the implementation C++ file. Classes whose instances may be constructed dynamically are given a global constructor function which returns a new object.

You can get the wxClassInfo for a class by using the CLASSINFO macro, e.g. CLASSINFO(wxFrame). You can get the wxClassInfo for an object using wxObject::GetClassInfo.

10.61.2 Example

In a header file frame.h:

```
class wxFrame : public wxWindow
{
    DECLARE_DYNAMIC_CLASS(wxFrame)

private:
    wxString m_title;

public:
...
};
```

In a C++ file frame.cpp:

```
IMPLEMENT_DYNAMIC_CLASS(wxFrame, wxWindow)

wxFrame::wxFrame()
{
...
}
```

10.62 Caveats When Not Using C++ RTTI

Note

C++ RTTI is usually enabled by default in most wxWidgets builds. If you do not know if your build has C++ RTTI enabled or not, then it probably is enabled, and you should not worry about anything mentioned in this section.

While in general wxWidgets standard Runtime Type Information (RTTI) is used throughout the library, there are some places where it won't work. One of those places is template classes.

When available, C++ RTTI is used to address this issue. If you have built the library with C++ RTTI disabled, an internal RTTI system is substituted. However, this system is not perfect and one proven scenario where it may break is a shared library or DLL build. More specifically, a template class instance created in one physical binary may not be recognized as its correct type when used in another one.

See also

Runtime Type Information (RTTI), wxEvtHandler::Bind(), wxAny

10.62.1 Bind() Issues

wxWidgets 2.9.0 introduced a new Dynamic Event Handling system, using wxEvtHandler::Bind<>() and Unbind<>(). This functionality uses templates behind the scenes and therefore is vulnerable to breakage in shared library builds, as described above.

Currently only Unbind<>() needs the type information, so you should be immune to this problem simply if you only need to use Bind<>() and not Unbind<>().

Also, if you only bind and unbind same event handler inside same binary, you should be fine.

10.62.2 wxAny Issues

wxAny is a dynamic type class which transparently uses templates to generate data type handlers, and therefore is vulnerable to breakage in shared library builds, as described above

You should be fine if you only create and use wxAny instances inside same physical binary. However, if you do need to be able to use wxAny freely across binary boundaries, (and for sake of code-safety, you probably do), then specializations for wxAnyValueTypeImpl<> templates need to be defined in one of your shared library (DLL) files. One specialization is required for every data type you use with wxAny. Easiest way to do this is using macros provided in wx/any.h. Note that you **do not** need to define specializations for C built-in types, nor for wxString or wxDateTime, because these are already provided in wxBase. However, you **do** need to define specializations for all pointer types except char* and wchar_t*.

Let's define a specialization for imaginary type 'MyClass'. In your shared library source code you will need to have this line:

```
WX_IMPLEMENT_ANY_VALUE_TYPE(wxAnyValueTypeImpl<MyClass>)
```

In your header file you will need the following:

```
wxDECLARE_ANY_TYPE(MyClass, WXIMPORT_OR_WXEXPORT)
```

Where WXIMPORT_OR_WXEXPORT is WXEXPORT when being included from the shared library that called the WX_IMPLEMENT_ANY_VALUE_TYPE() macro, and WXIMPORT otherwise.

10.63 Reference Counting

Many wxWidgets objects use a technique known as *reference counting*, also known as *copy on write* (COW).

This means that when an object is assigned to another, no copying really takes place. Only the reference count on the shared object data is incremented and both objects share the same data (a very fast operation).

But as soon as one of the two (or more) objects is modified, the data has to be copied because the changes to one of the objects shouldn't be seen in the others. As data copying only happens when the object is written to, this is known as COW.

What is important to understand is that all this happens absolutely transparently to the class users and that whether an object is shared or not is not seen from the outside of the class - in any case, the result of any operation on it is the same.

10.63.1 Object Comparison

The == and != operators of the reference counted classes always do a *deep comparison*. This means that the equality operator will return true if two objects are identical and not only if they share the same data.

Note that wxWidgets follows the *STL philosophy*: when a comparison operator cannot be implemented efficiently (like for e.g. wxImage's == operator which would need to compare the entire image's data, pixel-by-pixel), it's not implemented at all. That's why not all reference counted classes provide comparison operators.

Also note that if you only need to do a `shallow` comparison between two wxObject derived classes, you should not use the == and != operators but rather the wxObject::IsSameAs() function.

10.63.2 Object Destruction

When a COW object destructor is called, it may not delete the data: if it's shared, the destructor will just decrement the shared data's reference count without destroying it. Only when the destructor of the last object owning the data is called, the data is really destroyed. Just like all other COW-things, this happens transparently to the class users so that you shouldn't care about it.

10.63.3 List of Reference Counted Classes

The following classes in wxWidgets have efficient (i.e. fast) assignment operators and copy constructors since they are reference-counted:

- wxAcceleratorTable
- wxAnimation
- wxBitmap
- wxBrush
- wxCursor
- wxFont
- wxGraphicsBrush
- wxGraphicsContext
- wxGraphicsFont
- wxGraphicsMatrix
- wxGraphicsPath
- wxGraphicsPen
- wxIcon
- wxImage
- wxMetafile
- wxPalette
- wxPen
- wxRegion
- wxString
- wxVariant
- wxVariantData

Note that the list above reports the objects which are reference counted in all ports of wxWidgets; some ports may use this technique also for other classes.

All the objects implement a function **IsOk()** to test if they are referencing valid data; when the objects are in uninitialized state, you can only use the **IsOk()** getter; trying to call any other getter, e.g. wxBrush::GetStyle() on the wxNullBrush object, will result in an assert failure in debug builds.

10.63.4 Making Your Own Reference Counted Class

Reference counting can be implemented easily using wxObject or using the intermediate wxRefCounter class directly. Alternatively, you can also use the wxObjectDataPtr<T> template.

First, derive a new class from wxRefCounter (or wxObjectRefData when using a wxObject derived class) and put the memory-consuming data in it.

Then derive a new class from wxObject and implement there the public interface which will be seen by the user of your class. You'll probably want to add a function to your class which does the cast from wxObjectRefData to your class-specific shared data. For example:

```
MyClassRefData* GetData() const
{
    return wx_static_cast(MyClassRefData*, m_refData);
}
```

In fact, any time you need to read the data from your wxObject-derived class, you will need to call this function.

Note

Any time you need to actually modify the data placed inside your wxObject derived class, you must first call the wxObject::UnShare() function to ensure that the modifications won't affect other instances which are eventually sharing your object's data.

10.64 wxMBConv Overview

The wxMBConv classes in wxWidgets enable an Unicode-aware application to easily convert between Unicode and the variety of 8-bit encoding systems still in use.

See also

Text Conversion

10.64.1 Background: The Need for Conversion

As programs are becoming more and more globalized, and users exchange documents across country boundaries as never before, applications increasingly need to take into account all the different character sets in use around the world. It is no longer enough to just depend on the default byte-sized character set that computers have traditionally used.

A few years ago, a solution was proposed: the Unicode standard. Able to contain the complete set of characters in use in one unified global coding system, it would resolve the character set problems once and for all.

But it hasn't happened yet, and the migration towards Unicode has created new challenges, resulting in "compatibility encodings" such as UTF-8. A large number of systems out there still depends on the old 8-bit encodings, hampered by the huge amounts of legacy code still widely deployed. Even sending Unicode data from one Unicode-aware system to another may need encoding to an 8-bit multibyte encoding (UTF-7 or UTF-8 is typically used for this purpose), to pass unhindered through any traditional transport channels.

10.64.2 Background: The wxString Class

Todo rewrite this overview; it's not up2date with wxString changes

If you have compiled wxWidgets in Unicode mode, the wxChar type will become identical to wchar_t rather than char, and a wxString stores wxChars. Hence, all wxString manipulation in your application will then operate on Unicode strings, and almost as easily as working with ordinary char strings (you just need to remember to use the wxT() macro to encapsulate any string literals).

But often, your environment doesn't want Unicode strings. You could be sending data over a network, or processing a text file for some other application. You need a way to quickly convert your easily-handled Unicode data to and from a traditional 8-bit encoding. And this is what the wxMBConv classes do.

10.64.3 wxMBConv Classes

The base class for all these conversions is the wxMBConv class (which itself implements standard libc locale conversion). Derived classes include wxMBConvLibc, several different wxMBConvUTFxxx classes, and wxCSConv, which implement different kinds of conversions. You can also derive your own class for your own custom encoding and use it, should you need it. All you need to do is override the MB2WC and WC2MB methods.

10.64.4 wxMBConv Objects

Several of the wxWidgets-provided wxMBConv classes have predefined instances (wxConvLibc, wxConvFileName, wxConvUTF7, wxConvUTF8, wxConvLocal). You can use these predefined objects directly, or you can instantiate your own objects.

A variable, wxConvCurrent, points to the conversion object that the user interface is supposed to use, in the case that the user interface is not Unicode-based (like with GTK+ 1.2). By default, it points to wxConvLibc or wxConv↩ Local, depending on which works best on the current platform.

10.64.5 wxCSConv

The wxCSConv class is special because when it is instantiated, you can tell it which character set it should use, which makes it meaningful to keep many instances of them around, each with a different character set (or you can create a wxCSConv instance on the fly).

The predefined wxCSConv instance, wxConvLocal, is preset to use the default user character set, but you should rarely need to use it directly, it is better to go through wxConvCurrent.

10.64.6 Converting Strings

Once you have chosen which object you want to use to convert your text, here is how you would use them with wxString. These examples all assume that you are using a Unicode build of wxWidgets, although they will still compile in a non-Unicode build (they just won't convert anything).

Example 1: Constructing a wxString from input in current encoding.

```
wxString str(input_data, *wxConvCurrent);
```

Example 2: Input in UTF-8 encoding.

```
wxString str(input_data, wxConvUTF8);
```

Example 3: Input in KOI8-R. Construction of wxCSConv instance on the fly.

```
wxString str(input_data, wxCSConv(wxT("koi8-r")));
```

Example 4: Printing a wxString to stdout in UTF-8 encoding.

```
puts(str.mb_str(wxConvUTF8));
```

Example 5: Printing a wxString to stdout in custom encoding. Using preconstructed wxCSConv instance.

```
wxCSConv cust(user_encoding);
printf("Data: %s\n", (const char*) str.mb_str(cust));
```

Note

Since mb_str() returns a temporary wxCharBuffer to hold the result of the conversion, you need to explicitly cast it to const char* if you use it in a vararg context (like with printf).

10.64.7 Converting Buffers

If you have specialized needs, or just don't want to use wxString, you can also use the conversion methods of the conversion objects directly. This can even be useful if you need to do conversion in a non-Unicode build of wxWidgets; converting a string from UTF-8 to the current encoding should be possible by doing this:

```
wxString str(wxConvUTF8.cMB2WC(input_data), *wxConvCurrent);
```

Here, cMB2WC of the UTF8 object returns a wxWCharBuffer containing a Unicode string. The wxString constructor then converts it back to an 8-bit character set using the passed conversion object, *wxConvCurrent. (In a Unicode build of wxWidgets, the constructor ignores the passed conversion object and retains the Unicode data.)

This could also be done by first making a wxString of the original data:

```
wxString input_str(input_data);
wxString str(input_str.wc_str(wxConvUTF8), *wxConvCurrent);
```

To print a wxChar buffer to a non-Unicode stdout:

```
printf("Data: %s\n", (const char*) wxConvCurrent->cWX2MB(unicode_data));
```

If you need to do more complex processing on the converted data, you may want to store the temporary buffer in a local variable:

```
const wxWX2MBbuf tmp_buf = wxConvCurrent->cWX2MB(unicode_data);
const char *tmp_str = (const char*) tmp_buf;
printf("Data: %s\n", tmp_str);
process_data(tmp_str);
```

If a conversion had taken place in cWX2MB (i.e. in a Unicode build), the buffer will be deallocated as soon as tmp_buf goes out of scope. The macro wxWX2MBbuf reflects the correct return value of cWX2MB (either char* or wxCharBuffer), except for the const.

10.65 Writing Non-English Applications

This article describes how to write applications that communicate with the user in a language other than English.

Unfortunately many languages use different charsets under Unix and Windows (and other platforms, to make the situation even more complicated). These charsets usually differ in so many characters that it is impossible to use the same texts under all platforms.

The wxWidgets library provides a mechanism that helps you avoid distributing many identical, only differently encoded, packages with your application (e.g. help files and menu items in iso8859-13 and windows-1257). Thanks to this mechanism you can, for example, distribute only iso8859-13 data and it will be handled transparently under all systems.

Please read the Internationalization which describes the locales concept.

In the following text, wherever *iso8859-2* and *windows-1250* are used, any encodings are meant and any encodings may be substituted there.

10.65.1 Locales

The best way to ensure correctly displayed texts in a GUI across platforms is to use locales. Write your in-code messages in English or without diacritics and put real messages into the message catalog (see Internationalization).

A standard .po file begins with a header like this:

```
# SOME DESCRIPTIVE TITLE.
# Copyright (C) YEAR Free Software Foundation, Inc.
# FIRST AUTHOR <EMAIL@ADDRESS>, YEAR.
#
msgid ""
msgstr ""
"Project-Id-Version: PACKAGE VERSION\n"
"POT-Creation-Date: 1999-02-19 16:03+0100\n"
"PO-Revision-Date: YEAR-MO-DA HO:MI+ZONE\n"
"Last-Translator: FULL NAME <EMAIL@ADDRESS>\n"
"Language-Team: LANGUAGE <LL@li.org>\n"
"MIME-Version: 1.0\n"
"Content-Type: text/plain; charset=CHARSET\n"
"Content-Transfer-Encoding: ENCODING\n"
```

Note this particular line:

```
"Content-Type: text/plain; charset=CHARSET\n"
```

It specifies the charset used by the catalog. All strings in the catalog are encoded using this charset.

You have to fill in proper charset information. Your .po file may look like this after doing so:

```
# SOME DESCRIPTIVE TITLE.
# Copyright (C) YEAR Free Software Foundation, Inc.
# FIRST AUTHOR <EMAIL@ADDRESS>, YEAR.
#
msgid ""
msgstr ""
"Project-Id-Version: PACKAGE VERSION\n"
"POT-Creation-Date: 1999-02-19 16:03+0100\n"
"PO-Revision-Date: YEAR-MO-DA HO:MI+ZONE\n"
"Last-Translator: FULL NAME <EMAIL@ADDRESS>\n"
"Language-Team: LANGUAGE <LL@li.org>\n"
"MIME-Version: 1.0\n"
"Content-Type: text/plain; charset=iso8859-2\n"
"Content-Transfer-Encoding: 8bit\n"
```

(Make sure that the header is **not** marked as *fuzzy*.)

wxWidgets is able to use this catalog under any supported platform (although iso8859-2 is a Unix encoding and is normally not understood by Windows).

How is this done? When you tell the wxLocale class to load a message catalog that contains a correct header, it checks the charset. The catalog is then converted to the charset used (see wxLocale::GetSystemEncoding and wxLocale::GetSystemEncodingName) by the user's operating system.

10.65.2 Non-English Strings or 8-bit Characters in Source

By convention, you should only use characters without diacritics (i.e. 7-bit ASCII strings) for msgids in the source code and write them in English.

If you port software to wxWidgets, you may be confronted with legacy source code containing non-English string literals. Instead of translating the strings in the source code to English and putting the original strings into message catalog, you may configure wxWidgets to use non-English msgids and translate to English using message catalogs:

- If you use the program `xgettext` to extract the strings from the source code, specify the option `-from-code=<source code charset>`.
- Specify the source code language and charset as arguments to wxLocale::AddCatalog. For example:

```
locale.AddCatalog(wxT("myapp"), wxLANGUAGE_GERMAN, wxT("iso-8859-1"));
```

10.65.3 Font Mapping

You can use wxMBConv Overview and wxFontMapper to display text:

```
if (!wxFontMapper::Get()->IsEncodingAvailable(enc, facename))
{
    wxFontEncoding alternative;
    if (wxFontMapper::Get()->GetAltForEncoding(enc, &alternative,
                                               facename, false))
    {
        wxCSConv convFrom(wxFontMapper::Get()->GetEncodingName(enc));
        wxCSConv convTo(wxFontMapper::Get()->GetEncodingName(alternative));
        text = wxString(text.mb_str(convFrom), convTo);
    }
    else
        ...failure (or we may try iso8859-1/7bit ASCII)...
}
...display text...
```

10.65.4 Converting Data

You may want to store all program data (created documents etc.) in the same encoding, let's say `utf-8`. You can use wxCSConv to convert data to the encoding used by the system your application is running on (see wxLocale::GetSystemEncoding).

10.65.5 Help Files

If you're using wxHtmlHelpController there is no problem at all. You only need to make sure that all the HTML files contain the META tag:

```
<meta http-equiv="Content-Type" content="text/html; charset=iso8859-2">
```

Also, the hhp project file needs one additional line in the OPTIONS section:

```
Charset=iso8859-2
```

This additional entry tells the HTML help controller what encoding is used in contents and index tables.

10.66 Debugging

Various classes, functions and macros are provided in wxWidgets to help you debug your application.

Assertion macros allow you to insert various checks in your application which can be compiled out or disabled in release builds but are extremely useful while developing. Logging functions are also provided which are useful for inserting traces into your application code as well as debugging. Both assertions and debug logging are also used by wxWidgets itself so you may encounter them even if you don't use either of these features yourself.

See also

wxLog, Logging, Debugging macros

10.66.1 Configuring Debug Support

Starting with wxWidgets 2.9.1 debugging features are always available by default (and not only in a special "debug" build of the library) and you need to predefine wxDEBUG_LEVEL symbol as 0 when building both the library and your application to remove them completely from the generated object code. However the debugging features are disabled by default when the application itself is built with NDEBUG defined (i.e. in "release" or "production" mode) so there is no need to do this, unless the resources of the system your application will be running on are unusually constrained (notice that when asserts are disabled their condition is not even evaluated so the only run-time cost is a single condition check and the extra space taken by the asserts in the code).

This automatic deactivation of debugging code is done by IMPLEMENT_APP() macro so if you don't use you may need to explicitly call wxDISABLE_DEBUG_SUPPORT() yourself.

Also notice that it is possible to build your own application with a different value of wxDEBUG_LEVEL than the one which was used for wxWidgets itself. E.g. you may be using an official binary version of the library which will have been compiled with default

```
wxDEBUG_LEVEL == 1
```

but still predefine wxDEBUG_LEVEL as 0 for your own code.

On the other hand, if you do want to keep the asserts even in production builds, you will probably want to override the handling of assertion failures as the default behaviour which pops up a message box notifying the user about the problem is usually inappropriate. Use wxSetAssertHandler() to set up your own custom function which should be called instead of the standard assertion failure handler. Such function could log an appropriate message in the application log file or maybe notify the user about the problem in some more user-friendly way.

10.66.2 Assertion Macros

wxASSERT(), wxFAIL(), wxCHECK() as well as their other variants (see Debugging macros) are similar to the standard assert() macro but are more flexible and powerful. The first of them is equivalent to assert() itself, i.e. it

simply checks a condition and does nothing if it is true. The second one is equivalent to checking an always false condition and is supposed to be used for code paths which are supposed to be inaccessible (e.g. `default` branch of a `switch` statement which should never be executed). Finally, the wxCHECK() family of macros verifies the condition just as wxASSERT() does and performs some action such returning from the function if it fails – thus, it is useful for checking the functions preconditions.

All of the above functions exist in `_MSG` variants which allow you to provide a custom message which will be shown (or, more generally, passed to the assert handler) if the assertion fails, in addition to the usual file and line number information and the condition itself.

Example of using an assertion macro:

```
void GetTheAnswer(int *p)
{
    wxCHECK_RET( p, "pointer can't be NULL in GetTheAnswer()" );

    *p = 42;
};
```

If the condition is false, i.e. `p` is NULL, the assertion handler is called and, in any case (even when wxDEBUG_L↩ EVEL is 0), the function returns without dereferencing the NULL pointer on the next line thus avoiding a crash.

The default assertion handler behaviour depends on whether the application using wxWidgets was compiled in release build (with `NDEBUG` defined) or debug one (without) but may be changed in either case as explained above. If it wasn't changed, then nothing will happen in the release build and a message box showing the information about the assert as well as allowing to stop the program, ignore future asserts or break into the debugger is shown. On the platforms where wxStackWalker is supported the message box will also show the stack trace at the moment when the assert failed often allowing you to diagnose the problem without using the debugger at all. You can see an example of such message box in the Exception Sample.

10.66.3 Logging Functions

You can use the wxLogDebug and wxLogTrace functions to output debugging information in debug mode; it will do nothing for non-debugging code.

10.67 Window Styles

Window styles are used to specify alternative behaviour and appearances for windows, when they are created.

The symbols are defined in such a way that they can be combined in a 'bit-list' using the C++ *bitwise-or* operator.

For example:

```
wxCAPTION | wxMINIMIZE_BOX | wxMAXIMIZE_BOX |
      wxRESIZE_BORDER
```

For the window styles specific to each window class, please see the documentation for the window.

Most windows can use the generic styles listed for wxWindow in addition to their own styles.

10.68 Window Deletion

Window deletion can be a confusing subject, so this overview is provided to help make it clear when and how you delete windows, or respond to user requests to close windows.

See also

wxCloseEvent, wxWindow

10.68.1 Sequence of Events During Window Deletion

When the user clicks on the system close button or system close command, in a frame or a dialog, wxWidgets calls wxWindow::Close. This in turn generates an EVT_CLOSE event: see wxCloseEvent.

It is the duty of the application to define a suitable event handler, and decide whether or not to destroy the window. If the application is for some reason forcing the application to close (wxCloseEvent::CanVeto returns false), the window should always be destroyed, otherwise there is the option to ignore the request, or maybe wait until the user has answered a question before deciding whether it is safe to close. The handler for EVT_CLOSE should signal to the calling code if it does not destroy the window, by calling wxCloseEvent::Veto. Calling this provides useful information to the calling code.

The wxCloseEvent handler should only call wxWindow::Destroy to delete the window, and not use the `delete` operator. This is because for some window classes, wxWidgets delays actual deletion of the window until all events have been processed, since otherwise there is the danger that events will be sent to a non-existent window.

As reinforced in the next section, calling Close does not guarantee that the window will be destroyed. Call wx↩ Window::Destroy if you want to be certain that the window is destroyed.

10.68.2 Closing Windows

Your application can either use wxWindow::Close event just as the framework does, or it can call wxWindow::↩ Destroy directly. If using Close(), you can pass a true argument to this function to tell the event handler that we definitely want to delete the frame and it cannot be vetoed.

The advantage of using Close instead of Destroy is that it will call any clean-up code defined by the EVT_CLO↩ SE handler; for example it may close a document contained in a window after first asking the user whether the work should be saved. Close can be vetoed by this process (return false), whereas Destroy definitely destroys the window.

10.68.3 Default Window Close Behaviour

The default close event handler for wxDialog simulates a Cancel command, generating a wxID_CANCEL event. Since the handler for this cancel event might itself call Close, there is a check for infinite looping. The default handler for wxID_CANCEL hides the dialog (if modeless) or calls EndModal(wxID_CANCEL) (if modal). In other words, by default, the dialog *is* not destroyed (it might have been created on the stack, so the assumption of dynamic creation cannot be made).

The default close event handler for wxFrame destroys the frame using Destroy().

10.68.4 User Calls to Exit From a Menu

What should I do when the user calls up Exit from a menu? You can simply call wxWindow::Close on the frame. This will invoke your own close event handler which may destroy the frame.

You can do checking to see if your application can be safely exited at this point, either from within your close event handler, or from within your exit menu command handler. For example, you may wish to check that all files have been saved. Give the user a chance to save and quit, to not save but quit anyway, or to cancel the exit command altogether.

10.68.5 Exiting the Application Gracefully

A wxWidgets application automatically exits when the last top level window (wxFrame or wxDialog), is destroyed. Put any application-wide cleanup code in wxApp::OnExit (this is a virtual function, not an event handler).

10.68.6 Automatic Deletion of Child Windows

Child windows are deleted from within the parent destructor. This includes any children that are themselves frames or dialogs, so you may wish to close these child frame or dialog windows explicitly from within the parent close handler.

10.68.7 Other Kinds of Windows

So far we've been talking about 'managed' windows, i.e. frames and dialogs. Windows with parents, such as controls, don't have delayed destruction and don't usually have close event handlers, though you can implement them if you wish. For consistency, continue to use the wxWindow::Destroy function instead of the `delete` operator when deleting these kinds of windows explicitly.

10.69 Environment Variables

This section describes all environment variables that affect execution of wxWidgets programs.

WXTRACE	(Debug build only.) This variable can be set to a comma-separated list of trace masks used in wxLogTrace calls; wxLog::AddTraceMask is called for every mask in the list during wxWidgets initialization.
WXPREFIX	(Unix only.) Overrides installation prefix. Normally, the prefix is hard-coded and is the same as the value passed to `configure` via the `-prefix` switch when compiling the library (typically `/usr/local` or `/usr`). You can set WXPREFIX if you are for example distributing a binary version of an application and you don't know in advance where it will be installed.

10.70 Creating a Custom Widget

Typically combining the existing Controls controls in wxDialogs and wxFrames is sufficient to fullfill any GUI design.

Using the wxWidgets standard controls makes your GUI looks native on all ports and is obviously easier and faster.

However there are situations where you need to show some particular kind of data which is not suited to any existing control. In these cases rather than hacking an existing control for something it has not been conceived for, it's better to write a new widget.

10.70.1 Writing a Custom Widget

There are at least two very different ways to implement a new widget.

The first is to build it upon wxWidgets existing classes, thus deriving it from wxControl or wxWindow. In this way you'll get a **generic** widget. This method has the advantage that writing a single implementation works on all ports; the disadvantage is that it the widget will look the same on all platforms, and thus it may not integrate well with the native look and feel.

The second method is to build it directly upon the native toolkits of the platforms you want to support (e.g. GTK+, Carbon and GDI). In this way you'll get a **native** widget. This method in fact has the advantage of a native look and feel but requires different implementations and thus more work.

In both cases you'll want to better explore some hot topics like:

- Window Sizing Overview
- Custom Event Summary to implement your custom widget's events.

You will probably need also to gain some familiarity with the wxWidgets sources, since you'll need to interface with some undocumented wxWidgets internal mechanisms.

Writing a Generic Widget

Generic widgets are typically derived from wxControl or wxWindow. They are easy to write. The typical "template" is as follows:

```
enum MySpecialWidgetStyles
{
    SWS_LOOK_CRAZY = 1,
    SWS_LOOK_SERIOUS = 2,
    SWS_SHOW_BUTTON = 4,

    SWS_DEFAULT_STYLE = (SWS_SHOW_BUTTON|SWS_LOOK_SERIOUS)
};

class MySpecialWidget : public wxControl
{
public:
    MySpecialWidget() { Init(); }

    MySpecialWidget(wxWindow *parent,
                    wxWindowID winid,
                    const wxString& label,
                    const wxPoint& pos = wxDefaultPosition,
                    const wxSize& size = wxDefaultSize,
                    long style = SWS_DEFAULT_STYLE,
                    const wxValidator& val = wxDefaultValidator,
                    const wxString& name = "MySpecialWidget")
    {
        Init();

        Create(parent, winid, label, pos, size, style, val, name);
    }

    bool Create(wxWindow *parent,
                wxWindowID winid,
                const wxString& label,
                const wxPoint& pos = wxDefaultPosition,
                const wxSize& size = wxDefaultSize,
                long style = SWS_DEFAULT_STYLE,
                const wxValidator& val = wxDefaultValidator,
                const wxString& name = wxCollapsiblePaneNameStr);

    // accessors...

protected:

    void Init() {
        // init widget's internals...
    }

    virtual wxSize DoGetBestSize() const {
        // we need to calculate and return the best size of the widget...
    }

    void OnPaint(wxPaintEvent&) {
        // draw the widget on a wxDC...
    }

private:
    DECLARE_DYNAMIC_CLASS(MySpecialWidget)
    DECLARE_EVENT_TABLE()
};
```

Writing a Native Widget

Writing a native widget is typically more difficult as it requires you to know the APIs of the platforms you want to support. See Native Toolkit Documentation for links to the documentation manuals of the various toolkits.

The organization used by wxWidgets consists in:

- declaring the common interface of the control in a generic header, using the 'Base' postfix; e.g. MySpecial↩ WidgetBase. See for example the wxWidgets' `"wx/button.h"` file.

- declaring the real widget class inheriting from the Base version in platform-specific headers; see for example the wxWidgets' "`wx/gtk/button.h`" file.
- separating the different implementations in different source files, putting all common stuff in a separate source. See for example the wxWidgets' "`src/common/btncmn.cpp`", "`src/gtk/button.cpp`" and "`src/msw/button.cpp`" files.

Chapter 11

Translations to Other Languages

wxWidgets uses a certain number of user-readable strings such as "help" or "Load file" which should be translated to the users language if it is different from English.

wxWidgets has built in support for internationalization (*i18n* from now on) which allows for this to happen automatically if the translations to the current language are available.

You may find here the list of all existing translations with the addresses of the official translators whom you should contact if you would like to submit any corrections to the translations for your language.

Also, please see How to Help if you would like to translate wxWidgets to your language if it is not mentioned here (or to help with one which already is - it is quite helpful to have several translators for one language at least for proof reading).

11.1 Available Translations

Below is the table containing the list of languages supported by wxWidgets. The columns of this table have the obvious meaning: in each row you will see the language, the official translator (if any) for it and the status of the translations.

Please note that email addresses in the table below are intentionally invalid to foil spam robots, remove one @ from them.

Language	Status	Translator(s)
Afrikaans	68%	Petri Jooste
Albanian	75%	Besnik Bleta

11.2 How to Help

wxWidgets uses the standard GNU gettext tools for i18n so if you are already familiar with them you shouldn't have any problems with working on wxWidgets translations.

Here are the steps you should follow:

1. Get the latest version of the file `locale/wxstd.pot` from the wxWidgets source tree: if you're using Subversion or the daily snapshots you should already have it. Otherwise you can always retrieve it directly from the Subversion repository via the Web interface.
2. Rename it to `XY.po` where `"XY"` is the 2 letter ISO 639-2 language code for your language.
3. Translate the strings in this file using either your favourite text editor or a specialized tool such as Vaclav Slavik's excellent poEdit utility.
4. Verify that your translations can at least be compiled (even if they are yet incomplete) by running `msgfmt -v XY.po` command: please note that you *must* use the `-v` option. In particular, please fill the header fields because `msgfmt` doesn't accept the default values for them.
5. Send the finished translation to Vadim Zeitlin and it will be added to the next wxWidgets release or snapshot.

In addition, please consider subscribing to the very low volume wxWidgets translators mailing list on which the news especially important for the translators are announced.

Thank you in advance for your help!

Chapter 12

Utilities Overview

In addition to the wxWidgets libraries (see Library List), some utilities are available to the users in the `utils` hierarchy (even if some of them are explicitly conceived for wxWidgets maintainance and will probably be of little use to others).

Please note that these utilities do represent only the utilities developed and maintained by the wxWidgets team. There are lots of other user-contributed and user-maintained packages; see the wxWidgets download page: `http://www.wxwidgets.org/downloads` or directly `http://wxcode.sourceforge.net` or `http://www.wxcommunity.com/` .

12.1 Emulator

Xnest-based display emulator for X11-based PDA applications.

This program can be found in `utils/emulator`.

12.2 Help Viewer

Helpview is a program for displaying wxWidgets HTML Help files. In many cases, you may wish to use the wxWidgets HTML Help classes from within your application, but this provides a handy stand-alone viewer. See wxHTML Overview for more details.

You can find Helpview in `utils/helpview`.

12.3 HHP2Cached

This utility creates a "cached" version of a .hhp file; using cached .hhp files in wxHtmlHelpController can dramatically improve the performance of the help viewer. See wxHtmlHelpController for more details.

You can find HHP2Cached in `utils/hhp2cached`.

12.4 Interface Checker

This utility compares the wxWidgets real interface contained in the `include` hierarchy with the wxWidgets interface used for documentation purposes and kept in the `interface` hierarchy.

Ifacecheck warns about incoherences (mainly wrong prototype signatures) and can even correct them automatically. It uses the XML outputs of the gccxml utility (see `http://www.gccxml.org`) and of the Doxygen utility (see `http://www.doxygen.org`) to do the comparisons.

It's explicitly designed for wxWidgets documentation needs and is probably of little use for anything else than wx↩ Widgets docs reviewing.

You can find it in `utils/ifacecheck`.

12.5 Screenshot Generator

This utility automates the process of taking screenshots of various GUI components for use in the HTML documentation of wxWidgets.

You can find it in `utils/screenshotgen`.

12.6 wxWidgets XML Resource Compiler

This utility allows the user to compile *binary* versions of their XRC files, which are compressed and can be loaded faster than plain XRC files. See XML Based Resource System (XRC) for more info.

You can find it under `utils/wxrc`.

Chapter 13

Changes Since wxWidgets 2.8

This topic describes backwards-incompatible changes in wxWidgets 3.0 compared to the last stable release and is very important to read if you are updating from the 2.8 or an older version.

And even if you hadn't used any previous version of wxWidgets and are starting directly with 3.0, it can still be useful to have at least a quick look at it just to know that some of the older examples and tutorials may not be applicable any more to wxWidgets 3.0.

The incompatible changes can be grouped into the following categories:

- Unicode-related Changes
- Miscellaneous Other Changes

13.1 Unicode-related Changes

If you used Unicode build of wxWidgets 2.8 or previous version, please read Unicode Support in wxWidgets for the details about how the API changed in 3.0 as a lot of the information which was correct before doesn't apply any longer.

For example, the notorious (due to the confusion they created) macros `wxT()` and `_T()` are not needed at all any longer. Basically, you can remove them from any code which used them. On the other hand, there is no particular harm in leaving them neither as the code will still compile and work correctly – you only need to remove them if you think that your code looks tidier without them. You also don't need to use `wxChar` any longer but can directly use the standard `wchar_t` type even if, again, `wxChar` continues to work.

The most serious backwards-incompatible change is related to the change of return type of wxString::c_str() method: it returns a special proxy object instead of a simple `char*` or `wchar_t*` now. Because of this, you cannot pass its result to any standard vararg functions such as `printf()` any more as described in Unicode-Related Compilation Errors. All wxWidgets functions, such as wxPrintf(), wxLogMessage() &c still work with it, but passing it to `printf()` will now result in a crash. It is strongly advised to recompile your code with a compiler warning about passing non-POD objects to vararg functions, such as g++.

The change of the type of wxString::c_str() can also result in compilation errors when passing its result to a function overloaded to take both narrow and wide strings and in this case you must select the version which you really want to use, e.g.:

```
void OpenLogFile(const char *filename);
void OpenLogFile(const wchar_t *filename);

wxString s;
OpenLogFile(s);             // ERROR: ambiguity
OpenLogFile(s.c_str());     // ERROR: ambiguity
OpenLogFile(s.wx_str());    // OK: function called depends on the build
OpenLogFile(s.mb_str());    // OK: always calls narrow string overload
OpenLogFile(s.wc_str());    // OK: always calls wide string overload
```

A common example of such problem arises with `std::fstream` class constructor in Microsoft Visual C++ standard library implementation. In addition to a constructor from `const char *` which this class must have, it also provides a constructor taking a wide character file name. Because of this, code like the following

```
#include <fstream>

void MyFunc(const wxString& filename)
{
    std::ifstream ifs(filename.c_str());
    ...
}
```

does not compile when using Microsoft Visual C++ and needs to be changed to use mb_str() (which will not work for file names containing Unicode characters, consider using wxWidgets classes and functions to work with such file names as they are not supported by standard C++ library).

The other class of incompatible changes is due to modifying some virtual methods to use `wxString` parameters instead of `const wxChar*` ones to make them accept both narrow and wide strings. This is not a problem if you simply call these functions but you need to change the signature of the derived class versions if you override them as otherwise they wouldn't be called any more. Again, the best way to ensure that this problem doesn't arise is to rebuild your code using a compiler which warns about function signature mismatch (you can use `-Woverloaded-virtual` g++ option).

Finally, a few structure fields, notable `wxCmdLineEntryDesc::shortName`, `longName` and `description` fields have been changed to be of type `const char*` instead of `const wxChar*` so you will need to remove `wxT()` or `_T()` if you used it with their initializers.

13.2 Miscellaneous Other Changes

- Default location of wxFileConfig files has changed under Windows, you will need to update your code if you access these files directly.
- wxWindow::IsEnabled() now returns false if a window parent (and not necessarily the window itself) is disabled, new function IsThisEnabled() with the same behaviour as old IsEnabled() was added.
- Generating wxNavigationKeyEvent events doesn't work any more under wxGTK (and other platforms in the future), use wxWindow::Navigate() or NavigateIn() instead.
- Sizers distribute only the extra space between the stretchable items according to their proportions and not all available space. We believe the new behaviour corresponds better to user expectations but if you did rely on the old behaviour you will have to update your code to set the minimal sizes of the sizer items to be in the same proportion as the items proportions to return to the old behaviour.
- wxWindow::Freeze/Thaw() are not virtual any more, if you overrode them in your code you need to override DoFreeze/Thaw() instead now.
- wxCalendarCtrl has native implementation in wxGTK, but it has less features than the generic one. The native implementation is used by default, but you can still use wxGenericCalendarCtrl instead of wxCalendarCtrl in your code if you need the extra features.
- wxDocument::FileHistoryLoad() and wxFileHistory::Load() now take const reference to wxConfigBase argument and not just a reference, please update your code if you overrode these functions and change the functions in the derived classes to use const reference as well.
- Calling wxConfig::Write() with an enum value will fail to compile because wxConfig now tries to convert all unknown types to wxString automatically using wxToString() function.

  The simplest solution is to cast the enum value to int, e.g.

  ```
  enum Colour { Red, Green, Blue };

  wxConfig conf;
  conf.Write("MyFavouriteColour", Red);       // ERROR: no match
  conf.Write("MyFavouriteColour", int(Red));  // OK
  ```

Another possibility which exists now is to provide an overload of wxToString() (and wxFromString()) for your own type, e.g.

```
wxString wxToString(Colour col)
{
    return col == Red ? "R" : col == Green ? "G" : "B";
}

bool wxFromString(const wxString& s, Colour* col)
{
    if ( s.length() != 1 )
        return false;

    switch ( s[0].GetValue() )
    {
        case 'R': *col = Red; return true;
        case 'G': *col = Green; return true;
        case 'B': *col = Blue; return true;
    }

    return false;
}
```

Of course, this will change the format of the wxConfig output which may be undesirable.

- wxTE_AUTO_SCROLL style is deprecated as it's always on by default anyhow in the ports which support it so you should simply remove any mentions of it from your code.
- If you use wxScrolled<T>::SetTargetWindow() you must override wxScrolled<T>::GetSizeAvailableFor↩ ScrollTarget() method to compute the size available for the scroll target as function of the main window size, please see the documentation of this method for more details.
- Signature of wxDataViewCustomRenderer::StartDrag() virtual method changed. You will need to change it in your derived renderer class too if you override it.
- wxDataViewCustomRenderer::Activate() and wxDataViewCustomRenderer::LeftClick() were replaced with the new wxDataViewCustomRenderer::ActivateCell() method. You will need to change it in your derived renderer class accordingly.

Chapter 14

Todo List

Page Date and Time

WRITE THIS DOC PARAGRAPH.

Page Samples Overview

Write descriptions for the samples who description started with "This sample demonstrates", they are semi-auto generated.

This sample isn't very didactive; it's more than a set of tests rather than a sample and thus should be rewritten with CppUnit and moved under "tests"

Member wxAuiManagerDock

wxAuiPaneInfo dock direction types used with wxAuiManager.

Member wxAuiManagerEvent::GetDC ()

What is this?

Member wxAuiManagerEvent::SetDC (wxDC *pdc)

What is this?

Member wxBitmap::SetDepth (int depth)

since these functions do not affect the bitmap data, why they exist??

Class wxBitmapComboBox

create wxCB_PROCESS_ENTER rather than reusing wxTE_PROCESS_ENTER!

Member wxClipboard::IsSupported (const wxDataFormat &format)

The name of this function is misleading. This should be renamed to something that more accurately indicates what it does.

Class wxConnectionBase

Document this class.

Class wxDatagramSocket

docme

Class wxDateTimeHolidayAuthority

Write wxDateTimeHolidayAuthority documentation.

Class wxDateTimeWorkDays

Write wxDateTimeWorkDays documentation.

Class wxDC

Precise definition of default/initial state.

Pixelwise definition of operations (e.g. last point of a line not drawn).

Member wxDefaultDateTime

Would it be better to rename this wxNullDateTime so it's consistent with the rest of the "empty/invalid/null" global objects?

Member wxEvtHandler::SearchEventTable (wxEventTable &table, wxEvent &event)

this function in the header is listed as an "implementation only" function; are we sure we want to document it?

Member wxFFile::Eof () const

THIS METHOD MAY CRASH? DOESN'T SOUND GOOD

Member wxFFile::Error () const

THIS METHOD MAY CRASH? DOESN'T SOUND GOOD

Member wxFont::SetNativeFontInfoUserDesc (const wxString &info)

add an example for wxMac

Member wxGridCellAttr::SetDefAttr (wxGridCellAttr *defAttr)

Needs documentation.

Member wxHelpControllerBase::SetViewer (const wxString &viewer, long flags=wxHELP_NETSCAPE)

modernize this function with wxLaunchDefaultBrowser

Member wxHtmlDCRenderer::Render (int x, int y, wxArrayInt &known_pagebreaks, int from=0, int dont_↩ render=false, int to=INT_MAX)

docme

Parameters

from	y-coordinate of the very first visible cell.
dont_render	if true then this method only returns y coordinate of the next page and does not output anything.
to	y-coordinate of the last visible cell.

Member wxHtmlTag::GetBeginPos () const

provide deprecation description

Member wxHtmlTag::GetEndPos1 () const

provide deprecation description

Member wxHtmlTag::GetEndPos2 () const

provide deprecation description

Class wxHtmlTagHandler

describe me

Page wxListCtrl Overview

The wxListCtrl topic overview still needs to be written, sorry.

Page wxMBConv Overview

rewrite this overview; it's not up2date with wxString changes

Member wxMediaCtrl::Seek (wxFileOffset where, wxSeekMode mode=wxFromStart)

Document the wxSeekMode parameter *mode*, and perhaps also the wxFileOffset and wxSeekMode themselves.

Member wxPenCap

use wxPENCAP_ prefix

Member wxPenJoin

use wxPENJOIN_ prefix

Member wxPENSTYLE_STIPPLE_MASK

WHAT's this?

Member wxPENSTYLE_STIPPLE_MASK_OPAQUE

WHAT's this?

Member wxPGProperty::SetValueFromString (const wxString &text, int flags=0)

docme

Member wxPreviewControlBar::CreateButtons ()

which flags??

Member wxPrintout::GetTitle () const

the python note here was wrong

Member wxPropertyGridInterface::GetPropertiesWithFlag (wxArrayPGProperty *targetArr, wxPGProperty::FlagType flags, bool inverse=false, int iterFlags=(wxPG_ITERATE_PROPERTIES|wxPG_ITERATE_HIDDEN|wxPG_ITERATE_CATEGORIES)) const

docme

Parameters

flags	Property flags to use.
inverse	

docme

Parameters

iterFlags	Iterator flags to use. Default is everything expect private children. See wxPropertyGridIterator Flags.

Member wxPropertyGridInterface::GetPropertyValues (const wxString &listname=wxEmptyString, wxPGProperty *baseparent=NULL, long flags=0) const

docme

Parameters

baseparent	

docme

Parameters

flags	Use wxPG_KEEP_STRUCTURE to retain category structure; each sub category will be its own wxVariantList of wxVariant.

Member wxPropertyGridInterface::HideProperty (wxPGPropArg id, bool hide=true, int flags=wxPG_RECURSE)

docme

Parameters

hide	If true, hides property, otherwise reveals it.
flags	By default changes are applied recursively. Set this parameter wxPG_DONT_RECURSE to prevent this.

Member wxPropertyGridInterface::SetPropertyAttribute (wxPGPropArg id, const wxString &attrName, wxVariant value, long argFlags=0)

docme

Parameters

attrName	Text identifier of attribute. See wxPropertyGrid Property Attribute Identifiers.
value	Value of attribute.
argFlags	Optional. Use wxPG_RECURSE to set the attribute to child properties recursively.

Member wxPropertyGridInterface::SetPropertyEditor (wxPGPropArg id, const wxPGEditor *editor)

docme

Parameters

editor	For builtin editors, use wxPGEditor_X, where X is builtin editor's name (TextCtrl, Choice, etc. see wxPGEditor documentation for full list).

Class wxScrolled< T >

review docs for this class replacing SetVirtualSizeHints() with SetMinClientSize().

Member wxScrollWinEvent::GetOrientation () const

wxHORIZONTAL and wxVERTICAL should go in their own enum

Member wxSizerItem::SetInitSize (int x, int y)

docme.

Member wxSizerItem::SetWindow (wxWindow *window)

provide deprecation description

Class wxSocketClient

describe me.

Class wxSocketServer

describe me.

Class wxStyledTextEvent

list styled text ctrl events.

Member wxVListBox::OnDrawBackground (wxDC &dc, const wxRect &rect, size_t n) const

Change this function signature to non-const.

Member wxVListBox::OnDrawItem (wxDC &dc, const wxRect &rect, size_t n) const =0

Change this function signature to non-const.

Member wxVListBox::OnDrawSeparator (wxDC &dc, wxRect &rect, size_t n) const

Change this function signature to non-const.

Member wxWizard::SetBitmapPlacement (int placement)

describe this

Chapter 15

Deprecated List

Member wxApp::MacOpenFile (const wxString &fileName)

This function is kept mostly for backwards compatibility. Please override wxApp::MacOpenFiles method instead in any new code.

Member wxArtProvider::Insert (wxArtProvider *provider)

Use PushBack() instead.

Member wxCalendarCtrl::EnableYearChange (bool enable=true)

Member wxComboCtrl::GetTextIndent () const

Use GetMargins() instead.

Member wxComboCtrl::HidePopup (bool generateEvent=false)

Use Dismiss() instead.

Member wxComboCtrl::SetTextIndent (int indent)

Use SetMargins() instead.

Member wxComboCtrl::ShowPopup ()

Use Popup() instead.

Member wxDataViewCustomRenderer::Activate (wxRect cell, wxDataViewModel *model, const wxDataViewItem &item, unsigned int col)

Use ActivateCell instead.

Member wxDataViewCustomRenderer::LeftClick (wxPoint cursor, wxRect cell, wxDataViewModel *model, const wxDataViewItem &item, unsigned int col)

Use ActivateCell instead.

Member wxDebugContext::GetLevel ()

This is obsolete, replaced by wxLog functionality.

Member wxDebugContext::SetLevel (int level)

This is obsolete, replaced by wxLog functionality.

Member wxDos2UnixFilename (wxChar *s)

Construct a wxFileName with wxPATH_DOS and then use wxFileName::GetFullPath(wxPATH_UNIX) instead.

Member wxFileNameFromPath (const wxString &path)

This function is obsolete, please use wxFileName::SplitPath() instead.

Member wxFindWindowByLabel (const wxString &label, wxWindow *parent=NULL)

Replaced by wxWindow::FindWindowByLabel().

Member wxFindWindowByName (const wxString &name, wxWindow *parent=NULL)

Replaced by wxWindow::FindWindowByName().

Member wxGetEmailAddress (char *buf, int sz)

Use wxGetEmailAddress() instead.

Member wxGetHostName (char *buf, int sz)

Use wxGetHostName() instead.

Member wxGetTempFileName (const wxString &prefix, char *buf=NULL)

This function is obsolete, please use wxFileName::CreateTempFileName() instead.

Member wxGetUserId (char *buf, int sz)

Use wxGetUserId() instead.

Member wxGetUserName (char *buf, int sz)

Use wxGetUserName() instead.

Member wxGetWorkingDirectory (char *buf=NULL, int sz=1000)

This function is deprecated, use wxGetCwd() instead.

Member wxGrid::SetCellAlignment (int align, int row, int col)

Please use SetCellAlignment(row, col, horiz, vert) instead.

Member wxGrid::SetCellTextColour (const wxColour &val, int row, int col)

Please use SetCellTextColour(row, col, colour)

Member wxGrid::SetCellTextColour (const wxColour &colour)

Please use SetDefaultCellTextColour(colour) instead.

Member wxGrid::SetCellValue (const wxString &val, int row, int col)

Please use SetCellValue(int,int,const wxString&) or SetCellValue(const wxGridCellCoords&,const wxString&) instead.

Class wxHashTable

Please note that this class is retained for backward compatibility reasons; you should use wxHashMap.

Member wxHelpControllerBase::DisplayBlock (long blockNo)=0

This function is for backward compatibility only, and applications should use DisplaySection() instead.

Member wxHtmlTag::GetBeginPos () const

Member wxHtmlTag::GetEndPos1 () const

Member wxHtmlTag::GetEndPos2 () const

Member wxIconizeEvent::Iconized () const

This function is deprecated in favour of IsIconized().

Member wxList< T >::Nth (int n) const

This function is deprecated, use Item() instead.

Member wxList< T >::Number () const

This function is deprecated, use wxList::GetCount instead. Returns the number of elements in the list.

Member wxLocale::Init (const wxString &name, const wxString &shortName=wxEmptyString, const wxString &locale=wxEmptyString, bool bLoadDefault=true)

This form is deprecated, use the other one unless you know what you are doing.

Member wxLogTrace (wxTraceMask mask, const char *formatString,...)

This version of wxLogTrace() only logs the message if all the bits corresponding to the *mask* are set in the wxLog trace mask which can be set by calling wxLog::SetTraceMask(). This version is less flexible than wxLogTrace(const char*,const char*,...) because it doesn't allow defining the user trace masks easily. This is why it is deprecated in favour of using string trace masks.

Member wxMBConv::MB2WC (wchar_t *out, const char *in, size_t outLen) const

This function is deprecated, please use ToWChar() instead.

Member wxMBConv::WC2MB (char *buf, const wchar_t *psz, size_t n) const

This function is deprecated, please use FromWChar() instead.

Member wxMenu::Append (int id, const wxString &item, wxMenu *subMenu, const wxString &help↩ String=wxEmptyString)

This function is deprecated, use AppendSubMenu() instead.

Member wxMenuBar::GetLabelTop (size_t pos) const

This function is deprecated in favour of GetMenuLabel() and GetMenuLabelText().

Member wxMenuBar::SetLabelTop (size_t pos, const wxString &label)

This function has been deprecated in favour of SetMenuLabel().

Member wxMenuItem::GetLabel () const

This function is deprecated in favour of GetItemLabelText().

Member wxMenuItem::GetLabelFromText (const wxString &text)

This function is deprecated; please use GetLabelText() instead.

Member wxMenuItem::GetName () const

This function is deprecated. Please use GetItemLabel() or GetItemLabelText() instead.

Member wxMenuItem::GetText () const

This function is deprecated in favour of GetItemLabel().

Member wxMenuItem::SetText (const wxString &text)

This function is deprecated in favour of SetItemLabel().

Member wxNewId ()

Ids generated by it can conflict with the Ids defined by the user code, use `wxID_ANY` to assign ids which are guaranteed to not conflict with the user-defined ids for the controls and menu items you create instead of using this function.

Member wxPG_ATTR_INLINE_HELP

Use "Hint" (wxPG_ATTR_HINT) instead.

Member wxPGProperty::wxDEPRECATED (void AddChild(wxPGProperty *prop))

Use AddPrivateChild() instead.

Member wxPGProperty::wxDEPRECATED (wxString GetValueString(int argFlags=0) const)

Use GetValueAsString() instead.

Member wxPostDelete (wxObject *object)

Replaced by wxWindow::Close(). See the window deletion overview.

Member wxPrintDialogData::SetSetupDialog (bool flag)

This function has been deprecated since version 2.5.4.

Member wxShowEvent::GetShow () const

This function is deprecated in favour of IsShown().

Member wxSizer::Remove (wxWindow *window)

The overload of this method taking a wxWindow* parameter is deprecated as it does not destroy the window as would usually be expected from Remove(). You should use Detach() in new code instead. There is currently no wxSizer method that will both detach and destroy a wxWindow item.

Member wxSizer::SetVirtualSizeHints (wxWindow *window)

This is exactly the same as FitInside() in wxWidgets 2.9 and later, please replace calls to it with FitInside().

Member wxSizerItem::SetSizer (wxSizer *sizer)

This function does not free the old sizer which may result in memory leaks, use AssignSizer() which does free it instead.

Member wxSizerItem::SetSpacer (const wxSize &size)

This function does not free the old spacer which may result in memory leaks, use AssignSpacer() which does free it instead.

Member wxSizerItem::SetWindow (wxWindow *window)

Member wxSocketBase::LastCount () const

This function is kept mostly for backwards compatibility. Use LastReadCount() or LastWriteCount() instead. LastCount() is still needed for use with less commonly used functions: Discard(), Peek(), and Unread().

Member wxSplitPath (const wxString &fullname, wxString *path, wxString *name, wxString *ext)

This function is obsolete, please use wxFileName::SplitPath() instead.

Member wxStreamBuffer::Stream ()

use GetStream() instead

Member wxStyledTextEvent::GetDragText ()

Use GetString() instead.

Member wxStyledTextEvent::GetText () const

Use GetString() instead.

Member wxTextInputStream::ReadString ()

Use ReadLine() or ReadWord() instead.

Member wxThreadHelper::Create (unsigned int stackSize=0)

Use CreateThread() instead.

Member wxToolBar::OnRightClick (int toolId, long x, long y)

This is the old way of detecting tool right clicks; although it will still work, you should use the EVT_TOOL_RC↩ LICKED() macro instead.

Member WXTRACE (format,...)

Use one of the wxLogTrace() functions or one of the wxVLogTrace() functions instead.

Member wxTrace (const wxString &format,...)

Use one of the wxLogTrace() functions or one of the wxVLogTrace() functions instead.

Member wxTraceLevel (int level, const wxString &format,...)

Use one of the wxLogTrace() functions or one of the wxVLogTrace() functions instead.

Member WXTRACELEVEL (level, format,...)

Use one of the wxLogTrace() functions or one of the wxVLogTrace() functions instead.

Member wxUnix2DosFilename (wxChar *s)

Construct a wxFileName with wxPATH_UNIX and then use wxFileName::GetFullPath(wxPATH_DOS) instead.

Member wxUsleep (unsigned long milliseconds)

This function is deprecated because its name is misleading: notice that the argument is in milliseconds, not microseconds. Please use either wxMilliSleep() or wxMicroSleep() depending on the resolution you need.

Member wxWindow::SetInitialBestSize (const wxSize &size)

Use SetInitialSize() instead.

Member wxWindow::SetPalette (const wxPalette &pal)

use wxDC::SetPalette instead.

Member wxYield ()

This function is kept only for backwards compatibility. Please use the wxAppConsole::Yield method instead in any new code.

Module Documentation

20.1 Application Initialization and Termination

20.1.1 Detailed Description

The functions in this section are used on application startup/shutdown and also to control the behaviour of the main event loop of the GUI programs.

Related macros/global-functions group: Application and Process Management.

Functions

- wxAppDerivedClass & wxGetApp ()

  This function doesn't exist in wxWidgets but it is created by using the wxIMPLEMENT_APP() macro.
- bool wxHandleFatalExceptions (bool doIt=true)

  If doIt is true, the fatal exceptions (also known as general protection faults under Windows or segmentation violations in the Unix world) will be caught and passed to wxApp::OnFatalException.
- bool wxInitialize ()

  This function is used in wxBase only and only if you don't create wxApp object at all.
- void wxUninitialize ()

  This function is for use in console (wxBase) programs only.
- void wxWakeUpIdle ()

  This function wakes up the (internal and platform dependent) idle system, i.e.
- bool wxYield ()

  Calls wxAppConsole::Yield.
- bool wxSafeYield (wxWindow *win=NULL, bool onlyIfNeeded=false)

  Calls wxApp::SafeYield.
- int wxEntry (int &argc, wxChar **argv)

  This function initializes wxWidgets in a platform-dependent way.
- int wxEntry (HINSTANCE hInstance, HINSTANCE hPrevInstance=NULL, char *pCmdLine=NULL, int nCmdShow=SW_SHOWNORMAL)

  *See wxEntry(int&,wxChar**) for more info about this function.*
- void wxInitAllImageHandlers ()

  Initializes all available image handlers.
- bool wxEntryStart (int &argc, wxChar **argv)

  This function can be used to perform the initialization of wxWidgets if you can't use the default initialization code for any reason.
- bool wxEntryStart (HINSTANCE hInstance, HINSTANCE hPrevInstance=NULL, char *pCmdLine=NULL, int nCmdShow=SW_SHOWNORMAL)

*See wxEntryStart(int&,wxChar**) for more info about this function.*

- void wxEntryCleanup ()

  Free resources allocated by a successful call to wxEntryStart().

- bool wxInitialize (int argc=0, wxChar **argv=NULL)

  Initialize the library (may be called as many times as needed, but each call to wxInitialize() must be matched by wxUninitialize()).

20.1.2 Function Documentation

int wxEntry (int & *argc*, wxChar ** *argv*)

This function initializes wxWidgets in a platform-dependent way.

Use this if you are not using the default wxWidgets entry code (e.g. main or WinMain).

For example, you can initialize wxWidgets from an Microsoft Foundation Classes (MFC) application using this function.

Note

This overload of wxEntry is available under all platforms.

See also

wxEntryStart()

Include file:

```
#include <wx/app.h>
```

int wxEntry (HINSTANCE *hInstance*, HINSTANCE *hPrevInstance* = NULL, char * *pCmdLine* = NULL, int *nCmdShow* = SW_SHOWNORMAL)

See wxEntry(int&,wxChar**) for more info about this function.

Notice that under Windows CE platform, and only there, the type of *pCmdLine* is `wchar_t *`, otherwise it is `char *`, even in Unicode build.

Remarks

To clean up wxWidgets, call wxApp::OnExit followed by the static function wxApp::CleanUp. For example, if exiting from an MFC application that also uses wxWidgets:

```
1 int CTheApp::ExitInstance()
2 {
3     // OnExit isn't called by CleanUp so must be called explicitly.
4     wxTheApp->OnExit();
5     wxApp::CleanUp();
6
7     return CWinApp::ExitInstance();
8 }
```

Include file:

```
#include <wx/app.h>
```

void wxEntryCleanup ( )

Free resources allocated by a successful call to wxEntryStart().

Include file:

```
#include <wx/init.h>
```

bool wxEntryStart (int & *argc*, wxChar ** *argv*)

This function can be used to perform the initialization of wxWidgets if you can't use the default initialization code for any reason.

If the function returns true, the initialization was successful and the global wxApp object wxTheApp has been created. Moreover, wxEntryCleanup() must be called afterwards. If the function returns false, a catastrophic initialization error occurred and (at least the GUI part of) the library can't be used at all.

Notice that parameters `argc` and `argv` may be modified by this function.

Include file:

```
#include <wx/init.h>
```

bool wxEntryStart (HINSTANCE *hInstance*, HINSTANCE *hPrevInstance* = `NULL`, char * *pCmdLine* = `NULL`, int *nCmdShow* = `SW_SHOWNORMAL`)

See wxEntryStart(int&,wxChar**) for more info about this function.

This is an additional overload of wxEntryStart() provided under MSW only. It is meant to be called with the parameters passed to WinMain().

Note

Under Windows CE platform, and only there, the type of *pCmdLine* is `wchar_t *`, otherwise it is `char *`, even in Unicode build.

Availability: only available for the wxMSW port.

Include file:

```
#include <wx/init.h>
```

wxAppDerivedClass& wxGetApp ( )

This function doesn't exist in wxWidgets but it is created by using the wxIMPLEMENT_APP() macro.

Thus, before using it anywhere but in the same module where this macro is used, you must make it available using wxDECLARE_APP().

The advantage of using this function compared to directly using the global wxTheApp pointer is that the latter is of type wxApp* and so wouldn't allow you to access the functions specific to your application class but not present in wxApp while wxGetApp() returns the object of the right type.

Include file:

```
#include <wx/app.h>
```

bool wxHandleFatalExceptions (bool *doIt* = `true`)

If *doIt* is true, the fatal exceptions (also known as general protection faults under Windows or segmentation violations in the Unix world) will be caught and passed to wxApp::OnFatalException.

By default, i.e. before this function is called, they will be handled in the normal way which usually just means that the application will be terminated. Calling wxHandleFatalExceptions() with *doIt* equal to false will restore this default behaviour.

Notice that this function is only available if `wxUSE_ON_FATAL_EXCEPTION` is 1 and under Windows platform this requires a compiler with support for SEH (structured exception handling) which currently means only Microsoft Visual C++ or a recent Borland C++ version.

Include file:

```
#include <wx/app.h>
```

void wxInitAllImageHandlers ( )

Initializes all available image handlers.

This function calls wxImage::AddHandler() for all the available image handlers (see Available image handlers for the full list). Calling it is the simplest way to initialize wxImage but it creates and registers even the handlers your program may not use. If you want to avoid the overhead of doing this you need to call wxImage::AddHandler() manually just for the handlers that you do want to use.

See also

wxImage, wxImageHandler

Include file:

```
#include <wx/image.h>
```

bool wxInitialize (int *argc* = 0, wxChar ** *argv* = NULL)

Initialize the library (may be called as many times as needed, but each call to wxInitialize() must be matched by wxUninitialize()).

With this function you may avoid wxDECLARE_APP() and wxIMPLEMENT_APP() macros and use wxInitialize() and wxUninitialize() dynamically in the program startup and termination.

Include file:

```
#include <wx/init.h>
```

bool wxInitialize ( )

This function is used in wxBase only and only if you don't create wxApp object at all.

In this case you must call it from your `main()` function before calling any other wxWidgets functions.

If the function returns false the initialization could not be performed, in this case the library cannot be used and wxUninitialize() shouldn't be called neither.

This function may be called several times but wxUninitialize() must be called for each successful call to this function.

Include file:

```
#include <wx/app.h>
```

bool wxSafeYield (wxWindow * *win* = NULL, bool *onlyIfNeeded* = false)

Calls wxApp::SafeYield.

Include file:

```
#include <wx/app.h>
```

void wxUninitialize ( )

This function is for use in console (wxBase) programs only.

Clean up; the library can't be used any more after the last call to wxUninitialize().

It must be called once for each previous successful call to wxInitialize().

Include file:

```
#include <wx/app.h>
```

See wxInitialize() for more info.

Include file:

```
#include <wx/init.h>
```

void wxWakeUpIdle ( )

This function wakes up the (internal and platform dependent) idle system, i.e.

it will force the system to send an idle event even if the system currently *is* idle and thus would not send any idle event until after some other event would get sent. This is also useful for sending events between two threads and is used by the corresponding functions wxPostEvent() and wxEvtHandler::AddPendingEvent().

Include file:

```
#include <wx/app.h>
```

bool wxYield ( )

Calls wxAppConsole::Yield.

Deprecated This function is kept only for backwards compatibility. Please use the wxAppConsole::Yield method instead in any new code.

Include file:

```
#include <wx/app.h>
```

20.2 Application and Process Management

20.2.1 Detailed Description

The classes in this section represent the application (see wxApp) or parts of it (e.g. wxEventLoopBase, wxModule). They can be used for initialization/shutdown of the application itself.

Related macros/global-functions group: Application Initialization and Termination.

Classes

- class wxAppConsole

  This class is essential for writing console-only or hybrid apps without having to define `wxUSE_GUI=0`.
- class wxApp

  The wxApp class represents the application itself when `wxUSE_GUI=1`.
- class wxCmdLineParser

  wxCmdLineParser is a class for parsing the command line.
- class wxDynamicLibraryDetails

  This class is used for the objects returned by the wxDynamicLibrary::ListLoaded() method and contains the information about a single module loaded into the address space of the current process.
- class wxDynamicLibrary

  wxDynamicLibrary is a class representing dynamically loadable library (Windows DLL, shared library under Unix etc).
- class wxEventLoopBase

  Base class for all event loop implementations.
- class wxEventLoopActivator

  Makes an event loop temporarily active.
- class wxGUIEventLoop

  A generic implementation of the GUI event loop.
- class wxInitializer

  Create an object of this class on the stack to initialize/cleanup the library automatically.
- class wxModule

  The module system is a very simple mechanism to allow applications (and parts of wxWidgets itself) to define initialization and cleanup functions that are automatically called on wxWidgets startup and exit.
- class wxProcess

  The objects of this class are used in conjunction with the wxExecute() function.
- class wxSingleInstanceChecker

  wxSingleInstanceChecker class allows to check that only a single instance of a program is running.

20.3 Application and System configuration

20.3.1 Detailed Description

The classes in this section are used to handle application-wide settings and system-wide settings.

Classes

- class wxAppTraits

  The wxAppTraits class defines various configurable aspects of a wxApp.
- class wxConfigBase

  wxConfigBase defines the basic interface of all config classes.
- class wxConfigPathChanger

  A handy little class which changes the current path in a wxConfig object and restores it in dtor.
- class wxDisplay

  Determines the sizes and locations of displays connected to the system.
- class wxFileConfig

  wxFileConfig implements wxConfigBase interface for storing and retrieving configuration information using plain text files.
- class wxFontMapper

  wxFontMapper manages user-definable correspondence between logical font names and the fonts present on the machine.
- class wxLocale

  wxLocale class encapsulates all language-dependent settings and is a generalization of the C locale concept.
- class wxMimeTypesManager

  This class allows the application to retrieve information about all known MIME types from a system-specific location and the filename extensions to the MIME types and vice versa.
- class wxRegConfig

  wxRegConfig implements the wxConfigBase interface for storing and retrieving configuration information using Windows registry.
- class wxRegKey

  wxRegKey is a class representing the Windows registry (it is only available under Windows).
- class wxPlatformInfo

  This class holds information about the operating system, the toolkit and the basic architecture of the machine where the application is currently running.
- class wxSystemSettings

  wxSystemSettings allows the application to ask for details about the system.
- class wxSystemOptions

  wxSystemOptions stores option/value pairs that wxWidgets itself or applications can use to alter behaviour at runtime.
- struct wxVideoMode

  Determines the sizes and locations of displays connected to the system.
- class wxIdManager

  wxIdManager is responsible for allocating and releasing window IDs.
- class wxXLocale

  This class represents a locale object used by so-called xlocale API.

20.4 Archive support

20.4.1 Detailed Description

Classes for managing (eventually compressed) archives.

Classes

- class wxArchiveInputStream

  This is an abstract base class which serves as a common interface to archive input streams such as wxZipInputStream.
- class wxArchiveOutputStream

  This is an abstract base class which serves as a common interface to archive output streams such as wxZipOutputStream.
- class wxArchiveEntry

  This is an abstract base class which serves as a common interface to archive entry classes such as wxZipEntry.
- class wxArchiveClassFactory

  Allows the creation of streams to handle archive formats such as zip and tar.
- class wxArchiveNotifier

  If you need to know when a wxArchiveInputStream updates a wxArchiveEntry object, you can create a notifier by deriving from this abstract base class, overriding wxArchiveNotifier::OnEntryUpdated.
- class wxArchiveIterator

  An input iterator template class that can be used to transfer an archive's catalogue to a container.
- class wxTarInputStream

  Input stream for reading tar files.
- class wxTarClassFactory

  Class factory for the tar archive format.
- class wxTarEntry

  Holds the meta-data for an entry in a tar.
- class wxZipNotifier

  If you need to know when a wxZipInputStream updates a wxZipEntry, you can create a notifier by deriving from this abstract base class, overriding wxZipNotifier::OnEntryUpdated().
- class wxZipEntry

  Holds the meta-data for an entry in a zip.
- class wxZipInputStream

  Input stream for reading zip files.
- class wxZipClassFactory

  Class factory for the zip archive format.
- class wxZipOutputStream

  Output stream for writing zip files.
- class wxZlibOutputStream

  This stream compresses all data written to it.
- class wxZlibInputStream

  This filter stream decompresses a stream that is in zlib or gzip format.

20.5 Atomic Operations

20.5.1 Detailed Description

When using multi-threaded applications, it is often required to access or modify memory which is shared between threads.

Atomic integer and pointer operations are an efficient way to handle this issue (another, less efficient, way is to use a wxMutex or wxCriticalSection). A native implementation exists for Windows, Linux, Solaris and Mac OS X; for others, a wxCriticalSection is used to protect the data.

One particular application is reference counting (used by so-called smart pointers).

You should define your variable with the type wxAtomicInt in order to apply atomic operations to it.

Functions

- void wxAtomicInc (wxAtomicInt &value)

  This function increments value in an atomic manner.
- wxInt32 wxAtomicDec (wxAtomicInt &value)

  This function decrements value in an atomic manner.

20.5.2 Function Documentation

wxInt32 wxAtomicDec (wxAtomicInt & *value*)

This function decrements value in an atomic manner.

Returns 0 if value is 0 after decrement or any non-zero value (not necessarily equal to the value of the variable) otherwise.

See also

wxAtomicInc

Include file:

```
#include <wx/atomic.h>
```

void wxAtomicInc (wxAtomicInt & *value*)

This function increments *value* in an atomic manner.

Whenever possible wxWidgets provides an efficient, CPU-specific, implementation of this function. If such implementation is available, the symbol wxHAS_ATOMIC_OPS is defined. Otherwise this function still exists but is implemented in a generic way using a critical section which can be prohibitively expensive for use in performance-sensitive code.

Include file:

```
#include <wx/atomic.h>
```

20.6 Book Controls

20.6.1 Detailed Description

A book control contains pages of other controls.

Related overview: wxBookCtrl Overview

Classes

- class wxAuiNotebookEvent

  This class is used by the events generated by wxAuiNotebook.
- class wxBookCtrlBase

  A book control is a convenient way of displaying multiple pages of information, displayed one page at a time.
- class wxBookCtrlEvent

  This class represents the events generated by book controls (wxNotebook, wxListbook, wxChoicebook, wxTreebook, wxAuiNotebook).
- class wxChoicebook

  wxChoicebook is a class similar to wxNotebook, but uses a wxChoice control to show the labels instead of the tabs.
- class wxListbook

  wxListbook is a class similar to wxNotebook but which uses a wxListCtrl to show the labels instead of the tabs.
- class wxNotebook

  This class represents a notebook control, which manages multiple windows with associated tabs.
- class wxSimplebook

  wxSimplebook is a control showing exactly one of its several pages.
- class wxToolbook

  wxToolbook is a class similar to wxNotebook but which uses a wxToolBar to show the labels instead of the tabs.
- class wxTreebook

  This class is an extension of the wxNotebook class that allows a tree structured set of pages to be shown in a control.

20.7 Byte Order

20.7.1 Detailed Description

The endian-ness issues (that is the difference between big-endian and little-endian architectures) are important for the portable programs working with the external binary data (for example, data files or data coming from network) which is usually in some fixed, platform-independent format.

The macros are helpful for transforming the data to the correct format.

Macros

- #define wxINT32_SWAP_ALWAYS(wxInt32_value)

  This macro will swap the bytes of the value variable from little endian to big endian or vice versa unconditionally, i.e.
- #define wxUINT32_SWAP_ALWAYS(wxUint32_value)
- #define wxINT16_SWAP_ALWAYS(wxInt16_value)
- #define wxUINT16_SWAP_ALWAYS(wxUint16_value)
- #define wxINT32_SWAP_ON_BE(wxInt32_value)

  This macro will swap the bytes of the value variable from little endian to big endian or vice versa if the program is compiled on a big-endian architecture (such as Sun work stations).
- #define wxUINT32_SWAP_ON_BE(wxUint32_value)
- #define wxINT16_SWAP_ON_BE(wxInt16_value)
- #define wxUINT16_SWAP_ON_BE(wxUint16_value)
- #define wxINT32_SWAP_ON_LE(wxInt32_value)

  This macro will swap the bytes of the value variable from little endian to big endian or vice versa if the program is compiled on a little-endian architecture (such as Intel PCs).
- #define wxUINT32_SWAP_ON_LE(wxUint32_value)
- #define wxINT16_SWAP_ON_LE(wxInt16_value)
- #define wxUINT16_SWAP_ON_LE(wxUint16_value)
- #define wxFORCE_LINK_THIS_MODULE(moduleName)

  This macro can be used in conjunction with the wxFORCE_LINK_MODULE() macro to force the linker to include in its output a specific object file.
- #define wxFORCE_LINK_MODULE(moduleName)

  This macro can be used in conjunction with the wxFORCE_LINK_THIS_MODULE() macro to force the linker to include in its output a specific object file.

20.7.2 Macro Definition Documentation

#define wxFORCE_LINK_MODULE(*moduleName*)

This macro can be used in conjunction with the wxFORCE_LINK_THIS_MODULE() macro to force the linker to include in its output a specific object file.

In particular, you should use this macro in a source file which you know for sure is linked in the output (e.g. the source file containing the `main()` of your app). The `moduleName` is the name of the module you want to forcefully link (i.e. the name you used in the relative wxFORCE_LINK_THIS_MODULE() macro.

Include file:

```
#include <wx/link.h>
```

#define wxFORCE_LINK_THIS_MODULE(*moduleName*)

This macro can be used in conjunction with the wxFORCE_LINK_MODULE() macro to force the linker to include in its output a specific object file.

In particular, you should use this macro in the source file which you want to force for inclusion. The `moduleName` needs to be a name not already in use in other wxFORCE_LINK_THIS_MODULE() macros, but is not required to be e.g. the same name of the source file (even if it's a good choice).

Include file:

```
#include <wx/link.h>
```

#define wxINT16_SWAP_ALWAYS(*wxInt16_value*)

#define wxINT16_SWAP_ON_BE(*wxInt16_value*)

#define wxINT16_SWAP_ON_LE(*wxInt16_value*)

#define wxINT32_SWAP_ALWAYS(*wxInt32_value*)

This macro will swap the bytes of the *value* variable from little endian to big endian or vice versa unconditionally, i.e.

independently of the current platform.

Include file:

```
#include <wx/defs.h>
```

#define wxINT32_SWAP_ON_BE(*wxInt32_value*)

This macro will swap the bytes of the *value* variable from little endian to big endian or vice versa if the program is compiled on a big-endian architecture (such as Sun work stations).

If the program has been compiled on a little-endian architecture, the value will be unchanged.

Use these macros to read data from and write data to a file that stores data in little-endian (for example Intel i386) format.

Include file:

```
#include <wx/defs.h>
```

#define wxINT32_SWAP_ON_LE(*wxInt32_value*)

This macro will swap the bytes of the *value* variable from little endian to big endian or vice versa if the program is compiled on a little-endian architecture (such as Intel PCs).

If the program has been compiled on a big-endian architecture, the value will be unchanged.

Use these macros to read data from and write data to a file that stores data in big-endian format.

Include file:

```
#include <wx/defs.h>
```

#define wxUINT16_SWAP_ALWAYS(*wxUint16_value*)

#define wxUINT16_SWAP_ON_BE(*wxUint16_value*)

#define wxUINT16_SWAP_ON_LE(*wxUint16_value* **)**

#define wxUINT32_SWAP_ALWAYS(*wxUint32_value* **)**

#define wxUINT32_SWAP_ON_BE(*wxUint32_value* **)**

#define wxUINT32_SWAP_ON_LE(*wxUint32_value* **)**

20.8 Class List by Category

20.8.1 Detailed Description

This group contains all full class list groups.

The Overview of Available Classes provides a quick summary of these groups on one page.

Modules

- Application and Process Management

  The classes in this section represent the application (see wxApp) or parts of it (e.g.
- Application and System configuration

  The classes in this section are used to handle application-wide settings and system-wide settings.
- Archive support

  Classes for managing (eventually compressed) archives.
- Book Controls

  A book control contains pages of other controls.
- Clipboard and Drag & Drop

  Related Overviews: Drag and Drop Overview.
- Common Dialogs

  Common dialogs are ready-made dialog classes which are frequently used in an application.
- Containers

  These are classes, templates and class macros are used by wxWidgets.
- Controls

  Typically, these are small windows which provide interaction with the user.
- Data Structures

  These are the data structure classes provided by wxWidgets.
- Debugging

  wxWidgets supports some aspects of debugging an application through classes, functions and macros.
- Device Contexts

  Device contexts are surfaces that may be drawn on, and provide an abstraction that allows parameterisation of your drawing code by passing different device contexts.
- Document/View Framework

  wxWidgets supports a document/view framework which provides housekeeping for a document-centric application.
- Events

  An event object contains information about a specific event.
- File Handling

  wxWidgets has several small classes to work with disk files and directories.
- Graphics Device Interface (GDI)

  The following are classes related to GDI (Graphics Device Interface) access.
- Grid Related Classes

  Classes related to the wxGrid generic widget.
- HTML

  wxWidgets provides a set of classes to display text in HTML format.
- Help

  Classes for loading and displaying help manuals or help informations in general.
- Interprocess Communication

  wxWidgets provides simple interprocess communications facilities based on Windows DDE, but they are available on most platforms using TCP.
- Logging

wxWidgets provides several classes and functions for message logging.

- Managed Windows

  There are several types of window that are directly controlled by the window manager (such as MS Windows, or the Motif Window Manager).

- Menus

  Group of classes for handling menu bars and items.

- Miscellaneous

  Group of miscellaneous classes.

- Miscellaneous Windows

  The following are a variety of classes that are derived from wxWindow.

- Multimedia

  Classes for showing multimedia contents.

- Networking

  wxWidgets provides its own classes for socket based networking.

- OpenGL

  Classes interfacing wxWidgets with OpenGL (http://opengl.org/).

- Picker Controls

  A picker control is a control whose appearance and behaviour is highly platform-dependent.

- Printing Framework

  A printing and previewing framework is implemented to make it relatively straightforward to provide document printing facilities.

- Ribbon User Interface

  The wxRibbon library is a set of classes for writing a ribbon user interface.

- Rich Text

  wxWidgets provides a set of generic classes to edit and print simple rich text with character and paragraph formatting.

- Runtime Type Information (RTTI)

  wxWidgets supports runtime manipulation of class information, and dynamic creation of objects given class names.

- Scintilla Text Editor

  wxWidgets also provides a wrapper around the Scintilla text editor control, which is a control for plain-text editing with support for highlighting, smart indentation, etc.

- Smart Pointers

  wxWidgets provides a few smart pointer class templates.

- Streams

  wxWidgets has its own set of stream classes, as an alternative to often buggy standard stream libraries, and to provide enhanced functionality.

- Text Conversion

  These are the classes used for conversions between different text encodings.

- Threading

  wxWidgets provides a set of classes to make use of the native thread capabilities of the various platforms.

- Validators

  These are the window validators, used for filtering and validating user input.

- Virtual File System

  wxWidgets provides a set of classes that implement an extensible virtual file system, used internally by the HTML classes.

- WebView

  The wxWebView library is a set of classes for viewing complex web documents and for internet browsing.

- Window Docking (wxAUI)

  wxAUI is a set classes for writing a customizable application interface with built-in docking, floatable panes and a flexible MDI-like interface.

- Window Layout

  wxWidgets makes window layout and sizing easy and painless using a set of classes known as "sizers".

- XML

Group of classes loading and saving XML documents (http://www.w3.org/XML/).

- XML Based Resource System (XRC)

  Resources allow your application to create controls and other user interface elements from specifications stored in an XML format.

- wxDataViewCtrl Related Classes

  These are all classes used or provided for use with wxDataViewCtrl.

- wxPropertyGrid

  wxPropertyGrid is a specialized grid for editing properties (that is, name=value pairs).

20.9 Clipboard and Drag & Drop

20.9.1 Detailed Description

Related Overviews: Drag and Drop Overview.

Classes

- class wxClipboard

  A class for manipulating the clipboard.
- class wxDataFormat

  A wxDataFormat is an encapsulation of a platform-specific format handle which is used by the system for the clipboard and drag and drop operations.
- class wxDataObject

  A wxDataObject represents data that can be copied to or from the clipboard, or dragged and dropped.
- class wxCustomDataObject

  wxCustomDataObject is a specialization of wxDataObjectSimple for some application-specific data in arbitrary (either custom or one of the standard ones).
- class wxDataObjectComposite

  wxDataObjectComposite is the simplest wxDataObject derivation which may be used to support multiple formats.
- class wxDataObjectSimple

  This is the simplest possible implementation of the wxDataObject class.
- class wxBitmapDataObject

  wxBitmapDataObject is a specialization of wxDataObject for bitmap data.
- class wxURLDataObject

  wxURLDataObject is a wxDataObject containing an URL and can be used e.g.
- class wxTextDataObject

  wxTextDataObject is a specialization of wxDataObjectSimple for text data.
- class wxFileDataObject

  wxFileDataObject is a specialization of wxDataObject for file names.
- class wxHTMLDataObject

  wxHTMLDataObject is used for working with HTML-formatted text.
- class wxDropTarget

  This class represents a target for a drag and drop operation.
- class wxDropSource

  This class represents a source for a drag and drop operation.
- class wxTextDropTarget

  A predefined drop target for dealing with text data.
- class wxFileDropTarget

  This is a drop target which accepts files (dragged from File Manager or Explorer).
- class wxDragImage

  This class is used when you wish to drag an object on the screen, and a simple cursor is not enough.

20.10 Common Dialogs

20.10.1 Detailed Description

Common dialogs are ready-made dialog classes which are frequently used in an application.

Related Overviews: Common Dialogs

Classes

- class wxAboutDialogInfo

  wxAboutDialogInfo contains information shown in the standard About dialog displayed by the wxAboutBox() function.
- class wxBusyInfo

  This class makes it easy to tell your user that the program is temporarily busy.
- class wxMultiChoiceDialog

  This class represents a dialog that shows a list of strings, and allows the user to select one or more.
- class wxSingleChoiceDialog

  This class represents a dialog that shows a list of strings, and allows the user to select one.
- class wxPrintDialogData

  This class holds information related to the visual characteristics of wxPrintDialog.
- class wxColourDialog

  This class represents the colour chooser dialog.
- class wxColourData

  This class holds a variety of information related to colour dialogs.
- class wxDialog

  A dialog box is a window with a title bar and sometimes a system menu, which can be moved around the screen.
- class wxDirDialog

  This class represents the directory chooser dialog.
- class wxFindReplaceData

  wxFindReplaceData holds the data for wxFindReplaceDialog.
- class wxFindReplaceDialog

  wxFindReplaceDialog is a standard modeless dialog which is used to allow the user to search for some text (and possibly replace it with something else).
- class wxFileDialog

  This class represents the file chooser dialog.
- class wxFontData

  This class holds a variety of information related to font dialogs.
- class wxFontDialog

  This class represents the font chooser dialog.
- class wxGenericAboutDialog

  This class defines a customizable About dialog.
- class wxMessageDialog

  This class represents a dialog that shows a single or multi-line message, with a choice of OK, Yes, No and Cancel buttons.
- class wxGenericProgressDialog

  This class represents a dialog that shows a short message and a progress bar.
- class wxRearrangeDialog

  A dialog allowing the user to rearrange the specified items.
- class wxRichMessageDialog

  Extension of wxMessageDialog with additional functionality.
- class wxSymbolPickerDialog

wxSymbolPickerDialog presents the user with a choice of fonts and a grid of available characters.

- class wxPasswordEntryDialog

  This class represents a dialog that requests a one-line password string from the user.

- class wxTextEntryDialog

  This class represents a dialog that requests a one-line text string from the user.

- class wxWizard

  wxWizard is the central class for implementing 'wizard-like' dialogs.

20.11 Containers

20.11.1 Detailed Description

These are classes, templates and class macros are used by wxWidgets.

Most of these classes provide a subset or almost complete STL API.

Related Overviews: Container Classes

Classes

- class wxArray< T >

  This section describes the so called "dynamic arrays".
- class wxList< T >

  The wxList<T> class provides linked list functionality.
- class wxStack< T >

  wxStack<T> is similar to `std::stack` and can be used exactly like it.
- class wxVector< T >

  wxVector<T> is a template class which implements most of the `std::vector` class and can be used like it.
- class wxArrayString

  wxArrayString is an efficient container for storing wxString objects.
- class wxSortedArrayString

  wxSortedArrayString is an efficient container for storing wxString objects which always keeps the string in alphabetical order.
- class wxClientDataContainer

  This class is a mixin that provides storage and management of "client data".
- class wxClientData

  All classes deriving from wxEvtHandler (such as all controls and wxApp) can hold arbitrary data which is here referred to as "client data".
- class wxStringClientData

  Predefined client data class for holding a string.
- class wxHashTable
- class wxHashMap

  This is a simple, type-safe, and reasonably efficient hash map class, whose interface is a subset of the interface of STL containers.
- class wxHashSet

  This is a simple, type-safe, and reasonably efficient hash set class, whose interface is a subset of the interface of STL containers.
- class wxTreeItemData

  wxTreeItemData is some (arbitrary) user class associated with some item.

20.12 Controls

20.12.1 Detailed Description

Typically, these are small windows which provide interaction with the user.

Controls that are not static can have wxValidator associated with them.

Classes

- class wxAnimationCtrl

  This is a static control which displays an animation.
- class wxBitmapButton

  A bitmap button is a control that contains a bitmap.
- class wxBitmapComboBox

  A combobox that displays bitmap in front of the list items.
- class wxButton

  A button is a control that contains a text string, and is one of the most common elements of a GUI.
- class wxCalendarCtrl

  The calendar control allows the user to pick a date.
- class wxCheckBox

  A checkbox is a labelled box which by default is either on (checkmark is visible) or off (no checkmark).
- class wxCheckListBox

  A wxCheckListBox is like a wxListBox, but allows items to be checked or unchecked.
- class wxChoice

  A choice item is used to select one of a list of strings.
- class wxCollapsiblePane

  A collapsible pane is a container with an embedded button-like control which can be used by the user to collapse or expand the pane's contents.
- class wxComboPopup

  In order to use a custom popup with wxComboCtrl, an interface class must be derived from wxComboPopup.
- class wxComboCtrl

  A combo control is a generic combobox that allows totally custom popup.
- class wxComboBox

  A combobox is like a combination of an edit control and a listbox.
- class wxCommandLinkButton

  Objects of this class are similar in appearance to the normal wxButtons but are similar to the links in a web page in functionality.
- class wxControl

  This is the base class for a control or "widget".
- class wxItemContainerImmutable

  wxItemContainer defines an interface which is implemented by all controls which have string subitems each of which may be selected.
- class wxItemContainer

  This class is an abstract base class for some wxWidgets controls which contain several items such as wxListBox, wxCheckListBox, wxComboBox or wxChoice.
- class wxControlWithItems

  This is convenience class that derives from both wxControl and wxItemContainer.
- class wxDataViewCtrl

  wxDataViewCtrl is a control to display data either in a tree like fashion or in a tabular form or both.
- class wxDataViewListCtrl

This class is a wxDataViewCtrl which internally uses a wxDataViewListStore and forwards most of its API to that class.

- class wxDataViewTreeCtrl

  This class is a wxDataViewCtrl which internally uses a wxDataViewTreeStore and forwards most of its API to that class.
- class wxGenericDirCtrl

  This control can be used to place a directory listing (with optional files) on an arbitrary window.
- class wxEditableListBox

  An editable listbox is composite control that lets the user easily enter, delete and reorder a list of strings.
- class wxFileCtrl

  This control allows the user to select a file.
- class wxGauge

  A gauge is a horizontal or vertical bar which shows a quantity (often time).
- class wxHeaderColumn

  Represents a column header in controls displaying tabular data such as wxDataViewCtrl or wxGrid.
- class wxSettableHeaderColumn

  Adds methods to set the column attributes to wxHeaderColumn.
- class wxHeaderColumnSimple

  Simple container for the information about the column.
- class wxHeaderCtrl

  wxHeaderCtrl is the control containing the column headings which is usually used for display of tabular data.
- class wxHeaderCtrlSimple

  wxHeaderCtrlSimple is a concrete header control which can be used directly, without inheriting from it as you need to do when using wxHeaderCtrl itself.
- class wxHtmlListBox

  wxHtmlListBox is an implementation of wxVListBox which shows HTML content in the listbox rows.
- class wxSimpleHtmlListBox

  wxSimpleHtmlListBox is an implementation of wxHtmlListBox which shows HTML content in the listbox rows.
- class wxHyperlinkCtrl

  This class shows a static text element which links to an URL.
- class wxListBox

  A listbox is used to select one or more of a list of strings.
- class wxListCtrl

  A list control presents lists in a number of formats: list view, report view, icon view and small icon view.
- class wxListView

  This class currently simply presents a simpler to use interface for the wxListCtrl – it can be thought of as a façade for that complicated class.
- class wxActiveXContainer

  wxActiveXContainer is a host for an ActiveX control on Windows (and as such is a platform-specific class).
- class wxOwnerDrawnComboBox

  wxOwnerDrawnComboBox is a combobox with owner-drawn list items.
- class wxRadioBox

  A radio box item is used to select one of number of mutually exclusive choices.
- class wxRadioButton

  A radio button item is a button which usually denotes one of several mutually exclusive options.
- class wxRearrangeList

  A listbox-like control allowing the user to rearrange the items and to enable or disable them.
- class wxRearrangeCtrl

  A composite control containing a wxRearrangeList and the buttons allowing to move the items in it.
- class wxScrollBar

  A wxScrollBar is a control that represents a horizontal or vertical scrollbar.

- class wxSlider

  A slider is a control with a handle which can be pulled back and forth to change the value.
- class wxSpinButton

  A wxSpinButton has two small up and down (or left and right) arrow buttons.
- class wxSpinCtrl

  wxSpinCtrl combines wxTextCtrl and wxSpinButton in one control.
- class wxSpinCtrlDouble

  wxSpinCtrlDouble combines wxTextCtrl and wxSpinButton in one control and displays a real number.
- class wxSearchCtrl

  A search control is a composite control with a search button, a text control, and a cancel button.
- class wxStaticBitmap

  A static bitmap control displays a bitmap.
- class wxStaticBox

  A static box is a rectangle drawn around other windows to denote a logical grouping of items.
- class wxStaticLine

  A static line is just a line which may be used in a dialog to separate the groups of controls.
- class wxStaticText

  A static text control displays one or more lines of read-only text.
- class wxTextCtrl

  A text control allows text to be displayed and edited.
- class wxTextEntry

  Common base class for single line text entry fields.
- class wxToggleButton

  wxToggleButton is a button that stays pressed when clicked by the user.
- class wxBitmapToggleButton

  wxBitmapToggleButton is a wxToggleButton that contains a bitmap instead of text.
- class wxTreeCtrl

  A tree control presents information as a hierarchy, with items that may be expanded to show further items.
- class wxTreeListItem

  Unique identifier of an item in wxTreeListCtrl.
- class wxTreeListItemComparator

  Class defining sort order for the items in wxTreeListCtrl.
- class wxTreeListCtrl

  A control combining wxTreeCtrl and wxListCtrl features.
- class wxVListBox

  wxVListBox is a wxListBox-like control with the following two main differences from a regular wxListBox: it can have an arbitrarily huge number of items because it doesn't store them itself but uses the OnDrawItem() callback to draw them (so it is a virtual listbox) and its items can have variable height as determined by OnMeasureItem() (so it is also a listbox with the lines of variable height).
- class wxWebView

  This control may be used to render web (HTML / CSS / javascript) documents.

20.13 Data Structures

20.13.1 Detailed Description

These are the data structure classes provided by wxWidgets.

Some of them are used to store generic data (e.g. wxPoint, wxSize, etc), others are mainly helpers of other classes (e.g. wxListItem, wxCalendarDateAttr, wxFindReplaceDialogData, etc).

Classes

- class wxScopedCharTypeBuffer< T >

  wxScopedCharTypeBuffer<T> is a template class for storing characters.
- class wxCharTypeBuffer< T >

  wxCharTypeBuffer<T> is a template class for storing characters.
- class wxCharBuffer

  This is a specialization of wxCharTypeBuffer<T> for `char` type.
- class wxWCharBuffer

  This is a specialization of wxCharTypeBuffer<T> for `wchar_t` type.
- class wxNode< T >

  wxNode<T> is the node structure used in linked lists (see wxList) and derived classes.
- class wxAboutDialogInfo

  wxAboutDialogInfo contains information shown in the standard About dialog displayed by the wxAboutBox() function.
- class wxAcceleratorEntry

  An object used by an application wishing to create an accelerator table (see wxAcceleratorTable).
- class wxAcceleratorTable

  An accelerator table allows the application to specify a table of keyboard shortcuts for menu or button commands.
- class wxAny

  The wxAny class represents a container for any type.
- class wxAnyValueType

  wxAnyValueType is base class for value type functionality for C++ data types used with wxAny.
- class wxMemoryBuffer

  *A **wxMemoryBuffer** is a useful data structure for storing arbitrary sized blocks of memory.*
- class wxCalendarDateAttr

  wxCalendarDateAttr is a custom attributes for a calendar date.
- class wxPageSetupDialogData

  This class holds a variety of information related to wxPageSetupDialog.
- class wxPrintData

  This class holds a variety of information related to printers and printer device contexts.
- class wxPrintDialogData

  This class holds information related to the visual characteristics of wxPrintDialog.
- class wxColourData

  This class holds a variety of information related to colour dialogs.
- class wxConvAuto

  This class implements a Unicode to/from multibyte converter capable of automatically recognizing the encoding of the multibyte text on input.
- class wxDateTime

  wxDateTime class represents an absolute moment in time.
- class wxDateTimeWorkDays
- class wxDateSpan

This class is a "logical time span" and is useful for implementing program logic for such things as "add one month to the date" which, in general, doesn't mean to add 60∗60∗24∗31 seconds to it, but to take the same date the next month (to understand that this is indeed different consider adding one month to Feb, 15 – we want to get Mar, 15, of course).

- class wxTimeSpan

  wxTimeSpan class represents a time interval.
- class wxDateTimeHolidayAuthority
- class wxFindReplaceData

  wxFindReplaceData holds the data for wxFindReplaceDialog.
- class wxFontData

  This class holds a variety of information related to font dialogs.
- class wxRealPoint

  A wxRealPoint is a useful data structure for graphics operations.
- class wxRect

  A class for manipulating rectangles.
- class wxPoint

  A wxPoint is a useful data structure for graphics operations.
- class wxSize

  A wxSize is a useful data structure for graphics operations.
- class wxListItemAttr

  Represents the attributes (color, font, ...) of a wxListCtrl's wxListItem.
- class wxListItem

  This class stores information about a wxListCtrl item or column.
- class wxLongLong

  This class represents a signed 64 bit long number.
- class wxULongLong

  This class represents an unsigned 64 bit long number.
- class wxFileType

  This class holds information about a given file type.
- class wxVariantDataCurrency

  This class represents a thin wrapper for Microsoft Windows CURRENCY type.
- class wxVariantDataErrorCode

  This class represents a thin wrapper for Microsoft Windows SCODE type (which is the same as HRESULT).
- class wxVariantDataSafeArray

  This class represents a thin wrapper for Microsoft Windows SAFEARRAY type.
- class wxAutomationObject

  *The **wxAutomationObject** class represents an OLE automation object containing a single data member, an IDispatch pointer.*
- class wxPosition

  This class represents the position of an item in any kind of grid of rows and columns such as wxGridBagSizer, or wxHVScrolledWindow.
- class wxRegEx

  wxRegEx represents a regular expression.
- class wxRegion

  A wxRegion represents a simple or complex region on a device context or window.
- class wxStatusBarPane

  A status bar pane data container used by wxStatusBar.
- class wxString

  String class for passing textual data to or receiving it from wxWidgets.
- class wxStringBufferLength

  This tiny class allows you to conveniently access the wxString internal buffer as a writable pointer without any risk of forgetting to restore the string to the usable state later, and allows the user to set the internal length of the string.

- class wxStringBuffer

  This tiny class allows you to conveniently access the wxString internal buffer as a writable pointer without any risk of forgetting to restore the string to the usable state later.
- class wxStringTokenizer

  wxStringTokenizer helps you to break a string up into a number of tokens.
- class wxTreeItemId

  An opaque reference to a tree item.
- class wxUniChar

  This class represents a single Unicode character.
- class wxUniCharRef

  Writeable reference to a character in wxString.
- class wxUString

  wxUString is a class representing a Unicode character string where each character is stored using a 32-bit value.
- class wxVariant

  The wxVariant class represents a container for any type.
- class wxVariantData

  The wxVariantData class is used to implement a new type for wxVariant.
- class wxVersionInfo

  wxVersionInfo contains version information.

20.14 Debugging

20.14.1 Detailed Description

wxWidgets supports some aspects of debugging an application through classes, functions and macros.

Related Overviews: Debugging

Related macros/global-functions group: Debugging macros

Classes

- class wxDebugReportPreview

  This class presents the debug report to the user and allows him to veto report entirely or remove some parts of it.
- class wxDebugReportCompress

  wxDebugReportCompress is a wxDebugReport which compresses all the files in this debug report into a single ZIP file in its wxDebugReport::Process() function.
- class wxDebugReport

  wxDebugReport is used to generate a debug report, containing information about the program current state.
- class wxDebugReportPreviewStd

  wxDebugReportPreviewStd is a standard debug report preview window.
- class wxDebugReportUpload

  This class is used to upload a compressed file using HTTP POST request.
- class wxDebugContext

  A class for performing various debugging and memory tracing operations.
- class wxStackWalker

  wxStackWalker allows an application to enumerate, or walk, the stack frames (the function callstack).
- class wxStackFrame

  wxStackFrame represents a single stack frame, or a single function in the call stack, and is used exclusively together with wxStackWalker, see there for a more detailed discussion.

20.15 Debugging macros

20.15.1 Detailed Description

Useful macros and functions for error checking and defensive programming.

Starting with wxWidgets 2.9.1, debugging support in wxWidgets is always compiled in by default, you need to explicitly define wxDEBUG_LEVEL as 0 to disable it completely. However, by default debugging macros are dormant in the release builds, i.e. when the main program is compiled with the standard `NDEBUG` symbol being defined. You may explicitly activate the debugging checks in the release build by calling wxSetAssertHandler() with a custom function if needed.

When debugging support is active, failure of both wxASSERT() and wxCHECK() macros conditions result in a debug alert. When debugging support is inactive or turned off entirely at compilation time, wxASSERT() and wxFAIL() macros don't do anything while wxCHECK() still checks its condition and returns if it fails, even if no alerts are shown to the user.

Finally, the compile time assertions don't happen during the run-time but result in the compilation error messages if the condition they check fail. They are always enabled and are not affected by wxDEBUG_LEVEL.

Related class group: Debugging.

Macros

- #define wxDISABLE_DEBUG_SUPPORT()

  Use this macro to disable all debugging code in release build when not using wxIMPLEMENT_APP().
- #define wxDEBUG_LEVEL

  Preprocessor symbol defining the level of debug support available.
- #define __WXDEBUG__

  Compatibility macro indicating presence of debug support.
- #define wxASSERT(condition)

  Assert macro.
- #define wxASSERT_LEVEL_2(condition)

  Assert macro for expensive run-time checks.
- #define wxASSERT_LEVEL_2_MSG(condition, msg)

  Assert macro with a custom message for expensive run-time checks.
- #define wxASSERT_MIN_BITSIZE(type, size)

  This macro results in a compile time assertion failure if the size of the given `type` is less than `size` bits.
- #define wxASSERT_MSG(condition, message)

  Assert macro with message.
- #define wxASSERT_MSG_AT(condition, message, file, line, func)

  Assert macro pretending to assert at the specified location.
- #define wxCHECK(condition, retValue)

  Checks that the condition is true, returns with the given return value if not (stops execution in debug mode).
- #define wxCHECK_MSG(condition, retValue, message)

  Checks that the condition is true, returns with the given return value if not (stops execution in debug mode).
- #define wxCHECK_RET(condition, message)

  Checks that the condition is true, and returns if not (stops execution with the given error message in debug mode).
- #define wxCHECK2(condition, operation)

  Checks that the condition is true, and if not, it will wxFAIL() and execute the given `operation` if it is not.
- #define wxCHECK2_MSG(condition, operation, message)

  This is the same as wxCHECK2(), but wxFAIL_MSG() with the specified `message` is called instead of wxFAIL() if the `condition` is false.
- #define wxCOMPILE_TIME_ASSERT(condition, message)

  Using wxCOMPILE_TIME_ASSERT() results in a compilation error if the specified `condition` is false.

- #define wxCOMPILE_TIME_ASSERT2(condition, message, name)

  This macro is identical to wxCOMPILE_TIME_ASSERT() except that it allows you to specify a unique `name` *for the struct internally defined by this macro to avoid getting the compilation errors described for wxCOMPILE_TIME_ASSERT().*
- #define wxDISABLE_ASSERTS_IN_RELEASE_BUILD() wxDisableAsserts()

  Use this macro to disable asserts in release build when not using wxIMPLEMENT_APP().
- #define wxFAIL

  Will always generate an assert error if this code is reached (in debug mode).
- #define wxFAIL_MSG(message)

  Will always generate an assert error with specified message if this code is reached (in debug mode).
- #define wxFAIL_MSG_AT(message, file, line, func)

  Assert failure macro pretending to assert at the specified location.
- #define wxDISABLE_DEBUG_LOGGING_IN_RELEASE_BUILD()

  Use this macro to disable logging at debug and trace levels in release build when not using wxIMPLEMENT_APP().
- #define WXDEBUG_NEW(arg)

  This is defined in debug mode to be call the redefined new operator with filename and line number arguments.

Typedefs

- typedef void(∗ wxAssertHandler_t)(const wxString &file, int line, const wxString &func, const wxString &cond, const wxString &msg)

  Type for the function called in case of assert failure.

Functions

- void wxAbort ()

  Exits the program immediately.
- void wxDisableAsserts ()

  Disable the condition checks in the assertions.
- bool wxIsDebuggerRunning ()

  Returns true if the program is running under debugger, false otherwise.
- wxAssertHandler_t wxSetAssertHandler (wxAssertHandler_t handler)

  Sets the function to be called in case of assertion failure.
- void wxSetDefaultAssertHandler ()

  Reset the assert handler to default function which shows a message box when an assert happens.
- void wxTrap ()

  Generate a debugger exception meaning that the control is passed to the debugger if one is attached to the process.

20.15.2 Macro Definition Documentation

#define __WXDEBUG__

Compatibility macro indicating presence of debug support.

This symbol is defined if wxDEBUG_LEVEL is greater than 0 and undefined otherwise.

Include file:

```
#include <wx/debug.h>
```

#define wxASSERT(*condition*)

Assert macro.

An error message will be generated if the condition is false in debug mode, but nothing will be done in the release build.

Please note that the condition in wxASSERT() should have no side effects because it will not be executed in release mode at all.

This macro should be used to catch (in debug builds) logical errors done by the programmer.

See also

wxASSERT_MSG(), wxCOMPILE_TIME_ASSERT()

Include file:

```
#include <wx/debug.h>
```

#define wxASSERT_LEVEL_2(*condition*)

Assert macro for expensive run-time checks.

This macro does nothing unless wxDEBUG_LEVEL is 2 or more and is meant to be used for the assertions with noticeable performance impact and which, hence, should be disabled during run-time.

If wxDEBUG_LEVEL is 2 or more, it becomes the same as wxASSERT().

Include file:

```
#include <wx/debug.h>
```

#define wxASSERT_LEVEL_2_MSG(*condition, msg*)

Assert macro with a custom message for expensive run-time checks.

If wxDEBUG_LEVEL is 2 or more, this is the same as wxASSERT_MSG(), otherwise it doesn't do anything at all.

See also

wxASSERT_LEVEL_2()

Include file:

```
#include <wx/debug.h>
```

#define wxASSERT_MIN_BITSIZE(*type, size*)

This macro results in a compile time assertion failure if the size of the given `type` is less than `size` bits.

This macro should be used to catch (in debug builds) logical errors done by the programmer.

You may use it like this, for example:

```
1 // we rely on the int being able to hold values up to 2^32
2 wxASSERT_MIN_BITSIZE(int, 32);
3
4 // can't work with the platforms using UTF-8 for wchar_t
5 wxASSERT_MIN_BITSIZE(wchar_t, 16);
```

Include file:

```
#include <wx/debug.h>
```

#define wxASSERT_MSG(*condition, message*)

Assert macro with message.

An error message will be generated if the condition is false.

This macro should be used to catch (in debug builds) logical errors done by the programmer.

See also

wxASSERT(), wxCOMPILE_TIME_ASSERT()

Include file:

```
#include <wx/debug.h>
```

#define wxASSERT_MSG_AT(*condition, message, file, line, func*)

Assert macro pretending to assert at the specified location.

This macro is the same as wxASSERT_MSG(), but the assert message will use the specified source file, line number and function name instead of the values corresponding to the current location as done by wxASSERT_MSG() by default.

It is mostly useful for asserting inside functions called from macros, as by passing the usual **__FILE__**, **__LINE__** and **__FUNCTION__** values to a function, it's possible to pretend that the assert happens at the location of the macro in the source code (which can be useful) instead of inside the function itself (which is never useful as these values are always the same for the given assertion).

Since

3.1.0

Include file:

```
#include <wx/debug.h>
```

#define wxCHECK(*condition, retValue*)

Checks that the condition is true, returns with the given return value if not (stops execution in debug mode).

This check is done even in release mode.

This macro should be used to catch (both in debug and release builds) logical errors done by the programmer.

Include file:

```
#include <wx/debug.h>
```

#define wxCHECK2(*condition, operation*)

Checks that the condition is true, and if not, it will wxFAIL() and execute the given `operation` if it is not.

This is a generalisation of wxCHECK() and may be used when something else than just returning from the function must be done when the `condition` is false. This check is done even in release mode.

This macro should be used to catch (both in debug and release builds) logical errors done by the programmer.

Include file:

```
#include <wx/debug.h>
```

#define wxCHECK2_MSG(*condition, operation, message*)

This is the same as wxCHECK2(), but wxFAIL_MSG() with the specified `message` is called instead of wxFAIL() if the `condition` is false.

This macro should be used to catch (both in debug and release builds) logical errors done by the programmer.

Include file:

```
#include <wx/debug.h>
```

#define wxCHECK_MSG(*condition, retValue, message*)

Checks that the condition is true, returns with the given return value if not (stops execution in debug mode).

This check is done even in release mode.

This macro may be only used in non-void functions, see also wxCHECK_RET().

This macro should be used to catch (both in debug and release builds) logical errors done by the programmer.

Include file:

```
#include <wx/debug.h>
```

#define wxCHECK_RET(*condition, message*)

Checks that the condition is true, and returns if not (stops execution with the given error message in debug mode).

This check is done even in release mode.

This macro should be used in void functions instead of wxCHECK_MSG().

This macro should be used to catch (both in debug and release builds) logical errors done by the programmer.

Include file:

```
#include <wx/debug.h>
```

#define wxCOMPILE_TIME_ASSERT(*condition, message*)

Using wxCOMPILE_TIME_ASSERT() results in a compilation error if the specified `condition` is false.

The compiler error message should include the `message` identifier - please note that it must be a valid C++ identifier and not a string unlike in the other cases.

This macro is mostly useful for testing the expressions involving the `sizeof` operator as they can't be tested by the preprocessor but it is sometimes desirable to test them at the compile time.

Note that this macro internally declares a struct whose name it tries to make unique by using the **`LINE`** in it but it may still not work if you use it on the same line in two different source files. In this case you may either change the line in which either of them appears on or use the wxCOMPILE_TIME_ASSERT2() macro.

Also note that Microsoft Visual C++ has a bug which results in compiler errors if you use this macro with 'Program Database For Edit And Continue' (`/ZI`) option, so you shouldn't use it ('Program Database' (`/Zi`) is ok though) for the code making use of this macro.

This macro should be used to catch misconfigurations at compile-time.

See also

wxASSERT_MSG(), wxASSERT_MIN_BITSIZE()

Include file:

```
#include <wx/debug.h>
```

#define wxCOMPILE_TIME_ASSERT2(*condition, message, name*)

This macro is identical to wxCOMPILE_TIME_ASSERT() except that it allows you to specify a unique `name` for the struct internally defined by this macro to avoid getting the compilation errors described for wxCOMPILE_TIME_ASSERT().

This macro should be used to catch misconfigurations at compile-time.

Include file:

```
#include <wx/debug.h>
```

#define wxDEBUG_LEVEL

Preprocessor symbol defining the level of debug support available.

This symbol is defined to 1 by default meaning that asserts are compiled in (although they may be disabled by a call to wxDisableAsserts()). You may predefine it as 0 prior to including any wxWidgets headers to omit the calls to wxASSERT() and related macros entirely in your own code and you may also predefine it as 0 when building wxWidgets to also avoid including any asserts in wxWidgets itself.

Alternatively, you may predefine it as 2 to include wxASSERT_LEVEL_2() and similar macros which are used for asserts which have non-trivial run-time costs and so are disabled by default.

Since

2.9.1

Include file:

```
#include <wx/debug.h>
```

#define WXDEBUG_NEW(*arg*)

This is defined in debug mode to be call the redefined new operator with filename and line number arguments.

The definition is:

```
1 #define WXDEBUG_NEW new(__FILE__,__LINE__)
```

In non-debug mode, this is defined as the normal new operator.

Include file:

```
#include <wx/object.h>
```

#define wxDISABLE_ASSERTS_IN_RELEASE_BUILD( ) wxDisableAsserts()

Use this macro to disable asserts in release build when not using wxIMPLEMENT_APP().

By default, assert message boxes are suppressed in release build by wxIMPLEMENT_APP() which uses this macro. If you don't use wxIMPLEMENT_APP() because your application initializes wxWidgets directly (e.g. calls wxEntry() or wxEntryStart() itself) but still want to suppress assert notifications in release build you need to use this macro directly.

See also

wxDISABLE_DEBUG_SUPPORT()

Since

2.9.1

Include file:

```
#include <wx/debug.h>
```

#define wxDISABLE_DEBUG_LOGGING_IN_RELEASE_BUILD( )

Use this macro to disable logging at debug and trace levels in release build when not using wxIMPLEMENT_APP().

See also

wxDISABLE_DEBUG_SUPPORT(), wxDISABLE_ASSERTS_IN_RELEASE_BUILD(), Debugging

Since

2.9.1

Include file:

```
#include <wx/log.h>
```

#define wxDISABLE_DEBUG_SUPPORT( )

Value:

```
wxDISABLE_ASSERTS_IN_RELEASE_BUILD(); \
    wxDISABLE_DEBUG_LOGGING_IN_RELEASE_BUILD()
```

Use this macro to disable all debugging code in release build when not using wxIMPLEMENT_APP().

Currently this macro disables assert checking and debug and trace level logging messages in release build (i.e. when `NDEBUG` is defined). It is used by wxIMPLEMENT_APP() macro so you only need to use it explicitly if you don't use this macro but initialize wxWidgets directly (e.g. calls wxEntry() or wxEntryStart() itself).

If you do not want to disable debugging code even in release build of your application, you can use wxSetDefaultAssertHandler() and wxLog::SetLogLevel() with `wxLOG_Max` parameter to enable assertions and debug logging respectively.

See also

wxDISABLE_ASSERTS_IN_RELEASE_BUILD(), wxDISABLE_DEBUG_LOGGING_IN_RELEASE_BUILD(), Debugging

Since

2.9.1

Include file:

```
#include <wx/app.h>
```

#define wxFAIL

Will always generate an assert error if this code is reached (in debug mode).

Note that you don't have to (and cannot) use brackets when invoking this macro:

```
1 if (...some condition...) {
2     wxFAIL;
3 }
```

This macro should be used to catch (in debug builds) logical errors done by the programmer.

See also

wxFAIL_MSG()

Include file:

```
#include <wx/debug.h>
```

#define wxFAIL_MSG(*message*)

Will always generate an assert error with specified message if this code is reached (in debug mode).

This macro is useful for marking "unreachable" code areas, for example it may be used in the "default:" branch of a switch statement if all possible cases are processed above.

This macro should be used to catch (in debug builds) logical errors done by the programmer.

See also

wxFAIL()

Include file:

```
#include <wx/debug.h>
```

#define wxFAIL_MSG_AT(*message, file, line, func*)

Assert failure macro pretending to assert at the specified location.

This is a cross between wxASSERT_MSG_AT() and wxFAIL_MSG(), see their documentation for more details.

Since

3.1.0

Include file:

```
#include <wx/debug.h>
```

20.15.3 Typedef Documentation

typedef void(∗ wxAssertHandler_t)(const wxString &file, int line, const wxString &func, const wxString &cond, const wxString &msg)

Type for the function called in case of assert failure.

See also

wxSetAssertHandler()

20.15.4 Function Documentation

void wxAbort ( )

Exits the program immediately.

This is a simple wrapper for the standard abort() function which is not available under all platforms (currently only Windows CE doesn't provide it).

Since

2.9.4

void wxDisableAsserts ( )

Disable the condition checks in the assertions.

This is the same as calling wxSetAssertHandler() with NULL handler.

Since

2.9.0

Include file:

```
#include <wx/debug.h>
```

bool wxIsDebuggerRunning ( )

Returns true if the program is running under debugger, false otherwise.

Please note that this function is currently only implemented for Win32 and always returns false elsewhere.

Include file:

```
#include <wx/debug.h>
```

wxAssertHandler_t wxSetAssertHandler (wxAssertHandler_t *handler*)

Sets the function to be called in case of assertion failure.

The default assert handler forwards to wxApp::OnAssertFailure() whose default behaviour is, in turn, to show the standard assertion failure dialog if a wxApp object exists or shows the same dialog itself directly otherwise.

While usually it is enough – and more convenient – to just override OnAssertFailure(), to handle all assertion failures, including those occurring even before wxApp object creation of after its destruction you need to provide your assertion handler function.

This function also provides a simple way to disable all asserts: simply pass NULL pointer to it. Doing this will result in not even evaluating assert conditions at all, avoiding almost all run-time cost of asserts.

Notice that this function is not MT-safe, so you should call it before starting any other threads.

The return value of this function is the previous assertion handler. It can be called after any pre-processing by your handler and can also be restored later if you uninstall your handler.

Parameters

handler	The function to call in case of assertion failure or NULL.

Returns

The previous assert handler which is not NULL by default but could be NULL if it had been previously set to this value using this function.

Since

2.9.0

Include file:

```
#include <wx/debug.h>
```

void wxSetDefaultAssertHandler ( )

Reset the assert handler to default function which shows a message box when an assert happens.

This can be useful for the applications compiled in release build (with `NDEBUG` defined) for which the asserts are by default disabled: if you wish to enable them even in this case you need to call this function.

Since

2.9.1

Include file:

```
#include <wx/debug.h>
```

void wxTrap ( )

Generate a debugger exception meaning that the control is passed to the debugger if one is attached to the process.

Otherwise the program just terminates abnormally.

If `wxDEBUG_LEVEL` is 0 (which is not the default) this function does nothing.

Include file:

```
#include <wx/debug.h>
```

20.16 Device Contexts

20.16.1 Detailed Description

Device contexts are surfaces that may be drawn on, and provide an abstraction that allows parameterisation of your drawing code by passing different device contexts.

Related Overviews: Device Contexts

Classes

- struct wxFontMetrics

  Simple collection of various font metrics.
- class wxSVGBitmapHandler

  Abstract base class for handling bitmaps inside a wxSVGFileDC.
- class wxSVGBitmapEmbedHandler

  Handler embedding bitmaps as base64-encoded PNGs into the SVG.
- class wxSVGBitmapFileHandler

  Handler saving a bitmap to an external file and linking to it from the SVG.
- class wxDC

  A wxDC is a "device context" onto which graphics and text can be drawn.
- class wxBufferedDC

  This class provides a simple way to avoid flicker: when drawing on it, everything is in fact first drawn on an in-memory buffer (a wxBitmap) and then copied to the screen, using the associated wxDC, only once, when this object is destroyed.
- class wxAutoBufferedPaintDC

  This wxDC derivative can be used inside of an `EVT_PAINT()` event handler to achieve double-buffered drawing.
- class wxBufferedPaintDC

  This is a subclass of wxBufferedDC which can be used inside of an `EVT_PAINT()` event handler to achieve double-buffered drawing.
- class wxPaintDC

  A wxPaintDC must be constructed if an application wishes to paint on the client area of a window from within an EVT_PAINT() event handler.
- class wxClientDC

  A wxClientDC must be constructed if an application wishes to paint on the client area of a window from outside an EVT_PAINT() handler.
- class wxWindowDC

  A wxWindowDC must be constructed if an application wishes to paint on the whole area of a window (client and decorations).
- class wxGCDC

  wxGCDC is a device context that draws on a wxGraphicsContext.
- class wxMemoryDC

  A memory device context provides a means to draw graphics onto a bitmap.
- class wxMirrorDC

  wxMirrorDC is a simple wrapper class which is always associated with a real wxDC object and either forwards all of its operations to it without changes (no mirroring takes place) or exchanges x and y coordinates which makes it possible to reuse the same code to draw a figure and its mirror – i.e.
- class wxPostScriptDC

  This defines the wxWidgets Encapsulated PostScript device context, which can write PostScript files on any platform.
- class wxScreenDC

  A wxScreenDC can be used to paint on the screen.
- class wxSVGFileDC

A wxSVGFileDC is a device context onto which graphics and text can be drawn, and the output produced as a vector file, in SVG format.

- class wxGraphicsContext

  A wxGraphicsContext instance is the object that is drawn upon.

- class wxMetafileDC

  *This is a type of device context that allows a metafile object to be created (Windows only), and has most of the characteristics of a normal **wxDC**.*

20.17 Dialogs

20.17.1 Detailed Description

Below are a number of convenience functions for getting input from the user or displaying messages.

Note that in these functions the last three parameters are optional. However, it is recommended to pass a parent frame parameter, or (in MS Windows or Motif) the wrong window frame may be brought to the front when the dialog box is popped up.

Functions

- void wxAboutBox (const wxAboutDialogInfo &info, wxWindow *parent=NULL)

  This function shows the standard about dialog containing the information specified in info.
- void wxGenericAboutBox (const wxAboutDialogInfo &info, wxWindow *parent=NULL)

  This function does the same thing as wxAboutBox() except that it always uses the generic wxWidgets version of the dialog instead of the native one.
- int wxGetSingleChoiceIndex (const wxString &message, const wxString &caption, const wxArrayString &a↩ Choices, wxWindow *parent=NULL, int x=wxDefaultCoord, int y=wxDefaultCoord, bool centre=true, int width=wxCHOICE_WIDTH, int height=wxCHOICE_HEIGHT, int initialSelection=0)

  Same as wxGetSingleChoice() but returns the index representing the selected string.
- int wxGetSingleChoiceIndex (const wxString &message, const wxString &caption, int n, const wxString &choices[], wxWindow *parent=NULL, int x=wxDefaultCoord, int y=wxDefaultCoord, bool centre=true, int width=wxCHOICE_WIDTH, int height=wxCHOICE_HEIGHT, int initialSelection=0)
- int wxGetSingleChoiceIndex (const wxString &message, const wxString &caption, const wxArrayString &choices, int initialSelection, wxWindow *parent=NULL)
- int wxGetSingleChoiceIndex (const wxString &message, const wxString &caption, int n, const wxString *choices, int initialSelection, wxWindow *parent=NULL)
- wxString wxGetSingleChoice (const wxString &message, const wxString &caption, const wxArrayString &aChoices, wxWindow *parent=NULL, int x=wxDefaultCoord, int y=wxDefaultCoord, bool centre=true, int width=wxCHOICE_WIDTH, int height=wxCHOICE_HEIGHT, int initialSelection=0)

  Pops up a dialog box containing a message, OK/Cancel buttons and a single-selection listbox.
- wxString wxGetSingleChoice (const wxString &message, const wxString &caption, int n, const wxString &choices[], wxWindow *parent=NULL, int x=wxDefaultCoord, int y=wxDefaultCoord, bool centre=true, int width=wxCHOICE_WIDTH, int height=wxCHOICE_HEIGHT, int initialSelection=0)
- wxString wxGetSingleChoice (const wxString &message, const wxString &caption, const wxArrayString &choices, int initialSelection, wxWindow *parent=NULL)
- wxString wxGetSingleChoice (const wxString &message, const wxString &caption, int n, const wxString *choices, int initialSelection, wxWindow *parent=NULL)
- wxString wxGetSingleChoiceData (const wxString &message, const wxString &caption, const wxArrayString &aChoices, const wxString &client_data[], wxWindow *parent=NULL, int x=wxDefaultCoord, int y=wx↩ DefaultCoord, bool centre=true, int width=wxCHOICE_WIDTH, int height=wxCHOICE_HEIGHT, int initial↩ Selection=0)

  Same as wxGetSingleChoice but takes an array of client data pointers corresponding to the strings, and returns one of these pointers or NULL if Cancel was pressed.
- wxString wxGetSingleChoiceData (const wxString &message, const wxString &caption, int n, const wx↩ String &choices[], const wxString &client_data[], wxWindow *parent=NULL, int x=wxDefaultCoord, int y=wx↩ DefaultCoord, bool centre=true, int width=wxCHOICE_WIDTH, int height=wxCHOICE_HEIGHT, int initial↩ Selection=0)
- void * wxGetSingleChoiceData (const wxString &message, const wxString &caption, const wxArrayString &choices, void **client_data, int initialSelection, wxWindow *parent=NULL)
- void * wxGetSingleChoiceData (const wxString &message, const wxString &caption, int n, const wxString *choices, void **client_data, int initialSelection, wxWindow *parent=NULL)
- int wxGetSelectedChoices (wxArrayInt &selections, const wxString &message, const wxString &caption, const wxArrayString &aChoices, wxWindow *parent=NULL, int x=wxDefaultCoord, int y=wxDefaultCoord, bool centre=true, int width=wxCHOICE_WIDTH, int height=wxCHOICE_HEIGHT)

Pops up a dialog box containing a message, OK/Cancel buttons and a multiple-selection listbox.

- int wxGetSelectedChoices (wxArrayInt &selections, const wxString &message, const wxString &caption, int n, const wxString &choices[], wxWindow *parent=NULL, int x=wxDefaultCoord, int y=wxDefaultCoord, bool centre=true, int width=wxCHOICE_WIDTH, int height=wxCHOICE_HEIGHT)
- wxColour wxGetColourFromUser (wxWindow *parent, const wxColour &colInit, const wxString &caption=wxEmptyString, wxColourData *data=NULL)

  Shows the colour selection dialog and returns the colour selected by user or invalid colour (use wxColour::IsOk() to test whether a colour is valid) if the dialog was cancelled.
- wxString wxDirSelector (const wxString &message=wxDirSelectorPromptStr, const wxString &default_path=wxEmptyString, long style=0, const wxPoint &pos=wxDefaultPosition, wxWindow *parent=NULL)

  Pops up a directory selector dialog.
- wxString wxFileSelector (const wxString &message, const wxString &default_path=wxEmptyString, const wxString &default_filename=wxEmptyString, const wxString &default_extension=wxEmptyString, const wxString &wildcard=wxFileSelectorDefaultWildcardStr, int flags=0, wxWindow *parent=NULL, int x=wxDefaultCoord, int y=wxDefaultCoord)

  Pops up a file selector box.
- wxString wxFileSelectorEx (const wxString &message=wxFileSelectorPromptStr, const wxString &default_path=wxEmptyString, const wxString &default_filename=wxEmptyString, int *indexDefaultExtension=NULL, const wxString &wildcard=wxFileSelectorDefaultWildcardStr, int flags=0, wxWindow *parent=NULL, int x=wxDefaultCoord, int y=wxDefaultCoord)

  An extended version of wxFileSelector.
- wxString wxLoadFileSelector (const wxString &what, const wxString &extension, const wxString &default_name=wxEmptyString, wxWindow *parent=NULL)

  Ask for filename to load.
- wxString wxSaveFileSelector (const wxString &what, const wxString &extension, const wxString &default_name=wxEmptyString, wxWindow *parent=NULL)

  Ask for filename to save.
- wxFont wxGetFontFromUser (wxWindow *parent, const wxFont &fontInit, const wxString &caption=wxEmptyString)

  Shows the font selection dialog and returns the font selected by user or invalid font (use wxFont::IsOk() to test whether a font is valid) if the dialog was cancelled.
- int wxMessageBox (const wxString &message, const wxString &caption=wxMessageBoxCaptionStr, int style=wxOK|wxCENTRE, wxWindow *parent=NULL, int x=wxDefaultCoord, int y=wxDefaultCoord)

  Show a general purpose message dialog.
- long wxGetNumberFromUser (const wxString &message, const wxString &prompt, const wxString &caption, long value, long min=0, long max=100, wxWindow *parent=NULL, const wxPoint &pos=wxDefaultPosition)

  Shows a dialog asking the user for numeric input.
- wxString wxGetTextFromUser (const wxString &message, const wxString &caption=wxGetTextFromUserPromptStr, const wxString &default_value=wxEmptyString, wxWindow *parent=NULL, int x=wxDefaultCoord, int y=wxDefaultCoord, bool centre=true)

  Pop up a dialog box with title set to caption, `message`, and a `default_value`.
- wxString wxGetPasswordFromUser (const wxString &message, const wxString &caption=wxGetPasswordFromUserPromptStr, const wxString &default_value=wxEmptyString, wxWindow *parent=NULL, int x=wxDefaultCoord, int y=wxDefaultCoord, bool centre=true)

  Similar to wxGetTextFromUser() but the text entered in the dialog is not shown on screen but replaced with stars.
- wxTipProvider * wxCreateFileTipProvider (const wxString &filename, size_t currentTip)

  This function creates a wxTipProvider which may be used with wxShowTip().
- bool wxShowTip (wxWindow *parent, wxTipProvider *tipProvider, bool showAtStartup=true)

  This function shows a "startup tip" to the user.
- void wxBeginBusyCursor (const wxCursor *cursor=wxHOURGLASS_CURSOR)

  Changes the cursor to the given cursor for all windows in the application.
- void wxEndBusyCursor ()

  Changes the cursor back to the original cursor, for all windows in the application.
- bool wxIsBusy ()

Returns true if between two wxBeginBusyCursor() and wxEndBusyCursor() calls.

- void wxBell ()

  Ring the system bell.

- void wxInfoMessageBox (wxWindow *parent)

  Shows a message box with the information about the wxWidgets build used, including its version, most important build parameters and the version of the underlying GUI toolkit.

20.17.2 Function Documentation

void wxAboutBox (const wxAboutDialogInfo & *info*, wxWindow * *parent* = NULL)

This function shows the standard about dialog containing the information specified in *info*.

If the current platform has a native about dialog which is capable of showing all the fields in *info*, the native dialog is used, otherwise the function falls back to the generic wxWidgets version of the dialog, i.e. does the same thing as wxGenericAboutBox.

Here is an example of how this function may be used:

```
1 void MyFrame::ShowSimpleAboutDialog(wxCommandEvent& WXUNUSED(event))
2 {
3     wxAboutDialogInfo info;
4     info.SetName(_("My Program"));
5     info.SetVersion(_("1.2.3 Beta"));
6     info.SetDescription(_("This program does something great."));
7     info.SetCopyright(wxT("(C) 2007 Me <my@email.addre.ss>"));
8
9     wxAboutBox(info);
10 }
```

Please see the Dialogs Sample for more examples of using this function and wxAboutDialogInfo for the description of the information which can be shown in the about dialog.

Include file:

```
#include <wx/aboutdlg.h>
```

void wxBeginBusyCursor (const wxCursor * *cursor* = wxHOURGLASS_CURSOR)

Changes the cursor to the given cursor for all windows in the application.

Use wxEndBusyCursor() to revert the cursor back to its previous state. These two calls can be nested, and a counter ensures that only the outer calls take effect.

See also

wxIsBusy(), wxBusyCursor

Include file:

```
#include <wx/utils.h>
```

void wxBell ( )

Ring the system bell.

Note

This function is categorized as a GUI one and so is not thread-safe.

Include file:

```
#include <wx/utils.h>
```

Library: wxCore

wxTipProvider* wxCreateFileTipProvider (const wxString & *filename*, size_t *currentTip*)

This function creates a wxTipProvider which may be used with wxShowTip().

Parameters

filename	The name of the file containing the tips, one per line.
currentTip	The index of the first tip to show. Normally this index is remembered between the 2 program runs.

See also

wxTipProvider Overview

Include file:

```
#include <wx/tipdlg.h>
```

wxString wxDirSelector (const wxString & *message* = wxDirSelectorPromptStr, const wxString & *default_path* = wxEmptyString, long *style* = 0, const wxPoint & *pos* = wxDefaultPosition, wxWindow * *parent* = NULL)

Pops up a directory selector dialog.

The arguments have the same meaning as those of wxDirDialog::wxDirDialog(). The message is displayed at the top, and the default_path, if specified, is set as the initial selection.

The application must check for an empty return value (if the user pressed Cancel). For example:

```
1 const wxString& dir = wxDirSelector("Choose a folder");
2 if ( !dir.empty() )
3 {
4     ...
5 }
```

Include file:

```
#include <wx/dirdlg.h>
```

void wxEndBusyCursor ( )

Changes the cursor back to the original cursor, for all windows in the application.

Use with wxBeginBusyCursor().

See also

wxIsBusy(), wxBusyCursor

Include file:

```
#include <wx/utils.h>
```

wxString wxFileSelector (const wxString & *message*, const wxString & *default_path* = wxEmptyString, const wxString & *default_filename* = wxEmptyString, const wxString & *default_extension* = wxEmptyString, const wxString & *wildcard* = wxFileSelectorDefaultWildcardStr, int *flags* = 0, wxWindow * *parent* = NULL, int *x* = wxDefaultCoord, int *y* = wxDefaultCoord)

Pops up a file selector box.

In Windows, this is the common file selector dialog. In X, this is a file selector box with the same functionality. The path and filename are distinct elements of a full file pathname. If path is empty, the current directory will be used. If filename is empty, no default filename will be supplied. The wildcard determines what files are displayed in the file selector, and file extension supplies a type extension for the required filename. Flags may be a combination of wxFD_OPEN, wxFD_SAVE, wxFD_OVERWRITE_PROMPT or wxFD_FILE_MUST_EXIST.

Note

wxFD_MULTIPLE can only be used with wxFileDialog and not here since this function only returns a single file name.

Both the Unix and Windows versions implement a wildcard filter. Typing a filename containing wildcards (*, ?) in the filename text item, and clicking on Ok, will result in only those files matching the pattern being displayed.

The wildcard may be a specification for multiple types of file with a description for each, such as:

```
1 "BMP files (*.bmp)|*.bmp|GIF files (*.gif)|*.gif"
```

The application must check for an empty return value (the user pressed Cancel). For example:

```
1 wxString filename = wxFileSelector("Choose a file to open");
2 if ( !filename.empty() )
3 {
4     // work with the file
5     ...
6 }
7 //else: cancelled by user
```

Include file:

```
#include <wx/filedlg.h>
```

wxString wxFileSelectorEx (const wxString & *message* = wxFileSelectorPromptStr, const wxString & *default_path* = wxEmptyString, const wxString & *default_filename* = wxEmptyString, int * *indexDefaultExtension* = NULL, const wxString & *wildcard* = wxFileSelectorDefaultWildcardStr, int *flags* = 0, wxWindow * *parent* = NULL, int *x* = wxDefaultCoord, int *y* = wxDefaultCoord)

An extended version of wxFileSelector.

void wxGenericAboutBox (const wxAboutDialogInfo & *info*, wxWindow * *parent* = NULL)

This function does the same thing as wxAboutBox() except that it always uses the generic wxWidgets version of the dialog instead of the native one.

This is mainly useful if you need to customize the dialog by e.g. adding custom controls to it (customizing the native dialog is not currently supported).

See the Dialogs Sample for an example of about dialog customization.

See also

wxAboutDialogInfo

Include file:

```
#include <wx/aboutdlg.h>
```

wxColour wxGetColourFromUser (wxWindow * *parent*, const wxColour & *colInit*, const wxString & *caption* = wxEmptyString, wxColourData * *data* = NULL)

Shows the colour selection dialog and returns the colour selected by user or invalid colour (use wxColour::IsOk() to test whether a colour is valid) if the dialog was cancelled.

Parameters

parent	The parent window for the colour selection dialog.
colInit	If given, this will be the colour initially selected in the dialog.
caption	If given, this will be used for the dialog caption.
data	Optional object storing additional colour dialog settings, such as custom colours. If none is provided the same settings as the last time are used.

Include file:

```
#include <wx/colordlg.h>
```

wxFont wxGetFontFromUser (wxWindow * *parent*, const wxFont & *fontInit*, const wxString & *caption* = wxEmptyString)

Shows the font selection dialog and returns the font selected by user or invalid font (use wxFont::IsOk() to test whether a font is valid) if the dialog was cancelled.

Parameters

parent	The parent window for the font selection dialog.
fontInit	If given, this will be the font initially selected in the dialog.
caption	If given, this will be used for the dialog caption.

Include file:

```
#include <wx/fontdlg.h>
```

long wxGetNumberFromUser (const wxString & *message*, const wxString & *prompt*, const wxString & *caption*, long *value*, long *min* = 0, long *max* = 100, wxWindow * *parent* = NULL, const wxPoint & *pos* = wxDefaultPosition)

Shows a dialog asking the user for numeric input.

The dialogs title is set to `caption`, it contains a (possibly) multiline `message` above the single line `prompt` and the zone for entering the number.

The number entered must be in the range `min` to `max` (both of which should be positive) and `value` is the initial value of it. If the user enters an invalid value, it is forced to fall into the specified range. If the user cancels the dialog, the function returns -1.

Dialog is centered on its `parent` unless an explicit position is given in `pos`.

Include file:

```
#include <wx/numdlg.h>
```

wxString wxGetPasswordFromUser (const wxString & *message*, const wxString & *caption* = wxGetPasswordFromUserPromptStr, const wxString & *default_value* = wxEmptyString, wxWindow * *parent* = NULL, int *x* = wxDefaultCoord, int *y* = wxDefaultCoord, bool *centre* = true)

Similar to wxGetTextFromUser() but the text entered in the dialog is not shown on screen but replaced with stars.

This is intended to be used for entering passwords as the function name implies.

Include file:

```
#include <wx/textdlg.h>
```

int wxGetSelectedChoices (wxArrayInt & *selections*, const wxString & *message*, const wxString & *caption*, const wxArrayString & *aChoices*, wxWindow * *parent* = NULL, int *x* = wxDefaultCoord, int *y* = wxDefaultCoord, bool *centre* = true, int *width* = wxCHOICE_WIDTH, int *height* = wxCHOICE_HEIGHT)

Pops up a dialog box containing a message, OK/Cancel buttons and a multiple-selection listbox.

The user may choose an arbitrary (including 0) number of items in the listbox whose indices will be returned in `selections` array. The initial contents of this array will be used to select the items when the dialog is shown. If the user cancels the dialog, the function returns -1 and `selections` array is left unchanged.

You may pass the list of strings to choose from either using `choices` which is an array of *n* strings for the listbox or by using a single `aChoices` parameter of type wxArrayString.

If `centre` is true, the message text (which may include new line characters) is centred; if false, the message is left-justified.

Include file:

```
#include <wx/choicdlg.h>
```

wxPerl Note: Use an array reference for the *choices* parameter. In wxPerl there is no *selections* parameter; the function returns an array containing the user selections.

int wxGetSelectedChoices (wxArrayInt & *selections*, const wxString & *message*, const wxString & *caption*, int *n*, const wxString & *choices[]*, wxWindow * *parent* = NULL, int *x* = wxDefaultCoord, int *y* = wxDefaultCoord, bool *centre* = true, int *width* = wxCHOICE_WIDTH, int *height* = wxCHOICE_HEIGHT)

wxString wxGetSingleChoice (const wxString & *message*, const wxString & *caption*, const wxArrayString & *aChoices*, wxWindow * *parent* = NULL, int *x* = wxDefaultCoord, int *y* = wxDefaultCoord, bool *centre* = true, int *width* = wxCHOICE_WIDTH, int *height* = wxCHOICE_HEIGHT, int *initialSelection* = 0)

Pops up a dialog box containing a message, OK/Cancel buttons and a single-selection listbox.

The user may choose an item and press OK to return a string or Cancel to return the empty string. Use wxGetSingleChoiceIndex() if empty string is a valid choice and if you want to be able to detect pressing Cancel reliably.

You may pass the list of strings to choose from either using `choices` which is an array of *n* strings for the listbox or by using a single `aChoices` parameter of type wxArrayString.

If `centre` is true, the message text (which may include new line characters) is centred; if false, the message is left-justified.

Include file:

```
#include <wx/choicdlg.h>
```

wxPerl Note: Use an array reference for the *choices* parameter.

wxString wxGetSingleChoice (const wxString & *message*, const wxString & *caption*, int *n*, const wxString & *choices[]*, wxWindow * *parent* = NULL, int *x* = wxDefaultCoord, int *y* = wxDefaultCoord, bool *centre* = true, int *width* = wxCHOICE_WIDTH, int *height* = wxCHOICE_HEIGHT, int *initialSelection* = 0)

wxString wxGetSingleChoice (const wxString & *message*, const wxString & *caption*, const wxArrayString & *choices*, int *initialSelection*, wxWindow * *parent* = NULL)

wxString wxGetSingleChoice (const wxString & *message*, const wxString & *caption*, int *n*, const wxString * *choices*, int *initialSelection*, wxWindow * *parent* = NULL)

wxString wxGetSingleChoiceData (const wxString & *message*, const wxString & *caption*, const wxArrayString & *aChoices*, const wxString & *client_data[]*, wxWindow * *parent* = NULL, int *x* = wxDefaultCoord, int *y* = wxDefaultCoord, bool *centre* = true, int *width* = wxCHOICE_WIDTH, int *height* = wxCHOICE_HEIGHT, int *initialSelection* = 0)

Same as wxGetSingleChoice but takes an array of client data pointers corresponding to the strings, and returns one of these pointers or NULL if Cancel was pressed.

The `client_data` array must have the same number of elements as `choices` or `aChoices`!

Include file:

```
#include <wx/choicdlg.h>
```

wxPerl Note: Use an array reference for the *aChoices* and *client_data* parameters.

wxString wxGetSingleChoiceData (const wxString & *message*, const wxString & *caption*, int *n*, const wxString & *choices[]*, const wxString & *client_data[]*, wxWindow * *parent* = NULL, int *x* = wxDefaultCoord, int *y* = wxDefaultCoord, bool *centre* = true, int *width* = wxCHOICE_WIDTH, int *height* = wxCHOICE_HEIGHT, int *initialSelection* = 0)

void* wxGetSingleChoiceData (const wxString & *message*, const wxString & *caption*, const wxArrayString & *choices*, void ** *client_data*, int *initialSelection*, wxWindow * *parent* = NULL)

void* wxGetSingleChoiceData (const wxString & *message*, const wxString & *caption*, int *n*, const wxString * *choices*, void ** *client_data*, int *initialSelection*, wxWindow * *parent* = NULL)

int wxGetSingleChoiceIndex (const wxString & *message*, const wxString & *caption*, const wxArrayString & *aChoices*, wxWindow * *parent* = NULL, int *x* = wxDefaultCoord, int *y* = wxDefaultCoord, bool *centre* = true, int *width* = wxCHOICE_WIDTH, int *height* = wxCHOICE_HEIGHT, int *initialSelection* = 0)

Same as wxGetSingleChoice() but returns the index representing the selected string.

If the user pressed cancel, -1 is returned.

Include file:

```
#include <wx/choicdlg.h>
```

wxPerl Note: Use an array reference for the *aChoices* parameter.

int wxGetSingleChoiceIndex (const wxString & *message*, const wxString & *caption*, int *n*, const wxString & *choices[]*, wxWindow * *parent* = NULL, int *x* = wxDefaultCoord, int *y* = wxDefaultCoord, bool *centre* = true, int *width* = wxCHOICE_WIDTH, int *height* = wxCHOICE_HEIGHT, int *initialSelection* = 0)

int wxGetSingleChoiceIndex (const wxString & *message*, const wxString & *caption*, const wxArrayString & *choices*, int *initialSelection*, wxWindow * *parent* = NULL)

int wxGetSingleChoiceIndex (const wxString & *message*, const wxString & *caption*, int *n*, const wxString * *choices*, int *initialSelection*, wxWindow * *parent* = NULL)

wxString wxGetTextFromUser (const wxString & *message*, const wxString & *caption* = wxGetTextFromUser↩ PromptStr, const wxString & *default_value* = wxEmptyString, wxWindow * *parent* = NULL, int *x* = wxDefaultCoord, int *y* = wxDefaultCoord, bool *centre* = true)

Pop up a dialog box with title set to *caption*, `message`, and a `default_value`.

The user may type in text and press OK to return this text, or press Cancel to return the empty string.

If `centre` is true, the message text (which may include new line characters) is centred; if false, the message is left-justified.

This function is a wrapper around wxTextEntryDialog and while it is usually more convenient to use, using the dialog directly is more flexible, e.g. it allows you to specify the `wxTE_MULTILINE` to allow the user enter multiple lines of text while this function is limited to single line entry only.

Include file:

```
#include <wx/textdlg.h>
```

void wxInfoMessageBox (wxWindow * *parent*)

Shows a message box with the information about the wxWidgets build used, including its version, most important build parameters and the version of the underlying GUI toolkit.

This is mainly used for diagnostic purposes and can be invoked by Ctrl-Alt-middle clicking on any wxWindow which doesn't otherwise handle this event.

Since

2.9.0

See also

wxGetLibraryVersionInfo()

Include file:

```
#include <wx/utils.h>
```

bool wxIsBusy ( )

Returns true if between two wxBeginBusyCursor() and wxEndBusyCursor() calls.

See also

wxBusyCursor.

Include file:

```
#include <wx/utils.h>
```

wxString wxLoadFileSelector (const wxString & *what*, const wxString & *extension*, const wxString & *default_name* = wxEmptyString, wxWindow * *parent* = `NULL`)

Ask for filename to load.

int wxMessageBox (const wxString & *message*, const wxString & *caption* = wxMessageBoxCaptionStr, int *style* = wxOK|wxCENTRE, wxWindow * *parent* = `NULL`, int *x* = wxDefaultCoord, int *y* = wxDefaultCoord)

Show a general purpose message dialog.

This is a convenient function which is usually used instead of using wxMessageDialog directly. Notice however that some of the features, such as extended text and custom labels for the message box buttons, are not provided by this function but only by wxMessageDialog.

The return value is one of: `wxYES`, `wxNO`, `wxCANCEL`, `wxOK` or `wxHELP` (notice that this return value is **different** from the return value of wxMessageDialog::ShowModal()).

For example:

```
1 int answer = wxMessageBox("Quit program?", "Confirm",
2                           wxYES_NO | wxCANCEL, main_frame);
3 if (answer == wxYES)
4     main_frame->Close();
```

message may contain newline characters, in which case the message will be split into separate lines, to cater for large messages.

Parameters

message	Message to show in the dialog.
caption	The dialog title.
parent	Parent window.
style	Combination of style flags described in wxMessageDialog documentation.
x	Horizontal dialog position (ignored under MSW). Use wxDefaultCoord for *x* and *y* to let the system position the window.
y	Vertical dialog position (ignored under MSW).

Include file:

```
#include <wx/msgdlg.h>
```

wxString wxSaveFileSelector (const wxString & *what*, const wxString & *extension*, const wxString & *default_name* = wxEmptyString, wxWindow * *parent* = NULL)

Ask for filename to save.

bool wxShowTip (wxWindow * *parent*, wxTipProvider * *tipProvider*, bool *showAtStartup* = true)

This function shows a "startup tip" to the user.

The return value is the state of the "Show tips at startup" checkbox.

Parameters

parent	The parent window for the modal dialog.
tipProvider	An object which is used to get the text of the tips. It may be created with the wxCreateFileTipProvider() function.
showAtStartup	Should be true if startup tips are shown, false otherwise. This is used as the initial value for "Show tips at startup" checkbox which is shown in the tips dialog.

See also

wxTipProvider Overview

Include file:

```
#include <wx/tipdlg.h>
```

20.18 Document/View Framework

20.18.1 Detailed Description

wxWidgets supports a document/view framework which provides housekeeping for a document-centric application.

Related Overviews: Document/View Framework

Classes

- class wxCommand

  wxCommand is a base class for modelling an application command, which is an action usually performed by selecting a menu item, pressing a toolbar button or any other means provided by the application to change the data or view.
- class wxCommandProcessor

  wxCommandProcessor is a class that maintains a history of wxCommands, with undo/redo functionality built-in.
- class wxDocMDIParentFrame

  The wxDocMDIParentFrame class provides a default top-level frame for applications using the document/view framework.
- class wxDocMDIChildFrame

  The wxDocMDIChildFrame class provides a default frame for displaying documents on separate windows.
- class wxDocTemplate

  The wxDocTemplate class is used to model the relationship between a document class and a view class.
- class wxDocManager

  The wxDocManager class is part of the document/view framework supported by wxWidgets, and cooperates with the wxView, wxDocument and wxDocTemplate classes.
- class wxView

  The view class can be used to model the viewing and editing component of an application's file-based data.
- class wxDocChildFrame

  The wxDocChildFrame class provides a default frame for displaying documents on separate windows.
- class wxDocParentFrame

  The wxDocParentFrame class provides a default top-level frame for applications using the document/view framework.
- class wxDocument

  The document class can be used to model an application's file-based data.
- class wxFileHistory

  The wxFileHistory encapsulates a user interface convenience, the list of most recently visited files as shown on a menu (usually the File menu).

20.19 Environment

20.19.1 Detailed Description

These functions allow access to get or change the values of environment variables in a portable way.

They are currently implemented under Win32 and POSIX-like systems (Unix).

Remember that these functions add/change/delete environment variables of the current process only. Child processes copy the environment variables of the parent but do not share them (a wxSetEnv() in the parent process won't change the value returned by wxGetEnv() in the child process and viceversa).

For more evoluted interprocess communication tecniques see Interprocess Communication.

Typedefs

- typedef wxStringToStringHashMap wxEnvVariableHashMap

  A map type containing environment variables names and values.

Functions

- wxChar * wxGetenv (const wxString &var)

  This is a macro defined as `getenv()` or its wide char version in Unicode mode.
- bool wxGetEnv (const wxString &var, wxString *value)

  Returns the current value of the environment variable var in value.
- bool wxSetEnv (const wxString &var, const wxString &value)

  Sets the value of the environment variable var (adding it if necessary) to value.
- bool wxUnsetEnv (const wxString &var)

  Removes the variable var from the environment.
- bool wxGetEnvMap (wxEnvVariableHashMap *map)

  Fill a map with the complete content of current environment.

20.19.2 Typedef Documentation

typedef wxStringToStringHashMap wxEnvVariableHashMap

A map type containing environment variables names and values.

This type is used with wxGetEnvMap() function and wxExecuteEnv structure optionally passed to wxExecute().

Since

2.9.2

Include file:

```
#include <wx/utils.h>
```

20.19.3 Function Documentation

wxChar* wxGetenv (const wxString & *var*)

This is a macro defined as `getenv()` or its wide char version in Unicode mode.

Note that under Win32 it may not return correct value for the variables set with wxSetEnv(), use wxGetEnv() function instead.

Include file:

```
#include <wx/utils.h>
```

bool wxGetEnv (const wxString & *var,* wxString * *value*)

Returns the current value of the environment variable *var* in *value*.

value may be NULL if you just want to know if the variable exists and are not interested in its value.

Returns true if the variable exists, false otherwise.

Include file:

```
#include <wx/utils.h>
```

bool wxGetEnvMap (wxEnvVariableHashMap * *map*)

Fill a map with the complete content of current environment.

The map will contain the environment variable names as keys and their values as values.

Parameters

map	The environment map to fill, must be non-NULL.

Returns

true if environment was successfully retrieved or false otherwise.

Include file:

```
#include <wx/utils.h>
```

Since

2.9.2

bool wxSetEnv (const wxString & *var,* const wxString & *value*)

Sets the value of the environment variable *var* (adding it if necessary) to *value*.

Notice that under Windows platforms the program may have two different environment blocks: the first one is that of a Windows process and is always present, but the CRT may maintain its own independent copy of the environment. wxSetEnv() will always update the first copy, which means that wxGetEnv(), which uses it directly, will always return the expected value after this call. But wxSetEnv() only updates the second copy for some compilers/CRT implementations (currently only MSVC and MinGW which uses the same MSVC CRT) and so using wxGetenv() (notice the difference in case) may not return the updated value.

Parameters

var	The environment variable to be set, must not contain `'='` character.
value	New value of the variable.

Returns

true on success or false if changing the value failed.

See also

wxUnsetEnv()

Include file:

```
#include <wx/utils.h>
```

bool wxUnsetEnv (const wxString & *var*)

Removes the variable *var* from the environment.

wxGetEnv() will return NULL after the call to this function.

Returns true on success.

Include file:

```
#include <wx/utils.h>
```

20.20 Events

20.20.1 Detailed Description

An event object contains information about a specific event.

Event handlers (usually member functions) have a single, event argument.

Related Overviews: Events and Event Handling

Related macros/global-functions group: Events

Classes

- class wxEventFilter

  A global event filter for pre-processing all the events generated in the program.
- class wxKeyboardState

  Provides methods for testing the state of the keyboard modifier keys.
- class wxAuiNotebookEvent

  This class is used by the events generated by wxAuiNotebook.
- class wxAuiManagerEvent

  Event used to indicate various actions taken with wxAuiManager.
- class wxBookCtrlEvent

  This class represents the events generated by book controls (wxNotebook, wxListbook, wxChoicebook, wxTreebook, wxAuiNotebook).
- class wxCalendarEvent

  The wxCalendarEvent class is used together with wxCalendarCtrl.
- class wxColourPickerEvent

  This event class is used for the events generated by wxColourPickerCtrl.
- class wxCollapsiblePaneEvent

  This event class is used for the events generated by wxCollapsiblePane.
- class wxDataViewEvent

  This is the event class for the wxDataViewCtrl notifications.
- class wxDateEvent

  This event class holds information about a date change and is used together with wxDatePickerCtrl.
- class wxDialUpEvent

  This is the event class for the dialup events sent by wxDialUpManager.
- class wxEvent

  An event is a structure holding information about an event passed to a callback or member function.
- class wxEventBlocker

  This class is a special event handler which allows to discard any event (or a set of event types) directed to a specific window.
- class wxEvtHandler

  A class that can handle events from the windowing system.
- class wxKeyEvent

  This event class contains information about key press and release events.
- class wxJoystickEvent

  This event class contains information about joystick events, particularly events received by windows.
- class wxScrollWinEvent

  A scroll event holds information about events sent from scrolling windows.
- class wxSysColourChangedEvent

  This class is used for system colour change events, which are generated when the user changes the colour settings using the control panel.

- class wxCommandEvent

  This event class contains information about command events, which originate from a variety of simple controls.
- class wxWindowCreateEvent

  This event is sent just after the actual window associated with a wxWindow object has been created.
- class wxPaintEvent

  A paint event is sent when a window's contents needs to be repainted.
- class wxMaximizeEvent

  An event being sent when a top level window is maximized.
- class wxUpdateUIEvent

  This class is used for pseudo-events which are called by wxWidgets to give an application the chance to update various user interface elements.
- class wxClipboardTextEvent

  This class represents the events generated by a control (typically a wxTextCtrl but other windows can generate these events as well) when its content gets copied or cut to, or pasted from the clipboard.
- class wxMouseEvent

  This event class contains information about the events generated by the mouse: they include mouse buttons press and release events and mouse move events.
- class wxDropFilesEvent

  This class is used for drop files events, that is, when files have been dropped onto the window.
- class wxActivateEvent

  An activate event is sent when a window or application is being activated or deactivated.
- class wxContextMenuEvent

  This class is used for context menu events, sent to give the application a chance to show a context (popup) menu for a wxWindow.
- class wxEraseEvent

  An erase event is sent when a window's background needs to be repainted.
- class wxFocusEvent

  A focus event is sent when a window's focus changes.
- class wxChildFocusEvent

  A child focus event is sent to a (parent-)window when one of its child windows gains focus, so that the window could restore the focus back to its corresponding child if it loses it now and regains later.
- class wxMouseCaptureLostEvent

  A mouse capture lost event is sent to a window that had obtained mouse capture, which was subsequently lost due to an "external" event (for example, when a dialog box is shown or if another application captures the mouse).
- class wxNotifyEvent

  This class is not used by the event handlers by itself, but is a base class for other event classes (such as wxBook↩ CtrlEvent).
- class wxThreadEvent

  This class adds some simple functionality to wxEvent to facilitate inter-thread communication.
- class wxHelpEvent

  A help event is sent when the user has requested context-sensitive help.
- class wxScrollEvent

  A scroll event holds information about events sent from stand-alone scrollbars (see wxScrollBar) and sliders (see wxSlider).
- class wxIdleEvent

  This class is used for idle events, which are generated when the system becomes idle.
- class wxInitDialogEvent

  A wxInitDialogEvent is sent as a dialog or panel is being initialised.
- class wxWindowDestroyEvent

  This event is sent as early as possible during the window destruction process.
- class wxNavigationKeyEvent

  This event class contains information about navigation events, generated by navigation keys such as tab and page down.

- class wxMouseCaptureChangedEvent

  An mouse capture changed event is sent to a window that loses its mouse capture.
- class wxCloseEvent

  This event class contains information about window and session close events.
- class wxMenuEvent

  This class is used for a variety of menu-related events.
- class wxShowEvent

  An event being sent when the window is shown or hidden.
- class wxIconizeEvent

  An event being sent when the frame is iconized (minimized) or restored.
- class wxMoveEvent

  A move event holds information about wxTopLevelWindow move change events.
- class wxSizeEvent

  A size event holds information about size change events of wxWindow.
- class wxSetCursorEvent

  A wxSetCursorEvent is generated from wxWindow when the mouse cursor is about to be set as a result of mouse motion.
- class wxFindDialogEvent

  wxFindReplaceDialog events.
- class wxFileCtrlEvent

  A file control event holds information about events associated with wxFileCtrl objects.
- class wxFileDirPickerEvent

  This event class is used for the events generated by wxFilePickerCtrl and by wxDirPickerCtrl.
- class wxFontPickerEvent

  This event class is used for the events generated by wxFontPickerCtrl.
- class wxFileSystemWatcherEvent

  A class of events sent when a file system event occurs.
- class wxGridEvent

  This event class contains information about various grid events.
- class wxGridSizeEvent

  This event class contains information about a row/column resize event.
- class wxGridRangeSelectEvent
- class wxGridEditorCreatedEvent
- class wxHeaderCtrlEvent

  Event class representing the events generated by wxHeaderCtrl.
- class wxHyperlinkEvent

  This event class is used for the events generated by wxHyperlinkCtrl.
- class wxQueryLayoutInfoEvent

  This event is sent when wxLayoutAlgorithm wishes to get the size, orientation and alignment of a window.
- class wxCalculateLayoutEvent

  This event is sent by wxLayoutAlgorithm to calculate the amount of the remaining client area that the window should occupy.
- class wxListEvent

  A list event holds information about events associated with wxListCtrl objects.
- class wxMediaEvent

  Event wxMediaCtrl uses.
- class wxMouseEventsManager

  Helper for handling mouse input events in windows containing multiple items.
- class wxMouseState

  Represents the mouse state.
- class wxActiveXEvent

An event class for handling ActiveX events passed from wxActiveXContainer.

- class wxPowerEvent

  The power events are generated when the system power state changes, e.g.
- class wxProcessEvent

  A process event is sent to the wxEvtHandler specified to wxProcess when a process is terminated.
- class wxRibbonBarEvent

  Event used to indicate various actions relating to a wxRibbonBar.
- class wxRibbonButtonBarEvent

  Event used to indicate various actions relating to a button on a wxRibbonButtonBar.
- class wxRibbonGalleryEvent
- class wxRibbonPanelEvent

  Event used to indicate various actions relating to a wxRibbonPanel.
- class wxRichTextEvent

  This is the event class for wxRichTextCtrl notifications.
- class wxSashEvent

  A sash event is sent when the sash of a wxSashWindow has been dragged by the user.
- class wxSpinEvent

  This event class is used for the events generated by wxSpinButton and wxSpinCtrl.
- class wxSpinDoubleEvent

  This event class is used for the events generated by wxSpinCtrlDouble.
- class wxSplitterEvent

  This class represents the events generated by a splitter control.
- class wxStyledTextEvent

  The type of events sent from wxStyledTextCtrl.
- class wxTaskBarIconEvent

  The event class used by wxTaskBarIcon.
- class wxTimerEvent

  wxTimerEvent object is passed to the event handler of timer events (see wxTimer::SetOwner).
- class wxTreeEvent

  A tree event holds information about events associated with wxTreeCtrl objects.
- class wxWebViewEvent

  A navigation event holds information about events associated with wxWebView objects.
- class wxWizardEvent

  wxWizardEvent class represents an event generated by the wxWizard: this event is first sent to the page itself and, if not processed there, goes up the window hierarchy as usual.

Enumerations

- enum {
  wxEventFilter::Event_Skip = -1,
  wxEventFilter::Event_Ignore = 0,
  wxEventFilter::Event_Processed = 1 }

  Possible return values for FilterEvent().

20.20.2 Enumeration Type Documentation

anonymous enum

Possible return values for FilterEvent().

Enumerator

Event_Skip Process event as usual.

Event_Ignore Don't process the event normally at all.

Event_Processed Event was already handled, don't process it normally.

20.21 Events

20.21.1 Detailed Description

Below are a number of functions/macros used with wxWidgets event-handling system.

Related class group: Events

Macros

- #define wxDEFINE_EVENT(name, cls) const wxEventTypeTag< cls > name(wxNewEventType())

  Define a new event type associated with the specified event class.
- #define wxDECLARE_EVENT(name, cls) wxDECLARE_EXPORTED_EVENT(wxEMPTY_PARAMETER_↩ VALUE, name, cls)

  Declares a custom event type.
- #define wxDECLARE_EXPORTED_EVENT(expdecl, name, cls) extern const expdecl wxEventTypeTag< cls > name;

  Variant of wxDECLARE_EVENT() used for event types defined inside a shared library.
- #define wxEVENT_HANDLER_CAST(functype, func) (&func)

  Helper macro for definition of custom event table macros.
- #define wx__DECLARE_EVT1(evt, id, fn) wx__DECLARE_EVT2(evt, id, wxID_ANY, fn)

  This macro is used to define event table macros for handling custom events.
- #define wx__DECLARE_EVT2(evt, id1, id2, fn) DECLARE_EVENT_TABLE_ENTRY(evt, id1, id2, fn, NULL),

  Generalized version of the wx__DECLARE_EVT1() macro taking a range of IDs instead of a single one.
- #define wx__DECLARE_EVT0(evt, fn) wx__DECLARE_EVT1(evt, wxID_ANY, fn)

  Simplified version of the wx__DECLARE_EVT1() macro, to be used when the event type must be handled regardless of the ID associated with the specific event instances.
- #define wxDECLARE_EVENT_TABLE()

  Use this macro inside a class declaration to declare a static event table for that class.
- #define wxBEGIN_EVENT_TABLE(theClass, baseClass)

  Use this macro in a source file to start listing static event handlers for a specific class.
- #define wxEND_EVENT_TABLE()

  Use this macro in a source file to end listing static event handlers for a specific class.

Typedefs

- typedef int wxEventType

  A value uniquely identifying the type of the event.

Functions

- wxEventType wxNewEventType ()

  Generates a new unique event type.
- void wxPostEvent (wxEvtHandler *dest, const wxEvent &event)

  In a GUI application, this function posts event to the specified dest object using wxEvtHandler::AddPendingEvent().
- void wxQueueEvent (wxEvtHandler *dest, wxEvent *event)

  Queue an event for processing on the given object.

Variables

- wxEventType wxEVT_NULL

  A special event type usually used to indicate that some wxEvent has yet no type assigned.
- wxEventType wxEVT_ANY
- wxEventType wxEVT_BUTTON
- wxEventType wxEVT_CHECKBOX
- wxEventType wxEVT_CHOICE
- wxEventType wxEVT_LISTBOX
- wxEventType wxEVT_LISTBOX_DCLICK
- wxEventType wxEVT_CHECKLISTBOX
- wxEventType wxEVT_MENU
- wxEventType wxEVT_SLIDER
- wxEventType wxEVT_RADIOBOX
- wxEventType wxEVT_RADIOBUTTON
- wxEventType wxEVT_SCROLLBAR
- wxEventType wxEVT_VLBOX
- wxEventType wxEVT_COMBOBOX
- wxEventType wxEVT_TOOL_RCLICKED
- wxEventType wxEVT_TOOL_DROPDOWN
- wxEventType wxEVT_TOOL_ENTER
- wxEventType wxEVT_COMBOBOX_DROPDOWN
- wxEventType wxEVT_COMBOBOX_CLOSEUP
- wxEventType wxEVT_THREAD
- wxEventType wxEVT_LEFT_DOWN
- wxEventType wxEVT_LEFT_UP
- wxEventType wxEVT_MIDDLE_DOWN
- wxEventType wxEVT_MIDDLE_UP
- wxEventType wxEVT_RIGHT_DOWN
- wxEventType wxEVT_RIGHT_UP
- wxEventType wxEVT_MOTION
- wxEventType wxEVT_ENTER_WINDOW
- wxEventType wxEVT_LEAVE_WINDOW
- wxEventType wxEVT_LEFT_DCLICK
- wxEventType wxEVT_MIDDLE_DCLICK
- wxEventType wxEVT_RIGHT_DCLICK
- wxEventType wxEVT_SET_FOCUS
- wxEventType wxEVT_KILL_FOCUS
- wxEventType wxEVT_CHILD_FOCUS
- wxEventType wxEVT_MOUSEWHEEL
- wxEventType wxEVT_AUX1_DOWN
- wxEventType wxEVT_AUX1_UP
- wxEventType wxEVT_AUX1_DCLICK
- wxEventType wxEVT_AUX2_DOWN
- wxEventType wxEVT_AUX2_UP
- wxEventType wxEVT_AUX2_DCLICK
- wxEventType wxEVT_CHAR
- wxEventType wxEVT_CHAR_HOOK
- wxEventType wxEVT_NAVIGATION_KEY
- wxEventType wxEVT_KEY_DOWN
- wxEventType wxEVT_KEY_UP
- wxEventType wxEVT_HOTKEY
- wxEventType wxEVT_SET_CURSOR
- wxEventType wxEVT_SCROLL_TOP
- wxEventType wxEVT_SCROLL_BOTTOM

- wxEventType wxEVT_SCROLL_LINEUP
- wxEventType wxEVT_SCROLL_LINEDOWN
- wxEventType wxEVT_SCROLL_PAGEUP
- wxEventType wxEVT_SCROLL_PAGEDOWN
- wxEventType wxEVT_SCROLL_THUMBTRACK
- wxEventType wxEVT_SCROLL_THUMBRELEASE
- wxEventType wxEVT_SCROLL_CHANGED
- wxEventType wxEVT_SPIN_UP
- wxEventType wxEVT_SPIN_DOWN
- wxEventType wxEVT_SPIN
- wxEventType wxEVT_SCROLLWIN_TOP
- wxEventType wxEVT_SCROLLWIN_BOTTOM
- wxEventType wxEVT_SCROLLWIN_LINEUP
- wxEventType wxEVT_SCROLLWIN_LINEDOWN
- wxEventType wxEVT_SCROLLWIN_PAGEUP
- wxEventType wxEVT_SCROLLWIN_PAGEDOWN
- wxEventType wxEVT_SCROLLWIN_THUMBTRACK
- wxEventType wxEVT_SCROLLWIN_THUMBRELEASE
- wxEventType wxEVT_SIZE
- wxEventType wxEVT_MOVE
- wxEventType wxEVT_CLOSE_WINDOW
- wxEventType wxEVT_END_SESSION
- wxEventType wxEVT_QUERY_END_SESSION
- wxEventType wxEVT_ACTIVATE_APP
- wxEventType wxEVT_ACTIVATE
- wxEventType wxEVT_CREATE
- wxEventType wxEVT_DESTROY
- wxEventType wxEVT_SHOW
- wxEventType wxEVT_ICONIZE
- wxEventType wxEVT_MAXIMIZE
- wxEventType wxEVT_MOUSE_CAPTURE_CHANGED
- wxEventType wxEVT_MOUSE_CAPTURE_LOST
- wxEventType wxEVT_PAINT
- wxEventType wxEVT_ERASE_BACKGROUND
- wxEventType wxEVT_NC_PAINT
- wxEventType wxEVT_MENU_OPEN
- wxEventType wxEVT_MENU_CLOSE
- wxEventType wxEVT_MENU_HIGHLIGHT
- wxEventType wxEVT_CONTEXT_MENU
- wxEventType wxEVT_SYS_COLOUR_CHANGED
- wxEventType wxEVT_DISPLAY_CHANGED
- wxEventType wxEVT_QUERY_NEW_PALETTE
- wxEventType wxEVT_PALETTE_CHANGED
- wxEventType wxEVT_JOY_BUTTON_DOWN
- wxEventType wxEVT_JOY_BUTTON_UP
- wxEventType wxEVT_JOY_MOVE
- wxEventType wxEVT_JOY_ZMOVE
- wxEventType wxEVT_DROP_FILES
- wxEventType wxEVT_INIT_DIALOG
- wxEventType wxEVT_IDLE
- wxEventType wxEVT_UPDATE_UI
- wxEventType wxEVT_SIZING
- wxEventType wxEVT_MOVING
- wxEventType wxEVT_MOVE_START
- wxEventType wxEVT_MOVE_END

- wxEventType wxEVT_HIBERNATE
- wxEventType wxEVT_TEXT_COPY
- wxEventType wxEVT_TEXT_CUT
- wxEventType wxEVT_TEXT_PASTE
- wxEventType wxEVT_COMMAND_LEFT_CLICK
- wxEventType wxEVT_COMMAND_LEFT_DCLICK
- wxEventType wxEVT_COMMAND_RIGHT_CLICK
- wxEventType wxEVT_COMMAND_RIGHT_DCLICK
- wxEventType wxEVT_COMMAND_SET_FOCUS
- wxEventType wxEVT_COMMAND_KILL_FOCUS
- wxEventType wxEVT_COMMAND_ENTER
- wxEventType wxEVT_HELP
- wxEventType wxEVT_DETAILED_HELP
- wxEventType wxEVT_TOOL
- wxEventType wxEVT_WINDOW_MODAL_DIALOG_CLOSED

20.21.2 Macro Definition Documentation

#define wx__DECLARE_EVT0(*evt, fn*) wx__DECLARE_EVT1(evt, wxID_ANY, fn)

Simplified version of the wx__DECLARE_EVT1() macro, to be used when the event type must be handled regardless of the ID associated with the specific event instances.

#define wx__DECLARE_EVT1(*evt, id, fn*) wx__DECLARE_EVT2(evt, id, wxID_ANY, fn)

This macro is used to define event table macros for handling custom events.

Example of use:

```
1 class MyEvent : public wxEvent { ... };
2
3 // note that this is not necessary unless using old compilers: for the
4 // reasonably new ones just use &func instead of MyEventHandler(func)
5 typedef void (wxEvtHandler::*MyEventFunction)(MyEvent&);
6 #define MyEventHandler(func) wxEVENT_HANDLER_CAST(MyEventFunction, func)
7
8 wxDEFINE_EVENT(MY_EVENT_TYPE, MyEvent);
9
10 #define EVT_MY(id, func) \
11     wx__DECLARE_EVT1(MY_EVENT_TYPE, id, MyEventHandler(func))
12
13 ...
14
15 wxBEGIN_EVENT_TABLE(MyFrame, wxFrame)
16     EVT_MY(wxID_ANY, MyFrame::OnMyEvent)
17 wxEND_EVENT_TABLE()
```

Parameters

evt	The event type to handle.
id	The identifier of events to handle.
fn	The event handler method.

#define wx__DECLARE_EVT2(*evt, id1, id2, fn*) DECLARE_EVENT_TABLE_ENTRY(evt, id1, id2, fn, NULL),

Generalized version of the wx__DECLARE_EVT1() macro taking a range of IDs instead of a single one.

Argument *id1* is the first identifier of the range, *id2* is the second identifier of the range.

#define wxBEGIN_EVENT_TABLE(*theClass, baseClass*)

Use this macro in a source file to start listing *static* event handlers for a specific class.

Use wxEND_EVENT_TABLE() to terminate the event-declaration block.

See also

Event Handling with Event Tables

#define wxDECLARE_EVENT(*name, cls*) wxDECLARE_EXPORTED_EVENT(wxEMPTY_PARAMETER_VALUE, name, cls)

Declares a custom event type.

This macro declares a variable called *name* which must be defined elsewhere using wxDEFINE_EVENT().

The class *cls* must be the wxEvent-derived class associated with the events of this type and its full declaration must be visible from the point of use of this macro.

For example:

```
1 wxDECLARE_EVENT(MY_COMMAND_EVENT, wxCommandEvent);
2
3 class MyCustomEvent : public wxEvent { ... };
4 wxDECLARE_EVENT(MY_CUSTOM_EVENT, MyCustomEvent);
```

#define wxDECLARE_EVENT_TABLE( )

Use this macro inside a class declaration to declare a *static* event table for that class.

In the implementation file you'll need to use the wxBEGIN_EVENT_TABLE() and the wxEND_EVENT_TABLE() macros, plus some additional `EVT_xxx` macro to capture events.

Note that this macro requires a final semicolon.

See also

Event Handling with Event Tables

#define wxDECLARE_EXPORTED_EVENT(*expdecl, name, cls*) extern const expdecl wxEventTypeTag< cls > name;

Variant of wxDECLARE_EVENT() used for event types defined inside a shared library.

This is mostly used by wxWidgets internally, e.g.

```
1 wxDECLARE_EXPORTED_EVENT(WXDLLIMPEXP_CORE, wxEVT_BUTTON, wxCommandEvent)
```

#define wxDEFINE_EVENT(*name, cls*) const wxEventTypeTag< cls > name(wxNewEventType())

Define a new event type associated with the specified event class.

This macro defines a new unique event type *name* associated with the event class *cls*.

For example:

```
1 wxDEFINE_EVENT(MY_COMMAND_EVENT, wxCommandEvent);
2
3 class MyCustomEvent : public wxEvent { ... };
4 wxDEFINE_EVENT(MY_CUSTOM_EVENT, MyCustomEvent);
```

See also

wxDECLARE_EVENT(), Custom Event Summary

#define wxEND_EVENT_TABLE( )

Use this macro in a source file to end listing *static* event handlers for a specific class.

Use wxBEGIN_EVENT_TABLE() to start the event-declaration block.

See also

Event Handling with Event Tables

#define wxEVENT_HANDLER_CAST(*functype, func*) (&func)

Helper macro for definition of custom event table macros.

This macro must only be used if wxEVENTS_COMPATIBILITY_2_8 is 1, otherwise it is better and more clear to just use the address of the function directly as this is all this macro does in this case. However it needs to explicitly cast *func* to *functype*, which is the type of wxEvtHandler member function taking the custom event argument when wxEVENTS_COMPATIBILITY_2_8 is 0.

See wx__DECLARE_EVT0 for an example of use.

See also

Defining Your Own Event Class

20.21.3 Typedef Documentation

typedef int wxEventType

A value uniquely identifying the type of the event.

The values of this type should only be created using wxNewEventType().

See the macro DEFINE_EVENT_TYPE() for more info.

See also

Events and Event Handling

20.21.4 Function Documentation

wxEventType wxNewEventType ( )

Generates a new unique event type.

Usually this function is only used by wxDEFINE_EVENT() and not called directly.

void wxPostEvent (wxEvtHandler * *dest,* const wxEvent & *event*)

In a GUI application, this function posts *event* to the specified *dest* object using wxEvtHandler::AddPendingEvent().

Otherwise, it dispatches *event* immediately using wxEvtHandler::ProcessEvent(). See the respective documentation for details (and caveats). Because of limitation of wxEvtHandler::AddPendingEvent() this function is not thread-safe for event objects having wxString fields, use wxQueueEvent() instead.

Include file:

```
#include <wx/event.h>
```

void wxQueueEvent (wxEvtHandler * *dest,* wxEvent * *event*)

Queue an event for processing on the given object.

This is a wrapper around wxEvtHandler::QueueEvent(), see its documentation for more details.

Include file:

```
#include <wx/event.h>
```

Parameters

dest	The object to queue the event on, can't be NULL.
event	The heap-allocated and non-NULL event to queue, the function takes ownership of it.

20.22 File Handling

20.22.1 Detailed Description

wxWidgets has several small classes to work with disk files and directories.

Related Overviews: File Classes and Functions

Related macros/global-functions group: Files and Directories

Classes

- class wxDirTraverser

  wxDirTraverser is an abstract interface which must be implemented by objects passed to wxDir::Traverse() function.
- class wxDir

  wxDir is a portable equivalent of Unix open/read/closedir functions which allow enumerating of the files in a directory.
- class wxFFile

  wxFFile implements buffered file I/O.
- class wxTempFile

  wxTempFile provides a relatively safe way to replace the contents of the existing file.
- class wxFile

  A wxFile performs raw file I/O.
- class wxPathList

  The path list is a convenient way of storing a number of directories, and when presented with a filename without a directory, searching for an existing file in those directories.
- class wxFileName

  wxFileName encapsulates a file name.
- class wxFSFile

  This class represents a single file opened by wxFileSystem.
- class wxFileSystemWatcher

  The wxFileSystemWatcher class allows to receive notifications of file system changes.
- class wxStandardPaths

  wxStandardPaths returns the standard locations in the file system and should be used by applications to find their data files in a portable way.
- class wxTextFile

  The wxTextFile is a simple class which allows to work with text files on line by line basis.

20.23 Files and Directories

20.23.1 Detailed Description

These functions provide a platform-independent API for common file and directory functionality.

Related class group: File Handling

Macros

- #define wxCHANGE_UMASK(mask)

  Under Unix this macro changes the current process umask to the given value, unless it is equal to -1 in which case nothing is done, and restores it to the original value on scope exit.

Typedefs

- typedef off_t wxFileOffset

  The type used to store and provide byte offsets or byte sizes for files or streams.

Enumerations

- enum wxPosixPermissions {
  wxS_IRUSR = 00400,
  wxS_IWUSR = 00200,
  wxS_IXUSR = 00100,
  wxS_IRGRP = 00040,
  wxS_IWGRP = 00020,
  wxS_IXGRP = 00010,
  wxS_IROTH = 00004,
  wxS_IWOTH = 00002,
  wxS_IXOTH = 00001,
  wxPOSIX_USER_READ = wxS_IRUSR,
  wxPOSIX_USER_WRITE = wxS_IWUSR,
  wxPOSIX_USER_EXECUTE = wxS_IXUSR,
  wxPOSIX_GROUP_READ = wxS_IRGRP,
  wxPOSIX_GROUP_WRITE = wxS_IWGRP,
  wxPOSIX_GROUP_EXECUTE = wxS_IXGRP,
  wxPOSIX_OTHERS_READ = wxS_IROTH,
  wxPOSIX_OTHERS_WRITE = wxS_IWOTH,
  wxPOSIX_OTHERS_EXECUTE = wxS_IXOTH,
  wxS_DEFAULT,
  wxS_DIR_DEFAULT }

  File permission bit names.
- enum wxSeekMode {
  wxFromStart,
  wxFromCurrent,
  wxFromEnd }

  Parameter indicating how file offset should be interpreted.
- enum wxFileKind {
  wxFILE_KIND_UNKNOWN,
  wxFILE_KIND_DISK,
  wxFILE_KIND_TERMINAL,
  wxFILE_KIND_PIPE }

  File kind enumerations returned from wxGetFileKind().

Functions

- bool wxTransferFileToStream (const wxString &filename, ostream &stream)

  Copies the given file to stream.
- bool wxTransferStreamToFile (istream &stream, const wxString &filename)

  Copies the given stream to the file filename.
- bool wxGetDiskSpace (const wxString &path, wxLongLong total=NULL, wxLongLong free=NULL)

  This function returns the total number of bytes and number of free bytes on the disk containing the directory path (it should exist).
- wxString wxGetOSDirectory ()

  Returns the Windows directory under Windows; other platforms return an empty string.
- int wxParseCommonDialogsFilter (const wxString &wildCard, wxArrayString &descriptions, wxArrayString &filters)

  Parses the wildCard, returning the number of filters.
- void wxDos2UnixFilename (wxChar *s)

  Converts a DOS to a Unix filename by replacing backslashes with forward slashes.
- void wxUnix2DosFilename (wxChar *s)

  Converts a Unix to a DOS filename by replacing forward slashes with backslashes.
- bool wxDirExists (const wxString &dirname)

  Returns true if dirname exists and is a directory.
- void wxSplitPath (const wxString &fullname, wxString *path, wxString *name, wxString *ext)
- time_t wxFileModificationTime (const wxString &filename)

  Returns time of last modification of given file.
- bool wxRenameFile (const wxString &file1, const wxString &file2, bool overwrite=true)

  Renames file1 to file2, returning true if successful.
- bool wxCopyFile (const wxString &file1, const wxString &file2, bool overwrite=true)

  Copies file1 to file2, returning true if successful.
- bool wxFileExists (const wxString &filename)

  Returns true if the file exists and is a plain file.
- bool wxMatchWild (const wxString &pattern, const wxString &text, bool dot_special)

  Returns true if the pattern matches the text; if dot_special is true, filenames beginning with a dot are not matched with wildcard characters.
- wxString wxGetWorkingDirectory (char *buf=NULL, int sz=1000)
- wxString wxPathOnly (const wxString &path)

  Returns the directory part of the filename.
- bool wxIsWild (const wxString &pattern)

  Returns true if the pattern contains wildcards.
- bool wxIsAbsolutePath (const wxString &filename)

  Returns true if the argument is an absolute filename, i.e. with a slash or drive name at the beginning.
- wxString wxGetCwd ()

  Returns a string containing the current (or working) directory.
- bool wxSetWorkingDirectory (const wxString &dir)

  Sets the current working directory, returning true if the operation succeeded.
- bool wxConcatFiles (const wxString &file1, const wxString &file2, const wxString &file3)

  Concatenates file1 and file2 to file3, returning true if successful.
- bool wxRemoveFile (const wxString &file)

  Removes file, returning true if successful.
- bool wxMkdir (const wxString &dir, int perm=wxS_DIR_DEFAULT)

  Makes the directory dir, returning true if successful.
- bool wxRmdir (const wxString &dir, int flags=0)

  Removes the directory dir, returning true if successful.
- wxString wxFindNextFile ()

Returns the next file that matches the path passed to wxFindFirstFile().

- wxString wxFindFirstFile (const wxString &spec, int flags=0)

  This function does directory searching; returns the first file that matches the path spec, or the empty string.
- wxFileKind wxGetFileKind (int fd)

  Returns the type of an open file.
- wxFileKind wxGetFileKind (FILE *fp)
- wxString wxFileNameFromPath (const wxString &path)
- char * wxFileNameFromPath (char *path)
- char * wxGetTempFileName (const wxString &prefix, char *buf=NULL)
- bool wxGetTempFileName (const wxString &prefix, wxString &buf)

Variables

- const int wxInvalidOffset = -1

  A special return value of many wxWidgets classes to indicate that an invalid offset was given.

20.23.2 Macro Definition Documentation

#define wxCHANGE_UMASK(*mask*)

Under Unix this macro changes the current process umask to the given value, unless it is equal to -1 in which case nothing is done, and restores it to the original value on scope exit.

It works by declaring a variable which sets umask to *mask* in its constructor and restores it in its destructor. Under other platforms this macro expands to nothing.

Include file:

```
#include <wx/filefn.h>
```

20.23.3 Typedef Documentation

typedef off_t wxFileOffset

The type used to store and provide byte offsets or byte sizes for files or streams.

This type is usually just a synonym for `off_t` but can be defined as `wxLongLong_t` if `wxHAS_HUGE_FILES` is defined but `off_t` is only 32 bits.

20.23.4 Enumeration Type Documentation

enum wxFileKind

File kind enumerations returned from wxGetFileKind().

Also used by wxFFile::GetKind() and wxFile::GetKind().

Include file:

```
#include <wx/filefn.h>
```

Enumerator

wxFILE_KIND_UNKNOWN Unknown file kind, or unable to determine.

wxFILE_KIND_DISK A file supporting seeking to arbitrary offsets.

wxFILE_KIND_TERMINAL A tty.

wxFILE_KIND_PIPE A pipe.

enum wxPosixPermissions

File permission bit names.

We define these constants in wxWidgets because S_IREAD &c are not standard. However, we do assume that the values correspond to the Unix umask bits.

Enumerator

wxS_IRUSR Standard POSIX names for these permission flags with "wx" prefix.

wxS_IWUSR Standard POSIX names for these permission flags with "wx" prefix.

wxS_IXUSR Standard POSIX names for these permission flags with "wx" prefix.

wxS_IRGRP Standard POSIX names for these permission flags with "wx" prefix.

wxS_IWGRP Standard POSIX names for these permission flags with "wx" prefix.

wxS_IXGRP Standard POSIX names for these permission flags with "wx" prefix.

wxS_IROTH Standard POSIX names for these permission flags with "wx" prefix.

wxS_IWOTH Standard POSIX names for these permission flags with "wx" prefix.

wxS_IXOTH Standard POSIX names for these permission flags with "wx" prefix.

wxPOSIX_USER_READ Longer but more readable synonyms for the constants above.

wxPOSIX_USER_WRITE Longer but more readable synonyms for the constants above.

wxPOSIX_USER_EXECUTE Longer but more readable synonyms for the constants above.

wxPOSIX_GROUP_READ Longer but more readable synonyms for the constants above.

wxPOSIX_GROUP_WRITE Longer but more readable synonyms for the constants above.

wxPOSIX_GROUP_EXECUTE Longer but more readable synonyms for the constants above.

wxPOSIX_OTHERS_READ Longer but more readable synonyms for the constants above.

wxPOSIX_OTHERS_WRITE Longer but more readable synonyms for the constants above.

wxPOSIX_OTHERS_EXECUTE Longer but more readable synonyms for the constants above.

wxS_DEFAULT Default mode for the new files: allow reading/writing them to everybody but the effective file mode will be set after ANDing this value with umask and so won't include wxS_IW{GRP,OTH} for the default 022 umask value.

wxS_DIR_DEFAULT Default mode for the new directories (see wxFileName::Mkdir): allow reading/writing/executing them to everybody, but just like wxS_DEFAULT the effective directory mode will be set after ANDing this value with umask.

enum wxSeekMode

Parameter indicating how file offset should be interpreted.

This is used by wxFFile::Seek() and wxFile::Seek().

Include file:

```
#include <wx/filefn.h>
```

Enumerator

wxFromStart Seek from the file beginning.

wxFromCurrent Seek from the current position.

wxFromEnd Seek from end of the file.

20.23.5 Function Documentation

bool wxConcatFiles (const wxString & *file1,* const wxString & *file2,* const wxString & *file3*)

Concatenates *file1* and *file2* to *file3*, returning true if successful.

Include file:

```
#include <wx/filefn.h>
```

bool wxCopyFile (const wxString & *file1,* const wxString & *file2,* bool *overwrite* = `true`)

Copies *file1* to *file2*, returning true if successful.

If *overwrite* parameter is true (default), the destination file is overwritten if it exists, but if *overwrite* is false, the functions fails in this case.

This function supports resources forks under Mac OS.

Include file:

```
#include <wx/filefn.h>
```

bool wxDirExists (const wxString & *dirname*)

Returns true if *dirname* exists and is a directory.

Include file:

```
#include <wx/filefn.h>
```

void wxDos2UnixFilename (wxChar * *s*)

Converts a DOS to a Unix filename by replacing backslashes with forward slashes.

Deprecated Construct a wxFileName with wxPATH_DOS and then use wxFileName::GetFullPath(wxPATH_UNIX) instead.

Include file:

```
#include <wx/filefn.h>
```

bool wxFileExists (const wxString & *filename*)

Returns true if the file exists and is a plain file.

Include file:

```
#include <wx/filefn.h>
```

time_t wxFileModificationTime (const wxString & *filename*)

Returns time of last modification of given file.

The function returns `(time_t)-1` if an error occurred (e.g. file not found).

Include file:

```
#include <wx/filefn.h>
```

wxString wxFileNameFromPath (const wxString & *path*)

Deprecated This function is obsolete, please use wxFileName::SplitPath() instead.

Returns the filename for a full path. The second form returns a pointer to temporary storage that should not be deallocated.

Include file:

```
#include <wx/filefn.h>
```

char* wxFileNameFromPath (char * *path*)

wxString wxFindFirstFile (const wxString & *spec*, int *flags* = 0)

This function does directory searching; returns the first file that matches the path *spec*, or the empty string.

Use wxFindNextFile() to get the next matching file. Neither will report the current directory "." or the parent directory "..".

Warning

> As of 2.5.2, these functions are not thread-safe! (they use static variables). You probably want to use wxDir::GetFirst() or wxDirTraverser instead.

spec may contain wildcards.

flags may be wxDIR for restricting the query to directories, wxFILE for files or zero for either.

For example:

```
1 wxString f = wxFindFirstFile("/home/project/*.*");
2 while ( !f.empty() )
3 {
4     ...
5     f = wxFindNextFile();
6 }
```

Include file:

```
#include <wx/filefn.h>
```

wxString wxFindNextFile ( )

Returns the next file that matches the path passed to wxFindFirstFile().

See wxFindFirstFile() for an example.

Include file:

```
#include <wx/filefn.h>
```

wxString wxGetCwd ( )

Returns a string containing the current (or working) directory.

Include file:

```
#include <wx/filefn.h>
```

bool wxGetDiskSpace (const wxString & *path*, wxLongLong *total* = NULL, wxLongLong *free* = NULL)

This function returns the total number of bytes and number of free bytes on the disk containing the directory *path* (it should exist).

Both *total* and *free* parameters may be NULL if the corresponding information is not needed.

Since

2.3.2

Note

The generic Unix implementation depends on the system having the `statfs()` or `statvfs()` function.

Returns

true on success, false if an error occurred (for example, the directory doesn't exist).

Include file:

```
#include <wx/filefn.h>
```

wxFileKind wxGetFileKind (int *fd*)

Returns the type of an open file.

Possible return values are enumerations of wxFileKind.

Include file:

```
#include <wx/filefn.h>
```

wxFileKind wxGetFileKind (FILE * *fp*)

wxString wxGetOSDirectory ( )

Returns the Windows directory under Windows; other platforms return an empty string.

Include file:

```
#include <wx/filefn.h>
```

char* wxGetTempFileName (const wxString & *prefix*, char * *buf* = NULL)

Deprecated This function is obsolete, please use wxFileName::CreateTempFileName() instead.

Include file:

```
#include <wx/filefn.h>
```

bool wxGetTempFileName (const wxString & *prefix,* wxString & *buf*)

wxString wxGetWorkingDirectory (char * *buf* = NULL, int *sz* = 1000)

Deprecated This function is deprecated, use wxGetCwd() instead.

Copies the current working directory into the buffer if supplied, or copies the working directory into new storage (which you must delete yourself) if the buffer is NULL.

sz is the size of the buffer if supplied.

Include file:

```
#include <wx/filefn.h>
```

bool wxIsAbsolutePath (const wxString & *filename*)

Returns true if the argument is an absolute filename, i.e. with a slash or drive name at the beginning.

Include file:

```
#include <wx/filefn.h>
```

bool wxIsWild (const wxString & *pattern*)

Returns true if the pattern contains wildcards.

See also

wxMatchWild()

Include file:

```
#include <wx/filefn.h>
```

bool wxMatchWild (const wxString & *pattern,* const wxString & *text,* bool *dot_special*)

Returns true if the *pattern* matches the *text*; if *dot_special* is true, filenames beginning with a dot are not matched with wildcard characters.

See also

wxIsWild()

Include file:

```
#include <wx/filefn.h>
```

bool wxMkdir (const wxString & *dir,* int *perm* = wxS_DIR_DEFAULT)

Makes the directory *dir*, returning true if successful.

perm is the access mask for the directory for the systems on which it is supported (Unix) and doesn't have any effect on the other ones.

Include file:

```
#include <wx/filefn.h>
```

int wxParseCommonDialogsFilter (const wxString & *wildCard,* wxArrayString & *descriptions,* wxArrayString & *filters*)

Parses the *wildCard*, returning the number of filters.

Returns 0 if none or if there's a problem.

The arrays will contain an equal number of items found before the error. On platforms where native dialogs handle only one filter per entry, entries in arrays are automatically adjusted. *wildCard* is in the form:

```
1 "All files (*)|*|Image Files (*.jpeg *.png)|*.jpg;*.png"
```

Include file:

```
#include <wx/filefn.h>
```

wxString wxPathOnly (const wxString & *path*)

Returns the directory part of the filename.

Include file:

```
#include <wx/filefn.h>
```

bool wxRemoveFile (const wxString & *file*)

Removes *file*, returning true if successful.

Include file:

```
#include <wx/filefn.h>
```

bool wxRenameFile (const wxString & *file1,* const wxString & *file2,* bool *overwrite* = `true`)

Renames *file1* to *file2*, returning true if successful.

If *file2* is a directory, *file1* is moved into it (*overwrite* is ignored in this case). Otherwise, if *file2* is an existing file, it is overwritten if *overwrite* is true (default) and the function fails if *overwrite* is false.

Include file:

```
#include <wx/filefn.h>
```

bool wxRmdir (const wxString & *dir,* int *flags* = `0`)

Removes the directory *dir*, returning true if successful.

Does not work under VMS.

The *flags* parameter is reserved for future use.

Note

There is also a wxRmDir() function which simply wraps the standard POSIX `rmdir()` function and so return an integer error code instead of a boolean value (but otherwise is currently identical to wxRmdir()), don't confuse these two functions.

Include file:

```
#include <wx/filefn.h>
```

bool wxSetWorkingDirectory (const wxString & *dir*)

Sets the current working directory, returning true if the operation succeeded.

Under MS Windows, the current drive is also changed if *dir* contains a drive specification.

Include file:

```
#include <wx/filefn.h>
```

void wxSplitPath (const wxString & *fullname,* wxString * *path,* wxString * *name,* wxString * *ext*)

Deprecated This function is obsolete, please use wxFileName::SplitPath() instead.

This function splits a full file name into components: the path (including possible disk/drive specification under Windows), the base name, and the extension. Any of the output parameters (*path*, *name* or *ext*) may be NULL if you are not interested in the value of a particular component.

wxSplitPath() will correctly handle filenames with both DOS and Unix path separators under Windows, however it will not consider backslashes as path separators under Unix (where backslash is a valid character in a filename).

On entry, *fullname* should be non-NULL (it may be empty though).

On return, *path* contains the file path (without the trailing separator), *name* contains the file name and `ext` contains the file extension without leading dot. All three of them may be empty if the corresponding component is. The old contents of the strings pointed to by these parameters will be overwritten in any case (if the pointers are not NULL).

Include file:

```
#include <wx/filefn.h>
```

bool wxTransferFileToStream (const wxString & *filename,* ostream & *stream*)

Copies the given file to *stream*.

Useful when converting an old application to use streams (within the document/view framework, for example).

Include file:

```
#include <wx/docview.h>
```

bool wxTransferStreamToFile (istream & *stream,* const wxString & *filename*)

Copies the given stream to the file *filename*.

Useful when converting an old application to use streams (within the document/view framework, for example).

Include file:

```
#include <wx/docview.h>
```

void wxUnix2DosFilename (wxChar * *s*)

Converts a Unix to a DOS filename by replacing forward slashes with backslashes.

Deprecated Construct a wxFileName with wxPATH_UNIX and then use wxFileName::GetFullPath(wxPATH_DOS) instead.

Include file:

```
#include <wx/filefn.h>
```

20.23.6 Variable Documentation

const int wxInvalidOffset = -1

A special return value of many wxWidgets classes to indicate that an invalid offset was given.

20.24 Functions and Macros by Category

20.24.1 Detailed Description

This group defines all major function and macro groups.

Modules

- Application Initialization and Termination

  The functions in this section are used on application startup/shutdown and also to control the behaviour of the main event loop of the GUI programs.
- Atomic Operations

  When using multi-threaded applications, it is often required to access or modify memory which is shared between threads.
- Byte Order

  The endian-ness issues (that is the difference between big-endian and little-endian architectures) are important for the portable programs working with the external binary data (for example, data files or data coming from network) which is usually in some fixed, platform-independent format.
- Debugging macros

  Useful macros and functions for error checking and defensive programming.
- Dialogs

  Below are a number of convenience functions for getting input from the user or displaying messages.
- Environment

  These functions allow access to get or change the values of environment variables in a portable way.
- Events

  Below are a number of functions/macros used with wxWidgets event-handling system.
- Files and Directories

  These functions provide a platform-independent API for common file and directory functionality.
- Graphics Device Interface (GDI)

  The following are functions and macros related to GDI (Graphics Device Interface) access.
- Locale-dependent functions

  Below are a number of functions/macros which accept as last parameter a specific wxXLocale instance.
- Logging

  These functions provide a variety of logging functions.
- Math

  The functions in this section are typically related with math operations and floating point numbers.
- Miscellaneous

  Group of miscellaneous functions and macros.
- Network, User and OS

  The functions in this section are used to retrieve information about the current computer and/or user characteristics.
- Process Control

  The functions in this section are used to launch or terminate the other processes.
- Runtime Type Information (RTTI)

  wxWidgets uses its own RTTI ("run-time type identification") system which predates the current standard C++ RTTI and so is kept for backwards compatibility reasons but also because it allows some things which the standard RTTI doesn't directly support (such as creating a class from its name).
- Strings

  Global string functions and macros.
- Threads

  The functions and macros here mainly exist to make it possible to write code which may be compiled in multi thread build (wxUSE_THREADS = 1) as well as in single thread configuration (wxUSE_THREADS = 0).
- Time

The functions in this section deal with getting the current time and sleeping for the specified time interval.

- Versioning

  The following constants are defined in wxWidgets:

- Wrappers of CRT functions

  For documentation of these functions please refer to the documentation of the standard CRT functions (see e.g. http://www.cppreference.com/wiki/c/start*).*

20.25 Graphics Device Interface (GDI)

20.25.1 Detailed Description

The following are classes related to GDI (Graphics Device Interface) access.

They provide an API for drawing on device contexts, windows, and printing.

Related Overviews: Device Contexts, Bitmaps and Icons

Related macros/global-functions group: Graphics Device Interface (GDI)

Classes

- struct wxFontMetrics

  Simple collection of various font metrics.
- class wxGraphicsGradientStop

  Represents a single gradient stop in a collection of gradient stops as represented by wxGraphicsGradientStops.
- class wxGraphicsGradientStops

  Represents a collection of wxGraphicGradientStop values for use with CreateLinearGradientBrush and Create↩ RadialGradientBrush.
- class wxAnimation

  This class encapsulates the concept of a platform-dependent animation.
- class wxBitmapHandler

  This is the base class for implementing bitmap file loading/saving, and bitmap creation from data.
- class wxBitmap

  This class encapsulates the concept of a platform-dependent bitmap, either monochrome or colour or colour with alpha channel support.
- class wxMask

  This class encapsulates a monochrome mask bitmap, where the masked area is black and the unmasked area is white.
- class wxBrush

  A brush is a drawing tool for filling in areas.
- class wxBrushList

  A brush list is a list containing all brushes which have been created.
- class wxColour

  A colour is an object representing a combination of Red, Green, and Blue (RGB) intensity values, and is used to determine drawing colours.
- class wxCursor

  A cursor is a small bitmap usually used for denoting where the mouse pointer is, with a picture that might indicate the interpretation of a mouse click.
- class wxDC

  A wxDC is a "device context" onto which graphics and text can be drawn.
- class wxDCClipper

  wxDCClipper is a helper class for setting a clipping region on a wxDC during its lifetime.
- class wxDCBrushChanger

  wxDCBrushChanger is a small helper class for setting a brush on a wxDC and unsetting it automatically in the destructor, restoring the previous one.
- class wxDCPenChanger

  wxDCPenChanger is a small helper class for setting a pen on a wxDC and unsetting it automatically in the destructor, restoring the previous one.
- class wxDCTextColourChanger

  wxDCTextColourChanger is a small helper class for setting a foreground text colour on a wxDC and unsetting it automatically in the destructor, restoring the previous one.

- class wxDCFontChanger

  wxDCFontChanger is a small helper class for setting a font on a wxDC and unsetting it automatically in the destructor, restoring the previous one.
- class wxFont

  A font is an object which determines the appearance of text.
- class wxFontList

  A font list is a list containing all fonts which have been created.
- class wxFontEnumerator

  wxFontEnumerator enumerates either all available fonts on the system or only the ones with given attributes - either only fixed-width (suited for use in programs such as terminal emulators and the like) or the fonts available in the given encoding).
- class wxNativeFontInfo

  wxNativeFontInfo is platform-specific font representation: this class should be considered as an opaque font description only used by the native functions, the user code can only get the objects of this type from somewhere and pass it somewhere else (possibly save them somewhere using ToString() and restore them using FromString())
- class wxColourDatabase

  wxWidgets maintains a database of standard RGB colours for a predefined set of named colours.
- class wxGDIObject

  This class allows platforms to implement functionality to optimise GDI objects, such as wxPen, wxBrush and wxFont.
- class wxGraphicsPath

  A wxGraphicsPath is a native representation of a geometric path.
- class wxGraphicsObject

  This class is the superclass of native graphics objects like pens etc.
- class wxGraphicsContext

  A wxGraphicsContext instance is the object that is drawn upon.
- class wxGraphicsRenderer

  A wxGraphicsRenderer is the instance corresponding to the rendering engine used.
- class wxGraphicsBrush

  A wxGraphicsBrush is a native representation of a brush.
- class wxGraphicsFont

  A wxGraphicsFont is a native representation of a font.
- class wxGraphicsPen

  A wxGraphicsPen is a native representation of a pen.
- class wxGraphicsMatrix

  A wxGraphicsMatrix is a native representation of an affine matrix.
- class wxIcon

  An icon is a small rectangular bitmap usually used for denoting a minimized application.
- class wxIconBundle

  This class contains multiple copies of an icon in different sizes.
- class wxIconLocation

  wxIconLocation is a tiny class describing the location of an (external, i.e.
- class wxImageHandler

  This is the base class for implementing image file loading/saving, and image creation from data.
- class wxImage

  This class encapsulates a platform-independent image.
- class wxImageList

  A wxImageList contains a list of images, which are stored in an unspecified form.
- class wxMetafile

  *A **wxMetafile** represents the MS Windows metafile object, so metafile operations have no effect in X.*
- class wxPalette

  A palette is a table that maps pixel values to RGB colours.
- class wxPen

A pen is a drawing tool for drawing outlines.

- class wxPenList

  There is only one instance of this class: wxThePenList.

- class wxPixelData< Image, PixelFormat >

  A class template with ready to use implementations for getting direct and efficient access to wxBitmap's internal data and wxImage's internal data through a standard interface.

- class wxRegionIterator

  This class is used to iterate through the rectangles in a region, typically when examining the damaged regions of a window within an OnPaint call.

- class wxRegion

  A wxRegion represents a simple or complex region on a device context or window.

- struct wxSplitterRenderParams

  This is just a simple `struct` used as a return value of wxRendererNative::GetSplitterParams().

- struct wxHeaderButtonParams

  This `struct` can optionally be used with wxRendererNative::DrawHeaderButton() to specify custom values used to draw the text or bitmap label.

- class wxDelegateRendererNative

  wxDelegateRendererNative allows reuse of renderers code by forwarding all the wxRendererNative methods to the given object and thus allowing you to only modify some of its methods – without having to reimplement all of them.

- class wxRendererNative

  First, a brief introduction to wxRendererNative and why it is needed.

- struct wxRendererVersion

  This simple struct represents the wxRendererNative interface version and is only used as the return value of wxRendererNative::GetVersion().

- class wxTextWrapper

  Helps wrap lines of text to given width.

20.26 Graphics Device Interface (GDI)

20.26.1 Detailed Description

The following are functions and macros related to GDI (Graphics Device Interface) access.

Related Overviews: Device Contexts

Related class group: Graphics Device Interface (GDI)

Macros

- #define wxDROP_ICON(name)

  This macro creates either a cursor (MSW) or an icon (elsewhere) with the given name (of type `const char*`).
- #define wxBITMAP(bitmapName)

  This macro loads a bitmap from either application resources (on the platforms for which they exist, i.e. Windows) or from an XPM file.
- #define wxBITMAP_PNG(bitmapName)

  Creates a bitmap from either application resources or embedded image data in PNG format.
- #define wxBITMAP_PNG_FROM_DATA(bitmapName)

  Creates a bitmap from embedded image data in PNG format.
- #define wxICON(iconName)

  This macro loads an icon from either application resources (on the platforms for which they exist, i.e. Windows) or from an XPM file.

Functions

- bool wxIsDragResultOk (wxDragResult res)

  Returns true if res indicates that something was done during a DnD operation, i.e.
- bool wxColourDisplay ()

  Returns true if the display is colour, false otherwise.
- int wxDisplayDepth ()

  Returns the depth of the display (a value of 1 denotes a monochrome display).
- void wxSetCursor (const wxCursor &cursor)

  Globally sets the cursor; only has an effect on Windows, Mac and GTK+.
- void wxClientDisplayRect (int *x, int *y, int *width, int *height)

  Returns the dimensions of the work area on the display.
- wxRect wxGetClientDisplayRect ()

  Returns the dimensions of the work area on the display.
- wxSize wxGetDisplayPPI ()

  Returns the display resolution in pixels per inch.
- void wxDisplaySize (int *width, int *height)

  Returns the display size in pixels.
- wxSize wxGetDisplaySize ()

  Returns the display size in pixels.
- void wxDisplaySizeMM (int *width, int *height)

  Returns the display size in millimeters.
- wxSize wxGetDisplaySizeMM ()

  Returns the display size in millimeters.
- bool wxMakeMetafilePlaceable (const wxString &filename, int minX, int minY, int maxX, int maxY, float scale=1.0)

  Given a filename for an existing, valid metafile (as constructed using wxMetafileDC) makes it into a placeable metafile by prepending a header containing the given bounding box.

20.26.2 Macro Definition Documentation

#define wxBITMAP(*bitmapName*)

This macro loads a bitmap from either application resources (on the platforms for which they exist, i.e. Windows) or from an XPM file.

This can help to avoid using #ifdef when creating bitmaps.

See also

Bitmaps and Icons, wxICON()

Include file:

```
#include <wx/gdicmn.h>
```

#define wxBITMAP_PNG(*bitmapName*)

Creates a bitmap from either application resources or embedded image data in PNG format.

This macro is similar to wxBITMAP() but works with bitmap data in PNG format and not BMP or XPM.

Under Windows the given *bitmapName* must be present in the application resource file with the type `RCDATA` and refer to a PNG image. I.e. you should have a definition similar to the following in your .rc file:

```
1 mybitmap    RCDATA  "mybitmap.png"
```

to be able to use `wxBITMAP_PNG(mybitmap)` in the code.

Under OS X the file with the specified name and "png" extension must be present in the "Resources" subdirectory of the application bundle.

Under the other platforms, this is equivalent to wxBITMAP_PNG_FROM_DATA() and so loads the image data from the array called `bitmapName_png` that must exist. Notice that it *must* be an array and not a pointer as the macro needs to be able to determine its size. Such an array can be produced by a number of conversion programs. A very simple one is included in wxWidgets distribution as `misc/scripts/png2c.py`.

Finally notice that you must register PNG image handler to be able to load bitmaps from PNG data. This can be done either by calling wxInitAllImageHandlers() which also registers all the other image formats or including the necessary header:

```
1 #include <wx/imagpng.h>
```

and calling

```
1 wxImage::AddHandler(new wxPNGHandler);
```

in your application startup code.

See also

wxBITMAP_PNG_FROM_DATA()

Include file:

```
#include <wx/gdicmn.h>
```

Since

2.9.5

#define wxBITMAP_PNG_FROM_DATA(*bitmapName*)

Creates a bitmap from embedded image data in PNG format.

This macro is a thin wrapper around wxBitmap::NewFromPNGData() and takes just the base name of the array containing the image data and computes its size internally. In other words, the array called `bitmapName_png` must exist. Notice that it *must* be an array and not a pointer as the macro needs to be able to determine its size. Such an array can be produced by a number of conversion programs. A very simple one is included in wxWidgets distribution as `misc/scripts/png2c.py`.

You can use wxBITMAP_PNG() to load the PNG bitmaps from resources on the platforms that support this and only fall back to loading them from data under the other ones (i.e. not Windows and not OS X).

Include file:

```
#include <wx/gdicmn.h>
```

Since

2.9.5

#define wxDROP_ICON(*name*)

This macro creates either a cursor (MSW) or an icon (elsewhere) with the given *name* (of type `const char*`).

Under MSW, the cursor is loaded from the resource file and the icon is loaded from XPM file under other platforms.

This macro should be used with wxDropSource::wxDropSource().

Returns

wxCursor on MSW, otherwise returns a wxIcon

Include file:

```
#include <wx/dnd.h>
```

#define wxICON(*iconName*)

This macro loads an icon from either application resources (on the platforms for which they exist, i.e. Windows) or from an XPM file.

This can help to avoid using #ifdef when creating icons.

See also

Bitmaps and Icons, wxBITMAP()

Include file:

```
#include <wx/gdicmn.h>
```

20.26.3 Function Documentation

void wxClientDisplayRect (int * *x*, int * *y*, int * *width*, int * *height*)

Returns the dimensions of the work area on the display.

This is the same as wxGetClientDisplayRect() but allows to retrieve the individual components instead of the entire rectangle.

Any of the output pointers can be NULL if the corresponding value is not needed by the caller.

See also

wxDisplay

Include file:

```
#include <wx/gdicmn.h>
```

bool wxColourDisplay ( )

Returns true if the display is colour, false otherwise.
Include file:

```
#include <wx/gdicmn.h>
```

int wxDisplayDepth ( )

Returns the depth of the display (a value of 1 denotes a monochrome display).
Include file:

```
#include <wx/gdicmn.h>
```

void wxDisplaySize (int * *width*, int * *height*)

Returns the display size in pixels.

Either of output pointers can be NULL if the caller is not interested in the corresponding value.

See also

wxGetDisplaySize(), wxDisplay

Include file:

```
#include <wx/gdicmn.h>
```

void wxDisplaySizeMM (int * *width*, int * *height*)

Returns the display size in millimeters.

Either of output pointers can be NULL if the caller is not interested in the corresponding value.

See also

wxGetDisplaySizeMM(), wxDisplay

Include file:

```
#include <wx/gdicmn.h>
```

wxRect wxGetClientDisplayRect ( )

Returns the dimensions of the work area on the display.

On Windows this means the area not covered by the taskbar, etc. Other platforms are currently defaulting to the whole display until a way is found to provide this info for all window managers, etc.

See also

wxDisplay

Include file:

```
#include <wx/gdicmn.h>
```

wxSize wxGetDisplayPPI ( )

Returns the display resolution in pixels per inch.

The `x` component of the returned wxSize object contains the horizontal resolution and the `y` one – the vertical resolution.

Include file:

```
#include <wx/gdicmn.h>
```

See also

wxDisplay

Since

2.9.0

wxSize wxGetDisplaySize ( )

Returns the display size in pixels.

See also

wxDisplay

Include file:

```
#include <wx/gdicmn.h>
```

wxSize wxGetDisplaySizeMM ( )

Returns the display size in millimeters.

See also

wxDisplay

Include file:

```
#include <wx/gdicmn.h>
```

bool wxIsDragResultOk (wxDragResult *res*)

Returns true if res indicates that something was done during a DnD operation, i.e.

is neither error nor none nor cancel.

bool wxMakeMetafilePlaceable (const wxString & *filename,* int *minX,* int *minY,* int *maxX,* int *maxY,* float *scale* = 1.0)

Given a filename for an existing, valid metafile (as constructed using wxMetafileDC) makes it into a placeable metafile by prepending a header containing the given bounding box.

The bounding box may be obtained from a device context after drawing into it, using the functions wxDC::MinX(), wxDC::MinY(), wxDC::MaxX() and wxDC::MaxY().

In addition to adding the placeable metafile header, this function adds the equivalent of the following code to the start of the metafile data:

```
1 SetMapMode(dc, MM_ANISOTROPIC);
2 SetWindowOrg(dc, minX, minY);
3 SetWindowExt(dc, maxX - minX, maxY - minY);
```

This simulates the wxMM_TEXT mapping mode, which wxWidgets assumes.

Placeable metafiles may be imported by many Windows applications, and can be used in RTF (Rich Text Format) files.

scale allows the specification of scale for the metafile.

This function is only available under Windows.

Include file:

```
#include <wx/metafile.h>
```

void wxSetCursor (const wxCursor & *cursor*)

Globally sets the cursor; only has an effect on Windows, Mac and GTK+.

You should call this function with wxNullCursor to restore the system cursor.

See also

wxCursor, wxWindow::SetCursor()

Include file:

```
#include <wx/gdicmn.h>
```

20.27 Grid Related Classes

20.27.1 Detailed Description

Classes related to the wxGrid generic widget.

Classes

- class wxGridCellRenderer

  This class is responsible for actually drawing the cell in the grid.
- class wxGridCellAutoWrapStringRenderer

  This class may be used to format string data in a cell.
- class wxGridCellBoolRenderer

  This class may be used to format boolean data in a cell.
- class wxGridCellDateTimeRenderer

  This class may be used to format a date/time data in a cell.
- class wxGridCellEnumRenderer

  This class may be used to render in a cell a number as a textual equivalent.
- class wxGridCellFloatRenderer

  This class may be used to format floating point data in a cell.
- class wxGridCellNumberRenderer

  This class may be used to format integer data in a cell.
- class wxGridCellStringRenderer

  This class may be used to format string data in a cell; it is the default for string cells.
- class wxGridCellEditor

  This class is responsible for providing and manipulating the in-place edit controls for the grid.
- class wxGridCellAutoWrapStringEditor

  Grid cell editor for wrappable string/text data.
- class wxGridCellBoolEditor

  Grid cell editor for boolean data.
- class wxGridCellChoiceEditor

  Grid cell editor for string data providing the user a choice from a list of strings.
- class wxGridCellEnumEditor

  Grid cell editor which displays an enum number as a textual equivalent (eg.
- class wxGridCellTextEditor

  Grid cell editor for string/text data.
- class wxGridCellFloatEditor

  The editor for floating point numbers data.
- class wxGridCellNumberEditor

  Grid cell editor for numeric integer data.
- class wxGridCellAttr

  This class can be used to alter the cells' appearance in the grid by changing their attributes from the defaults.
- class wxGridTableBase

  The almost abstract base class for grid tables.
- class wxGridTableMessage

  A simple class used to pass messages from the table to the grid.
- class wxGridSizesInfo

  wxGridSizesInfo stores information about sizes of all wxGrid rows or columns.
- class wxGrid

  wxGrid and its related classes are used for displaying and editing tabular data.

- class wxGridUpdateLocker

  This small class can be used to prevent wxGrid from redrawing during its lifetime by calling wxGrid::BeginBatch() in its constructor and wxGrid::EndBatch() in its destructor.
- class wxGridEvent

  This event class contains information about various grid events.
- class wxGridSizeEvent

  This event class contains information about a row/column resize event.
- class wxGridRangeSelectEvent
- class wxGridEditorCreatedEvent

20.28 HTML

20.28.1 Detailed Description

wxWidgets provides a set of classes to display text in HTML format.

These classes include a help system based on the HTML widget.

Classes

- class wxHtmlHelpController

  This help controller provides an easy way of displaying HTML help in your application (see HTML Sample, test example).
- class wxHtmlModalHelp

  This class uses wxHtmlHelpController to display help in a modal dialog.
- class wxHtmlHelpData

  This class is used by wxHtmlHelpController and wxHtmlHelpFrame to access HTML help items.
- class wxHtmlHelpDialog

  This class is used by wxHtmlHelpController to display help.
- class wxHtmlHelpFrame

  This class is used by wxHtmlHelpController to display help.
- class wxHtmlHelpWindow

  This class is used by wxHtmlHelpController to display help within a frame or dialog, but you can use it yourself to create an embedded HTML help window.
- class wxHtmlRenderingStyle

  wxHtmlSelection is data holder with information about text selection.
- class wxHtmlRenderingState

  Selection state is passed to wxHtmlCell::Draw so that it can render itself differently e.g.
- class wxHtmlRenderingInfo

  This class contains information given to cells when drawing them.
- class wxHtmlCell

  Internal data structure.
- class wxHtmlContainerCell

  The wxHtmlContainerCell class is an implementation of a cell that may contain more cells in it.
- class wxHtmlLinkInfo

  This class stores all necessary information about hypertext links (as represented by <A> tag in HTML documents).
- class wxHtmlColourCell

  This cell changes the colour of either the background or the foreground.
- class wxHtmlWidgetCell

  wxHtmlWidgetCell is a class that provides a connection between HTML cells and widgets (an object derived from wxWindow).
- class wxHtmlWordCell

  This html cell represents a single word or text fragment in the document stream.
- class wxHtmlWordWithTabsCell

  wxHtmlWordCell is a specialization for storing text fragments with embedded tab characters.
- class wxHtmlFontCell

  This cell represents a font change in the document stream.
- class wxHtmlFilter

  This class is the parent class of input filters for wxHtmlWindow.
- class wxHtmlTagHandler
- class wxHtmlParser

*Classes derived from this handle the **generic** parsing of HTML documents: it scans the document and divide it into blocks of tags (where one block consists of beginning and ending tag and of text between these two tags).*

- class wxHtmlTag

  This class represents a single HTML tag.

- class wxHtmlWindow

  wxHtmlWindow is probably the only class you will directly use unless you want to do something special (like adding new tag handlers or MIME filters).

- class wxHtmlLinkEvent

  This event class is used for the events generated by wxHtmlWindow.

- class wxHtmlCellEvent

  This event class is used for the events generated by wxHtmlWindow.

- class wxHtmlDCRenderer

  This class can render HTML document into a specified area of a DC.

- class wxHtmlEasyPrinting

  This class provides very simple interface to printing architecture.

- class wxHtmlPrintout

  This class serves as printout class for HTML documents.

- class wxHtmlTagsModule

  This class provides easy way of filling wxHtmlWinParser's table of tag handlers.

- class wxHtmlWinTagHandler

  This is basically wxHtmlTagHandler except that it is extended with protected member m_WParser pointing to the wxHtmlWinParser object (value of this member is identical to wxHtmlParser's m_Parser).

- class wxHtmlWinParser

  This class is derived from wxHtmlParser and its main goal is to parse HTML input so that it can be displayed in wxHtmlWindow.

20.29 Help

20.29.1 Detailed Description

Classes for loading and displaying help manuals or help informations in general.

Classes

- class wxHelpProvider

  wxHelpProvider is an abstract class used by a program implementing context-sensitive help to show the help text for the given window.
- class wxHelpControllerHelpProvider

  wxHelpControllerHelpProvider is an implementation of wxHelpProvider which supports both context identifiers and plain text help strings.
- class wxContextHelp

  This class changes the cursor to a query and puts the application into a 'context-sensitive help mode'.
- class wxContextHelpButton

  Instances of this class may be used to add a question mark button that when pressed, puts the application into context-help mode.
- class wxSimpleHelpProvider

  wxSimpleHelpProvider is an implementation of wxHelpProvider which supports only plain text help strings, and shows the string associated with the control (if any) in a tooltip.
- class wxExtHelpController

  This class implements help via an external browser.
- class wxHelpControllerBase

  This is the abstract base class a family of classes by which applications may invoke a help viewer to provide on-line help.
- class wxHelpController

  This is an alias for one of a family of help controller classes which is most appropriate for the current platform.
- class wxHtmlHelpController

  This help controller provides an easy way of displaying HTML help in your application (see HTML Sample, test example).
- class wxHtmlModalHelp

  This class uses wxHtmlHelpController to display help in a modal dialog.
- class wxHtmlHelpData

  This class is used by wxHtmlHelpController and wxHtmlHelpFrame to access HTML help items.
- class wxHtmlHelpDialog

  This class is used by wxHtmlHelpController to display help.
- class wxHtmlHelpFrame

  This class is used by wxHtmlHelpController to display help.
- class wxHtmlHelpWindow

  This class is used by wxHtmlHelpController to display help within a frame or dialog, but you can use it yourself to create an embedded HTML help window.
- class wxToolTip

  This class holds information about a tooltip associated with a window (see wxWindow::SetToolTip()).

20.30 Interprocess Communication

20.30.1 Detailed Description

wxWidgets provides simple interprocess communications facilities based on Windows DDE, but they are available on most platforms using TCP.

Related Overviews: Interprocess Communication

Classes

- class wxDDEConnection

  A wxDDEConnection object represents the connection between a client and a server.
- class wxDDEClient

  A wxDDEClient object represents the client part of a client-server DDE (Dynamic Data Exchange) conversation.
- class wxDDEServer

  A wxDDEServer object represents the server part of a client-server DDE (Dynamic Data Exchange) conversation.
- class wxConnection

  A wxConnection object represents the connection between a client and a server.
- class wxClient

  A wxClient object represents the client part of a client-server DDE-like (Dynamic Data Exchange) conversation.
- class wxServer

  A wxServer object represents the server part of a client-server DDE-like (Dynamic Data Exchange) conversation.
- class wxConnectionBase
- class wxActiveXContainer

  wxActiveXContainer is a host for an ActiveX control on Windows (and as such is a platform-specific class).

20.31 Locale-dependent functions

20.31.1 Detailed Description

Below are a number of functions/macros which accept as last parameter a specific wxXLocale instance.

For the documentation of function `wxFunc_l()`, please see the documentation of the standard `Func()` function (see e.g. `http://www.cppreference.com/wiki/c/string/start`) and keep in mind that the wxWidgets function takes as last parameter the locale which should be internally used for locale-dependent operations.

Last, note that when the `wxHAS_XLOCALE_SUPPORT` symbol is not defined, then wxWidgets will provide implementations of these functions itself and that they are not granted to be thread-safe (and they will work only with the C locale; see Availability).

Functions

- int wxIsalnum_l (wchar_t c, const wxXLocale &loc)
- int wxIsalpha_l (wchar_t c, const wxXLocale &loc)
- int wxIscntrl_l (wchar_t c, const wxXLocale &loc)
- int wxIsdigit_l (wchar_t c, const wxXLocale &loc)
- int wxIsgraph_l (wchar_t c, const wxXLocale &loc)
- int wxIslower_l (wchar_t c, const wxXLocale &loc)
- int wxIsprint_l (wchar_t c, const wxXLocale &loc)
- int wxIspunct_l (wchar_t c, const wxXLocale &loc)
- int wxIsspace_l (wchar_t c, const wxXLocale &loc)
- int wxIsupper_l (wchar_t c, const wxXLocale &loc)
- int wxIsxdigit_l (wchar_t c, const wxXLocale &loc)
- wchar_t wxTolower_l (wchar_t c, const wxXLocale &loc)
- wchar_t wxToupper_l (wchar_t c, const wxXLocale &loc)
- double wxStrtod_l (const wchar_t *c, wchar_t **endptr, const wxXLocale &loc)
- long wxStrtol_l (const wchar_t *c, wchar_t **endptr, int base, const wxXLocale &loc)
- unsigned long wxStrtoul_l (const wchar_t *c, wchar_t **endptr, int base, const wxXLocale &loc)

20.31.2 Function Documentation

int wxIsalnum_l (wchar_t *c,* const wxXLocale & *loc*)

int wxIsalpha_l (wchar_t *c,* const wxXLocale & *loc*)

int wxIscntrl_l (wchar_t *c,* const wxXLocale & *loc*)

int wxIsdigit_l (wchar_t *c,* const wxXLocale & *loc*)

int wxIsgraph_l (wchar_t *c,* const wxXLocale & *loc*)

int wxIslower_l (wchar_t *c,* const wxXLocale & *loc*)

int wxIsprint_l (wchar_t *c,* const wxXLocale & *loc*)

int wxIspunct_l (wchar_t *c,* const wxXLocale & *loc*)

int wxIsspace_l (wchar_t *c,* const wxXLocale & *loc*)

int wxIsupper_l (wchar_t *c,* const wxXLocale & *loc*)

int wxIsxdigit_l (wchar_t *c,* const **wxXLocale** & *loc*)

double wxStrtod_l (const wchar_t * *c,* wchar_t ** *endptr,* const **wxXLocale** & *loc*)

long wxStrtol_l (const wchar_t * *c,* wchar_t ** *endptr,* int *base,* const **wxXLocale** & *loc*)

unsigned long wxStrtoul_l (const wchar_t * *c,* wchar_t ** *endptr,* int *base,* const **wxXLocale** & *loc*)

wchar_t wxTolower_l (wchar_t *c,* const **wxXLocale** & *loc*)

wchar_t wxToupper_l (wchar_t *c,* const **wxXLocale** & *loc*)

20.32 Logging

20.32.1 Detailed Description

wxWidgets provides several classes and functions for message logging.

Related Overviews: Logging Overview

Related macros/global-functions group: Logging

Classes

- class wxMessageOutput

  Simple class allowing to write strings to various output channels.
- class wxMessageOutputStderr

  Output messages to stderr or another STDIO file stream.
- class wxMessageOutputBest

  Output messages in the best possible way.
- class wxMessageOutputDebug

  Output messages to the system debug output channel.
- class wxMessageOutputMessageBox

  Output messages by showing them in a message box.
- class wxLogFormatter

  wxLogFormatter class is used to format the log messages.
- class wxLog

  wxLog class defines the interface for the log targets used by wxWidgets logging functions as explained in the Logging Overview.
- class wxLogChain

  This simple class allows you to chain log sinks, that is to install a new sink but keep passing log messages to the old one instead of replacing it completely as wxLog::SetActiveTarget does.
- class wxLogInterposer

  A special version of wxLogChain which uses itself as the new log target.
- class wxLogInterposerTemp

  A special version of wxLogChain which uses itself as the new log target.
- class wxLogStream

  This class can be used to redirect the log messages to a C++ stream.
- class wxLogStderr

  This class can be used to redirect the log messages to a C file stream (not to be confused with C++ streams).
- class wxLogBuffer

  wxLogBuffer is a very simple implementation of log sink which simply collects all the logged messages in a string (except the debug messages which are output in the usual way immediately as we're presumably not interested in collecting them for later).
- class wxLogNull

  This class allows you to temporarily suspend logging.
- class wxLogWindow

  This class represents a background log window: to be precise, it collects all log messages in the log frame which it manages but also passes them on to the log target which was active at the moment of its creation.
- class wxLogGui

  This is the default log target for the GUI wxWidgets applications.
- class wxLogTextCtrl

  Using these target all the log messages can be redirected to a text control.
- class wxStreamToTextRedirector

  This class can be used to (temporarily) redirect all output sent to a C++ ostream object to a wxTextCtrl instead.

20.33 Logging

20.33.1 Detailed Description

These functions provide a variety of logging functions.

The functions use (implicitly) the currently active log target, so their descriptions here may not apply if the log target is not the standard one (installed by wxWidgets in the beginning of the program).

Related Overviews: Logging Overview

Related class group: Logging

Macros

- #define WXTRACE(format,...)
- #define WXTRACELEVEL(level, format,...)

Functions

- void wxSafeShowMessage (const wxString &title, const wxString &text)

  This function shows a message to the user in a safe way and should be safe to call even before the application has been initialized or if it is currently in some other strange state (for example, about to crash).
- unsigned long wxSysErrorCode ()

  Returns the error code from the last system call.
- const wxChar * wxSysErrorMsg (unsigned long errCode=0)

  Returns the error message corresponding to the given system error code.
- void wxLogGeneric (wxLogLevel level, const char *formatString,...)

  Logs a message with the given wxLogLevel.
- void wxVLogGeneric (wxLogLevel level, const char *formatString, va_list argPtr)
- void wxLogMessage (const char *formatString,...)

  For all normal, informational messages.
- void wxVLogMessage (const char *formatString, va_list argPtr)
- void wxLogVerbose (const char *formatString,...)

  For verbose output.
- void wxVLogVerbose (const char *formatString, va_list argPtr)
- void wxLogWarning (const char *formatString,...)

  For warnings - they are also normally shown to the user, but don't interrupt the program work.
- void wxVLogWarning (const char *formatString, va_list argPtr)
- void wxLogFatalError (const char *formatString,...)

  Like wxLogError(), but also terminates the program with the exit code 3.
- void wxVLogFatalError (const char *formatString, va_list argPtr)
- void wxLogError (const char *formatString,...)

  The functions to use for error messages, i.e.
- void wxVLogError (const char *formatString, va_list argPtr)
- void wxLogTrace (const char *mask, const char *formatString,...)

  Log a message at `wxLOG_Trace` log level (see wxLogLevelValues enum).
- void wxVLogTrace (const char *mask, const char *formatString, va_list argPtr)
- void wxLogTrace (wxTraceMask mask, const char *formatString,...)

  Like wxLogDebug(), trace functions only do something in debug builds and expand to nothing in the release one.
- void wxVLogTrace (wxTraceMask mask, const char *formatString, va_list argPtr)
- void wxLogDebug (const char *formatString,...)

  The right functions for debug output.

- void wxVLogDebug (const char *formatString, va_list argPtr)
- void wxLogStatus (wxFrame *frame, const char *formatString,...)

  Messages logged by this function will appear in the statusbar of the frame or of the top level application window by default (i.e.
- void wxVLogStatus (wxFrame *frame, const char *formatString, va_list argPtr)
- void wxLogStatus (const char *formatString,...)
- void wxVLogStatus (const char *formatString, va_list argPtr)
- void wxLogSysError (const char *formatString,...)

  Mostly used by wxWidgets itself, but might be handy for logging errors after system call (API function) failure.
- void wxVLogSysError (const char *formatString, va_list argPtr)
- void wxTrace (const wxString &format,...)
- void wxTraceLevel (int level, const wxString &format,...)

20.33.2 Macro Definition Documentation

#define WXTRACE(*format, ...*)

Deprecated Use one of the wxLogTrace() functions or one of the wxVLogTrace() functions instead.

Calls wxTrace() with printf-style variable argument syntax. Output is directed to the current output stream (see wxDebugContext).

Include file:

```
#include <wx/memory.h>
```

#define WXTRACELEVEL(*level, format, ...*)

Deprecated Use one of the wxLogTrace() functions or one of the wxVLogTrace() functions instead.

Calls wxTraceLevel with printf-style variable argument syntax. Output is directed to the current output stream (see wxDebugContext). The first argument should be the level at which this information is appropriate. It will only be output if the level returned by wxDebugContext::GetLevel is equal to or greater than this value.

Include file:

```
#include <wx/memory.h>
```

20.33.3 Function Documentation

void wxLogDebug (const char * *formatString, ...*)

The right functions for debug output.

They only do something in debug mode (when the preprocessor symbol **WXDEBUG** is defined) and expand to nothing in release mode (otherwise).

Include file:

```
#include <wx/log.h>
```

void wxLogError (const char * *formatString,* ...)

The functions to use for error messages, i.e.

the messages that must be shown to the user. The default processing is to pop up a message box to inform the user about it.

Include file:

```
#include <wx/log.h>
```

void wxLogFatalError (const char * *formatString,* ...)

Like wxLogError(), but also terminates the program with the exit code 3.

Using *abort()* standard function also terminates the program with this exit code.

Include file:

```
#include <wx/log.h>
```

void wxLogGeneric (wxLogLevel *level,* const char * *formatString,* ...)

Logs a message with the given wxLogLevel.

E.g. using `wxLOG_Message` as first argument, this function behaves like wxLogMessage().

Include file:

```
#include <wx/log.h>
```

void wxLogMessage (const char * *formatString,* ...)

For all normal, informational messages.

They also appear in a message box by default (but it can be changed).

Include file:

```
#include <wx/log.h>
```

void wxLogStatus (wxFrame * *frame,* const char * *formatString,* ...)

Messages logged by this function will appear in the statusbar of the *frame* or of the top level application window by default (i.e.

when using the second version of the functions).

If the target frame doesn't have a statusbar, the message will be lost.

Include file:

```
#include <wx/log.h>
```

void wxLogStatus (const char * *formatString,* ...)

void wxLogSysError (const char * *formatString,* ...)

Mostly used by wxWidgets itself, but might be handy for logging errors after system call (API function) failure.

It logs the specified message text as well as the last system error code (*errno* or *GetLastError()* depending on the platform) and the corresponding error message. The second form of this function takes the error code explicitly as the first argument.

See also

wxSysErrorCode(), wxSysErrorMsg()

Include file:

```
#include <wx/log.h>
```

void wxLogTrace (const char * *mask*, const char * *formatString*, ...)

Log a message at `wxLOG_Trace` log level (see wxLogLevelValues enum).

Notice that the use of trace masks is not recommended any more as setting the log components (please see Log Messages Selection) provides a way to do the same thing for log messages of any level, and not just the tracing ones.

Like wxLogDebug(), trace functions only do something in debug builds and expand to nothing in the release one. The reason for making it a separate function is that usually there are a lot of trace messages, so it might make sense to separate them from other debug messages.

Trace messages can be separated into different categories; these functions in facts only log the message if the given *mask* is currently enabled in wxLog. This lets you selectively trace only some operations and not others by enabling the desired trace masks with wxLog::AddTraceMask() or by setting the `WXTRACE` environment variable.

The predefined string trace masks used by wxWidgets are:

wxTRACE_MemAlloc	Trace memory allocation (new/delete)
wxTRACE_Messages	Trace window messages/X callbacks
wxTRACE_ResAlloc	Trace GDI resource allocation
wxTRACE_RefCount	Trace various ref counting operations
wxTRACE_OleCalls	Trace OLE method calls (Win32 only)

Include file:

```
#include <wx/log.h>
```

void wxLogTrace (wxTraceMask *mask*, const char * *formatString*, ...)

Like wxLogDebug(), trace functions only do something in debug builds and expand to nothing in the release one.

The reason for making it a separate function is that usually there are a lot of trace messages, so it might make sense to separate them from other debug messages.

Deprecated This version of wxLogTrace() only logs the message if all the bits corresponding to the *mask* are set in the wxLog trace mask which can be set by calling wxLog::SetTraceMask(). This version is less flexible than wxLogTrace(const char*,const char*,...) because it doesn't allow defining the user trace masks easily. This is why it is deprecated in favour of using string trace masks.

The following bitmasks are defined for wxTraceMask:

wxTraceMemAlloc	Trace memory allocation (new/delete)
wxTraceMessages	Trace window messages/X callbacks

wxTraceResAlloc	Trace GDI resource allocation
wxTraceRefCount	Trace various ref counting operations
wxTraceOleCalls	Trace OLE method calls (Win32 only)

Include file:

```
#include <wx/log.h>
```

void wxLogVerbose (const char * *formatString,* ...)

For verbose output.

Normally, it is suppressed, but might be activated if the user wishes to know more details about the program progress (another, but possibly confusing name for the same function could be `wxLogInfo`).

Include file:

```
#include <wx/log.h>
```

void wxLogWarning (const char * *formatString,* ...)

For warnings - they are also normally shown to the user, but don't interrupt the program work.

Include file:

```
#include <wx/log.h>
```

void wxSafeShowMessage (const wxString & *title,* const wxString & *text*)

This function shows a message to the user in a safe way and should be safe to call even before the application has been initialized or if it is currently in some other strange state (for example, about to crash).

Under Windows this function shows a message box using a native dialog instead of wxMessageBox() (which might be unsafe to call), elsewhere it simply prints the message to the standard output using the title as prefix.

Parameters

title	The title of the message box shown to the user or the prefix of the message string.
text	The text to show to the user.

See also

wxLogFatalError()

Include file:

```
#include <wx/log.h>
```

unsigned long wxSysErrorCode ( )

Returns the error code from the last system call.

This function uses `errno` on Unix platforms and `GetLastError` under Win32.

See also

wxSysErrorMsg(), wxLogSysError()

Include file:

```
#include <wx/log.h>
```

const wxChar* wxSysErrorMsg (unsigned long *errCode* = 0)

Returns the error message corresponding to the given system error code.

If *errCode* is 0 (default), the last error code (as returned by wxSysErrorCode()) is used.

See also

wxSysErrorCode(), wxLogSysError()

Include file:

```
#include <wx/log.h>
```

void wxTrace (const wxString & *format*, ...)

Deprecated Use one of the wxLogTrace() functions or one of the wxVLogTrace() functions instead.

Takes printf-style variable argument syntax. Output is directed to the current output stream (see wxDebugContext).

Include file:

```
#include <wx/memory.h>
```

void wxTraceLevel (int *level*, const wxString & *format*, ...)

Deprecated Use one of the wxLogTrace() functions or one of the wxVLogTrace() functions instead.

Takes *printf()* style variable argument syntax. Output is directed to the current output stream (see wxDebugContext). The first argument should be the level at which this information is appropriate. It will only be output if the level returned by wxDebugContext::GetLevel() is equal to or greater than this value.

Include file:

```
#include <wx/memory.h>
```

void wxVLogDebug (const char * *formatString*, va_list *argPtr*)

void wxVLogError (const char * *formatString*, va_list *argPtr*)

void wxVLogFatalError (const char * *formatString*, va_list *argPtr*)

void wxVLogGeneric (wxLogLevel *level*, const char * *formatString*, va_list *argPtr*)

void wxVLogMessage (const char * *formatString*, va_list *argPtr*)

void wxVLogStatus (wxFrame * *frame*, const char * *formatString*, va_list *argPtr*)

void wxVLogStatus (const char * *formatString*, va_list *argPtr*)

void wxVLogSysError (const char * *formatString*, va_list *argPtr*)

void wxVLogTrace (const char * *mask*, const char * *formatString*, va_list *argPtr*)

void wxVLogTrace (wxTraceMask *mask*, const char * *formatString*, va_list *argPtr*)

void wxVLogVerbose (const char * *formatString,* va_list *argPtr*)

void wxVLogWarning (const char * *formatString,* va_list *argPtr*)

20.34 Managed Windows

20.34.1 Detailed Description

There are several types of window that are directly controlled by the window manager (such as MS Windows, or the Motif Window Manager).

Frames and dialogs are similar in wxWidgets, but only dialogs may be modal.

Related Overviews: Common Dialogs

Related macros/global-functions group: Dialogs

Classes

- class wxFrame

  A frame is a window whose size and position can (usually) be changed by the user.
- class wxMDIClientWindow

  An MDI client window is a child of wxMDIParentFrame, and manages zero or more wxMDIChildFrame objects.
- class wxMDIParentFrame

  An MDI (Multiple Document Interface) parent frame is a window which can contain MDI child frames in its client area which emulates the full desktop.
- class wxMDIChildFrame

  An MDI child frame is a frame that can only exist inside a wxMDIClientWindow, which is itself a child of wxMDI↩ ParentFrame.
- class wxMiniFrame

  A miniframe is a frame with a small title bar.
- class wxPopupWindow

  A special kind of top level window used for popup menus, combobox popups and such.
- class wxPopupTransientWindow

  A wxPopupWindow which disappears automatically when the user clicks mouse outside it or if it loses focus in any other way.
- class wxPropertySheetDialog

  This class represents a property sheet dialog: a tabbed dialog for showing settings.
- class wxSplashScreen

  wxSplashScreen shows a window with a thin border, displaying a bitmap describing your application.
- class wxTipWindow

  Shows simple text in a popup tip window on creation.
- class wxTopLevelWindow

  wxTopLevelWindow is a common base class for wxDialog and wxFrame.

20.35 Math

20.35.1 Detailed Description

The functions in this section are typically related with math operations and floating point numbers.

Functions

- int wxFinite (double x)

  Returns a non-zero value if x is neither infinite nor NaN (not a number), returns 0 otherwise.
- unsigned int wxGCD (unsigned int u, unsigned int v)

  Returns the greatest common divisor of the two given numbers.
- bool wxIsNaN (double x)

  Returns a non-zero value if x is NaN (not a number), returns 0 otherwise.
- wxFloat64 wxConvertFromIeeeExtended (const wxInt8 ∗bytes)

  Converts the given array of 10 bytes (corresponding to 80 bits) to a float number according to the IEEE floating point standard format (aka IEEE standard 754).
- void wxConvertToIeeeExtended (wxFloat64 num, wxInt8 ∗bytes)

  Converts the given floating number num in a sequence of 10 bytes which are stored in the given array bytes (which must be large enough) according to the IEEE floating point standard format (aka IEEE standard 754).
- double wxDegToRad (double deg)

  Convert degrees to radians.
- double wxRadToDeg (double rad)

  Convert radians to degrees.
- int wxRound (double x)

  Small wrapper around round().
- bool wxIsSameDouble (double x, double y)

  Returns true if both double values are identical.
- bool wxIsNullDouble (double x)

  Return true of x is exactly zero.

20.35.2 Function Documentation

wxFloat64 wxConvertFromIeeeExtended (const wxInt8 ∗ *bytes*)

Converts the given array of 10 bytes (corresponding to 80 bits) to a float number according to the IEEE floating point standard format (aka IEEE standard 754).

See also

wxConvertToIeeeExtended() to perform the opposite operation

void wxConvertToIeeeExtended (wxFloat64 *num*, wxInt8 ∗ *bytes*)

Converts the given floating number *num* in a sequence of 10 bytes which are stored in the given array *bytes* (which must be large enough) according to the IEEE floating point standard format (aka IEEE standard 754).

See also

wxConvertFromIeeeExtended() to perform the opposite operation

double wxDegToRad (double *deg*)

Convert degrees to radians.

This function simply returns its argument multiplied by `M_PI/180` but is more readable than writing this expression directly.

See also

wxRadToDeg()

Since

3.1.0

int wxFinite (double *x*)

Returns a non-zero value if *x* is neither infinite nor NaN (not a number), returns 0 otherwise.

Include file:

```
#include <wx/math.h>
```

unsigned int wxGCD (unsigned int *u*, unsigned int *v*)

Returns the greatest common divisor of the two given numbers.

Since

3.1.0

Include file:

```
#include <wx/math.h>
```

bool wxIsNaN (double *x*)

Returns a non-zero value if x is NaN (not a number), returns 0 otherwise.

Include file:

```
#include <wx/math.h>
```

bool wxIsNullDouble (double *x*)

Return true of *x* is exactly zero.

This is only reliable if it has been assigned 0.

bool wxIsSameDouble (double *x*, double *y*)

Returns true if both double values are identical.

This is only reliable if both values have been assigned the same value.

double wxRadToDeg (double *rad*)

Convert radians to degrees.

This function simply returns its argument multiplied by `180/M_PI` but is more readable than writing this expression directly.

See also

wxDegToRad()

Since

3.1.0

int wxRound (double *x*)

Small wrapper around round().

20.36 Menus

20.36.1 Detailed Description

Group of classes for handling menu bars and items.

Classes

- class wxMenuBar

  A menu bar is a series of menus accessible from the top of a frame.
- class wxMenu

  A menu is a popup (or pull down) list of items, one of which may be selected before the menu goes away (clicking elsewhere dismisses the menu).
- class wxMenuItem

  A menu item represents an item in a menu.

20.37 Miscellaneous

20.37.1 Detailed Description

Group of miscellaneous classes.

Related macros/global-functions group: Miscellaneous

Classes

- class wxPowerResource

  Helper functions for acquiring and releasing the given power resource.
- class wxPowerResourceBlocker

  Helper RAII class ensuring that power resources are released.
- class wxAccessible

  The wxAccessible class allows wxWidgets applications, and wxWidgets itself, to return extended information about user interface elements to client applications such as screen readers.
- class wxAffineMatrix2D

  A 3x2 matrix representing an affine 2D transformation.
- class wxMatrix2D

  A simple container for 2x2 matrix.
- class wxAffineMatrix2DBase

  A 2x3 matrix representing an affine 2D transformation.
- class wxAppProgressIndicator

  A helper class that can be used to update the progress bar in the taskbar button.
- class wxArtProvider

  wxArtProvider class is used to customize the look of wxWidgets application.
- class wxCaret

  A caret is a blinking cursor showing the position where the typed text will appear.
- class wxJoystick

  wxJoystick allows an application to control one or more joysticks.
- class wxNotificationMessage

  This class allows to show the user a message non intrusively.
- class wxQuantize

  Performs quantization, or colour reduction, on a wxImage.
- class wxRecursionGuardFlag

  This is a completely opaque class which exists only to be used with wxRecursionGuard, please see the example in that class' documentation.
- class wxRecursionGuard

  wxRecursionGuard is a very simple class which can be used to prevent reentrancy problems in a function.
- class wxScopeGuard

  Scope guard is an object which allows executing an action on scope exit.
- class wxStopWatch

  The wxStopWatch class allow you to measure time intervals.
- class wxTaskBarIcon

  This class represents a taskbar icon.
- class wxThumbBarButton

  A thumbnail toolbar button is a control that displayed in the thumbnail image of a window in a taskbar button flyout.
- class wxTaskBarButton

  A taskbar button that associated with the window under Windows 7 or later.
- class wxTaskBarJumpListItem

A wxTaskBarJumpListItem represents an item in a jump list category.

- class wxTaskBarJumpListCategory

  This class represents a category of jump list in the taskbar button.

- class wxTaskBarJumpList

  This class is an transparent wrapper around Windows Jump Lists.

- class wxTimer

  The wxTimer class allows you to execute code at specified intervals.

- class wxTipProvider

  This is the class used together with wxShowTip() function.

- class wxWindowDisabler

  This class disables all windows of the application (may be with the exception of one of them) in its constructor and enables them back in its destructor.

- class wxBusyCursor

  This class makes it easy to tell your user that the program is temporarily busy.

- class wxFSVolume

  wxFSVolume represents a volume (also known as 'drive') in a file system under wxMSW.

- class wxWindowUpdateLocker

  This tiny class prevents redrawing of a wxWindow during its lifetime by using wxWindow::Freeze() and wxWindow::Thaw() methods.

20.38 Miscellaneous

20.38.1 Detailed Description

Group of miscellaneous functions and macros.

Related class group: Miscellaneous

Macros

- #define wxCONCAT(x1, x2)

  This macro returns the concatenation of the arguments passed.
- #define wxCONCAT3(x1, x2, x3)
- #define wxCONCAT4(x1, x2, x3, x4)
- #define wxCONCAT5(x1, x2, x3, x4, x5)
- #define wxSTRINGIZE(x)

  Returns the string representation of the given symbol which can be either a literal or a macro (hence the advantage of using this macro instead of the standard preprocessor # operator which doesn't work with macros).
- #define wxSTRINGIZE_T(x)

  Returns the string representation of the given symbol as either an ASCII or Unicode string, depending on the current build.
- #define __WXFUNCTION__

  This macro expands to the name of the current function if the compiler supports any of ***`__FUNCTION__`****,* ***`__func__`*** *or equivalent variables or macros or to NULL if none of them is available.*
- #define wxDECLARE_NO_ASSIGN_CLASS(classname)

  This macro can be used in a class declaration to disable the generation of default assignment operator.
- #define wxDECLARE_NO_COPY_CLASS(classname)

  This macro can be used in a class declaration to disable the generation of default copy ctor and assignment operator.
- #define wxDECLARE_NO_COPY_TEMPLATE_CLASS(classname, arg)

  Analog of wxDECLARE_NO_COPY_CLASS() for template classes.
- #define wxDECLARE_NO_COPY_TEMPLATE_CLASS_2(classname, arg1, arg2)

  Analog of wxDECLARE_NO_COPY_TEMPLATE_CLASS() for templates with 2 parameters.
- #define wxDEPRECATED(function)

  Generate deprecation warning with the given message when a function is used.
- #define wxDEPRECATED_BUT_USED_INTERNALLY(function)

  This is a special version of wxDEPRECATED() macro which only does something when the deprecated function is used from the code outside wxWidgets itself but doesn't generate warnings when it is used from wxWidgets.
- #define wxDEPRECATED_INLINE(func, body)

  This macro is similar to wxDEPRECATED() but can be used to not only declare the function function as deprecated but to also provide its (inline) implementation body.
- #define wxDEPRECATED_ACCESSOR(func, what)

  A helper macro allowing to easily define a simple deprecated accessor.
- #define wxDEPRECATED_BUT_USED_INTERNALLY_INLINE(func, body)

  Combination of wxDEPRECATED_BUT_USED_INTERNALLY() and wxDEPRECATED_INLINE().
- #define wxEXPLICIT

  `wxEXPLICIT` is a macro which expands to the C++ `explicit` keyword if the compiler supports it or nothing otherwise.
- #define wxOVERRIDE

  `wxOVERRIDE` expands to the C++11 `override` keyword if it's supported by the compiler or nothing otherwise.
- #define wxSUPPRESS_GCC_PRIVATE_DTOR_WARNING(name)

  GNU C++ compiler gives a warning for any class whose destructor is private unless it has a friend.
- #define wxDYNLIB_FUNCTION(type, name, dynlib)

When loading a function from a DLL you always have to cast the returned `void *` pointer to the correct type and, even more annoyingly, you have to repeat this type twice if you want to declare and define a function pointer all in one line.

- #define wxLongLongFmtSpec

  This macro is defined to contain the `printf()` format specifier using which 64 bit integer numbers (i.e.

- #define wxON_BLOCK_EXIT(function,...)

  Ensure that the global function with a few (up to some implementation-defined limit) is executed on scope exit, whether due to a normal function return or because an exception has been thrown.

- #define wxON_BLOCK_EXIT0(function)
- #define wxON_BLOCK_EXIT1(function, p1)
- #define wxON_BLOCK_EXIT2(function, p1, p2)
- #define wxON_BLOCK_EXIT3(function, p1, p2, p3)
- #define wxON_BLOCK_EXIT_OBJ(object, method,...)

  This family of macros is similar to wxON_BLOCK_EXIT(), but calls a method of the given object instead of a free function.

- #define wxON_BLOCK_EXIT_OBJ0(object, method)
- #define wxON_BLOCK_EXIT_OBJ1(object, method, p1)
- #define wxON_BLOCK_EXIT_OBJ2(object, method, p1, p2)
- #define wxON_BLOCK_EXIT_OBJ3(object, method, p1, p2, p3)
- #define wxON_BLOCK_EXIT_THIS(method,...)

  This family of macros is similar to wxON_BLOCK_OBJ(), but calls a method of `this` object instead of a method of the specified object.

- #define wxON_BLOCK_EXIT_THIS0(method)
- #define wxON_BLOCK_EXIT_THIS1(method, p1)
- #define wxON_BLOCK_EXIT_THIS2(method, p1, p2)
- #define wxON_BLOCK_EXIT_THIS3(method, p1, p2, p3)
- #define wxON_BLOCK_EXIT_SET(var, value)

  This macro sets a variable to the specified value on scope exit.

- #define wxON_BLOCK_EXIT_NULL(ptr)

  This macro sets the pointer passed to it as argument to NULL on scope exit.

Typedefs

- typedef int(* wxSortCallback)(const void *pItem1, const void *pItem2, const void *user_data)

  Compare function type for use with wxQsort()

Enumerations

- enum wxBase64DecodeMode {
  wxBase64DecodeMode_Strict,
  wxBase64DecodeMode_SkipWS,
  wxBase64DecodeMode_Relaxed }

  Elements of this enum specify the possible behaviours of wxBase64Decode when an invalid character is encountered.

- enum {
  wxStrip_Mnemonics = 1,
  wxStrip_Accel = 2,
  wxStrip_All = wxStrip_Mnemonics | wxStrip_Accel }

  flags for wxStripMenuCodes

Functions

- size_t wxBase64Encode (char *dst, size_t dstLen, const void *src, size_t srcLen)

  This function encodes the given data using base64.
- wxString wxBase64Encode (const void *src, size_t srcLen)

  This function encodes the given data using base64 and returns the output as a wxString.
- wxString wxBase64Encode (const wxMemoryBuffer &buf)

  This function encodes the given data using base64 and returns the output as a wxString.
- size_t wxBase64DecodedSize (size_t srcLen)

  Returns the size of the buffer necessary to contain the data encoded in a base64 string of length srcLen.
- size_t wxBase64EncodedSize (size_t len)

  Returns the length of the string with base64 representation of a buffer of specified size len.
- size_t wxBase64Decode (void *dst, size_t dstLen, const char *src, size_t srcLen=wxNO_LEN, wxBase64DecodeMode mode=wxBase64DecodeMode_Strict, size_t *posErr=NULL)

  This function decodes a Base64-encoded string.
- size_t wxBase64Decode (void *dst, size_t dstLen, const wxString &str, wxBase64DecodeMode mode=wxBase64DecodeMode_Strict, size_t *posErr=NULL)

  Decode a Base64-encoded wxString.
- wxMemoryBuffer wxBase64Decode (const char *src, size_t srcLen=wxNO_LEN, wxBase64DecodeMode mode=wxBase64DecodeMode_Strict, size_t *posErr=NULL)

  Decode a Base64-encoded string and return decoded contents in a buffer.
- wxMemoryBuffer wxBase64Decode (const wxString &src, wxBase64DecodeMode mode=wxBase64DecodeMode_Strict, size_t *posErr=NULL)

  Decode a Base64-encoded wxString and return decoded contents in a buffer.
- bool wxFromString (const wxString &string, wxColour *colour)

  Converts string to a wxColour best represented by the given string.
- wxString wxToString (const wxColour &colour)

  Converts the given wxColour into a string.
- void wxDDECleanUp ()

  Called when wxWidgets exits, to clean up the DDE system.
- void wxDDEInitialize ()

  Initializes the DDE system.
- template<typename T >
  wxDELETE (T *&ptr)

  A function which deletes and nulls the pointer.
- template<typename T >
  wxDELETEA (T *&array)

  A function which deletes and nulls the pointer.
- template<typename T >
  wxSwap (T &first, T &second)

  Swaps the contents of two variables.
- void wxVaCopy (va_list argptrDst, va_list argptrSrc)

  This macro is the same as the standard C99 `va_copy` for the compilers which support it or its replacement for those that don't.
- bool wxFromString (const wxString &string, wxFont *font)

  Converts string to a wxFont best represented by the given string.
- wxString wxToString (const wxFont &font)

  Converts the given wxFont into a string.
- wxLongLong_t wxLL (number)

  This macro is defined for the platforms with a native 64 bit integer type and allow the use of 64 bit compile time constants:
- wxLongLong_t wxULL (number)

This macro is defined for the platforms with a native 64 bit integer type and allow the use of 64 bit compile time constants:

- template<typename F , typename P1 , ... , typename PN >
  wxScopeGuard wxMakeGuard (F func, P1 p1,..., PN pN)

  Returns a scope guard object which will call the specified function with the given parameters on scope exit.
- wxString wxGetStockLabel (wxWindowID id, long flags=wxSTOCK_WITH_MNEMONIC)

  Returns label that should be used for given id element.
- wxBatteryState wxGetBatteryState ()

  Returns battery state as one of `wxBATTERY_NORMAL_STATE`, `wxBATTERY_LOW_STATE`, `wxBATTERY_CRITICAL_STATE`, `wxBATTERY_SHUTDOWN_STATE` *or* `wxBATTERY_UNKNOWN_STATE`.
- wxPowerType wxGetPowerType ()

  Returns the type of power source as one of `wxPOWER_SOCKET`, `wxPOWER_BATTERY` *or* `wxPOWER_UNKNOWN`.
- wxString wxGetDisplayName ()

  Under X only, returns the current display name.
- bool wxGetKeyState (wxKeyCode key)

  For normal keys, returns true if the specified key is currently down.
- wxPoint wxGetMousePosition ()

  Returns the mouse position in screen coordinates.
- wxMouseState wxGetMouseState ()

  Returns the current state of the mouse.
- void wxEnableTopLevelWindows (bool enable=true)

  This function enables or disables all top level windows.
- wxWindow * wxFindWindowAtPoint (const wxPoint &pt)

  Find the deepest window at the given mouse position in screen coordinates, returning the window if found, or NULL if not.
- wxWindow * wxFindWindowByLabel (const wxString &label, wxWindow *parent=NULL)
- wxWindow * wxFindWindowByName (const wxString &name, wxWindow *parent=NULL)
- int wxFindMenuItemId (wxFrame *frame, const wxString &menuString, const wxString &itemString)

  Find a menu item identifier associated with the given frame's menu bar.
- int wxNewId ()
- void wxRegisterId (int id)

  Ensures that Ids subsequently generated by wxNewId() do not clash with the given id.
- bool wxLaunchDefaultApplication (const wxString &document, int flags=0)

  Opens the document in the application associated with the files of this type.
- bool wxLaunchDefaultBrowser (const wxString &url, int flags=0)

  Opens the url in user's default browser.
- bool wxLoadUserResource (const void **outData, size_t *outLen, const wxString &resourceName, const wxChar *resourceType="TEXT", WXHINSTANCE module=0)

  Loads an object from Windows resource file.
- char * wxLoadUserResource (const wxString &resourceName, const wxChar *resourceType="TEXT", int *pLen=NULL, WXHINSTANCE module=0)

  Loads a user-defined Windows resource as a string.
- void wxPostDelete (wxObject *object)
- void wxQsort (void *pbase, size_t total_elems, size_t size, wxSortCallback cmp, const void *user_data)

  Function implementing quick sort algorithm.
- void wxSetDisplayName (const wxString &displayName)

  Under X only, sets the current display name.
- wxString wxStripMenuCodes (const wxString &str, int flags=wxStrip_All)

  Strips any menu codes from str and returns the result.
- wxWindow * wxFindWindowAtPointer (wxPoint &pt)

  Find the deepest window at the mouse pointer position, returning the window and current pointer position in screen coordinates.

- wxWindow * wxGetActiveWindow ()

  Gets the currently active window (implemented for MSW and GTK only currently, always returns NULL in the other ports).
- wxWindow * wxGetTopLevelParent (wxWindow *window)

  Returns the first top level parent of the given window, or in other words, the frame or dialog containing it, or NULL.

20.38.2 Macro Definition Documentation

#define __WXFUNCTION__

This macro expands to the name of the current function if the compiler supports any of **`FUNCTION`**, **`func`** or equivalent variables or macros or to NULL if none of them is available.

Include file:

```
#include <wx/cpp.h>
```

#define wxCONCAT(*x1*, *x2*)

This macro returns the concatenation of the arguments passed.

Unlike when using the preprocessor operator, the arguments undergo macro expansion before being concatenated.

Include file:

```
#include <wx/cpp.h>
```

#define wxCONCAT3(*x1*, *x2*, *x3*)

#define wxCONCAT4(*x1*, *x2*, *x3*, *x4*)

#define wxCONCAT5(*x1*, *x2*, *x3*, *x4*, *x5*)

#define wxDECLARE_NO_ASSIGN_CLASS(*classname*)

This macro can be used in a class declaration to disable the generation of default assignment operator.

Some classes have a well-defined copy constructor but cannot have an assignment operator, typically because they can't be modified once created. In such case, this macro can be used to disable the automatic assignment operator generation.

See also

wxDECLARE_NO_COPY_CLASS()

#define wxDECLARE_NO_COPY_CLASS(*classname*)

This macro can be used in a class declaration to disable the generation of default copy ctor and assignment operator.

Some classes don't have a well-defined copying semantics. In this case the standard C++ convention is to not allow copying them. One way of achieving it is to use this macro which simply defines a private copy constructor and assignment operator.

Beware that simply not defining copy constructor and assignment operator is *not* enough as the compiler would provide its own automatically-generated versions of them – hence the usefulness of this macro.

Example of use:

```
1 class FooWidget
2 {
3 public:
4     FooWidget();
5     ...
6
7 private:
8     // widgets can't be copied
9     wxDECLARE_NO_COPY_CLASS(FooWidget);
10 };
```

Notice that a semicolon must be used after this macro and that it changes the access specifier to private internally so it is better to use it at the end of the class declaration.

See also

wxDECLARE_NO_ASSIGN_CLASS(), wxDECLARE_NO_COPY_TEMPLATE_CLASS()

#define wxDECLARE_NO_COPY_TEMPLATE_CLASS(*classname, arg*)

Analog of wxDECLARE_NO_COPY_CLASS() for template classes.

This macro can be used for template classes (with a single template parameter) for the same purpose as wxDECLARE_NO_COPY_CLASS() is used with the non-template classes.

Parameters

classname	The name of the template class.
arg	The name of the template parameter.

See also

wxDECLARE_NO_COPY_TEMPLATE_CLASS_2

#define wxDECLARE_NO_COPY_TEMPLATE_CLASS_2(*classname, arg1, arg2*)

Analog of wxDECLARE_NO_COPY_TEMPLATE_CLASS() for templates with 2 parameters.

This macro can be used for template classes with two template parameters for the same purpose as wxDECLARE_NO_COPY_CLASS() is used with the non-template classes.

Parameters

classname	The name of the template class.
arg1	The name of the first template parameter.
arg2	The name of the second template parameter.

See also

wxDECLARE_NO_COPY_TEMPLATE_CLASS

#define wxDEPRECATED(*function*)

Generate deprecation warning with the given message when a function is used.

This macro can be used to generate a warning indicating that a function is deprecated (i.e. scheduled for removal in the future) and explaining why is it so and/or what should it be replaced with. It applies to the declaration following it, for example:

```
1 wxDEPRECATED_MSG("use safer overload returning wxString instead")
2 void wxGetSomething(char* buf, size_t len);
3
4 wxString wxGetSomething();
```

For compilers other than clang, g++ 4.5 or later and MSVC 8 (MSVS 2005) or later, the message is ignored and a generic deprecation warning is given if possible, i.e. if the compiler is g++ (any supported version) or MSVC 7 (MSVS 2003) or later.

Since

3.0

Include file:

```
#include <wx/defs.h>
```

This macro can be used around a function declaration to generate warnings indicating that this function is deprecated (i.e. obsolete and planned to be removed in the future) when it is used.

Notice that this macro itself is deprecated in favour of wxDEPRECATED_MSG()!

Only Visual C++ 7 and higher and g++ compilers currently support this functionality.

Example of use:

```
1 // old function, use wxString version instead
2 wxDEPRECATED( void wxGetSomething(char *buf, size_t len) );
3
4 // ...
5 wxString wxGetSomething();
```

Include file:

```
#include <wx/defs.h>
```

#define wxDEPRECATED_ACCESSOR(*func, what*)

A helper macro allowing to easily define a simple deprecated accessor.

Compared to wxDEPRECATED_INLINE() it saves a `return` statement and, especially, a strangely looking semicolon inside a macro.

Example of use

```
1 class wxFoo
2 {
3 public:
4     int GetValue() const { return m_value; }
5
6     // this one is deprecated because it was erroneously non-const
7     wxDEPRECATED_ACCESSOR( int GetValue(), m_value )
8
9 private:
10     int m_value;
11 };
```

#define wxDEPRECATED_BUT_USED_INTERNALLY(*function*)

This is a special version of wxDEPRECATED() macro which only does something when the deprecated function is used from the code outside wxWidgets itself but doesn't generate warnings when it is used from wxWidgets.

It is used with the virtual functions which are called by the library itself – even if such function is deprecated the library still has to call it to ensure that the existing code overriding it continues to work, but the use of this macro ensures that a deprecation warning will be generated if this function is used from the user code or, in case of Visual C++, even when it is simply overridden.

Include file:

```
#include <wx/defs.h>
```

#define wxDEPRECATED_BUT_USED_INTERNALLY_INLINE(*func, body*)

Combination of wxDEPRECATED_BUT_USED_INTERNALLY() and wxDEPRECATED_INLINE().

This macro should be used for deprecated functions called by the library itself (usually for backwards compatibility reasons) and which are defined inline.

Include file:

```
#include <wx/defs.h>
```

#define wxDEPRECATED_INLINE(*func, body*)

This macro is similar to wxDEPRECATED() but can be used to not only declare the function *function* as deprecated but to also provide its (inline) implementation *body*.

It can be used as following:

```
1 class wxFoo
2 {
3 public:
4     // OldMethod() is deprecated, use NewMethod() instead
5     void NewMethod();
6     wxDEPRECATED_INLINE( void OldMethod(), NewMethod(); )
7 };
```

Include file:

```
#include <wx/defs.h>
```

#define wxDYNLIB_FUNCTION(*type, name, dynlib*)

When loading a function from a DLL you always have to cast the returned `void *` pointer to the correct type and, even more annoyingly, you have to repeat this type twice if you want to declare and define a function pointer all in one line.

This macro makes this slightly less painful by allowing you to specify the type only once, as the first parameter, and creating a variable of this type named after the function but with `pfn` prefix and initialized with the function *name* from the wxDynamicLibrary *dynlib*.

Parameters

type	The type of the function.
name	The name of the function to load, not a string (without quotes, it is quoted automatically by the macro).
dynlib	The library to load the function from.

Include file:

```
#include <wx/dynlib.h>
```

#define wxEXPLICIT

`wxEXPLICIT` is a macro which expands to the C++ `explicit` keyword if the compiler supports it or nothing otherwise.

Thus, it can be used even in the code which might have to be compiled with an old compiler without support for this language feature but still take advantage of it when it is available.

Include file:

```
#include <wx/defs.h>
```

#define wxLongLongFmtSpec

This macro is defined to contain the `printf()` format specifier using which 64 bit integer numbers (i.e. those of type `wxLongLong_t`) can be printed. Example of using it:

```
1 #ifdef wxLongLong_t
2     wxLongLong_t ll = wxLL(0x1234567890abcdef);
3     printf("Long long = %" wxLongLongFmtSpec "x\n", ll);
4 #endif
```

See also

wxLL()

Include file:

```
#include <wx/longlong.h>
```

#define wxON_BLOCK_EXIT(*function, ...*)

Ensure that the global *function* with a few (up to some implementation-defined limit) is executed on scope exit, whether due to a normal function return or because an exception has been thrown.

A typical example of its usage:

```
1 void *buf = malloc(size);
2 wxON_BLOCK_EXIT1(free, buf);
```

Please see the original article by Andrei Alexandrescu and Petru Marginean published in December 2000 issue of C/C++ Users Journal for more details.

See also

wxON_BLOCK_EXIT_OBJ0()

Include file:

```
#include <wx/scopeguard.h>
```

#define wxON_BLOCK_EXIT0(*function*)

#define wxON_BLOCK_EXIT1(*function, p1*)

#define wxON_BLOCK_EXIT2(*function, p1, p2*)

#define wxON_BLOCK_EXIT3(*function, p1, p2, p3*)

#define wxON_BLOCK_EXIT_NULL(*ptr*)

This macro sets the pointer passed to it as argument to NULL on scope exit.

It must be used instead of wxON_BLOCK_EXIT_SET() when the value being set is `NULL`.

Include file:

```
#include <wx/scopeguard.h>
```

#define wxON_BLOCK_EXIT_OBJ(*object, method, ...*)

This family of macros is similar to wxON_BLOCK_EXIT(), but calls a method of the given object instead of a free function.

Include file:

```
#include <wx/scopeguard.h>
```

#define wxON_BLOCK_EXIT_OBJ0(*object, method*)

#define wxON_BLOCK_EXIT_OBJ1(*object, method, p1*)

#define wxON_BLOCK_EXIT_OBJ2(*object, method, p1, p2*)

#define wxON_BLOCK_EXIT_OBJ3(*object, method, p1, p2, p3*)

#define wxON_BLOCK_EXIT_SET(*var, value*)

This macro sets a variable to the specified value on scope exit.

Example of usage:

```
1 void foo()
2 {
3     bool isDoingSomething = true;
4     {
5         wxON_BLOCK_EXIT_SET(isDoingSomething, false);
6         ... do something ...
7     }
8     ... isDoingSomething is false now ...
9 }
```

Notice that *value* is copied, i.e. stored by value, so it can be a temporary object returned by a function call, for example.

See also

wxON_BLOCK_EXIT_OBJ0(), wxON_BLOCK_EXIT_NULL()

Include file:

```
#include <wx/scopeguard.h>
```

#define wxON_BLOCK_EXIT_THIS(*method, ...*)

This family of macros is similar to wxON_BLOCK_OBJ(), but calls a method of `this` object instead of a method of the specified object.

Include file:

```
#include <wx/scopeguard.h>
```

#define wxON_BLOCK_EXIT_THIS0(*method*)

#define wxON_BLOCK_EXIT_THIS1(*method, p1*)

#define wxON_BLOCK_EXIT_THIS2(*method, p1, p2*)

#define wxON_BLOCK_EXIT_THIS3(*method, p1, p2, p3*)

#define wxOVERRIDE

`wxOVERRIDE` expands to the C++11 `override` keyword if it's supported by the compiler or nothing otherwise.

This macro is useful for writing code which may be compiled by both C++11 and non-C++11 compilers and still allow the use of `override` for the former.

Example of using this macro:

```
1 class MyApp : public wxApp {
2 public:
3     virtual bool OnInit() wxOVERRIDE;
4
5     // This would result in an error from a C++11 compiler as the
6     // method doesn't actually override the base class OnExit() due to
7     // a typo in its name.
8     //virtual int OnEzit() wxOVERRIDE;
9 };
```

Include file:

```
#include <wx/defs.h>
```

Since

3.1.0

#define wxSTRINGIZE(*x*)

Returns the string representation of the given symbol which can be either a literal or a macro (hence the advantage of using this macro instead of the standard preprocessor # operator which doesn't work with macros).

Notice that this macro always produces a `char` string, use wxSTRINGIZE_T() to build a wide string Unicode build.

See also

wxCONCAT()

Include file:

```
#include <wx/cpp.h>
```

#define wxSTRINGIZE_T(*x*)

Returns the string representation of the given symbol as either an ASCII or Unicode string, depending on the current build.

This is the Unicode-friendly equivalent of wxSTRINGIZE().

Include file:

```
#include <wx/cpp.h>
```

#define wxSUPPRESS_GCC_PRIVATE_DTOR_WARNING(*name*)

GNU C++ compiler gives a warning for any class whose destructor is private unless it has a friend.

This warning may sometimes be useful but it doesn't make sense for reference counted class which always delete themselves (hence destructor should be private) but don't necessarily have any friends, so this macro is provided

to disable the warning in such case. The *name* parameter should be the name of the class but is only used to construct a unique friend class name internally.

Example of using the macro:

```
1 class RefCounted
2 {
3 public:
4     RefCounted() { m_nRef = 1; }
5     void IncRef() { m_nRef++ ; }
6     void DecRef() { if ( !--m_nRef ) delete this; }
7
8 private:
9     ~RefCounted() { }
10
11     wxSUPPRESS_GCC_PRIVATE_DTOR(RefCounted)
12 };
```

Notice that there should be no semicolon after this macro.

Include file:

```
#include <wx/defs.h>
```

20.38.3 Typedef Documentation

typedef int(∗ wxSortCallback)(const void ∗pItem1, const void ∗pItem2, const void ∗user_data)

Compare function type for use with wxQsort()

Include file:

```
#include <wx/utils.h>
```

20.38.4 Enumeration Type Documentation

anonymous enum

flags for wxStripMenuCodes

Enumerator

wxStrip_Mnemonics

wxStrip_Accel

wxStrip_All

enum wxBase64DecodeMode

Elements of this enum specify the possible behaviours of wxBase64Decode when an invalid character is encountered.

Enumerator

wxBase64DecodeMode_Strict Normal behaviour: stop at any invalid characters.

wxBase64DecodeMode_SkipWS Skip whitespace characters.

wxBase64DecodeMode_Relaxed The most lenient behaviour: simply ignore all invalid characters.

20.38.5 Function Documentation

size_t wxBase64Decode (void * *dst*, size_t *dstLen*, const char * *src*, size_t *srcLen* = wxNO_LEN, wxBase64DecodeMode *mode* = wxBase64DecodeMode_Strict, size_t * *posErr* = NULL)

This function decodes a Base64-encoded string.

This overload is a raw decoding function and decodes the data into the provided buffer *dst* of the given size *dstLen*. An error is returned if the buffer is not large enough – that is not at least wxBase64DecodedSize(srcLen) bytes. Notice that the buffer will *not* be NULL-terminated.

This overload returns the number of bytes written to the buffer or the necessary buffer size if *dst* was NULL or wxCONV_FAILED on error, e.g. if the output buffer is too small or invalid characters were encountered in the input string.

Parameters

dst	Pointer to output buffer, may be NULL to just compute the necessary buffer size.
dstLen	The size of the output buffer, ignored if dst is NULL.
src	The input string, must not be NULL. For the version using wxString, the input string should contain only ASCII characters.
srcLen	The length of the input string or special value wxNO_LEN if the string is NULL-terminated and the length should be computed by this function itself.
mode	This parameter specifies the function behaviour when invalid characters are encountered in input. By default, any such character stops the decoding with error. If the mode is wxBase64DecodeMode_SkipWS, then the white space characters are silently skipped instead. And if it is wxBase64DecodeMode_Relaxed, then all invalid characters are skipped.
posErr	If this pointer is non-NULL and an error occurs during decoding, it is filled with the index of the invalid character.

Include file:

```
#include <wx/base64.h>
```

size_t wxBase64Decode (void * *dst*, size_t *dstLen*, const wxString & *str*, wxBase64DecodeMode *mode* = wxBase64DecodeMode_Strict, size_t * *posErr* = NULL)

Decode a Base64-encoded wxString.

See the wxBase64Decode(void*,size_t,const char*,size_t,wxBase64DecodeMode,size_t*) overload for more information about the parameters of this function, the only difference between it and this one is that a wxString is used instead of a char* pointer and its length.

Since

2.9.1

Include file:

```
#include <wx/base64.h>
```

wxMemoryBuffer wxBase64Decode (const char * *src*, size_t *srcLen* = wxNO_LEN, wxBase64DecodeMode *mode* = wxBase64DecodeMode_Strict, size_t * *posErr* = NULL)

Decode a Base64-encoded string and return decoded contents in a buffer.

See the wxBase64Decode(void*,size_t,const char*,size_t,wxBase64DecodeMode,size_t*) overload for more information about the parameters of this function. The difference of this overload is that it allocates a buffer of necessary size on its own and returns it, freeing you from the need to do it manually. Because of this, it is simpler to use and is recommended for normal use.

Include file:

```
#include <wx/base64.h>
```

wxMemoryBuffer wxBase64Decode (const wxString & *src*, wxBase64DecodeMode *mode* = wxBase64DecodeMode_Strict, size_t * *posErr* = NULL)

Decode a Base64-encoded wxString and return decoded contents in a buffer.

See the wxBase64Decode(void*,size_t,const char*,size_t,wxBase64DecodeMode,size_t*) overload for more information about the parameters of this function.

This overload takes as input a wxString and returns the internally-allocated memory as a wxMemoryBuffer, containing the Base64-decoded data.

Include file:

```
#include <wx/base64.h>
```

size_t wxBase64DecodedSize (size_t *srcLen*)

Returns the size of the buffer necessary to contain the data encoded in a base64 string of length *srcLen*.

This can be useful for allocating a buffer to be passed to wxBase64Decode().

Include file:

```
#include <wx/base64.h>
```

size_t wxBase64Encode (char * *dst*, size_t *dstLen*, const void * *src*, size_t *srcLen*)

This function encodes the given data using base64.

To allocate the buffer of the correct size, use wxBase64EncodedSize() or call this function with *dst* set to NULL – it will then return the necessary buffer size.

This raw encoding function overload writes the output string into the provided buffer; the other overloads return it as a wxString.

Parameters

dst	The output buffer, may be NULL to retrieve the needed buffer size.
dstLen	The output buffer size, ignored if dst is NULL.
src	The input buffer, must not be NULL.
srcLen	The length of the input data.

Returns

wxCONV_FAILED if the output buffer is too small.

Include file:

```
#include <wx/base64.h>
```

wxString wxBase64Encode (const void * *src*, size_t *srcLen*)

This function encodes the given data using base64 and returns the output as a wxString.

There is no error return.

To allocate the buffer of the correct size, use wxBase64EncodedSize() or call this function with *dst* set to NULL – it will then return the necessary buffer size.

Parameters

src	The input buffer, must not be NULL.
srcLen	The length of the input data.

Include file:

```
#include <wx/base64.h>
```

wxString wxBase64Encode (const wxMemoryBuffer & *buf*)

This function encodes the given data using base64 and returns the output as a wxString.

There is no error return.

Include file:

```
#include <wx/base64.h>
```

size_t wxBase64EncodedSize (size_t *len*)

Returns the length of the string with base64 representation of a buffer of specified size *len*.

This can be useful for allocating the buffer passed to wxBase64Encode().

Include file:

```
#include <wx/base64.h>
```

void wxDDECleanUp ( )

Called when wxWidgets exits, to clean up the DDE system.

This no longer needs to be called by the application.

See also

wxDDEInitialize()

Include file:

```
#include <wx/dde.h>
```

void wxDDEInitialize ( )

Initializes the DDE system.

May be called multiple times without harm.

This no longer needs to be called by the application: it will be called by wxWidgets if necessary.

See also

wxDDEServer, wxDDEClient, wxDDEConnection, wxDDECleanUp()

Include file:

```
#include <wx/dde.h>
```

template<typename T > wxDELETE (T *& *ptr*)

A function which deletes and nulls the pointer.

This function uses operator delete to free the pointer and also sets it to NULL. Notice that this does *not* work for arrays, use wxDELETEA() for them.

```
1 MyClass *ptr = new MyClass;
2 ...
3 wxDELETE(ptr);
4 wxASSERT(!ptr);
```

Include file:

```
#include <wx/defs.h>
```

template<typename T > wxDELETEA (T *& *array*)

A function which deletes and nulls the pointer.

This function uses vector operator delete (`delete[]`) to free the array pointer and also sets it to NULL. Notice that this does *not* work for non-array pointers, use wxDELETE() for them.

```
1 MyClass *array = new MyClass[17];
2 ...
3 wxDELETEA(array);
4 wxASSERT(!array);
```

See also

wxDELETE()

Include file:

```
#include <wx/defs.h>
```

void wxEnableTopLevelWindows (bool *enable* = `true`)

This function enables or disables all top level windows.

It is used by wxSafeYield().

Include file:

```
#include <wx/utils.h>
```

int wxFindMenuItemId (wxFrame * *frame*, const wxString & *menuString*, const wxString & *itemString*)

Find a menu item identifier associated with the given frame's menu bar.

Include file:

```
#include <wx/utils.h>
```

wxWindow* wxFindWindowAtPoint (const wxPoint & *pt*)

Find the deepest window at the given mouse position in screen coordinates, returning the window if found, or NULL if not.

This function takes child windows at the given position into account even if they are disabled. The hidden children are however skipped by it.

Include file:

```
#include <wx/utils.h>
```

wxWindow* wxFindWindowAtPointer (wxPoint & *pt*)

Find the deepest window at the mouse pointer position, returning the window and current pointer position in screen coordinates.

Include file:

```
#include <wx/window.h>
```

wxWindow* wxFindWindowByLabel (const wxString & *label,* wxWindow * *parent* = NULL)

Deprecated Replaced by wxWindow::FindWindowByLabel().

Find a window by its label. Depending on the type of window, the label may be a window title or panel item label. If *parent* is NULL, the search will start from all top-level frames and dialog boxes; if non-NULL, the search will be limited to the given window hierarchy. The search is recursive in both cases.

Include file:

```
#include <wx/utils.h>
```

wxWindow* wxFindWindowByName (const wxString & *name,* wxWindow * *parent* = NULL)

Deprecated Replaced by wxWindow::FindWindowByName().

Find a window by its name (as given in a window constructor or *Create* function call). If *parent* is NULL, the search will start from all top-level frames and dialog boxes; if non-NULL, the search will be limited to the given window hierarchy. The search is recursive in both cases.

If no such named window is found, wxFindWindowByLabel() is called.

Include file:

```
#include <wx/utils.h>
```

bool wxFromString (const wxString & *string,* wxColour * *colour*)

Converts string to a wxColour best represented by the given string.

Returns true on success.

See also

wxToString(const wxColour&)

Include file:

```
#include <wx/colour.h>
```

bool wxFromString (const wxString & *string,* wxFont * *font*)

Converts string to a wxFont best represented by the given string.

Returns true on success.

See also

wxToString(const wxFont&)

Include file:

```
#include <wx/font.h>
```

wxWindow* wxGetActiveWindow ( )

Gets the currently active window (implemented for MSW and GTK only currently, always returns NULL in the other ports).

Include file:

```
#include <wx/window.h>
```

wxBatteryState wxGetBatteryState ( )

Returns battery state as one of `wxBATTERY_NORMAL_STATE`, `wxBATTERY_LOW_STATE`, `wxBATTERY_CRITICAL_STATE`, `wxBATTERY_SHUTDOWN_STATE` or `wxBATTERY_UNKNOWN_STATE`.

`wxBATTERY_UNKNOWN_STATE` is also the default on platforms where this feature is not implemented (currently everywhere but MS Windows).

Include file:

```
#include <wx/utils.h>
```

wxString wxGetDisplayName ( )

Under X only, returns the current display name.

See also

wxSetDisplayName()

Include file:

```
#include <wx/utils.h>
```

bool wxGetKeyState (wxKeyCode *key*)

For normal keys, returns true if the specified key is currently down.

For togglable keys (Caps Lock, Num Lock and Scroll Lock), returns true if the key is toggled such that its LED indicator is lit. There is currently no way to test whether togglable keys are up or down.

Even though there are virtual key codes defined for mouse buttons, they cannot be used with this function currently.

Include file:

```
#include <wx/utils.h>
```

wxPoint wxGetMousePosition ( )

Returns the mouse position in screen coordinates.

Include file:

```
#include <wx/utils.h>
```

wxMouseState wxGetMouseState ( )

Returns the current state of the mouse.

Returns a wxMouseState instance that contains the current position of the mouse pointer in screen coordinates, as well as boolean values indicating the up/down status of the mouse buttons and the modifier keys.

Include file:

```
#include <wx/utils.h>
```

wxPowerType wxGetPowerType ( )

Returns the type of power source as one of `wxPOWER_SOCKET`, `wxPOWER_BATTERY` or `wxPOWER_UNKNOWN`.

`wxPOWER_UNKNOWN` is also the default on platforms where this feature is not implemented (currently everywhere but MS Windows).

Include file:

```
#include <wx/utils.h>
```

wxString wxGetStockLabel (wxWindowID *id,* long *flags* = wxSTOCK_WITH_MNEMONIC)

Returns label that should be used for given *id* element.

Parameters

id	Given id of the wxMenuItem, wxButton, wxToolBar tool, etc.
flags	Combination of the elements of wxStockLabelQueryFlag.

Include file:

```
#include <wx/stockitem.h>
```

wxWindow* wxGetTopLevelParent (wxWindow * *window*)

Returns the first top level parent of the given window, or in other words, the frame or dialog containing it, or NULL.

Notice that if *window* is itself already a TLW, it is returned directly.

Include file:

```
#include <wx/window.h>
```

bool wxLaunchDefaultApplication (const wxString & *document,* int *flags* = 0)

Opens the *document* in the application associated with the files of this type.

The *flags* parameter is currently not used

Returns true if the application was successfully launched.

See also

wxLaunchDefaultBrowser(), wxExecute()

Include file:

```
#include <wx/utils.h>
```

bool wxLaunchDefaultBrowser (const wxString & *url,* int *flags* = 0)

Opens the *url* in user's default browser.

If the *flags* parameter contains `wxBROWSER_NEW_WINDOW` flag, a new window is opened for the URL (currently this is only supported under Windows).

And unless the *flags* parameter contains `wxBROWSER_NOBUSYCURSOR` flag, a busy cursor is shown while the browser is being launched (using wxBusyCursor).

The parameter *url* is interpreted as follows:

- if it has a valid scheme (e.g. `"file:"`, `"http:"` or `"mailto:"`) it is passed to the appropriate browser configured in the user system.
- if it has no valid scheme (e.g. it's a local file path without the `"file:"` prefix), then wxFileExists and wxDirExists are used to test if it's a local file/directory; if it is, then the browser is called with the *url* parameter eventually prefixed by `"file:"`.
- if it has no valid scheme and it's not a local file/directory, then `"http:"` is prepended and the browser is called.

Returns true if the application was successfully launched.

Note

For some configurations of the running user, the application which is launched to open the given URL may be URL-dependent (e.g. a browser may be used for local URLs while another one may be used for remote URLs).

See also

wxLaunchDefaultApplication(), wxExecute()

Include file:

```
#include <wx/utils.h>
```

wxLongLong_t wxLL (number)

This macro is defined for the platforms with a native 64 bit integer type and allow the use of 64 bit compile time constants:

```
1 #ifdef wxLongLong_t
2     wxLongLong_t ll = wxLL(0x1234567890abcdef);
3 #endif
```

See also

wxULL(), wxLongLong

Include file:

```
#include <wx/longlong.h>
```

bool wxLoadUserResource (const void ** *outData,* size_t * *outLen,* const wxString & *resourceName,* const wxChar * *resourceType =* "TEXT", WXHINSTANCE *module =* 0)

Loads an object from Windows resource file.

This function loads the resource with the given name and type from the resources embedded into a Windows application.

The typical use for it is to load some data from the data files embedded into the program itself. For example, you could have the following fragment in your .rc file

```
1 mydata  MYDATA  "myfile.dat"
```

and then use it in the following way:

```
1 const void* data = NULL;
2 size_t size = 0;
3 if ( !wxLoadUserResource(&data, &size, "mydata", "MYDATA") ) {
4     ... handle error ...
5 }
6 else {
7     // Use the data in any way, for example:
8     wxMemoryInputStream is(data, size);
9     ... read the data from stream ...
10 }
```

Parameters

outData	Filled with the pointer to the data on successful return. Notice that this pointer does *not* need to be freed by the caller.
outLen	Filled with the length of the data in bytes.
resourceName	The name of the resource to load.
resourceType	The type of the resource in usual Windows format, i.e. either a real string like "MYDATA" or an integer created by the standard Windows MAKEINTRESOURCE() macro, including any constants for the standard resources types like RT_RCDATA.
module	The HINSTANCE of the module to load the resources from. The current module is used by default.

Returns

true if the data was loaded from resource or false if it couldn't be found (in which case no error is logged) or was found but couldn't be loaded (which is unexpected and does result in an error message).

This function is available under Windows only.

Library: wxBase

Include file:

```
#include <wx/utils.h>
```

Since

2.9.1

char* wxLoadUserResource (const wxString & *resourceName,* const wxChar * *resourceType =* "TEXT", int * *pLen =* NULL, WXHINSTANCE *module =* 0)

Loads a user-defined Windows resource as a string.

This is a wrapper for the general purpose overload wxLoadUserResource(const void∗∗, size_t∗, const wxString&, const wxChar∗, WXHINSTANCE) and can be more convenient for the string data, but does an extra copy compared to the general version.

Parameters

resourceName	The name of the resource to load.
resourceType	The type of the resource in usual Windows format, i.e. either a real string like "MYDATA" or an integer created by the standard Windows `MAKEINTRESOURCE()` macro, including any constants for the standard resources types like `RT_RCDATA`.
pLen	Filled with the length of the returned buffer if it is non-NULL. This parameter should be used if NUL characters can occur in the resource data. It is new since wxWidgets 2.9.1
module	The `HINSTANCE` of the module to load the resources from. The current module is used by default. This parameter is new since wxWidgets 2.9.1.

Returns

A pointer to the data to be `delete[]`d by caller on success or NULL on error.

This function is available under Windows only.

Library: wxBase

Include file:

```
#include <wx/utils.h>
```

template<typename F , typename P1 , ... , typename PN > wxScopeGuard wxMakeGuard (F *func,* P1 *p1,* ..., PN *pN*)

Returns a scope guard object which will call the specified function with the given parameters on scope exit.

This function is overloaded to take several parameters up to some implementation-defined (but relatively low) limit.

The *func* should be a functor taking parameters of the types P1, ..., PN, i.e. the expression `func`(p1, ..., pN) should be valid.

int wxNewId ( )

Deprecated Ids generated by it can conflict with the Ids defined by the user code, use `wxID_ANY` to assign ids which are guaranteed to not conflict with the user-defined ids for the controls and menu items you create instead of using this function.

Generates an integer identifier unique to this run of the program.

Include file:

```
#include <wx/utils.h>
```

void wxPostDelete (wxObject * *object*)

Deprecated Replaced by wxWindow::Close(). See the window deletion overview.

Tells the system to delete the specified object when all other events have been processed. In some environments, it is necessary to use this instead of deleting a frame directly with the delete operator, because some GUIs will still send events to a deleted window.

Include file:

```
#include <wx/utils.h>
```

void wxQsort (void * *pbase,* size_t *total_elems,* size_t *size,* wxSortCallback *cmp,* const void * *user_data*)

Function implementing quick sort algorithm.

This function sorts *total_elems* objects of size *size* located at *pbase*. It uses *cmp* function for comparing them and passes *user_data* pointer to the comparison function each time it's called.

Include file:

```
#include <wx/utils.h>
```

void wxRegisterId (int *id*)

Ensures that Ids subsequently generated by wxNewId() do not clash with the given *id*.

Include file:

```
#include <wx/utils.h>
```

void wxSetDisplayName (const wxString & *displayName*)

Under X only, sets the current display name.

This is the X host and display name such as "colonsay:0.0", and the function indicates which display should be used for creating windows from this point on. Setting the display within an application allows multiple displays to be used.

See also

wxGetDisplayName()

Include file:

```
#include <wx/utils.h>
```

wxString wxStripMenuCodes (const wxString & *str,* int *flags* = wxStrip_All)

Strips any menu codes from *str* and returns the result.

By default, the functions strips both the mnemonics character (`'&'`) which is used to indicate a keyboard shortkey, and the accelerators, which are used only in the menu items and are separated from the main text by the `\t` (TAB) character. By using *flags* of `wxStrip_Mnemonics` or `wxStrip_Accel` to strip only the former or the latter part, respectively.

Notice that in most cases wxMenuItem::GetLabelFromText() or wxControl::GetLabelText() can be used instead.

Include file:

```
#include <wx/utils.h>
```

template<typename T > wxSwap (T & *first,* T & *second*)

Swaps the contents of two variables.

This is similar to std::swap() but can be used even on the platforms where the standard C++ library is not available (if you don't target such platforms, please use std::swap() instead).

The function relies on type T being copy constructible and assignable.

Example of use:

```
1 int x = 3,
2     y = 4;
3 wxSwap(x, y);
4 wxASSERT( x == 4 && y == 3 );
```

wxString wxToString (const wxColour & *colour*)

Converts the given wxColour into a string.

See also

wxFromString(const wxString&, wxColour*)

Include file:

```
#include <wx/colour.h>
```

wxString wxToString (const wxFont & *font*)

Converts the given wxFont into a string.

See also

wxFromString(const wxString&, wxFont*)

Include file:

```
#include <wx/font.h>
```

wxLongLong_t wxULL (number)

This macro is defined for the platforms with a native 64 bit integer type and allow the use of 64 bit compile time constants:

```
1 #ifdef wxLongLong_t
2     unsigned wxLongLong_t ll = wxULL(0x1234567890abcdef);
3 #endif
```

See also

wxLL(), wxLongLong

Include file:

```
#include <wx/longlong.h>
```

void wxVaCopy (va_list *argptrDst*, va_list *argptrSrc*)

This macro is the same as the standard C99 `va_copy` for the compilers which support it or its replacement for those that don't.

It must be used to preserve the value of a `va_list` object if you need to use it after passing it to another function because it can be modified by the latter.

As with `va_start`, each call to `wxVaCopy` must have a matching `va_end`.

Include file:

```
#include <wx/defs.h>
```

20.39 Miscellaneous Windows

20.39.1 Detailed Description

The following are a variety of classes that are derived from wxWindow.

Classes

- class wxBannerWindow

  A simple banner window showing either a bitmap or text.
- class wxCustomBackgroundWindow< W >

  A helper class making it possible to use custom background for any window.
- class wxInfoBar

  An info bar is a transient window shown at top or bottom of its parent window to display non-critical information to the user.
- class wxRichToolTip

  Allows to show a tool tip with more customizations than wxToolTip.
- class wxScrolled< T >

  The wxScrolled class manages scrolling for its client area, transforming the coordinates according to the scrollbar positions, and setting the scroll positions, thumb sizes and ranges according to the area in view.
- class wxSashLayoutWindow

  wxSashLayoutWindow responds to OnCalculateLayout events generated by wxLayoutAlgorithm.
- class wxPanel

  A panel is a window on which controls are placed.
- class wxSashWindow

  wxSashWindow allows any of its edges to have a sash which can be dragged to resize the window.
- class wxSplitterWindow

  This class manages up to two subwindows.
- class wxStatusBar

  A status bar is a narrow window that can be placed along the bottom of a frame to give small amounts of status information.
- class wxToolBar

  A toolbar is a bar of buttons and/or other controls usually placed below the menu bar in a wxFrame.
- class wxVarScrollHelperBase

  This class provides all common base functionality for scroll calculations shared among all variable scrolled window implementations as well as automatic scrollbar functionality, saved scroll positions, controlling target windows to be scrolled, as well as defining all required virtual functions that need to be implemented for any orientation specific work.
- class wxVarVScrollHelper

  This class provides functions wrapping the wxVarScrollHelperBase class, targeted for vertical-specific scrolling.
- class wxVarHScrollHelper

  This class provides functions wrapping the wxVarScrollHelperBase class, targeted for horizontal-specific scrolling.
- class wxVarHVScrollHelper

  This class provides functions wrapping the wxVarHScrollHelper and wxVarVScrollHelper classes, targeted for scrolling a window in both axis.
- class wxVScrolledWindow

  In the name of this class, "V" may stand for "variable" because it can be used for scrolling rows of variable heights; "virtual", because it is not necessary to know the heights of all rows in advance – only those which are shown on the screen need to be measured; or even "vertical", because this class only supports scrolling vertically.
- class wxHScrolledWindow

  In the name of this class, "H" stands for "horizontal" because it can be used for scrolling columns of variable widths.
- class wxHVScrolledWindow

  This window inherits all functionality of both vertical and horizontal, variable scrolled windows.

- class wxWindow

  wxWindow is the base class for all windows and represents any visible object on screen.

- class wxWizardPage

  wxWizardPage is one of the screens in wxWizard: it must know what are the following and preceding pages (which may be NULL for the first/last page).

- class wxWizardPageSimple

  wxWizardPageSimple is the simplest possible wxWizardPage implementation: it just returns the pointers given to its constructor from wxWizardPage::GetNext() and wxWizardPage::GetPrev() functions.

Typedefs

- typedef wxScrolled< wxPanel > wxScrolledWindow

  Scrolled window derived from wxPanel.

- typedef wxScrolled< wxWindow > wxScrolledCanvas

  Alias for wxScrolled<wxWindow>.

20.39.2 Typedef Documentation

typedef wxScrolled<wxWindow> wxScrolledCanvas

Alias for wxScrolled<wxWindow>.

Scrolled window that doesn't have children and so doesn't need or want special handling of TAB traversal.

Since

2.9.0

Library: wxCore

Category: Miscellaneous Windows

See also

wxScrolled, wxScrolledWindow

typedef wxScrolled<wxPanel> wxScrolledWindow

Scrolled window derived from wxPanel.

See wxScrolled for a detailed description.

Note

Note that because this class derives from wxPanel, it shares its behaviour with regard to TAB traversal and focus handling (in particular, it forwards focus to its children). If you don't want this behaviour, use wxScrolled↩ Canvas instead.
wxScrolledWindow is an alias for wxScrolled<wxPanel> since version 2.9.0. In older versions, it was a standalone class.

Library: wxCore

Category: Miscellaneous Windows

See also

wxScrolled, wxScrolledCanvas

20.40 Multimedia

20.40.1 Detailed Description

Classes for showing multimedia contents.

Classes

- class wxMediaCtrl

  wxMediaCtrl is a class for displaying types of media, such as videos, audio files, natively through native codecs.
- class wxSound

  This class represents a short sound (loaded from Windows WAV file), that can be stored in memory and played.

20.41 Network, User and OS

20.41.1 Detailed Description

The functions in this section are used to retrieve information about the current computer and/or user characteristics.

Related class group: Networking, wxPlatformInfo.

Functions

- wxString wxGetEmailAddress ()

  Copies the user's email address into the supplied buffer, by concatenating the values returned by wxGetFullHostName() and wxGetUserId().
- bool wxGetEmailAddress (char *buf, int sz)
- wxMemorySize wxGetFreeMemory ()

  Returns the amount of free memory in bytes under environments which support it, and -1 if not supported or failed to perform measurement.
- wxString wxGetHomeDir ()

  Return the (current) user's home directory.
- wxString wxGetHostName ()

  Copies the current host machine's name into the supplied buffer.
- bool wxGetHostName (char *buf, int sz)
- wxString wxGetFullHostName ()

  Returns the FQDN (fully qualified domain host name) or an empty string on error.
- wxString wxGetUserHome (const wxString &user=wxEmptyString)

  Returns the home directory for the given user.
- wxString wxGetUserId ()

  This function returns the "user id" also known as "login name" under Unix (i.e.
- bool wxGetUserId (char *buf, int sz)
- wxString wxGetUserName ()

  This function returns the full user name (something like "Mr. John Smith").
- bool wxGetUserName (char *buf, int sz)
- wxString wxGetOsDescription ()

  Returns the string containing the description of the current platform in a user-readable form.
- wxOperatingSystemId wxGetOsVersion (int *major=NULL, int *minor=NULL)

  Gets the version and the operating system ID for currently running OS.
- bool wxIsPlatform64Bit ()

  Returns true if the operating system the program is running under is 64 bit.
- bool wxIsPlatformLittleEndian ()

  Returns true if the current platform is little endian (instead of big endian).
- wxLinuxDistributionInfo wxGetLinuxDistributionInfo ()

  Returns a structure containing information about the currently running Linux distribution.

20.41.2 Function Documentation

wxString wxGetEmailAddress ( )

Copies the user's email address into the supplied buffer, by concatenating the values returned by wxGetFullHostName() and wxGetUserId().

Returns

true if successful, false otherwise.

Include file:

```
#include <wx/utils.h>
```

bool wxGetEmailAddress (char * *buf*, int *sz*)

Deprecated Use wxGetEmailAddress() instead.

Parameters

buf	Buffer to store the email address in.
sz	Size of the buffer.

Returns

true if successful, false otherwise.

Include file:

```
#include <wx/utils.h>
```

wxMemorySize wxGetFreeMemory ( )

Returns the amount of free memory in bytes under environments which support it, and -1 if not supported or failed to perform measurement.

Include file:

```
#include <wx/utils.h>
```

wxString wxGetFullHostName ( )

Returns the FQDN (fully qualified domain host name) or an empty string on error.

See also

wxGetHostName()

Include file:

```
#include <wx/utils.h>
```

wxString wxGetHomeDir ( )

Return the (current) user's home directory.

See also

wxGetUserHome(), wxStandardPaths

Include file:

```
#include <wx/utils.h>
```

wxString wxGetHostName ( )

Copies the current host machine's name into the supplied buffer.

Please note that the returned name is *not* fully qualified, i.e. it does not include the domain name.

Under Windows or NT, this function first looks in the environment variable SYSTEM_NAME; if this is not found, the entry **HostName** in the wxWidgets section of the WIN.INI file is tried.

Returns

The hostname if successful or an empty string otherwise.

See also

wxGetFullHostName()

Include file:

```
#include <wx/utils.h>
```

bool wxGetHostName (char * *buf*, int *sz*)

Deprecated Use wxGetHostName() instead.

Parameters

buf	Buffer to store the host name in.
sz	Size of the buffer.

Returns

true if successful, false otherwise.

Include file:

```
#include <wx/utils.h>
```

wxLinuxDistributionInfo wxGetLinuxDistributionInfo ( )

Returns a structure containing information about the currently running Linux distribution.

This function uses the `lsb_release` utility which is part of the `Linux Standard Base Core` specification (see `http://refspecs.linux-foundation.org/lsb.shtml`) since the very first LSB release 1.↩ 0 (released in 2001). The `lsb_release` utility is very common on modern Linux distributions but in case it's not available, then this function will return a wxLinuxDistributionInfo structure containing empty strings.

This function is Linux-specific and is only available when the **`LINUX`** symbol is defined.

wxString wxGetOsDescription ( )

Returns the string containing the description of the current platform in a user-readable form.

For example, this function may return strings like "Windows NT Version 4.0" or "Linux 2.2.2 i386".

See also

wxGetOsVersion()

Include file:

```
#include <wx/utils.h>
```

wxOperatingSystemId wxGetOsVersion (int * *major* = NULL, int * *minor* = NULL)

Gets the version and the operating system ID for currently running OS.

The returned wxOperatingSystemId value can be used for a basic categorization of the OS family; the major and minor version numbers allows to detect a specific system.

For Unix-like systems (wxOS_UNIX) the major and minor version integers will contain the kernel major and minor version numbers (as returned by the 'uname -r' command); e.g. "2" and "6" if the machine is using kernel 2.6.19.

For Mac OS X systems (wxOS_MAC) the major and minor version integers are the natural version numbers associated with the OS; e.g. "10" and "6" if the machine is using Mac OS X Snow Leopard.

For Windows-like systems (wxOS_WINDOWS) the major and minor version integers will contain the following values:

Windows OS name	Major version	Minor version
Windows 7	6	1
Windows Server 2008 R2	6	1
Windows Server 2008	6	0
Windows Vista	6	0
Windows Server 2003 R2	5	2
Windows Server 2003	5	2
Windows XP	5	1
Windows 2000	5	0

See the MSDN for more info about the values above.

See also

wxGetOsDescription(), wxPlatformInfo

Include file:

```
#include <wx/utils.h>
```

wxString wxGetUserHome (const wxString & *user* = wxEmptyString)

Returns the home directory for the given user.

If the *user* is empty (default value), this function behaves like wxGetHomeDir() (i.e. returns the current user home directory).

If the home directory couldn't be determined, an empty string is returned.

Include file:

```
#include <wx/utils.h>
```

wxString wxGetUserId ( )

This function returns the "user id" also known as "login name" under Unix (i.e.

something like "jsmith"). It uniquely identifies the current user (on this system). Under Windows or NT, this function first looks in the environment variables USER and LOGNAME; if neither of these is found, the entry **UserId** in the **wxWidgets** section of the WIN.INI file is tried.

Returns

The login name if successful or an empty string otherwise.

See also

wxGetUserName()

Include file:

```
#include <wx/utils.h>
```

bool wxGetUserId (char * *buf*, int *sz*)

Deprecated Use wxGetUserId() instead.

Parameters

buf	Buffer to store the login name in.
sz	Size of the buffer.

Returns

true if successful, false otherwise.

Include file:

```
#include <wx/utils.h>
```

wxString wxGetUserName ( )

This function returns the full user name (something like "Mr. John Smith").

Under Windows or NT, this function looks for the entry UserName in the wxWidgets section of the WIN.INI file. If PenWindows is running, the entry Current in the section User of the PENWIN.INI file is used.

Returns

The full user name if successful or an empty string otherwise.

See also

wxGetUserId()

Include file:

```
#include <wx/utils.h>
```

bool wxGetUserName (char * *buf*, int *sz*)

Deprecated Use wxGetUserName() instead.

Parameters

buf	Buffer to store the full user name in.

sz	Size of the buffer.

Returns

true if successful, false otherwise.

Include file:

```
#include <wx/utils.h>
```

bool wxIsPlatform64Bit ( )

Returns true if the operating system the program is running under is 64 bit.

The check is performed at run-time and may differ from the value available at compile-time (at compile-time you can just check if `sizeof(void*) == 8`) since the program could be running in emulation mode or in a mixed 32/64 bit system (bi-architecture operating system).

Note

This function is not 100% reliable on some systems given the fact that there isn't always a standard way to do a reliable check on the OS architecture.

Include file:

```
#include <wx/utils.h>
```

bool wxIsPlatformLittleEndian ( )

Returns true if the current platform is little endian (instead of big endian).

The check is performed at run-time.

See also

Byte Order Functions and Macros

Include file:

```
#include <wx/utils.h>
```

20.42 Networking

20.42.1 Detailed Description

wxWidgets provides its own classes for socket based networking.

Related macros/global-functions group: Network, User and OS

Classes

- class wxProtocolLog

  Class allowing to log network operations performed by wxProtocol.
- class wxDialUpManager

  This class encapsulates functions dealing with verifying the connection status of the workstation (connected to the Internet via a direct connection, connected through a modem or not connected at all) and to establish this connection if possible/required (i.e.
- class wxFTP

  wxFTP can be used to establish a connection to an FTP server and perform all the usual operations.
- class wxHTTP

  wxHTTP can be used to establish a connection to an HTTP server.
- class wxProtocol

  Represents a protocol for use with wxURL.
- class wxTCPServer

  A wxTCPServer object represents the server part of a client-server conversation.
- class wxTCPClient

  A wxTCPClient object represents the client part of a client-server conversation.
- class wxTCPConnection

  A wxTCPClient object represents the connection between a client and a server.
- class wxSocketOutputStream

  This class implements an output stream which writes data from a connected socket.
- class wxSocketInputStream

  This class implements an input stream which reads data from a connected socket.
- class wxIPaddress

  wxIPaddress is an abstract base class for all internet protocol address objects.
- class wxIPV4address

  A class for working with IPv4 network addresses.
- class wxSocketServer
- class wxSocketClient
- class wxSockAddress

  You are unlikely to need to use this class: only wxSocketBase uses it.
- class wxSocketEvent

  This event class contains information about socket events.
- class wxSocketBase

  wxSocketBase is the base class for all socket-related objects, and it defines all basic IO functionality.
- class wxDatagramSocket
- class wxURI

  wxURI is used to extract information from a URI (Uniform Resource Identifier).
- class wxURL

  wxURL is a specialization of wxURI for parsing URLs.

20.43 OpenGL

20.43.1 Detailed Description

Classes interfacing wxWidgets with OpenGL (http://opengl.org/).

Classes

- class wxGLContext

  An instance of a wxGLContext represents the state of an OpenGL state machine and the connection between Open↩ GL and the system.
- class wxGLCanvas

  wxGLCanvas is a class for displaying OpenGL graphics.

20.44 Picker Controls

20.44.1 Detailed Description

A picker control is a control whose appearance and behaviour is highly platform-dependent.

Classes

- class wxColourPickerCtrl

  This control allows the user to select a colour.
- class wxDatePickerCtrl

  This control allows the user to select a date.
- class wxFilePickerCtrl

  This control allows the user to select a file.
- class wxDirPickerCtrl

  This control allows the user to select a directory.
- class wxFontPickerCtrl

  This control allows the user to select a font.
- class wxPickerBase

  Base abstract class for all pickers which support an auxiliary text control.
- class wxTimePickerCtrl

  This control allows the user to enter time.

Enumerations

- enum { wxTP_DEFAULT = 0 }

  Styles used with wxTimePickerCtrl.

20.44.2 Enumeration Type Documentation

anonymous enum

Styles used with wxTimePickerCtrl.

Currently no special styles are defined for this object.

Library: wxAdvanced

Category: Picker Controls

Since

2.9.3

Enumerator

wxTP_DEFAULT

20.45 Printing Framework

20.45.1 Detailed Description

A printing and previewing framework is implemented to make it relatively straightforward to provide document printing facilities.

Related Overviews: Printing Framework Overview

Classes

- class wxPageSetupDialogData

  This class holds a variety of information related to wxPageSetupDialog.
- class wxPrintData

  This class holds a variety of information related to printers and printer device contexts.
- class wxPrintDialogData

  This class holds information related to the visual characteristics of wxPrintDialog.
- class wxPrinterDC

  A printer device context is specific to MSW and Mac, and allows access to any printer with a Windows or Macintosh driver.
- class wxHtmlEasyPrinting

  This class provides very simple interface to printing architecture.
- class wxHtmlPrintout

  This class serves as printout class for HTML documents.
- class wxPreviewControlBar

  This is the default implementation of the preview control bar, a panel with buttons and a zoom control.
- class wxPreviewCanvas

  A preview canvas is the default canvas used by the print preview system to display the preview.
- class wxPreviewFrame

  This class provides the default method of managing the print preview interface.
- class wxPrintPreview

  Objects of this class manage the print preview process.
- class wxPrinter

  This class represents the Windows or PostScript printer, and is the vehicle through which printing may be launched by an application.
- class wxPrintout

  This class encapsulates the functionality of printing out an application document.
- class wxPrintDialog

  This class represents the print and print setup common dialogs.
- class wxPageSetupDialog

  This class represents the page setup common dialog.

20.46 Process Control

20.46.1 Detailed Description

The functions in this section are used to launch or terminate the other processes.

Classes

- struct wxExecuteEnv

  This structure can optionally be passed to wxExecute() to specify additional options to use for the child process.

Enumerations

- enum {
  wxEXEC_ASYNC = 0,
  wxEXEC_SYNC = 1,
  wxEXEC_SHOW_CONSOLE = 2,
  wxEXEC_MAKE_GROUP_LEADER = 4,
  wxEXEC_NODISABLE = 8,
  wxEXEC_NOEVENTS = 16,
  wxEXEC_HIDE_CONSOLE = 32,
  wxEXEC_BLOCK = wxEXEC_SYNC | wxEXEC_NOEVENTS }

  Bit flags that can be used with wxExecute().

Functions

- void wxExit ()

  Exits application after calling wxApp::OnExit.
- long wxExecute (const wxString &command, int flags=wxEXEC_ASYNC, wxProcess *callback=NULL, const wxExecuteEnv *env=NULL)

  Executes another program in Unix or Windows.
- long wxExecute (char **argv, int flags=wxEXEC_ASYNC, wxProcess *callback=NULL, const wxExecuteEnv *env=NULL)

  This is an overloaded version of wxExecute(const wxString&,int,wxProcess), please see its documentation for general information.*
- long wxExecute (wchar_t **argv, int flags=wxEXEC_ASYNC, wxProcess *callback=NULL, const wxExecuteEnv *env=NULL)
- long wxExecute (const wxString &command, wxArrayString &output, int flags=0, const wxExecuteEnv *env=NULL)

  This is an overloaded version of wxExecute(const wxString&,int,wxProcess), please see its documentation for general information.*
- long wxExecute (const wxString &command, wxArrayString &output, wxArrayString &errors, int flags=0, const wxExecuteEnv *env=NULL)

  This is an overloaded version of wxExecute(const wxString&,int,wxProcess), please see its documentation for general information.*
- unsigned long wxGetProcessId ()

  Returns the number uniquely identifying the current process in the system.
- int wxKill (long pid, wxSignal sig=wxSIGTERM, wxKillError *rc=NULL, int flags=wxKILL_NOCHILDREN)

  Equivalent to the Unix kill function: send the given signal sig to the process with PID pid.
- bool wxShell (const wxString &command=wxEmptyString)

  Executes a command in an interactive shell window.
- bool wxShutdown (int flags=wxSHUTDOWN_POWEROFF)

  This function shuts down or reboots the computer depending on the value of the flags.

20.46.2 Enumeration Type Documentation

anonymous enum

Bit flags that can be used with wxExecute().

Enumerator

wxEXEC_ASYNC Execute the process asynchronously. Notice that, due to its value, this is the default.

wxEXEC_SYNC Execute the process synchronously.

wxEXEC_SHOW_CONSOLE Always show the child process console under MSW. The child console is hidden by default if the child IO is redirected, this flag allows to change this and show it nevertheless.

This flag is ignored under the other platforms.

wxEXEC_MAKE_GROUP_LEADER Make the new process a group leader. Under Unix, if the process is the group leader then passing wxKILL_CHILDREN to wxKill() kills all children as well as pid.

Under MSW, applies only to console applications and is only supported under NT family (i.e. not under Windows 9x). It corresponds to the native `CREATE_NEW_PROCESS_GROUP` and, in particular, ensures that Ctrl-Break signals will be sent to all children of this process as well to the process itself. Support for this flag under MSW was added in version 2.9.4 of wxWidgets.

wxEXEC_NODISABLE Don't disable the program UI while running the child synchronously. By default synchronous execution disables all program windows to avoid that the user interacts with the program while the child process is running, you can use this flag to prevent this from happening.

This flag can only be used with wxEXEC_SYNC.

wxEXEC_NOEVENTS Don't dispatch events while the child process is executed. By default, the event loop is run while waiting for synchronous execution to complete and this flag can be used to simply block the main process until the child process finishes

This flag can only be used with wxEXEC_SYNC.

wxEXEC_HIDE_CONSOLE Hide child process console under MSW. Under MSW, hide the console of the child process if it has one, even if its IO is not redirected.

This flag is ignored under the other platforms.

wxEXEC_BLOCK Convenient synonym for flags given system()-like behaviour.

20.46.3 Function Documentation

long wxExecute (const wxString & *command*, int *flags* = wxEXEC_ASYNC, wxProcess * *callback* = `NULL`, const wxExecuteEnv * *env* = `NULL`)

Executes another program in Unix or Windows.

In the overloaded versions of this function, if *flags* parameter contains `wxEXEC_ASYNC` flag (the default), flow of control immediately returns. If it contains `wxEXEC_SYNC`, the current application waits until the other program has terminated.

In the case of synchronous execution, the return value is the exit code of the process (which terminates by the moment the function returns) and will be -1 if the process couldn't be started and typically 0 if the process terminated successfully. Also, while waiting for the process to terminate, wxExecute() will call wxYield(). Because of this, by default this function disables all application windows to avoid unexpected reentrancies which could result from the users interaction with the program while the child process is running. If you are sure that it is safe to not disable the program windows, you may pass `wxEXEC_NODISABLE` flag to prevent this automatic disabling from happening.

For asynchronous execution, however, the return value is the process id and zero value indicates that the command could not be executed. As an added complication, the return value of -1 in this case indicates that we didn't launch a new process, but connected to the running one (this can only happen when using DDE under Windows for command execution). In particular, in this case only, the calling code will not get the notification about process termination.

If *callback* isn't NULL and if execution is asynchronous, wxProcess::OnTerminate() will be called when the process finishes. Specifying this parameter also allows you to redirect the standard input and/or output of the process being launched by calling wxProcess::Redirect().

Under Windows, when launching a console process its console is shown by default but hidden if its IO is redirected. Both of these default behaviours may be overridden: if wxEXEC_HIDE_CONSOLE is specified, the console will never be shown. If wxEXEC_SHOW_CONSOLE is used, the console will be shown even if the child process IO is redirected. Neither of these flags affect non-console Windows applications or does anything under the other systems.

Under Unix the flag `wxEXEC_MAKE_GROUP_LEADER` may be used to ensure that the new process is a group leader (this will create a new session if needed). Calling wxKill() passing wxKILL_CHILDREN will kill this process as well as all of its children (except those which have started their own session). Under MSW, this flag can be used with console processes only and corresponds to the native `CREATE_NEW_PROCESS_GROUP` flag.

The `wxEXEC_NOEVENTS` flag prevents processing of any events from taking place while the child process is running. It should be only used for very short-lived processes as otherwise the application windows risk becoming unresponsive from the users point of view. As this flag only makes sense with `wxEXEC_SYNC`, `wxEXEC_BLOCK` equal to the sum of both of these flags is provided as a convenience.

Note

Currently wxExecute() can only be used from the main thread, calling this function from another thread will result in an assert failure in debug build and won't work.

Parameters

command	The command to execute and any parameters to pass to it as a single string, i.e. "emacs file.txt".
flags	Must include either wxEXEC_ASYNC or wxEXEC_SYNC and can also include wxEXEC_SHOW_CONSOLE, wxEXEC_HIDE_CONSOLE, wxEXEC_MAKE_GROUP_LEADER (in either case) or wxEXEC_NODISABLE and wxEXEC_NOEVENTS or wxEXEC_BLOCK, which is equal to their combination, in wxEXEC_SYNC case.
callback	An optional pointer to wxProcess.
env	An optional pointer to additional parameters for the child process, such as its initial working directory and environment variables. This parameter is available in wxWidgets 2.9.2 and later only.

See also

wxShell(), wxProcess, External Program Execution Sample, wxLaunchDefaultApplication(), wxLaunchDefaultBrowser()

Include file:

```
#include <wx/utils.h>
```

wxPerl Note: In wxPerl this function is called `Wx::ExecuteCommand`.

long wxExecute (char ** *argv*, int *flags* = wxEXEC_ASYNC, wxProcess * *callback* = NULL, const wxExecuteEnv * *env* = NULL)

This is an overloaded version of wxExecute(const wxString&,int,wxProcess*), please see its documentation for general information.

This version takes an array of values: a command, any number of arguments, terminated by NULL.

Parameters

argv	The command to execute should be the first element of this array, any additional ones are the command parameters and the array must be terminated with a NULL pointer.

flags	Same as for wxExecute(const wxString&,int,wxProcess*) overload.
callback	An optional pointer to wxProcess.
env	An optional pointer to additional parameters for the child process, such as its initial working directory and environment variables. This parameter is available in wxWidgets 2.9.2 and later only.

See also

wxShell(), wxProcess, External Program Execution Sample, wxLaunchDefaultApplication(), wxLaunchDefaultBrowser()

Include file:

```
#include <wx/utils.h>
```

wxPerl Note: In wxPerl this function is called `Wx::ExecuteArgs`.

long wxExecute (wchar_t ** *argv,* int *flags* = wxEXEC_ASYNC, wxProcess * *callback* = NULL, const wxExecuteEnv * *env* = NULL)

long wxExecute (const wxString & *command,* wxArrayString & *output,* int *flags* = 0, const wxExecuteEnv * *env* = NULL)

This is an overloaded version of wxExecute(const wxString&,int,wxProcess*), please see its documentation for general information.

This version can be used to execute a process (always synchronously, the contents of *flags* is or'd with `wxEXEC_SYNC`) and capture its output in the array *output*.

Parameters

command	The command to execute and any parameters to pass to it as a single string.
output	The string array where the stdout of the executed process is saved.
flags	Combination of flags to which wxEXEC_SYNC is always implicitly added.
env	An optional pointer to additional parameters for the child process, such as its initial working directory and environment variables. This parameter is available in wxWidgets 2.9.2 and later only.

See also

wxShell(), wxProcess, External Program Execution Sample, wxLaunchDefaultApplication(), wxLaunchDefaultBrowser()

Include file:

```
#include <wx/utils.h>
```

wxPerl Note: This function is called `Wx::ExecuteStdout`: it only takes the *command* argument, and returns a 2-element list (`status`, `output`), where `output` in an array reference.

long wxExecute (const wxString & *command,* wxArrayString & *output,* wxArrayString & *errors,* int *flags* = 0, const wxExecuteEnv * *env* = NULL)

This is an overloaded version of wxExecute(const wxString&,int,wxProcess*), please see its documentation for general information.

This version adds the possibility to additionally capture the messages from standard error output in the *errors* array. As with the above overload capturing standard output only, execution is always synchronous.

Parameters

command	The command to execute and any parameters to pass to it as a single string.
output	The string array where the stdout of the executed process is saved.
errors	The string array where the stderr of the executed process is saved.
flags	Combination of flags to which wxEXEC_SYNC is always implicitly added.
env	An optional pointer to additional parameters for the child process, such as its initial working directory and environment variables. This parameter is available in wxWidgets 2.9.2 and later only.

See also

wxShell(), wxProcess, External Program Execution Sample, wxLaunchDefaultApplication(), wxLaunchDefaultBrowser()

Include file:

```
#include <wx/utils.h>
```

wxPerl Note: This function is called `Wx::ExecuteStdoutStderr`: it only takes the *command* argument, and returns a 3-element list (`status`, `output`, `errors`), where `output` and `errors` are array references.

void wxExit ( )

Exits application after calling wxApp::OnExit.

Should only be used in an emergency: normally the top-level frame should be deleted (after deleting all other frames) to terminate the application. See wxCloseEvent and wxApp.

Include file:

```
#include <wx/app.h>
```

unsigned long wxGetProcessId ( )

Returns the number uniquely identifying the current process in the system.

If an error occurs, 0 is returned.

Include file:

```
#include <wx/utils.h>
```

int wxKill (long *pid*, wxSignal *sig* = wxSIGTERM, wxKillError * *rc* = NULL, int *flags* = wxKILL_NOCHILDREN)

Equivalent to the Unix kill function: send the given signal *sig* to the process with PID *pid*.

The valid signal values are:

```
1 enum wxSignal
2 {
3     wxSIGNONE = 0, // verify if the process exists under Unix
4     wxSIGHUP,
5     wxSIGINT,
6     wxSIGQUIT,
7     wxSIGILL,
8     wxSIGTRAP,
9     wxSIGABRT,
10     wxSIGEMT,
11     wxSIGFPE,
12     wxSIGKILL,     // forcefully kill, dangerous!
13     wxSIGBUS,
14     wxSIGSEGV,
```

```
15      wxSIGSYS,
16      wxSIGPIPE,
17      wxSIGALRM,
18      wxSIGTERM       // terminate the process gently
19 };
```

wxSIGNONE, wxSIGKILL and wxSIGTERM have the same meaning under both Unix and Windows but all the other signals are equivalent to wxSIGTERM under Windows. Moreover, under Windows, wxSIGTERM is implemented by posting a message to the application window, so it only works if the application does have windows. If it doesn't, as is notably always the case for the console applications, you need to use wxSIGKILL to actually kill the process. Of course, this doesn't allow the process to shut down gracefully and so should be avoided if possible.

Returns 0 on success, -1 on failure. If the *rc* parameter is not NULL, it will be filled with a value from the wxKill↩Error enum:

```
1 enum wxKillError
2 {
3     wxKILL_OK,              // no error
4     wxKILL_BAD_SIGNAL,      // no such signal
5     wxKILL_ACCESS_DENIED,   // permission denied
6     wxKILL_NO_PROCESS,      // no such process
7     wxKILL_ERROR            // another, unspecified error
8 };
```

The *flags* parameter can be wxKILL_NOCHILDREN (the default), or wxKILL_CHILDREN, in which case the child processes of this process will be killed too. Note that under Unix, for wxKILL_CHILDREN to work you should have created the process by passing wxEXEC_MAKE_GROUP_LEADER to wxExecute().

See also

wxProcess::Kill(), wxProcess::Exists(), External Program Execution Sample

Include file:

```
#include <wx/utils.h>
```

bool wxShell (const wxString & *command* = wxEmptyString)

Executes a command in an interactive shell window.

If no command is specified, then just the shell is spawned.

See also

wxExecute(), External Program Execution Sample

Include file:

```
#include <wx/utils.h>
```

bool wxShutdown (int *flags* = wxSHUTDOWN_POWEROFF)

This function shuts down or reboots the computer depending on the value of the *flags*.

Note

Note that performing the shutdown requires the corresponding access rights (superuser under Unix, SE_S↩HUTDOWN privilege under Windows NT) and that this function is only implemented under Unix and MSW.

Parameters

flags	One of `wxSHUTDOWN_POWEROFF`, `wxSHUTDOWN_REBOOT` or `wxSHUTDOWN_LOGOFF` (currently implemented only for MSW) possibly combined with `wxSHUTDOWN_FORCE` which forces shutdown under MSW by forcefully terminating all the applications. As doing this can result in a data loss, this flag shouldn't be used unless really necessary.

Returns

true on success, false if an error occurred.

Include file:

```
#include <wx/utils.h>
```

20.47 Ribbon User Interface

20.47.1 Detailed Description

The wxRibbon library is a set of classes for writing a ribbon user interface.

At the most generic level, this is a combination of a tab control with a toolbar. At a more functional level, it is similar to the user interface present in recent versions of Microsoft Office.

Classes

- class wxRibbonArtProvider

  wxRibbonArtProvider is responsible for drawing all the components of the ribbon interface.
- class wxRibbonBarEvent

  Event used to indicate various actions relating to a wxRibbonBar.
- class wxRibbonBar

  Top-level control in a ribbon user interface.
- class wxRibbonButtonBar

  A ribbon button bar is similar to a traditional toolbar.
- class wxRibbonButtonBarEvent

  Event used to indicate various actions relating to a button on a wxRibbonButtonBar.
- class wxRibbonControl

  wxRibbonControl serves as a base class for all controls which share the ribbon characteristics of having a ribbon art provider, and (optionally) non-continuous resizing.
- class wxRibbonGallery

  A ribbon gallery is like a wxListBox, but for bitmaps rather than strings.
- class wxRibbonGalleryEvent
- class wxRibbonPage

  Container for related ribbon panels, and a tab within a ribbon bar.
- class wxRibbonPanelEvent

  Event used to indicate various actions relating to a wxRibbonPanel.
- class wxRibbonPanel

  Serves as a container for a group of (ribbon) controls.
- class wxRibbonToolBar

  A ribbon tool bar is similar to a traditional toolbar which has no labels.

20.48 Rich Text

20.48.1 Detailed Description

wxWidgets provides a set of generic classes to edit and print simple rich text with character and paragraph formatting.

Classes

- class wxTextAttrDimension

  A class representing a rich text dimension, including units and position.
- class wxTextAttrDimensions

  A class for left, right, top and bottom dimensions.
- class wxTextAttrSize

  A class for representing width and height.
- class wxTextAttrDimensionConverter

  A class to make it easier to convert dimensions.
- class wxTextAttrBorder

  A class representing a rich text object border.
- class wxTextAttrBorders

  A class representing a rich text object's borders.
- class wxTextAttrShadow

  A class representing a shadow.
- class wxTextBoxAttr

  A class representing the box attributes of a rich text object.
- class wxRichTextAttr

  A class representing enhanced attributes for rich text objects.
- class wxRichTextProperties

  A simple property class using wxVariants.
- class wxRichTextFontTable

  Manages quick access to a pool of fonts for rendering rich text.
- class wxRichTextRange

  This stores beginning and end positions for a range of data.
- class wxRichTextSelection

  Stores selection information.
- class wxRichTextDrawingContext

  A class for passing information to drawing and measuring functions.
- class wxRichTextObject

  This is the base for drawable rich text objects.
- class wxRichTextCompositeObject

  Objects of this class can contain other objects.
- class wxRichTextParagraphLayoutBox

  This class knows how to lay out paragraphs.
- class wxRichTextBox

  This class implements a floating or inline text box, containing paragraphs.
- class wxRichTextField

  This class implements the general concept of a field, an object that represents additional functionality such as a footnote, a bookmark, a page number, a table of contents, and so on.
- class wxRichTextFieldType

  The base class for custom field types.
- class wxRichTextFieldTypeStandard

A field type that can handle fields with text or bitmap labels, with a small range of styles for implementing rectangular fields and fields that can be used for start and end tags.

- class wxRichTextLine

  This object represents a line in a paragraph, and stores offsets from the start of the paragraph representing the start and end positions of the line.
- class wxRichTextParagraph

  This object represents a single paragraph containing various objects such as text content, images, and further paragraph layout objects.
- class wxRichTextPlainText

  This object represents a single piece of text.
- class wxRichTextImageBlock

  This class stores information about an image, in binary in-memory form.
- class wxRichTextImage

  This class implements a graphic object.
- class wxRichTextBuffer

  This is a kind of paragraph layout box, used to represent the whole buffer.
- class wxRichTextObjectAddress

  A class for specifying an object anywhere in an object hierarchy, without using a pointer, necessary since wxRTC commands may delete and recreate sub-objects so physical object addresses change.
- class wxRichTextCommand

  Implements a command on the undo/redo stack.
- class wxRichTextAction

  Implements a part of a command.
- class wxRichTextFileHandler

  The base class for file handlers.
- class wxRichTextPlainTextHandler

  Implements saving a buffer to plain text.
- class wxRichTextDrawingHandler

  The base class for custom drawing handlers.
- class wxRichTextBufferDataObject

  Implements a rich text data object for clipboard transfer.
- class wxRichTextRenderer

  This class isolates some common drawing functionality.
- class wxRichTextStdRenderer

  The standard renderer for drawing bullets.
- class wxRichTextCtrl

  wxRichTextCtrl provides a generic, ground-up implementation of a text control capable of showing multiple styles and images.
- class wxRichTextEvent

  This is the event class for wxRichTextCtrl notifications.
- class wxRichTextFormattingDialogFactory

  This class provides pages for wxRichTextFormattingDialog, and allows other customization of the dialog.
- class wxRichTextFormattingDialog

  This dialog allows the user to edit a character and/or paragraph style.
- class wxRichTextHTMLHandler

  Handles HTML output (only) for wxRichTextCtrl content.
- class wxRichTextHeaderFooterData

  This class represents header and footer data to be passed to the wxRichTextPrinting and wxRichTextPrintout classes.
- class wxRichTextPrintout

  This class implements print layout for wxRichTextBuffer.
- class wxRichTextPrinting

  This class provides a simple interface for performing wxRichTextBuffer printing and previewing.

- class wxRichTextStyleOrganiserDialog

  This class shows a style sheet and allows the user to edit, add and remove styles.
- class wxRichTextStyleListCtrl

  This class incorporates a wxRichTextStyleListBox and a choice control that allows the user to select the category of style to view.
- class wxRichTextStyleDefinition

  This is a base class for paragraph and character styles.
- class wxRichTextParagraphStyleDefinition

  This class represents a paragraph style definition, usually added to a wxRichTextStyleSheet.
- class wxRichTextStyleListBox

  This is a listbox that can display the styles in a wxRichTextStyleSheet, and apply the selection to an associated wxRichTextCtrl.
- class wxRichTextStyleComboCtrl

  This is a combo control that can display the styles in a wxRichTextStyleSheet, and apply the selection to an associated wxRichTextCtrl.
- class wxRichTextCharacterStyleDefinition

  This class represents a character style definition, usually added to a wxRichTextStyleSheet.
- class wxRichTextListStyleDefinition

  This class represents a list style definition, usually added to a wxRichTextStyleSheet.
- class wxRichTextStyleSheet

  A style sheet contains named paragraph and character styles that make it easy for a user to apply combinations of attributes to a wxRichTextCtrl.
- class wxRichTextXMLHandler

  A handler for loading and saving content in an XML format specific to wxRichTextBuffer.
- class wxTextAttr

  wxTextAttr represents the character and paragraph attributes, or style, for a range of text in a wxTextCtrl or wxRich↩ TextCtrl.

20.49 Runtime Type Information (RTTI)

20.49.1 Detailed Description

wxWidgets supports runtime manipulation of class information, and dynamic creation of objects given class names.

Related Overviews: Runtime Type Information (RTTI)

Related macros/global-functions group: Runtime Type Information (RTTI)

Classes

- class wxObjectDataPtr< T >

  This is an helper template class primarily written to avoid memory leaks because of missing calls to wxRefCounter::DecRef() and wxObjectRefData::DecRef().
- class wxObjectRefData

  This class is just a typedef to wxRefCounter and is used by wxObject.
- class wxRefCounter

  This class is used to manage reference-counting providing a simple interface and a counter.
- class wxObject

  This is the root class of many of the wxWidgets classes.
- class wxClassInfo

  This class stores meta-information about classes.

20.50 Runtime Type Information (RTTI)

20.50.1 Detailed Description

wxWidgets uses its own RTTI ("run-time type identification") system which predates the current standard C++ RTTI and so is kept for backwards compatibility reasons but also because it allows some things which the standard RTTI doesn't directly support (such as creating a class from its name).

The standard C++ RTTI can be used in the user code without any problems and in general you shouldn't need to use the functions and the macros in this section unless you are thinking of modifying or adding any wxWidgets classes.

Related Overviews: Runtime Type Information (RTTI)

Related class group: Runtime Type Information (RTTI)

Macros

- #define wxDECLARE_APP(className)

  This is used in headers to create a forward declaration of the wxGetApp() function implemented by wxIMPLEMENT_APP().
- #define wxIMPLEMENT_APP(className)

  This is used in the application class implementation file to make the application class known to wxWidgets for dynamic construction.
- #define wxCLASSINFO(className)

  Returns a pointer to the wxClassInfo object associated with this class.
- #define wxDECLARE_ABSTRACT_CLASS(className)

  Used inside a class declaration to declare that the class should be made known to the class hierarchy, but objects of this class cannot be created dynamically.
- #define wxDECLARE_DYNAMIC_CLASS(className)

  Used inside a class declaration to make the class known to wxWidgets RTTI system and also declare that the objects of this class should be dynamically creatable from run-time type information.
- #define wxDECLARE_CLASS(className)

  Used inside a class declaration to declare that the class should be made known to the class hierarchy, but objects of this class cannot be created dynamically.
- #define wxIMPLEMENT_ABSTRACT_CLASS(className, baseClassName)

  Used in a C++ implementation file to complete the declaration of a class that has run-time type information.
- #define wxIMPLEMENT_ABSTRACT_CLASS2(className, baseClassName1, baseClassName2)

  Used in a C++ implementation file to complete the declaration of a class that has run-time type information and two base classes.
- #define wxIMPLEMENT_DYNAMIC_CLASS(className, baseClassName)

  Used in a C++ implementation file to complete the declaration of a class that has run-time type information, and whose instances can be created dynamically.
- #define wxIMPLEMENT_DYNAMIC_CLASS2(className, baseClassName1, baseClassName2)

  Used in a C++ implementation file to complete the declaration of a class that has run-time type information, and whose instances can be created dynamically.
- #define wxIMPLEMENT_CLASS(className, baseClassName)

  Used in a C++ implementation file to complete the declaration of a class that has run-time type information, and whose instances can be created dynamically.
- #define wxIMPLEMENT_CLASS2(className, baseClassName1, baseClassName2)

  Used in a C++ implementation file to complete the declaration of a class that has run-time type information and two base classes, and whose instances can be created dynamically.
- #define wx_const_cast(T, x)

  Same as `const_cast<T>(x)` if the compiler supports const cast or (T)x for old compilers.
- #define wx_reinterpret_cast(T, x)

Same as `reinterpret_cast<T>(x)` if the compiler supports reinterpret cast or (T)x for old compilers.

- #define wx_static_cast(T, x)

  Same as `static_cast<T>(x)` if the compiler supports static cast or (T)x for old compilers.
- #define wx_truncate_cast(T, x)

  This case doesn't correspond to any standard cast but exists solely to make casts which possibly result in a truncation of an integer value more readable.
- #define wxConstCast(ptr, classname)

  This macro expands into `const_cast<classname *>(ptr)` if the compiler supports const_cast or into an old, C-style cast, otherwise.
- #define wxDynamicCast(ptr, classname)

  *This macro returns the pointer ptr cast to the type classname * if the pointer is of this type (the check is done during the run-time) or NULL otherwise.*
- #define wxDynamicCastThis(classname)

  This macro is equivalent to `wxDynamicCast(this, classname)` but the latter provokes spurious compilation warnings from some compilers (because it tests whether `this` pointer is non-NULL which is always true), so this macro should be used to avoid them.
- #define wxStaticCast(ptr, classname)

  This macro checks that the cast is valid in debug mode (an assert failure will result if wxDynamicCast(ptr, classname) == NULL) and then returns the result of executing an equivalent of `static_cast<classname *>(ptr)`.
- #define wxGetVariantCast(var, classname)

  This macro returns a pointer to the data stored in var (wxVariant) cast to the type classname if the data is of this type (the check is done during the run-time) or NULL otherwise.

Functions

- wxObject * wxCreateDynamicObject (const wxString &className)

  Creates and returns an object of the given class, if the class has been registered with the dynamic class system using DECLARE...

20.50.2 Macro Definition Documentation

#define wx_const_cast(*T, x*)

Same as `const_cast<T>(x)` if the compiler supports const cast or (T)x for old compilers.

Unlike wxConstCast(), the cast it to the type `T` and not to `T *` and also the order of arguments is the same as for the standard cast.

Include file:

```
#include <wx/defs.h>
```

See also

wx_reinterpret_cast(), wx_static_cast()

#define wx_reinterpret_cast(*T, x*)

Same as `reinterpret_cast<T>(x)` if the compiler supports reinterpret cast or (T)x for old compilers.

Include file:

```
#include <wx/defs.h>
```

See also

wx_const_cast(), wx_static_cast()

#define wx_static_cast(*T, x*)

Same as `static_cast<T>(x)` if the compiler supports static cast or (T)x for old compilers.

Unlike wxStaticCast(), there are no checks being done and the meaning of the macro arguments is exactly the same as for the standard static cast, i.e. *T* is the full type name and star is not appended to it.

Include file:

```
#include <wx/defs.h>
```

See also

wx_const_cast(), wx_reinterpret_cast(), wx_truncate_cast()

#define wx_truncate_cast(*T, x*)

This case doesn't correspond to any standard cast but exists solely to make casts which possibly result in a truncation of an integer value more readable.

Include file:

```
#include <wx/defs.h>
```

#define wxCLASSINFO(*className*)

Returns a pointer to the wxClassInfo object associated with this class.

Include file:

```
#include <wx/object.h>
```

#define wxConstCast(*ptr, classname*)

This macro expands into `const_cast<classname *>(ptr)` if the compiler supports const_cast or into an old, C-style cast, otherwise.

Include file:

```
#include <wx/defs.h>
```

See also

wx_const_cast(), wxDynamicCast(), wxStaticCast()

#define wxDECLARE_ABSTRACT_CLASS(*className*)

Used inside a class declaration to declare that the class should be made known to the class hierarchy, but objects of this class cannot be created dynamically.

Include file:

```
#include <wx/object.h>
```

Example:

```
1 class wxCommand: public wxObject
2 {
3     wxDECLARE_ABSTRACT_CLASS(wxCommand);
4
5 private:
6     ...
7 public:
8     ...
9 };
```

#define wxDECLARE_APP(*className*)

This is used in headers to create a forward declaration of the wxGetApp() function implemented by wxIMPLEMENT_APP().

It creates the declaration `className& wxGetApp()` (requires a final semicolon).

Include file:

```
#include <wx/app.h>
```

Example:

```
1 wxDECLARE_APP(MyApp);
```

#define wxDECLARE_CLASS(*className*)

Used inside a class declaration to declare that the class should be made known to the class hierarchy, but objects of this class cannot be created dynamically.

The same as wxDECLARE_ABSTRACT_CLASS().

Include file:

```
#include <wx/object.h>
```

#define wxDECLARE_DYNAMIC_CLASS(*className*)

Used inside a class declaration to make the class known to wxWidgets RTTI system and also declare that the objects of this class should be dynamically creatable from run-time type information.

Notice that this implies that the class should have a default constructor, if this is not the case consider using wxDECLARE_ABSTRACT_CLASS().

Include file:

```
#include <wx/object.h>
```

Example:

```
1 class wxFrame: public wxWindow
2 {
3     wxDECLARE_DYNAMIC_CLASS(wxFrame);
4
5 private:
6     const wxString& frameTitle;
7 public:
8     ...
9 };
```

#define wxDynamicCast(*ptr, classname*)

This macro returns the pointer *ptr* cast to the type *classname* * if the pointer is of this type (the check is done during the run-time) or NULL otherwise.

Usage of this macro is preferred over obsoleted wxObject::IsKindOf() function.

The *ptr* argument may be NULL, in which case NULL will be returned.

Include file:

```
#include <wx/object.h>
```

Example:

```
1 wxWindow *win = wxWindow::FindFocus();
2 wxTextCtrl *text = wxDynamicCast(win, wxTextCtrl);
3 if ( text )
4 {
5     // a text control has the focus...
6 }
7 else
8 {
9     // no window has the focus or it is not a text control
10 }
```

See also

Runtime Type Information (RTTI), wxDynamicCastThis(), wxConstCast(), wxStaticCast()

#define wxDynamicCastThis(*classname*)

This macro is equivalent to `wxDynamicCast(this, classname)` but the latter provokes spurious compilation warnings from some compilers (because it tests whether `this` pointer is non-NULL which is always true), so this macro should be used to avoid them.

Include file:

```
#include <wx/object.h>
```

See also

wxDynamicCast()

#define wxGetVariantCast(*var, classname*)

This macro returns a pointer to the data stored in *var* (wxVariant) cast to the type *classname* if the data is of this type (the check is done during the run-time) or NULL otherwise.

Include file:

```
#include <wx/variant.h>
```

See also

Runtime Type Information (RTTI), wxDynamicCast()

#define wxIMPLEMENT_ABSTRACT_CLASS(*className, baseClassName*)

Used in a C++ implementation file to complete the declaration of a class that has run-time type information.

Include file:

```
#include <wx/object.h>
```

Example:

```
1 wxIMPLEMENT_ABSTRACT_CLASS(wxCommand, wxObject);
2
3 wxCommand::wxCommand(void)
4 {
5     ...
6 }
```

#define wxIMPLEMENT_ABSTRACT_CLASS2(*className, baseClassName1, baseClassName2*)

Used in a C++ implementation file to complete the declaration of a class that has run-time type information and two base classes.

Include file:

```
#include <wx/object.h>
```

#define wxIMPLEMENT_APP(*className*)

This is used in the application class implementation file to make the application class known to wxWidgets for dynamic construction.

Note that this macro requires a final semicolon.

Include file:

```
#include <wx/app.h>
```

Example:

```
1 wxIMPLEMENT_APP(MyApp);
```

See also

wxDECLARE_APP()

#define wxIMPLEMENT_CLASS(*className, baseClassName*)

Used in a C++ implementation file to complete the declaration of a class that has run-time type information, and whose instances can be created dynamically.

The same as wxIMPLEMENT_DYNAMIC_CLASS().

Include file:

```
#include <wx/object.h>
```

#define wxIMPLEMENT_CLASS2(*className, baseClassName1, baseClassName2*)

Used in a C++ implementation file to complete the declaration of a class that has run-time type information and two base classes, and whose instances can be created dynamically.

The same as wxIMPLEMENT_DYNAMIC_CLASS2().

Include file:

```
#include <wx/object.h>
```

#define wxIMPLEMENT_DYNAMIC_CLASS(*className, baseClassName*)

Used in a C++ implementation file to complete the declaration of a class that has run-time type information, and whose instances can be created dynamically.

Include file:

```
#include <wx/object.h>
```

Example:

```
1 wxIMPLEMENT_DYNAMIC_CLASS(wxFrame, wxWindow);
2
3 wxFrame::wxFrame(void)
4 {
5     ...
6 }
```

#define wxIMPLEMENT_DYNAMIC_CLASS2(*className, baseClassName1, baseClassName2*)

Used in a C++ implementation file to complete the declaration of a class that has run-time type information, and whose instances can be created dynamically.

Use this for classes derived from two base classes.

Include file:

```
#include <wx/object.h>
```

#define wxStaticCast(*ptr, classname*)

This macro checks that the cast is valid in debug mode (an assert failure will result if wxDynamicCast(ptr, classname) == NULL) and then returns the result of executing an equivalent of `static_cast<classname *>(ptr)`.

Include file:

```
#include <wx/object.h>
```

See also

wx_static_cast(), wxDynamicCast(), wxConstCast()

20.50.3 Function Documentation

wxObject* **wxCreateDynamicObject** (**const wxString &** *className*)

Creates and returns an object of the given class, if the class has been registered with the dynamic class system using DECLARE...

and IMPLEMENT... macros.

Include file:

```
#include <wx/object.h>
```

20.51 Scintilla Text Editor

20.51.1 Detailed Description

wxWidgets also provides a wrapper around the Scintilla text editor control, which is a control for plain-text editing with support for highlighting, smart indentation, etc.

Classes

- class wxStyledTextCtrl

  A wxWidgets implementation of the Scintilla source code editing component.
- class wxStyledTextEvent

  The type of events sent from wxStyledTextCtrl.

20.52 Smart Pointers

20.52.1 Detailed Description

wxWidgets provides a few smart pointer class templates.

Classes

- class wxObjectDataPtr< T >

  This is an helper template class primarily written to avoid memory leaks because of missing calls to wxRefCounter::DecRef() and wxObjectRefData::DecRef().
- class wxScopedArray< T >

  A scoped array template class.
- class wxScopedPtr< T >

  A scoped pointer template class.
- class wxSharedPtr< T >

  A smart pointer with non-intrusive reference counting.
- class wxWeakRefDynamic< T >

  wxWeakRefDynamic<T> is a template class for weak references that is used in the same way as wxWeakRef<T>.
- class wxWeakRef< T >

  wxWeakRef<T> is a template class for weak references to wxWidgets objects, such as wxEvtHandler, wxWindow and wxObject.
- class wxWindowPtr< T >

  A reference-counted smart pointer for holding wxWindow instances.
- class wxScopedPtr

  This is a simple scoped smart pointer implementation that is similar to the Boost smart pointers (see http://www.boost.org) but rewritten to use macros instead.
- class wxScopedTiedPtr

  This is a variation on the topic of wxScopedPtr.
- class wxTrackable

  Add-on base class for a trackable object.

20.53 Streams

20.53.1 Detailed Description

wxWidgets has its own set of stream classes, as an alternative to often buggy standard stream libraries, and to provide enhanced functionality.

Related overviews: Stream Classes Overview

Classes

- class wxFSInputStream

  Input stream for virtual file stream files.
- class wxArchiveInputStream

  This is an abstract base class which serves as a common interface to archive input streams such as wxZipInputStream.
- class wxArchiveOutputStream

  This is an abstract base class which serves as a common interface to archive output streams such as wxZipOutputStream.
- class wxArchiveEntry

  This is an abstract base class which serves as a common interface to archive entry classes such as wxZipEntry.
- class wxArchiveClassFactory

  Allows the creation of streams to handle archive formats such as zip and tar.
- class wxArchiveNotifier

  If you need to know when a wxArchiveInputStream updates a wxArchiveEntry object, you can create a notifier by deriving from this abstract base class, overriding wxArchiveNotifier::OnEntryUpdated.
- class wxArchiveIterator

  An input iterator template class that can be used to transfer an archive's catalogue to a container.
- class wxDataOutputStream

  This class provides functions that write binary data types in a portable way.
- class wxDataInputStream

  This class provides functions that read binary data types in a portable way.
- class wxMemoryOutputStream

  This class allows to use all methods taking a wxOutputStream reference to write to in-memory data.
- class wxMemoryInputStream

  This class allows to use all methods taking a wxInputStream reference to read in-memory data.
- class wxSocketOutputStream

  This class implements an output stream which writes data from a connected socket.
- class wxSocketInputStream

  This class implements an input stream which reads data from a connected socket.
- class wxStringInputStream

  This class implements an input stream which reads data from a string.
- class wxStringOutputStream

  This class implements an output stream which writes data either to a user-provided or internally allocated string.
- class wxStdInputStreamBuffer

  wxStdInputStreamBuffer is a std::streambuf derived stream buffer which reads from a wxInputStream.
- class wxStdInputStream

  wxStdInputStream is a std::istream derived stream which reads from a wxInputStream.
- class wxStdOutputStreamBuffer

  wxStdOutputStreamBuffer is a std::streambuf derived stream buffer which writes to a wxOutputStream.
- class wxStdOutputStream

  wxStdOutputStream is a std::ostream derived stream which writes to a wxOutputStream.

- class wxStreamBase

  This class is the base class of most stream related classes in wxWidgets.
- class wxStreamBuffer

  wxStreamBuffer is a cache manager for wxStreamBase: it manages a stream buffer linked to a stream.
- class wxOutputStream

  wxOutputStream is an abstract base class which may not be used directly.
- class wxInputStream

  wxInputStream is an abstract base class which may not be used directly.
- class wxCountingOutputStream

  wxCountingOutputStream is a specialized output stream which does not write any data anywhere, instead it counts how many bytes would get written if this were a normal stream.
- class wxBufferedInputStream

  This stream acts as a cache.
- class wxFilterClassFactory

  Allows the creation of filter streams to handle compression formats such as gzip and bzip2.
- class wxFilterOutputStream

  A filter stream has the capability of a normal stream but it can be placed on top of another stream.
- class wxFilterInputStream

  A filter stream has the capability of a normal stream but it can be placed on top of another stream.
- class wxBufferedOutputStream

  This stream acts as a cache.
- class wxWrapperInputStream

  A wrapper input stream is a kind of filter stream which forwards all the operations to its base stream.
- class wxTarInputStream

  Input stream for reading tar files.
- class wxTarClassFactory

  Class factory for the tar archive format.
- class wxTarOutputStream

  Output stream for writing tar files.
- class wxTarEntry

  Holds the meta-data for an entry in a tar.
- class wxTextInputStream

  This class provides functions that reads text data using an input stream, allowing you to read text, floats, and integers.
- class wxTextOutputStream

  This class provides functions that write text data using an output stream, allowing you to write text, floats, and integers.
- class wxTempFileOutputStream

  wxTempFileOutputStream is an output stream based on wxTempFile.
- class wxFFileOutputStream

  This class represents data written to a file.
- class wxFileOutputStream

  This class represents data written to a file.
- class wxFileInputStream

  This class represents data read in from a file.
- class wxFFileInputStream

  This class represents data read in from a file.
- class wxFFileStream

  This stream allows to both read from and write to a file using buffered STDIO functions.
- class wxFileStream

  This class represents data that can be both read from and written to a file.
- class wxZipNotifier

If you need to know when a wxZipInputStream updates a wxZipEntry, you can create a notifier by deriving from this abstract base class, overriding wxZipNotifier::OnEntryUpdated().

- class wxZipEntry

  Holds the meta-data for an entry in a zip.

- class wxZipInputStream

  Input stream for reading zip files.

- class wxZipClassFactory

  Class factory for the zip archive format.

- class wxZipOutputStream

  Output stream for writing zip files.

- class wxZlibOutputStream

  This stream compresses all data written to it.

- class wxZlibInputStream

  This filter stream decompresses a stream that is in zlib or gzip format.

20.54 Strings

20.54.1 Detailed Description

Global string functions and macros.

See wxString for the wxWidgets string class.

Please note that all functions of this group which are documented to take `char*` arrays are overloaded with `wchar_t*` variants.

Note also that wxWidgets wraps all standard CRT functions, even if the wrappers are not (all) documented.

Macros

- #define wxT(string)

  This macro can be used with character and string literals (in other words, `'x'` or `"foo"`) to automatically convert them to wide strings in Unicode builds of wxWidgets.
- #define wxT_2(string)

  Compatibility macro which expands to wxT() in wxWidgets 2 only.
- #define wxS(string)

  wxS is a macro which can be used with character and string literals (in other words, `'x'` or `"foo"`) to convert them either to wide characters or wide strings in `wchar_t`-based (UTF-16) builds, or to keep them unchanged in `char`-based (UTF-8) builds.
- #define _T(string)

  This macro is exactly the same as wxT() and is defined in wxWidgets simply because it may be more intuitive for Windows programmers as the standard Win32 headers also define it (as well as yet another name for the same macro which is _TEXT()).
- #define wxPLURAL(string, plural, n)

  This macro is identical to _() but for the plural variant of wxGetTranslation().
- #define wxTRANSLATE(string)

  This macro doesn't do anything in the program code – it simply expands to the value of its argument.

Typedefs

- typedef wxUSE_UNICODE_dependent wxChar

  wxChar is defined to be
  - `char` *when* `wxUSE_UNICODE==0`
  - `wchar_t` *when* `wxUSE_UNICODE==1` *(the default).*
- typedef wxUSE_UNICODE_dependent wxSChar

  wxSChar is defined to be
  - `signed char` *when* `wxUSE_UNICODE==0`
  - `wchar_t` *when* `wxUSE_UNICODE==1` *(the default).*
- typedef wxUSE_UNICODE_dependent wxUChar

  wxUChar is defined to be
  - `unsigned char` *when* `wxUSE_UNICODE==0`
  - `wchar_t` *when* `wxUSE_UNICODE==1` *(the default).*
- typedef wxUSE_UNICODE_WCHAR_dependent wxStringCharType

  wxStringCharType is defined to be:
  - `char` *when* `wxUSE_UNICODE==0`
  - `char` *when* `wxUSE_UNICODE_WCHAR==0` *and* `wxUSE_UNICODE==1`
  - `wchar_t` *when* `wxUSE_UNICODE_WCHAR==1` *and* `wxUSE_UNICODE==1`

Functions

- wxArrayString wxSplit (const wxString &str, const wxChar sep, const wxChar escape= '\\')

  Splits the given wxString object using the separator sep and returns the result as a wxArrayString.

- wxString wxJoin (const wxArrayString &arr, const wxChar sep, const wxChar escape= '\\')

  Concatenate all lines of the given wxArrayString object using the separator sep and returns the result as a wxString.

- template<bool(T)(const wxUniChar &c) >
  bool wxStringCheck (const wxString &val)

  Allows to extend a function with the signature:

- wxArrayString wxStringTokenize (const wxString &str, const wxString &delims=wxDEFAULT_DELIMITERS, wxStringTokenizerMode mode=wxTOKEN_DEFAULT)

  This is a convenience function wrapping wxStringTokenizer which simply returns all tokens found in the given str as an array.

- const wxString & wxGetTranslation (const wxString &string, const wxString &domain=wxEmptyString)

  This function returns the translation of string in the current `locale()`.

- const wxString & wxGetTranslation (const wxString &string, const wxString &plural, unsigned n, const wxString &domain=wxEmptyString)

  This is an overloaded version of wxGetTranslation(const wxString&, const wxString&), please see its documentation for general information.

- const wxString & _ (const wxString &string)

  Macro to be used around all literal strings that should be translated.

20.54.2 Macro Definition Documentation

#define _T(*string*)

This macro is exactly the same as wxT() and is defined in wxWidgets simply because it may be more intuitive for Windows programmers as the standard Win32 headers also define it (as well as yet another name for the same macro which is _TEXT()).

Don't confuse this macro with _()!

Note that since wxWidgets 2.9.0 the use of _T() is discouraged just like for wxT() and also that this macro may conflict with identifiers defined in standard headers of some compilers (such as Sun CC) so its use should really be avoided.

Include file:

```
#include <wx/chartype.h>
```

#define wxPLURAL(*string, plural, n*)

This macro is identical to _() but for the plural variant of wxGetTranslation().

Returns

A const wxString.

Include file:

```
#include <wx/intl.h>
```

#define wxS(*string*)

wxS is a macro which can be used with character and string literals (in other words, `'x'` or `"foo"`) to convert them either to wide characters or wide strings in `wchar_t-based` (UTF-16) builds, or to keep them unchanged in `char-based` (UTF-8) builds.

Basically this macro produces characters or strings of type wxStringCharType.

The use of this macro is optional as the translation will always be done at run-time even if there is a mismatch between the kind of the literal used and the string or character type used in the current build. However using it can be beneficial in **performance-sensitive code** to do the conversion at compile-time instead.

See also

Unicode Support in wxWidgets, wxT()

Include file:

```
#include <wx/chartype.h>
```

#define wxT(*string*)

This macro can be used with character and string literals (in other words, `'x'` or `"foo"`) to automatically convert them to wide strings in Unicode builds of wxWidgets.

This macro simply returns the value passed to it without changes in ASCII build. In fact, its definition is:

```
1 #ifdef UNICODE
2 #   define wxT(x)  L##x
3 #else // !Unicode
4 #   define wxT(x)  x
5 #endif
```

Note that since wxWidgets 2.9.0 you shouldn't use wxT() anymore in your program sources (it was previously required if you wanted to support Unicode).

See also

Unicode Support in wxWidgets, wxS()

Include file:

```
#include <wx/chartype.h>
```

#define wxT_2(*string*)

Compatibility macro which expands to wxT() in wxWidgets 2 only.

This macro can be used in code which needs to compile with both wxWidgets 2 and 3 versions, in places where the wx2 API requires a Unicode string (in Unicode build) but the wx3 API only accepts a standard narrow string, as in e.g. wxCmdLineEntryDesc structure objects initializers.

Example of use:

```
1 const wxCmdLineEntryDesc cmdLineDesc[] =
2 {
3     { wxCMD_LINE_SWITCH, wxT_2("q"), wxT_2("quiet"),
4       wxT_2("Don't output verbose messages") },
5     wxCMD_LINE_DESC_END
6 };
```

Without `wxT_2` the code above wouldn't compile with wxWidgets 2, but using `wxT` instead, it wouldn't compile with wxWidgets 3.

See also

wxT()

Since

2.8.12, 2.9.2

Include file:

```
#include <wx/chartype.h>
```

#define wxTRANSLATE(*string*)

This macro doesn't do anything in the program code – it simply expands to the value of its argument.

However it does have a purpose which is to mark the literal strings for the extraction into the message catalog created by `xgettext` program. Usually this is achieved using _() but that macro not only marks the string for extraction but also expands into a wxGetTranslation() call which means that it cannot be used in some situations, notably for static array initialization.

Here is an example which should make it more clear: suppose that you have a static array of strings containing the weekday names and which have to be translated (note that it is a bad example, really, as wxDateTime already can be used to get the localized week day names already). If you write:

```
1 static const char * const weekdays[] = { _("Mon"), ..., _("Sun") };
2 ...
3 // use weekdays[n] as usual
```

The code wouldn't compile because the function calls are forbidden in the array initializer. So instead you should do this:

```
1 static const char * const weekdays[] = { wxTRANSLATE("Mon"), ...,
2 wxTRANSLATE("Sun") };
3 ...
4 // use wxGetTranslation(weekdays[n])
```

Note that although the code **would** compile if you simply omit wxTRANSLATE() in the above, it wouldn't work as expected because there would be no translations for the weekday names in the program message catalog and wxGetTranslation() wouldn't find them.

Returns

A const wxChar*.

Include file:

```
#include <wx/intl.h>
```

20.54.3 Typedef Documentation

typedef wxUSE_UNICODE_dependent wxChar

wxChar is defined to be

- `char` when `wxUSE_UNICODE==0`
- `wchar_t` when `wxUSE_UNICODE==1` (the default).

typedef wxUSE_UNICODE_dependent wxSChar

wxSChar is defined to be

- `signed char` when `wxUSE_UNICODE==0`
- `wchar_t` when `wxUSE_UNICODE==1` (the default).

typedef wxUSE_UNICODE_WCHAR_dependent wxStringCharType

wxStringCharType is defined to be:

- `char` when `wxUSE_UNICODE==0`
- `char` when `wxUSE_UNICODE_WCHAR==0` and `wxUSE_UNICODE==1`
- `wchar_t` when `wxUSE_UNICODE_WCHAR==1` and `wxUSE_UNICODE==1`

The `wxUSE_UNICODE_WCHAR` symbol is defined to `1` when building on Windows while it's defined to `0` when building on Unix, Linux or OS X. (Note that `wxUSE_UNICODE_UTF8` symbol is defined as the opposite of `wxUSE_UNICODE_WCHAR`.)

Note that wxStringCharType (as the name says) is the type used by wxString for internal storage of the characters.

typedef wxUSE_UNICODE_dependent wxUChar

wxUChar is defined to be

- `unsigned char` when `wxUSE_UNICODE==0`
- `wchar_t` when `wxUSE_UNICODE==1` (the default).

20.54.4 Function Documentation

const wxString& _ (const wxString & *string*)

Macro to be used around all literal strings that should be translated.

This macro expands into a call to wxGetTranslation(), so it marks the message for the extraction by `xgettext` just as wxTRANSLATE() does, but also returns the translation of the string for the current locale during execution.

This macro is thread-safe.

Include file:

```
#include <wx/intl.h>
```

const wxString& wxGetTranslation (const wxString & *string,* const wxString & *domain* = wxEmptyString)

This function returns the translation of *string* in the current `locale()`.

If the string is not found in any of the loaded message catalogs (see Internationalization), the original string is returned. If you enable logging of trace messages with "i18n" mask (using wxLog::AddTraceMask()) and debug logging is enabled (see Debugging), a message is also logged in this case – which helps to find the strings which were not yet translated.

If *domain* is specified then only that domain/catalog is searched for a matching string. As this function is used very often, an alternative (and also common in Unix world) syntax is provided: the _() macro is defined to do the same thing as wxGetTranslation().

This function is thread-safe.

Note

This function is not suitable for literal strings using wxT() macro since this macro is not recognised by `xgettext`, and so such strings are not extracted to the message catalog. Instead, use the _() and wxPLURAL() macro for all literal strings.

See also

wxGetTranslation(const wxString&, const wxString&, unsigned, const wxString&)

Include file:

```
#include <wx/intl.h>
```

const wxString& wxGetTranslation (const wxString & *string,* const wxString & *plural,* unsigned *n,* const wxString & *domain* = wxEmptyString)

This is an overloaded version of wxGetTranslation(const wxString&, const wxString&), please see its documentation for general information.

This version is used when retrieving translation of string that has different singular and plural forms in English or different plural forms in some other language. Like wxGetTranslation(const wxString&,const wxString&), the *string* parameter must contain the singular form of the string to be converted and is used as the key for the search in the catalog. The *plural* parameter is the plural form (in English). The parameter *n* is used to determine the plural form. If no message catalog is found, *string* is returned if "n == 1", otherwise *plural* is returned.

See GNU gettext Manual for additional information on plural forms handling: http://www.gnu.org/software/gettext/manual/gettext.html#Plural-forms For a shorter alternative see the wxPLURAL() macro.

This function is thread-safe.

Include file:

```
#include <wx/intl.h>
```

wxString wxJoin (const wxArrayString & *arr,* const wxChar *sep,* const wxChar *escape* = '\\')

Concatenate all lines of the given wxArrayString object using the separator *sep* and returns the result as a wxString.

If the *escape* character is non-NULL, then it's used as prefix for each occurrence of *sep* in the strings contained in *arr* before joining them which is necessary in order to be able to recover the original array contents from the string later using wxSplit().

See also

wxSplit()

Include file:

```
#include <wx/arrstr.h>
```

wxArrayString wxSplit (const wxString & *str,* const wxChar *sep,* const wxChar *escape* = '\\')

Splits the given wxString object using the separator *sep* and returns the result as a wxArrayString.

If the *escape* character is non-NULL, then the occurrences of *sep* immediately prefixed with *escape* are not considered as separators. Note that empty tokens will be generated if there are two or more adjacent separators.

See also

wxJoin()

Include file:

```
#include <wx/arrstr.h>
```

template<bool(T)(const wxUniChar &c) > bool wxStringCheck (const wxString & *val*) [inline]

Allows to extend a function with the signature:

```
1 bool SomeFunc(const wxUniChar& c)
```

which operates on a single character, to an entire wxString.

E.g. if you want to check if an entire string contains only digits, you can do:

```
1 if (wxStringCheck<wxIsdigit>(myString))
2     ... // the entire string contains only digits!
3 else
4     ... // at least one character of myString is not a digit
```

Returns

true if the given function returns a non-zero value for all characters of the *val* string.

wxArrayString wxStringTokenize (const wxString & *str,* const wxString & *delims* = wxDEFAULT_DELIMITERS, wxStringTokenizerMode *mode* = wxTOKEN_DEFAULT)

This is a convenience function wrapping wxStringTokenizer which simply returns all tokens found in the given *str* as an array.

Please see wxStringTokenizer::wxStringTokenizer for the description of the other parameters.

Returns

The array with the parsed tokens.

Include file:

```
#include <wx/tokenzr.h>
```

20.55 Text Conversion

20.55.1 Detailed Description

These are the classes used for conversions between different text encodings.

Classes

- class wxEncodingConverter

  This class is capable of converting strings between two 8-bit encodings/charsets.
- class wxMBConv

  This class is the base class of a hierarchy of classes capable of converting text strings between multibyte (SBCS or DBCS) encodings and Unicode.
- class wxMBConvUTF7

  This class converts between the UTF-7 encoding and Unicode.
- class wxMBConvUTF8

  This class converts between the UTF-8 encoding and Unicode.
- class wxMBConvUTF16

  This class is used to convert between multibyte encodings and UTF-16 Unicode encoding (also known as UCS-2).
- class wxMBConvUTF32

  This class is used to convert between multibyte encodings and UTF-32 Unicode encoding (also known as UCS-4).
- class wxCSConv

  This class converts between any character set supported by the system and Unicode.

Variables

- wxMBConv * wxConvFileName

  Conversion object used for converting file names from their external representation to the one used inside the program.

20.55.2 Variable Documentation

wxMBConv* wxConvFileName

Conversion object used for converting file names from their external representation to the one used inside the program.

wxConvFileName converts filenames between filesystem multibyte encoding and Unicode. **wxConvFileName** can also be set to a something else at run-time which is used e.g. by wxGTK to use an object which checks the environment variable **G_FILESYSTEM_ENCODING** indicating that filenames should not be interpreted as UTF8 and also for converting invalid UTF8 characters (e.g. if there is a filename in iso8859_1) to strings with octal values.

Since some platforms (such as Win32) use Unicode in the filenames, and others (such as Unix) use multibyte encodings, this object should only be used directly if wxMBFILES is defined to 1. A convenience macro, `wxFNCONV`, is defined to `wxConvFileName->cWX2MB` in this case. You could use it like this:

```
1 wxChar *name = "rawfile.doc";
2 FILE *fil = fopen(wxFNCONV(name), "r");
```

(although it would be better to just use wxFopen(name, "r") in this particular case, you only need to use this object for functions taking file names not wrapped by wxWidgets.)

Library: wxBase

Category: Text Conversion

wxMBConv Overview

20.56 Threading

20.56.1 Detailed Description

wxWidgets provides a set of classes to make use of the native thread capabilities of the various platforms.

Related Overviews: Multithreading Overview

Related macros/global-functions group: Threads

Classes

- class wxMessageQueue< T >

  wxMessageQueue allows passing messages between threads.
- class wxThreadEvent

  This class adds some simple functionality to wxEvent to facilitate inter-thread communication.
- class wxCondition

  wxCondition variables correspond to pthread conditions or to Win32 event objects.
- class wxCriticalSectionLocker

  This is a small helper class to be used with wxCriticalSection objects.
- class wxThreadHelper

  The wxThreadHelper class is a mix-in class that manages a single background thread, either detached or joinable (see wxThread for the differences).
- class wxCriticalSection

  A critical section object is used for exactly the same purpose as a wxMutex.
- class wxThread

  A thread is basically a path of execution through a program.
- class wxSemaphore

  wxSemaphore is a counter limiting the number of threads concurrently accessing a shared resource.
- class wxMutexLocker

  This is a small helper class to be used with wxMutex objects.
- class wxMutex

  A mutex object is a synchronization object whose state is set to signaled when it is not owned by any thread, and nonsignaled when it is owned.

Enumerations

- enum wxMessageQueueError {
  wxMSGQUEUE_NO_ERROR = 0,
  wxMSGQUEUE_TIMEOUT,
  wxMSGQUEUE_MISC_ERROR }

  Error codes for wxMessageQueue<> operations.

20.56.2 Enumeration Type Documentation

enum wxMessageQueueError

Error codes for wxMessageQueue<> operations.

This enum contains the possible return value of wxMessageQueue<> methods.

Since

2.9.0

Category: Threading

Enumerator

wxMSGQUEUE_NO_ERROR Indicates that the operation completed successfully.

wxMSGQUEUE_TIMEOUT Indicates that no messages were received before timeout expired. This return value is only used by wxMessageQueue<>::ReceiveTimeout().

wxMSGQUEUE_MISC_ERROR Some unexpected (and fatal) error has occurred.

20.57 Threads

20.57.1 Detailed Description

The functions and macros here mainly exist to make it possible to write code which may be compiled in multi thread build (wxUSE_THREADS = 1) as well as in single thread configuration (wxUSE_THREADS = 0).

For example, a static variable must be protected against simultaneous access by multiple threads in the former configuration but in the latter the extra overhead of using the critical section is not needed. To solve this problem, the wxCRITICAL_SECTION() macro may be used to create and use the critical section only when needed.

See also

wxThread, wxMutex, Multithreading Overview

Related class group: Threading

Macros

- #define wxCRIT_SECT_DECLARE(cs)

  This macro declares a (static) critical section object named cs if `wxUSE_THREADS` is 1 and does nothing if it is 0.
- #define wxCRIT_SECT_DECLARE_MEMBER(cs)

  This macro declares a critical section object named cs if `wxUSE_THREADS` is 1 and does nothing if it is 0.
- #define wxCRIT_SECT_LOCKER(name, cs)

  This macro creates a wxCriticalSectionLocker named name and associated with the critical section cs if `wxUSE_THREADS` is 1 and does nothing if it is 0.
- #define wxCRITICAL_SECTION(name)

  This macro combines wxCRIT_SECT_DECLARE() and wxCRIT_SECT_LOCKER(): it creates a static critical section object and also the lock object associated with it.
- #define wxLEAVE_CRIT_SECT(critical_section)

  This macro is equivalent to critical_section.Leave() if `wxUSE_THREADS` is 1 and does nothing if it is 0.
- #define wxENTER_CRIT_SECT(critical_section)

  This macro is equivalent to critical_section.Enter() if `wxUSE_THREADS` is 1 and does nothing if it is 0.

Functions

- bool wxIsMainThread ()

  Returns true if this thread is the main one.
- void wxMutexGuiEnter ()

  This function must be called when any thread other than the main GUI thread wants to get access to the GUI library.
- void wxMutexGuiLeave ()

  This function is only defined on platforms which support preemptive threads.

20.57.2 Macro Definition Documentation

#define wxCRIT_SECT_DECLARE(*cs*)

This macro declares a (static) critical section object named *cs* if `wxUSE_THREADS` is 1 and does nothing if it is 0.

Include file:

```
#include <wx/thread.h>
```

#define wxCRIT_SECT_DECLARE_MEMBER(*cs*)

This macro declares a critical section object named *cs* if `wxUSE_THREADS` is 1 and does nothing if it is 0.

As it doesn't include the `static` keyword (unlike wxCRIT_SECT_DECLARE()), it can be used to declare a class or struct member which explains its name.

Include file:

```
#include <wx/thread.h>
```

#define wxCRIT_SECT_LOCKER(*name, cs*)

This macro creates a wxCriticalSectionLocker named *name* and associated with the critical section *cs* if `wxUSE_THREADS` is 1 and does nothing if it is 0.

Include file:

```
#include <wx/thread.h>
```

#define wxCRITICAL_SECTION(*name*)

This macro combines wxCRIT_SECT_DECLARE() and wxCRIT_SECT_LOCKER(): it creates a static critical section object and also the lock object associated with it.

Because of this, it can be only used inside a function, not at global scope. For example:

```
1 int IncCount()
2 {
3     static int s_counter = 0;
4
5     wxCRITICAL_SECTION(counter);
6
7     return ++s_counter;
8 }
```

Note that this example assumes that the function is called the first time from the main thread so that the critical section object is initialized correctly by the time other threads start calling it, if this is not the case this approach can **not** be used and the critical section must be made a global instead.

Include file:

```
#include <wx/thread.h>
```

#define wxENTER_CRIT_SECT(*critical_section*)

This macro is equivalent to critical_section.Enter() if `wxUSE_THREADS` is 1 and does nothing if it is 0.

Include file:

```
#include <wx/thread.h>
```

#define wxLEAVE_CRIT_SECT(*critical_section*)

This macro is equivalent to critical_section.Leave() if `wxUSE_THREADS` is 1 and does nothing if it is 0.

Include file:

```
#include <wx/thread.h>
```

20.57.3 Function Documentation

bool wxIsMainThread ( )

Returns true if this thread is the main one.

Always returns true if `wxUSE_THREADS` is 0.

Include file:

```
#include <wx/thread.h>
```

void wxMutexGuiEnter ( )

This function must be called when any thread other than the main GUI thread wants to get access to the GUI library.

This function will block the execution of the calling thread until the main thread (or any other thread holding the main GUI lock) leaves the GUI library and no other thread will enter the GUI library until the calling thread calls wxMutexGuiLeave().

Typically, these functions are used like this:

```
1 void MyThread::Foo(void)
2 {
3     // before doing any GUI calls we must ensure that
4     // this thread is the only one doing it!
5
6     wxMutexGuiEnter();
7
8     // Call GUI here:
9     my_window->DrawSomething();
10
11     wxMutexGuiLeave();
12 }
```

This function is only defined on platforms which support preemptive threads and only works under some ports (wxMSW currently).

Note

Under GTK, no creation of top-level windows is allowed in any thread but the main one.

Include file:

```
#include <wx/thread.h>
```

void wxMutexGuiLeave ( )

This function is only defined on platforms which support preemptive threads.

See also

wxMutexGuiEnter()

Include file:

```
#include <wx/thread.h>
```

20.58 Time

20.58.1 Detailed Description

The functions in this section deal with getting the current time and sleeping for the specified time interval.

Functions

- int wxGetTimeZone ()

  Returns the difference between UTC and local time in seconds.
- long wxGetLocalTime ()

  Returns the number of seconds since local time 00:00:00 Jan 1st 1970.
- wxLongLong wxGetLocalTimeMillis ()

  Returns the number of milliseconds since local time 00:00:00 Jan 1st 1970.
- long wxGetUTCTime ()

  Returns the number of seconds since GMT 00:00:00 Jan 1st 1970.
- wxLongLong wxGetUTCTimeMillis ()

  Returns the number of milliseconds since GMT 00:00:00 Jan 1st 1970.
- wxLongLong wxGetUTCTimeUSec ()

  Returns the number of microseconds since GMT 00:00:00 Jan 1st 1970.
- void wxMicroSleep (unsigned long microseconds)

  Sleeps for the specified number of microseconds.
- void wxMilliSleep (unsigned long milliseconds)

  Sleeps for the specified number of milliseconds.
- wxString wxNow ()

  Returns a string representing the current date and time.
- void wxSleep (int secs)

  Sleeps for the specified number of seconds.
- void wxUsleep (unsigned long milliseconds)

20.58.2 Function Documentation

long wxGetLocalTime ( )

Returns the number of seconds since local time 00:00:00 Jan 1st 1970.

See also

wxDateTime::Now()

Include file:

```
#include <wx/time.h>
```

wxLongLong wxGetLocalTimeMillis ( )

Returns the number of milliseconds since local time 00:00:00 Jan 1st 1970.

The use of wxGetUTCTimeMillis() is preferred as it provides a usually (except for changes to the system time) monotonic clock which the local time also changes whenever DST begins or ends.

See also

wxDateTime::Now(), wxGetUTCTimeMillis(), wxGetUTCTimeUSec()

Include file:

```
#include <wx/time.h>
```

int wxGetTimeZone ( )

Returns the difference between UTC and local time in seconds.
Include file:

```
#include <wx/time.h>
```

long wxGetUTCTime ( )

Returns the number of seconds since GMT 00:00:00 Jan 1st 1970.

See also

wxDateTime::Now()

Include file:

```
#include <wx/time.h>
```

wxLongLong wxGetUTCTimeMillis ( )

Returns the number of milliseconds since GMT 00:00:00 Jan 1st 1970.
Include file:

```
#include <wx/time.h>
```

Since

2.9.3

wxLongLong wxGetUTCTimeUSec ( )

Returns the number of microseconds since GMT 00:00:00 Jan 1st 1970.
Include file:

```
#include <wx/time.h>
```

Since

2.9.3

void wxMicroSleep (unsigned long *microseconds*)

Sleeps for the specified number of microseconds.

The microsecond resolution may not, in fact, be available on all platforms (currently only Unix platforms with nanosleep(2) may provide it) in which case this is the same as calling wxMilliSleep() with the argument of *microseconds/1000*.

Include file:

```
#include <wx/utils.h>
```

void wxMilliSleep (unsigned long *milliseconds*)

Sleeps for the specified number of milliseconds.

Notice that usage of this function is encouraged instead of calling usleep(3) directly because the standard *usleep()* function is not MT safe.

Include file:

```
#include <wx/utils.h>
```

wxString wxNow ( )

Returns a string representing the current date and time.

Include file:

```
#include <wx/utils.h>
```

void wxSleep (int *secs*)

Sleeps for the specified number of seconds.

Include file:

```
#include <wx/utils.h>
```

void wxUsleep (unsigned long *milliseconds*)

Deprecated This function is deprecated because its name is misleading: notice that the argument is in milliseconds, not microseconds. Please use either wxMilliSleep() or wxMicroSleep() depending on the resolution you need.

Sleeps for the specified number of milliseconds.

Include file:

```
#include <wx/utils.h>
```

20.59 Validators

20.59.1 Detailed Description

These are the window validators, used for filtering and validating user input.

Related Overviews: wxValidator Overview

Classes

- class wxNumValidator< T >

  wxNumValidator is the common base class for numeric validator classes.
- class wxIntegerValidator< T >

  Validator for text entries used for integer entry.
- class wxFloatingPointValidator< T >

  Validator for text entries used for floating point numbers entry.
- class wxGenericValidator

  wxGenericValidator performs data transfer (but not validation or filtering) for many type of controls.
- class wxValidator

  wxValidator is the base class for a family of validator classes that mediate between a class of control, and application data.
- class wxTextValidator

  wxTextValidator validates text controls, providing a variety of filtering behaviours.

Enumerations

- enum wxNumValidatorStyle {
  wxNUM_VAL_DEFAULT = 0,
  wxNUM_VAL_THOUSANDS_SEPARATOR = 1,
  wxNUM_VAL_ZERO_AS_BLANK = 2,
  wxNUM_VAL_NO_TRAILING_ZEROES }

  Bit masks used for numeric validator styles.

20.59.2 Enumeration Type Documentation

enum wxNumValidatorStyle

Bit masks used for numeric validator styles.

A combination of these flags can be used when creating wxIntegerValidator and wxFloatingPointValidator objects and with their SetStyle() methods.

Since

2.9.2

Category: Validators

Enumerator

wxNUM_VAL_DEFAULT Indicates absence of any other flags. This value corresponds to the default behaviour.

wxNUM_VAL_THOUSANDS_SEPARATOR Use thousands separators in the numbers. When this style is used, numbers are formatted using the thousands separators after validating the user entry (if the current locale uses the thousands separators character).

wxNUM_VAL_ZERO_AS_BLANK Show a value of zero as an empty string. With this style a value of zero in the associated variable is translated to an empty string and an empty value of the control is translated to a value of zero.

wxNUM_VAL_NO_TRAILING_ZEROES Remove trailing zeroes from the fractional part of the number. This style can only be used with wxFloatingPointValidator and indicates that trailing zeroes should be removed from the control text when it is validated. By default, as many zeroes as needed to satisfy the precision used when creating the validator will be appended.

For example, without this style a wxFloatingPointValidator with a precision 3 will show the value of 1.5 as "1.500" after validation. With this style, the value will be shown as just "1.5" (while a value of e.g. 1.567 will still be shown with all the three significant digits, of course).

20.60 Versioning

20.60.1 Detailed Description

The following constants are defined in wxWidgets:

wxMAJOR_VERSION	The major version of wxWidgets
wxMINOR_VERSION	The minor version of wxWidgets
wxRELEASE_NUMBER	The release number
wxSUBRELEASE_NUMBER	The subrelease number which is 0 for all official releases

For example, the values or these constants for wxWidgets 2.8.7 are 2, 8, 7 and 0.

Additionally, wxVERSION_STRING is a user-readable string containing the full wxWidgets version and wxVERSION_NUMBER is a combination of the three version numbers above: for 2.1.15, it is 2115 and it is 2200 for wxWidgets 2.2.

The subrelease number is only used for the sources in between official releases and so normally is not useful.

Include file:

```
#include <wx/version.h>
```

Macros

- #define wxCHECK_GCC_VERSION(major, minor)

  Returns true if the compiler being used is GNU C++ and its version is at least major.minor or greater.
- #define wxCHECK_SUNCC_VERSION(major, minor)

  Returns true if the compiler being used is Sun CC Pro and its version is at least major.minor or greater.
- #define wxCHECK_VISUALC_VERSION(major)

  Returns true if the compiler being used is Visual C++ and its version is at least major or greater.
- #define wxCHECK_W32API_VERSION(major, minor)

  Returns true if the version of w32api headers used is major.minor or greater.
- #define wxCHECK_VERSION(major, minor, release)

  This is a macro which evaluates to true if the current wxWidgets version is at least major.minor.release.
- #define wxCHECK_VERSION_FULL(major, minor, release, subrel)

  Same as wxCHECK_VERSION() but also checks that wxSUBRELEASE_NUMBER is at least subrel.

Functions

- wxVersionInfo wxGetLibraryVersionInfo ()

  Get wxWidgets version information.

20.60.2 Macro Definition Documentation

#define wxCHECK_GCC_VERSION(*major, minor*)

Returns true if the compiler being used is GNU C++ and its version is at least major.minor or greater.

Returns false otherwise.

Include file:

```
#include <wx/platform.h>
```

#define wxCHECK_SUNCC_VERSION(*major, minor*)

Returns true if the compiler being used is Sun CC Pro and its version is at least major.minor or greater.

Returns false otherwise.

Include file:

```
#include <wx/platform.h>
```

#define wxCHECK_VERSION(*major, minor, release*)

This is a macro which evaluates to true if the current wxWidgets version is at least major.minor.release.

For example, to test if the program is compiled with wxWidgets 2.2 or higher, the following can be done:

```
1     wxString s;
2 #if wxCHECK_VERSION(2, 2, 0)
3     if ( s.StartsWith("foo") )
4 #else // replacement code for old version
5     if ( strncmp(s, "foo", 3) == 0 )
6 #endif
7     {
8         ...
9     }
```

Include file:

```
#include <wx/version.h>
```

#define wxCHECK_VERSION_FULL(*major, minor, release, subrel*)

Same as wxCHECK_VERSION() but also checks that wxSUBRELEASE_NUMBER is at least subrel.

Include file:

```
#include <wx/version.h>
```

#define wxCHECK_VISUALC_VERSION(*major*)

Returns true if the compiler being used is Visual C++ and its version is at least major or greater.

Returns false otherwise.

Include file:

```
#include <wx/platform.h>
```

#define wxCHECK_W32API_VERSION(*major, minor*)

Returns true if the version of w32api headers used is major.minor or greater.

Otherwise, and also if we are not compiling with MinGW32/Cygwin under Win32 at all, returns false.

Include file:

```
#include <wx/platform.h>
```

20.60.3 Function Documentation

wxVersionInfo wxGetLibraryVersionInfo ( )

Get wxWidgets version information.

Since

2.9.2

See also

wxVersionInfo

Include file:

```
#include <wx/utils.h>
```

Library: wxCore

20.61 Virtual File System

20.61.1 Detailed Description

wxWidgets provides a set of classes that implement an extensible virtual file system, used internally by the HTML classes.

Classes

- class wxFileSystem

  This class provides an interface for opening files on different file systems.
- class wxFSFile

  This class represents a single file opened by wxFileSystem.
- class wxFileSystemHandler

  Classes derived from wxFileSystemHandler are used to access virtual file systems.
- class wxMemoryFSHandler

  This wxFileSystem handler can store arbitrary data in memory stream and make them accessible via an URL.

20.62 WebView

20.62.1 Detailed Description

The wxWebView library is a set of classes for viewing complex web documents and for internet browsing.

It is built around a series of backends, and exposes common functions for them.

Classes

- class wxWebViewHistoryItem

  A simple class that contains the URL and title of an element of the history of a wxWebView.
- class wxWebViewFactory

  An abstract factory class for creating wxWebView backends.
- class wxWebViewHandler

  The base class for handling custom schemes in wxWebView, for example to allow virtual file system support.
- class wxWebView

  This control may be used to render web (HTML / CSS / javascript) documents.
- class wxWebViewEvent

  A navigation event holds information about events associated with wxWebView objects.
- class wxWebViewArchiveHandler

  A custom handler for the file scheme which also supports loading from archives.
- class wxWebViewFSHandler

  A wxWebView file system handler to support standard wxFileSystem protocols of the form `example:page.htm` *The handler allows wxWebView to use wxFileSystem in a similar fashion to its use with wxHtml.*

20.63 Window Docking (wxAUI)

20.63.1 Detailed Description

wxAUI is a set classes for writing a customizable application interface with built-in docking, floatable panes and a flexible MDI-like interface.

Related Overviews: wxAUI Overview

Classes

- class wxAuiDefaultTabArt

  Default art provider for wxAuiNotebook.
- class wxAuiToolBarEvent

  wxAuiToolBarEvent is used for the events generated by wxAuiToolBar.
- class wxAuiToolBarItem

  wxAuiToolBarItem is part of the wxAUI class framework, representing a toolbar element.
- class wxAuiToolBarArt

  wxAuiToolBarArt is part of the wxAUI class framework.
- class wxAuiDefaultToolBarArt

  wxAuiDefaultToolBarArt is part of the wxAUI class framework.
- class wxAuiToolBar

  wxAuiToolBar is a dockable toolbar, part of the wxAUI class framework.
- class wxAuiNotebook

  wxAuiNotebook is part of the wxAUI class framework, which represents a notebook control, managing multiple windows with associated tabs.
- class wxAuiTabContainerButton

  A simple class which holds information about wxAuiNotebook tab buttons and their state.
- class wxAuiTabContainer

  wxAuiTabContainer is a class which contains information about each tab.
- class wxAuiTabArt

  Tab art provider defines all the drawing functions used by wxAuiNotebook.
- class wxAuiSimpleTabArt

  Another standard tab art provider for wxAuiNotebook.
- class wxAuiDockArt

  wxAuiDockArt is part of the wxAUI class framework.
- class wxAuiManager

  wxAuiManager is the central class of the wxAUI class framework.
- class wxAuiPaneInfo

  wxAuiPaneInfo is part of the wxAUI class framework.
- class wxAuiManagerEvent

  Event used to indicate various actions taken with wxAuiManager.

Enumerations

- enum wxAuiToolBarStyle {
  wxAUI_TB_TEXT = 1 << 0,
  wxAUI_TB_NO_TOOLTIPS = 1 << 1,
  wxAUI_TB_NO_AUTORESIZE = 1 << 2,
  wxAUI_TB_GRIPPER = 1 << 3,
  wxAUI_TB_OVERFLOW = 1 << 4,
  wxAUI_TB_VERTICAL = 1 << 5,
  wxAUI_TB_HORZ_LAYOUT = 1 << 6,
  wxAUI_TB_HORIZONTAL = 1 << 7,
  wxAUI_TB_PLAIN_BACKGROUND = 1 << 8,
  wxAUI_TB_HORZ_TEXT = (wxAUI_TB_HORZ_LAYOUT | wxAUI_TB_TEXT),
  wxAUI_ORIENTATION_MASK = (wxAUI_TB_VERTICAL | wxAUI_TB_HORIZONTAL),
  wxAUI_TB_DEFAULT_STYLE = 0 }

  wxAuiToolBarStyle is part of the wxAUI class framework, used to define the appearance of a wxAuiToolBar.
- enum wxAuiToolBarArtSetting {
  wxAUI_TBART_SEPARATOR_SIZE = 0,
  wxAUI_TBART_GRIPPER_SIZE = 1,
  wxAUI_TBART_OVERFLOW_SIZE = 2 }

  wxAuiToolBarArtSetting
- enum wxAuiToolBarToolTextOrientation {
  wxAUI_TBTOOL_TEXT_LEFT = 0,
  wxAUI_TBTOOL_TEXT_RIGHT = 1,
  wxAUI_TBTOOL_TEXT_TOP = 2,
  wxAUI_TBTOOL_TEXT_BOTTOM = 3 }

  wxAuiToolBarToolTextOrientation
- enum wxAuiPaneDockArtSetting {
  wxAUI_DOCKART_SASH_SIZE = 0,
  wxAUI_DOCKART_CAPTION_SIZE = 1,
  wxAUI_DOCKART_GRIPPER_SIZE = 2,
  wxAUI_DOCKART_PANE_BORDER_SIZE = 3,

  These are the possible pane dock art settings for wxAuiDefaultDockArt.

20.63.2 Enumeration Type Documentation

enum wxAuiPaneDockArtSetting

These are the possible pane dock art settings for wxAuiDefaultDockArt.

Library: wxAui

Category: Window Docking (wxAUI)

Enumerator

wxAUI_DOCKART_SASH_SIZE Customizes the sash size.

wxAUI_DOCKART_CAPTION_SIZE Customizes the caption size.

wxAUI_DOCKART_GRIPPER_SIZE Customizes the gripper size.

wxAUI_DOCKART_PANE_BORDER_SIZE Customizes the pane border size.

wxAUI_DOCKART_PANE_BUTTON_SIZE Customizes the pane button size.

wxAUI_DOCKART_BACKGROUND_COLOUR Customizes the background colour, which corresponds to the client area.

wxAUI_DOCKART_SASH_COLOUR Customizes the sash colour.

wxAUI_DOCKART_ACTIVE_CAPTION_COLOUR Customizes the active caption colour.

wxAUI_DOCKART_ACTIVE_CAPTION_GRADIENT_COLOUR Customizes the active caption gradient colour.

wxAUI_DOCKART_INACTIVE_CAPTION_COLOUR Customizes the inactive caption colour.

wxAUI_DOCKART_INACTIVE_CAPTION_GRADIENT_COLOUR Customizes the inactive gradient caption colour.

wxAUI_DOCKART_ACTIVE_CAPTION_TEXT_COLOUR Customizes the active caption text colour.

wxAUI_DOCKART_INACTIVE_CAPTION_TEXT_COLOUR Customizes the inactive caption text colour.

wxAUI_DOCKART_BORDER_COLOUR Customizes the border colour.

wxAUI_DOCKART_GRIPPER_COLOUR Customizes the gripper colour.

wxAUI_DOCKART_CAPTION_FONT Customizes the caption font.

wxAUI_DOCKART_GRADIENT_TYPE Customizes the gradient type (no gradient, vertical or horizontal)

enum wxAuiToolBarArtSetting

wxAuiToolBarArtSetting

Library: wxAui

Category: Window Docking (wxAUI)

Enumerator

wxAUI_TBART_SEPARATOR_SIZE wxAuiToolBar seperator size.

wxAUI_TBART_GRIPPER_SIZE wxAuiToolBar gripper size.

wxAUI_TBART_OVERFLOW_SIZE Overflow button size in wxAuiToolBar.

enum wxAuiToolBarStyle

wxAuiToolBarStyle is part of the wxAUI class framework, used to define the appearance of a wxAuiToolBar.

See also wxAUI Overview.

Library: wxAui

Category: Window Docking (wxAUI)

Enumerator

wxAUI_TB_TEXT Shows the text in the toolbar buttons; by default only icons are shown.

wxAUI_TB_NO_TOOLTIPS Don't show tooltips on wxAuiToolBar items.

wxAUI_TB_NO_AUTORESIZE Do not auto-resize the wxAuiToolBar.

wxAUI_TB_GRIPPER Shows a gripper on the wxAuiToolBar.

wxAUI_TB_OVERFLOW The wxAuiToolBar can contain overflow items.

wxAUI_TB_VERTICAL Using this style forces the toolbar to be vertical and be only dockable to the left or right sides of the window whereas by default it can be horizontal or vertical and be docked anywhere.

wxAUI_TB_HORZ_LAYOUT Shows the text and the icons alongside, not vertically stacked. This style must be used with wxAUI_TB_TEXT

wxAUI_TB_HORIZONTAL Analogous to wxAUI_TB_VERTICAL, but forces the toolbar to be horizontal, docking to the top or bottom of the window.

wxAUI_TB_PLAIN_BACKGROUND Draw a plain background (based on parent) instead of the default gradient background.

Since

2.9.5

wxAUI_TB_HORZ_TEXT Shows the text alongside the icons, not vertically stacked.

wxAUI_ORIENTATION_MASK Shows the text in the toolbar buttons; by default only icons are shown.

wxAUI_TB_DEFAULT_STYLE By default only icons are shown.

enum wxAuiToolBarToolTextOrientation

wxAuiToolBarToolTextOrientation

Library: wxAui

Category: Window Docking (wxAUI)

Enumerator

wxAUI_TBTOOL_TEXT_LEFT Text in wxAuiToolBar items is left aligned, currently unused/unimplemented.

wxAUI_TBTOOL_TEXT_RIGHT Text in wxAuiToolBar items is right aligned.

wxAUI_TBTOOL_TEXT_TOP Text in wxAuiToolBar items is top aligned, currently unused/unimplemented.

wxAUI_TBTOOL_TEXT_BOTTOM Text in wxAuiToolBar items is bottom aligned.

20.64 Window Layout

20.64.1 Detailed Description

wxWidgets makes window layout and sizing easy and painless using a set of classes known as "sizers".

Sizers allow for flexible window positioning and sizes that can help with automatically handling localization differences, as well as making it easy to write user resizable windows.

Related Overviews: Sizers Overview

Classes

- class wxDialogLayoutAdapter

  This abstract class is the base for classes that help wxWidgets perform run-time layout adaptation of dialogs.
- class wxGBPosition

  This class represents the position of an item in a virtual grid of rows and columns managed by a wxGridBagSizer.
- class wxGridBagSizer

  A wxSizer that can lay out items in a virtual grid like a wxFlexGridSizer but in this case explicit positioning of the items is allowed using wxGBPosition, and items can optionally span more than one row and/or column using wxGBSpan.
- class wxGBSizerItem

  The wxGBSizerItem class is used by the wxGridBagSizer for tracking the items in the sizer.
- class wxGBSpan

  This class is used to hold the row and column spanning attributes of items in a wxGridBagSizer.
- class wxLayoutAlgorithm

  wxLayoutAlgorithm implements layout of subwindows in MDI or SDI frames.
- class wxSizer

  wxSizer is the abstract base class used for laying out subwindows in a window.
- class wxStdDialogButtonSizer

  This class creates button layouts which conform to the standard button spacing and ordering defined by the platform or toolkit's user interface guidelines (if such things exist).
- class wxSizerItem

  The wxSizerItem class is used to track the position, size and other attributes of each item managed by a wxSizer.
- class wxSizerFlags

  Container for sizer items flags providing readable names for them.
- class wxFlexGridSizer

  A flex grid sizer is a sizer which lays out its children in a two-dimensional table with all table fields in one row having the same height and all fields in one column having the same width, but all rows or all columns are not necessarily the same height or width as in the wxGridSizer.
- class wxGridSizer

  A grid sizer is a sizer which lays out its children in a two-dimensional table with all table fields having the same size, i.e.
- class wxStaticBoxSizer

  wxStaticBoxSizer is a sizer derived from wxBoxSizer but adds a static box around the sizer.
- class wxBoxSizer

  The basic idea behind a box sizer is that windows will most often be laid out in rather simple basic geometry, typically in a row or a column or several hierarchies of either.
- class wxWrapSizer

  A wrap sizer lays out its items in a single line, like a box sizer – as long as there is space available in that direction.

20.65 Wrappers of CRT functions

20.65.1 Detailed Description

For documentation of these functions please refer to the documentation of the standard CRT functions (see e.g. http://www.cppreference.com/wiki/c/start).

Functions

- bool wxIsEmpty (const char *s)

20.66 XML

20.66.1 Detailed Description

Group of classes loading and saving XML documents (http://www.w3.org/XML/).

Classes

- class wxXmlNode

  Represents a node in an XML document.
- class wxXmlAttribute

  Represents a node attribute.
- class wxXmlDocument

  This class holds XML data/document as parsed by XML parser in the root node.

20.67 XML Based Resource System (XRC)

20.67.1 Detailed Description

Resources allow your application to create controls and other user interface elements from specifications stored in an XML format.

Related Overviews: XML Based Resource System (XRC)

Classes

- class wxXmlResourceHandler

  wxSizerXmlHandler is a class for resource handlers capable of creating a wxSizer object from an XML node.
- class wxXmlResource

  This is the main class for interacting with the XML-based resource system.

20.68 wxDataViewCtrl Related Classes

20.68.1 Detailed Description

These are all classes used or provided for use with wxDataViewCtrl.

Classes

- class wxDataViewChoiceRenderer

  A wxDataViewCtrl renderer using wxChoice control and values of strings in it.
- class wxDataViewChoiceByIndexRenderer

  A wxDataViewCtrl renderer using wxChoice control and indexes into it.
- class wxDataViewModel

  wxDataViewModel is the base class for all data model to be displayed by a wxDataViewCtrl.
- class wxDataViewListModel

  Base class with abstract API for wxDataViewIndexListModel and wxDataViewVirtualListModel.
- class wxDataViewIndexListModel

  wxDataViewIndexListModel is a specialized data model which lets you address an item by its position (row) rather than its wxDataViewItem (which you can obtain from this class).
- class wxDataViewVirtualListModel

  wxDataViewVirtualListModel is a specialized data model which lets you address an item by its position (row) rather than its wxDataViewItem and as such offers the exact same interface as wxDataViewIndexListModel.
- class wxDataViewItemAttr

  This class is used to indicate to a wxDataViewCtrl that a certain item (see wxDataViewItem) has extra font attributes for its renderer.
- class wxDataViewItem

  wxDataViewItem is a small opaque class that represents an item in a wxDataViewCtrl in a persistent way, i.e.
- class wxDataViewCtrl

  wxDataViewCtrl is a control to display data either in a tree like fashion or in a tabular form or both.
- class wxDataViewModelNotifier

  A wxDataViewModelNotifier instance is owned by a wxDataViewModel and mirrors its notification interface.
- class wxDataViewRenderer

  This class is used by wxDataViewCtrl to render the individual cells.
- class wxDataViewTextRenderer

  wxDataViewTextRenderer is used for rendering text.
- class wxDataViewIconTextRenderer

  The wxDataViewIconTextRenderer class is used to display text with a small icon next to it as it is typically done in a file manager.
- class wxDataViewProgressRenderer

  This class is used by wxDataViewCtrl to render progress bars.
- class wxDataViewSpinRenderer

  This is a specialized renderer for rendering integer values.
- class wxDataViewToggleRenderer

  This class is used by wxDataViewCtrl to render toggle controls.
- class wxDataViewDateRenderer

  This class is used by wxDataViewCtrl to render calendar controls.
- class wxDataViewCustomRenderer

  You need to derive a new class from wxDataViewCustomRenderer in order to write a new renderer.
- class wxDataViewBitmapRenderer

  This class is used by wxDataViewCtrl to render bitmap controls.
- class wxDataViewColumn

This class represents a column in a wxDataViewCtrl.

- class wxDataViewListCtrl

  This class is a wxDataViewCtrl which internally uses a wxDataViewListStore and forwards most of its API to that class.

- class wxDataViewTreeCtrl

  This class is a wxDataViewCtrl which internally uses a wxDataViewTreeStore and forwards most of its API to that class.

- class wxDataViewListStore

  wxDataViewListStore is a specialised wxDataViewModel for storing a simple table of data.

- class wxDataViewTreeStore

  wxDataViewTreeStore is a specialised wxDataViewModel for storing simple trees very much like wxTreeCtrl does and it offers a similar API.

- class wxDataViewIconText

  wxDataViewIconText is used by wxDataViewIconTextRenderer for data transfer.

- class wxDataViewEvent

  This is the event class for the wxDataViewCtrl notifications.

20.69 wxPropertyGrid

20.69.1 Detailed Description

wxPropertyGrid is a specialized grid for editing properties (that is, name=value pairs).

This style of control has also been known as property sheet or object grid.

Related Overviews: wxPropertyGrid Overview

Classes

- class wxPropertyGridIterator
- class wxPGEditor

  Base class for custom wxPropertyGrid editors.
- class wxPGMultiButton

  This class can be used to have multiple buttons in a property editor.
- class wxPropertyGridPage

  Holder of property grid page information.
- class wxPropertyGridManager

  wxPropertyGridManager is an efficient multi-page version of wxPropertyGrid, which can optionally have toolbar for mode and page selection, a help text box, and a header.
- class wxPGProperty

  wxPGProperty is base class for all wxPropertyGrid properties.
- class wxPGCell

  Base class for wxPropertyGrid cell information.
- class wxPGChoices

  Helper class for managing choices of wxPropertyGrid properties.
- class wxPropertyGrid

  wxPropertyGrid is a specialized grid for editing properties - in other words name = value pairs.
- class wxPropertyGridEvent

  A property grid event holds information about events associated with wxPropertyGrid objects.
- class wxPropertyGridInterface

  Most of the shared property manipulation interface shared by wxPropertyGrid, wxPropertyGridPage, and wx↩ PropertyGridManager is defined in this class.

Chapter 21

Class Documentation

21.1 wxMessageDialog::ButtonLabel Class Reference

`#include <wx/msgdlg.h>`

21.1.1 Detailed Description

Helper class allowing to use either stock id or string labels.

This class should never be used explicitly and is not really part of wxWidgets API but rather is just an implementation helper allowing the methods such as SetYesNoLabels() and SetOKCancelLabels() below to be callable with either stock ids (e.g. wxID_CLOSE) or strings ("&Close").

Public Member Functions

- ButtonLabel (int stockId)

  Construct the label from a stock id.
- ButtonLabel (const wxString &label)

  Construct the label from the specified string.
- wxString GetAsString () const

  Return the associated label as string.
- int GetStockId () const

  Return the stock id or wxID_NONE if this is not a stock label.

21.1.2 Constructor & Destructor Documentation

wxMessageDialog::ButtonLabel::ButtonLabel (int *stockId*)

Construct the label from a stock id.

wxMessageDialog::ButtonLabel::ButtonLabel (const wxString & *label*)

Construct the label from the specified string.

21.1.3 Member Function Documentation

wxString wxMessageDialog::ButtonLabel::GetAsString ( ) const

Return the associated label as string.

Get the string label, whether it was originally specified directly or as a stock id – this is only useful for platforms without native stock items id support

int wxMessageDialog::ButtonLabel::GetStockId ( ) const

Return the stock id or wxID_NONE if this is not a stock label.

21.2 wxWindow::ChildrenRepositioningGuard Class Reference

`#include <wx/window.h>`

21.2.1 Detailed Description

Helper for ensuring EndRepositioningChildren() is called correctly.

This class wraps the calls to BeginRepositioningChildren() and EndRepositioningChildren() by performing the former in its constructor and the latter in its destructor if, and only if, the first call returned true. This is the simplest way to call these methods and if this class is created as a local variable, it also ensures that EndRepositioningChildren() is correctly called (or not) on scope exit, so its use instead of calling these methods manually is highly recommended.

Since

2.9.5

Public Member Functions

- ChildrenRepositioningGuard (wxWindow *win)

  Constructor calls wxWindow::BeginRepositioningChildren().
- ~ChildrenRepositioningGuard ()

  Destructor calls wxWindow::EndRepositioningChildren() if necessary.

21.2.2 Constructor & Destructor Documentation

wxWindow::ChildrenRepositioningGuard::ChildrenRepositioningGuard (wxWindow * *win*) [explicit]

Constructor calls wxWindow::BeginRepositioningChildren().

Parameters

win	The window to call BeginRepositioningChildren() on. If it is NULL, nothing is done.

wxWindow::ChildrenRepositioningGuard::~ChildrenRepositioningGuard ( )

Destructor calls wxWindow::EndRepositioningChildren() if necessary.

EndRepositioningChildren() is called only if a valid window was passed to the constructor and if BeginRepositioningChildren() returned true.

21.3 wxImage::HSVValue Class Reference

`#include <wx/image.h>`

21.3.1 Detailed Description

A simple class which stores hue, saturation and value as doubles in the range 0.0-1.0.

Public Member Functions

- HSVValue (double h=0.0, double s=0.0, double v=0.0)

  Constructor for HSVValue, an object that contains values for hue, saturation and value which represent the value of a color.

Public Attributes

- double hue
- double saturation
- double value

21.3.2 Constructor & Destructor Documentation

wxImage::HSVValue::HSVValue (double *h* = 0.0, double *s* = 0.0, double *v* = 0.0)

Constructor for HSVValue, an object that contains values for hue, saturation and value which represent the value of a color.

It is used by wxImage::HSVtoRGB() and wxImage::RGBtoHSV(), which convert between HSV color space and RGB color space.

21.3.3 Member Data Documentation

double wxImage::HSVValue::hue

double wxImage::HSVValue::saturation

double wxImage::HSVValue::value

21.4 wxPixelData< Image, PixelFormat >::Iterator Class Reference

`#include <wx/rawbmp.h>`

21.4.1 Detailed Description

template<class Image, class PixelFormat = wxPixelFormatFor<Image>>class wxPixelData< Image, PixelFormat >::Iterator

The iterator of class wxPixelData.

Public Member Functions

- void Reset (const PixelData &data)

  Reset the iterator to point to (0, 0).
- Iterator (PixelData &data)

  Initializes the iterator to point to the origin of the given pixel data.
- Iterator (wxBitmap &bmp, PixelData &data)

  Initializes the iterator to point to the origin of the given Bitmap.
- Iterator ()

  Default constructor.
- bool IsOk () const

  Return true if this iterator is valid.
- Iterator & operator++ ()

  Advance the iterator to the next pixel, prefix version.
- Iterator operator++ (int)

  Advance the iterator to the next pixel, postfix (hence less efficient – don't use it unless you absolutely must) version.
- void Offset (const PixelData &data, int x, int y)

  Move x pixels to the right and y down.
- void OffsetX (const PixelData &data, int x)

  Move x pixels to the right.
- void OffsetY (const PixelData &data, int y)

  Move y rows to the bottom.
- void MoveTo (const PixelData &data, int x, int y)

  Go to the given position.

- ChannelType & Red ()

  Data Access: Access to individual colour components.
- ChannelType & Green ()

  Data Access: Access to individual colour components.
- ChannelType & Blue ()

  Data Access: Access to individual colour components.
- ChannelType & Alpha ()

  Data Access: Access to individual colour components.

21.4.2 Constructor & Destructor Documentation

template<class Image , class PixelFormat = wxPixelFormatFor<Image>> wxPixelData< Image, PixelFormat >::Iterator::Iterator (PixelData & *data*)

Initializes the iterator to point to the origin of the given pixel data.

template<class Image , class PixelFormat = wxPixelFormatFor<Image>> wxPixelData< Image, PixelFormat >::Iterator::Iterator (wxBitmap & *bmp,* PixelData & *data*)

Initializes the iterator to point to the origin of the given Bitmap.

template<class Image , class PixelFormat = wxPixelFormatFor<Image>> wxPixelData< Image, PixelFormat >::Iterator::Iterator ( )

Default constructor.

21.4.3 Member Function Documentation

template<class Image , class PixelFormat = wxPixelFormatFor<Image>> ChannelType& wxPixelData< Image, PixelFormat >::Iterator::Alpha ( )

Data Access: Access to individual colour components.

template<class Image , class PixelFormat = wxPixelFormatFor<Image>> ChannelType& wxPixelData< Image, PixelFormat >::Iterator::Blue ( )

Data Access: Access to individual colour components.

template<class Image , class PixelFormat = wxPixelFormatFor<Image>> ChannelType& wxPixelData< Image, PixelFormat >::Iterator::Green ( )

Data Access: Access to individual colour components.

template<class Image , class PixelFormat = wxPixelFormatFor<Image>> bool wxPixelData< Image, PixelFormat >::Iterator::IsOk ( ) const

Return true if this iterator is valid.

template<class Image , class PixelFormat = wxPixelFormatFor<Image>> void wxPixelData< Image, PixelFormat >::Iterator::MoveTo (const PixelData & *data,* int *x,* int *y*)

Go to the given position.

template<class Image , class PixelFormat = wxPixelFormatFor<Image>> void wxPixelData< Image, PixelFormat >::Iterator::Offset (const PixelData & *data,* int *x,* int *y*)

Move *x* pixels to the right and *y* down.

Note

The rows won't wrap automatically.

template<class Image , class PixelFormat = wxPixelFormatFor<Image>> void wxPixelData< Image, PixelFormat >::Iterator::OffsetX (const PixelData & *data,* int *x*)

Move *x* pixels to the right.

Note

The rows won't wrap automatically.

template<class Image , class PixelFormat = wxPixelFormatFor<Image>> void wxPixelData< Image, PixelFormat >::Iterator::OffsetY (const PixelData & *data,* int *y*)

Move *y* rows to the bottom.

template<class Image , class PixelFormat = wxPixelFormatFor<Image>> Iterator& wxPixelData< Image, PixelFormat >::Iterator::operator++ ( )

Advance the iterator to the next pixel, prefix version.

template<class Image , class PixelFormat = wxPixelFormatFor<Image>> Iterator wxPixelData< Image, PixelFormat >::Iterator::operator++ (int)

Advance the iterator to the next pixel, postfix (hence less efficient – don't use it unless you absolutely must) version.

template<class Image , class PixelFormat = wxPixelFormatFor<Image>> ChannelType& wxPixelData< Image, PixelFormat >::Iterator::Red ( )

Data Access: Access to individual colour components.

template<class Image , class PixelFormat = wxPixelFormatFor<Image>> void wxPixelData< Image, PixelFormat >::Iterator::Reset (const PixelData & *data*)

Reset the iterator to point to (0, 0).

21.5 wxFileType::MessageParameters Class Reference

`#include <wx/mimetype.h>`

21.5.1 Detailed Description

Class representing message parameters.

An object of this class may be passed to wxFileType::GetOpenCommand() and GetPrintCommand() if more than the file name needs to be specified.

Public Member Functions

- MessageParameters ()
  Trivial default constructor.
- MessageParameters (const wxString &filename, const wxString &mimetype=wxEmptyString)
  Constructor taking a filename and a mime type.
- const wxString & GetFileName () const
  Return the filename.
- const wxString & GetMimeType () const
  Return the MIME type.
- virtual wxString GetParamValue (const wxString &name) const
  Overridable method for derived classes. Returns empty string by default.
- virtual ~MessageParameters ()
  Trivial but virtual dtor as this class can be inherited from.

21.5.2 Constructor & Destructor Documentation

wxFileType::MessageParameters::MessageParameters ( )

Trivial default constructor.

wxFileType::MessageParameters::MessageParameters (const wxString & *filename,* const wxString & *mimetype =* wxEmptyString)

Constructor taking a filename and a mime type.

virtual wxFileType::MessageParameters::~MessageParameters ( ) [virtual]

Trivial but virtual dtor as this class can be inherited from.

21.5.3 Member Function Documentation

const wxString& wxFileType::MessageParameters::GetFileName ( ) const

Return the filename.

const wxString& wxFileType::MessageParameters::GetMimeType ( ) const

Return the MIME type.

virtual wxString wxFileType::MessageParameters::GetParamValue (const wxString & *name*) const [virtual]

Overridable method for derived classes. Returns empty string by default.

21.6 wxImage::RGBValue Class Reference

`#include <wx/image.h>`

21.6.1 Detailed Description

A simple class which stores red, green and blue values as 8 bit unsigned integers in the range of 0-255.

Public Member Functions

- RGBValue (unsigned char r=0, unsigned char g=0, unsigned char b=0)
  Constructor for RGBValue, an object that contains values for red, green and blue which represent the value of a color.

Public Attributes

- unsigned char red
- unsigned char green
- unsigned char blue

21.6.2 Constructor & Destructor Documentation

wxImage::RGBValue::RGBValue (unsigned char *r* = 0, unsigned char *g* = 0, unsigned char *b* = 0)

Constructor for RGBValue, an object that contains values for red, green and blue which represent the value of a color.

It is used by wxImage::HSVtoRGB and wxImage::RGBtoHSV, which convert between HSV color space and RGB color space.

21.6.3 Member Data Documentation

unsigned char wxImage::RGBValue::blue

unsigned char wxImage::RGBValue::green

unsigned char wxImage::RGBValue::red

21.7 wxDateTime::TimeZone Class Reference

`#include <wx/datetime.h>`

21.7.1 Detailed Description

Class representing a time zone.

The representation is simply the offset, in seconds, from UTC.

Public Member Functions

- TimeZone (TZ tz)
  Constructor for a named time zone.
- TimeZone (long offset=0)
  Constructor for the given offset in seconds.
- long GetOffset () const
  Return the offset of this time zone from UTC, in seconds.

Static Public Member Functions

- static TimeZone Make (long offset)
  Create a time zone with the given offset in seconds.

21.7.2 Constructor & Destructor Documentation

wxDateTime::TimeZone::TimeZone (TZ *tz*)

Constructor for a named time zone.

wxDateTime::TimeZone::TimeZone (long *offset* = `0`)

Constructor for the given offset in seconds.

21.7.3 Member Function Documentation

long wxDateTime::TimeZone::GetOffset ( ) const

Return the offset of this time zone from UTC, in seconds.

static TimeZone wxDateTime::TimeZone::Make (long *offset*) `[static]`

Create a time zone with the given offset in seconds.

21.8 wxDateTime::Tm Struct Reference

`#include <wx/datetime.h>`

21.8.1 Detailed Description

Contains broken down date-time representation.

This struct is analogous to standard C `struct tm` and uses the same, not always immediately obvious, conventions for its members: notably its mon and mday fields count from 0 while yday counts from 1.

Public Member Functions

- bool IsValid () const

  Check if the given date/time is valid (in Gregorian calendar).
- WeekDay GetWeekDay ()

  Return the week day corresponding to this date.

Public Attributes

- wxDateTime_t msec

  Number of milliseconds.
- wxDateTime_t sec

  Seconds in 0..59 (60 with leap seconds) range.
- wxDateTime_t min

  Minutes in 0..59 range.
- wxDateTime_t hour

  Hours since midnight in 0..23 range.
- wxDateTime_t mday

  Day of the month in 1..31 range.
- wxDateTime_t yday

  Day of the year in 0..365 range.
- Month mon

  Month, as an enumerated constant.
- int year

  Year.

21.8.2 Member Function Documentation

WeekDay wxDateTime::Tm::GetWeekDay ( )

Return the week day corresponding to this date.

Unlike the other fields, the week day is not always available and so must be accessed using this method as it is computed on demand when it is called.

bool wxDateTime::Tm::IsValid ( ) const

Check if the given date/time is valid (in Gregorian calendar).

Return false if the components don't correspond to a correct date.

21.8.3 Member Data Documentation

wxDateTime_t wxDateTime::Tm::hour

Hours since midnight in 0..23 range.

wxDateTime_t wxDateTime::Tm::mday

Day of the month in 1..31 range.

wxDateTime_t wxDateTime::Tm::min

Minutes in 0..59 range.

Month wxDateTime::Tm::mon

Month, as an enumerated constant.

wxDateTime_t wxDateTime::Tm::msec

Number of milliseconds.

wxDateTime_t wxDateTime::Tm::sec

Seconds in 0..59 (60 with leap seconds) range.

wxDateTime_t wxDateTime::Tm::yday

Day of the year in 0..365 range.

int wxDateTime::Tm::year

Year.

21.9 wxAboutDialogInfo Class Reference

`#include <wx/aboutdlg.h>`

21.9.1 Detailed Description

wxAboutDialogInfo contains information shown in the standard *About* dialog displayed by the wxAboutBox() function.

This class contains the general information about the program, such as its name, version, copyright and so on, as well as lists of the program developers, documentation writers, artists and translators. The simple properties from the former group are represented as a string with the exception of the program icon and the program web site, while the lists from the latter group are stored as wxArrayString and can be either set entirely at once using wx↩AboutDialogInfo::SetDevelopers and similar functions or built one by one using wxAboutDialogInfo::AddDeveloper etc.

Please also notice that while all the main platforms have the native implementation of the about dialog, they are often more limited than the generic version provided by wxWidgets and so the generic version is used if wxAboutDialogInfo has any fields not supported by the native version. Currently GTK+ version supports all the possible fields natively but MSW and Mac versions don't support URLs, licence text nor custom icons in the about dialog and if either of those is used, wxAboutBox() will automatically use the generic version so you should avoid specifying these fields to achieve more native look and feel.

Example of usage:

```
void MyFrame::OnAbout(wxCommandEvent& WXUNUSED(event))
{
    wxAboutDialogInfo aboutInfo;
    aboutInfo.SetName("MyApp");
    aboutInfo.SetVersion(MY_APP_VERSION_STRING);
    aboutInfo.SetDescription(_("My wxWidgets-based application!"));
    aboutInfo.SetCopyright("(C) 1992-2010");
    aboutInfo.SetWebSite("http://myapp.org");
    aboutInfo.AddDeveloper("My Self");

    wxAboutBox(aboutInfo);
}
```

Library: wxAdvanced

Category: Common Dialogs, Data Structures

See also

wxAboutDialogInfo::SetArtists

Public Member Functions

- wxAboutDialogInfo ()

  Default constructor leaves all fields are initially uninitialized, in general you should call at least SetVersion(), SetCopyright() and SetDescription().
- void AddArtist (const wxString &artist)

  Adds an artist name to be shown in the program credits.
- void AddDeveloper (const wxString &developer)

  Adds a developer name to be shown in the program credits.
- void AddDocWriter (const wxString &docwriter)

  Adds a documentation writer name to be shown in the program credits.
- void AddTranslator (const wxString &translator)

  Adds a translator name to be shown in the program credits.
- wxString GetName () const

  Get the name of the program.
- bool HasDescription () const

  Returns true if a description string has been specified.
- const wxString & GetDescription ()

  Get the description string.
- bool HasCopyright () const

  Returns true if a copyright string has been specified.
- const wxString & GetCopyright () const

  Get the copyright string.
- void SetArtists (const wxArrayString &artists)

  Sets the list of artists to be shown in the program credits.
- void SetCopyright (const wxString &copyright)

Set the short string containing the program copyright information.

- void SetDescription (const wxString &desc)

  Set brief, but possibly multiline, description of the program.
- void SetDevelopers (const wxArrayString &developers)

  Set the list of developers of the program.
- void SetDocWriters (const wxArrayString &docwriters)

  Set the list of documentation writers.
- void SetIcon (const wxIcon &icon)

  Set the icon to be shown in the dialog.
- void SetLicence (const wxString &licence)

  Set the long, multiline string containing the text of the program licence.
- void SetLicense (const wxString &licence)

  This is the same as SetLicence().
- void SetName (const wxString &name)

  Set the name of the program.
- void SetTranslators (const wxArrayString &translators)

  Set the list of translators.
- void SetVersion (const wxString &version, const wxString &longVersion=wxString())

  Set the version of the program.
- void SetWebSite (const wxString &url, const wxString &desc=wxEmptyString)

  Set the web site for the program and its description (which defaults to url itself if empty).

21.9.2 Constructor & Destructor Documentation

wxAboutDialogInfo::wxAboutDialogInfo ( )

Default constructor leaves all fields are initially uninitialized, in general you should call at least SetVersion(), SetCopyright() and SetDescription().

21.9.3 Member Function Documentation

void wxAboutDialogInfo::AddArtist (const wxString & *artist*)

Adds an artist name to be shown in the program credits.

See also

SetArtists()

void wxAboutDialogInfo::AddDeveloper (const wxString & *developer*)

Adds a developer name to be shown in the program credits.

See also

SetDevelopers()

void wxAboutDialogInfo::AddDocWriter (const wxString & *docwriter*)

Adds a documentation writer name to be shown in the program credits.

See also

SetDocWriters()

void wxAboutDialogInfo::AddTranslator (const wxString & *translator*)

Adds a translator name to be shown in the program credits.

Notice that if no translator names are specified explicitly, wxAboutBox() will try to use the translation of the string `translator-credits` from the currently used message catalog – this can be used to show just the name of the translator of the program in the current language.

See also

SetTranslators()

const wxString& wxAboutDialogInfo::GetCopyright ( ) const

Get the copyright string.

Returns

The copyright string

const wxString& wxAboutDialogInfo::GetDescription ( )

Get the description string.

Returns

The description string, free-form.

wxString wxAboutDialogInfo::GetName ( ) const

Get the name of the program.

Returns

Name of the program

See also

SetName()

bool wxAboutDialogInfo::HasCopyright ( ) const

Returns true if a copyright string has been specified.

See also

GetCopyright()

bool wxAboutDialogInfo::HasDescription ( ) const

Returns true if a description string has been specified.

See also

GetDescription()

void wxAboutDialogInfo::SetArtists (const wxArrayString & *artists*)

Sets the list of artists to be shown in the program credits.

See also

AddArtist()

void wxAboutDialogInfo::SetCopyright (const wxString & *copyright*)

Set the short string containing the program copyright information.

Notice that any occurrences of `"(C)"` in *copyright* will be replaced by the copyright symbol (circled C) automatically, which means that you can avoid using this symbol in the program source code which can be problematic,

void wxAboutDialogInfo::SetDescription (const wxString & *desc*)

Set brief, but possibly multiline, description of the program.

void wxAboutDialogInfo::SetDevelopers (const wxArrayString & *developers*)

Set the list of developers of the program.

See also

AddDeveloper()

void wxAboutDialogInfo::SetDocWriters (const wxArrayString & *docwriters*)

Set the list of documentation writers.

See also

AddDocWriter()

void wxAboutDialogInfo::SetIcon (const wxIcon & *icon*)

Set the icon to be shown in the dialog.

By default the icon of the main frame will be shown if the native about dialog supports custom icons. If it doesn't but a valid icon is specified using this method, the generic about dialog is used instead so you should avoid calling this function for maximally native look and feel.

void wxAboutDialogInfo::SetLicence (const wxString & *licence*)

Set the long, multiline string containing the text of the program licence.

Only GTK+ version supports showing the licence text in the native about dialog currently so the generic version will be used under all the other platforms if this method is called. To preserve the native look and feel it is advised that you do not call this method but provide a separate menu item in the `"Help"` menu for displaying the text of your program licence.

void wxAboutDialogInfo::SetLicense (const wxString & *licence*)

This is the same as SetLicence().

void wxAboutDialogInfo::SetName (const wxString & *name*)

Set the name of the program.

If this method is not called, the string returned by wxApp::GetAppName will be shown in the dialog.

void wxAboutDialogInfo::SetTranslators (const wxArrayString & *translators*)

Set the list of translators.

Please see AddTranslator() for additional discussion.

void wxAboutDialogInfo::SetVersion (const wxString & *version,* const wxString & *longVersion* = wxString ())

Set the version of the program.

The word "version" shouldn't be included in *version*. Example *version* values: "1.2" and "RC2". In about dialogs with more space set aside for version information, *longVersion* is used. Example *longVersion* values: "Version 1.2" and "Release Candidate 2". If *version* is non-empty but *longVersion* is empty, a long version is constructed automatically, using *version* (by simply prepending "Version " to *version*).

The generic about dialog and native GTK+ dialog use *version* only, as a suffix to the program name. The native MSW and OS X about dialogs use the long version.

void wxAboutDialogInfo::SetWebSite (const wxString & *url,* const wxString & *desc* = wxEmptyString)

Set the web site for the program and its description (which defaults to *url* itself if empty).

Please notice that only GTK+ version currently supports showing the link in the native about dialog so if this method is called, the generic version will be used under all the other platforms.

21.10 wxAcceleratorEntry Class Reference

`#include <wx/accel.h>`

21.10.1 Detailed Description

An object used by an application wishing to create an accelerator table (see wxAcceleratorTable).

Library: wxCore

Category: Data Structures

See also

wxAcceleratorTable, wxWindow::SetAcceleratorTable

Public Member Functions

- wxAcceleratorEntry (int flags=0, int keyCode=0, int cmd=0, wxMenuItem *item=NULL)
  Constructor.
- wxAcceleratorEntry (const wxAcceleratorEntry &entry)
  Copy ctor.

- int GetCommand () const

  Returns the command identifier for the accelerator table entry.
- int GetFlags () const

  Returns the flags for the accelerator table entry.
- int GetKeyCode () const

  Returns the keycode for the accelerator table entry.
- wxMenuItem * GetMenuItem () const

  Returns the menu item associated with this accelerator entry.
- void Set (int flags, int keyCode, int cmd, wxMenuItem *item=NULL)

  Sets the accelerator entry parameters.
- bool IsOk () const

  Returns true if this object is correctly initialized.
- wxString ToString () const

  Returns a textual representation of this accelerator.
- wxString ToRawString () const

  Returns a textual representation of this accelerator which is appropriate for saving in configuration files.
- bool FromString (const wxString &str)

  Parses the given string and sets the accelerator accordingly.
- wxAcceleratorEntry & operator= (const wxAcceleratorEntry &entry)
- bool operator== (const wxAcceleratorEntry &entry) const
- bool operator!= (const wxAcceleratorEntry &entry) const

21.10.2 Constructor & Destructor Documentation

wxAcceleratorEntry::wxAcceleratorEntry (int *flags* = `0`, int *keyCode* = `0`, int *cmd* = `0`, wxMenuItem * *item* = `NULL`)

Constructor.

Parameters

flags	A combination of the wxAcceleratorEntryFlags values, which indicates which modifier keys are held down.
keyCode	The keycode to be detected. See wxKeyCode for a full list of keycodes.
cmd	The menu or control command identifier (ID).
item	The menu item associated with this accelerator.

wxAcceleratorEntry::wxAcceleratorEntry (const wxAcceleratorEntry & *entry*)

Copy ctor.

21.10.3 Member Function Documentation

bool wxAcceleratorEntry::FromString (const wxString & *str*)

Parses the given string and sets the accelerator accordingly.

Parameters

str	This string may be either in the same format as returned by ToString(), i.e. contain the accelerator itself only, or have the format of a full menu item text with i.e. `Label TAB Accelerator`. In the latter case, the part of the string before the TAB is ignored. Notice that the latter format is only supported for the compatibility with the previous wxWidgets versions and the new code should pass only the accelerator string itself to this function.

Returns

true if the given string correctly initialized this object (i.e. if IsOk() returns true after this call)

int wxAcceleratorEntry::GetCommand ( ) const

Returns the command identifier for the accelerator table entry.

int wxAcceleratorEntry::GetFlags ( ) const

Returns the flags for the accelerator table entry.

int wxAcceleratorEntry::GetKeyCode ( ) const

Returns the keycode for the accelerator table entry.

wxMenuItem* wxAcceleratorEntry::GetMenuItem ( ) const

Returns the menu item associated with this accelerator entry.

bool wxAcceleratorEntry::IsOk ( ) const

Returns true if this object is correctly initialized.

bool wxAcceleratorEntry::operator!= (const wxAcceleratorEntry & *entry*) const

wxAcceleratorEntry& wxAcceleratorEntry::operator= (const wxAcceleratorEntry & *entry*)

bool wxAcceleratorEntry::operator== (const wxAcceleratorEntry & *entry*) const

void wxAcceleratorEntry::Set (int *flags*, int *keyCode*, int *cmd*, wxMenuItem * *item* = NULL)

Sets the accelerator entry parameters.

Parameters

flags	A combination of the wxAcceleratorEntryFlags values, which indicates which modifier keys are held down.
keyCode	The keycode to be detected. See wxKeyCode for a full list of keycodes.
cmd	The menu or control command identifier (ID).
item	The menu item associated with this accelerator.

wxString wxAcceleratorEntry::ToRawString ( ) const

Returns a textual representation of this accelerator which is appropriate for saving in configuration files.

Unlike the string returned by ToString(), this one is never translated so, while it's not suitable for showing to the user, it can be used to uniquely identify the accelerator independently of the user language.

The returned string can still be parsed by FromString().

Since

2.9.4

wxString wxAcceleratorEntry::ToString ( ) const

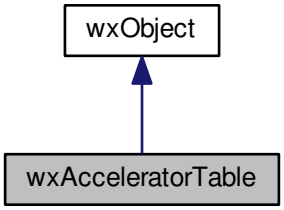
Returns a textual representation of this accelerator.

The returned string is of the form `[Alt+][Ctrl+][RawCtrl+][Shift+]Key` where the modifier keys are present only if the corresponding flag is set.

21.11 wxAcceleratorTable Class Reference

`#include <wx/accel.h>`

Inheritance diagram for wxAcceleratorTable:



21.11.1 Detailed Description

An accelerator table allows the application to specify a table of keyboard shortcuts for menu or button commands.

The object wxNullAcceleratorTable is defined to be a table with no data, and is the initial accelerator table for a window.

Example:

```
wxAcceleratorEntry entries[4];
entries[0].Set(wxACCEL_CTRL, (int) 'N', ID_NEW_WINDOW);
entries[1].Set(wxACCEL_CTRL, (int) 'X', wxID_EXIT);
entries[2].Set(wxACCEL_SHIFT, (int) 'A', ID_ABOUT);
entries[3].Set(wxACCEL_NORMAL, WXK_DELETE, wxID_CUT);

wxAcceleratorTable accel(4, entries);
frame->SetAcceleratorTable(accel);
```

Remarks

An accelerator takes precedence over normal processing and can be a convenient way to program some event handling. For example, you can use an accelerator table to enable a dialog with a multi-line text control to accept CTRL-Enter as meaning 'OK'.

Library: wxCore

Category: Data Structures

Predefined objects/pointers: wxNullAcceleratorTable

See also

wxAcceleratorEntry, wxWindow::SetAcceleratorTable

Public Member Functions

- wxAcceleratorTable ()

  Default ctor.
- wxAcceleratorTable (int n, const wxAcceleratorEntry entries[])

  Initializes the accelerator table from an array of wxAcceleratorEntry.
- wxAcceleratorTable (const wxString &resource)

  Loads the accelerator table from a Windows resource (Windows only).
- virtual ~wxAcceleratorTable ()

  Destroys the wxAcceleratorTable object.
- bool IsOk () const

  Returns true if the accelerator table is valid.

Additional Inherited Members

21.11.2 Constructor & Destructor Documentation

wxAcceleratorTable::wxAcceleratorTable ( )

Default ctor.

wxAcceleratorTable::wxAcceleratorTable (int *n*, const wxAcceleratorEntry *entries[]*)

Initializes the accelerator table from an array of wxAcceleratorEntry.

Parameters

n	Number of accelerator entries.
entries	The array of entries.

wxPerl Note: The wxPerl constructor accepts a list of either Wx::AcceleratorEntry objects or references to 3-element arrays [flags, keyCode, cmd] , like the parameters of Wx::AcceleratorEntry::new.

wxAcceleratorTable::wxAcceleratorTable (const wxString & *resource*)

Loads the accelerator table from a Windows resource (Windows only).

Availability: only available for the wxMSW port.

Parameters

resource	Name of a Windows accelerator.

virtual wxAcceleratorTable::~wxAcceleratorTable ( ) [virtual]

Destroys the wxAcceleratorTable object.

See Object Destruction for more info.

21.11.3 Member Function Documentation

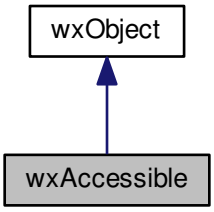
bool wxAcceleratorTable::IsOk ( ) const

Returns true if the accelerator table is valid.

21.12 wxAccessible Class Reference

`#include <wx/access.h>`

Inheritance diagram for wxAccessible:



21.12.1 Detailed Description

The wxAccessible class allows wxWidgets applications, and wxWidgets itself, to return extended information about user interface elements to client applications such as screen readers.

This is the main way in which wxWidgets implements accessibility features.

At present, only Microsoft Active Accessibility is supported by this class.

To use this class, derive from wxAccessible, implement appropriate functions, and associate an object of the class with a window using wxWindow::SetAccessible.

All functions return an indication of success, failure, or not implemented using values of the wxAccStatus enum type.

If you return `wxACC_NOT_IMPLEMENTED` from any function, the system will try to implement the appropriate functionality. However this will not work with all functions.

Most functions work with an object *id*, which can be zero to refer to 'this' UI element, or greater than zero to refer to the nth child element. This allows you to specify elements that don't have a corresponding wxWindow or wxAccessible; for example, the sash of a splitter window.

For details on the semantics of functions and types, please refer to the Microsoft Active Accessibility 1.2 documentation.

This class is compiled into wxWidgets only if the wxUSE_ACCESSIBILITY setup symbol is set to 1.

Availability: only available for the wxMSW port.

Library: wxCore

Category: Miscellaneous

See also

Accessibility Sample

Public Member Functions

- wxAccessible (wxWindow *win=NULL)

  Constructor, taking an optional window.
- ~wxAccessible ()

  Destructor.
- virtual wxAccStatus DoDefaultAction (int childId)

  Performs the default action for the object.
- virtual wxAccStatus GetChild (int childId, wxAccessible **child)

  Gets the specified child (starting from 1).
- virtual wxAccStatus GetChildCount (int *childCount)

  Returns the number of children in childCount.
- virtual wxAccStatus GetDefaultAction (int childId, wxString *actionName)

  Gets the default action for this object (0) or a child (greater than 0).
- virtual wxAccStatus GetDescription (int childId, wxString *description)

  Returns the description for this object or a child.
- virtual wxAccStatus GetFocus (int *childId, wxAccessible **child)

  Gets the window with the keyboard focus.
- virtual wxAccStatus GetHelpText (int childId, wxString *helpText)

  Returns help text for this object or a child, similar to tooltip text.
- virtual wxAccStatus GetKeyboardShortcut (int childId, wxString *shortcut)

  Returns the keyboard shortcut for this object or child.
- virtual wxAccStatus GetLocation (wxRect &rect, int elementId)

  Returns the rectangle for this object (id is 0) or a child element (id is greater than 0).
- virtual wxAccStatus GetName (int childId, wxString *name)

  Gets the name of the specified object.
- virtual wxAccStatus GetParent (wxAccessible **parent)

  Returns the parent of this object, or NULL.
- virtual wxAccStatus GetRole (int childId, wxAccRole *role)

  Returns a role constant describing this object.
- virtual wxAccStatus GetSelections (wxVariant *selections)

  Gets a variant representing the selected children of this object.
- virtual wxAccStatus GetState (int childId, long *state)

  Returns a state constant.
- virtual wxAccStatus GetValue (int childId, wxString *strValue)

  Returns a localized string representing the value for the object or child.
- wxWindow * GetWindow ()

  Returns the window associated with this object.
- virtual wxAccStatus HitTest (const wxPoint &pt, int *childId, wxAccessible **childObject)

  Returns a status value and object id to indicate whether the given point was on this or a child object.
- virtual wxAccStatus Navigate (wxNavDir navDir, int fromId, int *toId, wxAccessible **toObject)

  Navigates from fromId to toId or to toObject.
- virtual wxAccStatus Select (int childId, wxAccSelectionFlags selectFlags)

  Selects the object or child.
- void SetWindow (wxWindow *window)

  Sets the window associated with this object.

Static Public Member Functions

- static void NotifyEvent (int eventType, wxWindow *window, wxAccObject objectType, int objectType)
  Allows the application to send an event when something changes in an accessible object.

Additional Inherited Members

21.12.2 Constructor & Destructor Documentation

wxAccessible::wxAccessible (wxWindow * *win* = NULL)

Constructor, taking an optional window.

The object can be associated with a window later.

wxAccessible::~wxAccessible ( )

Destructor.

21.12.3 Member Function Documentation

virtual wxAccStatus wxAccessible::DoDefaultAction (int *childId*) [virtual]

Performs the default action for the object.

childId is 0 (the action for this object) or greater than 0 (the action for a child).

Returns

wxACC_NOT_SUPPORTED if there is no default action for this window (e.g. an edit control).

virtual wxAccStatus wxAccessible::GetChild (int *childId*, wxAccessible ** *child*) [virtual]

Gets the specified child (starting from 1).

If *child* is NULL and the return value is wxACC_OK, this means that the child is a simple element and not an accessible object.

virtual wxAccStatus wxAccessible::GetChildCount (int * *childCount*) [virtual]

Returns the number of children in *childCount*.

virtual wxAccStatus wxAccessible::GetDefaultAction (int *childId*, wxString * *actionName*) [virtual]

Gets the default action for this object (0) or a child (greater than 0).

Return wxACC_OK even if there is no action. *actionName* is the action, or the empty string if there is no action. The retrieved string describes the action that is performed on an object, not what the object does as a result. For example, a toolbar button that prints a document has a default action of "Press" rather than "Prints the current document."

virtual wxAccStatus wxAccessible::GetDescription (int *childId*, wxString * *description*) [virtual]

Returns the description for this object or a child.

virtual wxAccStatus wxAccessible::GetFocus (int * *childId,* wxAccessible ** *child*) [virtual]

Gets the window with the keyboard focus.

If childId is 0 and child is NULL, no object in this subhierarchy has the focus. If this object has the focus, child should be 'this'.

virtual wxAccStatus wxAccessible::GetHelpText (int *childId,* wxString * *helpText*) [virtual]

Returns help text for this object or a child, similar to tooltip text.

virtual wxAccStatus wxAccessible::GetKeyboardShortcut (int *childId,* wxString * *shortcut*) [virtual]

Returns the keyboard shortcut for this object or child.

Returns e.g. ALT+K.

virtual wxAccStatus wxAccessible::GetLocation (wxRect & *rect,* int *elementId*) [virtual]

Returns the rectangle for this object (id is 0) or a child element (id is greater than 0).

rect is in screen coordinates.

virtual wxAccStatus wxAccessible::GetName (int *childId,* wxString * *name*) [virtual]

Gets the name of the specified object.

virtual wxAccStatus wxAccessible::GetParent (wxAccessible ** *parent*) [virtual]

Returns the parent of this object, or NULL.

virtual wxAccStatus wxAccessible::GetRole (int *childId,* wxAccRole * *role*) [virtual]

Returns a role constant describing this object.

See wxAccRole for a list of these roles.

virtual wxAccStatus wxAccessible::GetSelections (wxVariant * *selections*) [virtual]

Gets a variant representing the selected children of this object.

Acceptable values are:

- a null variant (IsNull() returns true)
- a list variant (GetType() == "list")
- an integer representing the selected child element, or 0 if this object is selected (GetType() == "long")
- a "void*" pointer to a wxAccessible child object

virtual wxAccStatus wxAccessible::GetState (int *childId,* long * *state*) [virtual]

Returns a state constant.

See wxAccStatus for a list of these states.

virtual wxAccStatus wxAccessible::GetValue (int *childId,* wxString * *strValue*) [virtual]

Returns a localized string representing the value for the object or child.

wxWindow* wxAccessible::GetWindow ( )

Returns the window associated with this object.

virtual wxAccStatus wxAccessible::HitTest (const wxPoint & *pt,* int * *childId,* wxAccessible ** *childObject*) [virtual]

Returns a status value and object id to indicate whether the given point was on this or a child object.

Can return either a child object, or an integer representing the child element, starting from 1.

pt is in screen coordinates.

virtual wxAccStatus wxAccessible::Navigate (wxNavDir *navDir,* int *fromId,* int * *toId,* wxAccessible ** *toObject*) [virtual]

Navigates from *fromId* to *toId* or to *toObject*.

static void wxAccessible::NotifyEvent (int *eventType,* wxWindow * *window,* wxAccObject *objectType,* int *objectType*) [static]

Allows the application to send an event when something changes in an accessible object.

virtual wxAccStatus wxAccessible::Select (int *childId,* wxAccSelectionFlags *selectFlags*) [virtual]

Selects the object or child.

See wxAccSelectionFlags for a list of the selection actions.

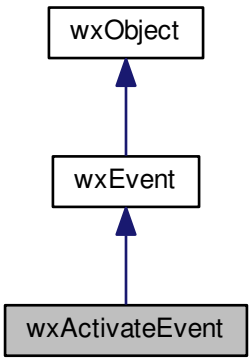
void wxAccessible::SetWindow (wxWindow * *window*)

Sets the window associated with this object.

21.13 wxActivateEvent Class Reference

```
#include <wx/event.h>
```

Inheritance diagram for wxActivateEvent:



21.13.1 Detailed Description

An activate event is sent when a window or application is being activated or deactivated.

Events using this class

The following event handler macros redirect the events to member function handlers '**func**' with prototypes like: void handlerFuncName(wxActivateEvent& event)

Event macros:

- EVT_ACTIVATE(func): Process a `wxEVT_ACTIVATE` event.
- EVT_ACTIVATE_APP(func): Process a `wxEVT_ACTIVATE_APP` event. This event is received by the wx↩ App-derived instance only.
- EVT_HIBERNATE(func): Process a hibernate event, supplying the member function. This event applies to wxApp only, and only on Windows SmartPhone and PocketPC. It is generated when the system is low on memory; the application should free up as much memory as possible, and restore full working state when it receives a `wxEVT_ACTIVATE` or `wxEVT_ACTIVATE_APP` event.

Library: wxCore

Category: Events

See also

Events and Event Handling, wxApp::IsActive

Public Types

- enum Reason {
  Reason_Mouse,
  Reason_Unknown }

Specifies the reason for the generation of this event.

Public Member Functions

- wxActivateEvent (wxEventType eventType=wxEVT_NULL, bool active=true, int id=0, Reason Activation↩ Reason=Reason_Unknown)

  Constructor.
- bool GetActive () const

  Returns true if the application or window is being activated, false otherwise.
- Reason GetActivationReason () const

  Allows to check if the window was activated by clicking it with the mouse or in some other way.

Additional Inherited Members

21.13.2 Member Enumeration Documentation

enum wxActivateEvent::Reason

Specifies the reason for the generation of this event.

See GetActivationReason().

Since

3.0

Enumerator

Reason_Mouse Window activated by mouse click.

Reason_Unknown Window was activated with some other method than mouse click.

21.13.3 Constructor & Destructor Documentation

wxActivateEvent::wxActivateEvent (wxEventType *eventType* = wxEVT_NULL, bool *active* = `true`, int *id* = `0`, Reason *ActivationReason* = Reason_Unknown)

Constructor.

21.13.4 Member Function Documentation

Reason wxActivateEvent::GetActivationReason ( ) const

Allows to check if the window was activated by clicking it with the mouse or in some other way.

This method is currently only implemented in wxMSW and returns `Reason_Mouse` there if the window was activated by a mouse click and `Reason_Unknown` if it was activated in any other way (e.g. from keyboard or programmatically).

Under all the other platforms, `Reason_Unknown` is always returned.

Since

3.0

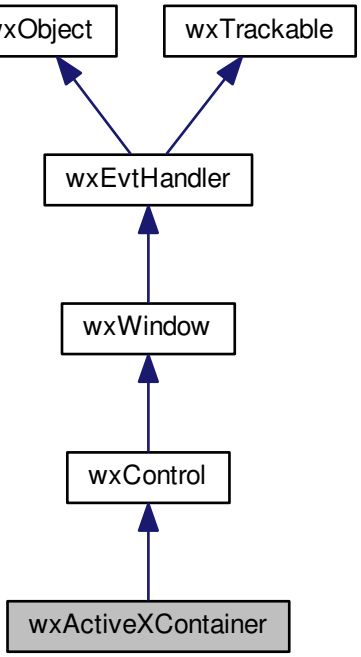
bool wxActivateEvent::GetActive ( ) const

Returns true if the application or window is being activated, false otherwise.

21.14 wxActiveXContainer Class Reference

`#include <wx/msw/ole/activex.h>`

Inheritance diagram for wxActiveXContainer:



21.14.1 Detailed Description

wxActiveXContainer is a host for an ActiveX control on Windows (and as such is a platform-specific class).

Note that the HWND that the class contains is the actual HWND of the ActiveX control so using dynamic events and connecting to `wxEVT_SIZE`, for example, will receive the actual size message sent to the control.

It is somewhat similar to the ATL class CAxWindow in operation.

The size of the ActiveX control's content is generally guaranteed to be that of the client size of the parent of this wxActiveXContainer.

You can also process ActiveX events through wxActiveXEvent.

21.14.2 Example

This is an example of how to use the Adobe Acrobat Reader ActiveX control to read PDF files (requires Acrobat Reader 4 and up). Controls like this are typically found and dumped from OLEVIEW.exe that is distributed with

Microsoft Visual C++. This example also demonstrates how to create a backend for wxMediaCtrl.

```
//++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++
//
// wxPDFMediaBackend
//

Public Member Functions

- wxActiveXContainer (wxWindow *parent, REFIID iid, IUnknown *pUnk)

  Creates this ActiveX container.
- virtual bool QueryClientSiteInterface (REFIID iid, void **_interface, const char *&desc)

  Queries host's site for interface.

Additional Inherited Members

21.14.3 Constructor & Destructor Documentation

wxActiveXContainer::wxActiveXContainer (wxWindow * *parent,* REFIID *iid,* IUnknown * *pUnk*)

Creates this ActiveX container.

Parameters

parent	parent of this control. Must not be NULL.
iid	COM IID of pUnk to query. Must be a valid interface to an ActiveX control.
pUnk	Interface of ActiveX control.

21.14.4 Member Function Documentation

virtual bool wxActiveXContainer::QueryClientSiteInterface (REFIID *iid,* void ** *_interface,* const char *& *desc*)
`[virtual]`

Queries host's site for interface.

Parameters

iid	The iid of the required interface.
_interface	Double pointer to outgoing interface. Supply your own interface if desired.
desc	The description of the outgoing interface.

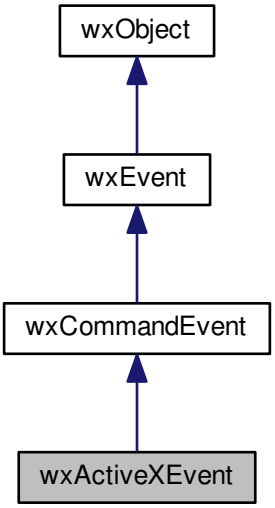
Returns

bool Return true if interface supplied else return false.

21.15 wxActiveXEvent Class Reference

```
#include <wx/msw/ole/activex.h>
```

Inheritance diagram for wxActiveXEvent:



21.15.1 Detailed Description

An event class for handling ActiveX events passed from wxActiveXContainer.

ActiveX events are basically a function call with the parameters passed through an array of wxVariants along with a return value that is a wxVariant itself. What type the parameters or return value are depends on the context (i.e. what the .idl specifies).

Events using this class

The following event handler macros redirect the events to member function handlers '**func**' with prototypes like: void handlerFuncName(wxActiveXEvent& event)

Event macros:

- EVT_ACTIVEX(func): Sent when the ActiveX control hosted by wxActiveXContainer receives an ActiveX event.

ActiveX event parameters can get extremely complex and may be beyond the abilities of wxVariant. If 'operator[]' fails, prints an error messages or crashes the application, event handlers should use GetNativeParameters() instead to obtain the original event information. Calls to operator[] and GetNativeParmeters() can be mixed. It is valid to handle some parameters of an event with operator[] and others directly through GetNativeParameters(). It is **not** valid however to manipulate the same parameter using both approaches at the same time.

Availability: only available for the wxMSW port.

Library: wxCore

Category: Events

Public Member Functions

- DISPID GetDispatchId (int idx) const

  Returns the dispatch id of this ActiveX event.
- size_t ParamCount () const

  Obtains the number of parameters passed through the ActiveX event.
- wxString ParamName (size_t idx) const

  Obtains the param name of the param number idx specifies as a string.
- wxString ParamType (size_t idx) const

  Obtains the param type of the param number idx specifies as a string.
- wxVariant operator[] (size_t idx)

  Obtains the actual parameter value specified by idx.
- wxActiveXEventNativeMSW * GetNativeParameters () const

  Obtain the original MSW parameters for the event.

Additional Inherited Members

21.15.2 Member Function Documentation

DISPID wxActiveXEvent::GetDispatchId (int *idx*) const

Returns the dispatch id of this ActiveX event.

This is the numeric value from the .idl file specified by the id().

wxActiveXEventNativeMSW* wxActiveXEvent::GetNativeParameters ( ) const

Obtain the original MSW parameters for the event.

Event handlers can use this information to handle complex event parameters that are beyond the scope of wx↩ Variant. The information returned here is the information passed to the original 'Invoke' method call.

Returns

a pointer to a struct containing the original MSW event parameters

wxVariant wxActiveXEvent::operator[] (size_t *idx*)

Obtains the actual parameter value specified by idx.

size_t wxActiveXEvent::ParamCount ( ) const

Obtains the number of parameters passed through the ActiveX event.

wxString wxActiveXEvent::ParamName (size_t *idx*) const

Obtains the param name of the param number idx specifies as a string.

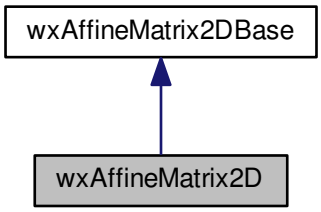
wxString wxActiveXEvent::ParamType (size_t *idx*) const

Obtains the param type of the param number idx specifies as a string.

21.16 wxAffineMatrix2D Class Reference

`#include <wx/affinematrix2d.h>`

Inheritance diagram for wxAffineMatrix2D:



21.16.1 Detailed Description

A 3x2 matrix representing an affine 2D transformation.

Library: wxCore

Category: Miscellaneous

Since

2.9.2

Public Member Functions

- wxAffineMatrix2D ()

  Default constructor.
- void Get (wxMatrix2D *mat2D, wxPoint2DDouble *tr) const

  Get the component values of the matrix.
- void Set (const wxMatrix2D &mat2D, const wxPoint2DDouble &tr)

  Set all elements of this matrix.
- void Concat (const wxAffineMatrix2DBase &t)

  Concatenate this matrix with another one.
- bool Invert ()

  Invert this matrix.
- bool IsIdentity () const

  Check if this is the identity matrix.
- bool operator!= (const wxAffineMatrix2DBase &t) const

  Check that this matrix differs from t.
- void Translate (wxDouble dx, wxDouble dy)

  Add the translation to this matrix.
- void Scale (wxDouble xScale, wxDouble yScale)

Add scaling to this matrix.

- void Mirror (int direction=wxHORIZONTAL)

  Add mirroring to this matrix.

- void Rotate (wxDouble cRadians)

  Add clockwise rotation to this matrix.

- wxPoint2DDouble TransformPoint (const wxPoint2DDouble &p) const

  Applies this matrix to the point.

- void TransformPoint (wxDouble *x, wxDouble *y) const
- wxPoint2DDouble TransformDistance (const wxPoint2DDouble &p) const

  Applies the linear part of this matrix, i.e. without translation.

- void TransformDistance (wxDouble *dx, wxDouble *dy) const

- void IsEqual (const wxAffineMatrix2DBase &t)

  Check that this matrix is identical with t.

- bool operator== (const wxAffineMatrix2DBase &t) const

  Check that this matrix is identical with t.

21.16.2 Constructor & Destructor Documentation

wxAffineMatrix2D::wxAffineMatrix2D ( )

Default constructor.

The matrix elements are initialize to the identity matrix.

21.16.3 Member Function Documentation

void wxAffineMatrix2D::Concat (const wxAffineMatrix2DBase & *t*) [virtual]

Concatenate this matrix with another one.

The parameter matrix is the multiplicand.

Parameters

t	The multiplicand.

```
//           | t.m_11  t.m_12  0 |   | m_11  m_12   0 |
// matrix' = | t.m_21  t.m_22  0 | x | m_21  m_22   0 |
//           | t.m_tx  t.m_ty  1 |   | m_tx  m_ty   1 |
```

Implements wxAffineMatrix2DBase.

void wxAffineMatrix2D::Get (wxMatrix2D * *mat2D*, wxPoint2DDouble * *tr*) const [virtual]

Get the component values of the matrix.

Parameters

mat2D	The rotational components of the matrix (upper 2 x 2), must be non-NULL.
tr	The translational components of the matrix, may be NULL.

Implements wxAffineMatrix2DBase.

bool wxAffineMatrix2D::Invert ( ) [virtual]

Invert this matrix.

If the matrix is not invertible, i.e. if its determinant is 0, returns false and doesn't modify it.

```
//           | m_11  m_12  0 |
// Invert    | m_21  m_22  0 |
//           | m_tx  m_ty  1 |
```

Implements wxAffineMatrix2DBase.

void wxAffineMatrix2D::IsEqual (const wxAffineMatrix2DBase & *t*)

Check that this matrix is identical with *t*.

Parameters

t	The matrix compared with this.

bool wxAffineMatrix2D::IsIdentity ( ) const [virtual]

Check if this is the identity matrix.

Implements wxAffineMatrix2DBase.

void wxAffineMatrix2D::Mirror (int *direction* = wxHORIZONTAL)

Add mirroring to this matrix.

Parameters

direction	The direction(s) used for mirroring. One of wxHORIZONTAL, wxVERTICAL or their combination wxBOTH.

bool wxAffineMatrix2D::operator!= (const wxAffineMatrix2DBase & *t*) const

Check that this matrix differs from *t*.

Parameters

t	The matrix compared with this.

bool wxAffineMatrix2D::operator== (const wxAffineMatrix2DBase & *t*) const

Check that this matrix is identical with *t*.

Parameters

t	The matrix compared with this.

void wxAffineMatrix2D::Rotate (wxDouble *cRadians*) [virtual]

Add clockwise rotation to this matrix.

Parameters

cRadians	Rotation angle in radians, clockwise.

```
//           | cos    sin   0 |   | m_11  m_12   0 |
// matrix' = | -sin   cos   0 | x | m_21  m_22   0 |
//           |  0      0    1 |   | m_tx  m_ty   1 |
```

Implements wxAffineMatrix2DBase.

void wxAffineMatrix2D::Scale (wxDouble *xScale,* wxDouble *yScale*) `[virtual]`

Add scaling to this matrix.

Parameters

xScale	Scaling in x direction.
yScale	Scaling in y direction.

```
//           | xScale   0      0 |   | m_11  m_12   0 |
// matrix' = |   0    yScale   0 | x | m_21  m_22   0 |
//           |   0      0      1 |   | m_tx  m_ty   1 |
```

Implements wxAffineMatrix2DBase.

void wxAffineMatrix2D::Set (const wxMatrix2D & *mat2D,* const wxPoint2DDouble & *tr*) `[virtual]`

Set all elements of this matrix.

Parameters

mat2D	The rotational components of the matrix (upper 2 x 2).
tr	The translational components of the matrix.

Implements wxAffineMatrix2DBase.

wxPoint2DDouble wxAffineMatrix2D::TransformDistance (const wxPoint2DDouble & *p*) const

Applies the linear part of this matrix, i.e. without translation.

Parameters

p	The source receiving the transformations.

Returns

The source with the transformations applied.

```
//                                | m_11  m_12   0 |
// dist' = | src.m_x  src._my  0 | x | m_21  m_22   0 |
//                                | m_tx  m_ty   1 |
```

void wxAffineMatrix2D::TransformDistance (wxDouble * *dx,* wxDouble * *dy*) const

wxPoint2DDouble wxAffineMatrix2D::TransformPoint (const wxPoint2DDouble & *p*) const

Applies this matrix to the point.

Parameters

p	The point receiving the transformations.

Returns

The point with the transformations applied.

```
//                                  | m_11  m_12   0 |
// point' = | src.m_x  src._my  1 | x | m_21  m_22   0 |
//                                  | m_tx  m_ty   1 |
```

void wxAffineMatrix2D::TransformPoint (wxDouble * *x*, wxDouble * *y*) const

void wxAffineMatrix2D::Translate (wxDouble *dx*, wxDouble *dy*) `[virtual]`

Add the translation to this matrix.

Parameters

dx	The translation in x direction.
dy	The translation in y direction.

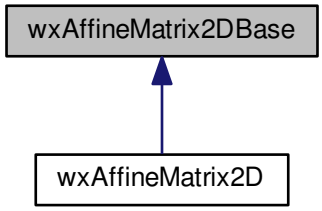
```
//           |  1   0   0 |   | m_11  m_12   0 |
// matrix' = |  0   1   0 | x | m_21  m_22   0 |
//           | dx  dy   1 |   | m_tx  m_ty   1 |
```

Implements wxAffineMatrix2DBase.

21.17 wxAffineMatrix2DBase Class Reference

`#include <wx/affinematrix2dbase.h>`

Inheritance diagram for wxAffineMatrix2DBase:



21.17.1 Detailed Description

A 2x3 matrix representing an affine 2D transformation.

This is an abstract base class implemented by wxAffineMatrix2D only so far, but in the future we also plan to derive wxGraphicsMatrix from it.

Library: wxCore

Category: Miscellaneous

Since

2.9.2

Public Member Functions

- wxAffineMatrix2DBase ()

  Default constructor.
- virtual ~wxAffineMatrix2DBase ()
- virtual void Set (const wxMatrix2D &mat2D, const wxPoint2DDouble &tr)=0

  Set all elements of this matrix.
- virtual void Get (wxMatrix2D *mat2D, wxPoint2DDouble *tr) const =0

  Get the component values of the matrix.
- virtual void Concat (const wxAffineMatrix2DBase &t)=0

  Concatenate this matrix with another one.
- virtual bool Invert ()=0

  Invert this matrix.
- virtual bool IsIdentity () const =0

  Check if this is the identity matrix.
- bool operator!= (const wxAffineMatrix2DBase &t) const

  Check that this matrix differs from t.
- virtual void Translate (wxDouble dx, wxDouble dy)=0

  Add the translation to this matrix.
- virtual void Scale (wxDouble xScale, wxDouble yScale)=0

  Add scaling to this matrix.
- virtual void Rotate (wxDouble cRadians)=0

  Add clockwise rotation to this matrix.
- void Mirror (int direction=wxHORIZONTAL)

  Add mirroring to this matrix.
- wxPoint2DDouble TransformPoint (const wxPoint2DDouble &p) const

  Applies this matrix to the point.
- void TransformPoint (wxDouble *x, wxDouble *y) const
- wxPoint2DDouble TransformDistance (const wxPoint2DDouble &p) const

  Applies the linear part of this matrix, i.e. without translation.
- void TransformDistance (wxDouble *dx, wxDouble *dy) const

- virtual bool IsEqual (const wxAffineMatrix2DBase &t) const =0

  Check that this matrix is identical with t.
- bool operator== (const wxAffineMatrix2DBase &t) const

  Check that this matrix is identical with t.

21.17.2 Constructor & Destructor Documentation

wxAffineMatrix2DBase::wxAffineMatrix2DBase ( )

Default constructor.

The matrix elements are initialize to the identity matrix.

virtual wxAffineMatrix2DBase::~wxAffineMatrix2DBase ( ) [virtual]

21.17.3 Member Function Documentation

virtual void wxAffineMatrix2DBase::Concat (const wxAffineMatrix2DBase & *t*) [pure virtual]

Concatenate this matrix with another one.

The parameter matrix is the multiplicand.

Parameters

t	The multiplicand.

```
//           | t.m_11  t.m_12  0 |    | m_11  m_12   0 |
// matrix' = | t.m_21  t.m_22  0 | x  | m_21  m_22   0 |
//           | t.m_tx  t.m_ty  1 |    | m_tx  m_ty   1 |
```

Implemented in wxAffineMatrix2D.

virtual void wxAffineMatrix2DBase::Get (wxMatrix2D * *mat2D*, wxPoint2DDouble * *tr*) const [pure virtual]

Get the component values of the matrix.

Parameters

mat2D	The rotational components of the matrix (upper 2 x 2), must be non-NULL.
tr	The translational components of the matrix, may be NULL.

Implemented in wxAffineMatrix2D.

virtual bool wxAffineMatrix2DBase::Invert ( ) [pure virtual]

Invert this matrix.

If the matrix is not invertible, i.e. if its determinant is 0, returns false and doesn't modify it.

```
//           | m_11  m_12  0 |
// Invert    | m_21  m_22  0 |
//           | m_tx  m_ty  1 |
```

Implemented in wxAffineMatrix2D.

virtual bool wxAffineMatrix2DBase::IsEqual (const wxAffineMatrix2DBase & *t*) const [pure virtual]

Check that this matrix is identical with *t*.

Parameters

t	The matrix compared with this.

virtual bool wxAffineMatrix2DBase::IsIdentity ( ) const [pure virtual]

Check if this is the identity matrix.

Implemented in wxAffineMatrix2D.

void wxAffineMatrix2DBase::Mirror (int *direction* = wxHORIZONTAL)

Add mirroring to this matrix.

Parameters

direction	The direction(s) used for mirroring. One of wxHORIZONTAL, wxVERTICAL or their combination wxBOTH.

bool wxAffineMatrix2DBase::operator!= (const wxAffineMatrix2DBase & *t*) const

Check that this matrix differs from *t*.

Parameters

t	The matrix compared with this.

bool wxAffineMatrix2DBase::operator== (const wxAffineMatrix2DBase & *t*) const

Check that this matrix is identical with *t*.

Parameters

t	The matrix compared with this.

virtual void wxAffineMatrix2DBase::Rotate (wxDouble *cRadians*) [pure virtual]

Add clockwise rotation to this matrix.

Parameters

cRadians	Rotation angle in radians, clockwise.

Implemented in wxAffineMatrix2D.

virtual void wxAffineMatrix2DBase::Scale (wxDouble *xScale,* wxDouble *yScale*) [pure virtual]

Add scaling to this matrix.

Parameters

xScale	Scaling in x direction.
yScale	Scaling in y direction.

Implemented in wxAffineMatrix2D.

virtual void wxAffineMatrix2DBase::Set (const wxMatrix2D & *mat2D,* const wxPoint2DDouble & *tr*) [pure virtual]

Set all elements of this matrix.

Parameters

mat2D	The rotational components of the matrix (upper 2 x 2).
tr	The translational components of the matrix.

Implemented in wxAffineMatrix2D.

wxPoint2DDouble wxAffineMatrix2DBase::TransformDistance (const wxPoint2DDouble & *p*) const

Applies the linear part of this matrix, i.e. without translation.

Parameters

p	The source receiving the transformations.

Returns

The source with the transformations applied.

void wxAffineMatrix2DBase::TransformDistance (wxDouble * *dx*, wxDouble * *dy*) const

wxPoint2DDouble wxAffineMatrix2DBase::TransformPoint (const wxPoint2DDouble & *p*) const

Applies this matrix to the point.

Parameters

p	The point receiving the transformations.

Returns

The point with the transformations applied.

void wxAffineMatrix2DBase::TransformPoint (wxDouble * *x*, wxDouble * *y*) const

virtual void wxAffineMatrix2DBase::Translate (wxDouble *dx*, wxDouble *dy*) `[pure virtual]`

Add the translation to this matrix.

Parameters

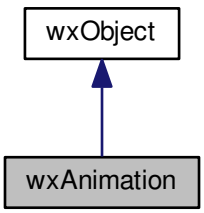
dx	The translation in x direction.
dy	The translation in y direction.

Implemented in wxAffineMatrix2D.

21.18 wxAnimation Class Reference

`#include <wx/animate.h>`

Inheritance diagram for wxAnimation:



21.18.1 Detailed Description

This class encapsulates the concept of a platform-dependent animation.

An animation is a sequence of frames of the same size. Sound is not supported by wxAnimation.

Note that on wxGTK wxAnimation is capable of loading the formats supported by the internally-used `gdk-pixbuf` library (typically this means only `wxANIMATION_TYPE_GIF`). On other platforms wxAnimation is always capable of loading both GIF and ANI formats (i.e. both `wxANIMATION_TYPE_GIF` and `wxANIMATION_TYPE_ANI`).

Library: wxAdvanced

Category: Graphics Device Interface (GDI)

Predefined objects/pointers: wxNullAnimation

See also

wxAnimationCtrl, Animation Sample

Public Member Functions

- wxAnimation ()
  Default ctor.
- wxAnimation (const wxAnimation &anim)
  Copy ctor.
- wxAnimation (const wxString &name, wxAnimationType type=wxANIMATION_TYPE_ANY)
  Loads an animation from a file.
- virtual ~wxAnimation ()
  Destructor.
- virtual int GetDelay (unsigned int i) const
  Returns the delay for the i-th frame in milliseconds.
- virtual wxImage GetFrame (unsigned int i) const
  Returns the i-th frame as a wxImage.
- virtual unsigned int GetFrameCount () const
  Returns the number of frames for this animation.
- virtual wxSize GetSize () const
  Returns the size of the animation.
- virtual bool IsOk () const
  Returns true if animation data is present.
- virtual bool Load (wxInputStream &stream, wxAnimationType type=wxANIMATION_TYPE_ANY)
  Loads an animation from the given stream.
- virtual bool LoadFile (const wxString &name, wxAnimationType type=wxANIMATION_TYPE_ANY)
  Loads an animation from a file.
- wxAnimation & operator= (const wxAnimation &brush)
  Assignment operator, using reference counting.

Additional Inherited Members

21.18.2 Constructor & Destructor Documentation

wxAnimation::wxAnimation ( )

Default ctor.

wxAnimation::wxAnimation (const wxAnimation & *anim*)

Copy ctor.

wxAnimation::wxAnimation (const wxString & *name*, wxAnimationType *type* = wxANIMATION_TYPE_ANY)

Loads an animation from a file.

Parameters

name	The name of the file to load.
type	See LoadFile() for more info.

virtual wxAnimation::~wxAnimation ( ) [virtual]

Destructor.

See Object Destruction for more info.

21.18.3 Member Function Documentation

virtual int wxAnimation::GetDelay (unsigned int *i*) const [virtual]

Returns the delay for the i-th frame in milliseconds.

If `-1` is returned the frame is to be displayed forever.

virtual wxImage wxAnimation::GetFrame (unsigned int *i*) const [virtual]

Returns the i-th frame as a wxImage.

This method is not implemented in the native wxGTK implementation of this class and always returns an invalid image there.

virtual unsigned int wxAnimation::GetFrameCount ( ) const [virtual]

Returns the number of frames for this animation.

This method is not implemented in the native wxGTK implementation of this class and always returns 0 there.

virtual wxSize wxAnimation::GetSize ( ) const [virtual]

Returns the size of the animation.

virtual bool wxAnimation::IsOk ( ) const [virtual]

Returns true if animation data is present.

virtual bool wxAnimation::Load (wxInputStream & *stream*, wxAnimationType *type* = wxANIMATION_TYPE_ANY) [virtual]

Loads an animation from the given stream.

Parameters

stream	The stream to use to load the animation. Under wxGTK may be any kind of stream; under other platforms this must be a seekable stream.
type	One of the wxAnimationType enumeration values.

Returns

true if the operation succeeded, false otherwise.

virtual bool wxAnimation::LoadFile (const wxString & *name,* wxAnimationType *type* = wxANIMATION_TYPE_ANY) `[virtual]`

Loads an animation from a file.

Parameters

name	A filename.
type	One of the wxAnimationType values; wxANIMATION_TYPE_ANY means that the function should try to autodetect the filetype.

Returns

true if the operation succeeded, false otherwise.

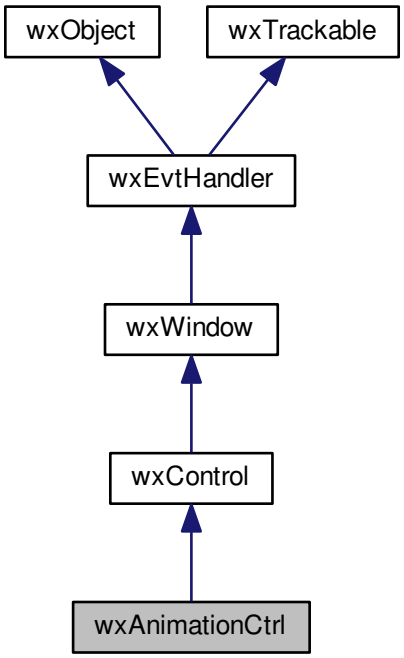
wxAnimation& wxAnimation::operator= (const wxAnimation & *brush*)

Assignment operator, using reference counting.

21.19 wxAnimationCtrl Class Reference

`#include <wx/animate.h>`

Inheritance diagram for wxAnimationCtrl:



21.19.1 Detailed Description

This is a static control which displays an animation.

wxAnimationCtrl API is as simple as possible and won't give you full control on the animation; if you need it then use wxMediaCtrl.

This control is useful to display a (small) animation while doing a long task (e.g. a "throbber").

It is only available if `wxUSE_ANIMATIONCTRL` is set to 1 (the default).

Styles

This class supports the following styles:

- wxAC_DEFAULT_STYLE: The default style: wxBORDER_NONE.
- wxAC_NO_AUTORESIZE: By default, the control will adjust its size to exactly fit to the size of the animation when SetAnimation is called. If this style flag is given, the control will not change its size

Library: wxAdvanced

Category: Controls

Implementations: native under wxGTK, wxMSW ports; a generic implementation is used elsewhere.

See also

wxAnimation, Animation Sample

Public Member Functions

- wxAnimationCtrl (wxWindow *parent, wxWindowID id, const wxAnimation &anim=wxNullAnimation, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, long style=wxAC_DEFAULT_STYLE, const wxString &name=wxAnimationCtrlNameStr)

  Initializes the object and calls Create() with all the parameters.
- bool Create (wxWindow *parent, wxWindowID id, const wxAnimation &anim=wxNullAnimation, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, long style=wxAC_DEFAULT_STYLE, const wxString &name=wxAnimationCtrlNameStr)

  Creates the control with the given anim animation.
- virtual wxAnimation GetAnimation () const

  Returns the animation associated with this control.
- wxBitmap GetInactiveBitmap () const

  Returns the inactive bitmap shown in this control when the; see SetInactiveBitmap() for more info.
- virtual bool IsPlaying () const

  Returns true if the animation is being played.
- virtual bool LoadFile (const wxString &file, wxAnimationType animType=wxANIMATION_TYPE_ANY)

  Loads the animation from the given file and calls SetAnimation().
- virtual bool Load (wxInputStream &file, wxAnimationType animType=wxANIMATION_TYPE_ANY)

  Loads the animation from the given stream and calls SetAnimation().
- virtual bool Play ()

  Starts playing the animation.
- virtual void SetAnimation (const wxAnimation &anim)

  Sets the animation to play in this control.
- virtual void SetInactiveBitmap (const wxBitmap &bmp)

  Sets the bitmap to show on the control when it's not playing an animation.
- virtual void Stop ()

  Stops playing the animation.

Additional Inherited Members

21.19.2 Constructor & Destructor Documentation

wxAnimationCtrl::wxAnimationCtrl (wxWindow * *parent*, wxWindowID *id*, const wxAnimation & *anim* = wxNullAnimation, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, long *style* = wxAC_DEFAULT_STYLE, const wxString & *name* = `wxAnimationCtrlNameStr`)

Initializes the object and calls Create() with all the parameters.

21.19.3 Member Function Documentation

bool wxAnimationCtrl::Create (wxWindow * *parent*, wxWindowID *id*, const wxAnimation & *anim* = wxNullAnimation, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, long *style* = wxAC_DEFAULT_STYLE, const wxString & *name* = `wxAnimationCtrlNameStr`)

Creates the control with the given *anim* animation.

After control creation you must explicitly call Play() to start to play the animation. Until that function won't be called, the first frame of the animation is displayed.

Parameters

parent	Parent window, must be non-NULL.
id	The identifier for the control.
anim	The initial animation shown in the control.
pos	Initial position.
size	Initial size.
style	The window style, see wxAC_∗ flags.
name	Control name.

Returns

true if the control was successfully created or false if creation failed.

virtual wxAnimation wxAnimationCtrl::GetAnimation ( ) const [virtual]

Returns the animation associated with this control.

wxBitmap wxAnimationCtrl::GetInactiveBitmap ( ) const

Returns the inactive bitmap shown in this control when the; see SetInactiveBitmap() for more info.

virtual bool wxAnimationCtrl::IsPlaying ( ) const [virtual]

Returns true if the animation is being played.

virtual bool wxAnimationCtrl::Load (wxInputStream & *file*, wxAnimationType *animType* = wxANIMATION_TYPE_ANY) [virtual]

Loads the animation from the given stream and calls SetAnimation().

See wxAnimation::Load() for more info.

virtual bool wxAnimationCtrl::LoadFile (const wxString & *file*, wxAnimationType *animType* = wxANIMATION_TYPE_ANY) [virtual]

Loads the animation from the given file and calls SetAnimation().

See wxAnimation::LoadFile for more info.

virtual bool wxAnimationCtrl::Play ( ) [virtual]

Starts playing the animation.

The animation is always played in loop mode (unless the last frame of the animation has an infinite delay time) and always start from the first frame even if you stopped it while some other frame was displayed.

virtual void wxAnimationCtrl::SetAnimation (const wxAnimation & *anim*) [virtual]

Sets the animation to play in this control.

If the previous animation is being played, it's Stop() stopped. Until Play() isn't called, a static image, the first frame of the given animation or the background colour will be shown (see SetInactiveBitmap() for more info).

virtual void wxAnimationCtrl::SetInactiveBitmap (const wxBitmap & *bmp*) `[virtual]`

Sets the bitmap to show on the control when it's not playing an animation.

If you set as inactive bitmap wxNullBitmap (which is the default), then the first frame of the animation is instead shown when the control is inactive; in this case, if there's no valid animation associated with the control (see SetAnimation()), then the background colour of the window is shown.

If the control is not playing the animation, the given bitmap will be immediately shown, otherwise it will be shown as soon as Stop() is called.

Note that the inactive bitmap, if smaller than the control's size, will be centered in the control; if bigger, it will be stretched to fit it.

virtual void wxAnimationCtrl::Stop ( ) `[virtual]`

Stops playing the animation.

The control will show the first frame of the animation, a custom static image or the window's background colour as specified by the last SetInactiveBitmap() call.

21.20 wxAny Class Reference

`#include <wx/any.h>`

21.20.1 Detailed Description

The wxAny class represents a container for any type.

Its value can be changed at run time, possibly to a different type of value.

wxAny is a backwards-incompatible (but convertible) successor class for wxVariant, essentially doing the same thing in a more modern, template- based manner and with transparent support for any user data type.

Some pseudo-code'ish example of use with arbitrary user data:

```
void SomeFunction()
{
    MyClass myObject;
    wxAny any = myObject;

    // Do something
    // ...

    // Let's do a sanity check to make sure that any still holds
    // data of correct type.
    if ( any.CheckType<MyClass>() )
    {
        // Thank goodness, still a correct type.
        MyClass myObject2 = any.As<MyClass>();
    }
    else
    {
        // Something has gone horribly wrong!
        wxFAIL();
    }
}
```

When compared to wxVariant, there are various internal implementation differences as well. For instance, wxAny only allocates separate data object in heap for large objects (i.e. ones with size more than WX_ANY_VALUE_BUFFER_SIZE, which at the time of writing is 16 bytes).

Note

When performing conversions between strings and floating point numbers, the representation of numbers in C locale is always used. I.e.

```
wxAny("1.23").GetAs<double>()
```

will always work, even if the current locale uses comma as decimal separator.

21.20.2 Constructor & Destructor Documentation

wxAny::wxAny ( )

Default constructor.

It seeds the object with a null value.

template<typename T > wxAny::wxAny (const T & *value*)

Constructs wxAny from data.

wxAny::wxAny (const wxAny & *any*)

Constructs wxAny from another wxAny.

wxAny::wxAny (const wxVariant & *variant*)

Constructs wxAny, converting value from wxVariant.

Remarks

Because of this conversion, it is not usually possible to have wxAny that actually holds a wxVariant. If wxVariant cannot be converted to a specific data type, wxAny will then hold and manage reference to wxVariantData* similar to how wxVariant does.

wxAny::~wxAny ( )

Destructor.

21.20.3 Member Function Documentation

template<typename T > T wxAny::As ( ) const

This template function converts wxAny into given type.

In most cases no type conversion is performed, so if the type is incorrect an assertion failure will occur.

Remarks

For convenience, conversion is done when T is wxString. This is useful when a string literal (which are treated as const char* and const wchar_t*) has been assigned to wxAny.

template<typename T > bool wxAny::CheckType ( ) const

Use this template function for checking if this wxAny holds a specific C++ data type.

See also

wxAnyValueType::CheckType()

template<typename T > bool wxAny::GetAs (T * *value*) const

Template function that retrieves and converts the value of this wxAny to the type that T* value is.

Returns

Returns true if conversion was successful.

bool wxAny::GetAs (wxVariant * *value*) const

Specialization of GetAs() that allows conversion of wxAny into wxVariant.

Returns

Returns true if conversion was successful. Conversion usually only fails if variant used custom wxVariantData that did not implement the wxAny to wxVariant conversion functions.

const wxAnyValueType* wxAny::GetType ( ) const

Returns the value type as wxAnyValueType instance.

Remarks

You cannot reliably test whether two wxAnys are of same value type by simply comparing return values of wxAny::GetType(). Instead, use wxAny::HasSameType().

See also

HasSameType()

bool wxAny::HasSameType (const wxAny & *other*) const

Returns true if this and another wxAny have the same value type.

bool wxAny::IsNull ( ) const

Tests if wxAny is null (that is, whether there is no data).

void wxAny::MakeNull ( )

Makes wxAny null (that is, clears it).

bool wxAny::operator!= (signed char *value*) const

bool wxAny::operator!= (signed short *value*) const

bool wxAny::operator!= (signed int *value*) const

bool wxAny::operator!= (signed long *value*) const

bool wxAny::operator!= (wxLongLong_t *value*) const

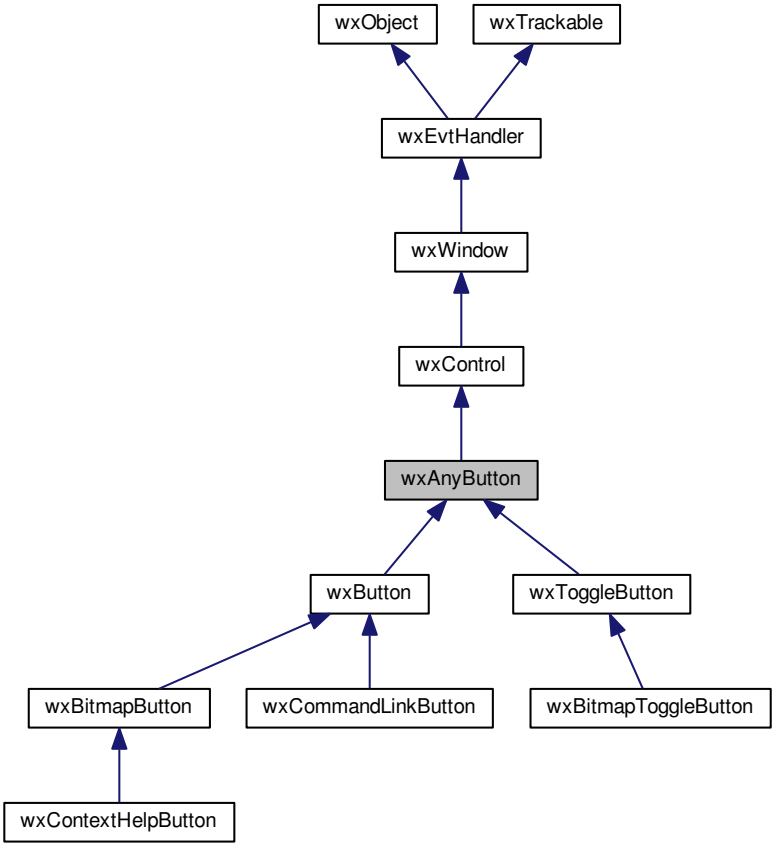
21.21 wxAnyButton Class Reference

#include <wx/anybutton.h>

Inheritance diagram for wxAnyButton:



21.21.1 Detailed Description

A class for common button functionality used as the base for the various button classes.

Public Member Functions

- wxAnyButton ()
- ~wxAnyButton ()
- wxBitmap GetBitmap () const

  Return the bitmap shown by the button.
- wxBitmap GetBitmapCurrent () const

  Returns the bitmap used when the mouse is over the button, which may be invalid.
- wxBitmap GetBitmapDisabled () const

  Returns the bitmap for the disabled state, which may be invalid.
- wxBitmap GetBitmapFocus () const

  Returns the bitmap for the focused state, which may be invalid.
- wxBitmap GetBitmapLabel () const

  Returns the bitmap for the normal state.
- wxBitmap GetBitmapPressed () const

Returns the bitmap for the pressed state, which may be invalid.

- void SetBitmap (const wxBitmap &bitmap, wxDirection dir=wxLEFT)

  Sets the bitmap to display in the button.
- void SetBitmapCurrent (const wxBitmap &bitmap)

  Sets the bitmap to be shown when the mouse is over the button.
- void SetBitmapDisabled (const wxBitmap &bitmap)

  Sets the bitmap for the disabled button appearance.
- void SetBitmapFocus (const wxBitmap &bitmap)

  Sets the bitmap for the button appearance when it has the keyboard focus.
- void SetBitmapLabel (const wxBitmap &bitmap)

  Sets the bitmap label for the button.
- void SetBitmapPressed (const wxBitmap &bitmap)

  Sets the bitmap for the selected (depressed) button appearance.
- wxSize GetBitmapMargins ()

  Get the margins between the bitmap and the text of the button.
- void SetBitmapPosition (wxDirection dir)

  Set the position at which the bitmap is displayed.

- void SetBitmapMargins (wxCoord x, wxCoord y)

  Set the margins between the bitmap and the text of the button.
- void SetBitmapMargins (const wxSize &sz)

  Set the margins between the bitmap and the text of the button.

Additional Inherited Members

21.21.2 Constructor & Destructor Documentation

wxAnyButton::wxAnyButton ( )

wxAnyButton::~wxAnyButton ( )

21.21.3 Member Function Documentation

wxBitmap wxAnyButton::GetBitmap ( ) const

Return the bitmap shown by the button.

The returned bitmap may be invalid only if the button doesn't show any images.

See also

SetBitmap()

Since

2.9.1

wxBitmap wxAnyButton::GetBitmapCurrent ( ) const

Returns the bitmap used when the mouse is over the button, which may be invalid.

See also

SetBitmapCurrent()

Since

2.9.1 (available as wxBitmapButton::GetBitmapHover() in previous versions)

wxBitmap wxAnyButton::GetBitmapDisabled ( ) const

Returns the bitmap for the disabled state, which may be invalid.

See also

SetBitmapDisabled()

Since

2.9.1 (available in wxBitmapButton only in previous versions)

wxBitmap wxAnyButton::GetBitmapFocus ( ) const

Returns the bitmap for the focused state, which may be invalid.

See also

SetBitmapFocus()

Since

2.9.1 (available in wxBitmapButton only in previous versions)

wxBitmap wxAnyButton::GetBitmapLabel ( ) const

Returns the bitmap for the normal state.

This is exactly the same as GetBitmap() but uses a name backwards-compatible with wxBitmapButton.

See also

SetBitmap(), SetBitmapLabel()

Since

2.9.1 (available in wxBitmapButton only in previous versions)

wxSize wxAnyButton::GetBitmapMargins ( )

Get the margins between the bitmap and the text of the button.

See also

SetBitmapMargins()

Since

2.9.1

wxBitmap wxAnyButton::GetBitmapPressed ( ) const

Returns the bitmap for the pressed state, which may be invalid.

See also

SetBitmapPressed()

Since

2.9.1 (available as wxBitmapButton::GetBitmapSelected() in previous versions)

void wxAnyButton::SetBitmap (const wxBitmap & *bitmap*, wxDirection *dir* = wxLEFT)

Sets the bitmap to display in the button.

The bitmap is displayed together with the button label. This method sets up a single bitmap which is used in all button states, use SetBitmapDisabled(), SetBitmapPressed(), SetBitmapCurrent() or SetBitmapFocus() to change the individual images used in different states.

Parameters

bitmap	The bitmap to display in the button. If the bitmap is invalid, any currently shown bitmaps are removed from the button.
dir	The position of the bitmap inside the button. By default it is positioned to the left of the text, near to the left button border. Other possible values include wxRIGHT, wxTOP and wxBOTTOM.

See also

SetBitmapPosition(), SetBitmapMargins()

Since

2.9.1

void wxAnyButton::SetBitmapCurrent (const wxBitmap & *bitmap*)

Sets the bitmap to be shown when the mouse is over the button.

If *bitmap* is invalid, the normal bitmap will be used in the current state.

See also

GetBitmapCurrent()

Since

2.9.1 (available as wxBitmapButton::SetBitmapHover() in previous versions)

void wxAnyButton::SetBitmapDisabled (const wxBitmap & *bitmap*)

Sets the bitmap for the disabled button appearance.

If *bitmap* is invalid, the disabled bitmap is set to the automatically generated greyed out version of the normal bitmap, i.e. the same bitmap as is used by default if this method is not called at all. Use SetBitmap() with an invalid bitmap to remove the bitmap completely (for all states).

See also

GetBitmapDisabled(), SetBitmapLabel(), SetBitmapPressed(), SetBitmapFocus()

Since

2.9.1 (available in wxBitmapButton only in previous versions)

void wxAnyButton::SetBitmapFocus (const wxBitmap & *bitmap*)

Sets the bitmap for the button appearance when it has the keyboard focus.

If *bitmap* is invalid, the normal bitmap will be used in the focused state.

See also

GetBitmapFocus(), SetBitmapLabel(), SetBitmapPressed(), SetBitmapDisabled()

Since

2.9.1 (available in wxBitmapButton only in previous versions)

void wxAnyButton::SetBitmapLabel (const wxBitmap & *bitmap*)

Sets the bitmap label for the button.

Remarks

This is the bitmap used for the unselected state, and for all other states if no other bitmaps are provided.

See also

SetBitmap(), GetBitmapLabel()

Since

2.9.1 (available in wxBitmapButton only in previous versions)

void wxAnyButton::SetBitmapMargins (wxCoord *x*, wxCoord *y*)

Set the margins between the bitmap and the text of the button.

This method is currently only implemented under MSW. If it is not called, default margin is used around the bitmap.

See also

SetBitmap(), SetBitmapPosition()

Since

2.9.1

void wxAnyButton::SetBitmapMargins (const wxSize & *sz*)

Set the margins between the bitmap and the text of the button.

This method is currently only implemented under MSW. If it is not called, default margin is used around the bitmap.

See also

SetBitmap(), SetBitmapPosition()

Since

2.9.1

void wxAnyButton::SetBitmapPosition (wxDirection *dir*)

Set the position at which the bitmap is displayed.

This method should only be called if the button does have an associated bitmap.

Since

2.9.1

Parameters

dir	Direction in which the bitmap should be positioned, one of wxLEFT, wxRIGHT, wxTOP or wxBOTTOM.

void wxAnyButton::SetBitmapPressed (const wxBitmap & *bitmap*)

Sets the bitmap for the selected (depressed) button appearance.

Since

2.9.1 (available as wxBitmapButton::SetBitmapSelected() in previous versions)

21.22 wxAnyValueBuffer Union Reference

`#include <wx/any.h>`

21.22.1 Detailed Description

Type for buffer within wxAny for holding data.

Public Attributes

- void * m_ptr
- wxByte m_buffer [WX_ANY_VALUE_BUFFER_SIZE]

21.22.2 Member Data Documentation

wxByte wxAnyValueBuffer::m_buffer[WX_ANY_VALUE_BUFFER_SIZE]

void* wxAnyValueBuffer::m_ptr

21.23 wxAnyValueType Class Reference

`#include <wx/any.h>`

21.23.1 Detailed Description

wxAnyValueType is base class for value type functionality for C++ data types used with wxAny.

Usually the default template will create a satisfactory wxAnyValueType implementation for a data type, but sometimes you may need to add some customization. To do this you will need to add specialized template of wxAnyValueTypeImpl<>. Often your only need may be to add dynamic type conversion which would be done like this:

```
template<>
class wxAnyValueTypeImpl<MyClass> :
    public wxAnyValueTypeImplBase<MyClass>
{
    WX_DECLARE_ANY_VALUE_TYPE(wxAnyValueTypeImpl<MyClass>)
public:
    wxAnyValueTypeImpl() :
        wxAnyValueTypeImplBase<MyClass>() { }
    virtual ~wxAnyValueTypeImpl() { }

    virtual bool ConvertValue(const wxAnyValueBuffer& src,
                              wxAnyValueType* dstType,
                              wxAnyValueBuffer& dst) const
    {
        // GetValue() is a static member function implemented
        // in wxAnyValueTypeImplBase<>.
        MyClass value = GetValue(src);

        // TODO: Convert value from src buffer to destination
        //       type and buffer. If cannot be done, return
        //       false. This is a simple sample.
        if ( dstType->CheckType<wxString>() )
        {
            wxString s = value.ToString();
            wxAnyValueTypeImpl<wxString>::SetValue(s, dst);
        }
        else
        {
            return false;
        }
    }
};

//
// Following must be placed somewhere in your source code
WX_IMPLEMENT_ANY_VALUE_TYPE(wxAnyValueTypeImpl<MyClass>)
```

wxAnyValueTypeImplBase<> template, from which we inherit in the above example, contains the bulk of the default wxAnyValueTypeImpl<> template implementation, and as such allows you to easily add some minor customization.

If you need a have complete control over the type interpretation, you will need to derive a class directly from wxAnyValueType, like this:

```
template <>
class wxAnyValueTypeImpl<MyClass> : public wxAnyValueType
{
    WX_DECLARE_ANY_VALUE_TYPE(wxAnyValueTypeImpl<MyClass>)
public:
    virtual void DeleteValue(wxAnyValueBuffer& buf) const
    {
        // TODO: Free the data in buffer
        // It is important to clear the buffer like this
        // at the end of DeleteValue().
```

```
        buf.m_ptr = NULL;
    }

    virtual void CopyBuffer(const wxAnyValueBuffer& src,
                            wxAnyValueBuffer& dst) const
    {
        // TODO: Copy value from one buffer to another.
        //       dst is already uninitialized and does not
        //       need to be freed.
    }

    virtual bool ConvertValue(const wxAnyValueBuffer& src,
                              wxAnyValueType* dstType,
                              wxAnyValueBuffer& dst) const
    {
        // TODO: Convert value from src buffer to destination
        //       type and buffer.
    }

    //
    // Following static functions must be implemented
    //

    static void SetValue(const T& value,
                         wxAnyValueBuffer& buf)
    {
        // TODO: Store value into buf.
    }

    static const T& GetValue(const wxAnyValueBuffer& buf)
    {
        // TODO: Return reference to value stored in buffer.
    }
};

//
// Following must be placed somewhere in your source code
WX_IMPLEMENT_ANY_VALUE_TYPE(wxAnyValueTypeImpl<MyClass>)
```

Public Member Functions

- wxAnyValueType ()

  Default constructor.
- virtual ~wxAnyValueType ()

  Destructor.
- template<typename T >
  bool CheckType () const

  Use this template function for checking if wxAnyValueType represents a specific C++ data type.
- virtual bool ConvertValue (const wxAnyValueBuffer &src, wxAnyValueType *dstType, wxAnyValueBuffer &dst) const =0

  Convert value into buffer of different type.
- virtual void CopyBuffer (const wxAnyValueBuffer &src, wxAnyValueBuffer &dst) const =0

  Implement this for buffer-to-buffer copy.
- virtual void DeleteValue (wxAnyValueBuffer &buf) const =0

  This function is called every time the data in wxAny buffer needs to be freed.
- virtual bool IsSameType (const wxAnyValueType *otherType) const =0

  This function is used for internal type matching.

21.23.2 Constructor & Destructor Documentation

wxAnyValueType::wxAnyValueType ( )

Default constructor.

virtual wxAnyValueType::~wxAnyValueType ( ) [virtual]

Destructor.

21.23.3 Member Function Documentation

template<typename T > bool wxAnyValueType::CheckType ( ) const

Use this template function for checking if wxAnyValueType represents a specific C++ data type.

See also

wxAny::CheckType()

virtual bool wxAnyValueType::ConvertValue (const wxAnyValueBuffer & *src*, wxAnyValueType * *dstType*, wxAnyValueBuffer & *dst*) const [pure virtual]

Convert value into buffer of different type.

Return false if not possible.

virtual void wxAnyValueType::CopyBuffer (const wxAnyValueBuffer & *src*, wxAnyValueBuffer & *dst*) const [pure virtual]

Implement this for buffer-to-buffer copy.

Parameters

src	This is the source data buffer.
dst	This is the destination data buffer that is in either uninitialized or freed state.

virtual void wxAnyValueType::DeleteValue (wxAnyValueBuffer & *buf*) const [pure virtual]

This function is called every time the data in wxAny buffer needs to be freed.

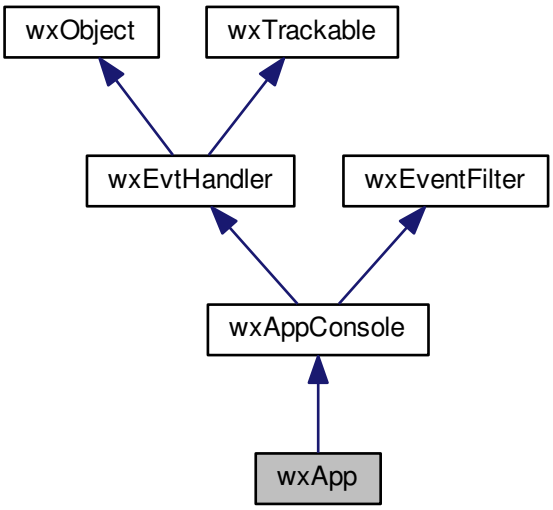
virtual bool wxAnyValueType::IsSameType (const wxAnyValueType * *otherType*) const [pure virtual]

This function is used for internal type matching.

21.24 wxApp Class Reference

```
#include <wx/app.h>
```

Inheritance diagram for wxApp:



21.24.1 Detailed Description

The wxApp class represents the application itself when `wxUSE_GUI=1`.

In addition to the features provided by wxAppConsole it keeps track of the *top window* (see SetTopWindow()) and adds support for video modes (see SetVideoMode()).

In general, application-wide settings for GUI-only apps are accessible from wxApp (or from wxSystemSettings or wxSystemOptions classes).

Events emitted by this class

Event macros for events emitted by this class:

- EVT_QUERY_END_SESSION(func): Process a query end session event, supplying the member function. See wxCloseEvent.
- EVT_END_SESSION(func): Process an end session event, supplying the member function. See wxCloseEvent.
- EVT_ACTIVATE_APP(func): Process a `wxEVT_ACTIVATE_APP` event. See wxActivateEvent.
- EVT_HIBERNATE(func): Process a hibernate event. See wxActivateEvent.
- EVT_DIALUP_CONNECTED(func): A connection with the network was established. See wxDialUpEvent.
- EVT_DIALUP_DISCONNECTED(func): The connection with the network was lost. See wxDialUpEvent.
- EVT_IDLE(func): Process a `wxEVT_IDLE` event. See wxIdleEvent.

Library: wxBase

Category: Application and Process Management

See also

wxApp Overview, wxAppTraits, wxEventLoopBase, wxSystemSettings

Public Member Functions

- wxApp ()

  Constructor.
- virtual ~wxApp ()

  Destructor.
- virtual wxVideoMode GetDisplayMode () const

  Get display mode that is used use.
- bool GetExitOnFrameDelete () const

  Returns true if the application will exit when the top-level frame is deleted.
- virtual wxLayoutDirection GetLayoutDirection () const

  Return the layout direction for the current locale or `wxLayout_Default` if it's unknown.
- bool GetUseBestVisual () const

  Returns true if the application will use the best visual on systems that support different visuals, false otherwise.
- virtual wxWindow * GetTopWindow () const

  Returns a pointer to the top window.
- virtual bool IsActive () const

  Returns true if the application is active, i.e. if one of its windows is currently in the foreground.
- virtual bool SafeYield (wxWindow *win, bool onlyIfNeeded)

  This function is similar to wxYield(), except that it disables the user input to all program windows before calling wxAppConsole::Yield and re-enables it again afterwards.
- virtual bool SafeYieldFor (wxWindow *win, long eventsToProcess)

  Works like SafeYield() with onlyIfNeeded == true except that it allows the caller to specify a mask of events to be processed.
- bool ProcessMessage (WXMSG *msg)

  Windows-only function for processing a message.
- virtual bool SetDisplayMode (const wxVideoMode &info)

  Set display mode to use.
- void SetExitOnFrameDelete (bool flag)

  Allows the programmer to specify whether the application will exit when the top-level frame is deleted.
- virtual bool SetNativeTheme (const wxString &theme)

  Allows runtime switching of the UI environment theme.
- void SetTopWindow (wxWindow *window)

  Sets the 'top' window.
- void SetUseBestVisual (bool flag, bool forceTrueColour=false)

  Allows the programmer to specify whether the application will use the best visual on systems that support several visual on the same display.

Mac-specific functions

- virtual void MacNewFile ()

  Called in response of an "open-application" Apple event.
- virtual void MacOpenFiles (const wxArrayString &fileNames)

  Called in response of an openFiles message with Cocoa, or an "open-document" Apple event with Carbon.

- virtual void MacOpenFile (const wxString &fileName)
  Called in response of an "open-document" Apple event.
- virtual void MacOpenURL (const wxString &url)
  Called in response of a "get-url" Apple event.
- virtual void MacPrintFile (const wxString &fileName)
  Called in response of a "print-document" Apple event.
- virtual void MacReopenApp ()
  Called in response of a "reopen-application" Apple event.
- virtual bool OSXIsGUIApplication ()
  May be overridden to indicate that the application is not a foreground GUI application under OS X.

Additional Inherited Members

21.24.2 Constructor & Destructor Documentation

wxApp::wxApp ( )

Constructor.

Called implicitly with a definition of a wxApp object.

virtual wxApp::~wxApp ( ) [virtual]

Destructor.

Will be called implicitly on program exit if the wxApp object is created on the stack.

21.24.3 Member Function Documentation

virtual wxVideoMode wxApp::GetDisplayMode ( ) const [virtual]

Get display mode that is used use.

This is only used in framebuffer wxWidgets ports such as wxDFB.

bool wxApp::GetExitOnFrameDelete ( ) const

Returns true if the application will exit when the top-level frame is deleted.

See also

SetExitOnFrameDelete()

virtual wxLayoutDirection wxApp::GetLayoutDirection ( ) const [virtual]

Return the layout direction for the current locale or `wxLayout_Default` if it's unknown.

virtual wxWindow* wxApp::GetTopWindow ( ) const [virtual]

Returns a pointer to the top window.

Remarks

If the top window hasn't been set using SetTopWindow(), this function will find the first top-level window (frame or dialog or instance of wxTopLevelWindow) from the internal top level window list and return that.

See also

SetTopWindow()

bool wxApp::GetUseBestVisual ( ) const

Returns true if the application will use the best visual on systems that support different visuals, false otherwise.

See also

SetUseBestVisual()

virtual bool wxApp::IsActive ( ) const `[virtual]`

Returns true if the application is active, i.e. if one of its windows is currently in the foreground.

If this function returns false and you need to attract users attention to the application, you may use wxTopLevelWindow::RequestUserAttention to do it.

virtual void wxApp::MacNewFile ( ) `[virtual]`

Called in response of an "open-application" Apple event.

Override this to create a new document in your app.

Availability: only available for the wxOSX port.

virtual void wxApp::MacOpenFile (const wxString & *fileName*) `[virtual]`

Called in response of an "open-document" Apple event.

Deprecated This function is kept mostly for backwards compatibility. Please override wxApp::MacOpenFiles method instead in any new code.

Availability: only available for the wxOSX port.

virtual void wxApp::MacOpenFiles (const wxArrayString & *fileNames*) `[virtual]`

Called in response of an openFiles message with Cocoa, or an "open-document" Apple event with Carbon.

You need to override this method in order to open one or more document files after the user double clicked on it or if the files and/or folders were dropped on either the application in the dock or the application icon in Finder.

By default this method calls MacOpenFile for each file/folder.

Availability: only available for the wxOSX port.

Since

2.9.3

virtual void wxApp::MacOpenURL (const wxString & *url*) `[virtual]`

Called in response of a "get-url" Apple event.

Availability: only available for the wxOSX port.

virtual void wxApp::MacPrintFile (const wxString & *fileName*) [virtual]

Called in response of a "print-document" Apple event.

Availability: only available for the wxOSX port.

virtual void wxApp::MacReopenApp ( ) [virtual]

Called in response of a "reopen-application" Apple event.

Availability: only available for the wxOSX port.

virtual bool wxApp::OSXIsGUIApplication ( ) [virtual]

May be overridden to indicate that the application is not a foreground GUI application under OS X.

This method is called during the application startup and returns true by default. In this case, wxWidgets ensures that the application is ran as a foreground, GUI application so that the user can interact with it normally, even if it is not bundled. If this is undesired, i.e. if the application doesn't need to be brought to the foreground, this method can be overridden to return false.

Notice that overriding it doesn't make any difference for the bundled applications which are always foreground unless `LSBackgroundOnly` key is specified in the `Info.plist` file.

Availability: only available for the wxOSX port.

Since

3.0.1

bool wxApp::ProcessMessage (WXMSG * *msg*)

Windows-only function for processing a message.

This function is called from the main message loop, checking for windows that may wish to process it.

The function returns true if the message was processed, false otherwise. If you use wxWidgets with another class library with its own message loop, you should make sure that this function is called to allow wxWidgets to receive messages. For example, to allow co-existence with the Microsoft Foundation Classes, override the PreTranslate↩ Message function:

```
// Provide wxWidgets message loop compatibility
BOOL CTheApp::PreTranslateMessage(MSG *msg)
{
    if (wxTheApp && wxTheApp->ProcessMessage((WXMSW *)msg))
        return true;
    else
        return CWinApp::PreTranslateMessage(msg);
}
```

Availability: only available for the wxMSW port.

virtual bool wxApp::SafeYield (wxWindow * *win*, bool *onlyIfNeeded*) [virtual]

This function is similar to wxYield(), except that it disables the user input to all program windows before calling wxAppConsole::Yield and re-enables it again afterwards.

If *win* is not NULL, this window will remain enabled, allowing the implementation of some limited user interaction. Returns the result of the call to wxAppConsole::Yield.

See also

wxSafeYield

virtual bool wxApp::SafeYieldFor (wxWindow * *win*, long *eventsToProcess*) [virtual]

Works like SafeYield() with *onlyIfNeeded* == true except that it allows the caller to specify a mask of events to be processed.

See wxAppConsole::YieldFor for more info.

virtual bool wxApp::SetDisplayMode (const wxVideoMode & *info*) [virtual]

Set display mode to use.

This is only used in framebuffer wxWidgets ports such as wxDFB.

void wxApp::SetExitOnFrameDelete (bool *flag*)

Allows the programmer to specify whether the application will exit when the top-level frame is deleted.

Parameters

flag	If true (the default), the application will exit when the top-level frame is deleted. If false, the application will continue to run.

See also

GetExitOnFrameDelete(), Application Shutdown

virtual bool wxApp::SetNativeTheme (const wxString & *theme*) [virtual]

Allows runtime switching of the UI environment theme.

Currently implemented for wxGTK2-only. Return true if theme was successfully changed.

Parameters

theme	The name of the new theme or an absolute path to a gtkrc-theme-file

void wxApp::SetTopWindow (wxWindow * *window*)

Sets the 'top' window.

You can call this from within OnInit() to let wxWidgets know which is the main window. You don't have to set the top window; it is only a convenience so that (for example) certain dialogs without parents can use a specific window as the top window.

If no top window is specified by the application, wxWidgets just uses the first frame or dialog (or better, any wxTopLevelWindow) in its top-level window list, when it needs to use the top window. If you previously called SetTopWindow() and now you need to restore this automatic behaviour you can call

```
wxApp::SetTopWindow(NULL)
```

.

Parameters

window	The new top window.

See also

GetTopWindow(), OnInit()

void wxApp::SetUseBestVisual (bool *flag,* bool *forceTrueColour* = `false`)

Allows the programmer to specify whether the application will use the best visual on systems that support several visual on the same display.

This is typically the case under Solaris and IRIX, where the default visual is only 8-bit whereas certain applications are supposed to run in TrueColour mode.

Note that this function has to be called in the constructor of the wxApp instance and won't have any effect when called later on. This function currently only has effect under GTK.

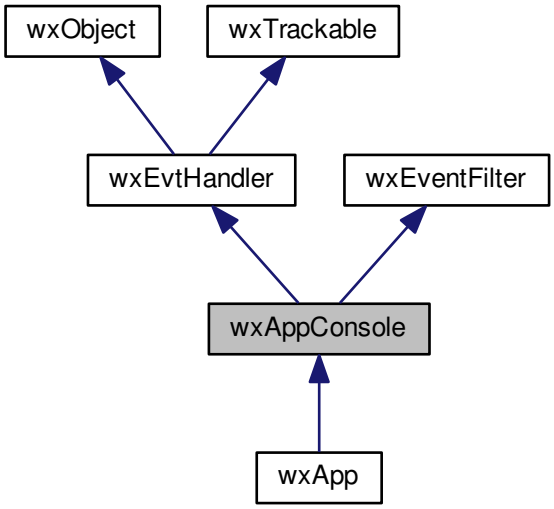
Parameters

flag	If true, the app will use the best visual.
forceTrueColour	If true then the application will try to force using a TrueColour visual and abort the app if none is found.

21.25 wxAppConsole Class Reference

`#include <wx/app.h>`

Inheritance diagram for wxAppConsole:



21.25.1 Detailed Description

This class is essential for writing console-only or hybrid apps without having to define `wxUSE_GUI=0`.

It is used to:

- set and get application-wide properties (see wxAppConsole::CreateTraits and wxAppConsole::SetXXX functions)
- implement the windowing system message or event loop: events in fact are supported even in console-mode applications (see wxAppConsole::HandleEvent and wxAppConsole::ProcessPendingEvents);
- initiate application processing via wxApp::OnInit;
- allow default processing of events not handled by other objects in the application (see wxAppConsole::FilterEvent)
- implement Apple-specific event handlers (see wxAppConsole::MacXXX functions)

You should use the macro wxIMPLEMENT_APP(appClass) in your application implementation file to tell wxWidgets how to create an instance of your application class.

Use wxDECLARE_APP(appClass) in a header file if you want the wxGetApp() function (which returns a reference to your application object) to be visible to other files.

Library: wxBase

Category: Application and Process Management

See also

wxApp Overview, wxApp, wxAppTraits, wxEventLoopBase

Public Member Functions

- virtual ~wxAppConsole ()

  Destructor.
- bool Yield (bool onlyIfNeeded=false)
- void SetCLocale ()

  Sets the C locale to the default locale for the current environment.

Event-handling

Note that you should look at wxEvtLoopBase for more event-processing documentation.

- virtual int MainLoop ()

  Called by wxWidgets on creation of the application.
- virtual void ExitMainLoop ()

  Call this to explicitly exit the main message (event) loop.
- virtual int FilterEvent (wxEvent &event)

  Overridden wxEventFilter method.
- wxEventLoopBase * GetMainLoop () const

  Returns the main event loop instance, i.e. the event loop which is started by OnRun() and which dispatches all events sent from the native toolkit to the application (except when new event loops are temporarily set-up).
- virtual void HandleEvent (wxEvtHandler *handler, wxEventFunction func, wxEvent &event) const

  This function simply invokes the given method func of the specified event handler handler with the event as parameter.
- virtual bool UsesEventLoop () const

  Returns true if the application is using an event loop.

Pending events

Pending events are handled by wxAppConsole rather than wxEventLoopBase to allow queuing of events even when there's no event loop (e.g.

in wxAppConsole::OnInit).

- virtual void ProcessPendingEvents ()

  Process all pending events; it is necessary to call this function to process events posted with wxEvtHandler::QueueEvent or wxEvtHandler::AddPendingEvent.
- void DeletePendingEvents ()

  Deletes the pending events of all wxEvtHandlers of this application.
- bool HasPendingEvents () const

  Returns true if there are pending events on the internal pending event list.
- void SuspendProcessingOfPendingEvents ()

  Temporary suspends processing of the pending events.
- void ResumeProcessingOfPendingEvents ()

  Resume processing of the pending events previously stopped because of a call to SuspendProcessingOfPendingEvents().

- void ScheduleForDestruction (wxObject *object)

  Delayed objects destruction.
- bool IsScheduledForDestruction (wxObject *object) const

  Check if the object had been scheduled for destruction with ScheduleForDestruction().

Callbacks for application-wide "events"

- virtual void OnAssertFailure (const wxChar *file, int line, const wxChar *func, const wxChar *cond, const wxChar *msg)

  This function is called when an assert failure occurs, i.e. the condition specified in wxASSERT() macro evaluated to false.
- virtual bool OnCmdLineError (wxCmdLineParser &parser)

  Called when command line parsing fails (i.e. an incorrect command line option was specified by the user).
- virtual bool OnCmdLineHelp (wxCmdLineParser &parser)

  Called when the help option (`-help`) was specified on the command line.
- virtual bool OnCmdLineParsed (wxCmdLineParser &parser)

  Called after the command line had been successfully parsed.
- virtual void OnEventLoopEnter (wxEventLoopBase *loop)

  Called by wxEventLoopBase::SetActive(): you can override this function and put here the code which needs an active event loop.
- virtual void OnEventLoopExit (wxEventLoopBase *loop)

  Called by wxEventLoopBase::OnExit() for each event loop which is exited.
- virtual int OnExit ()

  Override this member function for any processing which needs to be done as the application is about to exit.
- virtual void OnFatalException ()

  This function may be called if something fatal happens: an unhandled exception under Win32 or a fatal signal under Unix, for example.
- virtual bool OnInit ()

  This must be provided by the application, and will usually create the application's main window, optionally calling SetTopWindow().
- virtual void OnInitCmdLine (wxCmdLineParser &parser)

  Called from OnInit() and may be used to initialize the parser with the command line options for this application.
- virtual int OnRun ()

  This virtual function is where the execution of a program written in wxWidgets starts.

Exceptions support

Methods related to C++ exceptions handling.

See also

overview_exceptions

- virtual bool OnExceptionInMainLoop ()

  This function is called if an unhandled exception occurs inside the main application event loop.
- virtual void OnUnhandledException ()

  This function is called when an unhandled C++ exception occurs in user code called by wxWidgets.
- virtual bool StoreCurrentException ()

  Method to store exceptions not handled by OnExceptionInMainLoop().
- virtual void RethrowStoredException ()

  Method to rethrow exceptions stored by StoreCurrentException().

Application information

- wxString GetAppDisplayName () const

  Returns the user-readable application name.
- wxString GetAppName () const

  Returns the application name.
- wxString GetClassName () const

  Gets the class name of the application.
- wxAppTraits * GetTraits ()

  Returns a pointer to the wxAppTraits object for the application.
- const wxString & GetVendorDisplayName () const

  Returns the user-readable vendor name.
- const wxString & GetVendorName () const

  Returns the application's vendor name.
- void SetAppDisplayName (const wxString &name)

  Set the application name to be used in the user-visible places such as window titles.
- void SetAppName (const wxString &name)

  Sets the name of the application.
- void SetClassName (const wxString &name)

  Sets the class name of the application.
- void SetVendorDisplayName (const wxString &name)

  Set the vendor name to be used in the user-visible places.
- void SetVendorName (const wxString &name)

  Sets the name of application's vendor.

Static Public Member Functions

- static void SetInstance (wxAppConsole *app)

  Allows external code to modify global wxTheApp, but you should really know what you're doing if you call it.
- static wxAppConsole * GetInstance ()

  Returns the one and only global application object.
- static bool IsMainLoopRunning ()

  Returns true if the main event loop is currently running, i.e. if the application is inside OnRun().

Public Attributes

- int argc

  Number of command line arguments (after environment-specific processing).
- wxChar ** argv

  Command line arguments (after environment-specific processing).

Protected Member Functions

- virtual wxAppTraits * CreateTraits ()

  Creates the wxAppTraits object when GetTraits() needs it for the first time.

Additional Inherited Members

21.25.2 Constructor & Destructor Documentation

virtual wxAppConsole::~wxAppConsole ( ) [virtual]

Destructor.

21.25.3 Member Function Documentation

virtual wxAppTraits* wxAppConsole::CreateTraits ( ) [protected], [virtual]

Creates the wxAppTraits object when GetTraits() needs it for the first time.

See also

wxAppTraits

void wxAppConsole::DeletePendingEvents ( )

Deletes the pending events of all wxEvtHandlers of this application.

See wxEvtHandler::DeletePendingEvents() for warnings about deleting the pending events.

virtual void wxAppConsole::ExitMainLoop ( ) [virtual]

Call this to explicitly exit the main message (event) loop.

You should normally exit the main loop (and the application) by deleting the top window.

This function simply calls wxEvtLoopBase::Exit() on the active loop.

virtual int wxAppConsole::FilterEvent (wxEvent & *event*) [virtual]

Overridden wxEventFilter method.

This function is called before processing any event and allows the application to preempt the processing of some events, see wxEventFilter documentation for more information.

wxApp implementation of this method always return -1 indicating that the event should be processed normally.

Implements wxEventFilter.

wxString wxAppConsole::GetAppDisplayName ( ) const

Returns the user-readable application name.

The difference between this string and the one returned by GetAppName() is that this one is meant to be shown to the user and so should be used for the window titles, page headers and so on while the other one should be only used internally, e.g. for the file names or configuration file keys.

If the application name for display had been previously set by SetAppDisplayName(), it will be returned by this function. Otherwise, if SetAppName() had been called its value will be returned; also as is. Finally if none was called, this function returns the program name capitalized using wxString::Capitalize().

Since

2.9.0

wxString wxAppConsole::GetAppName ( ) const

Returns the application name.

If SetAppName() had been called, returns the string passed to it. Otherwise returns the program name, i.e. the value of `argv`[0] passed to the `main()` function.

See also

GetAppDisplayName()

wxString wxAppConsole::GetClassName ( ) const

Gets the class name of the application.

The class name may be used in a platform specific manner to refer to the application.

See also

SetClassName()

static wxAppConsole* wxAppConsole::GetInstance ( ) [static]

Returns the one and only global application object.

Usually wxTheApp is used instead.

See also

SetInstance()

wxEventLoopBase* wxAppConsole::GetMainLoop ( ) const

Returns the main event loop instance, i.e. the event loop which is started by OnRun() and which dispatches all events sent from the native toolkit to the application (except when new event loops are temporarily set-up).

The returned value maybe NULL. Put initialization code which needs a non-NULL main event loop into OnEvent↩LoopEnter().

wxAppTraits* wxAppConsole::GetTraits ( )

Returns a pointer to the wxAppTraits object for the application.

If you want to customize the wxAppTraits object, you must override the CreateTraits() function.

const wxString& wxAppConsole::GetVendorDisplayName ( ) const

Returns the user-readable vendor name.

The difference between this string and the one returned by GetVendorName() is that this one is meant to be shown to the user and so should be used for the window titles, page headers and so on while the other one should be only used internally, e.g. for the file names or configuration file keys.

By default, returns the same string as GetVendorName().

Since

2.9.0

const wxString& wxAppConsole::GetVendorName ( ) const

Returns the application's vendor name.

virtual void wxAppConsole::HandleEvent (wxEvtHandler * *handler,* wxEventFunction *func,* wxEvent & *event*) const `[virtual]`

This function simply invokes the given method *func* of the specified event handler *handler* with the *event* as parameter.

It exists solely to allow to catch the C++ exceptions which could be thrown by all event handlers in the application in one place: if you want to do this, override this function in your wxApp-derived class and add try/catch clause(s) to it.

bool wxAppConsole::HasPendingEvents ( ) const

Returns true if there are pending events on the internal pending event list.

Whenever wxEvtHandler::QueueEvent or wxEvtHandler::AddPendingEvent() are called (not only for wxApp itself, but for any event handler of the application!), the internal wxApp's list of handlers with pending events is updated and this function will return true.

static bool wxAppConsole::IsMainLoopRunning ( ) `[static]`

Returns true if the main event loop is currently running, i.e. if the application is inside OnRun().

This can be useful to test whether events can be dispatched. For example, if this function returns false, non-blocking sockets cannot be used because the events from them would never be processed.

bool wxAppConsole::IsScheduledForDestruction (wxObject * *object*) const

Check if the object had been scheduled for destruction with ScheduleForDestruction().

This function may be useful as an optimization to avoid doing something with an object which will be soon destroyed in any case.

virtual int wxAppConsole::MainLoop ( ) `[virtual]`

Called by wxWidgets on creation of the application.

Override this if you wish to provide your own (environment-dependent) main loop.

Returns

0 under X, and the wParam of the WM_QUIT message under Windows.

virtual void wxAppConsole::OnAssertFailure (const wxChar * *file*, int *line*, const wxChar * *func*, const wxChar * *cond*, const wxChar * *msg*) `[virtual]`

This function is called when an assert failure occurs, i.e. the condition specified in wxASSERT() macro evaluated to false.

It is only called in debug mode (when **WXDEBUG** is defined) as asserts are not left in the release code at all. The base class version shows the default assert failure dialog box proposing to the user to stop the program, continue or ignore all subsequent asserts.

Parameters

file	the name of the source file where the assert occurred
line	the line number in this file where the assert occurred
func	the name of the function where the assert occurred, may be empty if the compiler doesn't support C99 **FUNCTION**
cond	the condition of the failed assert in text form
msg	the message specified as argument to wxASSERT_MSG or wxFAIL_MSG, will be NULL if just wxASSERT or wxFAIL was used

virtual bool wxAppConsole::OnCmdLineError (wxCmdLineParser & *parser*) `[virtual]`

Called when command line parsing fails (i.e. an incorrect command line option was specified by the user).

The default behaviour is to show the program usage text and abort the program.

Return true to continue normal execution or false to return false from OnInit() thus terminating the program.

See also

OnInitCmdLine()

virtual bool wxAppConsole::OnCmdLineHelp (wxCmdLineParser & *parser*) `[virtual]`

Called when the help option (`-help`) was specified on the command line.

The default behaviour is to show the program usage text and abort the program.

Return true to continue normal execution or false to return false from OnInit() thus terminating the program.

See also

OnInitCmdLine()

virtual bool wxAppConsole::OnCmdLineParsed (wxCmdLineParser & *parser*) `[virtual]`

Called after the command line had been successfully parsed.

You may override this method to test for the values of the various parameters which could be set from the command line.

Don't forget to call the base class version unless you want to suppress processing of the standard command line options. Return true to continue normal execution or false to return false from OnInit() thus terminating the program.

See also

OnInitCmdLine()

virtual void wxAppConsole::OnEventLoopEnter (wxEventLoopBase * *loop*) [virtual]

Called by wxEventLoopBase::SetActive(): you can override this function and put here the code which needs an active event loop.

Note that this function is called whenever an event loop is activated; you may want to use wxEventLoopBase::IsMain() to perform initialization specific for the app's main event loop.

See also

OnEventLoopExit()

virtual void wxAppConsole::OnEventLoopExit (wxEventLoopBase * *loop*) [virtual]

Called by wxEventLoopBase::OnExit() for each event loop which is exited.

See also

OnEventLoopEnter()

virtual bool wxAppConsole::OnExceptionInMainLoop ( ) [virtual]

This function is called if an unhandled exception occurs inside the main application event loop.

It can return true to ignore the exception and to continue running the loop or false to exit the loop and terminate the program.

The default behaviour of this function is the latter in all ports except under Windows where a dialog is shown to the user which allows him to choose between the different options. You may override this function in your class to do something more appropriate.

If this method rethrows the exception and if the exception can't be stored for later processing using StoreCurrentException(), the program will terminate after calling OnUnhandledException().

You should consider overriding this method to perform whichever last resort exception handling that would be done in a typical C++ program in a `try/catch` block around the entire `main()` function. As this method is called during exception handling, you may use the C++ `throw` keyword to rethrow the current exception to catch it again and analyze it. For example:

```
class MyApp : public wxApp {
public:
    virtual bool OnExceptionInMainLoop()
    {
        wxString error;
        try {
            throw; // Rethrow the current exception.
        } catch (const MyException& e) {
            error = e.GetMyErrorMessage();
        } catch (const std::exception& e) {
            error = e.what();
        } catch ( ... ) {
            error = "unknown error.";
        }

        wxLogError("Unexpected exception has occurred: %s, the program will terminate.", error);

        // Exit the main loop and thus terminate the program.
        return false;
    }
};
```

virtual int wxAppConsole::OnExit ( ) [virtual]

Override this member function for any processing which needs to be done as the application is about to exit.

OnExit is called after destroying all application windows and controls, but before wxWidgets cleanup. Note that it is not called at all if OnInit() failed.

The return value of this function is currently ignored, return the same value as returned by the base class method if you override it.

virtual void wxAppConsole::OnFatalException ( ) [virtual]

This function may be called if something fatal happens: an unhandled exception under Win32 or a fatal signal under Unix, for example.

However, this will not happen by default: you have to explicitly call wxHandleFatalExceptions() to enable this.

Generally speaking, this function should only show a message to the user and return. You may attempt to save unsaved data but this is not guaranteed to work and, in fact, probably won't.

See also

wxHandleFatalExceptions()

virtual bool wxAppConsole::OnInit ( ) [virtual]

This must be provided by the application, and will usually create the application's main window, optionally calling SetTopWindow().

You may use OnExit() to clean up anything initialized here, provided that the function returns true.

Notice that if you want to use the command line processing provided by wxWidgets you have to call the base class version in the derived class OnInit().

Return true to continue processing, false to exit the application immediately.

virtual void wxAppConsole::OnInitCmdLine (wxCmdLineParser & *parser*) [virtual]

Called from OnInit() and may be used to initialize the parser with the command line options for this application.

The base class versions adds support for a few standard options only.

virtual int wxAppConsole::OnRun ( ) [virtual]

This virtual function is where the execution of a program written in wxWidgets starts.

The default implementation just enters the main loop and starts handling the events until it terminates, either because ExitMainLoop() has been explicitly called or because the last frame has been deleted and GetExitOnFrame↩ Delete() flag is true (this is the default).

The return value of this function becomes the exit code of the program, so it should return 0 in case of successful termination.

virtual void wxAppConsole::OnUnhandledException ( ) [virtual]

This function is called when an unhandled C++ exception occurs in user code called by wxWidgets.

Any unhandled exceptions thrown from (overridden versions of) OnInit() and OnExit() methods as well as any exceptions thrown from inside the main loop and re-thrown by OnUnhandledException() will result in a call to this function.

By the time this function is called, the program is already about to exit and the exception can't be handled nor ignored any more, override OnUnhandledException() or use explicit `try/catch` blocks around OnInit() body to be able to handle the exception earlier.

The default implementation dumps information about the exception using wxMessageOutputBest.

virtual void wxAppConsole::ProcessPendingEvents ( ) [virtual]

Process all pending events; it is necessary to call this function to process events posted with wxEvtHandler::QueueEvent or wxEvtHandler::AddPendingEvent.

This happens during each event loop iteration (see wxEventLoopBase) in GUI mode but it may be also called directly.

Note that this function does not only process the pending events for the wxApp object itself (which derives from wxEvtHandler) but also the pending events for *any* event handler of this application.

This function will immediately return and do nothing if SuspendProcessingOfPendingEvents() was called.

void wxAppConsole::ResumeProcessingOfPendingEvents ( )

Resume processing of the pending events previously stopped because of a call to SuspendProcessingOfPendingEvents().

virtual void wxAppConsole::RethrowStoredException ( ) [virtual]

Method to rethrow exceptions stored by StoreCurrentException().

Note

Just as with StoreCurrentException(), it is usually not necessary to override this method when using C++11.

If StoreCurrentException() is overridden, this function should be overridden as well to rethrow the exceptions stored by it when the control gets back to our code, i.e. when it's safe to do it.

See StoreCurrentException() for an example of implementing this method.

The default version does nothing when using C++98 and uses std::rethrow_exception() in C++11.

Since

3.1.0

void wxAppConsole::ScheduleForDestruction (wxObject * *object*)

Delayed objects destruction.

In applications using events it may be unsafe for an event handler to delete the object which generated the event because more events may be still pending for the same object. In this case the handler may call ScheduleForDestruction() instead. Schedule the object for destruction in the near future.

Notice that if the application is not using an event loop, i.e. if UsesEventLoop() returns false, this method will simply delete the object immediately.

Examples of using this function inside wxWidgets itself include deleting the top level windows when they are closed and sockets when they are disconnected.

void wxAppConsole::SetAppDisplayName (const wxString & *name*)

Set the application name to be used in the user-visible places such as window titles.

See GetAppDisplayName() for more about the differences between the display name and name.

Notice that if this function is called, the name is used as is, without any capitalization as done by default by GetAppDisplayName().

void wxAppConsole::SetAppName (const wxString & *name*)

Sets the name of the application.

This name should be used for file names, configuration file entries and other internal strings. For the user-visible strings, such as the window titles, the application display name set by SetAppDisplayName() is used instead.

By default the application name is set to the name of its executable file.

See also

GetAppName()

void wxAppConsole::SetClassName (const wxString & *name*)

Sets the class name of the application.

This may be used in a platform specific manner to refer to the application.

See also

GetClassName()

void wxAppConsole::SetCLocale ( )

Sets the C locale to the default locale for the current environment.

It is advised to call this to ensure that the underlying toolkit uses the locale in which the numbers and monetary amounts are shown in the format expected by user and so on.

Calling this function is roughly equivalent to calling

```
setlocale(LC_ALL, "");
```

but performs additional toolkit-specific tasks under some platforms and so should be used instead of `setlocale()` itself. Alternatively, you can use wxLocale to change the locale with more control.

Notice that this does *not* change the global C++ locale, you need to do it explicitly if you want, e.g.

```
std::locale::global(std::locale(""));
```

but be warned that locale support in C++ standard library can be poor or worse under some platforms, e.g. the above line results in an immediate crash under OS X up to the version 10.8.2.

Since

2.9.5

static void wxAppConsole::SetInstance (wxAppConsole * *app*) [static]

Allows external code to modify global wxTheApp, but you should really know what you're doing if you call it.

Parameters

app	Replacement for the global application object.

See also

GetInstance()

void wxAppConsole::SetVendorDisplayName (const wxString & *name*)

Set the vendor name to be used in the user-visible places.

See GetVendorDisplayName() for more about the differences between the display name and name.

void wxAppConsole::SetVendorName (const wxString & *name*)

Sets the name of application's vendor.

The name will be used in registry access. A default name is set by wxWidgets.

See also

GetVendorName()

virtual bool wxAppConsole::StoreCurrentException ( ) [virtual]

Method to store exceptions not handled by OnExceptionInMainLoop().

Note

The default implementation of this function when using C++98 compiler just returns false, as there is no generic way to store an arbitrary exception in C++98 and each application must do it on its own for the exceptions it uses in its overridden version. When using C++11, the default implementation uses std::current_exception() and returns true, so it's normally not necessary to override this method when using C++11.

This function can be overridden to store the current exception, in view of rethrowing it later when RethrowStoredException() is called. If the exception was stored, return true. If the exception can't be stored, i.e. if this function returns false, the program will abort after calling OnUnhandledException().

It is necessary to override this function if OnExceptionInMainLoop() doesn't catch all exceptions, but you still want to handle them using explicit `try/catch` statements. Typical use could be to allow code like the following to work:

```
void MyFrame::SomeFunction()
{
    try {
        MyDialog dlg(this);
        dlg.ShowModal();
    } catch ( const MyExpectedException& e ) {
        // Deal with the exceptions thrown from the dialog.
    }
}
```

By default, throwing an exception from an event handler called from the dialog modal event loop would terminate the application as the exception can't be safely propagated to the code in the catch clause because of the presence of the native system functions (through which C++ exceptions can't, generally speaking, propagate) in the call stack between them.

Overriding this method allows the exception to be stored when it is detected and rethrown using RethrowStoredException() when the native system function dispatching the dialog events terminates, with the result that the code above works as expected.

An example of implementing this method:

```
class MyApp : public wxApp {
public:
    virtual bool StoreCurrentException()
    {
        try {
            throw;
        } catch ( const std::runtime_exception& e ) {
            if ( !m_runtimeError.empty() ) {
                // This is not supposed to happen, only one exception,
                // at most, should be stored.
                return false;
            }

            m_runtimeError = e.what();

            // Don't terminate, let our code handle this exception later.
            return true;
        } catch ( ... ) {
            // This could be extended to store information about any
            // other exceptions too, but if we don't store them, we
            // should return false to let the program die.
        }

        return false;
    }

    virtual void RethrowStoredException()
    {
        if ( !m_runtimeError.empty() ) {
            std::runtime_exception e(m_runtimeError);
            m_runtimeError.clear();
            throw e;
        }
    }

private:
    std::string m_runtimeError;
};
```

See also

OnExceptionInMainLoop(), RethrowStoredException()

Since

3.1.0

void wxAppConsole::SuspendProcessingOfPendingEvents ( )

Temporary suspends processing of the pending events.

See also

ResumeProcessingOfPendingEvents()

virtual bool wxAppConsole::UsesEventLoop ( ) const [virtual]

Returns true if the application is using an event loop.

This function always returns true for the GUI applications which must use an event loop but by default only returns true for the console programs if an event loop is already running as it can't know whether one will be created in the future.

Thus, it only makes sense to override it in console applications which do use an event loop, to return true instead of checking if there is a currently active event loop.

bool wxAppConsole::Yield (bool *onlyIfNeeded* = `false`)

21.25.4 Member Data Documentation

int wxAppConsole::argc

Number of command line arguments (after environment-specific processing).

wxChar∗∗ wxAppConsole::argv

Command line arguments (after environment-specific processing).

Under Windows and Linux/Unix, you should parse the command line arguments and check for files to be opened when starting your application. Under OS X, you need to override MacOpenFiles() since command line arguments are used differently there.

You may use the wxCmdLineParser to parse command line arguments.

21.26 wxAppProgressIndicator Class Reference

`#include <wx/appprogress.h>`

21.26.1 Detailed Description

A helper class that can be used to update the progress bar in the taskbar button.

Library: wxCore

Category: Miscellaneous

Availability: only available for the wxMSW port.

See also

wxTaskBarButton

Since

3.1.0

Public Member Functions

- wxAppProgressIndicator (wxWindow ∗parent=NULL, int maxValue=100)

  Constructs the wxAppProgressIndicator.
- virtual ∼wxAppProgressIndicator ()

  Destructor, stops displaying progress and returns the indicator to its normal state.
- bool IsAvailable () const

  Check if the application progress display is available.
- void SetValue (int value)

  Set the progress value in taskbar button of parent window.
- void SetRange (int range)

  Set the progress range in taskbar button of parent window.

- bool Pulse ()

  Makes the progress bar run in indeterminate mode.

21.26.2 Constructor & Destructor Documentation

wxAppProgressIndicator::wxAppProgressIndicator (wxWindow * *parent* = NULL, int *maxValue* = 100)

Constructs the wxAppProgressIndicator.

Parameters

parent	The parent window of wxAppProgressIndicator. Note that the window should has taskbar button showing. If parent is NULL, the progress will reflect on the taskbar buttons of all the top level windows.
maxValue	Integer range (maximum value) of the progress indicator.

virtual wxAppProgressIndicator::~wxAppProgressIndicator ( ) [virtual]

Destructor, stops displaying progress and returns the indicator to its normal state.

21.26.3 Member Function Documentation

bool wxAppProgressIndicator::IsAvailable ( ) const

Check if the application progress display is available.

Currently this only returns true when using wxMSW and running under Vista or later system, which provide task bar button API.

If this method returns false, no other methods of this class do anything, but they may still be called without any ill effects.

bool wxAppProgressIndicator::Pulse ( )

Makes the progress bar run in indeterminate mode.

void wxAppProgressIndicator::SetRange (int *range*)

Set the progress range in taskbar button of parent window.

void wxAppProgressIndicator::SetValue (int *value*)

Set the progress value in taskbar button of parent window.

Parameters

value	The new value of the progress meter. It should be less than or equal to the range.

21.27 wxAppTraits Class Reference

`#include <wx/apptrait.h>`

21.27.1 Detailed Description

The wxAppTraits class defines various configurable aspects of a wxApp.

You can access it using wxApp::GetTraits() function and you can create your own wxAppTraits overriding the wxApp::CreateTraits() function.

Note that wxAppTraits is an abstract class since it contains many pure virtual functions. In fact, by default, wxWidgets creates a `wxConsoleAppTraits` object for console applications (i.e. those applications linked against wxBase library only - see the Library List page) and a `wxGUIAppTraits` object for GUI applications. Both these classes are derived by wxAppTraits and represent concrete implementation of the wxAppTraits interface.

Library: wxBase

Category: Application and System configuration

See also

wxApp Overview, wxApp

Public Member Functions

- virtual wxConfigBase * CreateConfig ()

  Called by wxWidgets to create the default configuration object for the application.
- virtual wxEventLoopBase * CreateEventLoop ()=0

  Used by wxWidgets to create the main event loop used by wxApp::OnRun().
- virtual wxFontMapper * CreateFontMapper ()=0

  Creates the global font mapper object used for encodings/charset mapping.
- virtual wxLog * CreateLogTarget ()=0

  Creates a wxLog class for the application to use for logging errors.
- virtual wxMessageOutput * CreateMessageOutput ()=0

  Creates the global object used for printing out messages.
- virtual wxRendererNative * CreateRenderer ()=0

  Returns the renderer to use for drawing the generic controls (return value may be NULL in which case the default renderer for the current platform is used); this is used in GUI mode only and always returns NULL in console.
- virtual wxString GetDesktopEnvironment () const =0

  This method returns the name of the desktop environment currently running in a Unix desktop.
- virtual wxStandardPaths & GetStandardPaths ()

  Returns the wxStandardPaths object for the application.
- virtual wxPortId GetToolkitVersion (int *major=NULL, int *minor=NULL) const =0

  Returns the wxWidgets port ID used by the running program and eventually fills the given pointers with the values of the major and minor digits of the native toolkit currently used.
- virtual bool HasStderr ()=0

  Returns true if `fprintf(stderr)` goes somewhere, false otherwise.
- virtual bool IsUsingUniversalWidgets () const =0

  Returns true if the library was built as wxUniversal.
- virtual bool ShowAssertDialog (const wxString &msg)=0

  Shows the assert dialog with the specified message in GUI mode or just prints the string to stderr in console mode.

21.27.2 Member Function Documentation

virtual wxConfigBase* wxAppTraits::CreateConfig ( ) [virtual]

Called by wxWidgets to create the default configuration object for the application.

The default version creates a registry-based wxRegConfig class under MSW and wxFileConfig under all other platforms.

The wxApp::GetAppName and wxApp::GetVendorName methods are used to determine the registry key or file name.

virtual wxEventLoopBase* wxAppTraits::CreateEventLoop ( ) [pure virtual]

Used by wxWidgets to create the main event loop used by wxApp::OnRun().

The default implementation of this method in wxGUIAppTraits returns the usual platform-specific GUI event loop. The version in wxConsoleAppTraits returns a console-specific event loop which can be used to handle timer and socket events in console programs under Unix and MSW or NULL under the other platforms where console event loops are not supported yet.

virtual wxFontMapper* wxAppTraits::CreateFontMapper ( ) [pure virtual]

Creates the global font mapper object used for encodings/charset mapping.

virtual wxLog* wxAppTraits::CreateLogTarget ( ) [pure virtual]

Creates a wxLog class for the application to use for logging errors.

The default implementation returns a new wxLogGui class.

See also

wxLog

virtual wxMessageOutput* wxAppTraits::CreateMessageOutput ( ) [pure virtual]

Creates the global object used for printing out messages.

virtual wxRendererNative* wxAppTraits::CreateRenderer ( ) [pure virtual]

Returns the renderer to use for drawing the generic controls (return value may be NULL in which case the default renderer for the current platform is used); this is used in GUI mode only and always returns NULL in console.

Note

the returned pointer needs to be deleted by the caller.

virtual wxString wxAppTraits::GetDesktopEnvironment ( ) const [pure virtual]

This method returns the name of the desktop environment currently running in a Unix desktop.

Currently only "KDE" or "GNOME" are supported and the code uses the X11 session protocol vendor name to figure out, which desktop environment is running. The method returns an empty string otherwise and on all other platforms.

virtual wxStandardPaths& wxAppTraits::GetStandardPaths ( ) [virtual]

Returns the wxStandardPaths object for the application.

It's normally the same for wxBase and wxGUI except in the case of wxMac and wxCocoa.

Note

The returned reference is to a `wxStandardPathsBase` class but you can consider it to be equivalent to wxStandardPaths (which is documented).

virtual wxPortId wxAppTraits::GetToolkitVersion (int * *major* = NULL, int * *minor* = NULL) const [pure virtual]

Returns the wxWidgets port ID used by the running program and eventually fills the given pointers with the values of the major and minor digits of the native toolkit currently used.

The version numbers returned are thus detected at run-time and not compile-time (except when this is not possible e.g. wxMotif).

E.g. if your program is using wxGTK port this function will return wxPORT_GTK and put in given pointers the versions of the GTK library in use. See wxPlatformInfo for more details.

virtual bool wxAppTraits::HasStderr ( ) [pure virtual]

Returns true if `fprintf(stderr)` goes somewhere, false otherwise.

virtual bool wxAppTraits::IsUsingUniversalWidgets ( ) const [pure virtual]

Returns true if the library was built as wxUniversal.

Always returns false for wxBase-only apps.

virtual bool wxAppTraits::ShowAssertDialog (const wxString & *msg*) [pure virtual]

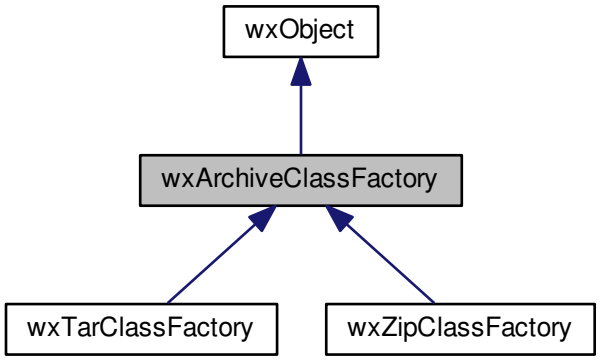
Shows the assert dialog with the specified message in GUI mode or just prints the string to stderr in console mode.

Returns true to suppress subsequent asserts, false to continue as before.

21.28 wxArchiveClassFactory Class Reference

`#include <wx/archive.h>`

Inheritance diagram for wxArchiveClassFactory:



21.28.1 Detailed Description

Allows the creation of streams to handle archive formats such as zip and tar.

For example, given a filename you can search for a factory that will handle it and create a stream to read it:

```
factory = wxArchiveClassFactory::Find(filename,
      wxSTREAM_FILEEXT);
if (factory)
    stream = factory->NewStream(new wxFFileInputStream(filename));
```

wxArchiveClassFactory::Find can also search for a factory by MIME type or wxFileSystem protocol.

The available factories can be enumerated using wxArchiveClassFactory::GetFirst() and wxArchiveClassFactory::GetNext().

Library: wxBase

Category: Archive support, Streams

See also

Archive Formats, Generic Archive Programming, wxArchiveEntry, wxArchiveInputStream, wxArchiveOutputStream, wxFilterClassFactory

- const wxArchiveClassFactory * GetNext () const

  GetFirst and GetNext can be used to enumerate the available factories.
- static const wxArchiveClassFactory * GetFirst ()

  GetFirst and GetNext can be used to enumerate the available factories.

Public Member Functions

- bool CanHandle (const wxString &protocol, wxStreamProtocolType type=wxSTREAM_PROTOCOL) const

Returns true if this factory can handle the given protocol, MIME type or file extension.

- wxMBConv & GetConv () const

  Returns the wxMBConv object that the created streams will use when translating meta-data.

- void SetConv (wxMBConv &conv)

  Sets the wxMBConv object that the created streams will use when translating meta-data.

- virtual wxString GetInternalName (const wxString &name, wxPathFormat format=wxPATH_NATIVE) const =0

  Calls the static GetInternalName() function for the archive entry type, for example wxZipEntry::GetInternalName.

- wxString GetProtocol () const

  Returns the wxFileSystem protocol supported by this factory.

- virtual const wxChar ** GetProtocols (wxStreamProtocolType type=wxSTREAM_PROTOCOL) const =0

  Returns the protocols, MIME types or file extensions supported by this factory, as an array of null terminated strings.

- wxArchiveEntry * NewEntry () const

  Create a new wxArchiveEntry object of the appropriate type.

- void PushFront ()

  Adds this class factory to the list returned by GetFirst() or GetNext().

- void Remove ()

  Removes this class factory from the list returned by GetFirst() and GetNext().

- wxArchiveInputStream * NewStream (wxInputStream &stream) const

  Create a new input or output stream to read or write an archive.

- wxArchiveOutputStream * NewStream (wxOutputStream &stream) const

  Create a new input or output stream to read or write an archive.

- wxArchiveInputStream * NewStream (wxInputStream *stream) const

  Create a new input or output stream to read or write an archive.

- wxArchiveOutputStream * NewStream (wxOutputStream *stream) const

  Create a new input or output stream to read or write an archive.

Static Public Member Functions

- static const wxArchiveClassFactory * Find (const wxString &protocol, wxStreamProtocolType type=wxSTREAM_PROTOCOL)

  A static member that finds a factory that can handle a given protocol, MIME type or file extension.

Additional Inherited Members

21.28.2 Member Function Documentation

bool wxArchiveClassFactory::CanHandle (const wxString & *protocol*, wxStreamProtocolType *type* = wxSTREAM_PROTOCOL) const

Returns true if this factory can handle the given protocol, MIME type or file extension.

When using wxSTREAM_FILEEXT for the second parameter, the first parameter can be a complete filename rather than just an extension.

static const wxArchiveClassFactory* wxArchiveClassFactory::Find (const wxString & *protocol,* wxStreamProtocolType *type* = wxSTREAM_PROTOCOL) [static]

A static member that finds a factory that can handle a given protocol, MIME type or file extension.

Returns a pointer to the class factory if found, or NULL otherwise. It does not give away ownership of the factory.

When using wxSTREAM_FILEEXT for the second parameter, the first parameter can be a complete filename rather than just an extension.

wxMBConv& wxArchiveClassFactory::GetConv ( ) const

Returns the wxMBConv object that the created streams will use when translating meta-data.

The initial default, set by the constructor, is wxConvLocal.

static const wxArchiveClassFactory* wxArchiveClassFactory::GetFirst ( ) [static]

GetFirst and GetNext can be used to enumerate the available factories.

For example, to list them:

```
wxString list;
const wxArchiveClassFactory *factory =
      wxArchiveClassFactory::GetFirst();

while (factory) {
    list << factory->GetProtocol() << wxT("\n");
    factory = factory->GetNext();
}
```

GetFirst() and GetNext() return a pointer to a factory or NULL if no more are available. They do not give away ownership of the factory.

virtual wxString wxArchiveClassFactory::GetInternalName (const wxString & *name,* wxPathFormat *format* = wxPATH_NATIVE) const [pure virtual]

Calls the static GetInternalName() function for the archive entry type, for example wxZipEntry::GetInternalName.

const wxArchiveClassFactory* wxArchiveClassFactory::GetNext ( ) const

GetFirst and GetNext can be used to enumerate the available factories.

For example, to list them:

```
wxString list;
const wxArchiveClassFactory *factory =
      wxArchiveClassFactory::GetFirst();

while (factory) {
    list << factory->GetProtocol() << wxT("\n");
    factory = factory->GetNext();
}
```

GetFirst() and GetNext() return a pointer to a factory or NULL if no more are available. They do not give away ownership of the factory.

wxString wxArchiveClassFactory::GetProtocol ( ) const

Returns the wxFileSystem protocol supported by this factory.

Equivalent to

```
wxString(*GetProtocols())
```

.

virtual const wxChar** wxArchiveClassFactory::GetProtocols (wxStreamProtocolType *type* = wxSTREAM_PROTOCOL) const [pure virtual]

Returns the protocols, MIME types or file extensions supported by this factory, as an array of null terminated strings.

It does not give away ownership of the array or strings. For example, to list the file extensions a factory supports:

```
wxString list;
const wxChar *const *p;

for (p = factory->GetProtocols(wxSTREAM_FILEEXT); *p; p++)
    list << *p << wxT("\n");
```

wxArchiveEntry* wxArchiveClassFactory::NewEntry ( ) const

Create a new wxArchiveEntry object of the appropriate type.

wxArchiveInputStream* wxArchiveClassFactory::NewStream (wxInputStream & *stream*) const

Create a new input or output stream to read or write an archive.

If the parent stream is passed as a pointer then the new archive stream takes ownership of it. If it is passed by reference then it does not.

wxArchiveOutputStream* wxArchiveClassFactory::NewStream (wxOutputStream & *stream*) const

Create a new input or output stream to read or write an archive.

If the parent stream is passed as a pointer then the new archive stream takes ownership of it. If it is passed by reference then it does not.

wxArchiveInputStream* wxArchiveClassFactory::NewStream (wxInputStream * *stream*) const

Create a new input or output stream to read or write an archive.

If the parent stream is passed as a pointer then the new archive stream takes ownership of it. If it is passed by reference then it does not.

wxArchiveOutputStream* wxArchiveClassFactory::NewStream (wxOutputStream * *stream*) const

Create a new input or output stream to read or write an archive.

If the parent stream is passed as a pointer then the new archive stream takes ownership of it. If it is passed by reference then it does not.

void wxArchiveClassFactory::PushFront ( )

Adds this class factory to the list returned by GetFirst() or GetNext().

It is not necessary to do this to use the archive streams. It is usually used when implementing streams, typically the implementation will add a static instance of its factory class.

It can also be used to change the order of a factory already in the list, bringing it to the front. This isn't a thread safe operation so can't be done when other threads are running that will be using the list. The list does not take ownership of the factory.

void wxArchiveClassFactory::Remove ( )

Removes this class factory from the list returned by GetFirst() and GetNext().

Removing from the list isn't a thread safe operation so can't be done when other threads are running that will be using the list. The list does not own the factories, so removing a factory does not delete it.

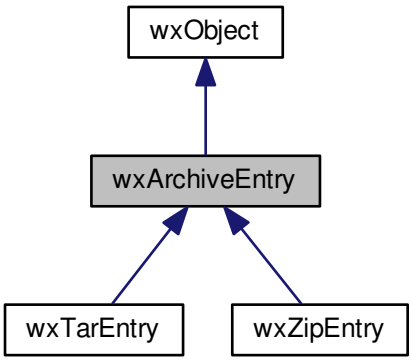
void wxArchiveClassFactory::SetConv (wxMBConv & *conv*)

Sets the wxMBConv object that the created streams will use when translating meta-data.

21.29 wxArchiveEntry Class Reference

`#include <wx/archive.h>`

Inheritance diagram for wxArchiveEntry:



21.29.1 Detailed Description

This is an abstract base class which serves as a common interface to archive entry classes such as wxZipEntry.

These hold the meta-data (filename, timestamp, etc.), for entries in archive files such as zips and tars.

21.29.2 About non-seekable streams

This information applies only when reading archives from non-seekable streams. When the stream is seekable GetNextEntry() returns a fully populated wxArchiveEntry. See Archives on Non-Seekable Streams for more information.

For generic programming, when the worst case must be assumed, you can rely on all the fields of wxArchiveEntry being fully populated when wxArchiveInputStream::GetNextEntry() returns, with the following exceptions:

- GetSize(): guaranteed to be available after the entry has been read to Eof(), or CloseEntry() has been called;
- IsReadOnly(): guaranteed to be available after the end of the archive has been reached, i.e. after GetNext↩ Entry() returns NULL and Eof() is true.

Library: wxBase

Public Member Functions

- wxArchiveEntry * Clone () const

  Returns a copy of this entry object.
- virtual wxDateTime GetDateTime () const =0

  Gets the entry's timestamp.
- virtual void SetDateTime (const wxDateTime &dt)=0

  Sets the entry's timestamp.
- virtual wxString GetName (wxPathFormat format=wxPATH_NATIVE) const =0

  Returns the entry's name, by default in the native format.
- virtual void SetName (const wxString &name, wxPathFormat format=wxPATH_NATIVE)=0

  Sets the entry's name.
- virtual wxFileOffset GetSize () const =0

  Returns the size of the entry's data in bytes.
- virtual void SetSize (wxFileOffset size)=0

  Sets the size of the entry's data in bytes.
- virtual wxPathFormat GetInternalFormat () const =0

  Returns the path format used internally within the archive to store filenames.
- virtual wxString GetInternalName () const =0

  Returns the entry's filename in the internal format used within the archive.
- virtual wxFileOffset GetOffset () const =0

  Returns a numeric value unique to the entry within the archive.
- virtual bool IsDir () const =0

  Returns true if this is a directory entry.
- virtual void SetIsDir (bool isDir=true)=0

  Marks this entry as a directory if isDir is true.
- virtual bool IsReadOnly () const =0

  Returns true if the entry is a read-only file.
- virtual void SetIsReadOnly (bool isReadOnly=true)=0

  Sets this entry as a read-only file.
- void SetNotifier (wxArchiveNotifier &notifier)

  Sets the notifier (see wxArchiveNotifier) for this entry.
- virtual void UnsetNotifier ()

  Unsets the notifier eventually attached to this entry.

Additional Inherited Members

21.29.3 Member Function Documentation

wxArchiveEntry* wxArchiveEntry::Clone ( ) const

Returns a copy of this entry object.

virtual wxDateTime wxArchiveEntry::GetDateTime ( ) const [pure virtual]

Gets the entry's timestamp.

virtual wxPathFormat wxArchiveEntry::GetInternalFormat ( ) const [pure virtual]

Returns the path format used internally within the archive to store filenames.

virtual wxString wxArchiveEntry::GetInternalName ( ) const [pure virtual]

Returns the entry's filename in the internal format used within the archive.

The name can include directory components, i.e. it can be a full path.

The names of directory entries are returned without any trailing path separator. This gives a canonical name that can be used in comparisons.

See also

Looking Up an Archive Entry by Name

Implemented in wxTarEntry, and wxZipEntry.

virtual wxString wxArchiveEntry::GetName (wxPathFormat *format* = wxPATH_NATIVE) const [pure virtual]

Returns the entry's name, by default in the native format.

The name can include directory components, i.e. it can be a full path.

If this is a directory entry, (i.e. if IsDir() is true) then the returned string is the name with a trailing path separator.

virtual wxFileOffset wxArchiveEntry::GetOffset ( ) const [pure virtual]

Returns a numeric value unique to the entry within the archive.

virtual wxFileOffset wxArchiveEntry::GetSize ( ) const [pure virtual]

Returns the size of the entry's data in bytes.

Implemented in wxTarEntry.

virtual bool wxArchiveEntry::IsDir ( ) const [pure virtual]

Returns true if this is a directory entry.

Directory entries are entries with no data, which are used to store the meta-data of directories. They also make it possible for completely empty directories to be stored.

Note

The names of entries within an archive can be complete paths, and unarchivers typically create whatever directories are necessary as they restore files, even if the archive contains no explicit directory entries.

virtual bool wxArchiveEntry::IsReadOnly ( ) const `[pure virtual]`

Returns true if the entry is a read-only file.

virtual void wxArchiveEntry::SetDateTime (const wxDateTime & *dt*) `[pure virtual]`

Sets the entry's timestamp.

virtual void wxArchiveEntry::SetIsDir (bool *isDir* = `true`) `[pure virtual]`

Marks this entry as a directory if *isDir* is true.

See IsDir() for more info.

virtual void wxArchiveEntry::SetIsReadOnly (bool *isReadOnly* = `true`) `[pure virtual]`

Sets this entry as a read-only file.

virtual void wxArchiveEntry::SetName (const wxString & *name*, wxPathFormat *format* = wxPATH_NATIVE) `[pure virtual]`

Sets the entry's name.

Setting a name with a trailing path separator sets IsDir().

See also

GetName()

void wxArchiveEntry::SetNotifier (wxArchiveNotifier & *notifier*)

Sets the notifier (see wxArchiveNotifier) for this entry.

Whenever the wxArchiveInputStream updates this entry, it will then invoke the associated notifier's wxArchiveNotifier::OnEntryUpdated method.

Setting a notifier is not usually necessary. It is used to handle certain cases when modifying an archive in a pipeline (i.e. between non-seekable streams).

virtual void wxArchiveEntry::SetSize (wxFileOffset *size*) `[pure virtual]`

Sets the size of the entry's data in bytes.

Implemented in wxTarEntry.

virtual void wxArchiveEntry::UnsetNotifier ( ) `[virtual]`

Unsets the notifier eventually attached to this entry.

Reimplemented in wxZipEntry.

21.30 wxArchiveFSHandler Class Reference

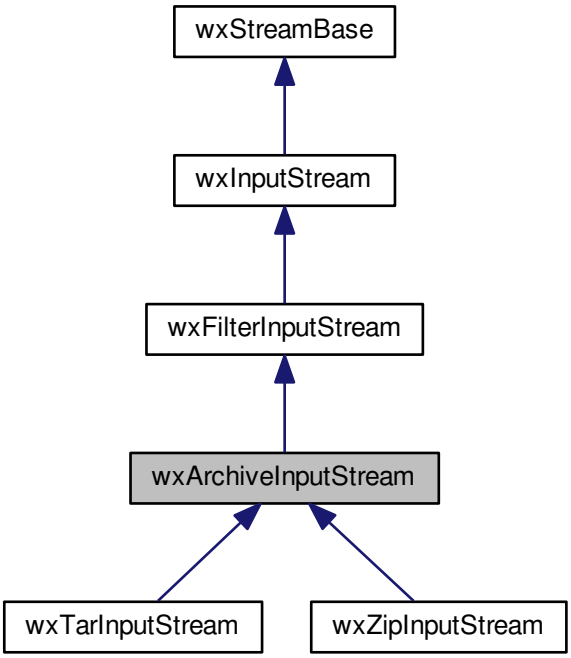
21.31 wxArchiveInputStream Class Reference

`#include <wx/archive.h>`

Inheritance diagram for wxArchiveInputStream:



21.31.1 Detailed Description

This is an abstract base class which serves as a common interface to archive input streams such as wxZipInputStream.

wxArchiveInputStream::GetNextEntry returns an wxArchiveEntry object containing the meta-data for the next entry in the archive (and gives away ownership).

Reading from the wxArchiveInputStream then returns the entry's data. Eof() becomes true after an attempt has been made to read past the end of the entry's data.

When there are no more entries, GetNextEntry() returns NULL and sets Eof().

Public Member Functions

- virtual bool CloseEntry ()=0

  Closes the current entry.

- wxArchiveEntry * GetNextEntry ()

  Closes the current entry if one is open, then reads the meta-data for the next entry and returns it in a wxArchiveEntry object, giving away ownership.
- virtual bool OpenEntry (wxArchiveEntry &entry)=0

  Closes the current entry if one is open, then opens the entry specified by the wxArchiveEntry object.

Additional Inherited Members

21.31.2 Member Function Documentation

virtual bool wxArchiveInputStream::CloseEntry ( ) [pure virtual]

Closes the current entry.

On a non-seekable stream reads to the end of the current entry first.

Implemented in wxZipInputStream, and wxTarInputStream.

wxArchiveEntry* wxArchiveInputStream::GetNextEntry ( )

Closes the current entry if one is open, then reads the meta-data for the next entry and returns it in a wxArchiveEntry object, giving away ownership.

Reading this wxArchiveInputStream then returns the entry's data.

virtual bool wxArchiveInputStream::OpenEntry (wxArchiveEntry & *entry*) [pure virtual]

Closes the current entry if one is open, then opens the entry specified by the wxArchiveEntry object.

entry must be from the same archive file that this wxArchiveInputStream is reading, and it must be reading it from a seekable stream.

21.32 wxArchiveIterator Class Reference

`#include <wx/archive.h>`

21.32.1 Detailed Description

An input iterator template class that can be used to transfer an archive's catalogue to a container.

It is only available if wxUSE_STL is set to 1 in setup.h, and the uses for it outlined below require a compiler which supports member templates.

```
template<class Arc, class T = typename Arc::entry_type*>
class wxArchiveIterator
{
    // this constructor creates an 'end of sequence' object
    wxArchiveIterator();

    // template parameter 'Arc' should be the type of an archive input stream
    wxArchiveIterator(Arc& arc) {
        // ...
    }
};
```

The first template parameter should be the type of archive input stream (e.g. wxArchiveInputStream) and the second can either be a pointer to an entry (e.g. wxArchiveEntry*), or a string/pointer pair (e.g. std::pair<wx↩String,wxArchiveEntry*>).

The wx/archive.h header defines the following typedefs:

```
typedef wxArchiveIterator<wxArchiveInputStream> wxArchiveIter;

typedef wxArchiveIterator<wxArchiveInputStream,
        std::pair<wxString, wxArchiveEntry*> > wxArchivePairIter;
```

The header for any implementation of this interface should define similar typedefs for its types, for example in wx/zipstrm.h there is:

```
typedef wxArchiveIterator<wxZipInputStream> wxZipIter;

typedef wxArchiveIterator<wxZipInputStream,
         std::pair<wxString, wxZipEntry*> > wxZipPairIter;
```

Transferring the catalogue of an archive *arc* to a vector *cat*, can then be done something like this:

```
std::vector<wxArchiveEntry*> cat((wxArchiveIter)arc, wxArchiveIter());
```

When the iterator is dereferenced, it gives away ownership of an entry object. So in the above example, when you have finished with *cat* you must delete the pointers it contains.

If you have smart pointers with normal copy semantics (i.e. not auto_ptr or wxScopedPtr), then you can create an iterator which uses them instead.

For example, with a smart pointer class for zip entries *ZipEntryPtr:*

```
typedef std::vector<ZipEntryPtr> ZipCatalog;
typedef wxArchiveIterator<wxZipInputStream, ZipEntryPtr>
      ZipIter;
ZipCatalog cat((ZipIter)zip, ZipIter());
```

Iterators that return std::pair objects can be used to populate a std::multimap, to allow entries to be looked up by name. The string is initialised using the wxArchiveEntry object's wxArchiveEntry::GetInternalName function.

```
typedef std::multimap<wxString, wxZipEntry*> ZipCatalog;
ZipCatalog cat((wxZipPairIter)zip, wxZipPairIter());
```

Note that this iterator also gives away ownership of an entry object each time it is dereferenced. So in the above example, when you have finished with *cat* you must delete the pointers it contains.

Or if you have them, a pair containing a smart pointer can be used (again *ZipEntryPtr*), no worries about ownership:

```
typedef std::multimap<wxString, ZipEntryPtr> ZipCatalog;
typedef wxArchiveIterator<wxZipInputStream,
            std::pair<wxString, ZipEntryPtr> > ZipPairIter;
ZipCatalog cat((ZipPairIter)zip, ZipPairIter());
```

wxArchiveIterator wxArchiveIterator::operator++ ( )

Position the input iterator at the next entry in the archive input stream.

wxArchiveIterator wxArchiveIterator::operator++ (int)

Position the input iterator at the next entry in the archive input stream.

21.33 wxArchiveNotifier Class Reference

`#include <wx/archive.h>`

21.33.1 Detailed Description

If you need to know when a wxArchiveInputStream updates a wxArchiveEntry object, you can create a notifier by deriving from this abstract base class, overriding wxArchiveNotifier::OnEntryUpdated.

An instance of your notifier class can then be assigned to the wxArchiveEntry object using wxArchiveEntry::Set↩ Notifier. Your OnEntryUpdated() method will then be invoked whenever the input stream updates the entry.

Setting a notifier is not usually necessary. It is used to handle certain cases when modifying an archive in a pipeline (i.e. between non-seekable streams). See Archives on Non-Seekable Streams.

Library: wxBase

- virtual bool Close ()

  Closes the archive, returning true if it was successfully written.
- virtual bool CloseEntry ()=0

  Close the current entry.
- virtual bool CopyArchiveMetaData (wxArchiveInputStream &stream)=0

  Some archive formats have additional meta-data that applies to the archive as a whole.
- virtual bool CopyEntry (wxArchiveEntry *entry, wxArchiveInputStream &stream)=0

  Takes ownership of entry and uses it to create a new entry in the archive.
- virtual bool PutNextDirEntry (const wxString &name, const wxDateTime &dt=wxDateTime::Now())=0

  Create a new directory entry (see wxArchiveEntry::IsDir) with the given name and timestamp.
- virtual bool PutNextEntry (wxArchiveEntry *entry)=0

  Takes ownership of entry and uses it to create a new entry in the archive.
- virtual bool PutNextEntry (const wxString &name, const wxDateTime &dt=wxDateTime::Now(), wxFileOffset size=wxInvalidOffset)=0

  Create a new entry with the given name, timestamp and size.

Additional Inherited Members

21.34.2 Constructor & Destructor Documentation

virtual wxArchiveOutputStream::~wxArchiveOutputStream ( ) [virtual]

Calls Close() if it has not already been called.

21.34.3 Member Function Documentation

virtual bool wxArchiveOutputStream::Close ( ) [virtual]

Closes the archive, returning true if it was successfully written.

Called by the destructor if not called explicitly.

See also

wxOutputStream::Close()

Reimplemented from wxOutputStream.

Reimplemented in wxZipOutputStream, and wxTarOutputStream.

virtual bool wxArchiveOutputStream::CloseEntry ( ) [pure virtual]

Close the current entry.

It is called implicitly whenever another new entry is created with CopyEntry() or PutNextEntry(), or when the archive is closed.

Implemented in wxZipOutputStream, and wxTarOutputStream.

virtual bool wxArchiveOutputStream::CopyArchiveMetaData (wxArchiveInputStream & *stream*) [pure virtual]

Some archive formats have additional meta-data that applies to the archive as a whole.

For example in the case of zip there is a comment, which is stored at the end of the zip file. CopyArchiveMetaData() can be used to transfer such information when writing a modified copy of an archive.

Since the position of the meta-data can vary between the various archive formats, it is best to call CopyArchive↩MetaData() before transferring the entries. The wxArchiveOutputStream will then hold on to the meta-data and write it at the correct point in the output file.

When the input archive is being read from a non-seekable stream, the meta-data may not be available when Copy↩ArchiveMetaData() is called, in which case the two streams set up a link and transfer the data when it becomes available.

virtual bool wxArchiveOutputStream::CopyEntry (wxArchiveEntry * *entry,* wxArchiveInputStream & *stream*) [pure virtual]

Takes ownership of *entry* and uses it to create a new entry in the archive.

entry is then opened in the input stream *stream* and its contents copied to this stream.

For archive types which compress entry data, CopyEntry() is likely to be much more efficient than transferring the data using Read() and Write() since it will copy them without decompressing and recompressing them.

entry must be from the same archive file that *stream* is accessing. For non-seekable streams, *entry* must also be the last thing read from *stream*.

virtual bool wxArchiveOutputStream::PutNextDirEntry (const wxString & *name,* const wxDateTime & *dt* = wxDateTime::Now()) [pure virtual]

Create a new directory entry (see wxArchiveEntry::IsDir) with the given name and timestamp.

PutNextEntry() can also be used to create directory entries, by supplying a name with a trailing path separator.

Implemented in wxZipOutputStream, and wxTarOutputStream.

virtual bool wxArchiveOutputStream::PutNextEntry (wxArchiveEntry * *entry*) [pure virtual]

Takes ownership of entry and uses it to create a new entry in the archive.

The entry's data can then be written by writing to this wxArchiveOutputStream.

virtual bool wxArchiveOutputStream::PutNextEntry (const wxString & *name,* const wxDateTime & *dt* = wxDateTime::Now (), wxFileOffset *size* = wxInvalidOffset) [pure virtual]

Create a new entry with the given name, timestamp and size.

The entry's data can then be written by writing to this wxArchiveOutputStream.

Implemented in wxZipOutputStream, and wxTarOutputStream.

21.35 wxArray< T > Class Template Reference

`#include <wx/dynarray.h>`

21.35.1 Detailed Description

template<typename T>class wxArray< T >

This section describes the so called *"dynamic arrays"*.

This is a C array-like type safe data structure i.e. the member access time is constant (and not linear according to the number of container elements as for linked lists). However, these arrays are dynamic in the sense that they will automatically allocate more memory if there is not enough of it for adding a new element. They also perform range checking on the index values but in debug mode only, so please be sure to compile your application in debug mode to use it (see Debugging for details). So, unlike the arrays in some other languages, attempt to access an element beyond the arrays bound doesn't automatically expand the array but provokes an assertion failure instead in debug build and does nothing (except possibly crashing your program) in the release build.

The array classes were designed to be reasonably efficient, both in terms of run-time speed and memory consumption and the executable size. The speed of array item access is, of course, constant (independent of the number of elements) making them much more efficient than linked lists (wxList). Adding items to the arrays is also implemented in more or less constant time, but the price is preallocating the memory in advance. In the "memory management" function section, you may find some useful hints about optimizing wxArray memory usage. As for executable size, all wxArray functions are inline, so they do not take *any* space at all.

wxWidgets has three different kinds of array. All of them derive from wxBaseArray class which works with untyped data and cannot be used directly. The standard macros WX_DEFINE_ARRAY(), WX_DEFINE_SORTED_ARRAY() and WX_DEFINE_OBJARRAY() are used to define a new class deriving from it. The classes declared will be called in this documentation wxArray, wxSortedArray and wxObjArray but you should keep in mind that no classes with such names actually exist, each time you use one of the WX_DEFINE_XXXARRAY() macros, you define a class with a new name. In fact, these names are "template" names and each usage of one of the macros mentioned above creates a template specialization for the given element type.

wxArray is suitable for storing integer types and pointers which it does not treat as objects in any way, i.e. the element pointed to by the pointer is not deleted when the element is removed from the array. It should be noted that all of wxArray's functions are inline, so it costs strictly nothing to define as many array types as you want (either in terms of the executable size or the speed) as long as at least one of them is defined and this is always the case because wxArrays are used by wxWidgets internally. This class has one serious limitation: it can only be used for storing integral types (bool, char, short, int, long and their unsigned variants) or pointers (of any kind). An attempt to use with objects of `sizeof()` greater than `sizeof(long)` will provoke a runtime assertion failure, however declaring a wxArray of floats will not (on the machines where "`sizeof(float) <= sizeof(long)`"), yet it will **not** work, please use wxObjArray for storing floats and doubles.

wxSortedArray is a wxArray variant which should be used when searching in the array is a frequently used operation. It requires you to define an additional function for comparing two elements of the array element type and always stores its items in the sorted order (according to this function). Thus, its Index() function execution time is "`O(log(N))`" instead of "`O(N)`" for the usual arrays but the Add() method is slower: it is "`O(log(N))`" instead of constant time (neglecting time spent in memory allocation routine). However, in a usual situation elements are added to an array much less often than searched inside it, so wxSortedArray may lead to huge performance improvements compared to wxArray. Finally, it should be noticed that, as wxArray, wxSortedArray can be only used

for storing integral types or pointers.

wxObjArray class treats its elements like "objects". It may delete them when they are removed from the array (invoking the correct destructor) and copies them using the objects copy constructor. In order to implement this behaviour the definition of the wxObjArray arrays is split in two parts: first, you should declare the new wxObjArray class using the WX_DECLARE_OBJARRAY() macro and then you must include the file defining the implementation of template type: <wx/arrimpl.cpp> and define the array class with the WX_DEFINE_OBJARRAY() macro from a point where the full (as opposed to 'forward') declaration of the array elements class is in scope. As it probably sounds very complicated here is an example:

```
#include <wx/dynarray.h>

// We must forward declare the array because it is used
// inside the class declaration.
class MyDirectory;
class MyFile;

// This defines two new types: ArrayOfDirectories and ArrayOfFiles which
// can be now used as shown below.
WX_DECLARE_OBJARRAY(MyDirectory, ArrayOfDirectories);
WX_DECLARE_OBJARRAY(MyFile,      ArrayOfFiles);

class MyDirectory
{
    // ...
    ArrayOfDirectories m_subdirectories; // All subdirectories
    ArrayOfFiles       m_files;          // All files in this directory
};

// ...

// Now that we have MyDirectory declaration in scope we may finish the
// definition of ArrayOfDirectories -- note that this expands into some C++
// code and so should only be compiled once (i.e., don't put this in the
// header, but into a source file or you will get linking errors)
#include <wx/arrimpl.cpp> // This is a magic incantation which must be done!
WX_DEFINE_OBJARRAY(ArrayOfDirectories);

// that's all!
```

It is not as elegant as writing this:

```
typedef std::vector<MyDirectory> ArrayOfDirectories;
```

But is not that complicated and allows the code to be compiled with any, however dumb, C++ compiler in the world.

Remember to include <wx/arrimpl.cpp> just before each WX_DEFINE_OBJARRAY() occurrence in your code, even if you have several in the same file.

Things are much simpler for wxArray and wxSortedArray however: it is enough just to write:

```
WX_DEFINE_ARRAY_INT(int, ArrayOfInts);
WX_DEFINE_SORTED_ARRAY_INT(int, ArrayOfSortedInts);
```

There is only one DEFINE macro and no need for separate DECLARE one. For the arrays of the primitive types, the macros WX_DEFINE_ARRAY_CHAR/SHORT/INT/SIZE_T/LONG/DOUBLE should be used depending on the sizeof of the values (notice that storing values of smaller type, e.g. shorts, in an array of larger one, e.g. ARRAY_INT, does not work on all architectures!).

21.35.2 Macros for Template Array Definition

To use an array you must first define the array class. This is done with the help of the macros in this section. The class of array elements must be (at least) forward declared for WX_DEFINE_ARRAY(), WX_DEFINE_SORTED_ARRAY() and WX_DECLARE_OBJARRAY() macros and must be fully declared before you use WX_DEFINE_OBJARRAY() macro.

- WX_DEFINE_ARRAY()
- WX_DEFINE_EXPORTED_ARRAY()

- WX_DEFINE_USER_EXPORTED_ARRAY()
- WX_DEFINE_SORTED_ARRAY()
- WX_DEFINE_SORTED_EXPORTED_ARRAY()
- WX_DEFINE_SORTED_USER_EXPORTED_ARRAY()
- WX_DECLARE_EXPORTED_OBJARRAY()
- WX_DECLARE_USER_EXPORTED_OBJARRAY()
- WX_DEFINE_OBJARRAY()
- WX_DEFINE_EXPORTED_OBJARRAY()
- WX_DEFINE_USER_EXPORTED_OBJARRAY()

To slightly complicate the matters even further, the operator "->" defined by default for the array iterators by these macros only makes sense if the array element type is not a pointer itself and, although it still works, this provokes warnings from some compilers and to avoid them you should use the _PTR versions of the macros above. For example, to define an array of pointers to double you should use:

```
WX_DEFINE_ARRAY_PTR(double *, MyArrayOfDoublePointers);
```

Note that the above macros are generally only useful for wxObject types. There are separate macros for declaring an array of a simple type, such as an int.

The following simple types are supported:

- int
- long
- size_t
- double

To create an array of a simple type, simply append the type you want in CAPS to the array definition.

For example, you'd use one of the following variants for an integer array:

- WX_DEFINE_ARRAY_INT()
- WX_DEFINE_EXPORTED_ARRAY_INT()
- WX_DEFINE_USER_EXPORTED_ARRAY_INT()
- WX_DEFINE_SORTED_ARRAY_INT()
- WX_DEFINE_SORTED_EXPORTED_ARRAY_INT()
- WX_DEFINE_SORTED_USER_EXPORTED_ARRAY_INT()

21.35.3 Predefined array types

wxWidgets defines the following dynamic array types:

- wxArrayShort
- wxArrayInt
- wxArrayDouble
- wxArrayLong
- wxArrayPtrVoid

To use them you don't need any macro; you just need to include dynarray.h.

Public Member Functions

Constructors and Destructors

Array classes are 100% C++ objects and as such they have the appropriate copy constructors and assignment operators.

Copying wxArray just copies the elements but copying wxObjArray copies the arrays items. However, for memory-efficiency sake, neither of these classes has virtual destructor. It is not very important for wxArray which has trivial destructor anyhow, but it does mean that you should avoid deleting wxObjArray through a wx↩ BaseArray pointer (as you would never use wxBaseArray anyhow it shouldn't be a problem) and that you should not derive your own classes from the array classes.

- wxArray ()
  Default constructor.
- wxObjArray ()
  Default constructor initializes an empty array object.
- wxSortedArray (int(∗)(T first, T second) compareFunction)
  There is no default constructor for wxSortedArray classes - you must initialize it with a function to use for item comparison.
- wxArray (const wxArray &array)
  Performs a shallow array copy (i.e. doesn't copy the objects pointed to even if the source array contains the items of pointer type).
- wxSortedArray (const wxSortedArray &array)
  Performs a shallow array copy (i.e. doesn't copy the objects pointed to even if the source array contains the items of pointer type).
- wxObjArray (const wxObjArray &array)
  Performs a deep copy (i.e. the array element are copied too).
- wxArray & operator= (const wxArray &array)
  Performs a shallow array copy (i.e. doesn't copy the objects pointed to even if the source array contains the items of pointer type).
- wxSortedArray & operator= (const wxSortedArray &array)
  Performs a shallow array copy (i.e. doesn't copy the objects pointed to even if the source array contains the items of pointer type).
- wxObjArray & operator= (const wxObjArray &array)
  Performs a deep copy (i.e. the array element are copied too).
- ∼wxArray ()
  This destructor does not delete all the items owned by the array, you may use the WX_CLEAR_ARRAY() macro for this.
- ∼wxSortedArray ()
  This destructor does not delete all the items owned by the array, you may use the WX_CLEAR_ARRAY() macro for this.
- ∼wxObjArray ()
  This destructor deletes all the items owned by the array.

Memory Management

Automatic array memory management is quite trivial: the array starts by preallocating some minimal amount of memory (defined by `WX_ARRAY_DEFAULT_INITIAL_SIZE`) and when further new items exhaust already allocated memory it reallocates it adding 50% of the currently allocated amount, but no more than some maximal number which is defined by the `ARRAY_MAXSIZE_INCREMENT` constant.

Of course, this may lead to some memory being wasted (`ARRAY_MAXSIZE_INCREMENT` in the worst case, i.e. 4Kb in the current implementation), so the Shrink() function is provided to deallocate the extra memory. The Alloc() function can also be quite useful if you know in advance how many items you are going to put in the array and will prevent the array code from reallocating the memory more times than needed.

- void Alloc (size_t count)

  Preallocates memory for a given number of array elements.
- void Shrink ()

  Frees all memory unused by the array.

Number of Elements and Simple Item Access

Functions in this section return the total number of array elements and allow to retrieve them - possibly using just the C array indexing [] operator which does exactly the same as the Item() method.

- size_t GetCount () const

  Return the number of items in the array.
- bool IsEmpty () const

  Returns true if the array is empty, false otherwise.
- T & Item (size_t index) const

  Returns the item at the given position in the array.
- T & Last () const

  Returns the last element in the array, i.e. is the same as calling "Item(GetCount() - 1)".

Adding Items

- void Add (T item, size_t copies=1)

  Appends the given number of copies of the item to the array consisting of the elements of type `T`.
- size_t Add (T item)

  Appends the item to the array consisting of the elements of type `T`.
- void Add (T *item)

  Appends the item to the array consisting of the elements of type `T`.
- void Add (T &item, size_t copies=1)

  Appends the given number of copies of the item to the array consisting of the elements of type `T`.
- void AddAt (T item, size_t index)

  Inserts the given item into the array in the specified index position.
- void Insert (T item, size_t n, size_t copies=1)

  Insert the given number of copies of the item into the array before the existing item n - thus, Insert(something, 0u) will insert an item in such way that it will become the first array element.
- void Insert (T *item, size_t n)

  Insert the item into the array before the existing item n - thus, Insert(something, 0u) will insert an item in such way that it will become the first array element.
- void Insert (T &item, size_t n, size_t copies=1)

  Insert the given number of copies of the item into the array before the existing item n - thus, Insert(something, 0u) will insert an item in such way that it will become the first array element.
- void SetCount (size_t count, T defval=T(0))

  This function ensures that the number of array elements is at least count.

Removing Items

- void Clear ()

  This function does the same as Empty() and additionally frees the memory allocated to the array.
- T * Detach (size_t index)

  Removes the element from the array, but unlike Remove(), it doesn't delete it.
- void Empty ()

  Empties the array.
- void Remove (T item)

  Removes an element from the array by value: the first item of the array equal to item is removed, an assert failure will result from an attempt to remove an item which doesn't exist in the array.
- void RemoveAt (size_t index, size_t count=1)

Removes count elements starting at index from the array.

Searching and Sorting

- int Index (T &item, bool searchFromEnd=false) const
  This version of Index() is for wxArray and wxObjArray only.
- int Index (T &item) const
  This version of Index() is for wxSortedArray only.
- size_t IndexForInsert (T item) const
  Search for a place to insert item into the sorted array (binary search).
- void Sort (CMPFUNC< T > compareFunction)
  The notation "CMPFUNC<T>" should be read as if we had the following declaration:

21.35.4 Constructor & Destructor Documentation

template<typename T > wxArray< T >::wxArray ( )

Default constructor.

template<typename T > wxArray< T >::wxArray (const wxArray< T > & *array*)

Performs a shallow array copy (i.e. doesn't copy the objects pointed to even if the source array contains the items of pointer type).

template<typename T > wxArray< T >::~wxArray ( )

This destructor does not delete all the items owned by the array, you may use the WX_CLEAR_ARRAY() macro for this.

template<typename T > wxArray< T >::~wxSortedArray ( )

This destructor does not delete all the items owned by the array, you may use the WX_CLEAR_ARRAY() macro for this.

template<typename T > wxArray< T >::~wxObjArray ( )

This destructor deletes all the items owned by the array.

21.35.5 Member Function Documentation

template<typename T > void wxArray< T >::Add (T *item*, size_t *copies* = 1)

Appends the given number of *copies* of the *item* to the array consisting of the elements of type T.

This version is used with wxArray.

You may also use WX_APPEND_ARRAY() macro to append all elements of one array to another one but it is more efficient to use the *copies* parameter and modify the elements in place later if you plan to append a lot of items.

template<typename T > size_t wxArray< T >::Add (T *item*)

Appends the *item* to the array consisting of the elements of type T.

This version is used with wxSortedArray, returning the index where *item* is stored.

template<typename T > void wxArray< T >::Add (T * *item*)

Appends the *item* to the array consisting of the elements of type `T`.

This version is used with wxObjArray. The array will take ownership of the *item*, deleting it when the item is deleted from the array. Note that you cannot append more than one pointer as reusing it would lead to deleting it twice (or more) resulting in a crash.

You may also use WX_APPEND_ARRAY() macro to append all elements of one array to another one but it is more efficient to use the *copies* parameter and modify the elements in place later if you plan to append a lot of items.

template<typename T > void wxArray< T >::Add (T & *item*, size_t *copies* = `1`)

Appends the given number of *copies* of the *item* to the array consisting of the elements of type `T`.

This version is used with wxObjArray. The array will make a copy of the item and will not take ownership of the original item.

You may also use WX_APPEND_ARRAY() macro to append all elements of one array to another one but it is more efficient to use the *copies* parameter and modify the elements in place later if you plan to append a lot of items.

template<typename T > void wxArray< T >::AddAt (T *item*, size_t *index*)

Inserts the given *item* into the array in the specified *index* position.

Be aware that you will set out the order of the array if you give a wrong position.

This function is useful in conjunction with IndexForInsert() for a common operation of "insert only if not found".

template<typename T > void wxArray< T >::Alloc (size_t *count*)

Preallocates memory for a given number of array elements.

It is worth calling when the number of items which are going to be added to the array is known in advance because it will save unneeded memory reallocation. If the array already has enough memory for the given number of items, nothing happens. In any case, the existing contents of the array is not modified.

template<typename T > void wxArray< T >::Clear ( )

This function does the same as Empty() and additionally frees the memory allocated to the array.

template<typename T > T* wxArray< T >::Detach (size_t *index*)

Removes the element from the array, but unlike Remove(), it doesn't delete it.

The function returns the pointer to the removed element.

template<typename T > void wxArray< T >::Empty ( )

Empties the array.

For wxObjArray classes, this destroys all of the array elements. For wxArray and wxSortedArray this does nothing except marking the array of being empty - this function does not free the allocated memory, use Clear() for this.

template<typename T > size_t wxArray< T >::GetCount ( ) const

Return the number of items in the array.

template<typename T > int wxArray< T >::Index (T & *item*, bool *searchFromEnd* = `false`) const

This version of Index() is for wxArray and wxObjArray only.

Searches the element in the array, starting from either beginning or the end depending on the value of *searchFromEnd* parameter. `wxNOT_FOUND` is returned if the element is not found, otherwise the index of the element is returned.

Note

Even for wxObjArray classes, the operator "==" of the elements in the array is **not** used by this function. It searches exactly the given element in the array and so will only succeed if this element had been previously added to the array, but fail even if another, identical, element is in the array.

template<typename T > int wxArray< T >::Index (T & *item*) const

This version of Index() is for wxSortedArray only.

Searches for the element in the array, using binary search.

`wxNOT_FOUND` is returned if the element is not found, otherwise the index of the element is returned.

template<typename T > size_t wxArray< T >::IndexForInsert (T *item*) const

Search for a place to insert *item* into the sorted array (binary search).

The index returned is just before the first existing item that is greater or equal (according to the compare function) to the given *item*.

You have to do extra work to know if the *item* already exists in array.

This function is useful in conjunction with AddAt() for a common operation of "insert only if not found".

template<typename T > void wxArray< T >::Insert (T *item*, size_t *n*, size_t *copies* = `1`)

Insert the given number of *copies* of the *item* into the array before the existing item *n* - thus, *Insert(something, 0u)* will insert an item in such way that it will become the first array element.

wxSortedArray doesn't have this function because inserting in wrong place would break its sorted condition.

Please see Add() for an explanation of the differences between the overloaded versions of this function.

template<typename T > void wxArray< T >::Insert (T * *item*, size_t *n*)

Insert the *item* into the array before the existing item *n* - thus, *Insert(something, 0u)* will insert an item in such way that it will become the first array element.

wxSortedArray doesn't have this function because inserting in wrong place would break its sorted condition.

Please see Add() for an explanation of the differences between the overloaded versions of this function.

template<typename T > void wxArray< T >::Insert (T & *item*, size_t *n*, size_t *copies* = `1`)

Insert the given number of *copies* of the *item* into the array before the existing item *n* - thus, *Insert(something, 0u)* will insert an item in such way that it will become the first array element.

wxSortedArray doesn't have this function because inserting in wrong place would break its sorted condition.

Please see Add() for an explanation of the differences between the overloaded versions of this function.

template<typename T > bool wxArray< T >::IsEmpty ( ) const

Returns true if the array is empty, false otherwise.

template<typename T > T& wxArray< T >::Item (size_t *index*) const

Returns the item at the given position in the array.

If *index* is out of bounds, an assert failure is raised in the debug builds but nothing special is done in the release build.

The returned value is of type "reference to the array element type" for all of the array classes.

template<typename T > T& wxArray< T >::Last ( ) const

Returns the last element in the array, i.e. is the same as calling "Item(GetCount() - 1)".

An assert failure is raised in the debug mode if the array is empty.

The returned value is of type "reference to the array element type" for all of the array classes.

template<typename T > wxArray& wxArray< T >::operator= (const wxArray< T > & *array*)

Performs a shallow array copy (i.e. doesn't copy the objects pointed to even if the source array contains the items of pointer type).

template<typename T > wxSortedArray& wxArray< T >::operator= (const wxSortedArray & *array*)

Performs a shallow array copy (i.e. doesn't copy the objects pointed to even if the source array contains the items of pointer type).

template<typename T > wxObjArray& wxArray< T >::operator= (const wxObjArray & *array*)

Performs a deep copy (i.e. the array element are copied too).

template<typename T > void wxArray< T >::Remove (T *item*)

Removes an element from the array by value: the first item of the array equal to *item* is removed, an assert failure will result from an attempt to remove an item which doesn't exist in the array.

When an element is removed from wxObjArray it is deleted by the array - use Detach() if you don't want this to happen. On the other hand, when an object is removed from a wxArray nothing happens - you should delete it manually if required:

```
T *item = array[n];
array.Remove(item);
delete item;
```

See also WX_CLEAR_ARRAY() macro which deletes all elements of a wxArray (supposed to contain pointers).

Notice that for sorted arrays this method uses binary search to find the item so it doesn't necessarily remove the first matching item, but the first one found by the binary search.

See also

RemoveAt()

template<typename T > void wxArray< T >::RemoveAt (size_t *index*, size_t *count* = 1)

Removes *count* elements starting at *index* from the array.

When an element is removed from wxObjArray it is deleted by the array - use Detach() if you don't want this to happen. On the other hand, when an object is removed from a wxArray nothing happens - you should delete it manually if required:

```
T *item = array[n];
delete item;
array.RemoveAt(n);
```

See also WX_CLEAR_ARRAY() macro which deletes all elements of a wxArray (supposed to contain pointers).

template<typename T > void wxArray< T >::SetCount (size_t *count*, T *defval* = T(0))

This function ensures that the number of array elements is at least *count*.

If the array has already *count* or more items, nothing is done. Otherwise, *count* - GetCount() elements are added and initialized to the value *defval*.

See also

GetCount()

template<typename T > void wxArray< T >::Shrink ( )

Frees all memory unused by the array.

If the program knows that no new items will be added to the array it may call Shrink() to reduce its memory usage. However, if a new item is added to the array, some extra memory will be allocated again.

template<typename T > void wxArray< T >::Sort (CMPFUNC< T > *compareFunction*)

The notation "CMPFUNCT<T>" should be read as if we had the following declaration:

```
template int CMPFUNC(T *first, T *second);
```

Where *T* is the type of the array elements. I.e. it is a function returning *int* which is passed two arguments of type *T**.

Sorts the array using the specified compare function: this function should return a negative, zero or positive value according to whether the first element passed to it is less than, equal to or greater than the second one.

wxSortedArray doesn't have this function because it is always sorted.

template<typename T > wxArray< T >::wxObjArray ( )

Default constructor initializes an empty array object.

template<typename T > wxArray< T >::wxObjArray (const wxObjArray & *array*)

Performs a deep copy (i.e. the array element are copied too).

template<typename T > wxArray< T >::wxSortedArray (int(*)(T first, T second) *compareFunction*)

There is no default constructor for wxSortedArray classes - you must initialize it with a function to use for item comparison.

It is a function which is passed two arguments of type `T` where `T` is the array element type and which should return a negative, zero or positive value according to whether the first element passed to it is less than, equal to or greater than the second one.

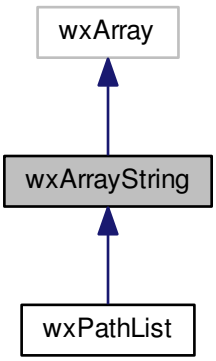
template<typename T > wxArray< T >::wxSortedArray (const wxSortedArray & *array*)

Performs a shallow array copy (i.e. doesn't copy the objects pointed to even if the source array contains the items of pointer type).

21.36 wxArrayString Class Reference

`#include <wx/arrstr.h>`

Inheritance diagram for wxArrayString:



21.36.1 Detailed Description

wxArrayString is an efficient container for storing wxString objects.

It has the same features as all wxArray classes, i.e. it dynamically expands when new items are added to it (so it is as easy to use as a linked list), but the access time to the elements is constant, instead of being linear in number of elements as in the case of linked lists. It is also very size efficient and doesn't take more space than a C array *wxString*[] type (wxArrayString uses its knowledge of internals of wxString class to achieve this).

This class is used in the same way as other dynamic arrays(), except that no WX_DEFINE_ARRAY declaration is needed for it. When a string is added or inserted in the array, a copy of the string is created, so the original string may be safely deleted (e.g. if it was a *wxChar* * pointer the memory it was using can be freed immediately after this). In general, there is no need to worry about string memory deallocation when using this class - it will always free the memory it uses itself.

The references returned by wxArrayString::Item, wxArrayString::Last or wxArrayString::operator[] are not constant, so the array elements may be modified in place like this:

```
array.Last().MakeUpper();
```

Note

none of the methods of wxArrayString is virtual including its destructor, so this class should not be used as a base class.

Although this is not true strictly speaking, this class may be considered as a specialization of wxArray class for the wxString member data: it is not implemented like this, but it does have all of the wxArray functions.

It also has the full set of `std::vector<wxString>` compatible methods, including nested `iterator` and `const_iterator` classes which should be used in the new code for forward compatibility with the future wxWidgets versions.

Library: wxBase

Category: Containers

See also

wxArray<T>, wxString, wxString Overview

Public Types

- typedef int(* CompareFunction)(const wxString &first, const wxString &second)

  The function type used with wxArrayString::Sort().

Public Member Functions

- wxArrayString ()

  Default constructor.
- wxArrayString (const wxArrayString &array)

  Copy constructor.
- wxArrayString (size_t sz, const wxString *arr)

  Constructor from a wxString array.
- ~wxArrayString ()

  Destructor frees memory occupied by the array strings.
- size_t Add (const wxString &str, size_t copies=1)

  Appends the given number of copies of the new item str to the array and returns the index of the first new item in the array.
- void Alloc (size_t nCount)

  Preallocates enough memory to store nCount items.
- void Clear ()

  Clears the array contents and frees memory.
- void Empty ()

  Empties the array: after a call to this function GetCount() will return 0.
- size_t GetCount () const

  Returns the number of items in the array.
- int Index (const wxString &sz, bool bCase=true, bool bFromEnd=false) const

  Search the element in the array, starting from the beginning if bFromEnd is false or from end otherwise.
- void Insert (wxString lItem, size_t nIndex, size_t copies=1)

Insert the given number of copies of the new element in the array before the position nIndex.

- bool IsEmpty () const

  Returns true if the array is empty, false otherwise.

- void Remove (const wxString &sz)

  Removes the first item matching this value.

- void RemoveAt (size_t nIndex, size_t count=1)

  Removes count items starting at position nIndex from the array.

- void Shrink ()

  Releases the extra memory allocated by the array.

- void Sort (bool reverseOrder=false)

  Sorts the array in alphabetical order or in reverse alphabetical order if reverseOrder is true.

- void Sort (CompareFunction compareFunction)

  Sorts the array using the specified compareFunction for item comparison.

- bool operator!= (const wxArrayString &array) const

  Compares 2 arrays respecting the case.

- wxArrayString & operator= (const wxArrayString &)

  Assignment operator.

- bool operator== (const wxArrayString &array) const

  Compares 2 arrays respecting the case.

- wxString & operator[] (size_t nIndex) const

  Return the array element at position nIndex.

- wxArrayString (size_t sz, const char **arr)

  Constructor from a C string array.

- wxArrayString (size_t sz, const wchar_t **arr)

  Constructor from a C string array.

- wxString & Item (size_t nIndex)

  Return the array element at position nIndex.

- const wxString & Item (size_t nIndex) const

  Return the array element at position nIndex.

- wxString & Last ()

  Returns the last element of the array.

- const wxString & Last () const

  Returns the last element of the array.

21.36.2 Member Typedef Documentation

typedef int(* wxArrayString::CompareFunction)(const wxString &first, const wxString &second)

The function type used with wxArrayString::Sort().

This function uses the same conventions as the standard `qsort()` comparison function, that is it should return a negative value if the first argument is less than the second one, a positive value if the first argument is greater than the second one and 0 if the arguments are equal.

Since

3.1.0

21.36.3 Constructor & Destructor Documentation

wxArrayString::wxArrayString ( )

Default constructor.

wxArrayString::wxArrayString (const wxArrayString & *array*)

Copy constructor.

wxArrayString::wxArrayString (size_t *sz,* const char ** *arr*)

Constructor from a C string array.

Pass a size *sz* and an array *arr*.

wxArrayString::wxArrayString (size_t *sz,* const wchar_t ** *arr*)

Constructor from a C string array.

Pass a size *sz* and an array *arr*.

wxArrayString::wxArrayString (size_t *sz,* const wxString * *arr*)

Constructor from a wxString array.

Pass a size *sz* and array *arr*.

wxArrayString::~wxArrayString ( )

Destructor frees memory occupied by the array strings.

For performance reasons it is not virtual, so this class should not be derived from.

21.36.4 Member Function Documentation

size_t wxArrayString::Add (const wxString & *str,* size_t *copies* = 1)

Appends the given number of *copies* of the new item *str* to the array and returns the index of the first new item in the array.

See also

Insert()

void wxArrayString::Alloc (size_t *nCount*)

Preallocates enough memory to store *nCount* items.

This function may be used to improve array class performance before adding a known number of items consecutively.

void wxArrayString::Clear ( )

Clears the array contents and frees memory.

See also

Empty()

void wxArrayString::Empty ( )

Empties the array: after a call to this function GetCount() will return 0.

However, this function does not free the memory used by the array and so should be used when the array is going to be reused for storing other strings. Otherwise, you should use Clear() to empty the array and free memory.

size_t wxArrayString::GetCount ( ) const

Returns the number of items in the array.

int wxArrayString::Index (const wxString & *sz*, bool *bCase* = `true`, bool *bFromEnd* = `false`) const

Search the element in the array, starting from the beginning if *bFromEnd* is false or from end otherwise.

If *bCase*, comparison is case sensitive (default), otherwise the case is ignored.

This function uses linear search for wxArrayString. Returns index of the first item matched or `wxNOT_FOUND` if there is no match.

void wxArrayString::Insert (wxString *lItem*, size_t *nIndex*, size_t *copies* = `1`)

Insert the given number of *copies* of the new element in the array before the position *nIndex*.

Thus, for example, to insert the string in the beginning of the array you would write:

```
Insert("foo", 0);
```

If *nIndex* is equal to GetCount() this function behaves as Add().

bool wxArrayString::IsEmpty ( ) const

Returns true if the array is empty, false otherwise.

This function returns the same result as GetCount() == 0 but is probably easier to read.

wxString& wxArrayString::Item (size_t *nIndex*)

Return the array element at position *nIndex*.

An assert failure will result from an attempt to access an element beyond the end of array in debug mode, but no check is done in release mode.

See also

operator[] for the operator version.

const wxString& wxArrayString::Item (size_t *nIndex*) const

Return the array element at position *nIndex*.

An assert failure will result from an attempt to access an element beyond the end of array in debug mode, but no check is done in release mode.

See also

operator[] for the operator version.

wxString& wxArrayString::Last ( )

Returns the last element of the array.

Attempt to access the last element of an empty array will result in assert failure in debug build, however no checks are done in release mode.

const wxString& wxArrayString::Last ( ) const

Returns the last element of the array.

Attempt to access the last element of an empty array will result in assert failure in debug build, however no checks are done in release mode.

bool wxArrayString::operator!= (const wxArrayString & *array*) const

Compares 2 arrays respecting the case.

Returns true if the arrays have different number of elements or if the elements don't match pairwise.

wxArrayString& wxArrayString::operator= (const wxArrayString &)

Assignment operator.

bool wxArrayString::operator== (const wxArrayString & *array*) const

Compares 2 arrays respecting the case.

Returns true only if the arrays have the same number of elements and the same strings in the same order.

wxString& wxArrayString::operator[] (size_t *nIndex*) const

Return the array element at position *nIndex*.

An assert failure will result from an attempt to access an element beyond the end of array in debug mode, but no check is done in release mode.

This is the operator version of the Item() method.

void wxArrayString::Remove (const wxString & *sz*)

Removes the first item matching this value.

An assert failure is provoked by an attempt to remove an element which does not exist in debug build.

See also

Index()

void wxArrayString::RemoveAt (size_t *nIndex*, size_t *count* = `1`)

Removes *count* items starting at position *nIndex* from the array.

void wxArrayString::Shrink ( )

Releases the extra memory allocated by the array.

This function is useful to minimize the array memory consumption.

See also

Alloc()

void wxArrayString::Sort (bool *reverseOrder* = `false`)

Sorts the array in alphabetical order or in reverse alphabetical order if *reverseOrder* is true.

The sort is case-sensitive.

void wxArrayString::Sort (CompareFunction *compareFunction*)

Sorts the array using the specified *compareFunction* for item comparison.

CompareFunction is defined as a function taking two *const wxString&* parameters and returning an *int* value less than, equal to or greater than 0 if the first string is less than, equal to or greater than the second one.

Example: The following example sorts strings by their length.

```
static int CompareStringLen(const wxString& first, const wxString& second)
{
    return first.length() - second.length();
}

...

wxArrayString array;

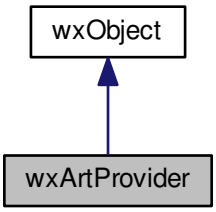
array.Add("one");
array.Add("two");
array.Add("three");
array.Add("four");

array.Sort(CompareStringLen);
```

21.37 wxArtProvider Class Reference

`#include <wx/artprov.h>`

Inheritance diagram for wxArtProvider:



21.37.1 Detailed Description

wxArtProvider class is used to customize the look of wxWidgets application.

When wxWidgets needs to display an icon or a bitmap (e.g. in the standard file dialog), it does not use a hard-coded resource but asks wxArtProvider for it instead. This way users can plug in their own wxArtProvider class and easily replace standard art with their own version.

All that is needed is to derive a class from wxArtProvider, override either its wxArtProvider::CreateBitmap() and/or its wxArtProvider::CreateIconBundle() methods and register the provider with wxArtProvider::Push():

```
class MyProvider : public wxArtProvider
{
protected:
  wxBitmap CreateBitmap(const wxArtID& id,
                        const wxArtClient& client,
                        const wxSize size)

  // optionally override this one as well
  wxIconBundle CreateIconBundle(const wxArtID& id,
                                const wxArtClient& client)
  { ... }
};
...
wxArtProvider::Push(new MyProvider);
```

If you need bitmap images (of the same artwork) that should be displayed at different sizes you should probably consider overriding wxArtProvider::CreateIconBundle and supplying icon bundles that contain different bitmap sizes.

There's another way of taking advantage of this class: you can use it in your code and use platform native icons as provided by wxArtProvider::GetBitmap or wxArtProvider::GetIcon.

21.37.2 Identifying art resources

Every bitmap and icon bundle are known to wxArtProvider under an unique ID that is used when requesting a resource from it. The ID is represented by the wxArtID type and can have one of these predefined values (you can see bitmaps represented by these constants in the Art Provider Sample):

- wxART_ERROR
- wxART_QUESTION
- wxART_WARNING
- wxART_INFORMATION
- wxART_ADD_BOOKMARK
- wxART_DEL_BOOKMARK
- wxART_HELP_SIDE_PANEL
- wxART_HELP_SETTINGS
- wxART_HELP_BOOK
- wxART_HELP_FOLDER
- wxART_HELP_PAGE
- wxART_GO_BACK
- wxART_GO_FORWARD
- wxART_GO_UP
- wxART_GO_DOWN
- wxART_GO_TO_PARENT
- wxART_GO_HOME
- wxART_GOTO_FIRST (since 2.9.2)
- wxART_GOTO_LAST (since 2.9.2)
- wxART_PRINT
- wxART_HELP
- wxART_TIP
- wxART_REPORT_VIEW
- wxART_LIST_VIEW
- wxART_NEW_DIR
- wxART_FOLDER
- wxART_FOLDER_OPEN
- wxART_GO_DIR_UP
- wxART_EXECUTABLE_FILE
- wxART_NORMAL_FILE
- wxART_TICK_MARK
- wxART_CROSS_MARK
- wxART_MISSING_IMAGE

- wxART_FLOPPY
- wxART_CDROM
- wxART_REMOVABLE

Additionally, any string recognized by custom art providers registered using wxArtProvider::Push may be used.

Note

When running under GTK+ 2, GTK+ stock item IDs (e.g. "gtk-cdrom") may be used as well:

```
#ifdef __WXGTK__
    wxBitmap bmp = wxArtProvider::GetBitmap("gtk-cdrom",
      wxART_MENU);
#endif
```

For a list of the GTK+ stock items please refer to the GTK+ documentation page. It is also possible to load icons from the current icon theme by specifying their name (without extension and directory components). Icon themes recognized by GTK+ follow the freedesktop.org Icon Themes specification. Note that themes are not guaranteed to contain all icons, so wxArtProvider may return wxNullBitmap or wxNullIcon. The default theme is typically installed in /usr/share/icons/hicolor.

21.37.3 Clients

The *client* is the entity that calls wxArtProvider's GetBitmap() or GetIcon() function. It is represented by wxClientID type and can have one of these values:

- wxART_TOOLBAR
- wxART_MENU

- wxART_BUTTON
- wxART_FRAME_ICON
- wxART_CMN_DIALOG
- wxART_HELP_BROWSER
- wxART_MESSAGE_BOX
- wxART_OTHER (used for all requests that don't fit into any of the categories above)

Client ID serve as a hint to wxArtProvider that is supposed to help it to choose the best looking bitmap. For example it is often desirable to use slightly different icons in menus and toolbars even though they represent the same action (e.g. wxART_FILE_OPEN). Remember that this is really only a hint for wxArtProvider – it is common that wxArtProvider::GetBitmap returns identical bitmap for different client values!

Library: wxCore

Category: Miscellaneous

See also

Art Provider Sample for an example of wxArtProvider usage; stock ID list

Public Member Functions

- virtual ~wxArtProvider ()

  The destructor automatically removes the provider from the provider stack used by GetBitmap().

Static Public Member Functions

- static bool Delete (wxArtProvider *provider)

  Delete the given provider.
- static wxBitmap GetBitmap (const wxArtID &id, const wxArtClient &client=wxART_OTHER, const wxSize &size=wxDefaultSize)

  Query registered providers for bitmap with given ID.
- static wxIcon GetIcon (const wxArtID &id, const wxArtClient &client=wxART_OTHER, const wxSize &size=wxDefaultSize)

  Same as wxArtProvider::GetBitmap, but return a wxIcon object (or wxNullIcon on failure).
- static wxSize GetNativeSizeHint (const wxArtClient &client)

  Returns native icon size for use specified by client hint.
- static wxSize GetSizeHint (const wxArtClient &client, bool platform_default=false)

  Returns a suitable size hint for the given wxArtClient.
- static wxIconBundle GetIconBundle (const wxArtID &id, const wxArtClient &client=wxART_OTHER)

  Query registered providers for icon bundle with given ID.
- static bool HasNativeProvider ()

  Returns true if the platform uses native icons provider that should take precedence over any customizations.
- static void Insert (wxArtProvider *provider)
- static bool Pop ()

  Remove latest added provider and delete it.
- static void Push (wxArtProvider *provider)

  Register new art provider and add it to the top of providers stack (i.e.

- static void PushBack (wxArtProvider *provider)

  Register new art provider and add it to the bottom of providers stack.
- static bool Remove (wxArtProvider *provider)

  Remove a provider from the stack if it is on it.
- static wxArtID GetMessageBoxIconId (int flags)

  Helper used by GetMessageBoxIcon(): return the art id corresponding to the standard wxICON_INFORMATION/↩ WARNING/ERROR/QUESTION flags (only one can be set)
- static wxIcon GetMessageBoxIcon (int flags)

  Helper used by several generic classes: return the icon corresponding to the standard wxICON_INFORMATION/↩ WARNING/ERROR/QUESTION flags (only one can be set)

Protected Member Functions

- virtual wxBitmap CreateBitmap (const wxArtID &id, const wxArtClient &client, const wxSize &size)

  Derived art provider classes must override this method to create requested art resource.
- virtual wxIconBundle CreateIconBundle (const wxArtID &id, const wxArtClient &client)

  This method is similar to CreateBitmap() but can be used when a bitmap (or an icon) exists in several sizes.

Additional Inherited Members

21.37.4 Constructor & Destructor Documentation

virtual wxArtProvider::~wxArtProvider ( ) `[virtual]`

The destructor automatically removes the provider from the provider stack used by GetBitmap().

21.37.5 Member Function Documentation

virtual wxBitmap wxArtProvider::CreateBitmap (const wxArtID & *id*, const wxArtClient & *client*, const wxSize & *size*) `[protected], [virtual]`

Derived art provider classes must override this method to create requested art resource.

Note that returned bitmaps are cached by wxArtProvider and it is therefore not necessary to optimize CreateBitmap() for speed (e.g. you may create wxBitmap objects from XPMs here).

Parameters

id	wxArtID unique identifier of the bitmap.
client	wxArtClient identifier of the client (i.e. who is asking for the bitmap). This only servers as a hint.
size	Preferred size of the bitmap. The function may return a bitmap of different dimensions, it will be automatically rescaled to meet client's request.

Note

This is not part of wxArtProvider's public API, use wxArtProvider::GetBitmap or wxArtProvider::GetIconBundle or wxArtProvider::GetIcon to query wxArtProvider for a resource.

See also

CreateIconBundle()

virtual **wxIconBundle** wxArtProvider::CreateIconBundle (const **wxArtID** & *id*, const **wxArtClient** & *client*) [protected], [virtual]

This method is similar to CreateBitmap() but can be used when a bitmap (or an icon) exists in several sizes.

static bool wxArtProvider::Delete (**wxArtProvider** * *provider*) [static]

Delete the given *provider*.

static **wxBitmap** wxArtProvider::GetBitmap (const **wxArtID** & *id*, const **wxArtClient** & *client* = **wxART_OTHER**, const **wxSize** & *size* = **wxDefaultSize**) [static]

Query registered providers for bitmap with given ID.

Parameters

id	wxArtID unique identifier of the bitmap.
client	wxArtClient identifier of the client (i.e. who is asking for the bitmap).
size	Size of the returned bitmap or wxDefaultSize if size doesn't matter.

Returns

The bitmap if one of registered providers recognizes the ID or wxNullBitmap otherwise.

static **wxIcon** wxArtProvider::GetIcon (const **wxArtID** & *id*, const **wxArtClient** & *client* = **wxART_OTHER**, const **wxSize** & *size* = **wxDefaultSize**) [static]

Same as wxArtProvider::GetBitmap, but return a wxIcon object (or wxNullIcon on failure).

static **wxIconBundle** wxArtProvider::GetIconBundle (const **wxArtID** & *id*, const **wxArtClient** & *client* = **wxART_OTHER**) [static]

Query registered providers for icon bundle with given ID.

Parameters

id	wxArtID unique identifier of the icon bundle.
client	wxArtClient identifier of the client (i.e. who is asking for the icon bundle).

Returns

The icon bundle if one of registered providers recognizes the ID or wxNullIconBundle otherwise.

static **wxIcon** wxArtProvider::GetMessageBoxIcon (int *flags*) [static]

Helper used by several generic classes: return the icon corresponding to the standard wxICON_INFORMATION/↩ WARNING/ERROR/QUESTION flags (only one can be set)

static **wxArtID** wxArtProvider::GetMessageBoxIconId (int *flags*) [static]

Helper used by GetMessageBoxIcon(): return the art id corresponding to the standard wxICON_INFORMATION/↩ WARNING/ERROR/QUESTION flags (only one can be set)

static wxSize wxArtProvider::GetNativeSizeHint (const wxArtClient & *client*) `[static]`

Returns native icon size for use specified by *client* hint.

If the platform has no commonly used default for this use or if *client* is not recognized, returns wxDefaultSize.

Note

In some cases, a platform may have *several* appropriate native sizes (for example, wxART_FRAME_ICON for frame icons). In that case, this method returns only one of them, picked reasonably.

Since

2.9.0

static wxSize wxArtProvider::GetSizeHint (const wxArtClient & *client*, bool *platform_default* = `false`) `[static]`

Returns a suitable size hint for the given *wxArtClient*.

If *platform_default* is true, return a size based on the current platform using GetNativeSizeHint(), otherwise return the size from the topmost wxArtProvider. *wxDefaultSize* may be returned if the client doesn't have a specified size, like wxART_OTHER for example.

See also

GetNativeSizeHint()

static bool wxArtProvider::HasNativeProvider ( ) `[static]`

Returns true if the platform uses native icons provider that should take precedence over any customizations.

This is true for any platform that has user-customizable icon themes, currently only wxGTK.

A typical use for this method is to decide whether a custom art provider should be plugged in using Push() or PushBack().

Since

2.9.0

static void wxArtProvider::Insert (wxArtProvider * *provider*) `[static]`

Deprecated Use PushBack() instead.

static bool wxArtProvider::Pop ( ) `[static]`

Remove latest added provider and delete it.

static void wxArtProvider::Push (wxArtProvider * *provider*) `[static]`

Register new art provider and add it to the top of providers stack (i.e.

it will be queried as the first provider).

See also

PushBack()

static void wxArtProvider::PushBack (wxArtProvider * *provider*) [static]

Register new art provider and add it to the bottom of providers stack.

In other words, it will be queried as the last one, after all others, including the default provider.

See also

Push()

Since

2.9.0

static bool wxArtProvider::Remove (wxArtProvider * *provider*) [static]

Remove a provider from the stack if it is on it.

The provider is not deleted, unlike when using Delete().

Public Member Functions

- wxAuiDefaultTabArt ()
- virtual ~wxAuiDefaultTabArt ()
- wxAuiTabArt * Clone ()

  Clones the art object.
- void SetFlags (unsigned int flags)

  Sets flags.
- void SetSizingInfo (const wxSize &tabCtrlSize, size_t tabCount)

  Sets sizing information.
- void SetNormalFont (const wxFont &font)

  Sets the normal font for drawing labels.
- void SetSelectedFont (const wxFont &font)

  Sets the font for drawing text for selected UI elements.
- void SetMeasuringFont (const wxFont &font)

  Sets the font used for calculating measurements.
- void SetColour (const wxColour &colour)

  Sets the colour of the inactive tabs.
- void SetActiveColour (const wxColour &colour)

  Sets the colour of the selected tab.
- void DrawBackground (wxDC &dc, wxWindow *wnd, const wxRect &rect)

  Draws a background on the given area.
- void DrawTab (wxDC &dc, wxWindow *wnd, const wxAuiNotebookPage &pane, const wxRect &inRect, int closeButtonState, wxRect *outTabRect, wxRect *outButtonRect, int *xExtent)

  Draws a tab.
- void DrawButton (wxDC &dc, wxWindow *wnd, const wxRect &inRect, int bitmapId, int buttonState, int orientation, wxRect *outRect)

  Draws a button.
- int GetIndentSize ()

  Returns the indent size.
- wxSize GetTabSize (wxDC &dc, wxWindow *wnd, const wxString &caption, const wxBitmap &bitmap, bool active, int closeButtonState, int *xExtent)

  Returns the tab size for the given caption, bitmap and state.
- int ShowDropDown (wxWindow *wnd, const wxAuiNotebookPageArray &items, int activeIdx)
- int GetBestTabCtrlSize (wxWindow *wnd, const wxAuiNotebookPageArray &pages, const wxSize &requiredBmpSize)

  Returns the tab control size.

21.40 wxAuiDockArt Class Reference

`#include <wx/aui/dockart.h>`

21.40.1 Detailed Description

wxAuiDockArt is part of the wxAUI class framework.

See also wxAUI Overview.

wxAuiDockArt is the art provider: provides all drawing functionality to the wxAui dock manager. This allows the dock manager to have a plugable look-and-feel.

By default, a wxAuiManager uses an instance of this class called wxAuiDefaultDockArt which provides bitmap art and a colour scheme that is adapted to the major platforms' look. You can either derive from that class to alter its behaviour or write a completely new dock art class. Call wxAuiManager::SetArtProvider to force wxAUI to use your new dock art provider.

virtual void wxAuiDockArt::SetMetric (int *id,* int *new_val*) [pure virtual]

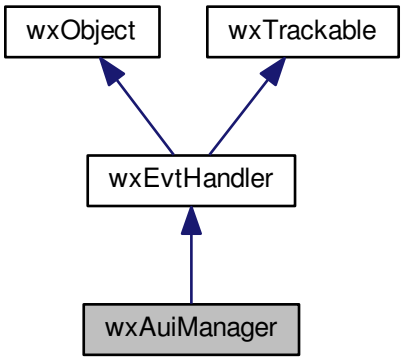
Set a certain setting with the value *new_val*.

id can be one of the size values of **wxAuiPaneDockArtSetting**.

21.41 wxAuiManager Class Reference

```
#include <wx/aui/framemanager.h>
```

Inheritance diagram for wxAuiManager:



21.41.1 Detailed Description

wxAuiManager is the central class of the wxAUI class framework.

wxAuiManager manages the panes associated with it for a particular wxFrame, using a pane's wxAuiPaneInfo information to determine each pane's docking and floating behaviour.

wxAuiManager uses wxWidgets' sizer mechanism to plan the layout of each frame. It uses a replaceable dock art class to do all drawing, so all drawing is localized in one area, and may be customized depending on an application's specific needs.

wxAuiManager works as follows: the programmer adds panes to the class, or makes changes to existing pane properties (dock position, floating state, show state, etc.). To apply these changes, wxAuiManager's Update() function is called. This batch processing can be used to avoid flicker, by modifying more than one pane at a time, and then "committing" all of the changes at once by calling Update().

Panes can be added quite easily:

```
wxTextCtrl* text1 = new wxTextCtrl(this, -1);
wxTextCtrl* text2 = new wxTextCtrl(this, -1);
m_mgr.AddPane(text1, wxLEFT, "Pane Caption");
m_mgr.AddPane(text2, wxBOTTOM, "Pane Caption");
m_mgr.Update();
```

Later on, the positions can be modified easily. The following will float an existing pane in a tool window:

```
m_mgr.GetPane(text1).Float();
```

21.41.2 Layers, Rows and Directions, Positions

Inside wxAUI, the docking layout is figured out by checking several pane parameters. Four of these are important for determining where a pane will end up:

- Direction: Each docked pane has a direction, Top, Bottom, Left, Right, or Center. This is fairly self-explanatory. The pane will be placed in the location specified by this variable.
- Position: More than one pane can be placed inside of a dock. Imagine two panes being docked on the left side of a window. One pane can be placed over another. In proportionally managed docks, the pane position

indicates its sequential position, starting with zero. So, in our scenario with two panes docked on the left side, the top pane in the dock would have position 0, and the second one would occupy position 1.

- Row: A row can allow for two docks to be placed next to each other. One of the most common places for this to happen is in the toolbar. Multiple toolbar rows are allowed, the first row being row 0, and the second row 1. Rows can also be used on vertically docked panes.
- Layer: A layer is akin to an onion. Layer 0 is the very center of the managed pane. Thus, if a pane is in layer 0, it will be closest to the center window (also sometimes known as the "content window"). Increasing layers "swallow up" all layers of a lower value. This can look very similar to multiple rows, but is different because all panes in a lower level yield to panes in higher levels. The best way to understand layers is by running the wxAUI sample.

Styles

This class supports the following styles:

- wxAUI_MGR_ALLOW_FLOATING: Allow a pane to be undocked to take the form of a wxMiniFrame.
- wxAUI_MGR_ALLOW_ACTIVE_PANE: Change the color of the title bar of the pane when it is activated.
- wxAUI_MGR_TRANSPARENT_DRAG: Make the pane transparent during its movement.
- wxAUI_MGR_TRANSPARENT_HINT: The possible location for docking is indicated by a translucent area.
- wxAUI_MGR_VENETIAN_BLINDS_HINT: The possible location for docking is indicated by gradually appearing partially transparent hint.
- wxAUI_MGR_RECTANGLE_HINT: The possible location for docking is indicated by a rectangular outline.
- wxAUI_MGR_HINT_FADE: The translucent area where the pane could be docked appears gradually.
- wxAUI_MGR_NO_VENETIAN_BLINDS_FADE: Used in complement of wxAUI_MGR_VENETIAN_BLIND↩ S_HINT to show the docking hint immediately.
- wxAUI_MGR_LIVE_RESIZE: When a docked pane is resized, its content is refreshed in live (instead of moving the border alone and refreshing the content at the end).
- wxAUI_MGR_DEFAULT: Default behavior, combines: wxAUI_MGR_ALLOW_FLOATING | wxAUI_MGR_↩ TRANSPARENT_HINT | wxAUI_MGR_HINT_FADE | wxAUI_MGR_NO_VENETIAN_BLINDS_FADE.

Events emitted by this class

The following event handler macros redirect the events to member function handlers '**func**' with prototypes like: void handlerFuncName(wxAuiManagerEvent& event)

Event macros for events emitted by this class:

- EVT_AUI_PANE_BUTTON(func): Triggered when any button is pressed for any docked panes.
- EVT_AUI_PANE_CLOSE(func): Triggered when a docked or floating pane is closed.
- EVT_AUI_PANE_MAXIMIZE(func): Triggered when a pane is maximized.
- EVT_AUI_PANE_RESTORE(func): Triggered when a pane is restored.
- EVT_AUI_PANE_ACTIVATED(func): Triggered when a pane is made 'active'. This event is new since wx↩ Widgets 2.9.4.
- EVT_AUI_RENDER(func): This event can be caught to override the default renderer in order to custom draw your wxAuiManager window (not recommended).

wxAUI Overview, wxAuiNotebook, wxAuiDockArt, wxAuiPaneInfo

Public Member Functions

- wxAuiManager (wxWindow *managed_wnd=NULL, unsigned int flags=wxAUI_MGR_DEFAULT)

  Constructor.
- virtual ~wxAuiManager ()

  Dtor.
- bool DetachPane (wxWindow *window)

  Tells the wxAuiManager to stop managing the pane specified by window.
- wxAuiPaneInfoArray & GetAllPanes ()

  Returns an array of all panes managed by the frame manager.
- wxAuiDockArt * GetArtProvider () const

  Returns the current art provider being used.
- void GetDockSizeConstraint (double *widthpct, double *heightpct) const

  Returns the current dock constraint values.
- unsigned int GetFlags () const

  Returns the current wxAuiManagerOption's flags.
- wxWindow * GetManagedWindow () const

  Returns the frame currently being managed by wxAuiManager.
- virtual void HideHint ()

  HideHint() hides any docking hint that may be visible.
- bool InsertPane (wxWindow *window, const wxAuiPaneInfo &insert_location, int insert_level=wxAUI_INSE↩ RT_PANE)

  This method is used to insert either a previously unmanaged pane window into the frame manager, or to insert a currently managed pane somewhere else.
- void LoadPaneInfo (wxString pane_part, wxAuiPaneInfo &pane)

  LoadPaneInfo() is similar to LoadPerspective, with the exception that it only loads information about a single pane.
- bool LoadPerspective (const wxString &perspective, bool update=true)

  Loads a saved perspective.
- wxString SavePaneInfo (wxAuiPaneInfo &pane)

  SavePaneInfo() is similar to SavePerspective, with the exception that it only saves information about a single pane.
- wxString SavePerspective ()

  Saves the entire user interface layout into an encoded wxString, which can then be stored by the application (probably using wxConfig).
- void SetArtProvider (wxAuiDockArt *art_provider)

  Instructs wxAuiManager to use art provider specified by parameter art_provider for all drawing calls.
- void SetDockSizeConstraint (double widthpct, double heightpct)

  When a user creates a new dock by dragging a window into a docked position, often times the large size of the window will create a dock that is unwieldly large.
- void SetFlags (unsigned int flags)

  This method is used to specify wxAuiManagerOption's flags.
- void SetManagedWindow (wxWindow *managed_wnd)

  Called to specify the frame or window which is to be managed by wxAuiManager.
- virtual void ShowHint (const wxRect &rect)

This function is used by controls to explicitly show a hint window at the specified rectangle.

- void UnInit ()

  Uninitializes the framework and should be called before a managed frame or window is destroyed.

- void Update ()

  This method is called after any number of changes are made to any of the managed panes.

- bool AddPane (wxWindow *window, const wxAuiPaneInfo &pane_info)

  AddPane() tells the frame manager to start managing a child window.

- bool AddPane (wxWindow *window, int direction=wxLEFT, const wxString &caption=wxEmptyString)

  AddPane() tells the frame manager to start managing a child window.

- bool AddPane (wxWindow *window, const wxAuiPaneInfo &pane_info, const wxPoint &drop_pos)

  AddPane() tells the frame manager to start managing a child window.

- wxAuiPaneInfo & GetPane (wxWindow *window)

  GetPane() is used to lookup a wxAuiPaneInfo object either by window pointer or by pane name, which acts as a unique id for a window pane.

- wxAuiPaneInfo & GetPane (const wxString &name)

  GetPane() is used to lookup a wxAuiPaneInfo object either by window pointer or by pane name, which acts as a unique id for a window pane.

Static Public Member Functions

- static wxAuiManager * GetManager (wxWindow *window)

  Calling this method will return the wxAuiManager for a given window.

Protected Member Functions

- virtual bool ProcessDockResult (wxAuiPaneInfo &target, const wxAuiPaneInfo &new_pos)

  ProcessDockResult() is a protected member of the wxAUI layout manager.

Additional Inherited Members

21.41.3 Constructor & Destructor Documentation

wxAuiManager::wxAuiManager (wxWindow * *managed_wnd* = NULL, unsigned int *flags* = wxAUI_MGR_DEFAULT)

Constructor.

Parameters

managed_wnd	Specifies the wxFrame which should be managed.
flags	Specifies the frame management behaviour and visual effects with the wxAuiManager↩ Option's style flags.

virtual wxAuiManager::~wxAuiManager ( ) [virtual]

Dtor.

21.41.4 Member Function Documentation

bool wxAuiManager::AddPane (wxWindow * *window,* const wxAuiPaneInfo & *pane_info*)

AddPane() tells the frame manager to start managing a child window.

There are several versions of this function. The first version allows the full spectrum of pane parameter possibilities. The second version is used for simpler user interfaces which do not require as much configuration. The last version allows a drop position to be specified, which will determine where the pane will be added.

bool wxAuiManager::AddPane (wxWindow * *window,* int *direction* = wxLEFT, const wxString & *caption* = wxEmptyString)

AddPane() tells the frame manager to start managing a child window.

There are several versions of this function. The first version allows the full spectrum of pane parameter possibilities. The second version is used for simpler user interfaces which do not require as much configuration. The last version allows a drop position to be specified, which will determine where the pane will be added.

bool wxAuiManager::AddPane (wxWindow * *window,* const wxAuiPaneInfo & *pane_info,* const wxPoint & *drop_pos*)

AddPane() tells the frame manager to start managing a child window.

There are several versions of this function. The first version allows the full spectrum of pane parameter possibilities. The second version is used for simpler user interfaces which do not require as much configuration. The last version allows a drop position to be specified, which will determine where the pane will be added.

bool wxAuiManager::DetachPane (wxWindow * *window*)

Tells the wxAuiManager to stop managing the pane specified by window.

The window, if in a floated frame, is reparented to the frame managed by wxAuiManager.

wxAuiPaneInfoArray& wxAuiManager::GetAllPanes ( )

Returns an array of all panes managed by the frame manager.

wxAuiDockArt* wxAuiManager::GetArtProvider ( ) const

Returns the current art provider being used.

See also

wxAuiDockArt.

void wxAuiManager::GetDockSizeConstraint (double * *widthpct,* double * *heightpct*) const

Returns the current dock constraint values.

See SetDockSizeConstraint() for more information.

unsigned int wxAuiManager::GetFlags ( ) const

Returns the current wxAuiManagerOption's flags.

wxWindow* wxAuiManager::GetManagedWindow ( ) const

Returns the frame currently being managed by wxAuiManager.

static wxAuiManager* wxAuiManager::GetManager (wxWindow * *window*) [static]

Calling this method will return the wxAuiManager for a given window.

The *window* parameter should specify any child window or sub-child window of the frame or window managed by wxAuiManager.

The *window* parameter need not be managed by the manager itself, nor does it even need to be a child or sub-child of a managed window. It must however be inside the window hierarchy underneath the managed window.

wxAuiPaneInfo& wxAuiManager::GetPane (wxWindow * *window*)

GetPane() is used to lookup a wxAuiPaneInfo object either by window pointer or by pane name, which acts as a unique id for a window pane.

The returned wxAuiPaneInfo object may then be modified to change a pane's look, state or position. After one or more modifications to wxAuiPaneInfo, wxAuiManager::Update() should be called to commit the changes to the user interface. If the lookup failed (meaning the pane could not be found in the manager), a call to the returned wxAuiPaneInfo's IsOk() method will return false.

wxAuiPaneInfo& wxAuiManager::GetPane (const wxString & *name*)

GetPane() is used to lookup a wxAuiPaneInfo object either by window pointer or by pane name, which acts as a unique id for a window pane.

The returned wxAuiPaneInfo object may then be modified to change a pane's look, state or position. After one or more modifications to wxAuiPaneInfo, wxAuiManager::Update() should be called to commit the changes to the user interface. If the lookup failed (meaning the pane could not be found in the manager), a call to the returned wxAuiPaneInfo's IsOk() method will return false.

virtual void wxAuiManager::HideHint ( ) [virtual]

HideHint() hides any docking hint that may be visible.

bool wxAuiManager::InsertPane (wxWindow * *window,* const wxAuiPaneInfo & *insert_location,* int *insert_level* = wxAUI_INSERT_PANE)

This method is used to insert either a previously unmanaged pane window into the frame manager, or to insert a currently managed pane somewhere else.

InsertPane() will push all panes, rows, or docks aside and insert the window into the position specified by *insert_location*.

Because *insert_location* can specify either a pane, dock row, or dock layer, the *insert_level* parameter is used to disambiguate this. The parameter *insert_level* can take a value of wxAUI_INSERT_PANE, wxAUI_INSERT_ROW or wxAUI_INSERT_DOCK.

void wxAuiManager::LoadPaneInfo (wxString *pane_part,* wxAuiPaneInfo & *pane*)

LoadPaneInfo() is similar to LoadPerspective, with the exception that it only loads information about a single pane.

It is used in combination with SavePaneInfo().

bool wxAuiManager::LoadPerspective (const wxString & *perspective,* bool *update* = `true`)

Loads a saved perspective.

If update is true, wxAuiManager::Update() is automatically invoked, thus realizing the saved perspective on screen.

virtual bool wxAuiManager::ProcessDockResult (wxAuiPaneInfo & *target,* const wxAuiPaneInfo & *new_pos*) `[protected], [virtual]`

ProcessDockResult() is a protected member of the wxAUI layout manager.

It can be overridden by derived classes to provide custom docking calculations.

wxString wxAuiManager::SavePaneInfo (wxAuiPaneInfo & *pane*)

SavePaneInfo() is similar to SavePerspective, with the exception that it only saves information about a single pane.

It is used in combination with LoadPaneInfo().

wxString wxAuiManager::SavePerspective ( )

Saves the entire user interface layout into an encoded wxString, which can then be stored by the application (probably using wxConfig).

When a perspective is restored using LoadPerspective(), the entire user interface will return to the state it was when the perspective was saved.

void wxAuiManager::SetArtProvider (wxAuiDockArt * *art_provider*)

Instructs wxAuiManager to use art provider specified by parameter *art_provider* for all drawing calls.

This allows plugable look-and-feel features. The previous art provider object, if any, will be deleted by wxAui↩ Manager.

See also

wxAuiDockArt.

void wxAuiManager::SetDockSizeConstraint (double *widthpct,* double *heightpct*)

When a user creates a new dock by dragging a window into a docked position, often times the large size of the window will create a dock that is unwieldly large.

wxAuiManager by default limits the size of any new dock to 1/3 of the window size. For horizontal docks, this would be 1/3 of the window height. For vertical docks, 1/3 of the width.

Calling this function will adjust this constraint value. The numbers must be between 0.0 and 1.0. For instance, calling SetDockSizeContraint with 0.5, 0.5 will cause new docks to be limited to half of the size of the entire managed window.

void wxAuiManager::SetFlags (unsigned int *flags*)

This method is used to specify wxAuiManagerOption's flags.

flags specifies options which allow the frame management behaviour to be modified.

void wxAuiManager::SetManagedWindow (wxWindow * *managed_wnd*)

Called to specify the frame or window which is to be managed by wxAuiManager.

Frame management is not restricted to just frames. Child windows or custom controls are also allowed.

virtual void wxAuiManager::ShowHint (const wxRect & *rect*) [virtual]

This function is used by controls to explicitly show a hint window at the specified rectangle.

It is rarely called, and is mostly used by controls implementing custom pane drag/drop behaviour. The specified rectangle should be in screen coordinates.

void wxAuiManager::UnInit ( )

Uninitializes the framework and should be called before a managed frame or window is destroyed.

UnInit() is usually called in the managed wxFrame's destructor. It is necessary to call this function before the managed frame or window is destroyed, otherwise the manager cannot remove its custom event handlers from a window.

void wxAuiManager::Update ( )

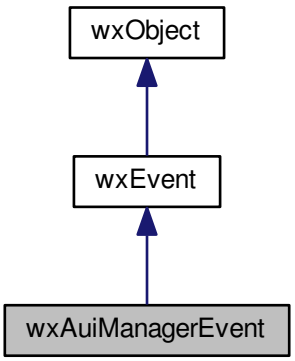
This method is called after any number of changes are made to any of the managed panes.

Update() must be invoked after AddPane() or InsertPane() are called in order to "realize" or "commit" the changes. In addition, any number of changes may be made to wxAuiPaneInfo structures (retrieved with wxAuiManager::GetPane), but to realize the changes, Update() must be called. This construction allows pane flicker to be avoided by updating the whole layout at one time.

21.42 wxAuiManagerEvent Class Reference

`#include <wx/aui/framemanager.h>`

Inheritance diagram for wxAuiManagerEvent:



21.42.1 Detailed Description

Event used to indicate various actions taken with wxAuiManager.

See wxAuiManager for available event types.

Events using this class

The following event handler macros redirect the events to member function handlers '**func**' with prototypes like: void handlerFuncName(wxAuiManagerEvent& event)

Event macros:

- EVT_AUI_PANE_BUTTON(func): Triggered when any button is pressed for any docked panes.
- EVT_AUI_PANE_CLOSE(func): Triggered when a docked or floating pane is closed.
- EVT_AUI_PANE_MAXIMIZE(func): Triggered when a pane is maximized.
- EVT_AUI_PANE_RESTORE(func): Triggered when a pane is restored.
- EVT_AUI_PANE_ACTIVATED(func): Triggered when a pane is made 'active'. This event is new since wx↩ Widgets 2.9.4.
- EVT_AUI_RENDER(func): This event can be caught to override the default renderer in order to custom draw your wxAuiManager window (not recommended).

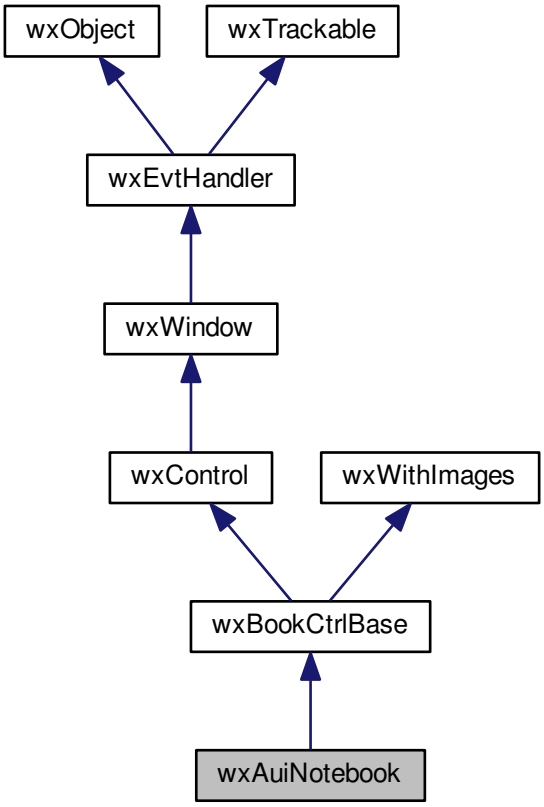
21.43 wxAuiNotebook Class Reference

`#include <wx/aui/auibook.h>`

Inheritance diagram for wxAuiNotebook:



21.43.1 Detailed Description

wxAuiNotebook is part of the wxAUI class framework, which represents a notebook control, managing multiple windows with associated tabs.

See also wxAUI Overview.

wxAuiNotebook is a notebook control which implements many features common in applications with dockable panes. Specifically, wxAuiNotebook implements functionality which allows the user to rearrange tab order via drag-and-drop, split the tab window into many different splitter configurations, and toggle through different themes to customize the control's look and feel.

The appearance of this class is configurable and can be changed by calling wxAuiNotebook::SetArtProvider(). By default, native art provider is used if available (currently only in wxGTK) and wxAuiGenericTabArt otherwise.

Styles

This class supports the following styles:

- wxAUI_NB_DEFAULT_STYLE: Defined as wxAUI_NB_TOP | wxAUI_NB_TAB_SPLIT | wxAUI_NB_TAB_↩ MOVE | wxAUI_NB_SCROLL_BUTTONS | wxAUI_NB_CLOSE_ON_ACTIVE_TAB | wxAUI_NB_MIDDLE↩ _CLICK_CLOSE.

- wxAUI_NB_TAB_SPLIT: Allows the tab control to be split by dragging a tab.
- wxAUI_NB_TAB_MOVE: Allows a tab to be moved horizontally by dragging.
- wxAUI_NB_TAB_EXTERNAL_MOVE: Allows a tab to be moved to another tab control.
- wxAUI_NB_TAB_FIXED_WIDTH: With this style, all tabs have the same width.
- wxAUI_NB_SCROLL_BUTTONS: With this style, left and right scroll buttons are displayed.
- wxAUI_NB_WINDOWLIST_BUTTON: With this style, a drop-down list of windows is available.
- wxAUI_NB_CLOSE_BUTTON: With this style, a close button is available on the tab bar.
- wxAUI_NB_CLOSE_ON_ACTIVE_TAB: With this style, the close button is visible on the active tab.
- wxAUI_NB_CLOSE_ON_ALL_TABS: With this style, the close button is visible on all tabs.
- wxAUI_NB_MIDDLE_CLICK_CLOSE: With this style, middle click on a tab closes the tab.
- wxAUI_NB_TOP: With this style, tabs are drawn along the top of the notebook.
- wxAUI_NB_BOTTOM: With this style, tabs are drawn along the bottom of the notebook.

Events emitted by this class

The following event handler macros redirect the events to member function handlers '**func**' with prototypes like: void handlerFuncName(wxAuiNotebookEvent& event)

Event macros for events emitted by this class:

- EVT_AUINOTEBOOK_PAGE_CLOSE(id, func): A page is about to be closed. Processes a `wxEVT_AUINOTEBOOK_PAGE_CLOSE` event.
- EVT_AUINOTEBOOK_PAGE_CLOSED(winid, fn): A page has been closed. Processes a `wxEVT_AUINOTEBOOK_PAGE_CLOSED` event.
- EVT_AUINOTEBOOK_PAGE_CHANGED(id, func): The page selection was changed. Processes a `wxEVT_AUINOTEBOOK_PAGE_CHANGED` event.
- EVT_AUINOTEBOOK_PAGE_CHANGING(id, func): The page selection is about to be changed. Processes a `wxEVT_AUINOTEBOOK_PAGE_CHANGING` event. This event can be vetoed.
- EVT_AUINOTEBOOK_BUTTON(id, func): The window list button has been pressed. Processes a `wxEVT_AUINOTEBOOK_BUTTON` event.
- EVT_AUINOTEBOOK_BEGIN_DRAG(id, func): Dragging is about to begin. Processes a `wxEVT_AUINOTEBOOK_BEGIN_DRAG` event.
- EVT_AUINOTEBOOK_END_DRAG(id, func): Dragging has ended. Processes a `wxEVT_AUINOTEBOOK_END_DRAG` event.
- EVT_AUINOTEBOOK_DRAG_MOTION(id, func): Emitted during a drag and drop operation. Processes a `wxEVT_AUINOTEBOOK_DRAG_MOTION` event.
- EVT_AUINOTEBOOK_ALLOW_DND(id, func): Whether to allow a tab to be dropped. Processes a `wxEVT_AUINOTEBOOK_ALLOW_DND` event. This event must be specially allowed.
- EVT_AUINOTEBOOK_DRAG_DONE(winid, fn): Notify that the tab has been dragged. Processes a `wxEVT_AUINOTEBOOK_DRAG_DONE` event.
- EVT_AUINOTEBOOK_TAB_MIDDLE_DOWN(winid, fn): The middle mouse button is pressed on a tab. Processes a `wxEVT_AUINOTEBOOK_TAB_MIDDLE_DOWN` event.
- EVT_AUINOTEBOOK_TAB_MIDDLE_UP(winid, fn): The middle mouse button is released on a tab. Processes a `wxEVT_AUINOTEBOOK_TAB_MIDDLE_UP` event.

- EVT_AUINOTEBOOK_TAB_RIGHT_DOWN(winid, fn): The right mouse button is pressed on a tab. Processes a `wxEVT_AUINOTEBOOK_TAB_RIGHT_DOWN` event.
- EVT_AUINOTEBOOK_TAB_RIGHT_UP(winid, fn): The right mouse button is released on a tab. Processes a `wxEVT_AUINOTEBOOK_TAB_RIGHT_UP` event.
- EVT_AUINOTEBOOK_BG_DCLICK(winid, fn): Double clicked on the tabs background area. Processes a `wxEVT_AUINOTEBOOK_BG_DCLICK` event.

Library: wxAui

Category: Window Docking (wxAUI)

Public Member Functions

- wxAuiNotebook ()

  Default ctor.
- wxAuiNotebook (wxWindow *parent, wxWindowID id=wxID_ANY, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, long style=wxAUI_NB_DEFAULT_STYLE)

  Constructor.
- bool AddPage (wxWindow *page, const wxString &caption, bool select=false, const wxBitmap &bitmap=wxNullBitmap)

  Adds a page.
- virtual bool AddPage (wxWindow *page, const wxString &text, bool select, int imageId)

  Adds a new page.
- void AdvanceSelection (bool forward=true)

  Sets the selection to the next or previous page.
- virtual int ChangeSelection (size_t n)

  Changes the selection for the given page, returning the previous selection.
- bool Create (wxWindow *parent, wxWindowID id=wxID_ANY, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, long style=0)

  Creates the notebook window.
- virtual bool DeleteAllPages ()

  Deletes all pages.
- bool DeletePage (size_t page)

  Deletes a page at the given index.
- wxAuiTabArt * GetArtProvider () const

  Returns the associated art provider.
- wxWindow * GetCurrentPage () const

  Returns the currently selected page or NULL.
- int GetHeightForPageHeight (int pageHeight)

  Returns the desired height of the notebook for the given page height.
- wxWindow * GetPage (size_t page_idx) const

  Returns the page specified by the given index.
- wxBitmap GetPageBitmap (size_t page) const

  Returns the tab bitmap for the page.
- size_t GetPageCount () const

  Returns the number of pages in the notebook.
- int GetPageIndex (wxWindow *page_wnd) const

  Returns the page index for the specified window.
- wxString GetPageText (size_t page) const

Returns the tab label for the page.

- wxString GetPageToolTip (size_t pageIdx) const

  Returns the tooltip for the tab label of the page.
- int GetSelection () const

  Returns the currently selected page.
- int GetTabCtrlHeight () const

  Returns the height of the tab control.
- bool InsertPage (size_t page_idx, wxWindow *page, const wxString &caption, bool select=false, const wxBitmap &bitmap=wxNullBitmap)

  InsertPage() is similar to AddPage, but allows the ability to specify the insert location.
- virtual bool InsertPage (size_t index, wxWindow *page, const wxString &text, bool select=false, int imageId=NO_IMAGE)

  Inserts a new page at the specified position.
- bool RemovePage (size_t page)

  Removes a page, without deleting the window pointer.
- void SetArtProvider (wxAuiTabArt *art)

  Sets the art provider to be used by the notebook.
- virtual bool SetFont (const wxFont &font)

  Sets the font for drawing the tab labels, using a bold version of the font for selected tab labels.
- void SetMeasuringFont (const wxFont &font)

  Sets the font for measuring tab labels.
- void SetNormalFont (const wxFont &font)

  Sets the font for drawing unselected tab labels.
- bool SetPageBitmap (size_t page, const wxBitmap &bitmap)

  Sets the bitmap for the page.
- virtual bool SetPageImage (size_t n, int imageId)

  Sets the image index for the given page.
- bool SetPageText (size_t page, const wxString &text)

  Sets the tab label for the page.
- bool SetPageToolTip (size_t page, const wxString &text)

  Sets the tooltip displayed when hovering over the tab label of the page.
- void SetSelectedFont (const wxFont &font)

  Sets the font for drawing selected tab labels.
- size_t SetSelection (size_t new_page)

  Sets the page selection.
- virtual void SetTabCtrlHeight (int height)

  Sets the tab height.
- bool ShowWindowMenu ()

  Shows the window menu for the active tab control associated with this notebook, and returns true if a selection was made.

- virtual void SetUniformBitmapSize (const wxSize &size)

  Split performs a split operation programmatically.
- virtual void Split (size_t page, int direction)

  Split performs a split operation programmatically.

Additional Inherited Members

21.43.2 Constructor & Destructor Documentation

wxAuiNotebook::wxAuiNotebook ( )

Default ctor.

wxAuiNotebook::wxAuiNotebook (wxWindow * *parent*, wxWindowID *id* = wxID_ANY, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, long *style* = `wxAUI_NB_DEFAULT_STYLE`)

Constructor.

Creates a wxAuiNotebok control.

21.43.3 Member Function Documentation

bool wxAuiNotebook::AddPage (wxWindow * *page*, const wxString & *caption*, bool *select* = `false`, const wxBitmap & *bitmap* = wxNullBitmap)

Adds a page.

If the *select* parameter is true, calling this will generate a page change event.

virtual bool wxAuiNotebook::AddPage (wxWindow * *page*, const wxString & *text*, bool *select*, int *imageId*) `[virtual]`

Adds a new page.

The page must have the book control itself as the parent and must not have been added to this control previously.

The call to this function may generate the page changing events.

Parameters

page	Specifies the new page.
text	Specifies the text for the new page.
select	Specifies whether the page should be selected.
imageId	Specifies the optional image index for the new page.

Returns

true if successful, false otherwise.

Remarks

Do not delete the page, it will be deleted by the book control.

See also

InsertPage()

Since

2.9.3

Reimplemented from wxBookCtrlBase.

void wxAuiNotebook::AdvanceSelection (bool *forward* = `true`)

Sets the selection to the next or previous page.

virtual int wxAuiNotebook::ChangeSelection (size_t *n*) `[virtual]`

Changes the selection for the given page, returning the previous selection.

This function behaves as SetSelection() but does *not* generate the page changing events.

See User Generated Events vs Programmatically Generated Events for more information.

Since

2.9.3

Implements wxBookCtrlBase.

bool wxAuiNotebook::Create (wxWindow * *parent*, wxWindowID *id* = wxID_ANY, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, long *style* = 0)

Creates the notebook window.

virtual bool wxAuiNotebook::DeleteAllPages ( ) `[virtual]`

Deletes all pages.

Since

2.9.3

Reimplemented from wxBookCtrlBase.

bool wxAuiNotebook::DeletePage (size_t *page*) `[virtual]`

Deletes a page at the given index.

Calling this method will generate a page change event.

Reimplemented from wxBookCtrlBase.

wxAuiTabArt* wxAuiNotebook::GetArtProvider ( ) const

Returns the associated art provider.

wxWindow* wxAuiNotebook::GetCurrentPage ( ) const

Returns the currently selected page or NULL.

Since

2.9.3

int wxAuiNotebook::GetHeightForPageHeight (int *pageHeight*)

Returns the desired height of the notebook for the given page height.

Use this to fit the notebook to a given page size.

wxWindow* wxAuiNotebook::GetPage (size_t *page_idx*) const

Returns the page specified by the given index.

wxBitmap wxAuiNotebook::GetPageBitmap (size_t *page*) const

Returns the tab bitmap for the page.

size_t wxAuiNotebook::GetPageCount ( ) const `[virtual]`

Returns the number of pages in the notebook.

Reimplemented from wxBookCtrlBase.

int wxAuiNotebook::GetPageIndex (wxWindow * *page_wnd*) const

Returns the page index for the specified window.

If the window is not found in the notebook, wxNOT_FOUND is returned.

wxString wxAuiNotebook::GetPageText (size_t *page*) const `[virtual]`

Returns the tab label for the page.

Implements wxBookCtrlBase.

wxString wxAuiNotebook::GetPageToolTip (size_t *pageIdx*) const

Returns the tooltip for the tab label of the page.

Since

2.9.4

int wxAuiNotebook::GetSelection ( ) const `[virtual]`

Returns the currently selected page.

Implements wxBookCtrlBase.

int wxAuiNotebook::GetTabCtrlHeight ( ) const

Returns the height of the tab control.

bool wxAuiNotebook::InsertPage (size_t *page_idx*, wxWindow * *page*, const wxString & *caption*, bool *select* = `false`, const wxBitmap & *bitmap* = wxNullBitmap)

InsertPage() is similar to AddPage, but allows the ability to specify the insert location.

If the *select* parameter is true, calling this will generate a page change event.

virtual bool wxAuiNotebook::InsertPage (size_t *index,* wxWindow * *page,* const wxString & *text,* bool *select* = `false`, int *imageId* = NO_IMAGE) [virtual]

Inserts a new page at the specified position.

Parameters

index	Specifies the position for the new page.
page	Specifies the new page.
text	Specifies the text for the new page.
select	Specifies whether the page should be selected.
imageId	Specifies the optional image index for the new page.

Returns

true if successful, false otherwise.

Remarks

Do not delete the page, it will be deleted by the book control.

See also

AddPage()

Since

2.9.3

Implements wxBookCtrlBase.

bool wxAuiNotebook::RemovePage (size_t *page*) [virtual]

Removes a page, without deleting the window pointer.

Reimplemented from wxBookCtrlBase.

void wxAuiNotebook::SetArtProvider (wxAuiTabArt * *art*)

Sets the art provider to be used by the notebook.

virtual bool wxAuiNotebook::SetFont (const wxFont & *font*) [virtual]

Sets the font for drawing the tab labels, using a bold version of the font for selected tab labels.

Reimplemented from wxWindow.

void wxAuiNotebook::SetMeasuringFont (const wxFont & *font*)

Sets the font for measuring tab labels.

void wxAuiNotebook::SetNormalFont (const wxFont & *font*)

Sets the font for drawing unselected tab labels.

bool wxAuiNotebook::SetPageBitmap (size_t *page*, const wxBitmap & *bitmap*)

Sets the bitmap for the page.

To remove a bitmap from the tab caption, pass wxNullBitmap.

virtual bool wxAuiNotebook::SetPageImage (size_t *n,* int *imageId*) `[virtual]`

Sets the image index for the given page.

image is an index into the image list which was set with SetImageList().

Since

2.9.3

Implements wxBookCtrlBase.

bool wxAuiNotebook::SetPageText (size_t *page,* const wxString & *text*) `[virtual]`

Sets the tab label for the page.

Implements wxBookCtrlBase.

bool wxAuiNotebook::SetPageToolTip (size_t *page,* const wxString & *text*)

Sets the tooltip displayed when hovering over the tab label of the page.

Returns

true if tooltip was updated, false if it failed, e.g. because the page index is invalid.

Since

2.9.4

void wxAuiNotebook::SetSelectedFont (const wxFont & *font*)

Sets the font for drawing selected tab labels.

size_t wxAuiNotebook::SetSelection (size_t *new_page*) `[virtual]`

Sets the page selection.

Calling this method will generate a page change event.

Implements wxBookCtrlBase.

virtual void wxAuiNotebook::SetTabCtrlHeight (int *height*) `[virtual]`

Sets the tab height.

By default, the tab control height is calculated by measuring the text height and bitmap sizes on the tab captions. Calling this method will override that calculation and set the tab control to the specified height parameter. A call to this method will override any call to SetUniformBitmapSize().

Specifying -1 as the height will return the control to its default auto-sizing behaviour.

virtual void wxAuiNotebook::SetUniformBitmapSize (const wxSize & *size*) `[virtual]`

Split performs a split operation programmatically.

The argument *page* indicates the page that will be split off. This page will also become the active page after the split.

The *direction* argument specifies where the pane should go, it should be one of the following: wxTOP, wxBOTTOM, wxLEFT, or wxRIGHT.

bool wxAuiNotebook::ShowWindowMenu ( )

Shows the window menu for the active tab control associated with this notebook, and returns true if a selection was made.

virtual void wxAuiNotebook::Split (size_t *page*, int *direction*) `[virtual]`

Split performs a split operation programmatically.

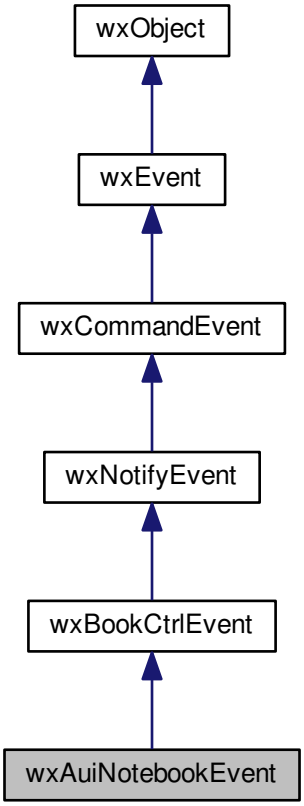
The argument *page* indicates the page that will be split off. This page will also become the active page after the split.

The *direction* argument specifies where the pane should go, it should be one of the following: wxTOP, wxBOTTOM, wxLEFT, or wxRIGHT.

21.44 wxAuiNotebookEvent Class Reference

```
#include <wx/aui/auibook.h>
```

Inheritance diagram for wxAuiNotebookEvent:



21.44.1 Detailed Description

This class is used by the events generated by wxAuiNotebook.

Events emitted by this class

The following event handler macros redirect the events to member function handlers '**func**' with prototypes like: void handlerFuncName(wxAuiNotebookEvent& event)

Event macros for events emitted by this class:

- EVT_AUINOTEBOOK_PAGE_CLOSE(id, func): A page is about to be closed. Processes a `wxEVT_AUINOTEBOOK_PAGE_CLOSE` event.
- EVT_AUINOTEBOOK_PAGE_CLOSED(winid, fn): A page has been closed. Processes a `wxEVT_AUINOTEBOOK_PAGE_CLOSED` event.
- EVT_AUINOTEBOOK_PAGE_CHANGED(id, func): The page selection was changed. Processes a `wxEVT_AUINOTEBOOK_PAGE_CHANGED` event.
- EVT_AUINOTEBOOK_PAGE_CHANGING(id, func): The page selection is about to be changed. Processes a `wxEVT_AUINOTEBOOK_PAGE_CHANGING` event. This event can be vetoed.

- EVT_AUINOTEBOOK_BUTTON(id, func): The window list button has been pressed. Processes a `wxEVT_AUINOTEBOOK_BUTTON` event.
- EVT_AUINOTEBOOK_BEGIN_DRAG(id, func): Dragging is about to begin. Processes a `wxEVT_AUINOTEBOOK_BEGIN_DRAG` event.
- EVT_AUINOTEBOOK_END_DRAG(id, func): Dragging has ended. Processes a `wxEVT_AUINOTEBOOK_END_DRAG` event.
- EVT_AUINOTEBOOK_DRAG_MOTION(id, func): Emitted during a drag and drop operation. Processes a `wxEVT_AUINOTEBOOK_DRAG_MOTION` event.
- EVT_AUINOTEBOOK_ALLOW_DND(id, func): Whether to allow a tab to be dropped. Processes a `wxEVT_AUINOTEBOOK_ALLOW_DND` event. This event must be specially allowed.
- EVT_AUINOTEBOOK_DRAG_DONE(winid, fn): Notify that the tab has been dragged. Processes a `wxEVT_AUINOTEBOOK_DRAG_DONE` event.
- EVT_AUINOTEBOOK_TAB_MIDDLE_DOWN(winid, fn): The middle mouse button is pressed on a tab. Processes a `wxEVT_AUINOTEBOOK_TAB_MIDDLE_DOWN` event.
- EVT_AUINOTEBOOK_TAB_MIDDLE_UP(winid, fn): The middle mouse button is released on a tab. Processes a `wxEVT_AUINOTEBOOK_TAB_MIDDLE_UP` event.
- EVT_AUINOTEBOOK_TAB_RIGHT_DOWN(winid, fn): The right mouse button is pressed on a tab. Processes a `wxEVT_AUINOTEBOOK_TAB_RIGHT_DOWN` event.
- EVT_AUINOTEBOOK_TAB_RIGHT_UP(winid, fn): The right mouse button is released on a tab. Processes a `wxEVT_AUINOTEBOOK_TAB_RIGHT_UP` event.
- EVT_AUINOTEBOOK_BG_DCLICK(winid, fn): Double clicked on the tabs background area. Processes a `wxEVT_AUINOTEBOOK_BG_DCLICK` event.

21.45 wxAuiPaneInfo Class Reference

`#include <wx/aui/framemanager.h>`

21.45.1 Detailed Description

wxAuiPaneInfo is part of the wxAUI class framework.

See also wxAUI Overview.

wxAuiPaneInfo specifies all the parameters for a pane. These parameters specify where the pane is on the screen, whether it is docked or floating, or hidden. In addition, these parameters specify the pane's docked position, floating position, preferred size, minimum size, caption text among many other parameters.

Library: wxAui

Category: Window Docking (wxAUI)

See also

wxAuiManager, wxAuiDockArt

Public Member Functions

- wxAuiPaneInfo ()
- wxAuiPaneInfo (const wxAuiPaneInfo &c)

  Copy constructor.
- wxAuiPaneInfo & Bottom ()

  Bottom() sets the pane dock position to the bottom side of the frame.
- wxAuiPaneInfo & BottomDockable (bool b=true)

  BottomDockable() indicates whether a pane can be docked at the bottom of the frame.
- wxAuiPaneInfo & Caption (const wxString &c)

  Caption() sets the caption of the pane.
- wxAuiPaneInfo & CaptionVisible (bool visible=true)

  CaptionVisible indicates that a pane caption should be visible.
- wxAuiPaneInfo & CloseButton (bool visible=true)

  CloseButton() indicates that a close button should be drawn for the pane.
- wxAuiPaneInfo & DefaultPane ()

  DefaultPane() specifies that the pane should adopt the default pane settings.
- wxAuiPaneInfo & DestroyOnClose (bool b=true)

  DestroyOnClose() indicates whether a pane should be destroyed when it is closed.
- wxAuiPaneInfo & Direction (int direction)

  Direction() determines the direction of the docked pane.
- wxAuiPaneInfo & Dock ()

  Dock() indicates that a pane should be docked.
- wxAuiPaneInfo & DockFixed (bool b=true)

  DockFixed() causes the containing dock to have no resize sash.

- wxAuiPaneInfo & Dockable (bool b=true)

  Dockable() specifies whether a frame can be docked or not.
- wxAuiPaneInfo & Fixed ()

  Fixed() forces a pane to be fixed size so that it cannot be resized.
- wxAuiPaneInfo & Float ()

  Float() indicates that a pane should be floated.
- wxAuiPaneInfo & Floatable (bool b=true)

  Floatable() sets whether the user will be able to undock a pane and turn it into a floating window.
- wxAuiPaneInfo & Gripper (bool visible=true)

  Gripper() indicates that a gripper should be drawn for the pane.
- wxAuiPaneInfo & GripperTop (bool attop=true)

  GripperTop() indicates that a gripper should be drawn at the top of the pane.
- bool HasBorder () const

  HasBorder() returns true if the pane displays a border.
- bool HasCaption () const

  HasCaption() returns true if the pane displays a caption.
- bool HasCloseButton () const

  HasCloseButton() returns true if the pane displays a button to close the pane.
- bool HasFlag (int flag) const

  HasFlag() returns true if the property specified by flag is active for the pane.
- bool HasGripper () const

  HasGripper() returns true if the pane displays a gripper.
- bool HasGripperTop () const

  HasGripper() returns true if the pane displays a gripper at the top.
- bool HasMaximizeButton () const

  HasMaximizeButton() returns true if the pane displays a button to maximize the pane.
- bool HasMinimizeButton () const

  HasMinimizeButton() returns true if the pane displays a button to minimize the pane.
- bool HasPinButton () const

  HasPinButton() returns true if the pane displays a button to float the pane.
- wxAuiPaneInfo & Hide ()

  Hide() indicates that a pane should be hidden.
- wxAuiPaneInfo & Icon (const wxBitmap &b)

  Icon() sets the icon of the pane.
- bool IsBottomDockable () const

  IsBottomDockable() returns true if the pane can be docked at the bottom of the managed frame.
- bool IsDockable () const

  Returns true if the pane can be docked at any side.
- bool IsDocked () const

  IsDocked() returns true if the pane is currently docked.
- bool IsFixed () const

  IsFixed() returns true if the pane cannot be resized.
- bool IsFloatable () const

  IsFloatable() returns true if the pane can be undocked and displayed as a floating window.
- bool IsFloating () const

  IsFloating() returns true if the pane is floating.
- bool IsLeftDockable () const

  IsLeftDockable() returns true if the pane can be docked on the left of the managed frame.
- bool IsMovable () const

  IsMoveable() returns true if the docked frame can be undocked or moved to another dock position.
- bool IsOk () const

IsOk() returns true if the wxAuiPaneInfo structure is valid.

- bool IsResizable () const

  IsResizable() returns true if the pane can be resized.
- bool IsRightDockable () const

  IsRightDockable() returns true if the pane can be docked on the right of the managed frame.
- bool IsShown () const

  IsShown() returns true if the pane is currently shown.
- bool IsToolbar () const

  IsToolbar() returns true if the pane contains a toolbar.
- bool IsTopDockable () const

  IsTopDockable() returns true if the pane can be docked at the top of the managed frame.
- wxAuiPaneInfo & Layer (int layer)

  Layer() determines the layer of the docked pane.
- wxAuiPaneInfo & Left ()

  Left() sets the pane dock position to the left side of the frame.
- wxAuiPaneInfo & LeftDockable (bool b=true)

  LeftDockable() indicates whether a pane can be docked on the left of the frame.
- wxAuiPaneInfo & MaximizeButton (bool visible=true)

  MaximizeButton() indicates that a maximize button should be drawn for the pane.
- wxAuiPaneInfo & MinimizeButton (bool visible=true)

  MinimizeButton() indicates that a minimize button should be drawn for the pane.
- wxAuiPaneInfo & Movable (bool b=true)

  Movable indicates whether a frame can be moved.
- wxAuiPaneInfo & Name (const wxString &n)

  Name() sets the name of the pane so it can be referenced in lookup functions.
- wxAuiPaneInfo & PaneBorder (bool visible=true)

  PaneBorder indicates that a border should be drawn for the pane.
- wxAuiPaneInfo & PinButton (bool visible=true)

  PinButton() indicates that a pin button should be drawn for the pane.
- wxAuiPaneInfo & Position (int pos)

  Position() determines the position of the docked pane.
- wxAuiPaneInfo & Resizable (bool resizable=true)

  Resizable() allows a pane to be resized if the parameter is true, and forces it to be a fixed size if the parameter is false.
- wxAuiPaneInfo & Right ()

  Right() sets the pane dock position to the right side of the frame.
- wxAuiPaneInfo & RightDockable (bool b=true)

  RightDockable() indicates whether a pane can be docked on the right of the frame.
- wxAuiPaneInfo & Row (int row)

  Row() determines the row of the docked pane.
- void SafeSet (wxAuiPaneInfo source)

  Write the safe parts of a newly loaded PaneInfo structure "source" into "this" used on loading perspectives etc.
- wxAuiPaneInfo & SetFlag (int flag, bool option_state)

  SetFlag() turns the property given by flag on or off with the option_state parameter.
- wxAuiPaneInfo & Show (bool show=true)

  Show() indicates that a pane should be shown.
- wxAuiPaneInfo & ToolbarPane ()

  ToolbarPane() specifies that the pane should adopt the default toolbar pane settings.
- wxAuiPaneInfo & Top ()

  Top() sets the pane dock position to the top of the frame.
- wxAuiPaneInfo & TopDockable (bool b=true)

TopDockable() indicates whether a pane can be docked at the top of the frame.

- wxAuiPaneInfo & Window (wxWindow *w)

  Window() assigns the window pointer that the wxAuiPaneInfo should use.
- wxAuiPaneInfo & operator= (const wxAuiPaneInfo &c)

  Makes a copy of the wxAuiPaneInfo object.

- wxAuiPaneInfo & BestSize (const wxSize &size)

  BestSize() sets the ideal size for the pane.
- wxAuiPaneInfo & BestSize (int x, int y)

  BestSize() sets the ideal size for the pane.

- wxAuiPaneInfo & Centre ()

  Center() sets the pane dock position to the left side of the frame.
- wxAuiPaneInfo & Center ()

  Center() sets the pane dock position to the left side of the frame.

- wxAuiPaneInfo & CentrePane ()

  CentrePane() specifies that the pane should adopt the default center pane settings.
- wxAuiPaneInfo & CenterPane ()

  CentrePane() specifies that the pane should adopt the default center pane settings.

- wxAuiPaneInfo & FloatingPosition (const wxPoint &pos)

  FloatingPosition() sets the position of the floating pane.
- wxAuiPaneInfo & FloatingPosition (int x, int y)

  FloatingPosition() sets the position of the floating pane.

- wxAuiPaneInfo & FloatingSize (const wxSize &size)

  FloatingSize() sets the size of the floating pane.
- wxAuiPaneInfo & FloatingSize (int x, int y)

  FloatingSize() sets the size of the floating pane.

- wxAuiPaneInfo & MaxSize (const wxSize &size)

  MaxSize() sets the maximum size of the pane.
- wxAuiPaneInfo & MaxSize (int x, int y)

  MaxSize() sets the maximum size of the pane.

- wxAuiPaneInfo & MinSize (const wxSize &size)

  MinSize() sets the minimum size of the pane.
- wxAuiPaneInfo & MinSize (int x, int y)

  MinSize() sets the minimum size of the pane.

21.45.2 Constructor & Destructor Documentation

wxAuiPaneInfo::wxAuiPaneInfo ( )

wxAuiPaneInfo::wxAuiPaneInfo (const wxAuiPaneInfo & *c*)

Copy constructor.

21.45.3 Member Function Documentation

wxAuiPaneInfo& wxAuiPaneInfo::BestSize (const wxSize & *size*)

BestSize() sets the ideal size for the pane.

The docking manager will attempt to use this size as much as possible when docking or floating the pane.

wxAuiPaneInfo& wxAuiPaneInfo::BestSize (int *x*, int *y*)

BestSize() sets the ideal size for the pane.

The docking manager will attempt to use this size as much as possible when docking or floating the pane.

wxAuiPaneInfo& wxAuiPaneInfo::Bottom ( )

Bottom() sets the pane dock position to the bottom side of the frame.

This is the same thing as calling Direction(wxAUI_DOCK_BOTTOM).

wxAuiPaneInfo& wxAuiPaneInfo::BottomDockable (bool *b* = `true`)

BottomDockable() indicates whether a pane can be docked at the bottom of the frame.

wxAuiPaneInfo& wxAuiPaneInfo::Caption (const wxString & *c*)

Caption() sets the caption of the pane.

wxAuiPaneInfo& wxAuiPaneInfo::CaptionVisible (bool *visible* = `true`)

CaptionVisible indicates that a pane caption should be visible.

If false, no pane caption is drawn.

wxAuiPaneInfo& wxAuiPaneInfo::Center ( )

Center() sets the pane dock position to the left side of the frame.

The centre pane is the space in the middle after all border panes (left, top, right, bottom) are subtracted from the layout. This is the same thing as calling Direction(wxAUI_DOCK_CENTRE).

wxAuiPaneInfo& wxAuiPaneInfo::CenterPane ( )

CentrePane() specifies that the pane should adopt the default center pane settings.

Centre panes usually do not have caption bars. This function provides an easy way of preparing a pane to be displayed in the center dock position.

wxAuiPaneInfo& wxAuiPaneInfo::Centre ( )

Center() sets the pane dock position to the left side of the frame.

The centre pane is the space in the middle after all border panes (left, top, right, bottom) are subtracted from the layout. This is the same thing as calling Direction(wxAUI_DOCK_CENTRE).

wxAuiPaneInfo& wxAuiPaneInfo::CentrePane ( )

CentrePane() specifies that the pane should adopt the default center pane settings.

Centre panes usually do not have caption bars. This function provides an easy way of preparing a pane to be displayed in the center dock position.

wxAuiPaneInfo& wxAuiPaneInfo::CloseButton (bool *visible* = `true`)

CloseButton() indicates that a close button should be drawn for the pane.

wxAuiPaneInfo& wxAuiPaneInfo::DefaultPane ( )

DefaultPane() specifies that the pane should adopt the default pane settings.

wxAuiPaneInfo& wxAuiPaneInfo::DestroyOnClose (bool *b* = `true`)

DestroyOnClose() indicates whether a pane should be destroyed when it is closed.

Normally a pane is simply hidden when the close button is clicked. Setting DestroyOnClose to true will cause the window to be destroyed when the user clicks the pane's close button.

wxAuiPaneInfo& wxAuiPaneInfo::Direction (int *direction*)

Direction() determines the direction of the docked pane.

It is functionally the same as calling Left(), Right(), Top() or Bottom(), except that docking direction may be specified programmatically via the parameter.

wxAuiPaneInfo& wxAuiPaneInfo::Dock ( )

Dock() indicates that a pane should be docked.

It is the opposite of Float().

wxAuiPaneInfo& wxAuiPaneInfo::Dockable (bool *b* = `true`)

Dockable() specifies whether a frame can be docked or not.

It is the same as specifying TopDockable(b).BottomDockable(b).LeftDockable(b).RightDockable(b).

wxAuiPaneInfo& wxAuiPaneInfo::DockFixed (bool *b* = `true`)

DockFixed() causes the containing dock to have no resize sash.

This is useful for creating panes that span the entire width or height of a dock, but should not be resizable in the other direction.

wxAuiPaneInfo& wxAuiPaneInfo::Fixed ( )

Fixed() forces a pane to be fixed size so that it cannot be resized.

After calling Fixed(), IsFixed() will return true.

wxAuiPaneInfo& wxAuiPaneInfo::Float ( )

Float() indicates that a pane should be floated.

It is the opposite of Dock().

wxAuiPaneInfo& wxAuiPaneInfo::Floatable (bool *b* = `true`)

Floatable() sets whether the user will be able to undock a pane and turn it into a floating window.

wxAuiPaneInfo& wxAuiPaneInfo::FloatingPosition (const wxPoint & *pos*)

FloatingPosition() sets the position of the floating pane.

wxAuiPaneInfo& wxAuiPaneInfo::FloatingPosition (int *x*, int *y*)

FloatingPosition() sets the position of the floating pane.

wxAuiPaneInfo& wxAuiPaneInfo::FloatingSize (const wxSize & *size*)

FloatingSize() sets the size of the floating pane.

wxAuiPaneInfo& wxAuiPaneInfo::FloatingSize (int *x*, int *y*)

FloatingSize() sets the size of the floating pane.

wxAuiPaneInfo& wxAuiPaneInfo::Gripper (bool *visible* = `true`)

Gripper() indicates that a gripper should be drawn for the pane.

wxAuiPaneInfo& wxAuiPaneInfo::GripperTop (bool *attop* = `true`)

GripperTop() indicates that a gripper should be drawn at the top of the pane.

bool wxAuiPaneInfo::HasBorder ( ) const

HasBorder() returns true if the pane displays a border.

bool wxAuiPaneInfo::HasCaption ( ) const

HasCaption() returns true if the pane displays a caption.

bool wxAuiPaneInfo::HasCloseButton ( ) const

HasCloseButton() returns true if the pane displays a button to close the pane.

bool wxAuiPaneInfo::HasFlag (int *flag*) const

HasFlag() returns true if the property specified by flag is active for the pane.

bool wxAuiPaneInfo::HasGripper ( ) const

HasGripper() returns true if the pane displays a gripper.

bool wxAuiPaneInfo::HasGripperTop ( ) const

HasGripper() returns true if the pane displays a gripper at the top.

bool wxAuiPaneInfo::HasMaximizeButton ( ) const

HasMaximizeButton() returns true if the pane displays a button to maximize the pane.

bool wxAuiPaneInfo::HasMinimizeButton ( ) const

HasMinimizeButton() returns true if the pane displays a button to minimize the pane.

bool wxAuiPaneInfo::HasPinButton ( ) const

HasPinButton() returns true if the pane displays a button to float the pane.

wxAuiPaneInfo& wxAuiPaneInfo::Hide ( )

Hide() indicates that a pane should be hidden.

wxAuiPaneInfo& wxAuiPaneInfo::Icon (const wxBitmap & *b*)

Icon() sets the icon of the pane.

Notice that the height of the icon should be smaller than the value returned by wxAuiDockArt::GetMetric(wxAUI_↩ DOCKART_CAPTION_SIZE) to ensure that it appears correctly.

Since

2.9.2

bool wxAuiPaneInfo::IsBottomDockable ( ) const

IsBottomDockable() returns true if the pane can be docked at the bottom of the managed frame.

See also

IsDockable()

bool wxAuiPaneInfo::IsDockable ( ) const

Returns true if the pane can be docked at any side.

See also

IsTopDockable(), IsBottomDockable(), IsLeftDockable(), IsRightDockable()

Since

2.9.2

bool wxAuiPaneInfo::IsDocked ( ) const

IsDocked() returns true if the pane is currently docked.

bool wxAuiPaneInfo::IsFixed ( ) const

IsFixed() returns true if the pane cannot be resized.

bool wxAuiPaneInfo::IsFloatable ( ) const

IsFloatable() returns true if the pane can be undocked and displayed as a floating window.

bool wxAuiPaneInfo::IsFloating ( ) const

IsFloating() returns true if the pane is floating.

bool wxAuiPaneInfo::IsLeftDockable ( ) const

IsLeftDockable() returns true if the pane can be docked on the left of the managed frame.

See also

IsDockable()

bool wxAuiPaneInfo::IsMovable ( ) const

IsMoveable() returns true if the docked frame can be undocked or moved to another dock position.

bool wxAuiPaneInfo::IsOk ( ) const

IsOk() returns true if the wxAuiPaneInfo structure is valid.

A pane structure is valid if it has an associated window.

bool wxAuiPaneInfo::IsResizable ( ) const

IsResizable() returns true if the pane can be resized.

bool wxAuiPaneInfo::IsRightDockable ( ) const

IsRightDockable() returns true if the pane can be docked on the right of the managed frame.

See also

IsDockable()

bool wxAuiPaneInfo::IsShown ( ) const

IsShown() returns true if the pane is currently shown.

bool wxAuiPaneInfo::IsToolbar ( ) const

IsToolbar() returns true if the pane contains a toolbar.

bool wxAuiPaneInfo::IsTopDockable ( ) const

IsTopDockable() returns true if the pane can be docked at the top of the managed frame.

See also

IsDockable()

wxAuiPaneInfo& wxAuiPaneInfo::Layer (int *layer*)

Layer() determines the layer of the docked pane.

The dock layer is similar to an onion, the inner-most layer being layer 0. Each shell moving in the outward direction has a higher layer number. This allows for more complex docking layout formation.

wxAuiPaneInfo& wxAuiPaneInfo::Left ( )

Left() sets the pane dock position to the left side of the frame.

This is the same thing as calling Direction(wxAUI_DOCK_LEFT).

wxAuiPaneInfo& wxAuiPaneInfo::LeftDockable (bool *b* = `true`)

LeftDockable() indicates whether a pane can be docked on the left of the frame.

wxAuiPaneInfo& wxAuiPaneInfo::MaximizeButton (bool *visible* = `true`)

MaximizeButton() indicates that a maximize button should be drawn for the pane.

wxAuiPaneInfo& wxAuiPaneInfo::MaxSize (const wxSize & *size*)

MaxSize() sets the maximum size of the pane.

wxAuiPaneInfo& wxAuiPaneInfo::MaxSize (int *x*, int *y*)

MaxSize() sets the maximum size of the pane.

wxAuiPaneInfo& wxAuiPaneInfo::MinimizeButton (bool *visible* = `true`)

MinimizeButton() indicates that a minimize button should be drawn for the pane.

wxAuiPaneInfo& wxAuiPaneInfo::MinSize (const wxSize & *size*)

MinSize() sets the minimum size of the pane.

Please note that this is only partially supported as of this writing.

wxAuiPaneInfo& wxAuiPaneInfo::MinSize (int *x,* int *y*)

MinSize() sets the minimum size of the pane.

Please note that this is only partially supported as of this writing.

wxAuiPaneInfo& wxAuiPaneInfo::Movable (bool *b* = `true`)

Movable indicates whether a frame can be moved.

wxAuiPaneInfo& wxAuiPaneInfo::Name (const wxString & *n*)

Name() sets the name of the pane so it can be referenced in lookup functions.

If a name is not specified by the user, a random name is assigned to the pane when it is added to the manager.

wxAuiPaneInfo& wxAuiPaneInfo::operator= (const wxAuiPaneInfo & *c*)

Makes a copy of the wxAuiPaneInfo object.

wxAuiPaneInfo& wxAuiPaneInfo::PaneBorder (bool *visible* = `true`)

PaneBorder indicates that a border should be drawn for the pane.

wxAuiPaneInfo& wxAuiPaneInfo::PinButton (bool *visible* = `true`)

PinButton() indicates that a pin button should be drawn for the pane.

wxAuiPaneInfo& wxAuiPaneInfo::Position (int *pos*)

Position() determines the position of the docked pane.

wxAuiPaneInfo& wxAuiPaneInfo::Resizable (bool *resizable* = `true`)

Resizable() allows a pane to be resized if the parameter is true, and forces it to be a fixed size if the parameter is false.

This is simply an antonym for Fixed().

wxAuiPaneInfo& wxAuiPaneInfo::Right ( )

Right() sets the pane dock position to the right side of the frame.

wxAuiPaneInfo& wxAuiPaneInfo::RightDockable (bool *b* = `true`)

RightDockable() indicates whether a pane can be docked on the right of the frame.

wxAuiPaneInfo& wxAuiPaneInfo::Row (int *row*)

Row() determines the row of the docked pane.

void wxAuiPaneInfo::SafeSet (wxAuiPaneInfo *source*)

Write the safe parts of a newly loaded PaneInfo structure "source" into "this" used on loading perspectives etc.

wxAuiPaneInfo& wxAuiPaneInfo::SetFlag (int *flag*, bool *option_state*)

SetFlag() turns the property given by flag on or off with the option_state parameter.

wxAuiPaneInfo& wxAuiPaneInfo::Show (bool *show* = `true`)

Show() indicates that a pane should be shown.

wxAuiPaneInfo& wxAuiPaneInfo::ToolbarPane ( )

ToolbarPane() specifies that the pane should adopt the default toolbar pane settings.

wxAuiPaneInfo& wxAuiPaneInfo::Top ( )

Top() sets the pane dock position to the top of the frame.

wxAuiPaneInfo& wxAuiPaneInfo::TopDockable (bool *b* = `true`)

TopDockable() indicates whether a pane can be docked at the top of the frame.

wxAuiPaneInfo& wxAuiPaneInfo::Window (wxWindow * *w*)

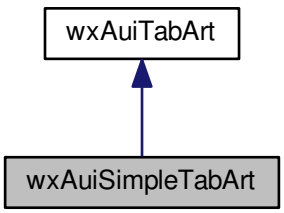
Window() assigns the window pointer that the wxAuiPaneInfo should use.

This normally does not need to be specified, as the window pointer is automatically assigned to the wxAuiPaneInfo structure as soon as it is added to the manager.

21.46 wxAuiSimpleTabArt Class Reference

`#include <wx/aui/auibook.h>`

Inheritance diagram for wxAuiSimpleTabArt:



21.46.1 Detailed Description

Another standard tab art provider for wxAuiNotebook.

wxAuiSimpleTabArt is derived from wxAuiTabArt demonstrating how to write a completely new tab art class. It can also be used as alternative to wxAuiDefaultTabArt.

Library: wxAui

Category: Window Docking (wxAUI)

Public Member Functions

- wxAuiSimpleTabArt ()
- virtual ~wxAuiSimpleTabArt ()
- wxAuiTabArt * Clone ()

  Clones the art object.
- void SetFlags (unsigned int flags)

  Sets flags.
- void SetSizingInfo (const wxSize &tabCtrlSize, size_t tabCount)

  Sets sizing information.
- void SetNormalFont (const wxFont &font)

  Sets the normal font for drawing labels.
- void SetSelectedFont (const wxFont &font)

  Sets the font for drawing text for selected UI elements.
- void SetMeasuringFont (const wxFont &font)

  Sets the font used for calculating measurements.
- void SetColour (const wxColour &colour)

  Sets the colour of the inactive tabs.
- void SetActiveColour (const wxColour &colour)

  Sets the colour of the selected tab.
- void DrawBackground (wxDC &dc, wxWindow *wnd, const wxRect &rect)

  Draws a background on the given area.
- void DrawTab (wxDC &dc, wxWindow *wnd, const wxAuiNotebookPage &pane, const wxRect &inRect, int closeButtonState, wxRect *outTabRect, wxRect *outButtonRect, int *xExtent)

  Draws a tab.
- void DrawButton (wxDC &dc, wxWindow *wnd, const wxRect &inRect, int bitmapId, int buttonState, int orientation, wxRect *outRect)

  Draws a button.
- int GetIndentSize ()

  Returns the indent size.
- wxSize GetTabSize (wxDC &dc, wxWindow *wnd, const wxString &caption, const wxBitmap &bitmap, bool active, int closeButtonState, int *xExtent)

  Returns the tab size for the given caption, bitmap and state.
- int ShowDropDown (wxWindow *wnd, const wxAuiNotebookPageArray &items, int activeIdx)
- int GetBestTabCtrlSize (wxWindow *wnd, const wxAuiNotebookPageArray &pages, const wxSize &requiredBmpSize)

  Returns the tab control size.

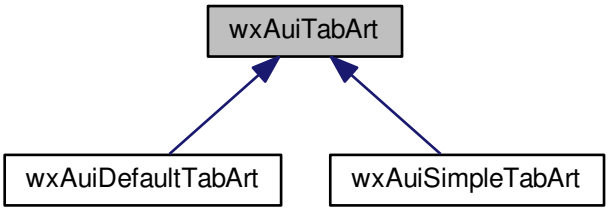
21.47 wxAuiTabArt Class Reference

`#include <wx/aui/auibook.h>`

Inheritance diagram for wxAuiTabArt:



21.47.1 Detailed Description

Tab art provider defines all the drawing functions used by wxAuiNotebook.

This allows the wxAuiNotebook to have a pluggable look-and-feel.

By default, a wxAuiNotebook uses an instance of this class called wxAuiDefaultTabArt which provides bitmap art and a colour scheme that is adapted to the major platforms' look. You can either derive from that class to alter its behaviour or write a completely new tab art class.

Another example of creating a new wxAuiNotebook tab bar is wxAuiSimpleTabArt.

Call wxAuiNotebook::SetArtProvider() to make use of this new tab art.

Library: wxAui

Category: Window Docking (wxAUI)

Public Member Functions

- wxAuiTabArt ()

  Constructor.
- virtual wxAuiTabArt * Clone ()=0

  Clones the art object.

virtual wxAuiTabArt* wxAuiTabArt::Clone ( ) `[pure virtual]`

Clones the art object.

Implemented in wxAuiSimpleTabArt, and wxAuiDefaultTabArt.

virtual void wxAuiTabArt::DrawBackground (wxDC & *dc*, wxWindow * *wnd*, const wxRect & *rect*) `[pure virtual]`

Draws a background on the given area.

Implemented in wxAuiSimpleTabArt, and wxAuiDefaultTabArt.

virtual void wxAuiTabArt::DrawButton (wxDC & *dc*, wxWindow * *wnd*, const wxRect & *in_rect*, int *bitmap_id*, int *button_state*, int *orientation*, wxRect * *out_rect*) `[pure virtual]`

Draws a button.

Implemented in wxAuiSimpleTabArt, and wxAuiDefaultTabArt.

virtual void wxAuiTabArt::DrawTab (wxDC & *dc*, wxWindow * *wnd*, const wxAuiNotebookPage & *page*, const wxRect & *rect*, int *close_button_state*, wxRect * *out_tab_rect*, wxRect * *out_button_rect*, int * *x_extent*) `[pure virtual]`

Draws a tab.

Implemented in wxAuiSimpleTabArt, and wxAuiDefaultTabArt.

virtual int wxAuiTabArt::GetBestTabCtrlSize (wxWindow * , const wxAuiNotebookPageArray & , const wxSize &) `[pure virtual]`

Returns the tab control size.

Implemented in wxAuiSimpleTabArt, and wxAuiDefaultTabArt.

virtual int wxAuiTabArt::GetIndentSize ( ) `[pure virtual]`

Returns the indent size.

Implemented in wxAuiSimpleTabArt, and wxAuiDefaultTabArt.

virtual wxSize wxAuiTabArt::GetTabSize (wxDC & *dc,* wxWindow * *wnd,* const wxString & *caption,* const wxBitmap & *bitmap,* bool *active,* int *close_button_state,* int * *x_extent*) `[pure virtual]`

Returns the tab size for the given caption, bitmap and state.

Implemented in wxAuiSimpleTabArt, and wxAuiDefaultTabArt.

virtual void wxAuiTabArt::SetActiveColour (const wxColour & *colour*) `[pure virtual]`

Sets the colour of the selected tab.

Since

2.9.2

Implemented in wxAuiSimpleTabArt, and wxAuiDefaultTabArt.

virtual void wxAuiTabArt::SetColour (const wxColour & *colour*) `[pure virtual]`

Sets the colour of the inactive tabs.

Since

2.9.2

Implemented in wxAuiSimpleTabArt, and wxAuiDefaultTabArt.

virtual void wxAuiTabArt::SetFlags (unsigned int *flags*) `[pure virtual]`

Sets flags.

Implemented in wxAuiSimpleTabArt, and wxAuiDefaultTabArt.

virtual void wxAuiTabArt::SetMeasuringFont (const wxFont & *font*) `[pure virtual]`

Sets the font used for calculating measurements.

Implemented in wxAuiSimpleTabArt, and wxAuiDefaultTabArt.

virtual void wxAuiTabArt::SetNormalFont (const wxFont & *font*) `[pure virtual]`

Sets the normal font for drawing labels.

Implemented in wxAuiSimpleTabArt, and wxAuiDefaultTabArt.

virtual void wxAuiTabArt::SetSelectedFont (const wxFont & *font*) `[pure virtual]`

Sets the font for drawing text for selected UI elements.

Implemented in wxAuiSimpleTabArt, and wxAuiDefaultTabArt.

virtual void wxAuiTabArt::SetSizingInfo (const wxSize & *tab_ctrl_size,* size_t *tab_count*) `[pure virtual]`

Sets sizing information.

Implemented in wxAuiSimpleTabArt, and wxAuiDefaultTabArt.

21.48 wxAuiTabContainer Class Reference

```
#include <wx/aui/auibook.h>
```

21.48.1 Detailed Description

wxAuiTabContainer is a class which contains information about each tab.

It also can render an entire tab control to a specified DC. It's not a window class itself, because this code will be used by the wxAuiNotebook, where it is disadvantageous to have separate windows for each tab control in the case of "docked tabs".

A derived class, wxAuiTabCtrl, is an actual wxWindow - derived window which can be used as a tab control in the normal sense.

21.49 wxAuiTabContainerButton Class Reference

`#include <wx/aui/auibook.h>`

21.49.1 Detailed Description

A simple class which holds information about wxAuiNotebook tab buttons and their state.

Library: wxAui

Category: Window Docking (wxAUI)

Public Attributes

- int id

  button's id
- int curState

  current state (normal, hover, pressed, etc.)
- int location

  buttons location (wxLEFT, wxRIGHT, or wxCENTER)
- wxBitmap bitmap

  button's hover bitmap
- wxBitmap disBitmap

  button's disabled bitmap
- wxRect rect

  button's hit rectangle

21.49.2 Member Data Documentation

wxBitmap wxAuiTabContainerButton::bitmap

button's hover bitmap

int wxAuiTabContainerButton::curState

current state (normal, hover, pressed, etc.)

wxBitmap wxAuiTabContainerButton::disBitmap

button's disabled bitmap

int wxAuiTabContainerButton::id

button's id

int wxAuiTabContainerButton::location

buttons location (wxLEFT, wxRIGHT, or wxCENTER)

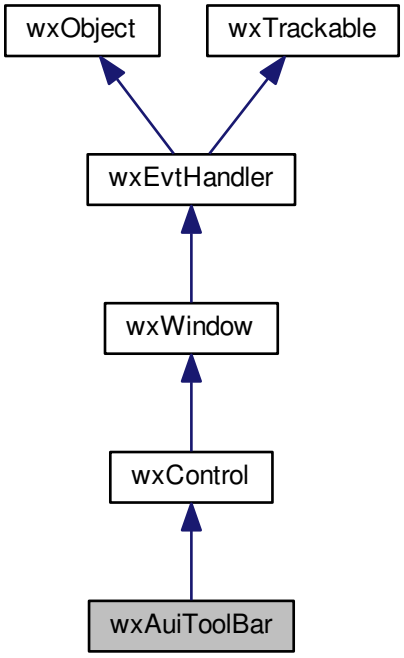
wxRect wxAuiTabContainerButton::rect

button's hit rectangle

21.50 wxAuiToolBar Class Reference

```
#include <wx/aui/auibar.h>
```

Inheritance diagram for wxAuiToolBar:



21.50.1 Detailed Description

wxAuiToolBar is a dockable toolbar, part of the wxAUI class framework.

See also wxAUI Overview.

Styles

This class supports the following styles:

- wxAUI_TB_TEXT:
- wxAUI_TB_NO_TOOLTIPS:
- wxAUI_TB_NO_AUTORESIZE:
- wxAUI_TB_GRIPPER:
- wxAUI_TB_OVERFLOW:
- wxAUI_TB_VERTICAL: using this style forces the toolbar to be vertical and be only dockable to the left or right sides of the window whereas by default it can be horizontal or vertical and be docked anywhere
- wxAUI_TB_HORZ_LAYOUT:
- wxAUI_TB_HORIZONTAL: analogous to wxAUI_TB_VERTICAL, but forces the toolbar to be horizontal
- wxAUI_TB_PLAIN_BACKGROUND: Draw a plain background (based on parent) instead of the default gradient background.

- wxAUI_TB_HORZ_TEXT: Equivalent to wxAUI_TB_HORZ_LAYOUT | wxAUI_TB_TEXT
- wxAUI_TB_DEFAULT_STYLE: The default is to have no styles

Events emitted by this class

The following event handler macros redirect the events to member function handlers '**func**' with prototypes like: void handlerFuncName(wxAuiToolBarEvent& event)

Event macros for events emitted by this class:

- EVT_AUITOOLBAR_TOOL_DROPDOWN(id, func): Process a wxEVT_AUITOOLBAR_TOOL_DROPDOWN event
- EVT_AUITOOLBAR_OVERFLOW_CLICK(id, func): Process a wxEVT_AUITOOLBAR_OVERFLOW_CLICK event
- EVT_AUITOOLBAR_RIGHT_CLICK(id, func): Process a wxEVT_AUITOOLBAR_RIGHT_CLICK event
- EVT_AUITOOLBAR_MIDDLE_CLICK(id, func): Process a wxEVT_AUITOOLBAR_MIDDLE_CLICK event
- EVT_AUITOOLBAR_BEGIN_DRAG(id, func): Process a wxEVT_AUITOOLBAR_BEGIN_DRAG event

Library: wxAui

Category: Window Docking (wxAUI)

Public Member Functions

- wxAuiToolBar ()

  Default constructor, use Create() later.
- wxAuiToolBar (wxWindow *parent, wxWindowID id=wxID_ANY, const wxPoint &position=wxDefaultPosition, const wxSize &size=wxDefaultSize, long style=wxAUI_TB_DEFAULT_STYLE)

  Constructor creating and initializing the object.
- bool Create (wxWindow *parent, wxWindowID id=wxID_ANY, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, long style=wxAUI_TB_DEFAULT_STYLE)

  Really create wxAuiToolBar created using default constructor.
- virtual ~wxAuiToolBar ()
- void SetWindowStyleFlag (long style)

  Sets the style of the window.
- long GetWindowStyleFlag () const

  Gets the window style that was passed to the constructor or Create() method.
- void SetArtProvider (wxAuiToolBarArt *art)
- wxAuiToolBarArt * GetArtProvider () const
- bool SetFont (const wxFont &font)

  Sets the font for this window.
- wxAuiToolBarItem * AddTool (int tool_id, const wxString &label, const wxBitmap &bitmap, const wxString &short_help_string=wxEmptyString, wxItemKind kind=wxITEM_NORMAL)
- wxAuiToolBarItem * AddTool (int tool_id, const wxString &label, const wxBitmap &bitmap, const wxBitmap &disabled_bitmap, wxItemKind kind, const wxString &short_help_string, const wxString &long_help_string, wxObject *client_data)

bool wxAuiToolBar::GetToolToggled (int *tool_id*) const

long wxAuiToolBar::GetWindowStyleFlag ( ) const `[virtual]`

Gets the window style that was passed to the constructor or Create() method.

GetWindowStyle() is another name for the same function.

Reimplemented from wxWindow.

bool wxAuiToolBar::IsPaneValid (const wxAuiPaneInfo & *pane*) const

bool wxAuiToolBar::Realize ( )

void wxAuiToolBar::SetArtProvider (wxAuiToolBarArt * *art*)

void wxAuiToolBar::SetCustomOverflowItems (const wxAuiToolBarItemArray & *prepend*, const wxAuiToolBarItemArray & *append*)

bool wxAuiToolBar::SetFont (const wxFont & *font*) `[virtual]`

Sets the font for this window.

This function should not be called for the parent window if you don't want its font to be inherited by its children, use SetOwnFont() instead in this case and see InheritAttributes() for more explanations.

Please notice that the given font is not automatically used for wxPaintDC objects associated with this window, you need to call wxDC::SetFont too. However this font is used by any standard controls for drawing their text as well as by GetTextExtent().

Parameters

font	Font to associate with this window, pass wxNullFont to reset to the default font.

Returns

true if the font was really changed, false if it was already set to this font and nothing was done.

See also

GetFont(), InheritAttributes()

Reimplemented from wxWindow.

`#include <wx/aui/auibar.h>`

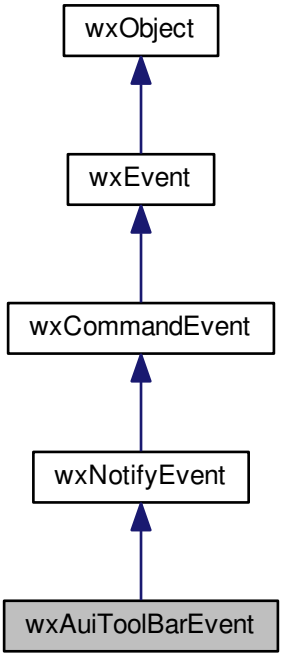
Inheritance diagram for wxAuiToolBarEvent:



21.52.1 Detailed Description

wxAuiToolBarEvent is used for the events generated by wxAuiToolBar.

Library: wxAui

Category: Window Docking (wxAUI)

Public Member Functions

- bool IsDropDownClicked () const

  Returns whether the drop down menu has been clicked.
- wxPoint GetClickPoint () const

  Returns the point where the user clicked with the mouse.
- wxRect GetItemRect () const

  Returns the wxAuiToolBarItem rectangle bounding the mouse click point.
- int GetToolId () const

  Returns the wxAuiToolBarItem identifier.

Additional Inherited Members

21.52.2 Member Function Documentation

wxPoint wxAuiToolBarEvent::GetClickPoint ( ) const

Returns the point where the user clicked with the mouse.

wxRect wxAuiToolBarEvent::GetItemRect ( ) const

Returns the wxAuiToolBarItem rectangle bounding the mouse click point.

int wxAuiToolBarEvent::GetToolId ( ) const

Returns the wxAuiToolBarItem identifier.

bool wxAuiToolBarEvent::IsDropDownClicked ( ) const

Returns whether the drop down menu has been clicked.

21.53 wxAuiToolBarItem Class Reference

`#include <wx/aui/auibar.h>`

21.53.1 Detailed Description

wxAuiToolBarItem is part of the wxAUI class framework, representing a toolbar element.

See also wxAuiToolBar and wxAUI Overview.

It has a unique id (except for the separators which always have id = -1), the style (telling whether it is a normal button, separator or a control), the state (toggled or not, enabled or not) and short and long help strings. The default implementations use the short help string for the tooltip text which is popped up when the mouse pointer enters the tool and the long help string for the applications status bar (currently not implemented).

void wxAuiToolBarItem::SetSticky (bool *b*)

void wxAuiToolBarItem::SetUserData (long *l*)

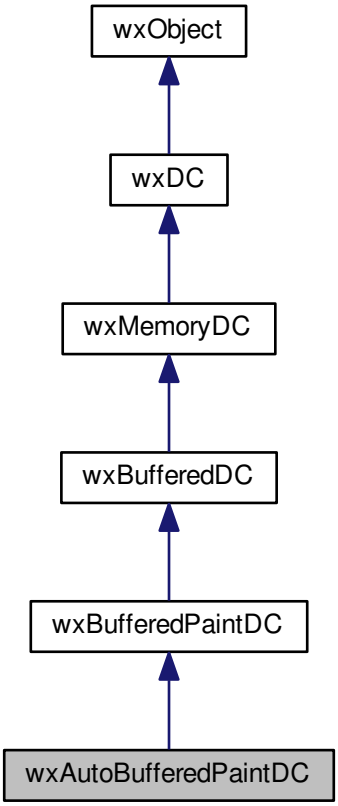
void wxAuiToolBarItem::SetWindow (wxWindow * *w*)

Assigns a window to the toolbar item.

21.54 wxAutoBufferedPaintDC Class Reference

`#include <wx/dcbuffer.h>`

Inheritance diagram for wxAutoBufferedPaintDC:



21.54.1 Detailed Description

This wxDC derivative can be used inside of an `EVT_PAINT()` event handler to achieve double-buffered drawing.

Just use this class instead of wxPaintDC and make sure wxWindow::SetBackgroundStyle() is called with wxBG_↩ STYLE_PAINT somewhere in the class initialization code, and that's all you have to do to (mostly) avoid flicker.

The difference between wxBufferedPaintDC and this class is that this class won't double-buffer on platforms which have native double-buffering already, avoiding any unnecessary buffering to avoid flicker.

wxAutoBufferedPaintDC is simply a typedef of wxPaintDC on platforms that have native double-buffering, otherwise, it is a typedef of wxBufferedPaintDC.

Library: wxCore

Category: Device Contexts

wxDC, wxBufferedPaintDC, wxPaintDC

Public Member Functions

- wxAutoBufferedPaintDC (wxWindow *window)

  Constructor.

Additional Inherited Members

21.54.2 Constructor & Destructor Documentation

wxAutoBufferedPaintDC::wxAutoBufferedPaintDC (wxWindow * *window*)

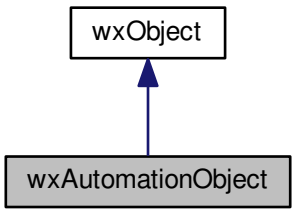
Constructor.

Pass a pointer to the window on which you wish to paint.

21.55 wxAutomationObject Class Reference

`#include <wx/msw/ole/automtn.h>`

Inheritance diagram for wxAutomationObject:



21.55.1 Detailed Description

The **wxAutomationObject** class represents an OLE automation object containing a single data member, an IDispatch pointer.

It contains a number of functions that make it easy to perform automation operations, and set and get properties. The class makes heavy use of the wxVariant class.

The usage of these classes is quite close to OLE automation usage in Visual Basic. The API is high-level, and the application can specify multiple properties in a single string. The following example gets the current Excel instance, and if it exists, makes the active cell bold.

```
wxAutomationObject excelObject;
  if (excelObject.GetInstance("Excel.Application"))
      excelObject.PutProperty("ActiveCell.Font.Bold", @true);
```

Note that this class obviously works under Windows only.

Availability: only available for the wxMSW port.

Library: wxCore

Category: Data Structures

See also

wxVariant, wxVariantDataCurrency, wxVariantDataErrorCode, wxVariantDataSafeArray

Public Member Functions

- wxAutomationObject (WXIDISPATCH *dispatchPtr=NULL)

  Constructor, taking an optional IDispatch pointer which will be released when the object is deleted.
- ~wxAutomationObject ()

  Destructor.
- bool CreateInstance (const wxString &progId) const

  Creates a new object based on the ProgID, returning true if the object was successfully created, or false if not.
- bool IsOk () const

  Checks if the object is in a valid state.
- void * GetDispatchPtr () const

  Gets the IDispatch pointer.
- bool GetInstance (const wxString &progId, int flags=wxAutomationInstance_CreateIfNeeded) const

  Retrieves the current object associated with the specified ProgID, and attaches the IDispatch pointer to this object.
- bool GetObject (wxAutomationObject &obj, const wxString &property, int noArgs=0, wxVariant args[]=NULL) const

  Retrieves a property from this object, assumed to be a dispatch pointer, and initialises obj with it.
- bool Invoke (const wxString &member, int action, wxVariant &retValue, int noArgs, wxVariant args[], const wxVariant *ptrArgs[]=0) const

  This function is a low-level implementation that allows access to the IDispatch Invoke function.
- void SetDispatchPtr (WXIDISPATCH *dispatchPtr)

  Sets the IDispatch pointer.
- LCID GetLCID () const

  Returns the locale identifier used in automation calls.
- void SetLCID (LCID lcid)

  Sets the locale identifier to be used in automation calls performed by this object.
- long GetConvertVariantFlags () const

  Returns the flags used for conversions between wxVariant and OLE VARIANT, see wxOleConvertVariantFlags.
- void SetConvertVariantFlags (long flags)

  Sets the flags used for conversions between wxVariant and OLE VARIANT, see wxOleConvertVariantFlags.

- wxVariant CallMethod (const wxString &method, int noArgs, wxVariant args[]) const

  Calls an automation method for this object.
- const wxVariant CallMethod (const wxString &method,...) const

  Calls an automation method for this object.

- wxVariant GetProperty (const wxString &property, int noArgs, wxVariant args[]) const

  Gets a property value from this object.
- const wxVariant GetProperty (const wxString &property,...) const

Gets a property value from this object.

- bool PutProperty (const wxString &property, int noArgs, wxVariant args[])

  Puts a property value into this object.
- const bool PutProperty (const wxString &property,...)

  Puts a property value into this object.

Additional Inherited Members

21.55.2 Constructor & Destructor Documentation

wxAutomationObject::wxAutomationObject (WXIDISPATCH * *dispatchPtr* = NULL)

Constructor, taking an optional IDispatch pointer which will be released when the object is deleted.

wxAutomationObject::~wxAutomationObject ( )

Destructor.

If the internal IDispatch pointer is non-null, it will be released.

21.55.3 Member Function Documentation

wxVariant wxAutomationObject::CallMethod (const wxString & *method,* int *noArgs,* wxVariant *args[]*) const

Calls an automation method for this object.

The first form takes a method name, number of arguments, and an array of variants. The second form takes a method name and zero to six constant references to variants. Since the variant class has constructors for the basic data types, and C++ provides temporary objects automatically, both of the following lines are syntactically valid:

Note that *method* can contain dot-separated property names, to save the application needing to call GetProperty several times using several temporary objects. For example:

const wxVariant wxAutomationObject::CallMethod (const wxString & *method,* ...) const

Calls an automation method for this object.

The first form takes a method name, number of arguments, and an array of variants. The second form takes a method name and zero to six constant references to variants. Since the variant class has constructors for the basic data types, and C++ provides temporary objects automatically, both of the following lines are syntactically valid:

Note that *method* can contain dot-separated property names, to save the application needing to call GetProperty several times using several temporary objects. For example:

bool wxAutomationObject::CreateInstance (const wxString & *progId*) const

Creates a new object based on the ProgID, returning true if the object was successfully created, or false if not.

long wxAutomationObject::GetConvertVariantFlags ( ) const

Returns the flags used for conversions between wxVariant and OLE VARIANT, see wxOleConvertVariantFlags.

The default value is wxOleConvertVariant_Default for compatibility but it can be changed using SetConvertVariant↩Flags().

Notice that objects obtained by GetObject() inherit the flags from the one that created them.

Since

3.0

void* wxAutomationObject::GetDispatchPtr ( ) const

Gets the IDispatch pointer.

Notice that the return value of this function is an untyped pointer but it can be safely cast to `IDispatch`.

bool wxAutomationObject::GetInstance (const wxString & *progId,* int *flags* = wxAutomationInstance_CreateIfNeeded) const

Retrieves the current object associated with the specified ProgID, and attaches the IDispatch pointer to this object.

If attaching to an existing object failed and *flags* includes wxAutomationInstance_CreateIfNeeded flag, a new object will be created. Otherwise this function will normally log an error message which may be undesirable if the object may or may not exist. The wxAutomationInstance_SilentIfNone flag can be used to prevent the error from being logged in this case.

Returns true if a pointer was successfully retrieved, false otherwise.

Note that this cannot cope with two instances of a given OLE object being active simultaneously, such as two copies of Excel running. Which object is referenced cannot currently be specified.

Parameters

progId	COM ProgID, e.g. "Excel.Application"
flags	The creation flags (this parameters was added in wxWidgets 2.9.2)

LCID wxAutomationObject::GetLCID ( ) const

Returns the locale identifier used in automation calls.

The default is LOCALE_SYSTEM_DEFAULT but the objects obtained by GetObject() inherit the locale identifier from the one that created them.

Since

2.9.5

bool wxAutomationObject::GetObject (wxAutomationObject & *obj,* const wxString & *property,* int *noArgs* = `0`, wxVariant *args[]* = `NULL`) const

Retrieves a property from this object, assumed to be a dispatch pointer, and initialises *obj* with it.

To avoid having to deal with IDispatch pointers directly, use this function in preference to GetProperty() when retrieving objects from other objects. Note that an IDispatch pointer is stored as a void* pointer in wxVariant objects.

See also

GetProperty()

wxVariant wxAutomationObject::GetProperty (const wxString & *property,* int *noArgs,* wxVariant *args[]*) const

Gets a property value from this object.

The first form takes a property name, number of arguments, and an array of variants. The second form takes a property name and zero to six constant references to variants. Since the variant class has constructors for the basic data types, and C++ provides temporary objects automatically, both of the following lines are syntactically valid:

Note that *property* can contain dot-separated property names, to save the application needing to call GetProperty several times using several temporary objects.

const wxVariant wxAutomationObject::GetProperty (const wxString & *property,* ...) const

Gets a property value from this object.

The first form takes a property name, number of arguments, and an array of variants. The second form takes a property name and zero to six constant references to variants. Since the variant class has constructors for the basic data types, and C++ provides temporary objects automatically, both of the following lines are syntactically valid:

Note that *property* can contain dot-separated property names, to save the application needing to call GetProperty several times using several temporary objects.

bool wxAutomationObject::Invoke (const wxString & *member,* int *action,* wxVariant & *retValue,* int *noArgs,* wxVariant *args[],* const wxVariant * *ptrArgs[]* = 0) const

This function is a low-level implementation that allows access to the IDispatch Invoke function.

It is not meant to be called directly by the application, but is used by other convenience functions.

Parameters

member	The member function or property name.
action	Bitlist: may contain DISPATCH_PROPERTYPUT, DISPATCH_PROPERTYPUTREF, DISPATCH_METHOD.
retValue	Return value (ignored if there is no return value)
noArgs	Number of arguments in args or ptrArgs.
args	If non-null, contains an array of variants.
ptrArgs	If non-null, contains an array of constant pointers to variants.

Returns

true if the operation was successful, false otherwise.

Remarks

Two types of argument array are provided, so that when possible pointers are used for efficiency.

bool wxAutomationObject::IsOk ( ) const

Checks if the object is in a valid state.

Returns true if the object was successfully initialized or false if it has no valid IDispatch pointer.

See also

GetDispatchPtr()

bool wxAutomationObject::PutProperty (const wxString & *property,* int *noArgs,* wxVariant *args[]*)

Puts a property value into this object.

The first form takes a property name, number of arguments, and an array of variants. The second form takes a property name and zero to six constant references to variants. Since the variant class has constructors for the basic data types, and C++ provides temporary objects automatically, both of the following lines are syntactically valid:

Note that *property* can contain dot-separated property names, to save the application needing to call GetProperty several times using several temporary objects.

const bool wxAutomationObject::PutProperty (const wxString & *property,* ...)

Puts a property value into this object.

The first form takes a property name, number of arguments, and an array of variants. The second form takes a property name and zero to six constant references to variants. Since the variant class has constructors for the basic data types, and C++ provides temporary objects automatically, both of the following lines are syntactically valid:

Note that *property* can contain dot-separated property names, to save the application needing to call GetProperty several times using several temporary objects.

void wxAutomationObject::SetConvertVariantFlags (long *flags*)

Sets the flags used for conversions between wxVariant and OLE VARIANT, see wxOleConvertVariantFlags.

The default value is wxOleConvertVariant_Default.

Since

3.0

void wxAutomationObject::SetDispatchPtr (WXIDISPATCH * *dispatchPtr*)

Sets the IDispatch pointer.

This function does not check if there is already an IDispatch pointer. You may need to cast from IDispatch* to WXIDISPATCH* when calling this function.

void wxAutomationObject::SetLCID (LCID *lcid*)

Sets the locale identifier to be used in automation calls performed by this object.

The default value is LOCALE_SYSTEM_DEFAULT.

Notice that any automation objects created by this one inherit the same LCID.

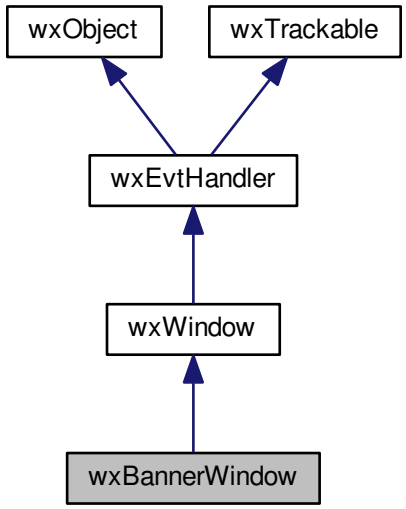
Since

2.9.5

21.56 wxBannerWindow Class Reference

`#include <wx/bannerwindow.h>`

Inheritance diagram for wxBannerWindow:



21.56.1 Detailed Description

A simple banner window showing either a bitmap or text.

Banner windows can be used to present some overview of the current window contents to the user in an aesthetically pleasant way. They are typically positioned along the left or top edge of the window (although this class also supports right- and bottom-aligned banners) and show either a bitmap with a logo or a few lines of text on a gradient-filled background.

Using this class is very simple, e.g.:

```
MyFrame::MyFrame(...)
{
    ... create the frame itself ...

    // Create and initialize the banner.
    wxBannerWindow* banner = new wxBannerWindow(this,
      wxTOP);
    banner->SetText("Welcome to my wonderful program",
                    "  Before doing anything else, you need to connect to "
                    "the online server.\n"
                    "  Please enter your credentials in the controls below.");

    // And position it along the left edge of the window.
    wxSizer* sizer = new wxBoxSizer(wxVERTICAL);
    sizer->Add(banner, wxSizerFlags().Expand());

    ... add the rest of the window contents to the same sizer ...

    SetSizerAndFit(sizer);
}
```

This class is currently implemented generically and so looks the same under all platforms.

Library: wxAdvanced

Category: Miscellaneous Windows

Since

2.9.3

Public Member Functions

- wxBannerWindow ()

  Default constructor, use Create() later.
- wxBannerWindow (wxWindow *parent, wxDirection dir=wxLEFT)

  Convenient constructor that should be used in the majority of cases.
- wxBannerWindow (wxWindow *parent, wxWindowID winid, wxDirection dir=wxLEFT, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, long style=0, const wxString &name=wxBannerWindowNameStr)

  Full constructor provided for consistency with the other classes only.
- bool Create (wxWindow *parent, wxWindowID winid, wxDirection dir=wxLEFT, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, long style=0, const wxString &name=wxBannerWindowNameStr)

  Really create the banner window for the objects created using the default constructor.
- void SetBitmap (const wxBitmap &bmp)

  Provide the bitmap to use as background.
- void SetText (const wxString &title, const wxString &message)

  Set the text to display.
- void SetGradient (const wxColour &start, const wxColour &end)

  Set the colours between which the gradient runs.

Additional Inherited Members

21.56.2 Constructor & Destructor Documentation

wxBannerWindow::wxBannerWindow ( )

Default constructor, use Create() later.

This constructor is only used for two-step creation, if possible, prefer using the constructor below directly instead of using this one and calling Create() later.

wxBannerWindow::wxBannerWindow (wxWindow * *parent*, wxDirection *dir* = wxLEFT)

Convenient constructor that should be used in the majority of cases.

The only really important arguments of the full constructor below are *parent* and *dir* so this class provides a convenient constructor taking only them.

The banner orientation changes how the text in it is displayed and also defines where is the bitmap truncated if it's too big to fit but doesn't do anything for the banner position, this is supposed to be taken care of in the usual way, e.g. using sizers.

wxBannerWindow::wxBannerWindow (wxWindow * *parent*, wxWindowID *winid*, wxDirection *dir* = wxLEFT, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, long *style* = 0, const wxString & *name* = wxBannerWindowNameStr)

Full constructor provided for consistency with the other classes only.

Prefer to use the shorter constructor documented above. You should rarely, if ever, need to use non-default values for any other parameters: as the banner window doesn't generate any events, its identifier is not particularly useful; its position and size will be almost always managed by the containing sizer and it doesn't have any specific styles. So only the parent and the banner direction need to be specified.

21.56.3 Member Function Documentation

bool wxBannerWindow::Create (wxWindow * *parent*, wxWindowID *winid*, wxDirection *dir* = wxLEFT, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, long *style* = 0, const wxString & *name* = wxBannerWindowNameStr)

Really create the banner window for the objects created using the default constructor.

It's an error to call Create() for the objects created using non-default constructor.

void wxBannerWindow::SetBitmap (const wxBitmap & *bmp*)

Provide the bitmap to use as background.

Notice that ideally the bitmap should be big enough to always cover the entire banner, e.g. for a horizontal banner with wxTOP style its width should be bigger than any reasonable window size. Otherwise the bitmap is extended to cover the entire window area with a solid colour taken from the bitmap pixel on the edge in which direction the extension occurs so all bitmap pixels on this edge (top for wxLEFT, right for wxTOP and wxBOTTOM and bottom for wxRIGHT) should have the same colour to avoid jarring discontinuity.

If, on the other hand, the bitmap is bigger than the window size, then it is truncated. For wxLEFT orientation the bitmap is truncated from the top, for wxTOP and wxBOTTOM – from the right and for wxRIGHT – from the bottom, so put the most important part of the bitmap information in the opposite direction where it will never be truncated.

If no valid background bitmap is specified, the banner draws gradient background but if a valid bitmap is given here, the gradient is not draw and the start and end colours specified for it are ignored.

Parameters

bmp	Bitmap to use as background. May be invalid to indicate that no background bitmap should be used.

void wxBannerWindow::SetGradient (const wxColour & *start*, const wxColour & *end*)

Set the colours between which the gradient runs.

The gradient colours are ignored if SetBitmap() is used.

void wxBannerWindow::SetText (const wxString & *title*, const wxString & *message*)

Set the text to display.

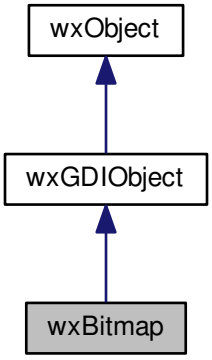
This is mutually exclusive with SetBitmap().

Title is rendered in bold and should be single line, message can have multiple lines but is not wrapped automatically, include explicit line breaks in the string if you want to have multiple lines.

21.57 wxBitmap Class Reference

```
#include <wx/bitmap.h>
```

Inheritance diagram for wxBitmap:



21.57.1 Detailed Description

This class encapsulates the concept of a platform-dependent bitmap, either monochrome or colour or colour with alpha channel support.

If you need direct access the bitmap data instead going through drawing to it using wxMemoryDC you need to use the wxPixelData class (either wxNativePixelData for RGB bitmaps or wxAlphaPixelData for bitmaps with an additionally alpha channel).

Note that many wxBitmap functions take a *type* parameter, which is a value of the wxBitmapType enumeration. The validity of those values depends however on the platform where your program is running and from the wxWidgets configuration. If all possible wxWidgets settings are used:

- wxMSW supports BMP and ICO files, BMP and ICO resources;
- wxGTK supports any file supported by gdk-pixbuf;
- wxMac supports PICT resources;
- wxX11 supports XPM files, XPM data, XBM data;

In addition, wxBitmap can load and save all formats that wxImage can; see wxImage for more info. Of course, you must have loaded the wxImage handlers (see wxInitAllImageHandlers() and wxImage::AddHandler). Note that all available wxBitmapHandlers for a given wxWidgets port are automatically loaded at startup so you won't need to use wxBitmap::AddHandler.

More on the difference between wxImage and wxBitmap: wxImage is just a buffer of RGB bytes with an optional buffer for the alpha bytes. It is all generic, platform independent and image file format independent code. It includes generic code for scaling, resizing, clipping, and other manipulations of the image data. OTOH, wxBitmap is intended to be a wrapper of whatever is the native image format that is quickest/easiest to draw to a DC or to be the target of the drawing operations performed on a wxMemoryDC. By splitting the responsibilities between wxImage/wxBitmap like this then it's easier to use generic code shared by all platforms and image types for generic operations and platform specific code where performance or compatibility is needed.

Bitmaps and Icons, Supported Bitmap File Formats, wxDC::Blit, wxIcon, wxCursor, wxMemoryDC, wxImage, wxPixelData

Public Member Functions

- wxBitmap ()

  Default constructor.
- wxBitmap (const wxBitmap &bitmap)

  Copy constructor, uses reference counting.
- wxBitmap (const char bits[], int width, int height, int depth=1)

  Creates a bitmap from the given array bits.
- wxBitmap (int width, int height, int depth=wxBITMAP_SCREEN_DEPTH)

  Creates a new bitmap.
- wxBitmap (const wxSize &sz, int depth=wxBITMAP_SCREEN_DEPTH)

  This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.
- wxBitmap (const char *const *bits)

  Creates a bitmap from XPM data.
- wxBitmap (const wxString &name, wxBitmapType type=wxBITMAP_DEFAULT_TYPE)

  Loads a bitmap from a file or resource.
- wxBitmap (const wxImage &img, int depth=wxBITMAP_SCREEN_DEPTH)

  Creates this bitmap object from the given image.
- wxBitmap (const wxCursor &cursor)

  Creates bitmap corresponding to the given cursor.
- virtual ~wxBitmap ()

  Destructor.
- virtual wxImage ConvertToImage () const

  Creates an image from a platform-dependent bitmap.
- virtual bool CopyFromIcon (const wxIcon &icon)

  Creates the bitmap from an icon.
- virtual bool Create (int width, int height, int depth=wxBITMAP_SCREEN_DEPTH)

  Creates a fresh bitmap.
- virtual bool Create (const wxSize &sz, int depth=wxBITMAP_SCREEN_DEPTH)

  This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.
- virtual int GetDepth () const

  Gets the colour depth of the bitmap.
- virtual int GetHeight () const

  Gets the height of the bitmap in pixels.
- virtual wxMask * GetMask () const

  Gets the associated mask (if any) which may have been loaded from a file or set for the bitmap.
- virtual wxPalette * GetPalette () const

  Gets the associated palette (if any) which may have been loaded from a file or set for the bitmap.
- virtual wxBitmap GetSubBitmap (const wxRect &rect) const

  Returns a sub bitmap of the current one as long as the rect belongs entirely to the bitmap.
- wxSize GetSize () const

  Returns the size of the bitmap in pixels.

- wxBitmap ConvertToDisabled (unsigned char brightness=255) const

  Returns disabled (dimmed) version of the bitmap.
- virtual int GetWidth () const

  Gets the width of the bitmap in pixels.
- virtual bool IsOk () const

  Returns true if bitmap data is present.
- virtual bool LoadFile (const wxString &name, wxBitmapType type=wxBITMAP_DEFAULT_TYPE)

  Loads a bitmap from a file or resource.
- virtual bool SaveFile (const wxString &name, wxBitmapType type, const wxPalette *palette=NULL) const

  Saves a bitmap in the named file.
- virtual void SetDepth (int depth)

  Sets the depth member (does not affect the bitmap data).
- virtual void SetHeight (int height)

  Sets the height member (does not affect the bitmap data).
- virtual void SetMask (wxMask *mask)

  Sets the mask for this bitmap.
- virtual void SetPalette (const wxPalette &palette)

  Sets the associated palette.
- virtual void SetWidth (int width)

  Sets the width member (does not affect the bitmap data).

Static Public Member Functions

- static void AddHandler (wxBitmapHandler *handler)

  Adds a handler to the end of the static list of format handlers.
- static void CleanUpHandlers ()

  Deletes all bitmap handlers.
- static wxBitmapHandler * FindHandler (const wxString &name)

  Finds the handler with the given name.
- static wxBitmapHandler * FindHandler (const wxString &extension, wxBitmapType bitmapType)

  Finds the handler associated with the given extension and type.
- static wxBitmapHandler * FindHandler (wxBitmapType bitmapType)

  Finds the handler associated with the given bitmap type.
- static wxList & GetHandlers ()

  Returns the static list of bitmap format handlers.
- static void InitStandardHandlers ()

  Adds the standard bitmap format handlers, which, depending on wxWidgets configuration, can be handlers for Windows bitmap, Windows bitmap resource, and XPM.
- static void InsertHandler (wxBitmapHandler *handler)

  Adds a handler at the start of the static list of format handlers.
- static wxBitmap NewFromPNGData (const void *data, size_t size)

  Loads a bitmap from the memory containing image data in PNG format.
- static bool RemoveHandler (const wxString &name)

  Finds the handler with the given name, and removes it.

Additional Inherited Members

21.57.2 Constructor & Destructor Documentation

wxBitmap::wxBitmap ( )

Default constructor.

Constructs a bitmap object with no data; an assignment or another member function such as Create() or LoadFile() must be called subsequently.

wxBitmap::wxBitmap (const wxBitmap & *bitmap*)

Copy constructor, uses reference counting.

To make a real copy, you can use:

```
wxBitmap newBitmap = oldBitmap.GetSubBitmap(
                     wxRect(0, 0, oldBitmap.GetWidth(), oldBitmap.GetHeight()));
```

wxBitmap::wxBitmap (const char *bits[]*, int *width*, int *height*, int *depth* = 1)

Creates a bitmap from the given array *bits*.

You should only use this function for monochrome bitmaps (depth 1) in portable programs: in this case the bits parameter should contain an XBM image.

For other bit depths, the behaviour is platform dependent: under Windows, the data is passed without any changes to the underlying CreateBitmap() API. Under other platforms, only monochrome bitmaps may be created using this constructor and wxImage should be used for creating colour bitmaps from static data.

Parameters

bits	Specifies an array of pixel values.
width	Specifies the width of the bitmap.
height	Specifies the height of the bitmap.
depth	Specifies the depth of the bitmap. If this is omitted, then a value of 1 (monochrome bitmap) is used.

wxPerl Note: In wxPerl use Wx::Bitmap->newFromBits(bits, width, height, depth).

wxBitmap::wxBitmap (int *width*, int *height*, int *depth* = wxBITMAP_SCREEN_DEPTH)

Creates a new bitmap.

A depth of wxBITMAP_SCREEN_DEPTH indicates the depth of the current screen or visual.

Some platforms only support 1 for monochrome and wxBITMAP_SCREEN_DEPTH for the current colour setting.

A depth of 32 including an alpha channel is supported under MSW, Mac and GTK+.

Parameters

width	The width of the bitmap in pixels, must be strictly positive.
height	The height of the bitmap in pixels, must be strictly positive.
depth	The number of bits used to represent each bitmap pixel.

wxBitmap::wxBitmap (const wxSize & *sz*, int *depth* = wxBITMAP_SCREEN_DEPTH)

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.

wxBitmap::wxBitmap (const char ∗const ∗ *bits*)

Creates a bitmap from XPM data.

wxPerl Note: In wxPerl use Wx::Bitmap->newFromXPM(data).

wxBitmap::wxBitmap (const wxString & *name*, wxBitmapType *type* = `wxBITMAP_DEFAULT_TYPE`)

Loads a bitmap from a file or resource.

Parameters

name	This can refer to a resource name or a filename under MS Windows and X. Its meaning is determined by the *type* parameter.
type	May be one of the wxBitmapType values and indicates which type of bitmap should be loaded. See the note in the class detailed description. Note that the wxBITMAP_DEFAULT_TYPE constant has different value under different wxWidgets ports. See the bitmap.h header for the value it takes for a specific port.

See also

LoadFile()

wxBitmap::wxBitmap (const wxImage & *img*, int *depth* = wxBITMAP_SCREEN_DEPTH)

Creates this bitmap object from the given image.

This has to be done to actually display an image as you cannot draw an image directly on a window.

The resulting bitmap will use the provided colour depth (or that of the current system if depth is wxBITMAP_SCR↩EEN_DEPTH) which entails that a colour reduction may take place.

On Windows, if there is a palette present (set with SetPalette), it will be used when creating the wxBitmap (most useful in 8-bit display mode). On other platforms, the palette is currently ignored.

Parameters

img	Platform-independent wxImage object.
depth	Specifies the depth of the bitmap. If this is omitted, the display depth of the screen is used.

wxBitmap::wxBitmap (const wxCursor & *cursor*) `[explicit]`

Creates bitmap corresponding to the given cursor.

This can be useful to display a cursor as it cannot be drawn directly on a window.

This constructor only exists in wxMSW and wxGTK (where it is implemented for GTK+ 2.8 or later) only.

Parameters

cursor	A valid wxCursor.

Since

3.1.0

virtual wxBitmap::∼wxBitmap ( ) `[virtual]`

Destructor.

See Object Destruction for more info.

If the application omits to delete the bitmap explicitly, the bitmap will be destroyed automatically by wxWidgets when the application exits.

Warning

Do not delete a bitmap that is selected into a memory device context.

21.57.3 Member Function Documentation

static void wxBitmap::AddHandler (wxBitmapHandler * *handler*) `[static]`

Adds a handler to the end of the static list of format handlers.

Parameters

handler	A new bitmap format handler object. There is usually only one instance of a given handler class in an application session.

Note that unlike wxImage::AddHandler, there's no documented list of the wxBitmapHandlers available in wxWidgets. This is because they are platform-specific and most important, they are all automatically loaded at startup.

If you want to be sure that wxBitmap can load a certain type of image, you'd better use wxImage::AddHandler.

See also

wxBitmapHandler

static void wxBitmap::CleanUpHandlers ( ) `[static]`

Deletes all bitmap handlers.

This function is called by wxWidgets on exit.

wxBitmap wxBitmap::ConvertToDisabled (unsigned char *brightness* = `255`) const

Returns disabled (dimmed) version of the bitmap.

This method is not available when `wxUSE_IMAGE == 0`.

Since

2.9.0

virtual wxImage wxBitmap::ConvertToImage ( ) const `[virtual]`

Creates an image from a platform-dependent bitmap.

This preserves mask information so that bitmaps and images can be converted back and forth without loss in that respect.

virtual bool wxBitmap::CopyFromIcon (const wxIcon & *icon*) `[virtual]`

Creates the bitmap from an icon.

virtual bool wxBitmap::Create (int *width,* int *height,* int *depth* = wxBITMAP_SCREEN_DEPTH) [virtual]

Creates a fresh bitmap.

If the final argument is omitted, the display depth of the screen is used.

Parameters

width	The width of the bitmap in pixels, must be strictly positive.
height	The height of the bitmap in pixels, must be strictly positive.
depth	The number of bits used to represent each bitmap pixel.

Returns

true if the creation was successful.

virtual bool wxBitmap::Create (const wxSize & *sz*, int *depth* = wxBITMAP_SCREEN_DEPTH) [virtual]

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.

static wxBitmapHandler* wxBitmap::FindHandler (const wxString & *name*) [static]

Finds the handler with the given *name*.

Returns

A pointer to the handler if found, NULL otherwise.

static wxBitmapHandler* wxBitmap::FindHandler (const wxString & *extension*, wxBitmapType *bitmapType*) [static]

Finds the handler associated with the given *extension* and *type*.

Parameters

extension	The file extension, such as "bmp" (without the dot).
bitmapType	The bitmap type managed by the handler, see wxBitmapType.

Returns

A pointer to the handler if found, NULL otherwise.

static wxBitmapHandler* wxBitmap::FindHandler (wxBitmapType *bitmapType*) [static]

Finds the handler associated with the given bitmap type.

Parameters

bitmapType	The bitmap type managed by the handler, see wxBitmapType.

Returns

A pointer to the handler if found, NULL otherwise.

See also

wxBitmapHandler

virtual int wxBitmap::GetDepth ( ) const `[virtual]`

Gets the colour depth of the bitmap.

A value of 1 indicates a monochrome bitmap.

static wxList& wxBitmap::GetHandlers ( ) `[static]`

Returns the static list of bitmap format handlers.

See also

wxBitmapHandler

virtual int wxBitmap::GetHeight ( ) const `[virtual]`

Gets the height of the bitmap in pixels.

See also

GetWidth(), GetSize()

virtual wxMask* wxBitmap::GetMask ( ) const `[virtual]`

Gets the associated mask (if any) which may have been loaded from a file or set for the bitmap.

See also

SetMask(), wxMask

virtual wxPalette* wxBitmap::GetPalette ( ) const `[virtual]`

Gets the associated palette (if any) which may have been loaded from a file or set for the bitmap.

See also

wxPalette

wxSize wxBitmap::GetSize ( ) const

Returns the size of the bitmap in pixels.

Since

2.9.0

See also

GetHeight(), GetWidth()

virtual wxBitmap wxBitmap::GetSubBitmap (const wxRect & *rect*) const `[virtual]`

Returns a sub bitmap of the current one as long as the rect belongs entirely to the bitmap.

This function preserves bit depth and mask information.

virtual int wxBitmap::GetWidth ( ) const `[virtual]`

Gets the width of the bitmap in pixels.

See also

GetHeight(), GetSize()

static void wxBitmap::InitStandardHandlers ( ) `[static]`

Adds the standard bitmap format handlers, which, depending on wxWidgets configuration, can be handlers for Windows bitmap, Windows bitmap resource, and XPM.

This function is called by wxWidgets on startup.

See also

wxBitmapHandler

static void wxBitmap::InsertHandler (wxBitmapHandler * *handler*) `[static]`

Adds a handler at the start of the static list of format handlers.

Parameters

handler	A new bitmap format handler object. There is usually only one instance of a given handler class in an application session.

See also

wxBitmapHandler

virtual bool wxBitmap::IsOk ( ) const `[virtual]`

Returns true if bitmap data is present.

virtual bool wxBitmap::LoadFile (const wxString & *name*, wxBitmapType *type* = wxBITMAP_DEFAULT_TYPE) `[virtual]`

Loads a bitmap from a file or resource.

Parameters

name	Either a filename or a Windows resource name. The meaning of name is determined by the *type* parameter.
type	One of the wxBitmapType values; see the note in the class detailed description. Note that the wxBITMAP_DEFAULT_TYPE constant has different value under different wxWidgets ports. See the bitmap.h header for the value it takes for a specific port.

Returns

true if the operation succeeded, false otherwise.

Remarks

A palette may be associated with the bitmap if one exists (especially for colour Windows bitmaps), and if the code supports it. You can check if one has been created by using the GetPalette() member.

See also

SaveFile()

static wxBitmap wxBitmap::NewFromPNGData (const void * *data*, size_t *size*) [static]

Loads a bitmap from the memory containing image data in PNG format.

This helper function provides the simplest way to create a wxBitmap from PNG image data. On most platforms, it's simply a wrapper around wxImage loading functions and so requires the PNG image handler to be registered by either calling wxInitAllImageHandlers() which also registers all the other image formats or including the necessary header:

```
#include <wx/imagpng.h>
```

and calling

```
wxImage::AddHandler(new wxPNGHandler);
```

in your application startup code.

However under OS X this function uses native image loading and so doesn't require wxWidgets PNG support.

Since

2.9.5

static bool wxBitmap::RemoveHandler (const wxString & *name*) [static]

Finds the handler with the given name, and removes it.

The handler is not deleted.

Parameters

name	The handler name.

Returns

true if the handler was found and removed, false otherwise.

See also

wxBitmapHandler

virtual bool wxBitmap::SaveFile (const wxString & *name*, wxBitmapType *type*, const wxPalette * *palette* = NULL) const [virtual]

Saves a bitmap in the named file.

Parameters

name	A filename. The meaning of name is determined by the type parameter.
type	One of the wxBitmapType values; see the note in the class detailed description.
palette	An optional palette used for saving the bitmap.

Returns

true if the operation succeeded, false otherwise.

Remarks

Depending on how wxWidgets has been configured, not all formats may be available.

See also

LoadFile()

virtual void wxBitmap::SetDepth (int *depth*) [virtual]

Sets the depth member (does not affect the bitmap data).

Todo since these functions do not affect the bitmap data, why they exist??

Parameters

depth	Bitmap depth.

virtual void wxBitmap::SetHeight (int *height*) [virtual]

Sets the height member (does not affect the bitmap data).

Parameters

height	Bitmap height in pixels.

virtual void wxBitmap::SetMask (wxMask * *mask*) [virtual]

Sets the mask for this bitmap.

Remarks

The bitmap object owns the mask once this has been called.

See also

GetMask(), wxMask

virtual void wxBitmap::SetPalette (const wxPalette & *palette*) [virtual]

Sets the associated palette.

(Not implemented under GTK+).

Parameters

palette	The palette to set.

See also

wxPalette

virtual void wxBitmap::SetWidth (int *width*) `[virtual]`

Sets the width member (does not affect the bitmap data).

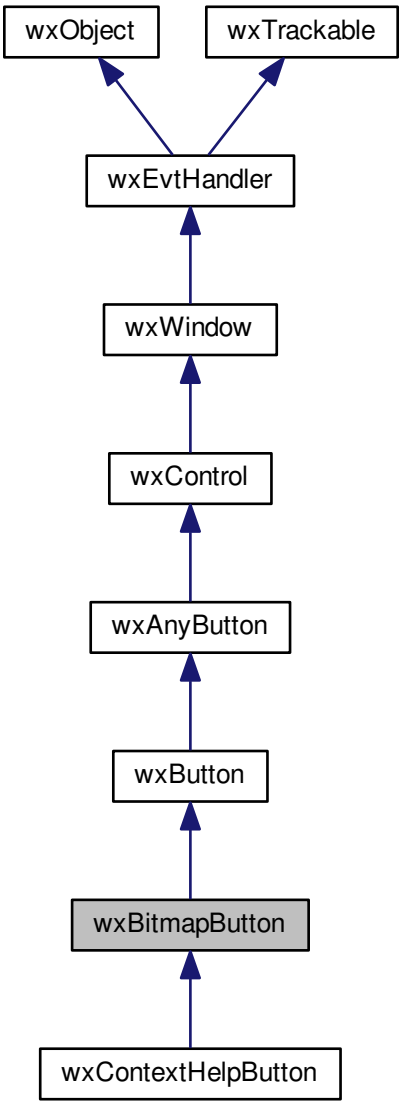
Parameters

width	Bitmap width in pixels.

21.58 wxBitmapButton Class Reference

`#include <wx/bmpbuttn.h>`

Inheritance diagram for wxBitmapButton:



21.58.1 Detailed Description

A bitmap button is a control that contains a bitmap.

Notice that since wxWidgets 2.9.1 bitmap display is supported by the base wxButton class itself and the only tiny advantage of using this class is that it allows to specify the bitmap in its constructor, unlike wxButton. Please see the base class documentation for more information about images support in wxButton.

Styles

This class supports the following styles:

- wxBU_LEFT: Left-justifies the bitmap label.
- wxBU_TOP: Aligns the bitmap label to the top of the button.
- wxBU_RIGHT: Right-justifies the bitmap label.
- wxBU_BOTTOM: Aligns the bitmap label to the bottom of the button.

Note that the wxBU_EXACTFIT style supported by wxButton is not used by this class as bitmap buttons don't have any minimal standard size by default.

Events emitted by this class

The following event handler macros redirect the events to member function handlers '**func**' with prototypes like: void handlerFuncName(wxCommandEvent& event)

Event macros for events emitted by this class:

- EVT_BUTTON(id, func): Process a `wxEVT_BUTTON` event, when the button is clicked.

Library: wxCore

Category: Controls

See also

wxButton

Public Member Functions

- wxBitmapButton ()

  Default ctor.
- wxBitmapButton (wxWindow *parent, wxWindowID id, const wxBitmap &bitmap, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, long style=wxBU_AUTODRAW, const wxValidator &validator=wxDefaultValidator, const wxString &name=wxButtonNameStr)

  Constructor, creating and showing a button.
- bool Create (wxWindow *parent, wxWindowID id, const wxBitmap &bitmap, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, long style=wxBU_AUTODRAW, const wxValidator &validator=wxDefaultValidator, const wxString &name=wxButtonNameStr)

  Button creation function for two-step creation.

Static Public Member Functions

- static wxBitmapButton * NewCloseButton (wxWindow *parent, wxWindowID winid)

  Helper function creating a standard-looking "Close" button.

Additional Inherited Members

21.58.2 Constructor & Destructor Documentation

wxBitmapButton::wxBitmapButton ( )

Default ctor.

wxBitmapButton::wxBitmapButton (wxWindow * *parent*, wxWindowID *id*, const wxBitmap & *bitmap*, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, long *style* = wxBU_AUTODRAW, const wxValidator & *validator* = wxDefaultValidator, const wxString & *name* = `wxButtonNameStr`)

Constructor, creating and showing a button.

Parameters

parent	Parent window. Must not be NULL.
id	Button identifier. The value wxID_ANY indicates a default value.
bitmap	Bitmap to be displayed.
pos	Button position. If wxDefaultPosition is specified then a default position is chosen.
size	Button size. If wxDefaultSize is specified then the button is sized appropriately for the bitmap.
style	Window style. See wxBitmapButton.
validator	Window validator.
name	Window name.

Remarks

The bitmap parameter is normally the only bitmap you need to provide, and wxWidgets will draw the button correctly in its different states. If you want more control, call any of the functions SetBitmapPressed(), SetBitmapFocus(), SetBitmapDisabled().

See also

Create(), wxValidator

21.58.3 Member Function Documentation

bool wxBitmapButton::Create (wxWindow * *parent*, wxWindowID *id*, const wxBitmap & *bitmap*, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, long *style* = wxBU_AUTODRAW, const wxValidator & *validator* = wxDefaultValidator, const wxString & *name* = `wxButtonNameStr`)

Button creation function for two-step creation.

For more details, see wxBitmapButton().

static wxBitmapButton* wxBitmapButton::NewCloseButton (wxWindow * *parent*, wxWindowID *winid*) `[static]`

Helper function creating a standard-looking "Close" button.

To get the best results, platform-specific code may need to be used to create a small, title bar-like "Close" button. This function is provided to avoid the need to test for the current platform and creates the button with as native look as possible.

Parameters

parent	The button parent window, must be non-NULL.
winid	The identifier for the new button.

Returns

The new button.

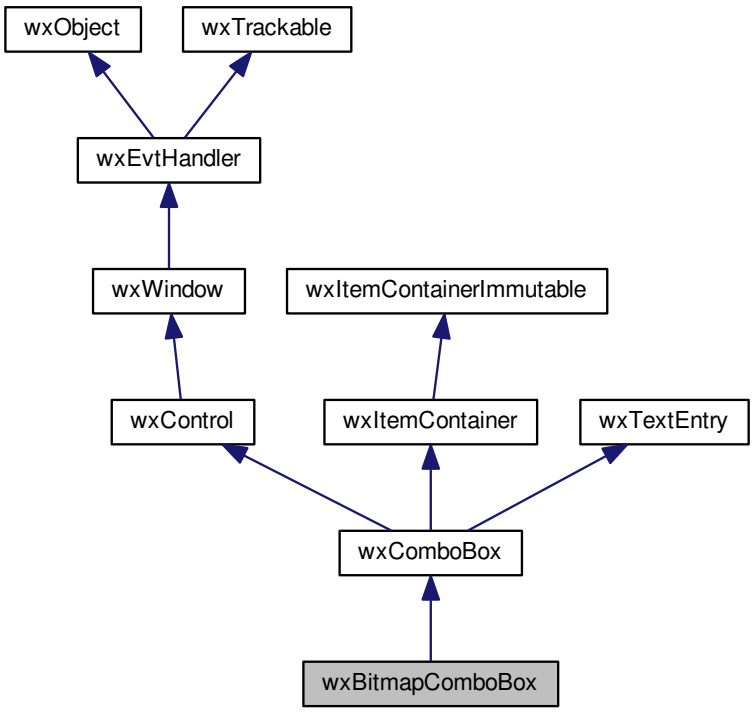
Since

2.9.5

21.59 wxBitmapComboBox Class Reference

```
#include <wx/bmpcbox.h>
```

Inheritance diagram for wxBitmapComboBox:



21.59.1 Detailed Description

A combobox that displays bitmap in front of the list items.

It currently only allows using bitmaps of one size, and resizes itself so that a bitmap can be shown next to the text field.

Remarks

While wxBitmapComboBox contains the wxComboBox API, but it might not actually be derived from that class. In fact, if the platform does not have a native implementation, wxBitmapComboBox will inherit from wxOwnerDrawnComboBox. You can determine if the implementation is generic by checking whether `wxG↩ ENERIC_BITMAPCOMBOBOX` is defined. Currently wxBitmapComboBox is implemented natively for MSW and GTK+.

Styles

This class supports the following styles:

- wxCB_READONLY: Creates a combobox without a text editor. On some platforms the control may appear very different when this style is used.
- wxCB_SORT: Sorts the entries in the list alphabetically.
- wxTE_PROCESS_ENTER: The control will generate the event wxEVT_TEXT_ENTER (otherwise pressing Enter key is either processed internally by the control or used for navigation between dialog controls). Windows only.

Todo create wxCB_PROCESS_ENTER rather than reusing wxTE_PROCESS_ENTER!

Events emitted by this class

The following event handler macros redirect the events to member function handlers '**func**' with prototypes like: void handlerFuncName(wxCommandEvent& event)

Event macros for events emitted by this class:

- EVT_COMBOBOX(id, func): Process a `wxEVT_COMBOBOX` event, when an item on the list is selected.
- EVT_TEXT(id, func): Process a `wxEVT_TEXT` event, when the combobox text changes.
- EVT_TEXT_ENTER(id, func): Process a `wxEVT_TEXT_ENTER` event, when RETURN is pressed in the combobox.

Library: wxAdvanced

Category: Controls

wxComboBox, wxChoice, wxOwnerDrawnComboBox, wxCommandEvent

Public Member Functions

- wxBitmapComboBox ()

  Default ctor.
- wxBitmapComboBox (wxWindow *parent, wxWindowID id=wxID_ANY, const wxString &value=wxEmptyString, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, int n=0, const wxString choices[]=NULL, long style=0, const wxValidator &validator=wxDefaultValidator, const wxString &name=wxBitmapComboBoxNameStr)

  Constructor, creating and showing a combobox.
- wxBitmapComboBox (wxWindow *parent, wxWindowID id, const wxString &value, const wxPoint &pos, const wxSize &size, const wxArrayString &choices, long style, const wxValidator &validator=wxDefaultValidator, const wxString &name=wxBitmapComboBoxNameStr)

  Constructor, creating and showing a combobox.
- virtual ~wxBitmapComboBox ()

  Destructor, destroying the combobox.
- int Append (const wxString &item, const wxBitmap &bitmap=wxNullBitmap)

  Adds the item to the end of the combo box.
- int Append (const wxString &item, const wxBitmap &bitmap, void *clientData)

  Adds the item to the end of the combo box, associating the given untyped, client data pointer clientData with the item.
- int Append (const wxString &item, const wxBitmap &bitmap, wxClientData *clientData)

  Adds the item to the end of the combo box, associating the given typed client data pointer clientData with the item.
- bool Create (wxWindow *parent, wxWindowID id, const wxString &value, const wxPoint &pos, const wxSize &size, int n, const wxString choices[], long style=0, const wxValidator &validator=wxDefaultValidator, const wxString &name=wxBitmapComboBoxNameStr)

  Creates the combobox for two-step construction.
- bool Create (wxWindow *parent, wxWindowID id, const wxString &value, const wxPoint &pos, const wxSize &size, const wxArrayString &choices, long style=0, const wxValidator &validator=wxDefaultValidator, const wxString &name=wxBitmapComboBoxNameStr)

  Creates the combobox for two-step construction.

- virtual wxSize GetBitmapSize () const

  Returns the size of the bitmaps used in the combo box.
- virtual wxBitmap GetItemBitmap (unsigned int n) const

  Returns the bitmap of the item with the given index.
- int Insert (const wxString &item, const wxBitmap &bitmap, unsigned int pos)

  Inserts the item into the list before pos.
- int Insert (const wxString &item, const wxBitmap &bitmap, unsigned int pos, void *clientData)

  Inserts the item into the list before pos, associating the given untyped, client data pointer with the item.
- int Insert (const wxString &item, const wxBitmap &bitmap, unsigned int pos, wxClientData *clientData)

  Inserts the item into the list before pos, associating the given typed client data pointer with the item.
- virtual void SetItemBitmap (unsigned int n, const wxBitmap &bitmap)

  Sets the bitmap for the given item.

Additional Inherited Members

21.59.2 Constructor & Destructor Documentation

wxBitmapComboBox::wxBitmapComboBox ( )

Default ctor.

wxBitmapComboBox::wxBitmapComboBox (wxWindow * *parent*, wxWindowID *id* = wxID_ANY, const wxString & *value* = wxEmptyString, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, int *n* = 0, const wxString *choices[]* = NULL, long *style* = 0, const wxValidator & *validator* = wxDefaultValidator, const wxString & *name* = wxBitmapComboBoxNameStr)

Constructor, creating and showing a combobox.

Parameters

parent	Parent window. Must not be NULL.
id	Window identifier. The value wxID_ANY indicates a default value.
value	Initial selection string. An empty string indicates no selection.
pos	Initial position.
size	Initial size.
n	Number of strings with which to initialise the control.
choices	An array of strings with which to initialise the control.
style	The window style, see wxCB_* flags.
validator	Validator which can be used for additional data checks.
name	Control name.

See also

Create(), wxValidator

wxBitmapComboBox::wxBitmapComboBox (wxWindow * *parent*, wxWindowID *id*, const wxString & *value*, const wxPoint & *pos*, const wxSize & *size*, const wxArrayString & *choices*, long *style*, const wxValidator & *validator* = wxDefaultValidator, const wxString & *name* = wxBitmapComboBoxNameStr)

Constructor, creating and showing a combobox.

Parameters

parent	Parent window. Must not be NULL.
id	Window identifier. The value wxID_ANY indicates a default value.
value	Initial selection string. An empty string indicates no selection.
pos	Initial position.
size	Initial size.
choices	An wxArrayString with which to initialise the control.
style	The window style, see wxCB_* flags.
validator	Validator which can be used for additional data checks.
name	Control name.

See also

Create(), wxValidator

virtual wxBitmapComboBox::~wxBitmapComboBox ( ) [virtual]

Destructor, destroying the combobox.

21.59.3 Member Function Documentation

int wxBitmapComboBox::Append (const wxString & *item*, const wxBitmap & *bitmap* = wxNullBitmap)

Adds the item to the end of the combo box.

int wxBitmapComboBox::Append (const wxString & *item*, const wxBitmap & *bitmap*, void * *clientData*)

Adds the item to the end of the combo box, associating the given untyped, client data pointer *clientData* with the item.

int wxBitmapComboBox::Append (const wxString & *item*, const wxBitmap & *bitmap*, wxClientData * *clientData*)

Adds the item to the end of the combo box, associating the given typed client data pointer *clientData* with the item.

bool wxBitmapComboBox::Create (wxWindow * *parent*, wxWindowID *id*, const wxString & *value*, const wxPoint & *pos*, const wxSize & *size*, int *n*, const wxString *choices[]*, long *style* = 0, const wxValidator & *validator* = wxDefaultValidator, const wxString & *name* = wxBitmapComboBoxNameStr)

Creates the combobox for two-step construction.

bool wxBitmapComboBox::Create (wxWindow * *parent*, wxWindowID *id*, const wxString & *value*, const wxPoint & *pos*, const wxSize & *size*, const wxArrayString & *choices*, long *style* = 0, const wxValidator & *validator* = wxDefaultValidator, const wxString & *name* = wxBitmapComboBoxNameStr)

Creates the combobox for two-step construction.

virtual wxSize wxBitmapComboBox::GetBitmapSize ( ) const [virtual]

Returns the size of the bitmaps used in the combo box.

If the combo box is empty, then wxDefaultSize is returned.

virtual wxBitmap wxBitmapComboBox::GetItemBitmap (unsigned int *n*) const `[virtual]`

Returns the bitmap of the item with the given index.

int wxBitmapComboBox::Insert (const wxString & *item,* const wxBitmap & *bitmap,* unsigned int *pos*)

Inserts the item into the list before *pos*.

Not valid for `wxCB_SORT` style, use Append() instead.

int wxBitmapComboBox::Insert (const wxString & *item,* const wxBitmap & *bitmap,* unsigned int *pos,* void * *clientData*)

Inserts the item into the list before pos, associating the given untyped, client data pointer with the item.

Not valid for `wxCB_SORT` style, use Append() instead.

int wxBitmapComboBox::Insert (const wxString & *item,* const wxBitmap & *bitmap,* unsigned int *pos,* wxClientData * *clientData*)

Inserts the item into the list before pos, associating the given typed client data pointer with the item.

Not valid for `wxCB_SORT` style, use Append() instead.

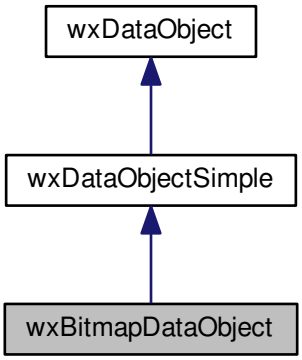
virtual void wxBitmapComboBox::SetItemBitmap (unsigned int *n,* const wxBitmap & *bitmap*) `[virtual]`

Sets the bitmap for the given item.

21.60 wxBitmapDataObject Class Reference

`#include <wx/dataobj.h>`

Inheritance diagram for wxBitmapDataObject:



21.60.1 Detailed Description

wxBitmapDataObject is a specialization of wxDataObject for bitmap data.

It can be used without change to paste data into the wxClipboard or a wxDropSource. A user may wish to derive a new class from this class for providing a bitmap on-demand in order to minimize memory consumption when offering data in several formats, such as a bitmap and GIF.

This class may be used as is, but GetBitmap() may be overridden to increase efficiency.

Library: wxCore

Category: Clipboard and Drag & Drop

See also

Drag and Drop Overview, wxDataObject, wxDataObjectSimple, wxFileDataObject, wxTextDataObject, wxDataObject

Public Member Functions

- wxBitmapDataObject (const wxBitmap &bitmap=wxNullBitmap)

  Constructor, optionally passing a bitmap (otherwise use SetBitmap() later).
- virtual wxBitmap GetBitmap () const

  Returns the bitmap associated with the data object.
- virtual void SetBitmap (const wxBitmap &bitmap)

  Sets the bitmap associated with the data object.

Additional Inherited Members

21.60.2 Constructor & Destructor Documentation

wxBitmapDataObject::wxBitmapDataObject (const wxBitmap & *bitmap* = wxNullBitmap)

Constructor, optionally passing a bitmap (otherwise use SetBitmap() later).

21.60.3 Member Function Documentation

virtual wxBitmap wxBitmapDataObject::GetBitmap ( ) const `[virtual]`

Returns the bitmap associated with the data object.

You may wish to override this method when offering data on-demand, but this is not required by wxWidgets' internals. Use this method to get data in bitmap form from the wxClipboard.

virtual void wxBitmapDataObject::SetBitmap (const wxBitmap & *bitmap*) `[virtual]`

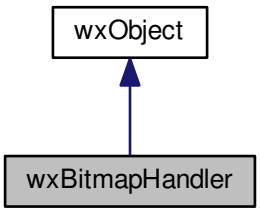
Sets the bitmap associated with the data object.

This method is called when the data object receives data. Usually there will be no reason to override this function.

21.61 wxBitmapHandler Class Reference

`#include <wx/bitmap.h>`

Inheritance diagram for wxBitmapHandler:



21.61.1 Detailed Description

This is the base class for implementing bitmap file loading/saving, and bitmap creation from data.

It is used within wxBitmap and is not normally seen by the application.

If you wish to extend the capabilities of wxBitmap, derive a class from wxBitmapHandler and add the handler using wxBitmap::AddHandler() in your application initialization.

Note that all wxBitmapHandlers provided by wxWidgets are part of the wxCore library. For details about the default handlers, please see the note in the wxBitmap class documentation.

Library: wxCore

Category: Graphics Device Interface (GDI)

See also

Bitmaps and Icons, wxBitmap, wxIcon, wxCursor

Public Member Functions

- wxBitmapHandler ()

  Default constructor.
- virtual ~wxBitmapHandler ()

  Destroys the wxBitmapHandler object.
- virtual bool Create (wxBitmap *bitmap, const void *data, wxBitmapType type, int width, int height, int depth=1)

  Creates a bitmap from the given data, which can be of arbitrary type.
- const wxString & GetExtension () const

  Gets the file extension associated with this handler.
- const wxString & GetName () const

  Gets the name of this handler.
- wxBitmapType GetType () const

  Gets the bitmap type associated with this handler.

- virtual bool LoadFile (wxBitmap *bitmap, const wxString &name, wxBitmapType type, int desiredWidth, int desiredHeight)

  Loads a bitmap from a file or resource, putting the resulting data into bitmap.
- virtual bool SaveFile (const wxBitmap *bitmap, const wxString &name, wxBitmapType type, const wxPalette *palette=NULL) const

  Saves a bitmap in the named file.
- void SetExtension (const wxString &extension)

  Sets the handler extension.
- void SetName (const wxString &name)

  Sets the handler name.
- void SetType (wxBitmapType type)

  Sets the handler type.

Additional Inherited Members

21.61.2 Constructor & Destructor Documentation

wxBitmapHandler::wxBitmapHandler ( )

Default constructor.

In your own default constructor, initialise the members m_name, m_extension and m_type.

virtual wxBitmapHandler::~wxBitmapHandler ( ) [virtual]

Destroys the wxBitmapHandler object.

21.61.3 Member Function Documentation

virtual bool wxBitmapHandler::Create (wxBitmap * *bitmap,* const void * *data,* wxBitmapType *type,* int *width,* int *height,* int *depth* = 1) [virtual]

Creates a bitmap from the given data, which can be of arbitrary type.

The wxBitmap object *bitmap* is manipulated by this function.

Parameters

bitmap	The wxBitmap object.
width	The width of the bitmap in pixels.
height	The height of the bitmap in pixels.
depth	The depth of the bitmap in pixels. If this is wxBITMAP_SCREEN_DEPTH, the screen depth is used.
data	Data whose type depends on the value of type.
type	A bitmap type identifier - see wxBitmapType for a list of possible values.

Returns

true if the call succeeded, false otherwise (the default).

const wxString& wxBitmapHandler::GetExtension ( ) const

Gets the file extension associated with this handler.

const wxString& wxBitmapHandler::GetName ( ) const

Gets the name of this handler.

wxBitmapType wxBitmapHandler::GetType ( ) const

Gets the bitmap type associated with this handler.

virtual bool wxBitmapHandler::LoadFile (wxBitmap * *bitmap,* const wxString & *name,* wxBitmapType *type,* int *desiredWidth,* int *desiredHeight*) [virtual]

Loads a bitmap from a file or resource, putting the resulting data into *bitmap*.

Note

Under MSW, when loading a bitmap from resources (i.e. using `wxBITMAP_TYPE_BMP_RESOURCE` as *type*), the light grey colour is considered to be transparent, for historical reasons. If you want to handle the light grey pixels normally instead, call SetMask(NULL) after loading the bitmap.

Parameters

bitmap	The bitmap object which is to be affected by this operation.
name	Either a filename or a Windows resource name. The meaning of name is determined by the type parameter.
type	See wxBitmapType for values this can take.
desiredWidth	The desired width for the loaded bitmap.
desiredHeight	The desired height for the loaded bitmap.

Returns

true if the operation succeeded, false otherwise.

See also

wxBitmap::LoadFile, wxBitmap::SaveFile, SaveFile()

virtual bool wxBitmapHandler::SaveFile (const wxBitmap * *bitmap,* const wxString & *name,* wxBitmapType *type,* const wxPalette * *palette* = `NULL`) const [virtual]

Saves a bitmap in the named file.

Parameters

bitmap	The bitmap object which is to be affected by this operation.
name	A filename. The meaning of name is determined by the type parameter.
type	See wxBitmapType for values this can take.
palette	An optional palette used for saving the bitmap.

Returns

true if the operation succeeded, false otherwise.

See also

wxBitmap::LoadFile, wxBitmap::SaveFile, LoadFile()

void wxBitmapHandler::SetExtension (const wxString & *extension*)

Sets the handler extension.

Parameters

extension	Handler extension.

void wxBitmapHandler::SetName (const wxString & *name*)

Sets the handler name.

Parameters

name	Handler name.

void wxBitmapHandler::SetType (wxBitmapType *type*)

Sets the handler type.

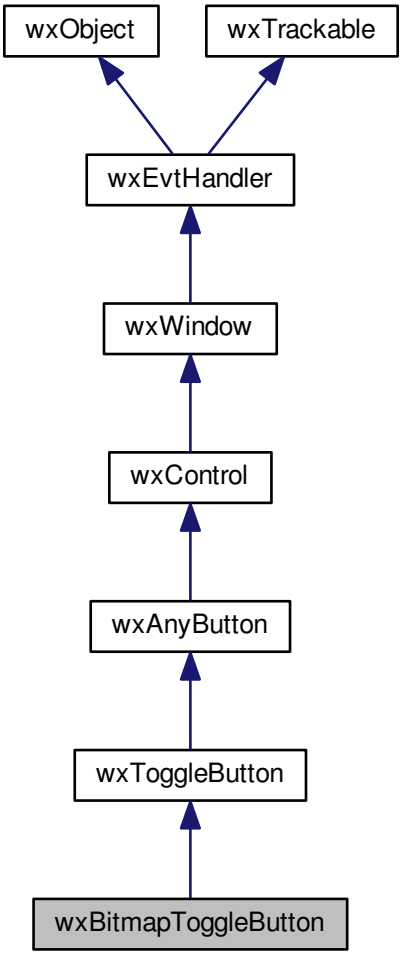
Parameters

type	Handler type.

21.62 wxBitmapToggleButton Class Reference

```
#include <wx/tglbtn.h>
```

Inheritance diagram for wxBitmapToggleButton:



21.62.1 Detailed Description

wxBitmapToggleButton is a wxToggleButton that contains a bitmap instead of text.

This class is not available in all ports currently (although it is available in the major ones), test for `wxHAS_BITMAPTOGGLEBUTTON` to determine whether it can be used (in addition for possibly testing for `wxUSE_TOGGLEBTN` which can be set to 0 to explicitly disable support for this class and wxToggleButton).

This control emits an update UI event.

Events emitted by this class

The following event handler macros redirect the events to member function handlers '**func**' with prototypes like: void handlerFuncName(wxCommandEvent& event)

Event macros for events emitted by this class:

- EVT_TOGGLEBUTTON(id, func): Handles a wxEVT_TOGGLEBUTTON event.

Library: wxCore

Category: Controls

Public Member Functions

- wxBitmapToggleButton ()

  Default constructor.
- wxBitmapToggleButton (wxWindow *parent, wxWindowID id, const wxBitmap &label, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, long style=0, const wxValidator &val=wxDefaultValidator, const wxString &name=wxCheckBoxNameStr)

  Constructor, creating and showing a toggle button with the bitmap label.
- bool Create (wxWindow *parent, wxWindowID id, const wxBitmap &label, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, long style=0, const wxValidator &val=wxDefaultValidator, const wxString &name=wxCheckBoxNameStr)

  Create method for two-step construction.
- virtual bool GetValue () const

  Gets the state of the toggle button.
- virtual void SetValue (bool state)

  Sets the toggle button to the given state.

Additional Inherited Members

21.62.2 Constructor & Destructor Documentation

wxBitmapToggleButton::wxBitmapToggleButton ( )

Default constructor.

wxBitmapToggleButton::wxBitmapToggleButton (wxWindow * *parent*, wxWindowID *id*, const wxBitmap & *label*, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, long *style* = `0`, const wxValidator & *val* = wxDefaultValidator, const wxString & *name* = `wxCheckBoxNameStr`)

Constructor, creating and showing a toggle button with the bitmap *label*.

Internally calls Create().

21.62.3 Member Function Documentation

bool wxBitmapToggleButton::Create (wxWindow * *parent*, wxWindowID *id*, const wxBitmap & *label*, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, long *style* = `0`, const wxValidator & *val* = wxDefaultValidator, const wxString & *name* = `wxCheckBoxNameStr`)

Create method for two-step construction.

virtual bool wxBitmapToggleButton::GetValue ( ) const `[virtual]`

Gets the state of the toggle button.

Returns

Returns true if it is pressed, false otherwise.

Reimplemented from wxToggleButton.

virtual void wxBitmapToggleButton::SetValue (bool *state*) [virtual]

Sets the toggle button to the given state.

This does not cause a EVT_TOGGLEBUTTON event to be emitted.

Parameters

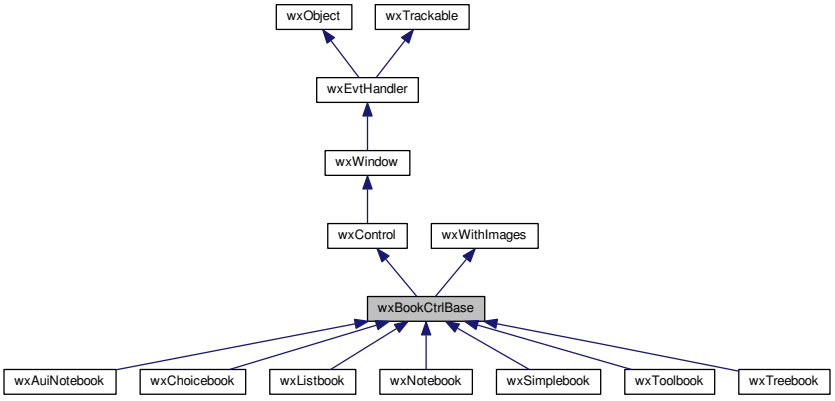
state	If true, the button is pressed.

Reimplemented from wxToggleButton.

21.63 wxBookCtrlBase Class Reference

#include <wx/bookctrl.h>

Inheritance diagram for wxBookCtrlBase:



21.63.1 Detailed Description

A book control is a convenient way of displaying multiple pages of information, displayed one page at a time.

wxWidgets has five variants of this control:

- wxChoicebook: controlled by a wxChoice
- wxListbook: controlled by a wxListCtrl
- wxNotebook: uses a row of tabs
- wxTreebook: controlled by a wxTreeCtrl
- wxToolbook: controlled by a wxToolBar

This abstract class is the parent of all these book controls, and provides their basic interface. This is a pure virtual class so you cannot allocate it directly.

Library: wxCore

Category: Book Controls

See also

wxBookCtrl Overview

Public Types

- enum { NO_IMAGE = -1 }

Public Member Functions

- wxBookCtrlBase ()

  Default ctor.
- wxBookCtrlBase (wxWindow *parent, wxWindowID winid, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, long style=0, const wxString &name=wxEmptyString)

  Constructs the book control with the given parameters.
- bool Create (wxWindow *parent, wxWindowID winid, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, long style=0, const wxString &name=wxEmptyString)

  Constructs the book control with the given parameters.
- virtual void SetPageSize (const wxSize &size)

  Sets the width and height of the pages.
- virtual int HitTest (const wxPoint &pt, long *flags=NULL) const

  Returns the index of the tab at the specified position or `wxNOT_FOUND` if none.

Image list functions

Each page may have an attached image.

The functions of this group manipulate that image.

- virtual int GetPageImage (size_t nPage) const =0

  Returns the image index for the given page.
- virtual bool SetPageImage (size_t page, int image)=0

  Sets the image index for the given page.

Page text functions

Each page has a text string attached.

The functions of this group manipulate that text.

- virtual wxString GetPageText (size_t nPage) const =0

  Returns the string for the given page.
- virtual bool SetPageText (size_t page, const wxString &text)=0

  Sets the text for the given page.

Selection functions

The functions of this group manipulate the selection.

- virtual int GetSelection () const =0

  Returns the currently selected page, or `wxNOT_FOUND` if none was selected.
- wxWindow * GetCurrentPage () const

  Returns the currently selected page or NULL.
- virtual int SetSelection (size_t page)=0

Sets the selection to the given page, returning the previous selection.

- void AdvanceSelection (bool forward=true)

  Cycles through the tabs.
- virtual int ChangeSelection (size_t page)=0

  Changes the selection to the given page, returning the previous selection.
- int FindPage (const wxWindow *page) const

  Returns the index of the specified tab window or `wxNOT_FOUND` if not found.

Page management functions

Functions for adding/removing pages from this control.

- virtual bool AddPage (wxWindow *page, const wxString &text, bool select=false, int imageId=NO_IMAGE)

  Adds a new page.
- virtual bool DeleteAllPages ()

  Deletes all pages.
- virtual bool DeletePage (size_t page)

  Deletes the specified page, and the associated window.
- virtual bool InsertPage (size_t index, wxWindow *page, const wxString &text, bool select=false, int imageId=NO_IMAGE)=0

  Inserts a new page at the specified position.
- virtual bool RemovePage (size_t page)

  Deletes the specified page, without deleting the associated window.
- virtual size_t GetPageCount () const

  Returns the number of pages in the control.
- wxWindow * GetPage (size_t page) const

  Returns the window at the given page position.

Additional Inherited Members

21.63.2 Member Enumeration Documentation

anonymous enum

Enumerator

NO_IMAGE Symbolic constant indicating that no image should be used.

21.63.3 Constructor & Destructor Documentation

wxBookCtrlBase::wxBookCtrlBase ( )

Default ctor.

wxBookCtrlBase::wxBookCtrlBase (wxWindow * *parent*, wxWindowID *winid*, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, long *style* = `0`, const wxString & *name* = wxEmptyString)

Constructs the book control with the given parameters.

See Create() for two-step construction.

21.63.4 Member Function Documentation

virtual bool wxBookCtrlBase::AddPage (wxWindow * *page*, const wxString & *text*, bool *select* = `false`, int *imageId* = NO_IMAGE) `[virtual]`

Adds a new page.

The page must have the book control itself as the parent and must not have been added to this control previously.

The call to this function may generate the page changing events.

Parameters

page	Specifies the new page.
text	Specifies the text for the new page.
select	Specifies whether the page should be selected.
imageId	Specifies the optional image index for the new page.

Returns

true if successful, false otherwise.

Remarks

Do not delete the page, it will be deleted by the book control.

See also

InsertPage()

Reimplemented in wxAuiNotebook, and wxTreebook.

void wxBookCtrlBase::AdvanceSelection (bool *forward* = `true`)

Cycles through the tabs.

The call to this function generates the page changing events.

virtual int wxBookCtrlBase::ChangeSelection (size_t *page*) `[pure virtual]`

Changes the selection to the given page, returning the previous selection.

This function behaves as SetSelection() but does *not* generate the page changing events.

See User Generated Events vs Programmatically Generated Events for more information.

Implemented in wxNotebook, and wxAuiNotebook.

bool wxBookCtrlBase::Create (wxWindow * *parent*, wxWindowID *winid*, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, long *style* = `0`, const wxString & *name* = wxEmptyString)

Constructs the book control with the given parameters.

virtual bool wxBookCtrlBase::DeleteAllPages ( ) `[virtual]`

Deletes all pages.

Reimplemented in wxAuiNotebook.

virtual bool wxBookCtrlBase::DeletePage (size_t *page*) `[virtual]`

Deletes the specified page, and the associated window.

The call to this function generates the page changing events.

Reimplemented in wxAuiNotebook, and wxTreebook.

int wxBookCtrlBase::FindPage (const wxWindow * *page*) const

Returns the index of the specified tab window or `wxNOT_FOUND` if not found.

Parameters

page	One of the control pages.

Returns

The zero-based tab index or `wxNOT_FOUND` if not found.

Since

2.9.5

wxWindow* wxBookCtrlBase::GetCurrentPage ( ) const

Returns the currently selected page or NULL.

wxWindow* wxBookCtrlBase::GetPage (size_t *page*) const

Returns the window at the given page position.

virtual size_t wxBookCtrlBase::GetPageCount ( ) const [virtual]

Returns the number of pages in the control.

Reimplemented in wxAuiNotebook.

virtual int wxBookCtrlBase::GetPageImage (size_t *nPage*) const [pure virtual]

Returns the image index for the given page.

Implemented in wxNotebook.

virtual wxString wxBookCtrlBase::GetPageText (size_t *nPage*) const [pure virtual]

Returns the string for the given page.

Implemented in wxAuiNotebook, and wxNotebook.

virtual int wxBookCtrlBase::GetSelection ( ) const [pure virtual]

Returns the currently selected page, or `wxNOT_FOUND` if none was selected.

Note that this method may return either the previously or newly selected page when called from the `EVT_BOOKCTRL_PAGE_CHANGED` handler depending on the platform and so wxBookCtrlEvent::GetSelection should be used instead in this case.

Implemented in wxAuiNotebook, wxNotebook, and wxTreebook.

virtual int wxBookCtrlBase::HitTest (const wxPoint & *pt*, long * *flags* = NULL) const [virtual]

Returns the index of the tab at the specified position or `wxNOT_FOUND` if none.

If *flags* parameter is non-NULL, the position of the point inside the tab is returned as well.

Parameters

pt	Specifies the point for the hit test.
flags	Return more details about the point, see returned value is a combination of wxBK_HITTEST_NOWHERE, wxBK_HITTEST_ONICON, wxBK_HITTEST_ONLABEL, wxBK_HITTEST_ONITEM, wxBK_HITTEST_ONPAGE.

Returns

Returns the zero-based tab index or `wxNOT_FOUND` if there is no tab at the specified position.

virtual bool wxBookCtrlBase::InsertPage (size_t *index*, wxWindow * *page*, const wxString & *text*, bool *select* = `false`, int *imageId* = NO_IMAGE) `[pure virtual]`

Inserts a new page at the specified position.

Parameters

index	Specifies the position for the new page.
page	Specifies the new page.
text	Specifies the text for the new page.
select	Specifies whether the page should be selected.
imageId	Specifies the optional image index for the new page.

Returns

true if successful, false otherwise.

Remarks

Do not delete the page, it will be deleted by the book control.

See also

AddPage()

Implemented in wxAuiNotebook, wxNotebook, and wxTreebook.

virtual bool wxBookCtrlBase::RemovePage (size_t *page*) `[virtual]`

Deletes the specified page, without deleting the associated window.

Reimplemented in wxAuiNotebook.

virtual bool wxBookCtrlBase::SetPageImage (size_t *page*, int *image*) `[pure virtual]`

Sets the image index for the given page.

image is an index into the image list which was set with SetImageList().

Implemented in wxAuiNotebook, and wxNotebook.

virtual void wxBookCtrlBase::SetPageSize (const wxSize & *size*) `[virtual]`

Sets the width and height of the pages.

Note

This method is currently not implemented for wxGTK.

virtual bool wxBookCtrlBase::SetPageText (size_t *page*, const wxString & *text*) [pure virtual]

Sets the text for the given page.

Implemented in wxAuiNotebook, and wxNotebook.

virtual int wxBookCtrlBase::SetSelection (size_t *page*) [pure virtual]

Sets the selection to the given page, returning the previous selection.

Notice that the call to this function generates the page changing events, use the ChangeSelection() function if you don't want these events to be generated.

See also

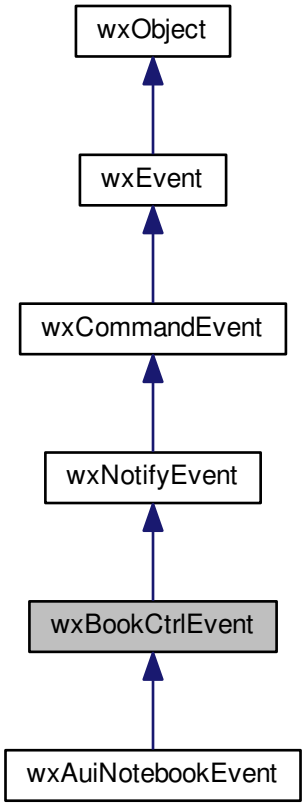
GetSelection()

Implemented in wxAuiNotebook, and wxNotebook.

21.64 wxBookCtrlEvent Class Reference

`#include <wx/bookctrl.h>`

Inheritance diagram for wxBookCtrlEvent:



21.64.1 Detailed Description

This class represents the events generated by book controls (wxNotebook, wxListbook, wxChoicebook, wxTreebook, wxAuiNotebook).

The PAGE_CHANGING events are sent before the current page is changed. It allows the program to examine the current page (which can be retrieved with wxBookCtrlEvent::GetOldSelection) and to veto the page change by calling wxNotifyEvent::Veto if, for example, the current values in the controls of the old page are invalid.

The PAGE_CHANGED events are sent after the page has been changed and the program cannot veto it any more, it just informs it about the page change.

To summarize, if the program is interested in validating the page values before allowing the user to change it, it should process the PAGE_CHANGING event, otherwise PAGE_CHANGED is probably enough. In any case, it is probably unnecessary to process both events at once.

Library: wxCore

Category: Events, Book Controls

wxNotebook, wxListbook, wxChoicebook, wxTreebook, wxToolbook, wxAuiNotebook

Public Member Functions

- wxBookCtrlEvent (wxEventType eventType=wxEVT_NULL, int id=0, int sel=wxNOT_FOUND, int oldSel=wxNOT_FOUND)

  Constructor (used internally by wxWidgets only).
- int GetOldSelection () const

  Returns the page that was selected before the change, `wxNOT_FOUND` if none was selected.
- int GetSelection () const

  Returns the currently selected page, or `wxNOT_FOUND` if none was selected.
- void SetOldSelection (int page)

  Sets the id of the page selected before the change.
- void SetSelection (int page)

  Sets the selection member variable.

Additional Inherited Members

21.64.2 Constructor & Destructor Documentation

wxBookCtrlEvent::wxBookCtrlEvent (wxEventType *eventType* = wxEVT_NULL, int *id* = 0, int *sel* = wxNOT_FOUND, int *oldSel* = wxNOT_FOUND)

Constructor (used internally by wxWidgets only).

21.64.3 Member Function Documentation

int wxBookCtrlEvent::GetOldSelection ( ) const

Returns the page that was selected before the change, `wxNOT_FOUND` if none was selected.

int wxBookCtrlEvent::GetSelection ( ) const

Returns the currently selected page, or `wxNOT_FOUND` if none was selected.

Note

under Windows, GetSelection() will return the same value as GetOldSelection() when called from the `EVT_BOOKCTRL_PAGE_CHANGING` handler and not the page which is going to be selected.

void wxBookCtrlEvent::SetOldSelection (int *page*)

Sets the id of the page selected before the change.

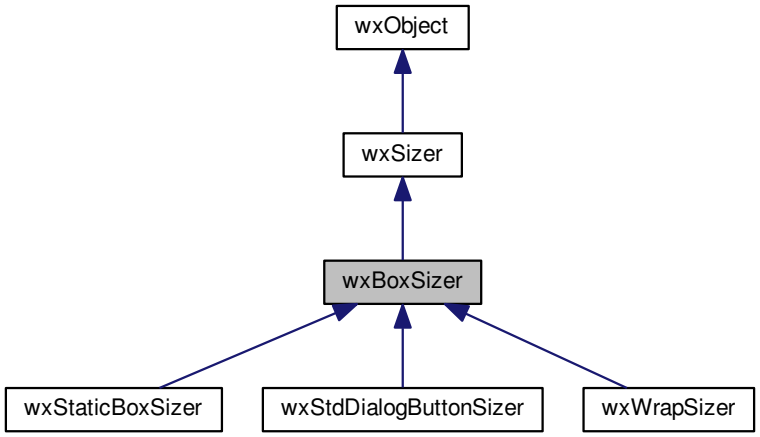
void wxBookCtrlEvent::SetSelection (int *page*)

Sets the selection member variable.

21.65 wxBoxSizer Class Reference

`#include <wx/sizer.h>`

Inheritance diagram for wxBoxSizer:



21.65.1 Detailed Description

The basic idea behind a box sizer is that windows will most often be laid out in rather simple basic geometry, typically in a row or a column or several hierarchies of either.

For more information, please see Programming with wxBoxSizer.

Library: wxCore

Category: Window Layout

See also

wxSizer, Sizers Overview

Public Member Functions

- wxBoxSizer (int orient)

  Constructor for a wxBoxSizer.
- virtual wxSizerItem * AddSpacer (int size)

  Adds non-stretchable space to the main orientation of the sizer only.
- virtual wxSize CalcMin ()

  Implements the calculation of a box sizer's minimal.
- int GetOrientation () const

  Returns the orientation of the box sizer, either wxVERTICAL or wxHORIZONTAL.
- void SetOrientation (int orient)

  Sets the orientation of the box sizer, either wxVERTICAL or wxHORIZONTAL.
- virtual void RecalcSizes ()

  Implements the calculation of a box sizer's dimensions and then sets the size of its children (calling wxWindow::SetSize if the child is a window).

Additional Inherited Members

21.65.2 Constructor & Destructor Documentation

wxBoxSizer::wxBoxSizer (int *orient*)

Constructor for a wxBoxSizer.

orient may be either of wxVERTICAL or wxHORIZONTAL for creating either a column sizer or a row sizer.

21.65.3 Member Function Documentation

virtual wxSizerItem* wxBoxSizer::AddSpacer (int *size*) `[virtual]`

Adds non-stretchable space to the main orientation of the sizer only.

More readable way of calling:

```
if ( wxBoxSizer::IsVertical() )
{
    wxBoxSizer::Add(0, size, 0).
}
else
{
    wxBoxSizer::Add(size, 0, 0).
}
```

Reimplemented from wxSizer.

virtual wxSize wxBoxSizer::CalcMin ( ) `[virtual]`

Implements the calculation of a box sizer's minimal.

It is used internally only and must not be called by the user. Documented for information.

Implements wxSizer.

Reimplemented in wxStaticBoxSizer, wxStdDialogButtonSizer, and wxWrapSizer.

int wxBoxSizer::GetOrientation ( ) const

Returns the orientation of the box sizer, either wxVERTICAL or wxHORIZONTAL.

virtual void wxBoxSizer::RecalcSizes ( ) [virtual]

Implements the calculation of a box sizer's dimensions and then sets the size of its children (calling wxWindow::SetSize if the child is a window).

It is used internally only and must not be called by the user (call Layout() if you want to resize). Documented for information.

Implements wxSizer.

Reimplemented in wxStaticBoxSizer, wxStdDialogButtonSizer, and wxWrapSizer.

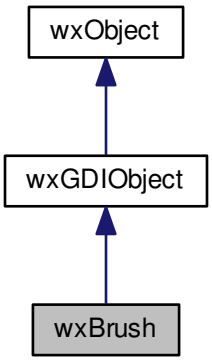
void wxBoxSizer::SetOrientation (int *orient*)

Sets the orientation of the box sizer, either wxVERTICAL or wxHORIZONTAL.

21.66 wxBrush Class Reference

`#include <wx/brush.h>`

Inheritance diagram for wxBrush:



21.66.1 Detailed Description

A brush is a drawing tool for filling in areas.

It is used for painting the background of rectangles, ellipses, etc. It has a colour and a style.

On a monochrome display, wxWidgets shows all brushes as white unless the colour is really black.

Do not initialize objects on the stack before the program commences, since other required structures may not have been set up yet. Instead, define global pointers to objects and create them in wxApp::OnInit or when required.

An application may wish to create brushes with different characteristics dynamically, and there is the consequent danger that a large number of duplicate brushes will be created. Therefore an application may wish to get a pointer

to a brush by using the global list of brushes wxTheBrushList, and calling the member function wxBrushList::FindOrCreateBrush().

This class uses reference counting and copy-on-write internally so that assignments between two instances of this class are very cheap. You can therefore use actual objects instead of pointers without efficiency problems. If an instance of this class is changed it will create its own data internally so that other instances, which previously shared the data using the reference counting, are not affected.

Library: wxCore

Category: Graphics Device Interface (GDI)

Predefined objects/pointers:

- wxNullBrush
- wxBLACK_BRUSH
- wxBLUE_BRUSH
- wxCYAN_BRUSH
- wxGREEN_BRUSH
- wxYELLOW_BRUSH
- wxGREY_BRUSH
- wxLIGHT_GREY_BRUSH
- wxMEDIUM_GREY_BRUSH
- wxRED_BRUSH
- wxTRANSPARENT_BRUSH
- wxWHITE_BRUSH

See also

wxBrushList, wxDC, wxDC::SetBrush

Public Member Functions

- wxBrush ()

  Default constructor.
- wxBrush (const wxColour &colour, wxBrushStyle style=wxBRUSHSTYLE_SOLID)

  Constructs a brush from a colour object and style.
- wxBrush (const wxBitmap &stippleBitmap)

  Constructs a stippled brush using a bitmap.
- wxBrush (const wxBrush &brush)

  Copy constructor, uses reference counting.
- virtual ~wxBrush ()

  Destructor.
- virtual wxColour GetColour () const

  Returns a reference to the brush colour.
- virtual wxBitmap * GetStipple () const

  Gets a pointer to the stipple bitmap.

- virtual wxBrushStyle GetStyle () const

  Returns the brush style, one of the wxBrushStyle values.
- virtual bool IsHatch () const

  Returns true if the style of the brush is any of hatched fills.
- virtual bool IsOk () const

  Returns true if the brush is initialised.
- bool IsNonTransparent () const

  Returns true if the brush is a valid non-transparent brush.
- bool IsTransparent () const

  Returns true if the brush is transparent.
- virtual void SetStipple (const wxBitmap &bitmap)

  Sets the stipple bitmap.
- virtual void SetStyle (wxBrushStyle style)

  Sets the brush style.
- bool operator!= (const wxBrush &brush) const

  Inequality operator.
- bool operator== (const wxBrush &brush) const

  Equality operator.

- virtual void SetColour (const wxColour &colour)

  Sets the brush colour using red, green and blue values.
- virtual void SetColour (unsigned char red, unsigned char green, unsigned char blue)

  Sets the brush colour using red, green and blue values.

Additional Inherited Members

21.66.2 Constructor & Destructor Documentation

wxBrush::wxBrush ( )

Default constructor.

The brush will be uninitialised, and wxBrush:IsOk() will return false.

wxBrush::wxBrush (const wxColour & *colour*, wxBrushStyle *style* = wxBRUSHSTYLE_SOLID)

Constructs a brush from a colour object and *style*.

Parameters

colour	Colour object.
style	One of the wxBrushStyle enumeration values.

wxBrush::wxBrush (const wxBitmap & *stippleBitmap*)

Constructs a stippled brush using a bitmap.

The brush style will be set to `wxBRUSHSTYLE_STIPPLE`.

wxBrush::wxBrush (const wxBrush & *brush*)

Copy constructor, uses reference counting.

virtual wxBrush::~wxBrush ( ) [virtual]

Destructor.

See Object Destruction for more info.

Remarks

Although all remaining brushes are deleted when the application exits, the application should try to clean up all brushes itself. This is because wxWidgets cannot know if a pointer to the brush object is stored in an application data structure, and there is a risk of double deletion.

21.66.3 Member Function Documentation

virtual wxColour wxBrush::GetColour ( ) const [virtual]

Returns a reference to the brush colour.

See also

SetColour()

virtual wxBitmap* wxBrush::GetStipple ( ) const [virtual]

Gets a pointer to the stipple bitmap.

If the brush does not have a wxBRUSHSTYLE_STIPPLE style, this bitmap may be non-NULL but uninitialised (i.e. wxBitmap:IsOk() returns false).

See also

SetStipple()

virtual wxBrushStyle wxBrush::GetStyle ( ) const [virtual]

Returns the brush style, one of the wxBrushStyle values.

See also

SetStyle(), SetColour(), SetStipple()

virtual bool wxBrush::IsHatch ( ) const [virtual]

Returns true if the style of the brush is any of hatched fills.

See also

GetStyle()

bool wxBrush::IsNonTransparent ( ) const

Returns true if the brush is a valid non-transparent brush.

This method returns true if the brush object is initialized and has a non-transparent style. Notice that this should be used instead of simply testing whether GetStyle() returns a style different from wxBRUSHSTYLE_TRANSPARENT if the brush may be invalid as GetStyle() would assert in this case.

See also

IsTransparent()

Since

2.9.2.

virtual bool wxBrush::IsOk ( ) const `[virtual]`

Returns true if the brush is initialised.

Notice that an uninitialized brush object can't be queried for any brush properties and all calls to the accessor methods on it will result in an assert failure.

bool wxBrush::IsTransparent ( ) const

Returns true if the brush is transparent.

A transparent brush is simply a brush with wxBRUSHSTYLE_TRANSPARENT style.

Notice that this function works even for non-initialized brushes (for which it returns false) unlike tests of the form `GetStyle() == wxBRUSHSTYLE_TRANSPARENT` which would assert if the brush is invalid.

See also

IsNonTransparent()

Since

2.9.2.

bool wxBrush::operator!= (const wxBrush & *brush*) const

Inequality operator.

See Object Comparison for more info.

bool wxBrush::operator== (const wxBrush & *brush*) const

Equality operator.

See Object Comparison for more info.

virtual void wxBrush::SetColour (const wxColour & *colour*) `[virtual]`

Sets the brush colour using red, green and blue values.

See also

GetColour()

virtual void wxBrush::SetColour (unsigned char *red,* unsigned char *green,* unsigned char *blue*) `[virtual]`

Sets the brush colour using red, green and blue values.

See also

GetColour()

virtual void wxBrush::SetStipple (const wxBitmap & *bitmap*) `[virtual]`

Sets the stipple bitmap.

Parameters

bitmap	The bitmap to use for stippling.

Remarks

The style will be set to `wxBRUSHSTYLE_STIPPLE`, unless the bitmap has a mask associated to it, in which case the style will be set to `wxBRUSHSTYLE_STIPPLE_MASK_OPAQUE`.

See also

wxBitmap

virtual void wxBrush::SetStyle (wxBrushStyle *style*) `[virtual]`

Sets the brush style.

Parameters

style	One of the wxBrushStyle values.

See also

GetStyle()

21.67 wxBrushList Class Reference

`#include <wx/brush.h>`

21.67.1 Detailed Description

A brush list is a list containing all brushes which have been created.

The application should not construct its own brush list: it should use the object pointer wxTheBrushList.

Library: wxCore

Category: Graphics Device Interface (GDI)

See also

wxBrush

Public Member Functions

- wxBrush * FindOrCreateBrush (const wxColour &colour, wxBrushStyle style=wxBRUSHSTYLE_SOLID)

  Finds a brush with the specified attributes and returns it, else creates a new brush, adds it to the brush list, and returns it.

21.67.2 Member Function Documentation

wxBrush* wxBrushList::FindOrCreateBrush (const wxColour & *colour,* wxBrushStyle *style* = wxBRUSHSTYLE_SOLID)

Finds a brush with the specified attributes and returns it, else creates a new brush, adds it to the brush list, and returns it.

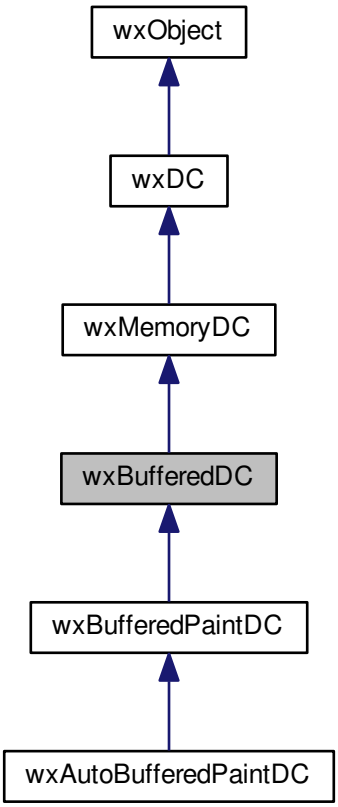
Parameters

colour	Colour object.
style	Brush style. See wxBrushStyle for a list of styles.

21.68 wxBufferedDC Class Reference

```
#include <wx/dcbuffer.h>
```

Inheritance diagram for wxBufferedDC:



21.68.1 Detailed Description

This class provides a simple way to avoid flicker: when drawing on it, everything is in fact first drawn on an in-memory buffer (a wxBitmap) and then copied to the screen, using the associated wxDC, only once, when this object is destroyed.

wxBufferedDC itself is typically associated with wxClientDC, if you want to use it in your `EVT_PAINT` handler, you should look at wxBufferedPaintDC instead.

When used like this, a valid *DC* must be specified in the constructor while the *buffer* bitmap doesn't have to be explicitly provided, by default this class will allocate the bitmap of required size itself. However using a dedicated bitmap can speed up the redrawing process by eliminating the repeated creation and destruction of a possibly big bitmap. Otherwise, wxBufferedDC can be used in the same way as any other device context.

There is another possible use for wxBufferedDC is to use it to maintain a backing store for the window contents. In this case, the associated *DC* may be NULL but a valid backing store bitmap should be specified.

Finally, please note that GTK+ 2.0 as well as OS X provide double buffering themselves natively. You can either use wxWindow::IsDoubleBuffered() to determine whether you need to use buffering or not, or use wxAutoBufferedPaintDC to avoid needless double buffering on the systems which already do it automatically.

Library: wxCore

Category: Device Contexts

See also

wxDC, wxMemoryDC, wxBufferedPaintDC, wxAutoBufferedPaintDC

Public Member Functions

- wxBufferedDC ()

  Default constructor.
- wxBufferedDC (wxDC *dc, const wxSize &area, int style=wxBUFFER_CLIENT_AREA)

  Creates a buffer for the provided dc.
- wxBufferedDC (wxDC *dc, wxBitmap &buffer=wxNullBitmap, int style=wxBUFFER_CLIENT_AREA)

  Creates a buffer for the provided dc.
- virtual ~wxBufferedDC ()

  Copies everything drawn on the DC so far to the underlying DC associated with this object, if any.
- void UnMask ()

  Blits the buffer to the dc, and detaches the dc from the buffer (so it can be effectively used once only).
- void SetStyle (int style)

  Set the style.
- int GetStyle () const

  Get the style.

- void Init (wxDC *dc, const wxSize &area, int style=wxBUFFER_CLIENT_AREA)

  Initializes the object created using the default constructor.
- void Init (wxDC *dc, wxBitmap &buffer=wxNullBitmap, int style=wxBUFFER_CLIENT_AREA)

  Initializes the object created using the default constructor.

Additional Inherited Members

21.68.2 Constructor & Destructor Documentation

wxBufferedDC::wxBufferedDC ( )

Default constructor.

You must call one of the Init() methods later in order to use the device context.

wxBufferedDC::wxBufferedDC (wxDC * *dc,* const wxSize & *area,* int *style* = wxBUFFER_CLIENT_AREA)

Creates a buffer for the provided *dc*.

Init() must not be called when using this constructor.

Parameters

dc	The underlying DC: everything drawn to this object will be flushed to this DC when this object is destroyed. You may pass NULL in order to just initialize the buffer, and not flush it.

area	The size of the bitmap to be used for buffering (this bitmap is created internally when it is not given explicitly).
style	wxBUFFER_CLIENT_AREA to indicate that just the client area of the window is buffered, or wxBUFFER_VIRTUAL_AREA to indicate that the buffer bitmap covers the virtual area.

wxBufferedDC::wxBufferedDC (wxDC * *dc*, wxBitmap & *buffer* = wxNullBitmap, int *style* = wxBUFFER_CLIENT_AREA)

Creates a buffer for the provided dc.

Init() must not be called when using this constructor.

Parameters

dc	The underlying DC: everything drawn to this object will be flushed to this DC when this object is destroyed. You may pass NULL in order to just initialize the buffer, and not flush it.
buffer	Explicitly provided bitmap to be used for buffering: this is the most efficient solution as the bitmap doesn't have to be recreated each time but it also requires more memory as the bitmap is never freed. The bitmap should have appropriate size, anything drawn outside of its bounds is clipped.
style	wxBUFFER_CLIENT_AREA to indicate that just the client area of the window is buffered, or wxBUFFER_VIRTUAL_AREA to indicate that the buffer bitmap covers the virtual area.

virtual wxBufferedDC::~wxBufferedDC ( ) [virtual]

Copies everything drawn on the DC so far to the underlying DC associated with this object, if any.

21.68.3 Member Function Documentation

int wxBufferedDC::GetStyle ( ) const

Get the style.

void wxBufferedDC::Init (wxDC * *dc*, const wxSize & *area*, int *style* = wxBUFFER_CLIENT_AREA)

Initializes the object created using the default constructor.

Please see the constructors for parameter details.

void wxBufferedDC::Init (wxDC * *dc*, wxBitmap & *buffer* = wxNullBitmap, int *style* = wxBUFFER_CLIENT_AREA)

Initializes the object created using the default constructor.

Please see the constructors for parameter details.

void wxBufferedDC::SetStyle (int *style*)

Set the style.

void wxBufferedDC::UnMask ( )

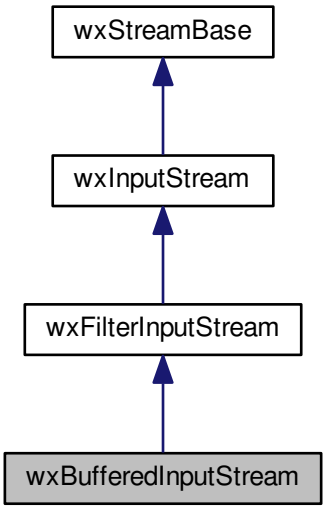
Blits the buffer to the dc, and detaches the dc from the buffer (so it can be effectively used once only).

Usually only called in the destructor or by the destructor of derived classes if the BufferedDC must blit before the derived class (which may own the dc it's blitting to) is destroyed.

21.69 wxBufferedInputStream Class Reference

`#include <wx/stream.h>`

Inheritance diagram for wxBufferedInputStream:



21.69.1 Detailed Description

This stream acts as a cache.

It caches the bytes read from the specified input stream (see wxFilterInputStream). It uses wxStreamBuffer and sets the default in-buffer size to 1024 bytes. This class may not be used without some other stream to read the data from (such as a file stream or a memory stream).

Library: wxBase

Category: Streams

See also

wxStreamBuffer, wxInputStream, wxBufferedOutputStream

Public Member Functions

- wxBufferedInputStream (wxInputStream &stream, wxStreamBuffer *buffer=NULL)

  Constructor using the provided buffer or default.

- wxBufferedInputStream (wxInputStream &stream, size_t bufsize)

  Constructor allowing to specify the size of the buffer.

- virtual ~wxBufferedInputStream ()

  Destructor.

Additional Inherited Members

21.69.2 Constructor & Destructor Documentation

wxBufferedInputStream::wxBufferedInputStream (wxInputStream & *stream*, wxStreamBuffer * *buffer* = NULL)

Constructor using the provided buffer or default.

Parameters

stream	The associated low-level stream.
buffer	The buffer to use if non-NULL. Notice that the ownership of this buffer is taken by the stream, i.e. it will delete it. If this parameter is NULL a default 1KB buffer is used.

wxBufferedInputStream::wxBufferedInputStream (wxInputStream & *stream*, size_t *bufsize*)

Constructor allowing to specify the size of the buffer.

This is just a more convenient alternative to creating a wxStreamBuffer of the given size and using the other overloaded constructor of this class.

Parameters

stream	The associated low-level stream.
bufsize	The size of the buffer, in bytes.

Since

2.9.0

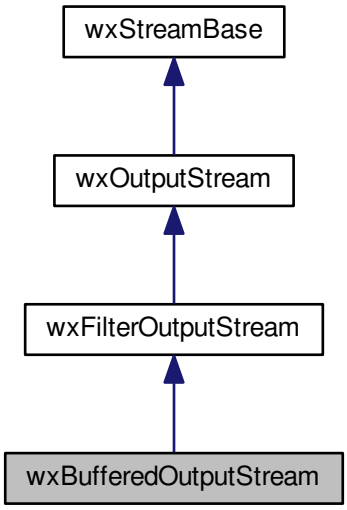
virtual wxBufferedInputStream::~wxBufferedInputStream ( ) [virtual]

Destructor.

21.70 wxBufferedOutputStream Class Reference

```
#include <wx/stream.h>
```

Inheritance diagram for wxBufferedOutputStream:



21.70.1 Detailed Description

This stream acts as a cache.

It caches the bytes to be written to the specified output stream (See wxFilterOutputStream). The data is only written when the cache is full, when the buffered stream is destroyed or when calling SeekO().

This class may not be used without some other stream to write the data to (such as a file stream or a memory stream).

Library: wxBase

Category: Streams

See also

wxStreamBuffer, wxOutputStream

Public Member Functions

- wxBufferedOutputStream (wxOutputStream &stream, wxStreamBuffer *buffer=NULL)

  Constructor using the provided buffer or default.
- wxBufferedOutputStream (wxOutputStream &stream, size_t bufsize)

  Constructor allowing to specify the size of the buffer.
- virtual ~wxBufferedOutputStream ()

  Destructor.
- virtual wxFileOffset SeekO (wxFileOffset pos, wxSeekMode mode=wxFromStart)

  Calls Sync() and changes the stream position.

- virtual void Sync ()

  Flushes the buffer and calls Sync() on the parent stream.

Additional Inherited Members

21.70.2 Constructor & Destructor Documentation

wxBufferedOutputStream::wxBufferedOutputStream (wxOutputStream & *stream*, wxStreamBuffer * *buffer* = NULL)

Constructor using the provided buffer or default.

Parameters

stream	The associated low-level stream.
buffer	The buffer to use if non-NULL. Notice that the ownership of this buffer is taken by the stream, i.e. it will delete it. If this parameter is NULL a default 1KB buffer is used.

wxBufferedOutputStream::wxBufferedOutputStream (wxOutputStream & *stream*, size_t *bufsize*)

Constructor allowing to specify the size of the buffer.

This is just a more convenient alternative to creating a wxStreamBuffer of the given size and using the other overloaded constructor of this class.

Parameters

stream	The associated low-level stream.
bufsize	The size of the buffer, in bytes.

Since

2.9.0

virtual wxBufferedOutputStream::~wxBufferedOutputStream ( ) [virtual]

Destructor.

Calls Sync() and destroys the internal buffer.

21.70.3 Member Function Documentation

virtual wxFileOffset wxBufferedOutputStream::SeekO (wxFileOffset *pos*, wxSeekMode *mode* = wxFromStart) [virtual]

Calls Sync() and changes the stream position.

Reimplemented from wxOutputStream.

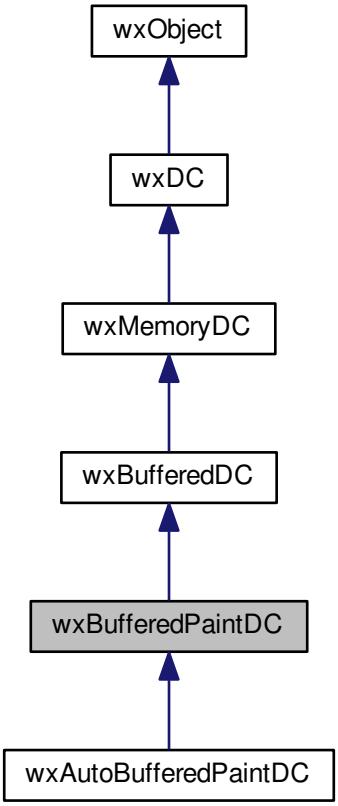
virtual void wxBufferedOutputStream::Sync ( ) [virtual]

Flushes the buffer and calls Sync() on the parent stream.

21.71 wxBufferedPaintDC Class Reference

`#include <wx/dcbuffer.h>`

Inheritance diagram for wxBufferedPaintDC:



21.71.1 Detailed Description

This is a subclass of wxBufferedDC which can be used inside of an `EVT_PAINT()` event handler to achieve double-buffered drawing.

Just use this class instead of wxPaintDC and make sure wxWindow::SetBackgroundStyle() is called with wxBG_↩ STYLE_PAINT somewhere in the class initialization code, and that's all you have to do to (mostly) avoid flicker. The only thing to watch out for is that if you are using this class together with wxScrolled, you probably do **not** want to call wxScrolled::PrepareDC() on it as it already does this internally for the real underlying wxPaintDC.

Library: wxCore

Category: Device Contexts

See also

wxDC, wxBufferedDC, wxAutoBufferedPaintDC, wxPaintDC

Public Member Functions

- virtual ~wxBufferedPaintDC ()

  Copies everything drawn on the DC so far to the window associated with this object, using a wxPaintDC.

- wxBufferedPaintDC (wxWindow *window, wxBitmap &buffer, int style=wxBUFFER_CLIENT_AREA)

  As with wxBufferedDC, you may either provide the bitmap to be used for buffering or let this object create one internally (in the latter case, the size of the client part of the window is used).

- wxBufferedPaintDC (wxWindow *window, int style=wxBUFFER_CLIENT_AREA)

  As with wxBufferedDC, you may either provide the bitmap to be used for buffering or let this object create one internally (in the latter case, the size of the client part of the window is used).

Additional Inherited Members

21.71.2 Constructor & Destructor Documentation

wxBufferedPaintDC::wxBufferedPaintDC (wxWindow * *window,* wxBitmap & *buffer,* int *style* = wxBUFFER_CLIENT_AREA)

As with wxBufferedDC, you may either provide the bitmap to be used for buffering or let this object create one internally (in the latter case, the size of the client part of the window is used).

Pass wxBUFFER_CLIENT_AREA for the *style* parameter to indicate that just the client area of the window is buffered, or wxBUFFER_VIRTUAL_AREA to indicate that the buffer bitmap covers the virtual area.

wxBufferedPaintDC::wxBufferedPaintDC (wxWindow * *window,* int *style* = wxBUFFER_CLIENT_AREA)

As with wxBufferedDC, you may either provide the bitmap to be used for buffering or let this object create one internally (in the latter case, the size of the client part of the window is used).

Pass wxBUFFER_CLIENT_AREA for the *style* parameter to indicate that just the client area of the window is buffered, or wxBUFFER_VIRTUAL_AREA to indicate that the buffer bitmap covers the virtual area.

virtual wxBufferedPaintDC::~wxBufferedPaintDC ( ) [virtual]

Copies everything drawn on the DC so far to the window associated with this object, using a wxPaintDC.

21.72 wxBusyCursor Class Reference

```
#include <wx/utils.h>
```

21.72.1 Detailed Description

This class makes it easy to tell your user that the program is temporarily busy.

Just create a wxBusyCursor object on the stack, and within the current scope, the hourglass will be shown.

For example:

```
wxBusyCursor wait;

for (int i = 0; i < 100000; i++)
    DoACalculation();
```

It works by calling wxBeginBusyCursor() in the constructor, and wxEndBusyCursor() in the destructor.

Library: wxCore

Category: Miscellaneous

See also

wxBeginBusyCursor(), wxEndBusyCursor(), wxWindowDisabler

Public Member Functions

- wxBusyCursor (const wxCursor *cursor=wxHOURGLASS_CURSOR)

  Constructs a busy cursor object, calling wxBeginBusyCursor().
- ~wxBusyCursor ()

  Destroys the busy cursor object, calling wxEndBusyCursor().

21.72.2 Constructor & Destructor Documentation

wxBusyCursor::wxBusyCursor (const wxCursor * *cursor* = wxHOURGLASS_CURSOR)

Constructs a busy cursor object, calling wxBeginBusyCursor().

wxBusyCursor::~wxBusyCursor ( )

Destroys the busy cursor object, calling wxEndBusyCursor().

21.73 wxBusyInfo Class Reference

```
#include <wx/busyinfo.h>
```

21.73.1 Detailed Description

This class makes it easy to tell your user that the program is temporarily busy.

Normally the main thread should always return to the main loop to continue dispatching events as quickly as possible, hence this class shouldn't be needed. However if the main thread does need to block, this class provides a simple way to at least show this to the user: just create a wxBusyInfo object on the stack, and within the current scope, a message window will be shown.

For example:

```
wxBusyInfo wait("Please wait, working...");

for (int i = 0; i < 100000; i++)
{
    DoACalculation();
}
```

It works by creating a window in the constructor, and deleting it in the destructor.

This window is rather plain by default but can be customized by passing wxBusyInfo constructor an object of wxBusyInfoFlags class instead of a simple message. Here is an example from the page_samples_dialogs:

```
wxBusyInfo info
    (
        wxBusyInfoFlags()
            .Parent(this)
            .Icon(wxArtProvider::GetIcon(wxART_PRINT,
                                         wxART_OTHER, wxSize(128, 128)))
            .Title("<b>Printing your document</b>")
            .Text("Please wait...")
            .Foreground(*wxWHITE)
            .Background(*wxBLACK)
            .Transparency(4*wxALPHA_OPAQUE/5)
    );
```

showing that separate title and text can be set, and that simple markup (wxControl::SetLabelMarkup()) can be used in them, and that it's also possible to add an icon and customize the colours and transparency of the window.

You may also want to call wxTheApp->Yield() to refresh the window periodically (in case it had been obscured by other windows, for example) like this:

```
wxWindowDisabler disableAll;
wxBusyInfo wait("Please wait, working...");

for (int i = 0; i < 100000; i++)
{
    DoACalculation();

    if ( !(i % 1000) )
        wxTheApp->Yield();
}
```

but take care to not cause undesirable reentrancies when doing it (see wxApp::Yield for more details). The simplest way to do it is to use wxWindowDisabler class as illustrated in the above example.

Note that a wxBusyInfo is always built with the `wxSTAY_ON_TOP` window style (see wxFrame window styles for more info).

Library: wxCore

Category: Common Dialogs

Public Member Functions

- wxBusyInfo (const wxBusyInfoFlags &flags)

  General constructor.
- wxBusyInfo (const wxString &msg, wxWindow *parent=NULL)

  Simple constructor specifying only the message and the parent.
- virtual ~wxBusyInfo ()

  Hides and closes the window containing the information text.

21.73.2 Constructor & Destructor Documentation

wxBusyInfo::wxBusyInfo (const wxBusyInfoFlags & *flags*)

General constructor.

This constructor allows to specify all supported attributes by calling the appropriate methods on wxBusyInfoFlags object passed to it as parameter. All of them are optional but usually at least the message should be specified.

Since

3.1.0

wxBusyInfo::wxBusyInfo (const wxString & *msg*, wxWindow * *parent* = NULL)

Simple constructor specifying only the message and the parent.

This constructs a busy info window as child of *parent* and displays *msg* in it. It is exactly equivalent to using

```
wxBusyInfo(wxBusyInfoFlags().Parent(parent).Label(message))
```

Note

If *parent* is not NULL you must ensure that it is not closed while the busy info is shown.

virtual wxBusyInfo::~wxBusyInfo ( ) [virtual]

Hides and closes the window containing the information text.

21.74 wxBusyInfoFlags Class Reference

```
#include <wx/busyinfo.h>
```

21.74.1 Detailed Description

Parameters for wxBusyInfo.

This class exists only in order to make passing attributes to wxBusyInfo constructor easier and the code doing it more readable.

All methods of this class return the reference to the object on which they are called, making it possible to chain them together, e.g. typically you would just create a temporary wxBusyInfoFlags object and then call the methods corresponding to the attributes you want to set, before finally passing the result to wxBusyInfo constructor, e.g.:

```
wxBusyInfo info
    (
        wxBusyInfoFlags()
            .Parent(window)
            .Icon(icon)
            .Title("Some text")
            .Text("Some more text")
            .Foreground(wxColour(...))
            .Background(wxColour(...))
    );
```

Since

3.1.0

Public Member Functions

- wxBusyInfoFlags ()

  Default constructor initializes all attributes to default values.
- wxBusyInfoFlags & Parent (wxWindow *parent)

  Sets the parent for wxBusyInfo.

- wxBusyInfoFlags & Icon (const wxIcon &icon)

  Sets the icon to show in wxBusyInfo.
- wxBusyInfoFlags & Title (const wxString &title)

  Sets the title, shown prominently in wxBusyInfo window.
- wxBusyInfoFlags & Text (const wxString &text)

  Sets the more detailed text, shown under the title, if any.
- wxBusyInfoFlags & Label (const wxString &label)

  Same as Text() but doesn't interpret the string as containing markup.
- wxBusyInfoFlags & Foreground (const wxColour &foreground)

  Sets the foreground colour of the title and text strings.
- wxBusyInfoFlags & Background (const wxColour &background)

  Sets the background colour of wxBusyInfo window.
- wxBusyInfoFlags & Transparency (wxByte alpha)

  Sets the transparency of wxBusyInfo window.

21.74.2 Constructor & Destructor Documentation

wxBusyInfoFlags::wxBusyInfoFlags ( )

Default constructor initializes all attributes to default values.

Call the other methods to really fill in the object.

21.74.3 Member Function Documentation

wxBusyInfoFlags& wxBusyInfoFlags::Background (const wxColour & *background*)

Sets the background colour of wxBusyInfo window.

wxBusyInfoFlags& wxBusyInfoFlags::Foreground (const wxColour & *foreground*)

Sets the foreground colour of the title and text strings.

wxBusyInfoFlags& wxBusyInfoFlags::Icon (const wxIcon & *icon*)

Sets the icon to show in wxBusyInfo.

wxBusyInfoFlags& wxBusyInfoFlags::Label (const wxString & *label*)

Same as Text() but doesn't interpret the string as containing markup.

This method should be used if the text shown in wxBusyInfo comes from external source and so may contain characters having special meaning in simple markup, e.g. '<'.

wxBusyInfoFlags& wxBusyInfoFlags::Parent (wxWindow * *parent*)

Sets the parent for wxBusyInfo.

wxBusyInfoFlags& wxBusyInfoFlags::Text (const wxString & *text*)

Sets the more detailed text, shown under the title, if any.

The *text* string may contain markup as described in wxControl::SetLabelMarkup().

wxBusyInfoFlags& wxBusyInfoFlags::Title (const wxString & *title*)

Sets the title, shown prominently in wxBusyInfo window.

The *title* string may contain markup as described in wxControl::SetLabelMarkup().

wxBusyInfoFlags& wxBusyInfoFlags::Transparency (wxByte *alpha*)

Sets the transparency of wxBusyInfo window.

Parameters

alpha	Value in wxALPHA_TRANSPARENT (0) to wxALPHA_OPAQUE (255) range.

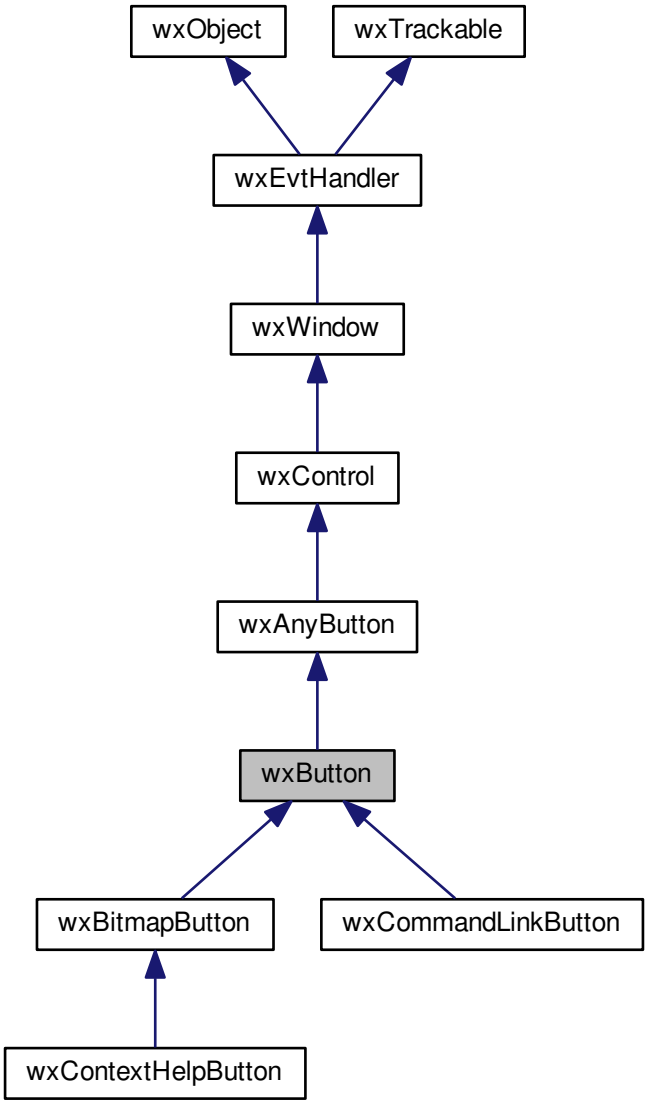
See also

wxTopLevelWindow::SetTransparent()

21.75 wxButton Class Reference

```
#include <wx/button.h>
```

Inheritance diagram for wxButton:



21.75.1 Detailed Description

A button is a control that contains a text string, and is one of the most common elements of a GUI.

It may be placed on a dialog box or on a wxPanel panel, or indeed on almost any other window.

By default, i.e. if none of the alignment styles are specified, the label is centered both horizontally and vertically. If the button has both a label and a bitmap, the alignment styles above specify the location of the rectangle combining both the label and the bitmap and the bitmap position set with wxButton::SetBitmapPosition() defines the relative position of the bitmap with respect to the label (however currently non-default alignment combinations are not implemented on all platforms).

Since version 2.9.1 wxButton supports showing both text and an image (currently only when using wxMSW, wxGTK or wxOSX/Cocoa ports), see SetBitmap() and SetBitmapLabel(), SetBitmapDisabled() &c methods. In the previous

wxWidgets versions this functionality was only available in (the now trivial) wxBitmapButton class which was only capable of showing an image without text.

A button may have either a single image for all states or different images for the following states (different images are not currently supported under OS X where the normal image is used for all states):

- **normal:** the default state
- **disabled:** bitmap shown when the button is disabled.
- **pressed:** bitmap shown when the button is pushed (e.g. while the user keeps the mouse button pressed on it)
- **focus:** bitmap shown when the button has keyboard focus (but is not pressed as in this case the button is in the pressed state)
- **current:** bitmap shown when the mouse is over the button (but it is not pressed although it may have focus). Notice that if current bitmap is not specified but the current platform UI uses hover images for the buttons (such as Windows XP or GTK+), then the focus bitmap is used for hover state as well. This makes it possible to set focus bitmap only to get reasonably good behaviour on all platforms.

All of the bitmaps must be of the same size and the normal bitmap must be set first (to a valid bitmap), before setting any other ones. Also, if the size of the bitmaps is changed later, you need to change the size of the normal bitmap before setting any other bitmaps with the new size (and you do need to reset all of them as their original values can be lost when the normal bitmap size changes).

The position of the image inside the button be configured using SetBitmapPosition(). By default the image is on the left of the text.

Please also notice that GTK+ uses a global setting called `gtk-button-images` to determine if the images should be shown in the buttons at all. If it is off (which is the case in e.g. Gnome 2.28 by default), no images will be shown, consistently with the native behaviour.

Styles

This class supports the following styles:

- wxBU_LEFT: Left-justifies the label. Windows and GTK+ only.
- wxBU_TOP: Aligns the label to the top of the button. Windows and GTK+ only.
- wxBU_RIGHT: Right-justifies the bitmap label. Windows and GTK+ only.
- wxBU_BOTTOM: Aligns the label to the bottom of the button. Windows and GTK+ only.
- wxBU_EXACTFIT: By default, all buttons are made of at least the standard button size, even if their contents is small enough to fit into a smaller size. This is done for consistency as most platforms use buttons of the same size in the native dialogs, but can be overridden by specifying this flag. If it is given, the button will be made just big enough for its contents. Notice that under MSW the button will still have at least the standard height, even with this style, if it has a non-empty label.
- wxBU_NOTEXT: Disables the display of the text label in the button even if it has one or its id is one of the standard stock ids with an associated label: without using this style a button which is only supposed to show a bitmap but uses a standard id would display a label too.
- wxBORDER_NONE: Creates a button without border. This is currently implemented in MSW, GTK2 and OSX/Cocoa and OSX/Carbon ports but in the latter only applies to buttons with bitmaps and using bitmap of one of the standard sizes only, namely 128∗128, 48∗48, 24∗24 or 16∗16. In all the other cases wxBORDER_NONE is ignored under OSX/Carbon (these restrictions don't exist in OSX/Cocoa however).

Events emitted by this class

The following event handler macros redirect the events to member function handlers '**func**' with prototypes like: void handlerFuncName(wxCommandEvent& event)

Event macros for events emitted by this class:

- EVT_BUTTON(id, func): Process a `wxEVT_BUTTON` event, when the button is clicked.

Library: wxCore

Category: Controls

wxBitmapButton

Public Member Functions

- wxButton ()

  Default ctor.
- wxButton (wxWindow *parent, wxWindowID id, const wxString &label=wxEmptyString, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, long style=0, const wxValidator &validator=wxDefaultValidator, const wxString &name=wxButtonNameStr)

  Constructor, creating and showing a button.
- bool Create (wxWindow *parent, wxWindowID id, const wxString &label=wxEmptyString, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, long style=0, const wxValidator &validator=wxDefaultValidator, const wxString &name=wxButtonNameStr)

  Button creation function for two-step creation.
- bool GetAuthNeeded () const

  Returns true if an authentication needed symbol is displayed on the button.
- wxString GetLabel () const

  Returns the string label for the button.
- void SetAuthNeeded (bool needed=true)

  Sets whether an authentication needed symbol should be displayed on the button.
- virtual wxWindow * SetDefault ()

  This sets the button to be the default item in its top-level window (e.g.
- void SetLabel (const wxString &label)

  Sets the string label for the button.

Static Public Member Functions

- static wxSize GetDefaultSize ()

  Returns the default size for the buttons.

Additional Inherited Members

21.75.2 Constructor & Destructor Documentation

wxButton::wxButton ( )

Default ctor.

wxButton::wxButton (wxWindow * *parent*, wxWindowID *id*, const wxString & *label* = wxEmptyString, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, long *style* = 0, const wxValidator & *validator* = wxDefaultValidator, const wxString & *name* = wxButtonNameStr)

Constructor, creating and showing a button.

The preferred way to create standard buttons is to use default value of *label*. If no label is supplied and *id* is one of standard IDs from this list, a standard label will be used. In other words, if you use a predefined `wxID_XXX` constant, just omit the label completely rather than specifying it. In particular, help buttons (the ones with *id* of `wxID_HELP`) under Mac OS X can't display any label at all and while wxButton will detect if the standard "Help" label is used and ignore it, using any other label will prevent the button from correctly appearing as a help button and so should be avoided.

In addition to that, the button will be decorated with stock icons under GTK+ 2.

Parameters

parent	Parent window. Must not be NULL.
id	Button identifier. A value of `wxID_ANY` indicates a default value.
label	Text to be displayed on the button.
pos	Button position.
size	Button size. If the default size is specified then the button is sized appropriately for the text.
style	Window style. See wxButton class description.
validator	Window validator.
name	Window name.

See also

Create(), wxValidator

21.75.3 Member Function Documentation

bool wxButton::Create (wxWindow * *parent*, wxWindowID *id*, const wxString & *label* = wxEmptyString, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, long *style* = 0, const wxValidator & *validator* = wxDefaultValidator, const wxString & *name* = wxButtonNameStr)

Button creation function for two-step creation.

For more details, see wxButton().

bool wxButton::GetAuthNeeded ( ) const

Returns true if an authentication needed symbol is displayed on the button.

Remarks

This method always returns false if the platform is not Windows Vista or newer.

See also

SetAuthNeeded()

Since

2.9.1

static wxSize wxButton::GetDefaultSize ( ) [static]

Returns the default size for the buttons.

It is advised to make all the dialog buttons of the same size and this function allows to retrieve the (platform and current font dependent size) which should be the best suited for this.

wxString wxButton::GetLabel ( ) const [virtual]

Returns the string label for the button.

See also

SetLabel()

Reimplemented from wxWindow.

Reimplemented in wxCommandLinkButton.

void wxButton::SetAuthNeeded (bool *needed* = true)

Sets whether an authentication needed symbol should be displayed on the button.

Remarks

This method doesn't do anything if the platform is not Windows Vista or newer.

See also

GetAuthNeeded()

Since

2.9.1

virtual wxWindow* wxButton::SetDefault ( ) [virtual]

This sets the button to be the default item in its top-level window (e.g.

the panel or the dialog box containing it).

As normal, pressing return causes the default button to be depressed when the return key is pressed.

See also wxWindow::SetFocus() which sets the keyboard focus for windows and text panel items, and wxTopLevelWindow::SetDefaultItem().

Remarks

Under Windows, only dialog box buttons respond to this function.

Returns

the old default item (possibly NULL)

void wxButton::SetLabel (const wxString & *label*) [virtual]

Sets the string label for the button.

Parameters

label	The label to set.

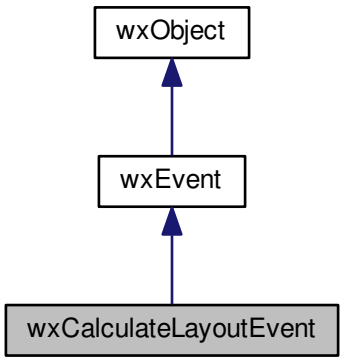
Reimplemented from wxWindow.

Reimplemented in wxCommandLinkButton.

21.76 wxCalculateLayoutEvent Class Reference

`#include <wx/laywin.h>`

Inheritance diagram for wxCalculateLayoutEvent:



21.76.1 Detailed Description

This event is sent by wxLayoutAlgorithm to calculate the amount of the remaining client area that the window should occupy.

Events using this class

The following event handler macros redirect the events to member function handlers '**func**' with prototypes like: void handlerFuncName(wxCalculateLayoutEvent& event)

Event macros:

- EVT_CALCULATE_LAYOUT(func): Process a `wxEVT_CALCULATE_LAYOUT` event, which asks the window to take a 'bite' out of a rectangle provided by the algorithm.

Library: wxAdvanced

Category: Events

See also

wxQueryLayoutInfoEvent, wxSashLayoutWindow, wxLayoutAlgorithm.

Public Member Functions

- wxCalculateLayoutEvent (wxWindowID id=0)

  Constructor.
- int GetFlags () const

  Returns the flags associated with this event.
- wxRect GetRect () const

  Before the event handler is entered, returns the remaining parent client area that the window could occupy.
- void SetFlags (int flags)

  Sets the flags associated with this event.
- void SetRect (const wxRect &rect)

  Call this to specify the new remaining parent client area, after the space occupied by the window has been subtracted.

Additional Inherited Members

21.76.2 Constructor & Destructor Documentation

wxCalculateLayoutEvent::wxCalculateLayoutEvent (wxWindowID *id* = 0)

Constructor.

21.76.3 Member Function Documentation

int wxCalculateLayoutEvent::GetFlags ( ) const

Returns the flags associated with this event.

Not currently used.

wxRect wxCalculateLayoutEvent::GetRect ( ) const

Before the event handler is entered, returns the remaining parent client area that the window could occupy.

When the event handler returns, this should contain the remaining parent client rectangle, after the event handler has subtracted the area that its window occupies.

void wxCalculateLayoutEvent::SetFlags (int *flags*)

Sets the flags associated with this event.

Not currently used.

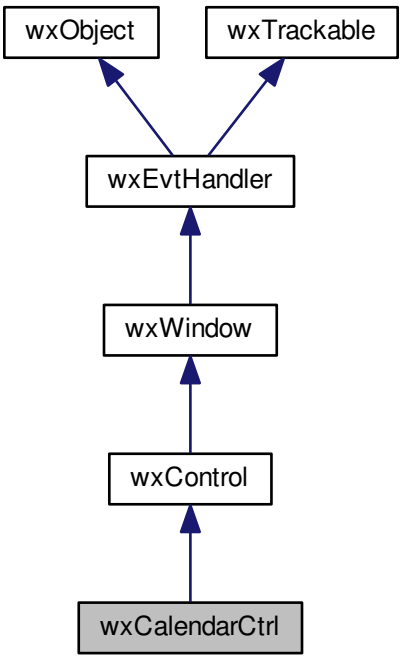
void wxCalculateLayoutEvent::SetRect (const wxRect & *rect*)

Call this to specify the new remaining parent client area, after the space occupied by the window has been subtracted.

21.77 wxCalendarCtrl Class Reference

`#include <wx/calctrl.h>`

Inheritance diagram for wxCalendarCtrl:



21.77.1 Detailed Description

The calendar control allows the user to pick a date.

The user can move the current selection using the keyboard and select the date (generating `EVT_CALENDAR` event) by pressing `<Return>` or double clicking it.

Generic calendar has advanced possibilities for the customization of its display, described below. If you want to use these possibilities on every platform, use wxGenericCalendarCtrl instead of wxCalendarCtrl.

All global settings (such as colours and fonts used) can, of course, be changed. But also, the display style for each day in the month can be set independently using wxCalendarDateAttr class.

An item without custom attributes is drawn with the default colours and font and without border, but setting custom attributes with SetAttr() allows to modify its appearance. Just create a custom attribute object and set it for the day you want to be displayed specially (note that the control will take ownership of the pointer, i.e. it will delete it itself). A day may be marked as being a holiday, even if it is not recognized as one by wxDateTime using the wxCalendarDateAttr::SetHoliday() method.

As the attributes are specified for each day, they may change when the month is changed, so you will often want to update them in `EVT_CALENDAR_PAGE_CHANGED` event handler.

Styles

This class supports the following styles:

- wxCAL_SUNDAY_FIRST: Show Sunday as the first day in the week (not in wxGTK)
- wxCAL_MONDAY_FIRST: Show Monday as the first day in the week (not in wxGTK)
- wxCAL_SHOW_HOLIDAYS: Highlight holidays in the calendar (only generic)
- wxCAL_NO_YEAR_CHANGE: Disable the year changing (deprecated, only generic)
- wxCAL_NO_MONTH_CHANGE: Disable the month (and, implicitly, the year) changing
- wxCAL_SHOW_SURROUNDING_WEEKS: Show the neighbouring weeks in the previous and next months (only generic, always on for the native controls)
- wxCAL_SEQUENTIAL_MONTH_SELECTION: Use alternative, more compact, style for the month and year selection controls. (only generic)
- wxCAL_SHOW_WEEK_NUMBERS: Show week numbers on the left side of the calendar. (not in generic)

Events emitted by this class

The following event handler macros redirect the events to member function handlers '**func**' with prototypes like: void handlerFuncName(wxCalendarEvent& event)

Event macros for events emitted by this class:

- EVT_CALENDAR(id, func): A day was double clicked in the calendar.
- EVT_CALENDAR_SEL_CHANGED(id, func): The selected date changed.
- EVT_CALENDAR_PAGE_CHANGED(id, func): The selected month (and/or year) changed.
- EVT_CALENDAR_WEEKDAY_CLICKED(id, func): User clicked on the week day header (only generic).
- EVT_CALENDAR_WEEK_CLICKED(id, func): User clicked on the week of the year number (only generic).

Note

Changing the selected date will trigger an EVT_CALENDAR_DAY, MONTH or YEAR event as well as an EVT_CALENDAR_SEL_CHANGED event.

Library: wxAdvanced

Category: Controls

Implementations: native under wxGTK, wxMSW ports; a generic implementation is used elsewhere.

See also

Calendar Sample, wxCalendarDateAttr, wxCalendarEvent, wxDatePickerCtrl

Public Member Functions

- wxCalendarCtrl ()

  Default constructor.
- wxCalendarCtrl (wxWindow *parent, wxWindowID id, const wxDateTime &date=wxDefaultDateTime, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, long style=wxCAL_SHOW_HOLIDAYS, const wxString &name=wxCalendarNameStr)

  Does the same as Create() method.
- ~wxCalendarCtrl ()

  Destroys the control.
- bool Create (wxWindow *parent, wxWindowID id, const wxDateTime &date=wxDefaultDateTime, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, long style=wxCAL_SHOW_HOLIDAYS, const wxString &name=wxCalendarNameStr)

  Creates the control.
- virtual void EnableHolidayDisplay (bool display=true)

  This function should be used instead of changing `wxCAL_SHOW_HOLIDAYS` style bit directly.
- virtual bool EnableMonthChange (bool enable=true)

  This function should be used instead of changing `wxCAL_NO_MONTH_CHANGE` style bit.
- virtual void EnableYearChange (bool enable=true)
- virtual wxCalendarDateAttr * GetAttr (size_t day) const

  Returns the attribute for the given date (should be in the range 1...31).
- virtual wxDateTime GetDate () const

  Gets the currently selected date.
- virtual const wxColour & GetHeaderColourBg () const

  Gets the background colour of the header part of the calendar window.
- virtual const wxColour & GetHeaderColourFg () const

  Gets the foreground colour of the header part of the calendar window.
- virtual const wxColour & GetHighlightColourBg () const

  Gets the background highlight colour.
- virtual const wxColour & GetHighlightColourFg () const

  Gets the foreground highlight colour.
- virtual const wxColour & GetHolidayColourBg () const

  Return the background colour currently used for holiday highlighting.
- virtual const wxColour & GetHolidayColourFg () const

  Return the foreground colour currently used for holiday highlighting.
- virtual wxCalendarHitTestResult HitTest (const wxPoint &pos, wxDateTime *date=NULL, wxDateTime::WeekDay *wd=NULL)

  Returns one of wxCalendarHitTestResult constants and fills either date or wd pointer with the corresponding value depending on the hit test code.
- virtual void ResetAttr (size_t day)

  Clears any attributes associated with the given day (in the range 1...31).
- virtual void SetAttr (size_t day, wxCalendarDateAttr *attr)

  Associates the attribute with the specified date (in the range 1...31).
- virtual bool SetDate (const wxDateTime &date)

  Sets the current date.
- virtual void SetHeaderColours (const wxColour &colFg, const wxColour &colBg)

  Set the colours used for painting the weekdays at the top of the control.
- virtual void SetHighlightColours (const wxColour &colFg, const wxColour &colBg)

  Set the colours to be used for highlighting the currently selected date.
- virtual void SetHoliday (size_t day)

  Marks the specified day as being a holiday in the current month.
- virtual void SetHolidayColours (const wxColour &colFg, const wxColour &colBg)

Sets the colours to be used for the holidays highlighting.

- virtual void Mark (size_t day, bool mark)

  Mark or unmark the day.

Date Range Functions

- virtual bool SetDateRange (const wxDateTime &lowerdate=wxDefaultDateTime, const wxDateTime &upperdate=wxDefaultDateTime)

  Restrict the dates that can be selected in the control to the specified range.
- virtual bool GetDateRange (wxDateTime *lowerdate, wxDateTime *upperdate) const

  Returns the limits currently being used.

Additional Inherited Members

21.77.2 Constructor & Destructor Documentation

wxCalendarCtrl::wxCalendarCtrl ( )

Default constructor.

wxCalendarCtrl::wxCalendarCtrl (wxWindow * *parent*, wxWindowID *id*, const wxDateTime & *date* = wxDefaultDateTime, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, long *style* = wxCAL_SHOW_HOLIDAYS, const wxString & *name* = `wxCalendarNameStr`)

Does the same as Create() method.

wxCalendarCtrl::~wxCalendarCtrl ( )

Destroys the control.

21.77.3 Member Function Documentation

bool wxCalendarCtrl::Create (wxWindow * *parent*, wxWindowID *id*, const wxDateTime & *date* = wxDefaultDateTime, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, long *style* = wxCAL_SHOW_HOLIDAYS, const wxString & *name* = `wxCalendarNameStr`)

Creates the control.

See wxWindow::wxWindow() for the meaning of the parameters and the control overview for the possible styles.

virtual void wxCalendarCtrl::EnableHolidayDisplay (bool *display* = `true`) `[virtual]`

This function should be used instead of changing `wxCAL_SHOW_HOLIDAYS` style bit directly.

It enables or disables the special highlighting of the holidays.

virtual bool wxCalendarCtrl::EnableMonthChange (bool *enable* = `true`) `[virtual]`

This function should be used instead of changing `wxCAL_NO_MONTH_CHANGE` style bit.

It allows or disallows the user to change the month interactively. Note that if the month cannot be changed, the year cannot be changed neither.

Returns

true if the value of this option really changed or false if it was already set to the requested value.

virtual void wxCalendarCtrl::EnableYearChange (bool *enable* = `true`) `[virtual]`

Deprecated

This function should be used instead of changing `wxCAL_NO_YEAR_CHANGE` style bit directly. It allows or disallows the user to change the year interactively. Only in generic wxCalendarCtrl.

virtual wxCalendarDateAttr* wxCalendarCtrl::GetAttr (size_t *day*) const `[virtual]`

Returns the attribute for the given date (should be in the range 1...31).

The returned pointer may be NULL. Only in generic wxCalendarCtrl.

virtual wxDateTime wxCalendarCtrl::GetDate ( ) const `[virtual]`

Gets the currently selected date.

virtual bool wxCalendarCtrl::GetDateRange (wxDateTime * *lowerdate*, wxDateTime * *upperdate*) const `[virtual]`

Returns the limits currently being used.

See also

SetDateRange()

Parameters

lowerdate	If non-NULL, the value of the low limit for the dates shown by the control is returned (which may be wxDefaultDateTime if no limit is set).
upperdate	If non-NULL, the value of the upper limit for the dates shown by the control is returned (which may be wxDefaultDateTime if no limit is set).

Returns

true if either limit is set, false otherwise

virtual const wxColour& wxCalendarCtrl::GetHeaderColourBg ( ) const `[virtual]`

Gets the background colour of the header part of the calendar window.

This method is currently only implemented in generic wxCalendarCtrl and always returns `wxNullColour` in the native versions.

See also

SetHeaderColours()

virtual const wxColour& wxCalendarCtrl::GetHeaderColourFg ( ) const `[virtual]`

Gets the foreground colour of the header part of the calendar window.

This method is currently only implemented in generic wxCalendarCtrl and always returns `wxNullColour` in the native versions.

See also

SetHeaderColours()

virtual const wxColour& wxCalendarCtrl::GetHighlightColourBg ( ) const `[virtual]`

Gets the background highlight colour.

Only in generic wxCalendarCtrl.

This method is currently only implemented in generic wxCalendarCtrl and always returns `wxNullColour` in the native versions.

See also

SetHighlightColours()

virtual const wxColour& wxCalendarCtrl::GetHighlightColourFg ( ) const `[virtual]`

Gets the foreground highlight colour.

Only in generic wxCalendarCtrl.

This method is currently only implemented in generic wxCalendarCtrl and always returns `wxNullColour` in the native versions.

See also

SetHighlightColours()

virtual const wxColour& wxCalendarCtrl::GetHolidayColourBg ( ) const `[virtual]`

Return the background colour currently used for holiday highlighting.

Only useful with generic wxCalendarCtrl as native versions currently don't support holidays display at all and always return `wxNullColour`.

See also

SetHolidayColours()

virtual const wxColour& wxCalendarCtrl::GetHolidayColourFg ( ) const `[virtual]`

Return the foreground colour currently used for holiday highlighting.

Only useful with generic wxCalendarCtrl as native versions currently don't support holidays display at all and always return `wxNullColour`.

See also

SetHolidayColours()

virtual **wxCalendarHitTestResult** wxCalendarCtrl::HitTest (const **wxPoint** & *pos*, **wxDateTime** * *date* = NULL, **wxDateTime::WeekDay** * *wd* = NULL) [virtual]

Returns one of wxCalendarHitTestResult constants and fills either *date* or *wd* pointer with the corresponding value depending on the hit test code.

Not implemented in wxGTK currently.

virtual void wxCalendarCtrl::Mark (size_t *day*, bool *mark*) [virtual]

Mark or unmark the day.

This day of month will be marked in every month. In generic wxCalendarCtrl,

virtual void wxCalendarCtrl::ResetAttr (size_t *day*) [virtual]

Clears any attributes associated with the given day (in the range 1...31).

Only in generic wxCalendarCtrl.

virtual void wxCalendarCtrl::SetAttr (size_t *day*, **wxCalendarDateAttr** * *attr*) [virtual]

Associates the attribute with the specified date (in the range 1...31).

If the pointer is NULL, the items attribute is cleared. Only in generic wxCalendarCtrl.

virtual bool wxCalendarCtrl::SetDate (const **wxDateTime** & *date*) [virtual]

Sets the current date.

The *date* parameter must be valid and in the currently valid range as set by SetDateRange(), otherwise the current date is not changed and the function returns false.

virtual bool wxCalendarCtrl::SetDateRange (const **wxDateTime** & *lowerdate* = **wxDefaultDateTime**, const **wxDateTime** & *upperdate* = **wxDefaultDateTime**) [virtual]

Restrict the dates that can be selected in the control to the specified range.

If either date is set, the corresponding limit will be enforced and true returned. If none are set, the existing restrictions are removed and false is returned.

See also

GetDateRange()

Parameters

lowerdate	The low limit for the dates shown by the control or wxDefaultDateTime.
upperdate	The high limit for the dates shown by the control or wxDefaultDateTime.

Returns

true if either limit is valid, false otherwise

virtual void wxCalendarCtrl::SetHeaderColours (const **wxColour** & *colFg*, const **wxColour** & *colBg*) [virtual]

Set the colours used for painting the weekdays at the top of the control.

This method is currently only implemented in generic wxCalendarCtrl and does nothing in the native versions.

virtual void wxCalendarCtrl::SetHighlightColours (const wxColour & *colFg,* const wxColour & *colBg*) `[virtual]`

Set the colours to be used for highlighting the currently selected date.

This method is currently only implemented in generic wxCalendarCtrl and does nothing in the native versions.

virtual void wxCalendarCtrl::SetHoliday (size_t *day*) `[virtual]`

Marks the specified day as being a holiday in the current month.

This method is only implemented in the generic version of the control and does nothing in the native ones.

virtual void wxCalendarCtrl::SetHolidayColours (const wxColour & *colFg,* const wxColour & *colBg*) `[virtual]`

Sets the colours to be used for the holidays highlighting.

This method is only implemented in the generic version of the control and does nothing in the native ones. It should also only be called if the window style includes `wxCAL_SHOW_HOLIDAYS` flag or EnableHolidayDisplay() had been called.

21.78 wxCalendarDateAttr Class Reference

`#include <wx/calctrl.h>`

21.78.1 Detailed Description

wxCalendarDateAttr is a custom attributes for a calendar date.

The objects of this class are used with wxCalendarCtrl.

Library: wxAdvanced

Category: Data Structures

wxCalendarCtrl

Public Member Functions

- wxCalendarDateAttr (const wxColour &colText=wxNullColour, const wxColour &colBack=wxNullColour, const wxColour &colBorder=wxNullColour, const wxFont &font=wxNullFont, wxCalendarDateBorder border=wxCAL_BORDER_NONE)

  Constructor for specifying all wxCalendarDateAttr properties.
- wxCalendarDateAttr (wxCalendarDateBorder border, const wxColour &colBorder=wxNullColour)

  Constructor using default properties except the given border.
- const wxColour & GetBackgroundColour () const

  Returns the background colour set for the calendar date.
- wxCalendarDateBorder GetBorder () const

  Returns the border set for the calendar date.
- const wxColour & GetBorderColour () const

  Returns the border colour set for the calendar date.

- const wxFont & GetFont () const

  Returns the font set for the calendar date.
- const wxColour & GetTextColour () const

  Returns the text colour set for the calendar date.
- bool HasBackgroundColour () const

  Returns true if a non-default text background colour is set.
- bool HasBorder () const

  Returns true if a non-default (i.e. any) border is set.
- bool HasBorderColour () const

  Returns true if a non-default border colour is set.
- bool HasFont () const

  Returns true if a non-default font is set.
- bool HasTextColour () const

  Returns true if a non-default text foreground colour is set.
- bool IsHoliday () const

  Returns true if this calendar day is displayed as a holiday.
- void SetBackgroundColour (const wxColour &colBack)

  Sets the text background colour to use.
- void SetBorder (wxCalendarDateBorder border)

  Sets the border to use.
- void SetBorderColour (const wxColour &col)

  Sets the border colour to use.
- void SetFont (const wxFont &font)

  Sets the font to use.
- void SetHoliday (bool holiday)

  If holiday is true, this calendar day will be displayed as a holiday.
- void SetTextColour (const wxColour &colText)

  Sets the text (foreground) colour to use.

Static Public Member Functions

- static const wxCalendarDateAttr & GetMark ()

  Used (internally) by the generic wxCalendarCtrl::Mark().
- static void SetMark (const wxCalendarDateAttr &m)

  Set the attributes that will be used to Mark() days on the generic wxCalendarCtrl.

21.78.2 Constructor & Destructor Documentation

wxCalendarDateAttr::wxCalendarDateAttr (const wxColour & *colText* = wxNullColour, const wxColour & *colBack* = wxNullColour, const wxColour & *colBorder* = wxNullColour, const wxFont & *font* = wxNullFont, wxCalendarDateBorder *border* = wxCAL_BORDER_NONE)

Constructor for specifying all wxCalendarDateAttr properties.

wxCalendarDateAttr::wxCalendarDateAttr (wxCalendarDateBorder *border*, const wxColour & *colBorder* = wxNullColour)

Constructor using default properties except the given border.

21.78.3 Member Function Documentation

const wxColour& wxCalendarDateAttr::GetBackgroundColour ( ) const

Returns the background colour set for the calendar date.

wxCalendarDateBorder wxCalendarDateAttr::GetBorder ( ) const

Returns the border set for the calendar date.

const wxColour& wxCalendarDateAttr::GetBorderColour ( ) const

Returns the border colour set for the calendar date.

const wxFont& wxCalendarDateAttr::GetFont ( ) const

Returns the font set for the calendar date.

static const wxCalendarDateAttr& wxCalendarDateAttr::GetMark ( ) [static]

Used (internally) by the generic wxCalendarCtrl::Mark().

const wxColour& wxCalendarDateAttr::GetTextColour ( ) const

Returns the text colour set for the calendar date.

bool wxCalendarDateAttr::HasBackgroundColour ( ) const

Returns true if a non-default text background colour is set.

bool wxCalendarDateAttr::HasBorder ( ) const

Returns true if a non-default (i.e. any) border is set.

bool wxCalendarDateAttr::HasBorderColour ( ) const

Returns true if a non-default border colour is set.

bool wxCalendarDateAttr::HasFont ( ) const

Returns true if a non-default font is set.

bool wxCalendarDateAttr::HasTextColour ( ) const

Returns true if a non-default text foreground colour is set.

bool wxCalendarDateAttr::IsHoliday ( ) const

Returns true if this calendar day is displayed as a holiday.

void wxCalendarDateAttr::SetBackgroundColour (const wxColour & *colBack*)

Sets the text background colour to use.

void wxCalendarDateAttr::SetBorder (wxCalendarDateBorder *border*)

Sets the border to use.

void wxCalendarDateAttr::SetBorderColour (const wxColour & *col*)

Sets the border colour to use.

void wxCalendarDateAttr::SetFont (const wxFont & *font*)

Sets the font to use.

void wxCalendarDateAttr::SetHoliday (bool *holiday*)

If *holiday* is true, this calendar day will be displayed as a holiday.

static void wxCalendarDateAttr::SetMark (const wxCalendarDateAttr & *m*) `[static]`

Set the attributes that will be used to Mark() days on the generic wxCalendarCtrl.

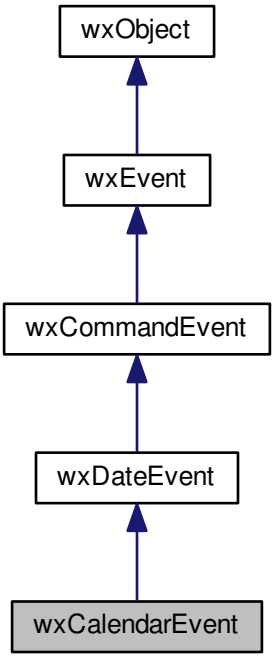
void wxCalendarDateAttr::SetTextColour (const wxColour & *colText*)

Sets the text (foreground) colour to use.

21.79 wxCalendarEvent Class Reference

`#include <wx/calctrl.h>`

Inheritance diagram for wxCalendarEvent:



21.79.1 Detailed Description

The wxCalendarEvent class is used together with wxCalendarCtrl.

Library: wxAdvanced

Category: Events

See also

wxCalendarCtrl

Public Member Functions

- wxCalendarEvent ()
- wxCalendarEvent (wxWindow *win, const wxDateTime &dt, wxEventType type)
- wxDateTime::WeekDay GetWeekDay () const

  Returns the week day on which the user clicked in `EVT_CALENDAR_WEEKDAY_CLICKED` *handler.*
- void SetWeekDay (const wxDateTime::WeekDay day)

  Sets the week day carried by the event, normally only used by the library internally.

Additional Inherited Members

21.79.2 Constructor & Destructor Documentation

wxCalendarEvent::wxCalendarEvent ( )

wxCalendarEvent::wxCalendarEvent (wxWindow * *win,* const wxDateTime & *dt,* wxEventType *type*)

21.79.3 Member Function Documentation

wxDateTime::WeekDay wxCalendarEvent::GetWeekDay ( ) const

Returns the week day on which the user clicked in `EVT_CALENDAR_WEEKDAY_CLICKED` handler.

It doesn't make sense to call this function in other handlers.

void wxCalendarEvent::SetWeekDay (const wxDateTime::WeekDay *day*)

Sets the week day carried by the event, normally only used by the library internally.

21.80 wxCaret Class Reference

```
#include <wx/caret.h>
```

21.80.1 Detailed Description

A caret is a blinking cursor showing the position where the typed text will appear.

Text controls usually have their own caret but wxCaret provides a way to use a caret in other windows.

Currently, the caret appears as a rectangle of the given size. In the future, it will be possible to specify a bitmap to be used for the caret shape.

A caret is always associated with a window and the current caret can be retrieved using wxWindow::GetCaret(). The same caret can't be reused in two different windows.

Library: wxCore

Category: Miscellaneous

Public Member Functions

- wxCaret ()

  Default constructor.
- wxWindow * GetWindow () const

  Get the window the caret is associated with.
- virtual void Hide ()

  Hides the caret, same as Show(false).
- bool IsOk () const

  Returns true if the caret was created successfully.
- bool IsVisible () const

Returns true if the caret is visible and false if it is permanently hidden (if it is blinking and not shown currently but will be after the next blink, this method still returns true).

- virtual void Show (bool show=true)

  Shows or hides the caret.

- wxCaret (wxWindow *window, int width, int height)

  Creates a caret with the given size (in pixels) and associates it with the window.
- wxCaret (wxWindow *window, const wxSize &size)

  Creates a caret with the given size (in pixels) and associates it with the window.

- bool Create (wxWindow *window, int width, int height)

  Creates a caret with the given size (in pixels) and associates it with the window (same as the equivalent constructors).
- bool Create (wxWindow *window, const wxSize &size)

  Creates a caret with the given size (in pixels) and associates it with the window (same as the equivalent constructors).

- void GetPosition (int *x, int *y) const

  Get the caret position (in pixels).
- wxPoint GetPosition () const

  Get the caret position (in pixels).

- void GetSize (int *width, int *height) const

  Get the caret size.
- wxSize GetSize () const

  Get the caret size.

- void Move (int x, int y)

  Move the caret to given position (in logical coordinates).
- void Move (const wxPoint &pt)

  Move the caret to given position (in logical coordinates).

- void SetSize (int width, int height)

  Changes the size of the caret.
- void SetSize (const wxSize &size)

  Changes the size of the caret.

Static Public Member Functions

- static int GetBlinkTime ()

  Returns the blink time which is measured in milliseconds and is the time elapsed between 2 inversions of the caret (blink time of the caret is the same for all carets, so this functions is static).
- static void SetBlinkTime (int milliseconds)

  Sets the blink time for all the carets.

21.80.2 Constructor & Destructor Documentation

wxCaret::wxCaret ( )

Default constructor.

wxCaret::wxCaret (wxWindow * *window,* int *width,* int *height*)

Creates a caret with the given size (in pixels) and associates it with the *window*.

wxCaret::wxCaret (wxWindow * *window,* const wxSize & *size*)

Creates a caret with the given size (in pixels) and associates it with the *window*.

21.80.3 Member Function Documentation

bool wxCaret::Create (wxWindow * *window,* int *width,* int *height*)

Creates a caret with the given size (in pixels) and associates it with the *window* (same as the equivalent constructors).

bool wxCaret::Create (wxWindow * *window,* const wxSize & *size*)

Creates a caret with the given size (in pixels) and associates it with the *window* (same as the equivalent constructors).

static int wxCaret::GetBlinkTime ( ) [static]

Returns the blink time which is measured in milliseconds and is the time elapsed between 2 inversions of the caret (blink time of the caret is the same for all carets, so this functions is static).

void wxCaret::GetPosition (int * *x,* int * *y*) const

Get the caret position (in pixels).

wxPerl Note: In wxPerl there are two methods instead of a single overloaded method:

- GetPosition(): returns a Wx::Point object.
- GetPositionXY(): returns a 2-element list (x, y).

wxPoint wxCaret::GetPosition ( ) const

Get the caret position (in pixels).

wxPerl Note: In wxPerl there are two methods instead of a single overloaded method:

- GetPosition(): returns a Wx::Point object.
- GetPositionXY(): returns a 2-element list (x, y).

void wxCaret::GetSize (int * *width,* int * *height*) const

Get the caret size.

wxPerl Note: In wxPerl there are two methods instead of a single overloaded method:

- GetSize(): returns a Wx::Size object.
- GetSizeWH(): returns a 2-element list (width, height).

wxSize wxCaret::GetSize ( ) const

Get the caret size.

wxPerl Note: In wxPerl there are two methods instead of a single overloaded method:

- GetSize(): returns a Wx::Size object.
- GetSizeWH(): returns a 2-element list (width, height).

wxWindow* wxCaret::GetWindow ( ) const

Get the window the caret is associated with.

virtual void wxCaret::Hide ( ) [virtual]

Hides the caret, same as Show(false).

bool wxCaret::IsOk ( ) const

Returns true if the caret was created successfully.

bool wxCaret::IsVisible ( ) const

Returns true if the caret is visible and false if it is permanently hidden (if it is blinking and not shown currently but will be after the next blink, this method still returns true).

void wxCaret::Move (int *x*, int *y*)

Move the caret to given position (in logical coordinates).

void wxCaret::Move (const wxPoint & *pt*)

Move the caret to given position (in logical coordinates).

static void wxCaret::SetBlinkTime (int *milliseconds*) [static]

Sets the blink time for all the carets.

Warning

Under Windows, this function will change the blink time for all carets permanently (until the next time it is called), even for carets in other applications.

See also

GetBlinkTime()

void wxCaret::SetSize (int *width*, int *height*)

Changes the size of the caret.

void wxCaret::SetSize (const wxSize & *size*)

Changes the size of the caret.

virtual void wxCaret::Show (bool *show* = `true`) [virtual]

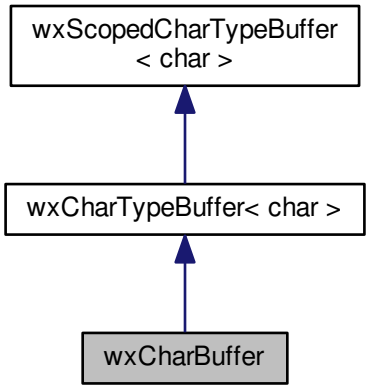
Shows or hides the caret.

Notice that if the caret was hidden N times, it must be shown N times as well to reappear on the screen.

21.81 wxCharBuffer Class Reference

`#include <wx/buffer.h>`

Inheritance diagram for wxCharBuffer:



21.81.1 Detailed Description

This is a specialization of wxCharTypeBuffer<T> for `char` type.

Library: None; this class implementation is entirely header-based.

Category: Data Structures

Public Types

- typedef wxCharTypeBuffer< char > wxCharTypeBufferBase
- typedef wxScopedCharTypeBuffer < char > wxScopedCharTypeBufferBase

Public Member Functions

- wxCharBuffer (const wxCharTypeBufferBase &buf)
- wxCharBuffer (const wxScopedCharTypeBufferBase &buf)
- wxCharBuffer (const CharType *str=NULL)
- wxCharBuffer (size_t len)
- wxCharBuffer (const wxCStrData &cstr)

Additional Inherited Members

21.81.2 Member Typedef Documentation

typedef wxCharTypeBuffer<char> wxCharBuffer::wxCharTypeBufferBase

typedef wxScopedCharTypeBuffer<char> wxCharBuffer::wxScopedCharTypeBufferBase

21.81.3 Constructor & Destructor Documentation

wxCharBuffer::wxCharBuffer (const wxCharTypeBufferBase & *buf*)

wxCharBuffer::wxCharBuffer (const wxScopedCharTypeBufferBase & *buf*)

wxCharBuffer::wxCharBuffer (const CharType * *str* = NULL)

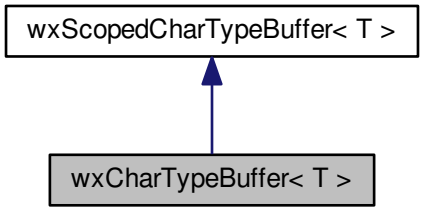
wxCharBuffer::wxCharBuffer (size_t *len*)

wxCharBuffer::wxCharBuffer (const wxCStrData & *cstr*)

21.82 wxCharTypeBuffer< T > Class Template Reference

`#include <wx/buffer.h>`

Inheritance diagram for wxCharTypeBuffer< T >:



21.82.1 Detailed Description

template<typename T>class wxCharTypeBuffer< T >

wxCharTypeBuffer<T> is a template class for storing characters.

The difference from wxScopedCharTypeBuffer<T> is that this class doesn't have non-owned mode and the data stored in it are valid for as long as the buffer instance exists. Other than that, this class' behaviour is the same as wxScopedCharTypeBuffer<T>'s – in particular, the data are reference-counted and copying the buffer is cheap.

wxScopedCharTypeBuffer<T> buffers can be converted into wxCharTypeBuffer<T>.

Template Parameters

T	The type of the characters stored in this class.

Since

2.9.0

Library: None; this class implementation is entirely header-based.

Category: Data Structures

Public Member Functions

- wxCharTypeBuffer (const CharType *str=NULL, size_t len=wxNO_LEN)

  Creates (owned) buffer from str and takes ownership of it.
- wxCharTypeBuffer (size_t len)

  Creates (owned) buffer of size len.
- wxCharTypeBuffer (const wxCharTypeBuffer &src)

  Copy constructor.
- wxCharTypeBuffer (const wxScopedCharTypeBuffer< T > &src)

  Makes a copy of scoped buffer src.
- wxCharTypeBuffer & operator= (const CharType *str)

  Assigns str to this buffer and takes ownership of it (i.e. the buffer becomes "owned").
- wxCharTypeBuffer & operator= (const wxCharTypeBuffer &src)

  Assignment operator behaves in the same way as the copy constructor.
- wxCharTypeBuffer & operator= (const wxScopedCharTypeBuffer< T > &src)

  Assigns a scoped buffer to this buffer.
- bool extend (size_t len)

  Extends the buffer to have size len.
- bool shrink (size_t len)

  Shrinks the buffer to have size len and NUL-terminates the string at this length.

Additional Inherited Members

21.82.2 Constructor & Destructor Documentation

template<typename T> wxCharTypeBuffer< T >::wxCharTypeBuffer (const CharType * *str* = NULL, size_t *len* = wxNO_LEN)

Creates (owned) buffer from *str* and takes ownership of it.

Parameters

str	String data.
len	If specified, length of the string, otherwise the string is considered to be NUL-terminated.

See also

wxScopedCharTypeBuffer<T>::CreateOwned()

template<typename T> wxCharTypeBuffer< T >::wxCharTypeBuffer (size_t *len*)

Creates (owned) buffer of size *len*.

See also

wxScopedCharTypeBuffer<T>::CreateOwned()

template<typename T> wxCharTypeBuffer< T >::wxCharTypeBuffer (const wxCharTypeBuffer< T > & *src*)

Copy constructor.

Increases reference count on the data, does *not* make wxStrdup() copy of the data.

template<typename T> wxCharTypeBuffer< T >::wxCharTypeBuffer (const wxScopedCharTypeBuffer< T > & *src*)

Makes a copy of scoped buffer *src*.

If *src* is a non-owned buffer, a copy of its data is made using wxStrdup(). If *src* is an owned buffer, this constructor behaves in the usual way (reference count on buffer data is incremented).

21.82.3 Member Function Documentation

template<typename T> bool wxCharTypeBuffer< T >::extend (size_t *len*)

Extends the buffer to have size *len*.

Can only be called on buffers that don't share data with another buffer (i.e. reference count of the data is 1).

See also

shrink()

template<typename T> wxCharTypeBuffer& wxCharTypeBuffer< T >::operator= (const CharType * *str*)

Assigns *str* to this buffer and takes ownership of it (i.e. the buffer becomes "owned").

template<typename T> wxCharTypeBuffer& wxCharTypeBuffer< T >::operator= (const wxCharTypeBuffer< T > & *src*)

Assignment operator behaves in the same way as the copy constructor.

template<typename T> wxCharTypeBuffer& wxCharTypeBuffer< T >::operator= (const wxScopedCharTypeBuffer< T > & *src*)

Assigns a scoped buffer to this buffer.

If *src* is a non-owned buffer, a copy of its data is made using wxStrdup(). If *src* is an owned buffer, the assignment behaves in the usual way (reference count on buffer data is incremented).

template<typename T> bool wxCharTypeBuffer< T >::shrink (size_t *len*)

Shrinks the buffer to have size *len* and NUL-terminates the string at this length.

Can only be called on buffers that don't share data with another buffer (i.e. reference count of the data is 1).

Parameters

len	Length to shrink to. Must not be larger than current length.

Note

The string is not reallocated to take less memory.

Since

2.9.0

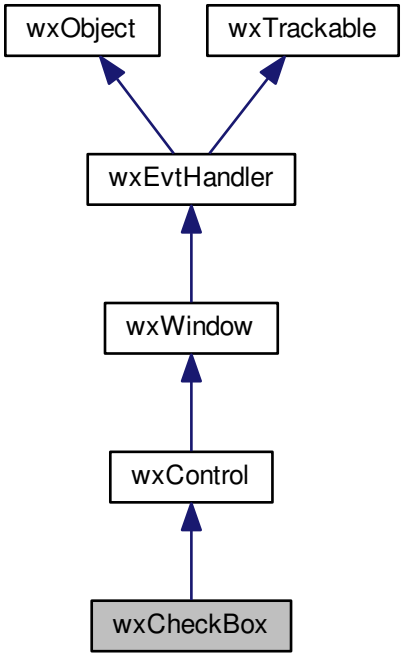
See also

extend()

21.83 wxCheckBox Class Reference

```
#include <wx/checkbox.h>
```

Inheritance diagram for wxCheckBox:



21.83.1 Detailed Description

A checkbox is a labelled box which by default is either on (checkmark is visible) or off (no checkmark).

Optionally (when the wxCHK_3STATE style flag is set) it can have a third state, called the mixed or undetermined state. Often this is used as a "Does Not Apply" state.

Styles

This class supports the following styles:

- wxCHK_2STATE: Create a 2-state checkbox. This is the default.
- wxCHK_3STATE: Create a 3-state checkbox. Not implemented in wxGTK1.
- wxCHK_ALLOW_3RD_STATE_FOR_USER: By default a user can't set a 3-state checkbox to the third state. It can only be done from code. Using this flags allows the user to set the checkbox to the third state by clicking.
- wxALIGN_RIGHT: Makes the text appear on the left of the checkbox.

Events emitted by this class

The following event handler macros redirect the events to member function handlers '**func**' with prototypes like: void handlerFuncName(wxCommandEvent& event)

Event macros for events emitted by this class:

- EVT_CHECKBOX(id, func): Process a `wxEVT_CHECKBOX` event, when the checkbox is clicked.

Library: wxCore

Category: Controls

See also

wxRadioButton, wxCommandEvent

Public Member Functions

- wxCheckBox ()

  Default constructor.
- wxCheckBox (wxWindow *parent, wxWindowID id, const wxString &label, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, long style=0, const wxValidator &validator=wxDefaultValidator, const wxString &name=wxCheckBoxNameStr)

  Constructor, creating and showing a checkbox.
- virtual ~wxCheckBox ()

  Destructor, destroying the checkbox.
- bool Create (wxWindow *parent, wxWindowID id, const wxString &label, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, long style=0, const wxValidator &validator=wxDefaultValidator, const wxString &name=wxCheckBoxNameStr)

  Creates the checkbox for two-step construction.
- virtual bool GetValue () const

  Gets the state of a 2-state checkbox.
- wxCheckBoxState Get3StateValue () const

  Gets the state of a 3-state checkbox.
- bool Is3State () const

  Returns whether or not the checkbox is a 3-state checkbox.
- bool Is3rdStateAllowedForUser () const

  Returns whether or not the user can set the checkbox to the third state.
- bool IsChecked () const

  This is just a maybe more readable synonym for GetValue(): just as the latter, it returns true if the checkbox is checked and false otherwise.
- virtual void SetValue (bool state)

  Sets the checkbox to the given state.
- void Set3StateValue (wxCheckBoxState state)

  Sets the checkbox to the given state.

Additional Inherited Members

21.83.2 Constructor & Destructor Documentation

wxCheckBox::wxCheckBox ( )

Default constructor.

See also

Create(), wxValidator

wxCheckBox::wxCheckBox (wxWindow * *parent*, wxWindowID *id*, const wxString & *label*, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, long *style* = `0`, const wxValidator & *validator* = wxDefaultValidator, const wxString & *name* = `wxCheckBoxNameStr`)

Constructor, creating and showing a checkbox.

Parameters

parent	Parent window. Must not be NULL.
id	Checkbox identifier. The value wxID_ANY indicates a default value.
label	Text to be displayed next to the checkbox.
pos	Checkbox position. If wxDefaultPosition is specified then a default position is chosen.
size	Checkbox size. If wxDefaultSize is specified then a default size is chosen.
style	Window style. See wxCheckBox.
validator	Window validator.
name	Window name.

See also

Create(), wxValidator

virtual wxCheckBox::~wxCheckBox ( ) [virtual]

Destructor, destroying the checkbox.

21.83.3 Member Function Documentation

bool wxCheckBox::Create (wxWindow * *parent*, wxWindowID *id*, const wxString & *label*, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, long *style* = 0, const wxValidator & *validator* = wxDefaultValidator, const wxString & *name* = wxCheckBoxNameStr)

Creates the checkbox for two-step construction.

See wxCheckBox() for details.

wxCheckBoxState wxCheckBox::Get3StateValue ( ) const

Gets the state of a 3-state checkbox.

Asserts when the function is used with a 2-state checkbox.

virtual bool wxCheckBox::GetValue ( ) const [virtual]

Gets the state of a 2-state checkbox.

Returns

Returns true if it is checked, false otherwise.

bool wxCheckBox::Is3rdStateAllowedForUser ( ) const

Returns whether or not the user can set the checkbox to the third state.

Returns

true if the user can set the third state of this checkbox, false if it can only be set programmatically or if it's a 2-state checkbox.

bool wxCheckBox::Is3State ( ) const

Returns whether or not the checkbox is a 3-state checkbox.

Returns

true if this checkbox is a 3-state checkbox, false if it's a 2-state checkbox.

bool wxCheckBox::IsChecked ( ) const

This is just a maybe more readable synonym for GetValue(): just as the latter, it returns true if the checkbox is checked and false otherwise.

void wxCheckBox::Set3StateValue (wxCheckBoxState *state*)

Sets the checkbox to the given state.

This does not cause a `wxEVT_CHECKBOX` event to get emitted.

Asserts when the checkbox is a 2-state checkbox and setting the state to wxCHK_UNDETERMINED.

virtual void wxCheckBox::SetValue (bool *state*) [virtual]

Sets the checkbox to the given state.

This does not cause a `wxEVT_CHECKBOX` event to get emitted.

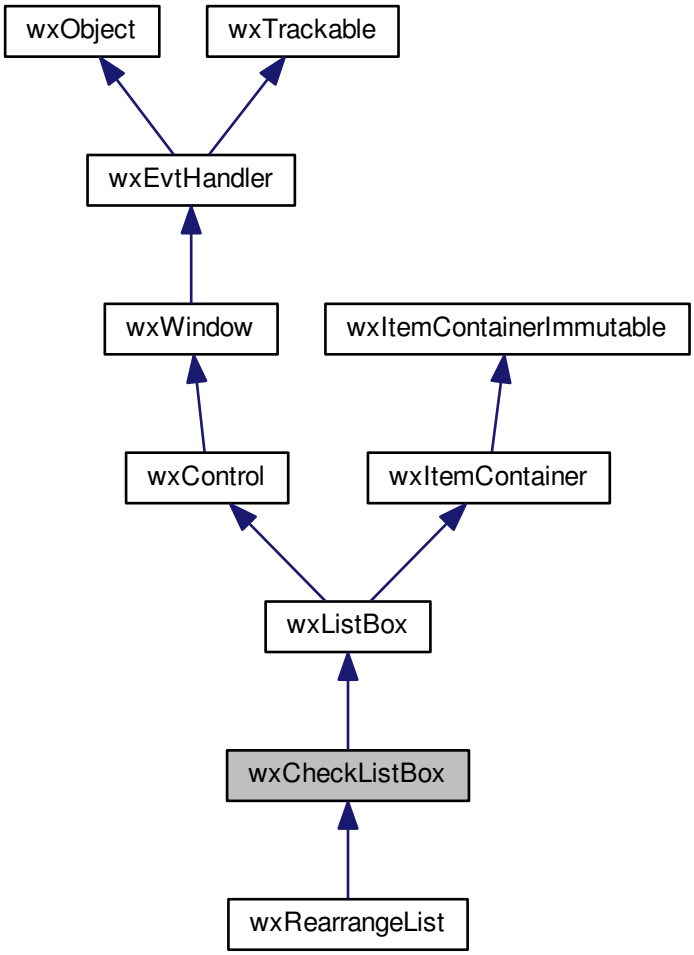
Parameters

state	If true, the check is on, otherwise it is off.

21.84 wxCheckListBox Class Reference

`#include <wx/checklst.h>`

Inheritance diagram for wxCheckListBox:



21.84.1 Detailed Description

A wxCheckListBox is like a wxListBox, but allows items to be checked or unchecked.

When using this class under Windows wxWidgets must be compiled with wxUSE_OWNER_DRAWN set to 1.

Events emitted by this class

The following event handler macros redirect the events to member function handlers '**func**' with prototypes like: void handlerFuncName(wxCommandEvent& event)

Event macros for events emitted by this class:

- EVT_CHECKLISTBOX(id, func): Process a `wxEVT_CHECKLISTBOX` event, when an item in the check list box is checked or unchecked. wxCommandEvent::GetInt() will contain the index of the item that was checked or unchecked. wxCommandEvent::IsChecked() is not valid! Use wxCheckListBox::IsChecked() instead.

Library: wxCore

Category: Controls

- virtual ~wxCheckListBox ()

  Destructor, destroying the list box.
- void Check (unsigned int item, bool check=true)

  Checks the given item.
- bool IsChecked (unsigned int item) const

  Returns true if the given item is checked, false otherwise.
- unsigned int GetCheckedItems (wxArrayInt &checkedItems) const

  Return the indices of the checked items.

- wxCheckListBox (wxWindow *parent, wxWindowID id, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, int n=0, const wxString choices[]=NULL, long style=0, const wxValidator &validator=wxDefaultValidator, const wxString &name="listBox")

  Constructor, creating and showing a list box.
- wxCheckListBox (wxWindow *parent, wxWindowID id, const wxPoint &pos, const wxSize &size, const wxArrayString &choices, long style=0, const wxValidator &validator=wxDefaultValidator, const wxString &name="listBox")

  Constructor, creating and showing a list box.

Additional Inherited Members

21.84.2 Constructor & Destructor Documentation

wxCheckListBox::wxCheckListBox ( )

Default constructor.

wxCheckListBox::wxCheckListBox (wxWindow * *parent*, wxWindowID *id*, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, int *n* = 0, const wxString *choices[]* = NULL, long *style* = 0, const wxValidator & *validator* = wxDefaultValidator, const wxString & *name* = "listBox")

Constructor, creating and showing a list box.

Parameters

parent	Parent window. Must not be NULL.
id	Window identifier. The value wxID_ANY indicates a default value.
pos	Window position. If wxDefaultPosition is specified then a default position is chosen.
size	Window size. If wxDefaultSize is specified then the window is sized appropriately.
n	Number of strings with which to initialise the control.
choices	An array of strings with which to initialise the control.
style	Window style. See wxCheckListBox.
validator	Window validator.
name	Window name.

wxPerl Note: Not supported by wxPerl.

wxCheckListBox::wxCheckListBox (wxWindow * *parent*, wxWindowID *id*, const wxPoint & *pos*, const wxSize & *size*, const wxArrayString & *choices*, long *style* = 0, const wxValidator & *validator* = wxDefaultValidator, const wxString & *name* = "listBox")

Constructor, creating and showing a list box.

Parameters

parent	Parent window. Must not be NULL.
id	Window identifier. The value wxID_ANY indicates a default value.
pos	Window position.
size	Window size. If wxDefaultSize is specified then the window is sized appropriately.
choices	An array of strings with which to initialise the control.
style	Window style. See wxCheckListBox.
validator	Window validator.
name	Window name.

wxPerl Note: Use an array reference for the *choices* parameter.

virtual wxCheckListBox::~wxCheckListBox ( ) [virtual]

Destructor, destroying the list box.

21.84.3 Member Function Documentation

void wxCheckListBox::Check (unsigned int *item*, bool *check* = true)

Checks the given item.

Note that calling this method does not result in a wxEVT_CHECKLISTBOX event being emitted.

Parameters

item	Index of item to check.
check	true if the item is to be checked, false otherwise.

bool wxCheckListBox::Create (wxWindow * *parent*, wxWindowID *id*, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, int *nStrings* = 0, const wxString *choices[]* = NULL, long *style* = 0, const wxValidator & *validator* = wxDefaultValidator, const wxString & *name* = wxListBoxNameStr)

bool wxCheckListBox::Create (wxWindow * *parent*, wxWindowID *id*, const wxPoint & *pos*, const wxSize & *size*, const wxArrayString & *choices*, long *style* = 0, const wxValidator & *validator* = wxDefaultValidator, const wxString & *name* = wxListBoxNameStr)

unsigned int wxCheckListBox::GetCheckedItems (wxArrayInt & *checkedItems*) const

Return the indices of the checked items.

Parameters

checkedItems	A reference to the array that is filled with the indices of the checked items.

Returns

The number of checked items.

See also

Check(), IsChecked()

Since

2.9.5

bool wxCheckListBox::IsChecked (unsigned int *item*) const

Returns true if the given item is checked, false otherwise.

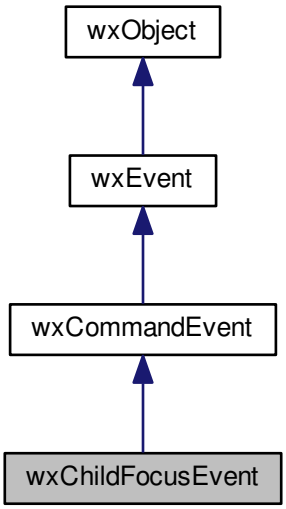
Parameters

item	Index of item whose check status is to be returned.

21.85 wxChildFocusEvent Class Reference

`#include <wx/event.h>`

Inheritance diagram for wxChildFocusEvent:



21.85.1 Detailed Description

A child focus event is sent to a (parent-)window when one of its child windows gains focus, so that the window could restore the focus back to its corresponding child if it loses it now and regains later.

Notice that child window is the direct child of the window receiving event. Use wxWindow::FindFocus() to retrieve the window which is actually getting focus.

Events using this class

The following event handler macros redirect the events to member function handlers '**func**' with prototypes like: void handlerFuncName(wxChildFocusEvent& event)

Event macros:

- EVT_CHILD_FOCUS(func): Process a `wxEVT_CHILD_FOCUS` event.

Library: wxCore

Category: Events

See also

Events and Event Handling

Public Member Functions

- wxChildFocusEvent (wxWindow *win=NULL)

  Constructor.
- wxWindow * GetWindow () const

  Returns the direct child which receives the focus, or a (grand-)parent of the control receiving the focus.

Additional Inherited Members

21.85.2 Constructor & Destructor Documentation

wxChildFocusEvent::wxChildFocusEvent (wxWindow * *win* = `NULL`)

Constructor.

Parameters

win	The direct child which is (or which contains the window which is) receiving the focus.

21.85.3 Member Function Documentation

wxWindow* wxChildFocusEvent::GetWindow ( ) const

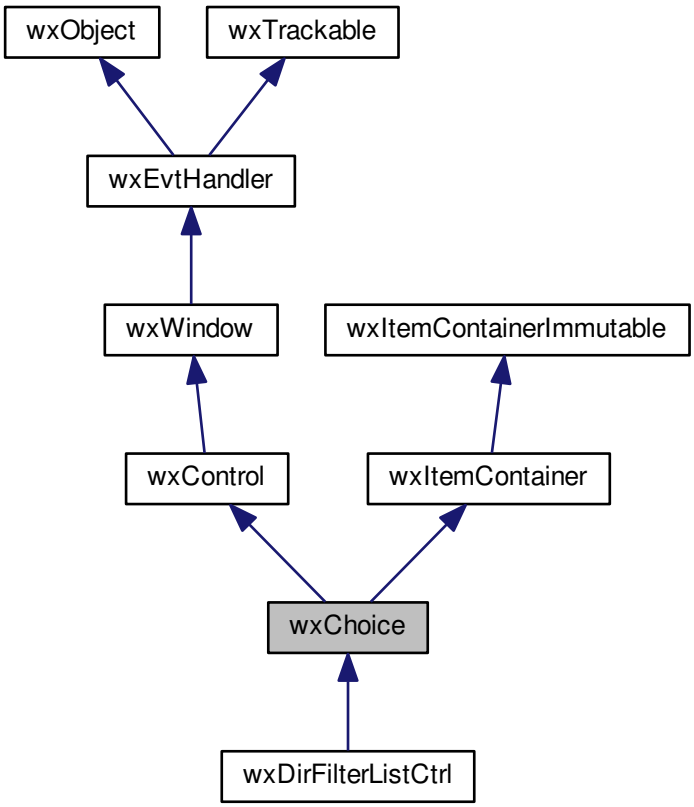
Returns the direct child which receives the focus, or a (grand-)parent of the control receiving the focus.

To get the actually focused control use wxWindow::FindFocus.

21.86 wxChoice Class Reference

`#include <wx/choice.h>`

Inheritance diagram for wxChoice:



21.86.1 Detailed Description

A choice item is used to select one of a list of strings.

Unlike a wxListBox, only the selection is visible until the user pulls down the menu of choices.

Styles

This class supports the following styles:

- wxCB_SORT: Sorts the entries alphabetically.

Events emitted by this class

The following event handler macros redirect the events to member function handlers '**func**' with prototypes like: void handlerFuncName(wxCommandEvent& event)

Event macros for events emitted by this class:

- EVT_CHOICE(id, func): Process a `wxEVT_CHOICE` event, when an item on the list is selected.

Library: wxCore

Category: Controls

See also

wxListBox, wxComboBox, wxCommandEvent

Public Member Functions

- wxChoice ()

  Default constructor.
- wxChoice (wxWindow *parent, wxWindowID id, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, int n=0, const wxString choices[]=NULL, long style=0, const wxValidator &validator=wxDefaultValidator, const wxString &name=wxChoiceNameStr)

  Constructor, creating and showing a choice.
- wxChoice (wxWindow *parent, wxWindowID id, const wxPoint &pos, const wxSize &size, const wxArrayString &choices, long style=0, const wxValidator &validator=wxDefaultValidator, const wxString &name=wxChoiceNameStr)

  Constructor, creating and showing a choice.
- virtual ~wxChoice ()

  Destructor, destroying the choice item.
- virtual int GetColumns () const

  Gets the number of columns in this choice item.
- virtual int GetCurrentSelection () const

  Unlike wxControlWithItems::GetSelection() which only returns the accepted selection value (the selection in the control once the user closes the dropdown list), this function returns the current selection.
- virtual void SetColumns (int n=1)

  Sets the number of columns in this choice item.
- virtual bool IsSorted () const
- virtual unsigned int GetCount () const

  Returns the number of items in the control.
- virtual int GetSelection () const

  Returns the index of the selected item or `wxNOT_FOUND` if no item is selected.
- virtual void SetSelection (int n)

  Sets the selection to the given item n or removes the selection entirely if n == `wxNOT_FOUND`.
- virtual int FindString (const wxString &s, bool bCase=false) const

  Finds an item whose label matches the given string.
- virtual wxString GetString (unsigned int n) const

  Returns the label of the item with the given index.
- virtual void SetString (unsigned int pos, const wxString &s)

  Sets the label for the given item.

- bool Create (wxWindow *parent, wxWindowID id, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, int n=0, const wxString choices[]=NULL, long style=0, const wxValidator &validator=wxDefaultValidator, const wxString &name=wxChoiceNameStr)

  Creates the choice for two-step construction.

- bool Create (wxWindow *parent, wxWindowID id, const wxPoint &pos, const wxSize &size, const wxArrayString &choices, long style=0, const wxValidator &validator=wxDefaultValidator, const wxString &name=wxChoiceNameStr)

  Creates the choice for two-step construction.

Additional Inherited Members

21.86.2 Constructor & Destructor Documentation

wxChoice::wxChoice ( )

Default constructor.

See also

Create(), wxValidator

wxChoice::wxChoice (wxWindow * *parent*, wxWindowID *id*, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, int *n* = 0, const wxString *choices[]* = NULL, long *style* = 0, const wxValidator & *validator* = wxDefaultValidator, const wxString & *name* = wxChoiceNameStr)

Constructor, creating and showing a choice.

Parameters

parent	Parent window. Must not be NULL.
id	Window identifier. The value wxID_ANY indicates a default value.
pos	Window position. If wxDefaultPosition is specified then a default position is chosen.
size	Window size. If wxDefaultSize is specified then the choice is sized appropriately.
n	Number of strings with which to initialise the choice control.
choices	An array of strings with which to initialise the choice control.
style	Window style. See wxChoice.
validator	Window validator.
name	Window name.

See also

Create(), wxValidator

wxPerl Note: Not supported by wxPerl.

wxChoice::wxChoice (wxWindow * *parent*, wxWindowID *id*, const wxPoint & *pos*, const wxSize & *size*, const wxArrayString & *choices*, long *style* = 0, const wxValidator & *validator* = wxDefaultValidator, const wxString & *name* = wxChoiceNameStr)

Constructor, creating and showing a choice.

Parameters

parent	Parent window. Must not be NULL.
id	Window identifier. The value wxID_ANY indicates a default value.
pos	Window position.

size	Window size. If wxDefaultSize is specified then the choice is sized appropriately.
choices	An array of strings with which to initialise the choice control.
style	Window style. See wxChoice.
validator	Window validator.
name	Window name.

See also

Create(), wxValidator

wxPerl Note: Use an array reference for the *choices* parameter.

virtual wxChoice::~wxChoice ( ) [virtual]

Destructor, destroying the choice item.

21.86.3 Member Function Documentation

bool wxChoice::Create (wxWindow * *parent*, wxWindowID *id*, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, int *n* = 0, const wxString *choices[]* = NULL, long *style* = 0, const wxValidator & *validator* = wxDefaultValidator, const wxString & *name* = wxChoiceNameStr)

Creates the choice for two-step construction.

See wxChoice().

bool wxChoice::Create (wxWindow * *parent*, wxWindowID *id*, const wxPoint & *pos*, const wxSize & *size*, const wxArrayString & *choices*, long *style* = 0, const wxValidator & *validator* = wxDefaultValidator, const wxString & *name* = wxChoiceNameStr)

Creates the choice for two-step construction.

See wxChoice().

virtual int wxChoice::FindString (const wxString & *string*, bool *caseSensitive* = false) const [virtual]

Finds an item whose label matches the given string.

Parameters

string	String to find.
caseSensitive	Whether search is case sensitive (default is not).

Returns

The zero-based position of the item, or wxNOT_FOUND if the string was not found.

Reimplemented from wxItemContainerImmutable.

virtual int wxChoice::GetColumns ( ) const [virtual]

Gets the number of columns in this choice item.

Remarks

This is implemented for GTK and Motif only and always returns 1 for the other platforms.

virtual unsigned int wxChoice::GetCount ( ) const `[virtual]`

Returns the number of items in the control.

See also

IsEmpty()

Implements wxItemContainerImmutable.

virtual int wxChoice::GetCurrentSelection ( ) const `[virtual]`

Unlike wxControlWithItems::GetSelection() which only returns the accepted selection value (the selection in the control once the user closes the dropdown list), this function returns the current selection.

That is, while the dropdown list is shown, it returns the currently selected item in it. When it is not shown, its result is the same as for the other function.

Since

2.6.2. In older versions, wxControlWithItems::GetSelection() itself behaved like this.

virtual int wxChoice::GetSelection ( ) const `[virtual]`

Returns the index of the selected item or `wxNOT_FOUND` if no item is selected.

Returns

The position of the current selection.

Remarks

This method can be used with single selection list boxes only, you should use wxListBox::GetSelections() for the list boxes with wxLB_MULTIPLE style.

See also

SetSelection(), GetStringSelection()

Implements wxItemContainerImmutable.

virtual wxString wxChoice::GetString (unsigned int *n*) const `[virtual]`

Returns the label of the item with the given index.

Parameters

n	The zero-based index.

Returns

The label of the item or an empty string if the position was invalid.

Implements wxItemContainerImmutable.

virtual bool wxChoice::IsSorted ( ) const `[virtual]`

virtual void wxChoice::SetColumns (int *n* = `1`) `[virtual]`

Sets the number of columns in this choice item.

Parameters

n	Number of columns.

Remarks

This is implemented for GTK and Motif only and doesn't do anything under other platforms.

virtual void wxChoice::SetSelection (int *n*) [virtual]

Sets the selection to the given item *n* or removes the selection entirely if *n* == wxNOT_FOUND.

Note that this does not cause any command events to be emitted nor does it deselect any other items in the controls which support multiple selections.

Parameters

n	The string position to select, starting from zero.

See also

SetString(), SetStringSelection()

Implements wxItemContainerImmutable.

virtual void wxChoice::SetString (unsigned int *n*, const wxString & *string*) [virtual]

Sets the label for the given item.

Parameters

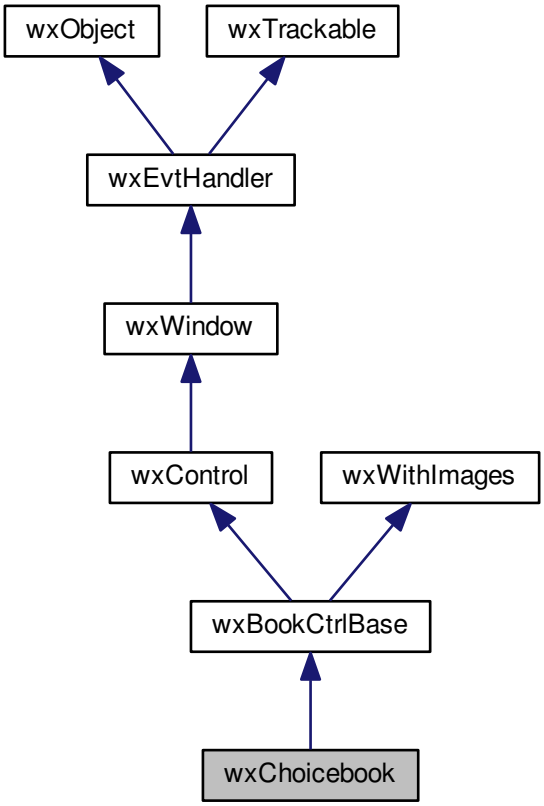
n	The zero-based item index.
string	The label to set.

Implements wxItemContainerImmutable.

21.87 wxChoicebook Class Reference

```
#include <wx/choicebk.h>
```

Inheritance diagram for wxChoicebook:



21.87.1 Detailed Description

wxChoicebook is a class similar to wxNotebook, but uses a wxChoice control to show the labels instead of the tabs.

For usage documentation of this class, please refer to the base abstract class wxBookCtrl. You can also use the Notebook Sample to see wxChoicebook in action.

wxChoicebook allows the use of wxBookCtrlBase::GetControlSizer(), allowing a program to add other controls next to the choice control. This is particularly useful when screen space is restricted, as it often is when wxChoicebook is being employed.

Styles

This class supports the following styles:

- wxCHB_DEFAULT: Choose the default location for the labels depending on the current platform (left everywhere except Mac where it is top).
- wxCHB_TOP: Place labels above the page area.
- wxCHB_LEFT: Place labels on the left side.
- wxCHB_RIGHT: Place labels on the right side.

- wxCHB_BOTTOM: Place labels below the page area.

Events emitted by this class

The following event handler macros redirect the events to member function handlers '**func**' with prototypes like: void handlerFuncName(wxBookCtrlEvent& event)

Event macros for events emitted by this class:

- EVT_CHOICEBOOK_PAGE_CHANGED(id, func): The page selection was changed. Processes a `wxEVT_CHOICEBOOK_PAGE_CHANGED` event.
- EVT_CHOICEBOOK_PAGE_CHANGING(id, func): The page selection is about to be changed. Processes a `wxEVT_CHOICEBOOK_PAGE_CHANGING` event. This event can be vetoed (using wxNotifyEvent::Veto()).

Library: wxCore

Public Member Functions

- bool Create (wxWindow *parent, wxWindowID id, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, long style=0, const wxString &name=wxEmptyString)

  Create the choicebook control that has already been constructed with the default constructor.
- wxChoice * GetChoiceCtrl () const

  Returns the wxChoice associated with the control.

- wxChoicebook ()

  Constructs a choicebook control.
- wxChoicebook (wxWindow *parent, wxWindowID id, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, long style=0, const wxString &name=wxEmptyString)

  Constructs a choicebook control.

Additional Inherited Members

21.87.2 Constructor & Destructor Documentation

wxChoicebook::wxChoicebook ( )

Constructs a choicebook control.

wxChoicebook::wxChoicebook (wxWindow * *parent*, wxWindowID *id*, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, long *style* = 0, const wxString & *name* = wxEmptyString)

Constructs a choicebook control.

21.87.3 Member Function Documentation

bool wxChoicebook::Create (wxWindow * *parent*, wxWindowID *id*, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, long *style* = 0, const wxString & *name* = wxEmptyString)

Create the choicebook control that has already been constructed with the default constructor.

wxChoice* wxChoicebook::GetChoiceCtrl ( ) const

Returns the wxChoice associated with the control.

21.88 wxClassInfo Class Reference

`#include <wx/object.h>`

21.88.1 Detailed Description

This class stores meta-information about classes.

Instances of this class are not generally defined directly by an application, but indirectly through use of macros such as wxDECLARE_DYNAMIC_CLASS and wxIMPLEMENT_DYNAMIC_CLASS.

Library: wxBase

Category: Runtime Type Information (RTTI)

See also

wxClassInfo, wxObject

Public Member Functions

- wxClassInfo (const wxChar *className, const wxClassInfo *baseClass1, const wxClassInfo *baseClass2, int size, wxObjectConstructorFn fn)

  Constructs a wxClassInfo object.
- wxObject * CreateObject () const

  Creates an object of the appropriate kind.
- const wxChar * GetBaseClassName1 () const

  Returns the name of the first base class (NULL if none).
- const wxChar * GetBaseClassName2 () const

  Returns the name of the second base class (NULL if none).
- const wxChar * GetClassName () const

  Returns the string form of the class name.
- int GetSize () const

  Returns the size of the class.
- bool IsDynamic () const

  Returns true if this class info can create objects of the associated class.
- bool IsKindOf (const wxClassInfo *info) const

  Returns true if this class is a kind of (inherits from) the given class.

Static Public Member Functions

- static wxClassInfo * FindClass (const wxString &className)

  Finds the wxClassInfo object for a class with the given name.

21.88.2 Constructor & Destructor Documentation

wxClassInfo::wxClassInfo (const wxChar * *className*, const wxClassInfo * *baseClass1*, const wxClassInfo * *baseClass2*, int *size*, wxObjectConstructorFn *fn*)

Constructs a wxClassInfo object.

The supplied macros implicitly construct objects of this class, so there is no need to create such objects explicitly in an application.

21.88.3 Member Function Documentation

wxObject* wxClassInfo::CreateObject ( ) const

Creates an object of the appropriate kind.

Returns

NULL if the class has not been declared dynamically creatable (typically, this happens for abstract classes).

static wxClassInfo* wxClassInfo::FindClass (const wxString & *className*) [static]

Finds the wxClassInfo object for a class with the given *name*.

const wxChar* wxClassInfo::GetBaseClassName1 ( ) const

Returns the name of the first base class (NULL if none).

const wxChar* wxClassInfo::GetBaseClassName2 ( ) const

Returns the name of the second base class (NULL if none).

const wxChar* wxClassInfo::GetClassName ( ) const

Returns the string form of the class name.

int wxClassInfo::GetSize ( ) const

Returns the size of the class.

bool wxClassInfo::IsDynamic ( ) const

Returns true if this class info can create objects of the associated class.

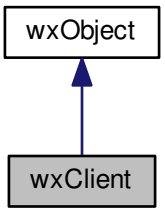
bool wxClassInfo::IsKindOf (const wxClassInfo * *info*) const

Returns true if this class is a kind of (inherits from) the given class.

21.89 wxClient Class Reference

`#include <wx/ipc.h>`

Inheritance diagram for wxClient:



21.89.1 Detailed Description

A wxClient object represents the client part of a client-server DDE-like (Dynamic Data Exchange) conversation.

The actual DDE-based implementation using wxDDEClient is available on Windows only, but a platform-independent, socket-based version of this API is available using wxTCPClient, which has the same API.

To create a client which can communicate with a suitable server, you need to derive a class from wxConnection and another from wxClient. The custom wxConnection class will intercept communications in a 'conversation' with a server, and the custom wxClient is required so that a user-overridden wxClient::OnMakeConnection member can return a wxConnection of the required class, when a connection is made.

Look at the IPC sample and the Interprocess Communication for an example of how to do this.

Library: wxBase

Category: Interprocess Communication

See also

wxServer, wxConnection, Interprocess Communication

Public Member Functions

- wxClient ()

  Constructs a client object.
- wxConnectionBase * MakeConnection (const wxString &host, const wxString &service, const wxString &topic)

  Tries to make a connection with a server by host (machine name under UNIX - use 'localhost' for same machine; ignored when using native DDE in Windows), service name and topic string.
- wxConnectionBase * OnMakeConnection ()

  Called by MakeConnection(), by default this simply returns a new wxConnection object.
- bool ValidHost (const wxString &host)

  Returns true if this is a valid host name, false otherwise.

Additional Inherited Members

21.89.2 Constructor & Destructor Documentation

wxClient::wxClient ( )

Constructs a client object.

21.89.3 Member Function Documentation

wxConnectionBase* wxClient::MakeConnection (const wxString & *host,* const wxString & *service,* const wxString & *topic*)

Tries to make a connection with a server by host (machine name under UNIX - use 'localhost' for same machine; ignored when using native DDE in Windows), service name and topic string.

If the server allows a connection, a wxConnection object will be returned. The type of wxConnection returned can be altered by overriding the OnMakeConnection() member to return your own derived connection object.

Under Unix, the service name may be either an integer port identifier in which case an Internet domain socket will be used for the communications, or a valid file name (which shouldn't exist and will be deleted afterwards) in which case a Unix domain socket is created.

Note

Using Internet domain sockets is extremely insecure for IPC as there is absolutely no access control for them, use Unix domain sockets whenever possible!

wxConnectionBase* wxClient::OnMakeConnection ( )

Called by MakeConnection(), by default this simply returns a new wxConnection object.

Override this method to return a wxConnection descendant customised for the application.

The advantage of deriving your own connection class is that it will enable you to intercept messages initiated by the server, such as wxConnection::OnAdvise. You may also want to store application-specific data in instances of the new class.

bool wxClient::ValidHost (const wxString & *host*)

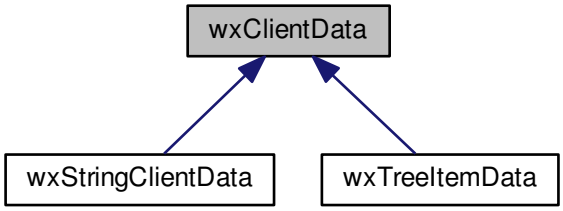
Returns true if this is a valid host name, false otherwise.

This always returns true under MS Windows.

21.90 wxClientData Class Reference

`#include <wx/clntdata.h>`

Inheritance diagram for wxClientData:



21.90.1 Detailed Description

All classes deriving from wxEvtHandler (such as all controls and wxApp) can hold arbitrary data which is here referred to as "client data".

This is useful e.g. for scripting languages which need to handle shadow objects for most of wxWidgets' classes and which store a handle to such a shadow class as client data in that class. This data can either be of type void - in which case the data *container* does not take care of freeing the data again or it is of type wxClientData or its derivatives. In that case the container (e.g. a control) will free the memory itself later. Note that you *must* not assign both void data and data derived from the wxClientData class to a container.

Some controls can hold various items and these controls can additionally hold client data for each item. This is the case for wxChoice, wxComboBox and wxListBox. wxTreeCtrl has a specialized class wxTreeItemData for each item in the tree.

If you want to add client data to your own classes, you may use the mix-in class wxClientDataContainer.

Library: wxBase

Category: Containers

  Constructor.
- virtual ~wxClientData ()

  Virtual destructor.

21.90.2 Constructor & Destructor Documentation

wxClientData::wxClientData ( )

Constructor.

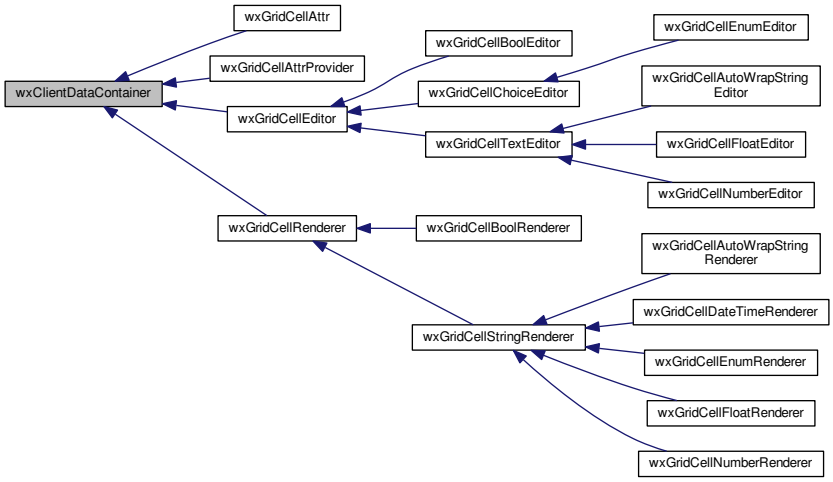
virtual wxClientData::~wxClientData ( ) [virtual]

Virtual destructor.

21.91 wxClientDataContainer Class Reference

`#include <wx/clntdata.h>`

Inheritance diagram for wxClientDataContainer:



21.91.1 Detailed Description

This class is a mixin that provides storage and management of "client data".

This data can either be of type void - in which case the data *container* does not take care of freeing the data again or it is of type wxClientData or its derivatives. In that case the container will free the memory itself later. Note that you *must* not assign both void data and data derived from the wxClientData class to a container.

Note

This functionality is currently duplicated in wxEvtHandler in order to avoid having more than one vtable in that class hierarchy.

Library: wxBase

Category: Containers

void* wxClientDataContainer::GetClientData ( ) const

Get the untyped client data.

wxClientData* wxClientDataContainer::GetClientObject ( ) const

Get a pointer to the client data object.

void wxClientDataContainer::SetClientData (void * *data*)

Set the untyped client data.

void wxClientDataContainer::SetClientObject (wxClientData * *data*)

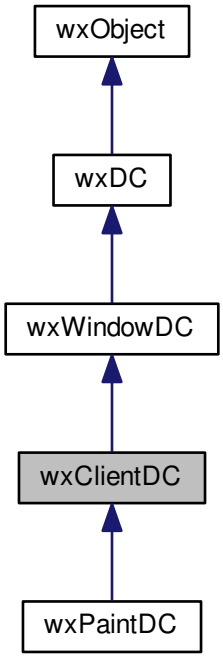
Set the client data object.

Any previous object will be deleted.

21.92 wxClientDC Class Reference

`#include <wx/dcclient.h>`

Inheritance diagram for wxClientDC:



21.92.1 Detailed Description

A wxClientDC must be constructed if an application wishes to paint on the client area of a window from outside an EVT_PAINT() handler.

This should normally be constructed as a temporary stack object; don't store a wxClientDC object.

To draw on a window from within an EVT_PAINT() handler, construct a wxPaintDC object instead.

To draw on the whole window including decorations, construct a wxWindowDC object (Windows only).

A wxClientDC object is initialized to use the same font and colours as the window it is associated with.

Library: wxCore

Category: Device Contexts

Public Member Functions

- wxClientDC (wxWindow *window)

  Constructor.

Additional Inherited Members

21.92.2 Constructor & Destructor Documentation

wxClientDC::wxClientDC (wxWindow * *window*)

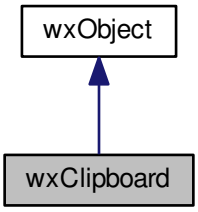
Constructor.

Pass a pointer to the window on which you wish to paint.

21.93 wxClipboard Class Reference

`#include <wx/clipbrd.h>`

Inheritance diagram for wxClipboard:



21.93.1 Detailed Description

A class for manipulating the clipboard.

To use the clipboard, you call member functions of the global wxTheClipboard object.

See the wxDataObject Overview for further information.

Call wxClipboard::Open() to get ownership of the clipboard. If this operation returns true, you now own the clipboard. Call wxClipboard::SetData() to put data on the clipboard, or wxClipboard::GetData() to retrieve data from the clipboard. Call wxClipboard::Close() to close the clipboard and relinquish ownership. You should keep the clipboard open only momentarily.

For example:

```
// Write some text to the clipboard
if (wxTheClipboard->Open())
{
    // This data objects are held by the clipboard,
    // so do not delete them in the app.
    wxTheClipboard->SetData( new wxTextDataObject("Some text") );
    wxTheClipboard->Close();
}

// Read some text
if (wxTheClipboard->Open())
{
    if (wxTheClipboard->IsSupported( wxDF_TEXT ))
    {
        wxTextDataObject data;
        wxTheClipboard->GetData( data );
        wxMessageBox( data.GetText() );
    }
```

```
    wxTheClipboard->Close();
}
```

Drag and Drop Overview, wxDataObject Overview, wxDataObject

Public Member Functions

- wxClipboard ()

  Default constructor.
- virtual ~wxClipboard ()

  Destructor.
- virtual bool AddData (wxDataObject *data)

  Call this function to add the data object to the clipboard.
- virtual void Clear ()

  Clears the global clipboard object and the system's clipboard if possible.
- virtual void Close ()

  Call this function to close the clipboard, having opened it with Open().
- virtual bool Flush ()

  Flushes the clipboard: this means that the data which is currently on clipboard will stay available even after the application exits (possibly eating memory), otherwise the clipboard will be emptied on exit.
- virtual bool GetData (wxDataObject &data)

  Call this function to fill data with data on the clipboard, if available in the required format.
- virtual bool IsOpened () const

  Returns true if the clipboard has been opened.
- virtual bool IsSupported (const wxDataFormat &format)

  *Returns true if there is data which matches the data format of the given data object currently **available** on the clipboard.*
- bool IsUsingPrimarySelection () const

  Returns true if we are using the primary selection, false if clipboard one.
- virtual bool Open ()

  Call this function to open the clipboard before calling SetData() and GetData().
- virtual bool SetData (wxDataObject *data)

  Call this function to set the data object to the clipboard.
- virtual void UsePrimarySelection (bool primary=false)

  On platforms supporting it (all X11-based ports), wxClipboard uses the CLIPBOARD X11 selection by default.

Static Public Member Functions

- static wxClipboard * Get ()

  Returns the global instance (wxTheClipboard) of the clipboard object.

Additional Inherited Members

21.93.2 Constructor & Destructor Documentation

wxClipboard::wxClipboard ( )

Default constructor.

virtual wxClipboard::~wxClipboard ( ) [virtual]

Destructor.

21.93.3 Member Function Documentation

virtual bool wxClipboard::AddData (wxDataObject * *data*) [virtual]

Call this function to add the data object to the clipboard.

You may call this function repeatedly after having cleared the clipboard using Clear().

After this function has been called, the clipboard owns the data, so do not delete the data explicitly.

See also

SetData()

virtual void wxClipboard::Clear ( ) [virtual]

Clears the global clipboard object and the system's clipboard if possible.

virtual void wxClipboard::Close ( ) [virtual]

Call this function to close the clipboard, having opened it with Open().

virtual bool wxClipboard::Flush ( ) [virtual]

Flushes the clipboard: this means that the data which is currently on clipboard will stay available even after the application exits (possibly eating memory), otherwise the clipboard will be emptied on exit.

Currently this method is not implemented in X11-based ports, i.e. wxGTK, wxX11 and wxMotif and always returns false there.

Returns

false if the operation is unsuccessful for any reason.

static wxClipboard* wxClipboard::Get ( ) [static]

Returns the global instance (wxTheClipboard) of the clipboard object.

virtual bool wxClipboard::GetData (wxDataObject & *data*) [virtual]

Call this function to fill *data* with data on the clipboard, if available in the required format.

Returns true on success.

virtual bool wxClipboard::IsOpened ( ) const `[virtual]`

Returns true if the clipboard has been opened.

virtual bool wxClipboard::IsSupported (const wxDataFormat & *format*) `[virtual]`

Returns true if there is data which matches the data format of the given data object currently **available** on the clipboard.

Todo The name of this function is misleading. This should be renamed to something that more accurately indicates what it does.

bool wxClipboard::IsUsingPrimarySelection ( ) const

Returns true if we are using the primary selection, false if clipboard one.

See also

UsePrimarySelection()

virtual bool wxClipboard::Open ( ) `[virtual]`

Call this function to open the clipboard before calling SetData() and GetData().

Call Close() when you have finished with the clipboard. You should keep the clipboard open for only a very short time.

Returns

true on success. This should be tested (as in the sample shown above).

virtual bool wxClipboard::SetData (wxDataObject * *data*) `[virtual]`

Call this function to set the data object to the clipboard.

This function will clear all previous contents in the clipboard, so calling it several times does not make any sense.

After this function has been called, the clipboard owns the data, so do not delete the data explicitly.

See also

AddData()

virtual void wxClipboard::UsePrimarySelection (bool *primary* = `false`) `[virtual]`

On platforms supporting it (all X11-based ports), wxClipboard uses the CLIPBOARD X11 selection by default.

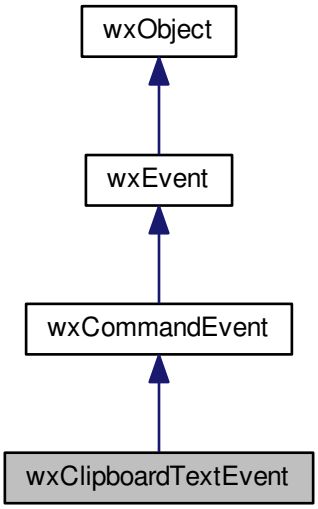
When this function is called with true, all subsequent clipboard operations will use PRIMARY selection until this function is called again with false.

On the other platforms, there is no PRIMARY selection and so all clipboard operations will fail. This allows to implement the standard X11 handling of the clipboard which consists in copying data to the CLIPBOARD selection only when the user explicitly requests it (i.e. by selecting the "Copy" menu command) but putting the currently selected text into the PRIMARY selection automatically, without overwriting the normal clipboard contents with the currently selected text on the other platforms.

21.94 wxClipboardTextEvent Class Reference

`#include <wx/event.h>`

Inheritance diagram for wxClipboardTextEvent:



21.94.1 Detailed Description

This class represents the events generated by a control (typically a wxTextCtrl but other windows can generate these events as well) when its content gets copied or cut to, or pasted from the clipboard.

There are three types of corresponding events `wxEVT_TEXT_COPY`, `wxEVT_TEXT_CUT` and `wxEVT_TEXT_PASTE`.

If any of these events is processed (without being skipped) by an event handler, the corresponding operation doesn't take place which allows to prevent the text from being copied from or pasted to a control. It is also possible to examine the clipboard contents in the PASTE event handler and transform it in some way before inserting in a control – for example, changing its case or removing invalid characters.

Finally notice that a CUT event is always preceded by the COPY event which makes it possible to only process the latter if it doesn't matter if the text was copied or cut.

Note

These events are currently only generated by wxTextCtrl in wxGTK and wxOSX but are also generated by wxComboBox without wxCB_READONLY style in wxMSW.

Events using this class

The following event handler macros redirect the events to member function handlers '**func**' with prototypes like: void handlerFuncName(wxClipboardTextEvent& event)

Event macros:

- EVT_TEXT_COPY(id, func): Some or all of the controls content was copied to the clipboard.

- EVT_TEXT_CUT(id, func): Some or all of the controls content was cut (i.e. copied and deleted).
- EVT_TEXT_PASTE(id, func): Clipboard content was pasted into the control.

Constructor.

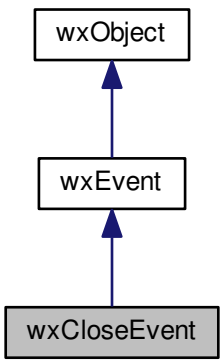
21.95 wxCloseEvent Class Reference

`#include <wx/event.h>`

Inheritance diagram for wxCloseEvent:



21.95.1 Detailed Description

This event class contains information about window and session close events.

The handler function for EVT_CLOSE is called when the user has tried to close a a frame or dialog box using the window manager (X) or system menu (Windows). It can also be invoked by the application itself programmatically, for example by calling the wxWindow::Close function.

You should check whether the application is forcing the deletion of the window using wxCloseEvent::CanVeto. If this is false, you *must* destroy the window using wxWindow::Destroy.

If the return value is true, it is up to you whether you respond by destroying the window.

If you don't destroy the window, you should call wxCloseEvent::Veto to let the calling code know that you did not destroy the window. This allows the wxWindow::Close function to return true or false depending on whether the close instruction was honoured or not.

Example of a wxCloseEvent handler:

```
void MyFrame::OnClose(wxCloseEvent& event)
{
    if ( event.CanVeto() && m_bFileNotSaved )
    {
        if ( wxMessageBox("The file has not been saved... continue closing?",
                          "Please confirm",
                          wxICON_QUESTION | wxYES_NO) !=
      wxYES )
        {
            event.Veto();
            return;
        }
    }

    Destroy();  // you may also do:  event.Skip();
                // since the default event handler does call Destroy(), too
}
```

The EVT_END_SESSION event is slightly different as it is sent by the system when the user session is ending (e.g. because of log out or shutdown) and so all windows are being forcefully closed. At least under MSW, after the handler for this event is executed the program is simply killed by the system. Because of this, the default handler for this event provided by wxWidgets calls all the usual cleanup code (including wxApp::OnExit()) so that it could still be executed and exit()s the process itself, without waiting for being killed. If this behaviour is for some reason undesirable, make sure that you define a handler for this event in your wxApp-derived class and do not call `event.Skip()` in it (but be aware that the system will still kill your application).

Events using this class

The following event handler macros redirect the events to member function handlers '**func**' with prototypes like: void handlerFuncName(wxCloseEvent& event)

Event macros:

- EVT_CLOSE(func): Process a `wxEVT_CLOSE_WINDOW` command event, supplying the member function. This event applies to wxFrame and wxDialog classes.
- EVT_QUERY_END_SESSION(func): Process a `wxEVT_QUERY_END_SESSION` session event, supplying the member function. This event can be handled in wxApp-derived class only.
- EVT_END_SESSION(func): Process a `wxEVT_END_SESSION` session event, supplying the member function. This event can be handled in wxApp-derived class only.

wxWindow::Close, Window Deletion

Public Member Functions

- wxCloseEvent (wxEventType commandEventType=wxEVT_NULL, int id=0)

  Constructor.
- bool CanVeto () const

  Returns true if you can veto a system shutdown or a window close event.
- bool GetLoggingOff () const

  Returns true if the user is just logging off or false if the system is shutting down.
- void SetCanVeto (bool canVeto)

  Sets the 'can veto' flag.
- void SetLoggingOff (bool loggingOff)

  Sets the 'logging off' flag.
- void Veto (bool veto=true)

  Call this from your event handler to veto a system shutdown or to signal to the calling application that a window close did not happen.
- bool GetVeto () const

  Returns whether the Veto flag was set.

Additional Inherited Members

21.95.2 Constructor & Destructor Documentation

wxCloseEvent::wxCloseEvent (wxEventType *commandEventType* = wxEVT_NULL, int *id* = 0)

Constructor.

21.95.3 Member Function Documentation

bool wxCloseEvent::CanVeto ( ) const

Returns true if you can veto a system shutdown or a window close event.

Vetoing a window close event is not possible if the calling code wishes to force the application to exit, and so this function must be called to check this.

bool wxCloseEvent::GetLoggingOff ( ) const

Returns true if the user is just logging off or false if the system is shutting down.

This method can only be called for end session and query end session events, it doesn't make sense for close window event.

bool wxCloseEvent::GetVeto ( ) const

Returns whether the Veto flag was set.

void wxCloseEvent::SetCanVeto (bool *canVeto*)

Sets the 'can veto' flag.

void wxCloseEvent::SetLoggingOff (bool *loggingOff*)

Sets the 'logging off' flag.

void wxCloseEvent::Veto (bool *veto* = `true`)

Call this from your event handler to veto a system shutdown or to signal to the calling application that a window close did not happen.

You can only veto a shutdown if CanVeto() returns true.

21.96 wxCmdLineArg Class Reference

`#include <wx/cmdline.h>`

21.96.1 Detailed Description

The interface wxCmdLineArg provides information for an instance of argument passed on command line.

Example of use:

```
wxCmdLineParser parser;

for (wxCmdLineArgs::const_iterator itarg=parser.GetArguments().begin();
                                   itarg!=parser.GetArguments().end();
                                   ++itarg)
{
    wxString optionName;
    switch (itarg->GetKind())
    {
    case wxCMD_LINE_SWITCH:
        if (itarg->IsNegated()) {
        }
        else {
        }
        break;

    case wxCMD_LINE_OPTION:
        // assuming that all the options have a short name
        optionName = itarg->GetShortName();

        switch (itarg->GetType()) {
            case wxCMD_LINE_VAL_NUMBER:
                // do something with itarg->GetLongVal();
                break;

            case wxCMD_LINE_VAL_DOUBLE:
                // do something with itarg->GetDoubleVal();
                break;

            case wxCMD_LINE_VAL_DATE:
                // do something with itarg->GetDateVal();
                break;

            case wxCMD_LINE_VAL_STRING:
                // do something with itarg->GetStrVal();
                break;
        }
        break;

    case wxCMD_LINE_PARAM:
        // do something with itarg->GetStrVal();
        break;
    }
}
```

With C++11, the for loop could be written:

```
for (const auto &arg : parser.GetArguments()) {
    // working on arg as with *itarg above
}
```

Since

3.1.0

Public Member Functions

- virtual ~wxCmdLineArg ()
- virtual const wxDateTime & GetDateVal () const =0

  Returns the command line argument value as a wxDateTime.
- virtual double GetDoubleVal () const =0

  Returns the command line argument value as a double.
- virtual wxCmdLineEntryType GetKind () const =0

  Returns the command line argument entry kind.
- virtual long GetLongVal () const =0

  Returns the command line argument value as a long.
- virtual wxString GetLongName () const =0

  Returns the command line argument long name if any.
- virtual wxString GetShortName () const =0

  Returns the command line argument short name if any.
- virtual const wxString & GetStrVal () const =0

  Returns the command line argument value as a string.
- virtual wxCmdLineParamType GetType () const =0

  Returns the command line argument parameter type.
- virtual bool IsNegated () const =0

  Returns true if the switch was negated.

21.96.2 Constructor & Destructor Documentation

virtual wxCmdLineArg::~wxCmdLineArg ( ) [inline], [virtual]

21.96.3 Member Function Documentation

virtual const wxDateTime& wxCmdLineArg::GetDateVal ( ) const [pure virtual]

Returns the command line argument value as a wxDateTime.

Note

This call works only for `wxCMD_LINE_VAL_DATE` options

virtual double wxCmdLineArg::GetDoubleVal ( ) const [pure virtual]

Returns the command line argument value as a double.

Note

This call works only for `wxCMD_LINE_VAL_DOUBLE` options

virtual wxCmdLineEntryType wxCmdLineArg::GetKind ( ) const `[pure virtual]`

Returns the command line argument entry kind.

Note

Parameters can only be retrieved as strings, with GetStrVal()

See also

wxCmdLineEntryType, GetType()

virtual wxString wxCmdLineArg::GetLongName ( ) const `[pure virtual]`

Returns the command line argument long name if any.

Note

This call makes sense only for options and switches

virtual long wxCmdLineArg::GetLongVal ( ) const `[pure virtual]`

Returns the command line argument value as a long.

Note

This call works only for `wxCMD_LINE_VAL_NUMBER` options

virtual wxString wxCmdLineArg::GetShortName ( ) const `[pure virtual]`

Returns the command line argument short name if any.

Note

This call makes sense only for options and switches

virtual const wxString& wxCmdLineArg::GetStrVal ( ) const `[pure virtual]`

Returns the command line argument value as a string.

Note

This call works only for `wxCMD_LINE_VAL_STRING` options and parameters

virtual wxCmdLineParamType wxCmdLineArg::GetType ( ) const `[pure virtual]`

Returns the command line argument parameter type.

Note

This call makes sense only for options (i.e. GetKind() == `wxCMD_LINE_OPTION`).

See also

wxCmdLineParamType, GetKind()

virtual bool wxCmdLineArg::IsNegated ( ) const `[pure virtual]`

Returns true if the switch was negated.

Note

This call works only for switches.

21.97 wxCmdLineArgs Class Reference

`#include <wx/cmdline.h>`

21.97.1 Detailed Description

An ordered collection of wxCmdLineArg providing an iterator to enumerate the arguments passed on command line.

See also

wxCmdLineParser::GetArguments()

Since

3.1.0

Public Member Functions

- const_iterator begin () const
- const_iterator end () const
- size_t size () const

  Returns the number of command line arguments in this collection.

21.97.2 Member Function Documentation

const_iterator wxCmdLineArgs::begin ( ) const

const_iterator wxCmdLineArgs::end ( ) const

size_t wxCmdLineArgs::size ( ) const

Returns the number of command line arguments in this collection.

21.98 wxCmdLineEntryDesc Struct Reference

`#include <wx/cmdline.h>`

21.98.1 Detailed Description

The structure wxCmdLineEntryDesc is used to describe a command line switch, option or parameter.

An array of such structures should be passed to wxCmdLineParser::SetDesc().

Note that the meanings of parameters of the wxCmdLineParser::AddXXX() functions are the same as of the corresponding fields in this structure.

Public Attributes

- wxCmdLineEntryType kind

  The kind of this program argument.
- const char ∗ shortName

  The usual, short, name of the switch or the option.
- const char ∗ longName

  The long name for this program argument (may be empty if the option has no long name).
- const char ∗ description

  This description is used by the wxCmdLineParser::Usage() method to construct a help message explaining the syntax of the program.
- wxCmdLineParamType type

  The type associated with this option (ignored if `kind != wxCMD_LINE_OPTION`).
- int flags

  A combination of one or more wxCmdLineEntryFlags enum values.

21.98.2 Member Data Documentation

const char∗ wxCmdLineEntryDesc::description

This description is used by the wxCmdLineParser::Usage() method to construct a help message explaining the syntax of the program.

int wxCmdLineEntryDesc::flags

A combination of one or more wxCmdLineEntryFlags enum values.

wxCmdLineEntryType wxCmdLineEntryDesc::kind

The kind of this program argument.

See wxCmdLineEntryType for more info.

const char∗ wxCmdLineEntryDesc::longName

The long name for this program argument (may be empty if the option has no long name).

It may contain only letters, digits and the underscores. This field is unused if `kind == wxCMD_LINE_PARAM`.

const char∗ wxCmdLineEntryDesc::shortName

The usual, short, name of the switch or the option.

It may contain only letters, digits and the underscores. This field is unused if `kind == wxCMD_LINE_PARAM`.

wxCmdLineParamType wxCmdLineEntryDesc::type

The type associated with this option (ignored if `kind != wxCMD_LINE_OPTION`).

See wxCmdLineParamType for more info.

21.99 wxCmdLineParser Class Reference

`#include <wx/cmdline.h>`

21.99.1 Detailed Description

wxCmdLineParser is a class for parsing the command line.

It has the following features:

- distinguishes options, switches and parameters
- allows option grouping
- allows both short and long options
- automatically generates the usage message from the command line description
- checks types of the options values (number, date, ...).

To use it you should follow these steps:

1. Construct an object of this class giving it the command line to parse and optionally its description or use the `AddXXX()` functions later.
2. Call Parse().
3. Use Found() to retrieve the results.

You can also use wxApp's default command line processing just overriding wxAppConsole::OnInitCmdLine() and wxAppConsole::OnCmdLineParsed().

In the documentation below the following terminology is used:

- **switch:** a boolean option which can be given or not, but which doesn't have any value. We use the word *switch* to distinguish such boolean options from more generic options like those described below. For example, `"-v"` might be a switch meaning "enable verbose mode".
- **option:** a switch with a value associated to it. For example, `"-o filename"` might be an option for specifying the name of the output file.
- **parameter:** a required program argument.

21.99.2 Construction

Before Parse() can be called, the command line parser object must have the command line to parse and also the rules saying which switches, options and parameters are valid - this is called command line description in what follows.

You have complete freedom of choice as to when specify the required information, the only restriction is that it must be done before calling Parse().

To specify the command line to parse you may use either one of constructors accepting it (wxCmdLineParser(int, char**) or wxCmdLineParser(const wxString&) usually) or, if you use the default constructor, you can do it later by calling SetCmdLine().

The same holds for command line description: it can be specified either in the constructor (with or without the command line itself) or constructed later using either SetDesc() or combination of AddSwitch(), AddOption(), AddParam() and AddUsageText() methods.

Using constructors or SetDesc() uses a (usually const static) table containing the command line description. If you want to decide which options to accept during the run-time, using one of the AddXXX() functions above might be preferable.

21.99.3 Customization

wxCmdLineParser has several global options which may be changed by the application. All of the functions described in this section should be called before Parse().

First global option is the support for long (also known as GNU-style) options. The long options are the ones which start with two dashes and look like "\--verbose", i.e. they generally are complete words and not some abbreviations of them. As long options are used by more and more applications, they are enabled by default, but may be disabled with DisableLongOptions().

Another global option is the set of characters which may be used to start an option (otherwise, the word on the command line is assumed to be a parameter). Under Unix, "-" is always used, but Windows has at least two common choices for this: "-" and "/". Some programs also use "+". The default is to use what suits most the current platform, but may be changed with SetSwitchChars() method.

Finally, SetLogo() can be used to show some application-specific text before the explanation given by Usage() function.

21.99.4 Parsing the Command Line

After the command line description was constructed and the desired options were set, you can finally call Parse() method. It returns 0 if the command line was correct and was parsed, -1 if the help option was specified (this is a separate case as, normally, the program will terminate after this) or a positive number if there was an error during the command line parsing.

In the latter case, the appropriate error message and usage information are logged by wxCmdLineParser itself using the standard wxWidgets logging functions.

21.99.5 Getting Results

After calling Parse() (and if it returned 0), you may access the results of parsing using one of overloaded Found() methods.

For a simple switch, you will simply call Found to determine if the switch was given or not, for an option or a parameter, you will call a version of Found() which also returns the associated value in the provided variable. All Found() functions return true if the switch or option were found in the command line or false if they were not specified.

wxApp::argc, wxApp::argv, Console Program Sample

Public Member Functions

- wxCmdLineParser ()

  Default constructor, you must use SetCmdLine() later.
- wxCmdLineParser (int argc, char **argv)

  Constructor which specifies the command line to parse.
- wxCmdLineParser (int argc, wchar_t **argv)

  Constructor which specifies the command line to parse.
- wxCmdLineParser (const wxString &cmdline)

  Constructor which specify the command line to parse in Windows format.

- wxCmdLineParser (const wxCmdLineEntryDesc *desc)

  Specifies the command line description but not the command line.
- wxCmdLineParser (const wxCmdLineEntryDesc *desc, int argc, char **argv)

  Specifies both the command line (in Unix format) and the command line description.
- wxCmdLineParser (const wxCmdLineEntryDesc *desc, const wxString &cmdline)

  Specifies both the command line (in Windows format) and the command line description.
- ~wxCmdLineParser ()

  Frees resources allocated by the object.
- void AddLongOption (const wxString &lng, const wxString &desc=wxEmptyString, wxCmdLineParamType type=wxCMD_LINE_VAL_STRING, int flags=0)

  Adds an option with only long form.
- void AddLongSwitch (const wxString &lng, const wxString &desc=wxEmptyString, int flags=0)

  Adds a switch with only long form.
- void AddOption (const wxString &name, const wxString &lng=wxEmptyString, const wxString &desc=wxEmptyString, wxCmdLineParamType type=wxCMD_LINE_VAL_STRING, int flags=0)

  Add an option name with an optional long name lng (no long name if it is empty, which is default) taking a value of the given type (string by default) to the command line description.
- void AddParam (const wxString &desc=wxEmptyString, wxCmdLineParamType type=wxCMD_LINE_VAL_STRING, int flags=0)

  Add a parameter of the given type to the command line description.
- void AddSwitch (const wxString &name, const wxString &lng=wxEmptyString, const wxString &desc=wxEmptyString, int flags=0)

  Add a switch name with an optional long name lng (no long name if it is empty, which is default), description desc and flags flags to the command line description.
- void AddUsageText (const wxString &text)

  Add a string text to the command line description shown by Usage().
- bool AreLongOptionsEnabled () const

  Returns true if long options are enabled, otherwise false.
- void DisableLongOptions ()

  Identical to EnableLongOptions(false).
- void EnableLongOptions (bool enable=true)

  Enable or disable support for the long options.
- bool Found (const wxString &name) const

  Returns true if the given switch was found, false otherwise.
- wxCmdLineSwitchState FoundSwitch (const wxString &name) const

  Returns whether the switch was found on the command line and whether it was negated.
- bool Found (const wxString &name, wxString *value) const

  Returns true if an option taking a string value was found and stores the value in the provided pointer (which should not be NULL).
- bool Found (const wxString &name, long *value) const

  Returns true if an option taking an integer value was found and stores the value in the provided pointer (which should not be NULL).
- bool Found (const wxString &name, double *value) const

  Returns true if an option taking a float value was found and stores the value in the provided pointer (which should not be NULL).
- bool Found (const wxString &name, wxDateTime *value) const

  Returns true if an option taking a date value was found and stores the value in the provided pointer (which should not be NULL).
- wxString GetParam (size_t n=0) const

  Returns the value of Nth parameter (as string only).
- size_t GetParamCount () const

  Returns the number of parameters found.

- wxCmdLineArgs GetArguments () const

  Returns the collection of arguments.
- int Parse (bool giveUsage=true)

  Parse the command line, return 0 if ok, -1 if "-h" or "\--help" option was encountered and the help message was given or a positive value if a syntax error occurred.
- void SetDesc (const wxCmdLineEntryDesc *desc)

  Constructs the command line description.
- void SetLogo (const wxString &logo)

  The logo is some extra text which will be shown by Usage() method.
- void SetSwitchChars (const wxString &switchChars)

  switchChars contains all characters with which an option or switch may start.
- void Usage () const

  Give the standard usage message describing all program options.
- wxString GetUsageString () const

  Return the string containing the program usage description.

- void SetCmdLine (int argc, char **argv)

  Set the command line to parse after using one of the constructors which don't do it.
- void SetCmdLine (int argc, wchar_t **argv)

  Set the command line to parse after using one of the constructors which don't do it.
- void SetCmdLine (const wxString &cmdline)

  Set the command line to parse after using one of the constructors which don't do it.

Static Public Member Functions

- static wxArrayString ConvertStringToArgs (const wxString &cmdline, wxCmdLineSplitType flags=wxCMD_LINE_SPLIT_DOS)

  Breaks down the string containing the full command line in words.

21.99.6 Constructor & Destructor Documentation

wxCmdLineParser::wxCmdLineParser ( )

Default constructor, you must use SetCmdLine() later.

wxCmdLineParser::wxCmdLineParser (int *argc*, char ** *argv*)

Constructor which specifies the command line to parse.

This is the traditional (Unix) command line format. The parameters *argc* and *argv* have the same meaning as the typical `main()` function.

This constructor is available in both ANSI and Unicode modes because under some platforms the command line arguments are passed as ASCII strings even to Unicode programs.

wxCmdLineParser::wxCmdLineParser (int *argc*, wchar_t ** *argv*)

Constructor which specifies the command line to parse.

This is the traditional (Unix) command line format.

The parameters *argc* and *argv* have the same meaning as the typical `main()` function.

This constructor is only available in Unicode build.

wxCmdLineParser::wxCmdLineParser (const wxString & *cmdline*)

Constructor which specify the command line to parse in Windows format.

The parameter cmdline has the same meaning as the corresponding parameter of `WinMain()`.

wxCmdLineParser::wxCmdLineParser (const wxCmdLineEntryDesc * *desc*)

Specifies the command line description but not the command line.

You must use SetCmdLine() later.

wxCmdLineParser::wxCmdLineParser (const wxCmdLineEntryDesc * *desc*, int *argc*, char ** *argv*)

Specifies both the command line (in Unix format) and the command line description.

wxCmdLineParser::wxCmdLineParser (const wxCmdLineEntryDesc * *desc*, const wxString & *cmdline*)

Specifies both the command line (in Windows format) and the command line description.

wxCmdLineParser::~wxCmdLineParser ( )

Frees resources allocated by the object.

Note

This destructor is not virtual, don't use this class polymorphically.

21.99.7 Member Function Documentation

void wxCmdLineParser::AddLongOption (const wxString & *lng*, const wxString & *desc* = wxEmptyString, wxCmdLineParamType *type* = wxCMD_LINE_VAL_STRING, int *flags* = 0)

Adds an option with only long form.

This is just a convenient wrapper for AddOption() passing an empty string as short option name.

Since

2.9.3

void wxCmdLineParser::AddLongSwitch (const wxString & *lng*, const wxString & *desc* = wxEmptyString, int *flags* = 0)

Adds a switch with only long form.

This is just a convenient wrapper for AddSwitch() passing an empty string as short switch name.

Since

2.9.3

void wxCmdLineParser::AddOption (const wxString & *name*, const wxString & *lng* = wxEmptyString, const wxString & *desc* = wxEmptyString, wxCmdLineParamType *type* = wxCMD_LINE_VAL_STRING, int *flags* = 0)

Add an option *name* with an optional long name *lng* (no long name if it is empty, which is default) taking a value of the given type (string by default) to the command line description.

void wxCmdLineParser::AddParam (const wxString & *desc* = wxEmptyString, wxCmdLineParamType *type* = wxCMD_LINE_VAL_STRING, int *flags* = 0)

Add a parameter of the given *type* to the command line description.

void wxCmdLineParser::AddSwitch (const wxString & *name*, const wxString & *lng* = wxEmptyString, const wxString & *desc* = wxEmptyString, int *flags* = 0)

Add a switch *name* with an optional long name *lng* (no long name if it is empty, which is default), description *desc* and flags *flags* to the command line description.

void wxCmdLineParser::AddUsageText (const wxString & *text*)

Add a string *text* to the command line description shown by Usage().

Since

2.9.0

bool wxCmdLineParser::AreLongOptionsEnabled ( ) const

Returns true if long options are enabled, otherwise false.

See also

EnableLongOptions()

static wxArrayString wxCmdLineParser::ConvertStringToArgs (const wxString & *cmdline*, wxCmdLineSplitType *flags* = wxCMD_LINE_SPLIT_DOS) [static]

Breaks down the string containing the full command line in words.

Words are separated by whitespace and double quotes can be used to preserve the spaces inside the words.

By default, this function uses Windows-like word splitting algorithm, i.e. single quotes have no special meaning and backslash can't be used to escape spaces neither. With wxCMD_LINE_SPLIT_UNIX flag Unix semantics is used, i.e. both single and double quotes can be used and backslash can be used to escape all the other special characters.

void wxCmdLineParser::DisableLongOptions ( )

Identical to EnableLongOptions(false).

void wxCmdLineParser::EnableLongOptions (bool *enable* = true)

Enable or disable support for the long options.

As long options are not (yet) POSIX-compliant, this option allows to disable them.

See also

Customization and AreLongOptionsEnabled()

bool wxCmdLineParser::Found (const wxString & *name*) const

Returns true if the given switch was found, false otherwise.

bool wxCmdLineParser::Found (const wxString & *name*, wxString * *value*) const

Returns true if an option taking a string value was found and stores the value in the provided pointer (which should not be NULL).

bool wxCmdLineParser::Found (const wxString & *name*, long * *value*) const

Returns true if an option taking an integer value was found and stores the value in the provided pointer (which should not be NULL).

bool wxCmdLineParser::Found (const wxString & *name*, double * *value*) const

Returns true if an option taking a float value was found and stores the value in the provided pointer (which should not be NULL).

bool wxCmdLineParser::Found (const wxString & *name*, wxDateTime * *value*) const

Returns true if an option taking a date value was found and stores the value in the provided pointer (which should not be NULL).

wxCmdLineSwitchState wxCmdLineParser::FoundSwitch (const wxString & *name*) const

Returns whether the switch was found on the command line and whether it was negated.

This method can be used for any kind of switch but is especially useful for switches that can be negated, i.e. were added with wxCMD_LINE_SWITCH_NEGATABLE flag, as otherwise Found() is simpler to use.

However Found() doesn't allow to distinguish between switch specified normally, i.e. without dash following it, and negated switch, i.e. with the following dash. This method will return `wxCMD_SWITCH_ON` or `wxCMD_SWITCH_OFF` depending on whether the switch was negated or not. And if the switch was not found at all, `wxCMD_SWITCH_NOT_FOUND` is returned.

Since

2.9.2

wxCmdLineArgs wxCmdLineParser::GetArguments ( ) const

Returns the collection of arguments.

Note

The returned object just refers to the command line parser. The command line parser must live longer than it.

See also

wxCmdLineArgs

Since

3.1.0

wxString wxCmdLineParser::GetParam (size_t *n* = 0) const

Returns the value of Nth parameter (as string only).

size_t wxCmdLineParser::GetParamCount ( ) const

Returns the number of parameters found.

This function makes sense mostly if you had used `wxCMD_LINE_PARAM_MULTIPLE` flag.

wxString wxCmdLineParser::GetUsageString ( ) const

Return the string containing the program usage description.

Call Usage() to directly show this string to the user.

int wxCmdLineParser::Parse (bool *giveUsage* = `true`)

Parse the command line, return 0 if ok, -1 if `"-h"` or `"\--help"` option was encountered and the help message was given or a positive value if a syntax error occurred.

Parameters

giveUsage	If true (default), the usage message is given if a syntax error was encountered while parsing the command line or if help was requested. If false, only error messages about possible syntax errors are given, use Usage to show the usage message from the caller if needed.

void wxCmdLineParser::SetCmdLine (int *argc*, char ** *argv*)

Set the command line to parse after using one of the constructors which don't do it.

void wxCmdLineParser::SetCmdLine (int *argc*, wchar_t ** *argv*)

Set the command line to parse after using one of the constructors which don't do it.

void wxCmdLineParser::SetCmdLine (const wxString & *cmdline*)

Set the command line to parse after using one of the constructors which don't do it.

void wxCmdLineParser::SetDesc (const wxCmdLineEntryDesc * *desc*)

Constructs the command line description.

Take the command line description from the wxCMD_LINE_NONE terminated table.

Example of usage:

```
static const wxCmdLineEntryDesc cmdLineDesc[] =
{
    { wxCMD_LINE_SWITCH, "v", "verbose", "be verbose" },
    { wxCMD_LINE_SWITCH, "q", "quiet",   "be quiet" },

    { wxCMD_LINE_OPTION, "o", "output",  "output file" },
    { wxCMD_LINE_OPTION, "i", "input",   "input dir" },
    { wxCMD_LINE_OPTION, "s", "size",    "output block size",
      wxCMD_LINE_VAL_NUMBER },
    { wxCMD_LINE_OPTION, "d", "date",    "output file date",
      wxCMD_LINE_VAL_DATE },
```

```
    { wxCMD_LINE_PARAM,  NULL, NULL, "input file",
      wxCMD_LINE_VAL_STRING, wxCMD_LINE_PARAM_MULTIPLE },

    { wxCMD_LINE_NONE }
};

wxCmdLineParser parser;

parser.SetDesc(cmdLineDesc);
```

void wxCmdLineParser::SetLogo (const wxString & *logo*)

The *logo* is some extra text which will be shown by Usage() method.

void wxCmdLineParser::SetSwitchChars (const wxString & *switchChars*)

switchChars contains all characters with which an option or switch may start.

Default is "-" for Unix, "-/" for Windows.

void wxCmdLineParser::Usage ( ) const

Give the standard usage message describing all program options.

It will use the options and parameters descriptions specified earlier, so the resulting message will not be helpful to the user unless the descriptions were indeed specified.

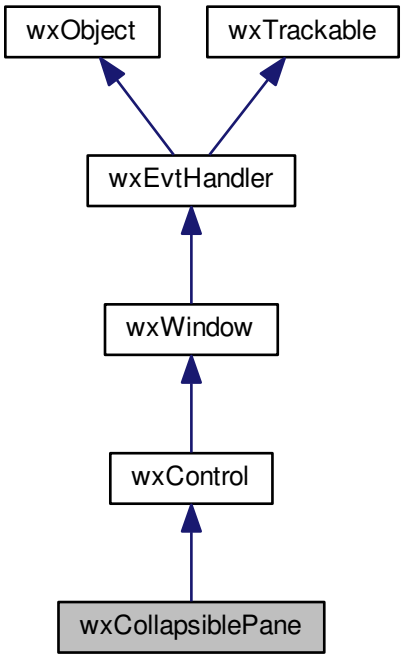
SetLogo()

21.100 wxCollapsiblePane Class Reference

```
#include <wx/collpane.h>
```

Inheritance diagram for wxCollapsiblePane:



21.100.1 Detailed Description

A collapsible pane is a container with an embedded button-like control which can be used by the user to collapse or expand the pane's contents.

Once constructed you should use the GetPane() function to access the pane and add your controls inside it (i.e. use the returned pointer from GetPane() as parent for the controls which must go in the pane, **not** the wxCollapsiblePane itself!).

Note that because of its nature of control which can dynamically (and drastically) change its size at run-time under user-input, when putting wxCollapsiblePane inside a wxSizer you should be careful to add it with a proportion value of zero; this is because otherwise all other windows with non-null proportion values will automatically resize each time the user expands or collapse the pane window usually resulting in a weird, flickering effect.

Usage sample:

```
wxCollapsiblePane *collpane = new wxCollapsiblePane(this,
      wxID_ANY, "Details:");

// add the pane with a zero proportion value to the 'sz' sizer which contains it
sz->Add(collpane, 0, wxGROW|wxALL, 5);

// now add a test label in the collapsible pane using a sizer to layout it:
wxWindow *win = collpane->GetPane();
wxSizer *paneSz = new wxBoxSizer(wxVERTICAL);
paneSz->Add(new wxStaticText(win, wxID_ANY, "test!"), 1,
      wxGROW|wxALL, 2);
win->SetSizer(paneSz);
paneSz->SetSizeHints(win);
```

It is only available if `wxUSE_COLLPANE` is set to 1 (the default).

Styles

This class supports the following styles:

- wxCP_DEFAULT_STYLE: The default style. It includes wxTAB_TRAVERSAL and wxBORDER_NONE.
- wxCP_NO_TLW_RESIZE: By default wxCollapsiblePane resizes the top level window containing it when its own size changes. This allows to easily implement dialogs containing an optionally shown part, for example, and so is the default behaviour but can be inconvenient in some specific cases – use this flag to disable this automatic parent resizing then.

Events emitted by this class

The following event handler macros redirect the events to member function handlers '**func**' with prototypes like: void handlerFuncName(wxCollapsiblePaneEvent& event) or void handlerFuncName(wxNavigationKeyEvent& event)

Event macros for events emitted by this class:

- EVT_COLLAPSIBLEPANE_CHANGED(id, func): The user expanded or collapsed the collapsible pane.
- EVT_NAVIGATION_KEY(func): Process a navigation key event.

Library: wxCore

Category: Controls

Public Member Functions

- wxCollapsiblePane ()

  Default constructor.
- wxCollapsiblePane (wxWindow *parent, wxWindowID id, const wxString &label, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, long style=wxCP_DEFAULT_STYLE, const wxValidator &validator=wxDefaultValidator, const wxString &name=wxCollapsiblePaneNameStr)

  Initializes the object and calls Create() with all the parameters.
- bool Create (wxWindow *parent, wxWindowID id, const wxString &label, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, long style=wxCP_DEFAULT_STYLE, const wxValidator &validator=wxDefaultValidator, const wxString &name=wxCollapsiblePaneNameStr)
- virtual void Collapse (bool collapse=true)

  Collapses or expands the pane window.
- void Expand ()

  Same as calling Collapse(false).
- virtual wxWindow * GetPane () const

  Returns a pointer to the pane window.
- virtual bool IsCollapsed () const

  Returns true if the pane window is currently hidden.
- bool IsExpanded () const

  Returns true if the pane window is currently shown.

Additional Inherited Members

21.100.2 Constructor & Destructor Documentation

wxCollapsiblePane::wxCollapsiblePane ( )

Default constructor.

wxCollapsiblePane::wxCollapsiblePane (wxWindow * *parent*, wxWindowID *id*, const wxString & *label*, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, long *style* = wxCP_DEFAULT_STYLE, const wxValidator & *validator* = wxDefaultValidator, const wxString & *name* = `wxCollapsiblePaneNameStr`)

Initializes the object and calls Create() with all the parameters.

21.100.3 Member Function Documentation

virtual void wxCollapsiblePane::Collapse (bool *collapse* = `true`) `[virtual]`

Collapses or expands the pane window.

bool wxCollapsiblePane::Create (wxWindow * *parent*, wxWindowID *id*, const wxString & *label*, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, long *style* = wxCP_DEFAULT_STYLE, const wxValidator & *validator* = wxDefaultValidator, const wxString & *name* = `wxCollapsiblePaneNameStr`)

Parameters

parent	Parent window, must not be non-NULL.
id	The identifier for the control.
label	The initial label shown in the button which allows the user to expand or collapse the pane window.
pos	Initial position.
size	Initial size.
style	The window style, see wxCP_* flags.
validator	Validator which can be used for additional date checks.
name	Control name.

Returns

true if the control was successfully created or false if creation failed.

void wxCollapsiblePane::Expand ( )

Same as calling Collapse(false).

virtual wxWindow* wxCollapsiblePane::GetPane ( ) const `[virtual]`

Returns a pointer to the pane window.

Add controls to the returned wxWindow to make them collapsible.

virtual bool wxCollapsiblePane::IsCollapsed ( ) const `[virtual]`

Returns true if the pane window is currently hidden.

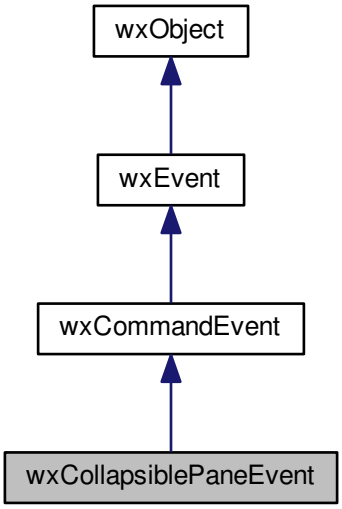
bool wxCollapsiblePane::IsExpanded ( ) const

Returns true if the pane window is currently shown.

21.101 wxCollapsiblePaneEvent Class Reference

`#include <wx/collpane.h>`

Inheritance diagram for wxCollapsiblePaneEvent:



21.101.1 Detailed Description

This event class is used for the events generated by wxCollapsiblePane.

Events using this class

The following event handler macros redirect the events to member function handlers '**func**' with prototypes like: void handlerFuncName(wxCollapsiblePaneEvent& event)

Event macros:

- EVT_COLLAPSIBLEPANE_CHANGED(id, func): The user expanded or collapsed the collapsible pane.

Library: wxCore

Category: Events

wxCollapsiblePane

Public Member Functions

- wxCollapsiblePaneEvent (wxObject *generator, int id, bool collapsed)

  The constructor is not normally used by the user code.
- bool GetCollapsed () const

  Returns true if the pane has been collapsed.
- void SetCollapsed (bool collapsed)

  Sets this as a collapsed pane event (if collapsed is true) or as an expanded pane event (if collapsed is false).

Additional Inherited Members

21.101.2 Constructor & Destructor Documentation

wxCollapsiblePaneEvent::wxCollapsiblePaneEvent (wxObject * *generator,* int *id,* bool *collapsed*)

The constructor is not normally used by the user code.

21.101.3 Member Function Documentation

bool wxCollapsiblePaneEvent::GetCollapsed ( ) const

Returns true if the pane has been collapsed.

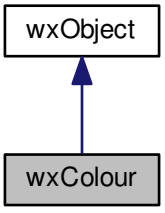
void wxCollapsiblePaneEvent::SetCollapsed (bool *collapsed*)

Sets this as a collapsed pane event (if *collapsed* is true) or as an expanded pane event (if *collapsed* is false).

21.102 wxColour Class Reference

`#include <wx/colour.h>`

Inheritance diagram for wxColour:



21.102.1 Detailed Description

A colour is an object representing a combination of Red, Green, and Blue (RGB) intensity values, and is used to determine drawing colours.

See the entry for wxColourDatabase for how a pointer to a predefined, named colour may be returned instead of creating a new colour.

Valid RGB values are in the range 0 to 255.

You can retrieve the current system colour settings with wxSystemSettings.

Library: wxCore

Category: Graphics Device Interface (GDI)

Predefined objects/pointers:

- wxNullColour - An empty, invalid colour.
- wxTransparentColour - Valid but fully transparent colour (new in 2.9.1).
- wxBLACK
- wxBLUE
- wxCYAN
- wxGREEN
- wxYELLOW
- wxLIGHT_GREY
- wxRED
- wxWHITE

See also

wxColourDatabase, wxPen, wxBrush, wxColourDialog, wxSystemSettings

Public Member Functions

- wxColour ()

  Default constructor.
- wxColour (unsigned char red, unsigned char green, unsigned char blue, unsigned char alpha=wxALPHA_OPAQUE)
- wxColour (const wxString &colourName)
- wxColour (unsigned long colRGB)
- wxColour (const wxColour &colour)

  Copy constructor.
- virtual unsigned char Alpha () const

  Returns the alpha value, on platforms where alpha is not yet supported, this always returns wxALPHA_OPAQUE.
- virtual unsigned char Blue () const

  Returns the blue intensity.
- virtual wxString GetAsString (long flags=wxC2S_NAME|wxC2S_CSS_SYNTAX) const

  Converts this colour to a wxString using the given flags.
- wxIntPtr GetPixel () const

  Returns a pixel value which is platform-dependent.
- virtual unsigned char Green () const

  Returns the green intensity.
- virtual bool IsOk () const

Returns true if the colour object is valid (the colour has been initialised with RGB values).

- virtual unsigned char Red () const

  Returns the red intensity.
- bool operator!= (const wxColour &colour) const

  Tests the inequality of two colours by comparing individual red, green, blue colours and alpha values.
- wxColour & operator= (const wxColour &colour)

  Assignment operator, using a colour name to be found in the colour database.
- bool operator== (const wxColour &colour) const

  Tests the equality of two colours by comparing individual red, green, blue colours and alpha values.
- wxColour & MakeDisabled (unsigned char brightness=255)

  Make a disabled version of this colour.
- wxColour ChangeLightness (int ialpha) const

  wxColour wrapper for ChangeLightness(r,g,b,ialpha).

- void SetRGB (wxUint32 colRGB)

  Sets the RGB or RGBA colour values from a single 32 bit value.
- void SetRGBA (wxUint32 colRGBA)

  Sets the RGB or RGBA colour values from a single 32 bit value.

- wxUint32 GetRGB () const

  Gets the RGB or RGBA colour values as a single 32 bit value.
- wxUint32 GetRGBA () const

  Gets the RGB or RGBA colour values as a single 32 bit value.

- void Set (unsigned char red, unsigned char green, unsigned char blue, unsigned char alpha=wxALPHA_OPAQUE)

  Sets the RGB intensity values using the given values (first overload), extracting them from the packed long (second overload), using the given string (third overload).
- void Set (unsigned long RGB)

  Sets the RGB intensity values using the given values (first overload), extracting them from the packed long (second overload), using the given string (third overload).
- bool Set (const wxString &str)

  Sets the RGB intensity values using the given values (first overload), extracting them from the packed long (second overload), using the given string (third overload).

Static Public Member Functions

- static void MakeMono (unsigned char *r, unsigned char *g, unsigned char *b, bool on)

  Assign 0 or 255 to rgb out parameters.
- static void MakeDisabled (unsigned char *r, unsigned char *g, unsigned char *b, unsigned char brightness=255)

  Create a disabled (dimmed) colour from (in/out) rgb parameters.
- static void MakeGrey (unsigned char *r, unsigned char *g, unsigned char *b)

  Create a grey colour from (in/out) rgb parameters using integer arithmetic.
- static void MakeGrey (unsigned char *r, unsigned char *g, unsigned char *b, double weight_r, double weight_g, double weight_b)

  Create a grey colour from (in/out) rgb parameters using floating point arithmetic.
- static unsigned char AlphaBlend (unsigned char fg, unsigned char bg, double alpha)

  Blend colour, taking alpha into account.
- static void ChangeLightness (unsigned char *r, unsigned char *g, unsigned char *b, int ialpha)

  ChangeLightness() is a utility function that simply darkens or lightens a color, based on the specified percentage ialpha of 0 would be completely black, 200 completely white an ialpha of 100 returns the same colour.

Additional Inherited Members

21.102.2 Constructor & Destructor Documentation

wxColour::wxColour ( )

Default constructor.

wxColour::wxColour (unsigned char *red,* unsigned char *green,* unsigned char *blue,* unsigned char *alpha =* wxALPHA_OPAQUE)

Parameters

red	The red value.
green	The green value.
blue	The blue value.
alpha	The alpha value. Alpha values range from 0 (wxALPHA_TRANSPARENT) to 255 (wxALP↩ HA_OPAQUE).

wxColour::wxColour (const wxString & *colourName*)

Parameters

colourName	The colour name.

wxColour::wxColour (unsigned long *colRGB*)

Parameters

colRGB	A packed RGB value.

wxColour::wxColour (const wxColour & *colour*)

Copy constructor.

21.102.3 Member Function Documentation

virtual unsigned char wxColour::Alpha ( ) const `[virtual]`

Returns the alpha value, on platforms where alpha is not yet supported, this always returns wxALPHA_OPAQUE.

static unsigned char wxColour::AlphaBlend (unsigned char *fg,* unsigned char *bg,* double *alpha*) `[static]`

Blend colour, taking alpha into account.

Since

2.9.0

virtual unsigned char wxColour::Blue ( ) const `[virtual]`

Returns the blue intensity.

static void wxColour::ChangeLightness (unsigned char * *r*, unsigned char * *g*, unsigned char * *b*, int *ialpha*) [static]

ChangeLightness() is a utility function that simply darkens or lightens a color, based on the specified percentage ialpha of 0 would be completely black, 200 completely white an ialpha of 100 returns the same colour.

Since

2.9.0

wxColour wxColour::ChangeLightness (int *ialpha*) const

wxColour wrapper for ChangeLightness(r,g,b,ialpha).

Since

2.9.0

virtual wxString wxColour::GetAsString (long *flags* = wxC2S_NAME|wxC2S_CSS_SYNTAX) const [virtual]

Converts this colour to a wxString using the given flags.

The supported flags are `wxC2S_NAME`, to obtain the colour name (e.g. wxColour(255,0,0) == "red"), `wxC2S_CSS_SYNTAX`, to obtain the colour in the "rgb(r,g,b)" or "rgba(r,g,b,a)" syntax (e.g. wxColour(255,0,0,85) == "rgba(255,0,0,0.333)"), and `wxC2S_HTML_SYNTAX`, to obtain the colour as "#" followed by 6 hexadecimal digits (e.g. wxColour(255,0,0) == "#FF0000").

This function never fails and always returns a non-empty string but asserts if the colour has alpha channel (i.e. is non opaque) but `wxC2S_CSS_SYNTAX` (which is the only one supporting alpha) is not specified in flags.

Since

2.7.0

wxIntPtr wxColour::GetPixel ( ) const

Returns a pixel value which is platform-dependent.

On Windows, a COLORREF is returned. On X, an allocated pixel value is returned. If the pixel is invalid (on X, unallocated), `-1` is returned.

wxUint32 wxColour::GetRGB ( ) const

Gets the RGB or RGBA colour values as a single 32 bit value.

The returned value is of the same form as expected by SetRGB() and SetRGBA().

Notice that GetRGB() returns the value with 0 as its highest byte independently of the value actually returned by Alpha(). So for a fully opaque colour, the return value of GetRGBA() is `0xFFBBGGRR` while that of GetRGB() is `0x00BBGGRR`.

Since

2.9.1

wxUint32 wxColour::GetRGBA ( ) const

Gets the RGB or RGBA colour values as a single 32 bit value.

The returned value is of the same form as expected by SetRGB() and SetRGBA().

Notice that GetRGB() returns the value with 0 as its highest byte independently of the value actually returned by Alpha(). So for a fully opaque colour, the return value of GetRGBA() is `0xFFBBGGRR` while that of GetRGB() is `0x00BBGGRR`.

Since

2.9.1

virtual unsigned char wxColour::Green ( ) const `[virtual]`

Returns the green intensity.

virtual bool wxColour::IsOk ( ) const `[virtual]`

Returns true if the colour object is valid (the colour has been initialised with RGB values).

static void wxColour::MakeDisabled (unsigned char * *r*, unsigned char * *g*, unsigned char * *b*, unsigned char *brightness* = `255`) `[static]`

Create a disabled (dimmed) colour from (in/out) rgb parameters.

Since

2.9.0

wxColour& wxColour::MakeDisabled (unsigned char *brightness* = `255`)

Make a disabled version of this colour.

This method modifies the object in place and returns the object itself.

Since

2.9.5

static void wxColour::MakeGrey (unsigned char * *r*, unsigned char * *g*, unsigned char * *b*) `[static]`

Create a grey colour from (in/out) rgb parameters using integer arithmetic.

Since

2.9.0

static void wxColour::MakeGrey (unsigned char * *r*, unsigned char * *g*, unsigned char * *b*, double *weight_r*, double *weight_g*, double *weight_b*) `[static]`

Create a grey colour from (in/out) rgb parameters using floating point arithmetic.

Defaults to using the standard ITU-T BT.601 when converting to YUV, where every pixel equals (R * *weight_r*) + (G * *weight_g*) + (B * *weight_b*).

Since

2.9.0

static void wxColour::MakeMono (unsigned char * *r,* unsigned char * *g,* unsigned char * *b,* bool *on*) [static]

Assign 0 or 255 to rgb out parameters.

Since

2.9.0

bool wxColour::operator!= (const wxColour & *colour*) const

Tests the inequality of two colours by comparing individual red, green, blue colours and alpha values.

wxColour& wxColour::operator= (const wxColour & *colour*)

Assignment operator, using a colour name to be found in the colour database.

See also

wxColourDatabase

bool wxColour::operator== (const wxColour & *colour*) const

Tests the equality of two colours by comparing individual red, green, blue colours and alpha values.

virtual unsigned char wxColour::Red ( ) const [virtual]

Returns the red intensity.

void wxColour::Set (unsigned char *red,* unsigned char *green,* unsigned char *blue,* unsigned char *alpha* = wxALPHA_OPAQUE)

Sets the RGB intensity values using the given values (first overload), extracting them from the packed long (second overload), using the given string (third overload).

When using third form, Set() accepts: colour names (those listed in wxColourDatabase), the CSS-like "rgb(r,g,b)" or "rgba(r,g,b,a)" syntax (case insensitive) and the HTML-like syntax: "#" followed by 6 hexadecimal digits for red, green, blue components.

Returns true if the conversion was successful, false otherwise.

Since

2.7.0

void wxColour::Set (unsigned long *RGB*)

Sets the RGB intensity values using the given values (first overload), extracting them from the packed long (second overload), using the given string (third overload).

When using third form, Set() accepts: colour names (those listed in wxColourDatabase), the CSS-like "`rgb(r,g,b)`" or "`rgba(r,g,b,a)`" syntax (case insensitive) and the HTML-like syntax: "`#`" followed by 6 hexadecimal digits for red, green, blue components.

Returns true if the conversion was successful, false otherwise.

Since

2.7.0

bool wxColour::Set (const wxString & *str*)

Sets the RGB intensity values using the given values (first overload), extracting them from the packed long (second overload), using the given string (third overload).

When using third form, Set() accepts: colour names (those listed in wxColourDatabase), the CSS-like "`rgb(r,g,b)`" or "`rgba(r,g,b,a)`" syntax (case insensitive) and the HTML-like syntax: "`#`" followed by 6 hexadecimal digits for red, green, blue components.

Returns true if the conversion was successful, false otherwise.

Since

2.7.0

void wxColour::SetRGB (wxUint32 *colRGB*)

Sets the RGB or RGBA colour values from a single 32 bit value.

The arguments *colRGB* and *colRGBA* should be of the form 0x00BBGGRR and 0xAABBGGRR respectively where `0xRR`, `0xGG`, `0xBB` and `0xAA` are the values of the red, blue, green and alpha components.

Notice the right-to-left order of components!

See also

GetRGB(), GetRGBA()

Since

2.9.1

void wxColour::SetRGBA (wxUint32 *colRGBA*)

Sets the RGB or RGBA colour values from a single 32 bit value.

The arguments *colRGB* and *colRGBA* should be of the form 0x00BBGGRR and 0xAABBGGRR respectively where `0xRR`, `0xGG`, `0xBB` and `0xAA` are the values of the red, blue, green and alpha components.

Notice the right-to-left order of components!

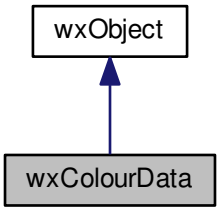
21.103 wxColourData Class Reference

`#include <wx/colourdata.h>`

Inheritance diagram for wxColourData:



21.103.1 Detailed Description

This class holds a variety of information related to colour dialogs.

Library: wxCore

Category: Common Dialogs, Data Structures

See also

wxColour, wxColourDialog, wxColourDialog Overview

Public Types

- enum { NUM_CUSTOM = 16 }

  number of custom colours we store

Public Member Functions

- wxColourData ()

  Constructor.
- virtual ~wxColourData ()

  Destructor.
- bool GetChooseFull () const

  Under Windows, determines whether the Windows colour dialog will display the full dialog with custom colour selection controls.
- wxColour & GetColour ()

Gets the current colour associated with the colour dialog.

- wxColour GetCustomColour (int i) const

  Returns custom colours associated with the colour dialog.

- void SetChooseFull (bool flag)

  Under Windows, tells the Windows colour dialog to display the full dialog with custom colour selection controls.

- void SetColour (const wxColour &colour)

  Sets the default colour for the colour dialog.

- void SetCustomColour (int i, const wxColour &colour)

  Sets custom colours for the colour dialog.

- wxString ToString () const

  Converts the colours saved in this class in a string form, separating the various colours with a comma.

- bool FromString (const wxString &str)

  Decodes the given string, which should be in the same format returned by ToString(), and sets the internal colours.

- wxColourData & operator= (const wxColourData &data)

  Assignment operator for the colour data.

Additional Inherited Members

21.103.2 Member Enumeration Documentation

anonymous enum

number of custom colours we store

Enumerator

NUM_CUSTOM

21.103.3 Constructor & Destructor Documentation

wxColourData::wxColourData ( )

Constructor.

Initializes the custom colours to `wxNullColour`, the *data* colour setting to black, and the *choose* full setting to true.

virtual wxColourData::~wxColourData ( ) [virtual]

Destructor.

21.103.4 Member Function Documentation

bool wxColourData::FromString (const wxString & *str*)

Decodes the given string, which should be in the same format returned by ToString(), and sets the internal colours.

bool wxColourData::GetChooseFull ( ) const

Under Windows, determines whether the Windows colour dialog will display the full dialog with custom colour selection controls.

Has no meaning under other platforms.

The default value is true.

wxColour& wxColourData::GetColour ( )

Gets the current colour associated with the colour dialog.

The default colour is black.

wxColour wxColourData::GetCustomColour (int *i*) const

Returns custom colours associated with the colour dialog.

Parameters

i	An integer between 0 and 15, being any of the 15 custom colours that the user has saved. The default custom colours are invalid colours.

wxColourData& wxColourData::operator= (const wxColourData & *data*)

Assignment operator for the colour data.

void wxColourData::SetChooseFull (bool *flag*)

Under Windows, tells the Windows colour dialog to display the full dialog with custom colour selection controls.

Under other platforms, has no effect.

The default value is true.

void wxColourData::SetColour (const wxColour & *colour*)

Sets the default colour for the colour dialog.

The default colour is black.

void wxColourData::SetCustomColour (int *i,* const wxColour & *colour*)

Sets custom colours for the colour dialog.

Parameters

i	An integer between 0 and 15 for whatever custom colour you want to set. The default custom colours are invalid colours.
colour	The colour to set

wxString wxColourData::ToString ( ) const

Converts the colours saved in this class in a string form, separating the various colours with a comma.

21.104 wxColourDatabase Class Reference

```
#include <wx/gdicmn.h>
```

21.104.1 Detailed Description

wxWidgets maintains a database of standard RGB colours for a predefined set of named colours.

The application may add to this set if desired by using AddColour() and may use it to look up colours by names using Find() or find the names for the standard colour using FindName().

There is one predefined, global instance of this class called wxTheColourDatabase.

The standard database contains at least the following colours:

AQUAMARINE	FIREBRICK	MEDIUM FOREST	RED
BLACK	FOREST GREEN	GREEN	SALMON
BLUE	GOLD	MEDIUM GOLDENROD	SEA GREEN
BLUE VIOLET	GOLDENROD	MEDIUM ORCHID	SIENNA
BROWN	GREY	MEDIUM SEA GREEN	SKY BLUE
CADET BLUE	GREEN	MEDIUM SLATE BLUE	SLATE BLUE
CORAL	GREEN YELLOW	MEDIUM SPRING	SPRING GREEN
CORNFLOWER BLUE	INDIAN RED	GREEN	STEEL BLUE
CYAN	KHAKI	MEDIUM TURQUOISE	TAN
DARK GREY	LIGHT BLUE	MEDIUM VIOLET RED	THISTLE
DARK GREEN	LIGHT GREY	MIDNIGHT BLUE	TURQUOISE
DARK OLIVE GREEN	LIGHT STEEL BLUE	NAVY	VIOLET
DARK ORCHID	LIME GREEN	ORANGE	VIOLET RED
DARK SLATE BLUE	MAGENTA	ORANGE RED	WHEAT
DARK SLATE GREY	MAROON	ORCHID	WHITE
DARK TURQUOISE	MEDIUM AQUAMARINE	PALE GREEN	YELLOW
DIM GREY		PINK	YELLOW GREEN
	MEDIUM BLUE	PLUM	
		PURPLE

wxColour

Public Member Functions

- wxColourDatabase ()

  Constructs the colour database.
- void AddColour (const wxString &colourName, const wxColour &colour)

  Adds a colour to the database.
- wxColour Find (const wxString &colourName) const

  Finds a colour given the name.
- wxString FindName (const wxColour &colour) const

  Finds a colour name given the colour.

21.104.2 Constructor & Destructor Documentation

wxColourDatabase::wxColourDatabase ( )

Constructs the colour database.

It will be initialized at the first use.

21.104.3 Member Function Documentation

void wxColourDatabase::AddColour (const wxString & *colourName,* const wxColour & *colour*)

Adds a colour to the database.

If a colour with the same name already exists, it is replaced.

wxColour wxColourDatabase::Find (const wxString & *colourName*) const

Finds a colour given the name.

Returns an invalid colour object (that is, wxColour::IsOk() will return false) if the colour wasn't found in the database.

wxString wxColourDatabase::FindName (const wxColour & *colour*) const

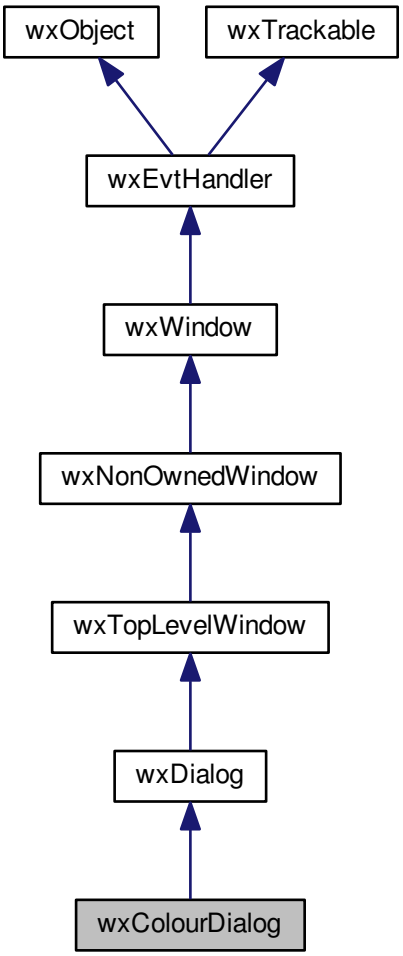
Finds a colour name given the colour.

Returns an empty string if the colour is not found in the database.

21.105 wxColourDialog Class Reference

```
#include <wx/colordlg.h>
```

Inheritance diagram for wxColourDialog:



21.105.1 Detailed Description

This class represents the colour chooser dialog.

Library: wxCore

wxColourDialog Overview, wxColour, wxColourData, wxGetColourFromUser()

Public Member Functions

- wxColourDialog (wxWindow *parent, wxColourData *data=NULL)

Constructor.

- virtual ~wxColourDialog ()

  Destructor.

- bool Create (wxWindow *parent, wxColourData *data=NULL)

  Same as wxColourDialog().

- wxColourData & GetColourData ()

  Returns the colour data associated with the colour dialog.

- virtual int ShowModal ()

  Shows the dialog, returning wxID_OK if the user pressed OK, and wxID_CANCEL otherwise.

Additional Inherited Members

21.105.2 Constructor & Destructor Documentation

wxColourDialog::wxColourDialog (wxWindow * *parent,* wxColourData * *data* = NULL)

Constructor.

Pass a parent window, and optionally a pointer to a block of colour data, which will be copied to the colour dialog's colour data.

Custom colours from colour data object will be used in the dialog's colour palette. Invalid entries in custom colours list will be ignored on some platforms(GTK) or replaced with white colour on platforms where custom colours palette has fixed size (MSW).

wxColourData

virtual wxColourDialog::~wxColourDialog ( ) [virtual]

Destructor.

21.105.3 Member Function Documentation

bool wxColourDialog::Create (wxWindow * *parent,* wxColourData * *data* = NULL)

Same as wxColourDialog().

wxColourData& wxColourDialog::GetColourData ( )

Returns the colour data associated with the colour dialog.

virtual int wxColourDialog::ShowModal ( ) [virtual]

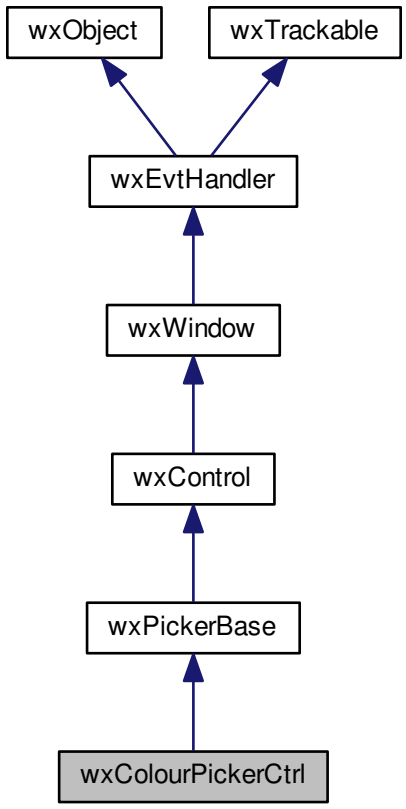
Shows the dialog, returning wxID_OK if the user pressed OK, and wxID_CANCEL otherwise.

Reimplemented from wxDialog.

21.106 wxColourPickerCtrl Class Reference

`#include <wx/clrpicker.h>`

Inheritance diagram for wxColourPickerCtrl:



21.106.1 Detailed Description

This control allows the user to select a colour.

The generic implementation is a button which brings up a wxColourDialog when clicked. Native implementation may differ but this is usually a (small) widget which give access to the colour-chooser dialog. It is only available if `wxUSE_COLOURPICKERCTRL` is set to 1 (the default).

Styles

This class supports the following styles:

- wxCLRP_DEFAULT_STYLE: The default style: 0.
- wxCLRP_USE_TEXTCTRL: Creates a text control to the left of the picker button which is completely managed by the wxColourPickerCtrl and which can be used by the user to specify a colour (see SetColour). The text control is automatically synchronized with button's value. Use functions defined in wxPickerBase to modify the text control.

- wxCLRP_SHOW_LABEL: Shows the colour in HTML form (AABBCC) as colour button label (instead of no label at all).

Events emitted by this class

The following event handler macros redirect the events to member function handlers '**func**' with prototypes like: void handlerFuncName(wxColourPickerEvent& event)

Event macros for events emitted by this class:

- EVT_COLOURPICKER_CHANGED(id, func): The user changed the colour selected in the control either using the button or using text control (see `wxCLRP_USE_TEXTCTRL`; note that in this case the event is fired only if the user's input is valid, i.e. recognizable).

Library: wxCore

Category: Picker Controls

Public Member Functions

- wxColourPickerCtrl ()
- wxColourPickerCtrl (wxWindow *parent, wxWindowID id, const wxColour &colour=*wxBLACK, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, long style=wxCLRP_DEFAULT_STYLE, const wxValidator &validator=wxDefaultValidator, const wxString &name=wxColourPickerCtrlNameStr)

  Initializes the object and calls Create() with all the parameters.
- bool Create (wxWindow *parent, wxWindowID id, const wxColour &colour=*wxBLACK, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, long style=wxCLRP_DEFAULT_STYLE, const wxValidator &validator=wxDefaultValidator, const wxString &name=wxColourPickerCtrlNameStr)

  Creates a colour picker with the given arguments.
- wxColour GetColour () const

  Returns the currently selected colour.
- void SetColour (const wxColour &col)

  Sets the currently selected colour.
- void SetColour (const wxString &colname)

  Sets the currently selected colour.

Additional Inherited Members

21.106.2 Constructor & Destructor Documentation

wxColourPickerCtrl::wxColourPickerCtrl ( )

wxColourPickerCtrl::wxColourPickerCtrl (wxWindow * *parent*, wxWindowID *id*, const wxColour & *colour* = *wxBLACK, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, long *style* = wxCLRP_DEFAULT_STYLE, const wxValidator & *validator* = wxDefaultValidator, const wxString & *name* = `wxColourPickerCtrlNameStr`)

Initializes the object and calls Create() with all the parameters.

21.106.3 Member Function Documentation

bool wxColourPickerCtrl::Create (wxWindow * *parent*, wxWindowID *id*, const wxColour & *colour* = *wxBLACK, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, long *style* = wxCLRP_DEFAULT_STYLE, const wxValidator & *validator* = wxDefaultValidator, const wxString & *name* = wxColourPickerCtrlNameStr)

Creates a colour picker with the given arguments.

Parameters

parent	Parent window, must not be non-NULL.
id	The identifier for the control.
colour	The initial colour shown in the control.
pos	Initial position.
size	Initial size.
style	The window style, see wxCRLP_* flags.
validator	Validator which can be used for additional date checks.
name	Control name.

Returns

true if the control was successfully created or false if creation failed.

wxColour wxColourPickerCtrl::GetColour ( ) const

Returns the currently selected colour.

void wxColourPickerCtrl::SetColour (const wxColour & *col*)

Sets the currently selected colour.

See wxColour::Set().

void wxColourPickerCtrl::SetColour (const wxString & *colname*)

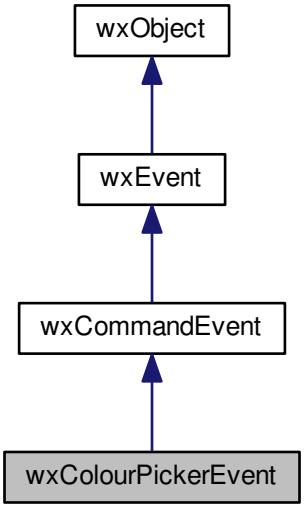
Sets the currently selected colour.

See wxColour::Set().

21.107 wxColourPickerEvent Class Reference

`#include <wx/clrpicker.h>`

Inheritance diagram for wxColourPickerEvent:



21.107.1 Detailed Description

This event class is used for the events generated by wxColourPickerCtrl.

Events using this class

The following event handler macros redirect the events to member function handlers '**func**' with prototypes like: void handlerFuncName(wxColourPickerEvent& event)

Event macros:

- EVT_COLOURPICKER_CHANGED(id, func): Generated whenever the selected colour changes.

Library: wxCore

Category: Events

21.107.3 Member Function Documentation

wxColour wxColourPickerEvent::GetColour ( ) const

Retrieve the colour the user has just selected.

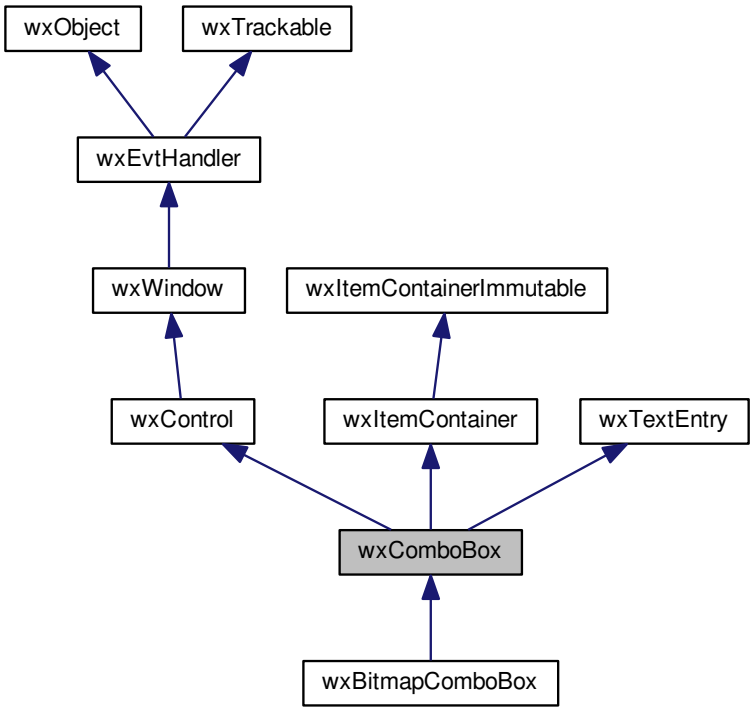
void wxColourPickerEvent::SetColour (const wxColour & *pos*)

Set the colour associated with the event.

21.108 wxComboBox Class Reference

`#include <wx/combobox.h>`

Inheritance diagram for wxComboBox:



21.108.1 Detailed Description

A combobox is like a combination of an edit control and a listbox.

It can be displayed as static list with editable or read-only text field; or a drop-down list with text field; or a drop-down list without a text field depending on the platform and presence of wxCB_READONLY style.

A combobox permits a single selection only. Combobox items are numbered from zero.

If you need a customized combobox, have a look at wxComboCtrl, wxOwnerDrawnComboBox, wxComboPopup and the ready-to-use wxBitmapComboBox.

Please refer to wxTextEntry documentation for the description of methods operating with the text entry part of the combobox and to wxItemContainer for the methods operating with the list of strings. Notice that at least under MSW wxComboBox doesn't behave correctly if it contains strings differing in case only so portable programs should avoid adding such strings to this control.

Styles

This class supports the following styles:

- wxCB_SIMPLE: Creates a combobox with a permanently displayed list. Windows only.
- wxCB_DROPDOWN: Creates a combobox with a drop-down list. MSW and Motif only.
- wxCB_READONLY: A combobox with this style behaves like a wxChoice (and may look in the same way as well, although this is platform-dependent), i.e. it allows the user to choose from the list of options but doesn't allow to enter a value not present in the list.

- wxCB_SORT: Sorts the entries in the list alphabetically.
- wxTE_PROCESS_ENTER: The control will generate the event `wxEVT_TEXT_ENTER` (otherwise pressing Enter key is either processed internally by the control or used for navigation between dialog controls).

Events emitted by this class

The following event handler macros redirect the events to member function handlers '**func**' with prototypes like: void handlerFuncName(wxCommandEvent& event)

Event macros for events emitted by this class:

- EVT_COMBOBOX(id, func): Process a `wxEVT_COMBOBOX` event, when an item on the list is selected. Note that calling GetValue() returns the new value of selection.
- EVT_TEXT(id, func): Process a `wxEVT_TEXT` event, when the combobox text changes.
- EVT_TEXT_ENTER(id, func): Process a `wxEVT_TEXT_ENTER` event, when RETURN is pressed in the combobox (notice that the combobox must have been created with wxTE_PROCESS_ENTER style to receive this event).
- EVT_COMBOBOX_DROPDOWN(id, func): Process a `wxEVT_COMBOBOX_DROPDOWN` event, which is generated when the list box part of the combo box is shown (drops down). Notice that this event is only supported by wxMSW, wxGTK with GTK+ 2.10 or later, and wxOSX/Cocoa.
- EVT_COMBOBOX_CLOSEUP(id, func): Process a `wxEVT_COMBOBOX_CLOSEUP` event, which is generated when the list box of the combo box disappears (closes up). This event is only generated for the same platforms as `wxEVT_COMBOBOX_DROPDOWN` above. Also note that only wxMSW and wxOSX/Cocoa support adding or deleting items in this event.

Library: wxCore

Category: Controls

wxListBox, wxTextCtrl, wxChoice, wxCommandEvent

Public Member Functions

- wxComboBox ()

  Default constructor.
- wxComboBox (wxWindow *parent, wxWindowID id, const wxString &value=wxEmptyString, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, int n=0, const wxString choices[]=NULL, long style=0, const wxValidator &validator=wxDefaultValidator, const wxString &name=wxComboBoxNameStr)

  Constructor, creating and showing a combobox.
- wxComboBox (wxWindow *parent, wxWindowID id, const wxString &value, const wxPoint &pos, const wxSize &size, const wxArrayString &choices, long style=0, const wxValidator &validator=wxDefaultValidator, const wxString &name=wxComboBoxNameStr)

  Constructor, creating and showing a combobox.
- virtual ~wxComboBox ()

  Destructor, destroying the combobox.
- virtual int GetCurrentSelection () const

  Returns the item being selected right now.
- virtual long GetInsertionPoint () const

Same as wxTextEntry::GetInsertionPoint().

- bool IsEmpty () const

  IsEmpty() is not available in this class.

- bool IsListEmpty () const

  Returns true if the list of combobox choices is empty.

- bool IsTextEmpty () const

  Returns true if the text of the combobox is empty.

- virtual void SetSelection (long from, long to)

  Same as wxTextEntry::SetSelection().

- virtual void SetValue (const wxString &text)

  Sets the text for the combobox text field.

- virtual void Popup ()

  Shows the list box portion of the combo box.

- virtual void Dismiss ()

  Hides the list box portion of the combo box.

- virtual int GetSelection () const

  Returns the index of the selected item or `wxNOT_FOUND` if no item is selected.

- virtual void GetSelection (long *from, long *to) const

  Gets the current selection span.

- virtual void SetSelection (int n)

  Sets the selection to the given item n or removes the selection entirely if n == `wxNOT_FOUND`.

- virtual int FindString (const wxString &s, bool bCase=false) const

  Finds an item whose label matches the given string.

- virtual wxString GetString (unsigned int n) const

  Returns the label of the item with the given index.

- virtual wxString GetStringSelection () const

  Gets the text currently selected in the control.

- virtual void SetString (unsigned int n, const wxString &text)

  Changes the text of the specified combobox item.

- virtual unsigned int GetCount () const

  Returns the number of items in the control.

- bool Create (wxWindow *parent, wxWindowID id, const wxString &value=wxEmptyString, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, int n=0, const wxString choices[]=(const wxString *) NULL, long style=0, const wxValidator &validator=wxDefaultValidator, const wxString &name=wxComboBoxNameStr)

  Creates the combobox for two-step construction.

- bool Create (wxWindow *parent, wxWindowID id, const wxString &value, const wxPoint &pos, const wxSize &size, const wxArrayString &choices, long style=0, const wxValidator &validator=wxDefaultValidator, const wxString &name=wxComboBoxNameStr)

  Creates the combobox for two-step construction.

Additional Inherited Members

21.108.2 Constructor & Destructor Documentation

wxComboBox::wxComboBox ( )

Default constructor.

wxComboBox::wxComboBox (wxWindow ∗ ***parent*****, wxWindowID** ***id*****,** const **wxString** & ***value*** **= wxEmptyString**, const **wxPoint** & ***pos*** **= wxDefaultPosition**, const **wxSize** & ***size*** **= wxDefaultSize**, int ***n*** **=** `0`, const **wxString** ***choices[]*** **=** `NULL`, long ***style*** **=** `0`, const **wxValidator** & ***validator*** **= wxDefaultValidator**, const **wxString** & ***name*** **=** `wxComboBoxNameStr` **)**

Constructor, creating and showing a combobox.

Parameters

parent	Parent window. Must not be NULL.
id	Window identifier. The value wxID_ANY indicates a default value.
value	Initial selection string. An empty string indicates no selection. Notice that for the controls with `wxCB_READONLY` style this string must be one of the valid choices if it is not empty.
pos	Window position. If wxDefaultPosition is specified then a default position is chosen.
size	Window size. If wxDefaultSize is specified then the window is sized appropriately.
n	Number of strings with which to initialise the control.
choices	An array of strings with which to initialise the control.
style	Window style. See wxComboBox.
validator	Window validator.
name	Window name.

wxPerl Note: Not supported by wxPerl.

See also

Create(), wxValidator

wxComboBox::wxComboBox (wxWindow * *parent*, wxWindowID *id*, const wxString & *value*, const wxPoint & *pos*, const wxSize & *size*, const wxArrayString & *choices*, long *style* = `0`, const wxValidator & *validator* = wxDefaultValidator, const wxString & *name* = `wxComboBoxNameStr`)

Constructor, creating and showing a combobox.

Parameters

parent	Parent window. Must not be NULL.
id	Window identifier. The value wxID_ANY indicates a default value.
value	Initial selection string. An empty string indicates no selection.
pos	Window position.
size	Window size. If wxDefaultSize is specified then the window is sized appropriately.
choices	An array of strings with which to initialise the control.
style	Window style. See wxComboBox.
validator	Window validator.
name	Window name.

wxPerl Note: Use an array reference for the *choices* parameter.

See also

Create(), wxValidator

virtual wxComboBox::~wxComboBox ( ) `[virtual]`

Destructor, destroying the combobox.

21.108.3 Member Function Documentation

bool wxComboBox::Create (wxWindow * *parent*, wxWindowID *id*, const wxString & *value* = wxEmptyString, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, int *n* = `0`, const wxString *choices[]* = `(const wxString *) NULL`, long *style* = `0`, const wxValidator & *validator* = wxDefaultValidator, const wxString & *name* = `wxComboBoxNameStr`)

Creates the combobox for two-step construction.

Derived classes should call or replace this function. See wxComboBox() for further details.

bool wxComboBox::Create (wxWindow * *parent*, wxWindowID *id*, const wxString & *value*, const wxPoint & *pos*, const wxSize & *size*, const wxArrayString & *choices*, long *style* = 0, const wxValidator & *validator* = wxDefaultValidator, const wxString & *name* = wxComboBoxNameStr)

Creates the combobox for two-step construction.

Derived classes should call or replace this function. See wxComboBox() for further details.

virtual void wxComboBox::Dismiss ( ) [virtual]

Hides the list box portion of the combo box.

Currently this method is implemented in wxMSW, wxGTK and wxOSX/Cocoa.

Notice that calling this function will generate a wxEVT_COMBOBOX_CLOSEUP event except under wxOSX where generation of this event is not supported at all.

Since

2.9.1

virtual int wxComboBox::FindString (const wxString & *string*, bool *caseSensitive* = false) const [virtual]

Finds an item whose label matches the given string.

Parameters

string	String to find.
caseSensitive	Whether search is case sensitive (default is not).

Returns

The zero-based position of the item, or wxNOT_FOUND if the string was not found.

Reimplemented from wxItemContainerImmutable.

virtual unsigned int wxComboBox::GetCount ( ) const [virtual]

Returns the number of items in the control.

See also

IsEmpty()

Implements wxItemContainerImmutable.

virtual int wxComboBox::GetCurrentSelection ( ) const [virtual]

Returns the item being selected right now.

This function does the same things as wxChoice::GetCurrentSelection() and returns the item currently selected in the dropdown list if it's open or the same thing as wxControlWithItems::GetSelection() otherwise.

virtual long wxComboBox::GetInsertionPoint ( ) const [virtual]

Same as wxTextEntry::GetInsertionPoint().

Note

Under wxMSW, this function always returns 0 if the combobox doesn't have the focus.

Reimplemented from wxTextEntry.

virtual int wxComboBox::GetSelection ( ) const `[virtual]`

Returns the index of the selected item or `wxNOT_FOUND` if no item is selected.

Returns

The position of the current selection.

Remarks

This method can be used with single selection list boxes only, you should use wxListBox::GetSelections() for the list boxes with wxLB_MULTIPLE style.

See also

SetSelection(), GetStringSelection()

Implements wxItemContainerImmutable.

virtual void wxComboBox::GetSelection (long * *from*, long * *to*) const `[virtual]`

Gets the current selection span.

If the returned values are equal, there was no selection. Please note that the indices returned may be used with the other wxTextCtrl methods but don't necessarily represent the correct indices into the string returned by GetValue() for multiline controls under Windows (at least,) you should use GetStringSelection() to get the selected text.

Parameters

from	The returned first position.
to	The returned last position.

wxPerl Note: In wxPerl this method takes no parameters and returns a 2-element list (from, to).

Reimplemented from wxTextEntry.

virtual wxString wxComboBox::GetString (unsigned int *n*) const `[virtual]`

Returns the label of the item with the given index.

Parameters

n	The zero-based index.

Returns

The label of the item or an empty string if the position was invalid.

Implements wxItemContainerImmutable.

virtual wxString wxComboBox::GetStringSelection ( ) const `[virtual]`

Gets the text currently selected in the control.

If there is no selection, the returned string is empty.

Reimplemented from wxTextEntry.

bool wxComboBox::IsEmpty ( ) const `[virtual]`

IsEmpty() is not available in this class.

This method is documented here only to notice that it can't be used with this class because of the ambiguity between the methods with the same name inherited from wxItemContainer and wxTextEntry base classes.

Because of this, any attempt to call it results in a compilation error and you should use either IsListEmpty() or IsTextEmpty() depending on what exactly do you want to test.

Reimplemented from wxTextEntry.

bool wxComboBox::IsListEmpty ( ) const

Returns true if the list of combobox choices is empty.

Use this method instead of (not available in this class) IsEmpty() to test if the list of items is empty.

Since

2.9.3

bool wxComboBox::IsTextEmpty ( ) const

Returns true if the text of the combobox is empty.

Use this method instead of (not available in this class) IsEmpty() to test if the text currently entered into the combobox is empty.

Since

2.9.3

virtual void wxComboBox::Popup ( ) `[virtual]`

Shows the list box portion of the combo box.

Currently this method is implemented in wxMSW, wxGTK and wxOSX/Cocoa.

Notice that calling this function will generate a `wxEVT_COMBOBOX_DROPDOWN` event except under wxOSX where generation of this event is not supported at all.

Since

2.9.1

virtual void wxComboBox::SetSelection (long *from*, long *to*) `[virtual]`

Same as wxTextEntry::SetSelection().

Reimplemented from wxTextEntry.

virtual void wxComboBox::SetSelection (int *n*) `[virtual]`

Sets the selection to the given item *n* or removes the selection entirely if *n* == `wxNOT_FOUND`.

Note that this does not cause any command events to be emitted nor does it deselect any other items in the controls which support multiple selections.

Parameters

n	The string position to select, starting from zero.

See also

SetString(), SetStringSelection()

Implements wxItemContainerImmutable.

virtual void wxComboBox::SetString (unsigned int *n*, const wxString & *text*) [virtual]

Changes the text of the specified combobox item.

Notice that if the item is the currently selected one, i.e. if its text is displayed in the text part of the combobox, then the text is also replaced with the new *text*.

Implements wxItemContainerImmutable.

virtual void wxComboBox::SetValue (const wxString & *text*) [virtual]

Sets the text for the combobox text field.

Notice that this method will generate a `wxEVT_TEXT` event, use wxTextEntry::ChangeValue() if this is undesirable.

Note

For a combobox with `wxCB_READONLY` style the string must be in the combobox choices list, otherwise the call to SetValue() is ignored. This is case insensitive.

Parameters

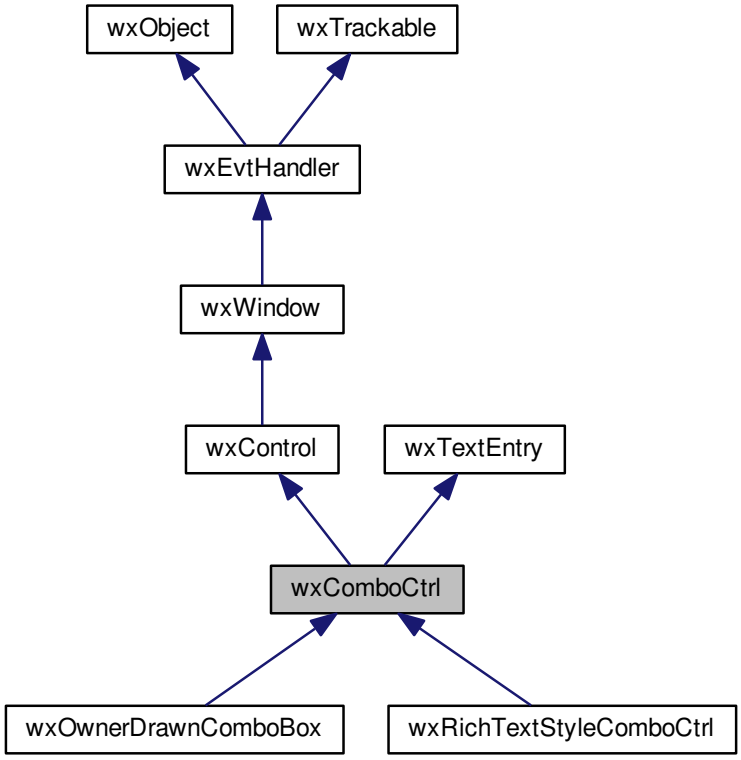
text	The text to set.

Reimplemented from wxTextEntry.

21.109 wxComboCtrl Class Reference

```
#include <wx/combo.h>
```

Inheritance diagram for wxComboCtrl:



21.109.1 Detailed Description

A combo control is a generic combobox that allows totally custom popup.

In addition it has other customization features. For instance, position and size of the dropdown button can be changed.

21.109.2 Setting Custom Popup for wxComboCtrl

wxComboCtrl needs to be told somehow which control to use and this is done by SetPopupControl(). However, we need something more than just a wxControl in this method as, for example, we need to call SetStringValue("initial text value") and wxControl doesn't have such method. So we also need a wxComboPopup which is an interface which must be implemented by a control to be usable as a popup.

We couldn't derive wxComboPopup from wxControl as this would make it impossible to have a class deriving from a wxWidgets control and from it, so instead it is just a mix-in.

Here's a minimal sample of wxListView popup:

```
#include <wx/combo.h>
#include <wx/listctrl.h>

class wxListViewComboPopup : public wxListView, public wxComboPopup
{
public:
    // Initialize member variables
    virtual void Init()
```

```
    {
        m_value = -1;
    }

    // Create popup control
    virtual bool Create(wxWindow* parent)
    {
        return wxListView::Create(parent,1,wxPoint(0,0),
      wxDefaultSize);
    }

    // Return pointer to the created control
    virtual wxWindow *GetControl() { return this; }

    // Translate string into a list selection
    virtual void SetStringValue(const wxString& s)
    {
        int n = wxListView::FindItem(-1,s);
        if ( n >= 0 && n < wxListView::GetItemCount() )
            wxListView::Select(n);
    }

    // Get list selection as a string
    virtual wxString GetStringValue() const
    {
        if ( m_value >= 0 )
        return wxListView::GetItemText(m_value);
        return wxEmptyString;
    }

    // Do mouse hot-tracking (which is typical in list popups)
    void OnMouseMove(wxMouseEvent& event)
    {
        // TODO: Move selection to cursor
    }

    // On mouse left up, set the value and close the popup
    void OnMouseClick(wxMouseEvent& WXUNUSED(event))
    {
        m_value = wxListView::GetFirstSelected();

        // TODO: Send event as well

        Dismiss();
    }

protected:

    int m_value; // current item index

private:
    wxDECLARE_EVENT_TABLE();
};

wxBEGIN_EVENT_TABLE(wxListViewComboPopup, wxListView)
    EVT_MOTION(wxListViewComboPopup::OnMouseMove)
    EVT_LEFT_UP(wxListViewComboPopup::OnMouseClick)
wxEND_EVENT_TABLE()
```

Here's how you would create and populate it in a dialog constructor:

```
wxComboCtrl* comboCtrl = new wxComboCtrl(this, wxID_ANY,
      wxEmptyString);

wxListViewComboPopup* popupCtrl = new wxListViewComboPopup();

// It is important to call SetPopupControl() as soon as possible
comboCtrl->SetPopupControl(popupCtrl);

// Populate using wxListView methods
popupCtrl->InsertItem(popupCtrl->GetItemCount(), "First Item");
popupCtrl->InsertItem(popupCtrl->GetItemCount(), "Second Item");
popupCtrl->InsertItem(popupCtrl->GetItemCount(), "Third Item");
```

Styles

This class supports the following styles:

- wxCB_READONLY: Text will not be editable.
- wxCB_SORT: Sorts the entries in the list alphabetically.

- wxTE_PROCESS_ENTER: The control will generate the event `wxEVT_TEXT_ENTER` (otherwise pressing Enter key is either processed internally by the control or used for navigation between dialog controls). Windows only.
- wxCC_SPECIAL_DCLICK: Double-clicking triggers a call to popup's OnComboDoubleClick. Actual behaviour is defined by a derived class. For instance, wxOwnerDrawnComboBox will cycle an item. This style only applies if wxCB_READONLY is used as well.
- wxCC_STD_BUTTON: Drop button will behave more like a standard push button.

Events emitted by this class

The following event handler macros redirect the events to member function handlers '**func**' with prototypes like: void handlerFuncName(wxCommandEvent& event)

Event macros for events emitted by this class:

- EVT_TEXT(id, func): Process a `wxEVT_TEXT` event, when the text changes.
- EVT_TEXT_ENTER(id, func): Process a `wxEVT_TEXT_ENTER` event, when RETURN is pressed in the combo control.
- EVT_COMBOBOX_DROPDOWN(id, func): Process a `wxEVT_COMBOBOX_DROPDOWN` event, which is generated when the popup window is shown (drops down).
- EVT_COMBOBOX_CLOSEUP(id, func): Process a `wxEVT_COMBOBOX_CLOSEUP` event, which is generated when the popup window of the combo control disappears (closes up). You should avoid adding or deleting items in this event.

Library: wxCore

wxComboBox, wxChoice, wxOwnerDrawnComboBox, wxComboPopup, wxCommandEvent

Public Member Functions

- wxComboCtrl ()

  Default constructor.
- wxComboCtrl (wxWindow *parent, wxWindowID id=wxID_ANY, const wxString &value=wxEmptyString, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, long style=0, const wxValidator &validator=wxDefaultValidator, const wxString &name=wxComboBoxNameStr)

  Constructor, creating and showing a combo control.
- virtual ~wxComboCtrl ()

  Destructor, destroying the combo control.
- virtual void Copy ()

  Copies the selected text to the clipboard.
- bool Create (wxWindow *parent, wxWindowID id=wxID_ANY, const wxString &value=wxEmptyString, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, long style=0, const wxValidator &validator=wxDefaultValidator, const wxString &name=wxComboBoxNameStr)

  Creates the combo control for two-step construction.
- virtual void Cut ()

  Copies the selected text to the clipboard and removes the selection.

- virtual void Dismiss ()

  Dismisses the popup window.
- void EnablePopupAnimation (bool enable=true)

  Enables or disables popup animation, if any, depending on the value of the argument.
- virtual bool IsKeyPopupToggle (const wxKeyEvent &event) const

  Returns true if given key combination should toggle the popup.
- virtual void PrepareBackground (wxDC &dc, const wxRect &rect, int flags) const

  Prepare background of combo control or an item in a dropdown list in a way typical on platform.
- bool ShouldDrawFocus () const

  Returns true if focus indicator should be drawn in the control.
- const wxBitmap & GetBitmapDisabled () const

  Returns disabled button bitmap that has been set with SetButtonBitmaps().
- const wxBitmap & GetBitmapHover () const

  Returns button mouse hover bitmap that has been set with SetButtonBitmaps().
- const wxBitmap & GetBitmapNormal () const

  Returns default button bitmap that has been set with SetButtonBitmaps().
- const wxBitmap & GetBitmapPressed () const

  Returns depressed button bitmap that has been set with SetButtonBitmaps().
- wxSize GetButtonSize ()

  Returns current size of the dropdown button.
- int GetCustomPaintWidth () const

  Returns custom painted area in control.
- virtual wxString GetHint () const

  Returns the current hint string.
- virtual long GetInsertionPoint () const

  Returns the insertion point for the combo control's text field.
- virtual long GetLastPosition () const

  Returns the last position in the combo control text field.
- wxPoint GetMargins () const

  Returns the margins used by the control.
- wxComboPopup * GetPopupControl ()

  Returns current popup interface that has been set with SetPopupControl().
- wxWindow * GetPopupWindow () const

  Returns popup window containing the popup control.
- wxTextCtrl * GetTextCtrl () const

  Get the text control which is part of the combo control.
- wxCoord GetTextIndent () const

  Returns actual indentation in pixels.
- const wxRect & GetTextRect () const

  Returns area covered by the text field (includes everything except borders and the dropdown button).
- virtual wxString GetValue () const

  Returns text representation of the current value.
- virtual void HidePopup (bool generateEvent=false)

  Dismisses the popup window.
- bool IsPopupShown () const

  Returns true if the popup is currently shown.
- bool IsPopupWindowState (int state) const

  Returns true if the popup window is in the given state.
- virtual void OnButtonClick ()

  Implement in a derived class to define what happens on dropdown button click.
- virtual void Paste ()

Pastes text from the clipboard to the text field.

- virtual void Popup ()

  Shows the popup portion of the combo control.

- virtual void Remove (long from, long to)

  Removes the text between the two positions in the combo control text field.

- virtual void Replace (long from, long to, const wxString &text)

  Replaces the text between two positions with the given text, in the combo control text field.

- void SetButtonBitmaps (const wxBitmap &bmpNormal, bool pushButtonBg=false, const wxBitmap &bmpPressed=wxNullBitmap, const wxBitmap &bmpHover=wxNullBitmap, const wxBitmap &bmpDisabled=wxNullBitmap)

  Sets custom dropdown button graphics.

- void SetButtonPosition (int width=-1, int height=-1, int side=wxRIGHT, int spacingX=0)

  Sets size and position of dropdown button.

- void SetCustomPaintWidth (int width)

  Set width, in pixels, of custom painted area in control without `wxCB_READONLY` style.

- virtual bool SetHint (const wxString &hint)

  Sets a hint shown in an empty unfocused combo control.

- virtual void SetInsertionPoint (long pos)

  Sets the insertion point in the text field.

- virtual void SetInsertionPointEnd ()

  Sets the insertion point at the end of the combo control text field.

- void SetPopupAnchor (int anchorSide)

  Set side of the control to which the popup will align itself.

- void SetPopupControl (wxComboPopup *popup)

  Set popup interface class derived from wxComboPopup.

- void SetPopupExtents (int extLeft, int extRight)

  Extends popup size horizontally, relative to the edges of the combo control.

- void SetPopupMaxHeight (int height)

  Sets preferred maximum height of the popup.

- void SetPopupMinWidth (int width)

  Sets minimum width of the popup.

- virtual void SetSelection (long from, long to)

  Selects the text between the two positions, in the combo control text field.

- void SetText (const wxString &value)

  Sets the text for the text field without affecting the popup.

- void SetTextCtrlStyle (int style)

  Set a custom window style for the embedded wxTextCtrl.

- void SetTextIndent (int indent)

  This will set the space in pixels between left edge of the control and the text, regardless whether control is read-only or not.

- virtual void SetValue (const wxString &value)

  Sets the text for the combo control text field.

- void SetValueByUser (const wxString &value)

  Changes value of the control as if user had done it by selecting an item from a combo box drop-down list.

- virtual void ShowPopup ()

  Show the popup.

- virtual void Undo ()

  Undoes the last edit in the text field.

- void UseAltPopupWindow (bool enable=true)

  Enable or disable usage of an alternative popup window, which guarantees ability to focus the popup control, and allows common native controls to function normally.

- bool SetMargins (const wxPoint &pt)

  Attempts to set the control margins.
- bool SetMargins (wxCoord left, wxCoord top=-1)

  Attempts to set the control margins.

Static Public Member Functions

- static int GetFeatures ()

  Returns features supported by wxComboCtrl.

Protected Types

- enum {
  ShowBelow = 0x0000,
  ShowAbove = 0x0001,
  CanDeferShow = 0x0002 }

  Flags for DoShowPopup() and AnimateShow().

Protected Member Functions

- virtual bool AnimateShow (const wxRect &rect, int flags)

  This member function is not normally called in application code.
- virtual void DoSetPopupControl (wxComboPopup *popup)

  This member function is not normally called in application code.
- virtual void DoShowPopup (const wxRect &rect, int flags)

  This member function is not normally called in application code.

Additional Inherited Members

21.109.3 Member Enumeration Documentation

anonymous enum `[protected]`

Flags for DoShowPopup() and AnimateShow().

Enumerator

ShowBelow Show popup below the control.

ShowAbove Show popup above the control.

CanDeferShow Can only return true from AnimateShow() if this is set.

21.109.4 Constructor & Destructor Documentation

wxComboCtrl::wxComboCtrl ( )

Default constructor.

wxComboCtrl::wxComboCtrl (wxWindow * *parent*, wxWindowID *id* = wxID_ANY, const wxString & *value* = wxEmptyString, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, long *style* = `0`, const wxValidator & *validator* = wxDefaultValidator, const wxString & *name* = `wxComboBoxNameStr`)

Constructor, creating and showing a combo control.

Parameters

parent	Parent window. Must not be NULL.
id	Window identifier. The value wxID_ANY indicates a default value.
value	Initial selection string. An empty string indicates no selection.
pos	Window position. If wxDefaultPosition is specified then a default position is chosen.
size	Window size. If wxDefaultSize is specified then the window is sized appropriately.
style	Window style. See wxComboCtrl.
validator	Window validator.
name	Window name.

See also

Create(), wxValidator

virtual wxComboCtrl::~wxComboCtrl ( ) [virtual]

Destructor, destroying the combo control.

21.109.5 Member Function Documentation

virtual bool wxComboCtrl::AnimateShow (const wxRect & *rect*, int *flags*) [protected], [virtual]

This member function is not normally called in application code.

Instead, it can be implemented in a derived class to create a custom popup animation.

The parameters are the same as those for DoShowPopup().

Returns

true if animation finishes before the function returns, false otherwise. In the latter case you need to manually call DoShowPopup() after the animation ends.

virtual void wxComboCtrl::Copy ( ) [virtual]

Copies the selected text to the clipboard.

Reimplemented from wxTextEntry.

bool wxComboCtrl::Create (wxWindow * *parent*, wxWindowID *id* = wxID_ANY, const wxString & *value* = wxEmptyString, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, long *style* = 0, const wxValidator & *validator* = wxDefaultValidator, const wxString & *name* = wxComboBoxNameStr)

Creates the combo control for two-step construction.

Derived classes should call or replace this function. See wxComboCtrl() for further details.

virtual void wxComboCtrl::Cut ( ) [virtual]

Copies the selected text to the clipboard and removes the selection.

Reimplemented from wxTextEntry.

virtual void wxComboCtrl::Dismiss ( ) [virtual]

Dismisses the popup window.

Notice that calling this function will generate a `wxEVT_COMBOBOX_CLOSEUP` event.

Since

2.9.2

virtual void wxComboCtrl::DoSetPopupControl (wxComboPopup * *popup*) [protected], [virtual]

This member function is not normally called in application code.

Instead, it can be implemented in a derived class to return default wxComboPopup, in case *popup* is NULL.

Note

If you have implemented OnButtonClick() to do something else than show the popup, then DoSetPopupControl() must always set *popup* to NULL.

virtual void wxComboCtrl::DoShowPopup (const wxRect & *rect,* int *flags*) [protected], [virtual]

This member function is not normally called in application code.

Instead, it must be called in a derived class to make sure popup is properly shown after a popup animation has finished (but only if AnimateShow() did not finish the animation within its function scope).

Parameters

rect	Position to show the popup window at, in screen coordinates.
flags	Combination of any of the following: wxComboCtrl::ShowAbove, and wxComboCtrl::CanDeferShow.

void wxComboCtrl::EnablePopupAnimation (bool *enable* = `true`)

Enables or disables popup animation, if any, depending on the value of the argument.

const wxBitmap& wxComboCtrl::GetBitmapDisabled ( ) const

Returns disabled button bitmap that has been set with SetButtonBitmaps().

Returns

A reference to the disabled state bitmap.

const wxBitmap& wxComboCtrl::GetBitmapHover ( ) const

Returns button mouse hover bitmap that has been set with SetButtonBitmaps().

Returns

A reference to the mouse hover state bitmap.

const wxBitmap& wxComboCtrl::GetBitmapNormal ( ) const

Returns default button bitmap that has been set with SetButtonBitmaps().

Returns

A reference to the normal state bitmap.

const wxBitmap& wxComboCtrl::GetBitmapPressed ( ) const

Returns depressed button bitmap that has been set with SetButtonBitmaps().

Returns

A reference to the depressed state bitmap.

wxSize wxComboCtrl::GetButtonSize ( )

Returns current size of the dropdown button.

int wxComboCtrl::GetCustomPaintWidth ( ) const

Returns custom painted area in control.

See also

SetCustomPaintWidth().

static int wxComboCtrl::GetFeatures ( ) [static]

Returns features supported by wxComboCtrl.

If needed feature is missing, you need to instead use wxGenericComboCtrl, which however may lack a native look and feel (but otherwise sports identical API).

Returns

Value returned is a combination of the flags defined in wxComboCtrlFeatures.

virtual wxString wxComboCtrl::GetHint ( ) const [virtual]

Returns the current hint string.

See SetHint() for more information about hints.

Since

2.9.1

Reimplemented from wxTextEntry.

virtual long wxComboCtrl::GetInsertionPoint ( ) const `[virtual]`

Returns the insertion point for the combo control's text field.

Note

Under Windows, this function always returns 0 if the combo control doesn't have the focus.

Reimplemented from wxTextEntry.

virtual long wxComboCtrl::GetLastPosition ( ) const `[virtual]`

Returns the last position in the combo control text field.

Reimplemented from wxTextEntry.

wxPoint wxComboCtrl::GetMargins ( ) const

Returns the margins used by the control.

The `x` field of the returned point is the horizontal margin and the `y` field is the vertical one.

Remarks

If given margin cannot be accurately determined, its value will be set to -1.

See also

SetMargins()

Since

2.9.1

wxComboPopup* wxComboCtrl::GetPopupControl ( )

Returns current popup interface that has been set with SetPopupControl().

wxWindow* wxComboCtrl::GetPopupWindow ( ) const

Returns popup window containing the popup control.

wxTextCtrl* wxComboCtrl::GetTextCtrl ( ) const

Get the text control which is part of the combo control.

wxCoord wxComboCtrl::GetTextIndent ( ) const

Returns actual indentation in pixels.

Deprecated Use GetMargins() instead.

const wxRect& wxComboCtrl::GetTextRect ( ) const

Returns area covered by the text field (includes everything except borders and the dropdown button).

virtual wxString wxComboCtrl::GetValue ( ) const `[virtual]`

Returns text representation of the current value.

For writable combo control it always returns the value in the text field.

Reimplemented from wxTextEntry.

virtual void wxComboCtrl::HidePopup (bool *generateEvent* = `false`) `[virtual]`

Dismisses the popup window.

Parameters

generateEvent	Set this to true in order to generate `wxEVT_COMBOBOX_CLOSEUP` event.

Deprecated Use Dismiss() instead.

virtual bool wxComboCtrl::IsKeyPopupToggle (const wxKeyEvent & *event*) const `[virtual]`

Returns true if given key combination should toggle the popup.

bool wxComboCtrl::IsPopupShown ( ) const

Returns true if the popup is currently shown.

bool wxComboCtrl::IsPopupWindowState (int *state*) const

Returns true if the popup window is in the given state.

Possible values are:

wxComboCtrl::Hidden	Popup window is hidden.
wxComboCtrl::Animating	Popup window is being shown, but the popup animation has not yet finished.
wxComboCtrl::Visible	Popup window is fully visible.

virtual void wxComboCtrl::OnButtonClick ( ) `[virtual]`

Implement in a derived class to define what happens on dropdown button click.

Default action is to show the popup.

Note

If you implement this to do something else than show the popup, you must then also implement DoSetPopupControl() to always return NULL.

virtual void wxComboCtrl::Paste ( ) `[virtual]`

Pastes text from the clipboard to the text field.

Reimplemented from wxTextEntry.

virtual void wxComboCtrl::Popup ( ) [virtual]

Shows the popup portion of the combo control.

Notice that calling this function will generate a `wxEVT_COMBOBOX_DROPDOWN` event.

Since

2.9.2

virtual void wxComboCtrl::PrepareBackground (wxDC & *dc*, const wxRect & *rect*, int *flags*) const [virtual]

Prepare background of combo control or an item in a dropdown list in a way typical on platform.

This includes painting the focus/disabled background and setting the clipping region.

Unless you plan to paint your own focus indicator, you should always call this in your wxComboPopup::PaintComboControl implementation. In addition, it sets pen and text colour to what looks good and proper against the background.

flags: wxRendererNative flags: wxCONTROL_ISSUBMENU: is drawing a list item instead of combo control wxCONTROL_SELECTED: list item is selected wxCONTROL_DISABLED: control/item is disabled

virtual void wxComboCtrl::Remove (long *from*, long *to*) [virtual]

Removes the text between the two positions in the combo control text field.

Parameters

from	The first position.
to	The last position.

Reimplemented from wxTextEntry.

virtual void wxComboCtrl::Replace (long *from*, long *to*, const wxString & *text*) [virtual]

Replaces the text between two positions with the given text, in the combo control text field.

Parameters

from	The first position.
to	The second position.
text	The text to insert.

Reimplemented from wxTextEntry.

void wxComboCtrl::SetButtonBitmaps (const wxBitmap & *bmpNormal*, bool *pushButtonBg* = `false`, const wxBitmap & *bmpPressed* = wxNullBitmap, const wxBitmap & *bmpHover* = wxNullBitmap, const wxBitmap & *bmpDisabled* = wxNullBitmap)

Sets custom dropdown button graphics.

Parameters

bmpNormal	Default button image.
pushButtonBg	If true, blank push button background is painted below the image.

bmpPressed	Depressed button image.
bmpHover	Button image when mouse hovers above it. This should be ignored on platforms and themes that do not generally draw different kind of button on mouse hover.
bmpDisabled	Disabled button image.

void wxComboCtrl::SetButtonPosition (int *width* = -1, int *height* = -1, int *side* = wxRIGHT, int *spacingX* = 0)

Sets size and position of dropdown button.

Parameters

width	Button width. Value = 0 specifies default.
height	Button height. Value = 0 specifies default.
side	Indicates which side the button will be placed. Value can be wxLEFT or wxRIGHT.
spacingX	Horizontal spacing around the button. Default is 0.

void wxComboCtrl::SetCustomPaintWidth (int *width*)

Set width, in pixels, of custom painted area in control without `wxCB_READONLY` style.

In read-only wxOwnerDrawnComboBox, this is used to indicate area that is not covered by the focus rectangle.

virtual bool wxComboCtrl::SetHint (const wxString & *hint*) [virtual]

Sets a hint shown in an empty unfocused combo control.

Notice that hints are known as *cue banners* under MSW or *placeholder strings* under OS X.

See also

wxTextEntry::SetHint()

Since

2.9.1

Reimplemented from wxTextEntry.

virtual void wxComboCtrl::SetInsertionPoint (long *pos*) [virtual]

Sets the insertion point in the text field.

Parameters

pos	The new insertion point.

Reimplemented from wxTextEntry.

virtual void wxComboCtrl::SetInsertionPointEnd ( ) [virtual]

Sets the insertion point at the end of the combo control text field.

Reimplemented from wxTextEntry.

bool wxComboCtrl::SetMargins (const wxPoint & *pt*)

Attempts to set the control margins.

When margins are given as wxPoint, x indicates the left and y the top margin. Use -1 to indicate that an existing value should be used.

Returns

true if setting of all requested margins was successful.

Since

2.9.1

bool wxComboCtrl::SetMargins (wxCoord *left*, wxCoord *top* = -1)

Attempts to set the control margins.

When margins are given as wxPoint, x indicates the left and y the top margin. Use -1 to indicate that an existing value should be used.

Returns

true if setting of all requested margins was successful.

Since

2.9.1

void wxComboCtrl::SetPopupAnchor (int *anchorSide*)

Set side of the control to which the popup will align itself.

Valid values are `wxLEFT`, `wxRIGHT` and 0. The default value 0 means that the most appropriate side is used (which, currently, is always `wxLEFT`).

void wxComboCtrl::SetPopupControl (wxComboPopup * *popup*)

Set popup interface class derived from wxComboPopup.

This method should be called as soon as possible after the control has been created, unless OnButtonClick() has been overridden.

void wxComboCtrl::SetPopupExtents (int *extLeft*, int *extRight*)

Extends popup size horizontally, relative to the edges of the combo control.

Parameters

extLeft	How many pixel to extend beyond the left edge of the control. Default is 0.
extRight	How many pixel to extend beyond the right edge of the control. Default is 0.

Remarks

Popup minimum width may override arguments. It is up to the popup to fully take this into account.

void wxComboCtrl::SetPopupMaxHeight (int *height*)

Sets preferred maximum height of the popup.

Remarks

Value -1 indicates the default.

void wxComboCtrl::SetPopupMinWidth (int *width*)

Sets minimum width of the popup.

If wider than combo control, it will extend to the left.

Remarks

Value -1 indicates the default. Also, popup implementation may choose to ignore this.

virtual void wxComboCtrl::SetSelection (long *from,* long *to*) `[virtual]`

Selects the text between the two positions, in the combo control text field.

Parameters

from	The first position.
to	The second position.

Reimplemented from wxTextEntry.

void wxComboCtrl::SetText (const wxString & *value*)

Sets the text for the text field without affecting the popup.

Thus, unlike SetValue(), it works equally well with combo control using `wxCB_READONLY` style.

void wxComboCtrl::SetTextCtrlStyle (int *style*)

Set a custom window style for the embedded wxTextCtrl.

Usually you will need to use this during two-step creation, just before Create(). For example:

```
wxComboCtrl* comboCtrl = new wxComboCtrl();

// Let's make the text right-aligned
comboCtrl->SetTextCtrlStyle(wxTE_RIGHT);

comboCtrl->Create(parent, wxID_ANY, wxEmptyString);
```

void wxComboCtrl::SetTextIndent (int *indent*)

This will set the space in pixels between left edge of the control and the text, regardless whether control is read-only or not.

Value -1 can be given to indicate platform default.

Deprecated Use SetMargins() instead.

virtual void wxComboCtrl::SetValue (const wxString & *value*) `[virtual]`

Sets the text for the combo control text field.

Note

For a combo control with `wxCB_READONLY` style the string must be accepted by the popup (for instance, exist in the dropdown list), otherwise the call to SetValue() is ignored.

Reimplemented from wxTextEntry.

void wxComboCtrl::SetValueByUser (const wxString & *value*)

Changes value of the control as if user had done it by selecting an item from a combo box drop-down list.

bool wxComboCtrl::ShouldDrawFocus ( ) const

Returns true if focus indicator should be drawn in the control.

virtual void wxComboCtrl::ShowPopup ( ) `[virtual]`

Show the popup.

Deprecated Use Popup() instead.

virtual void wxComboCtrl::Undo ( ) `[virtual]`

Undoes the last edit in the text field.

Windows only.

Reimplemented from wxTextEntry.

void wxComboCtrl::UseAltPopupWindow (bool *enable* = `true`)

Enable or disable usage of an alternative popup window, which guarantees ability to focus the popup control, and allows common native controls to function normally.

This alternative popup window is usually a wxDialog, and as such, when it is shown, its parent top-level window will appear as if the focus has been lost from it.

21.110 wxComboCtrlFeatures Struct Reference

`#include <wx/combo.h>`

21.110.1 Detailed Description

Features enabled for wxComboCtrl.

See also

wxComboCtrl::GetFeatures()

Public Types

- enum {
  MovableButton = 0x0001,
  BitmapButton = 0x0002,
  ButtonSpacing = 0x0004,
  TextIndent = 0x0008,
  PaintControl = 0x0010,
  PaintWritable = 0x0020,
  Borderless = 0x0040,
  All }

21.110.2 Member Enumeration Documentation

anonymous enum

Enumerator

MovableButton Button can be on either side of control.

BitmapButton Button may be replaced with bitmap.

ButtonSpacing Button can have spacing from the edge of the control.

TextIndent wxComboCtrl::SetMargins() can be used.

PaintControl Combo control itself can be custom painted.

PaintWritable A variable-width area in front of writable combo control's textctrl can be custom painted.

Borderless wxNO_BORDER window style works.

All All features.

21.111 wxComboPopup Class Reference

```
#include <wx/combo.h>
```

21.111.1 Detailed Description

In order to use a custom popup with wxComboCtrl, an interface class must be derived from wxComboPopup.

For more information on how to use it, see Setting Custom Popup for wxComboCtrl.

Library: wxCore

Category: Controls

wxComboCtrl

Public Member Functions

- wxComboPopup ()
  Default constructor.
- virtual bool Create (wxWindow *parent)=0
  The derived class must implement this to create the popup control.

- virtual void DestroyPopup ()

  You only need to implement this member function if you create your popup class in non-standard way.
- void Dismiss ()

  Utility function that hides the popup.
- virtual bool FindItem (const wxString &item, wxString *trueItem=NULL)

  Implement to customize matching of value string to an item container entry.
- virtual wxSize GetAdjustedSize (int minWidth, int prefHeight, int maxHeight)

  The derived class may implement this to return adjusted size for the popup control, according to the variables given.
- wxComboCtrl * GetComboCtrl () const

  Returns pointer to the associated parent wxComboCtrl.
- virtual wxWindow * GetControl ()=0

  The derived class must implement this to return pointer to the associated control created in Create().
- virtual wxString GetStringValue () const =0

  The derived class must implement this to return string representation of the value.
- virtual void Init ()

  The derived class must implement this to initialize its internal variables.
- bool IsCreated () const

  Utility method that returns true if Create has been called.
- virtual bool LazyCreate ()

  The derived class may implement this to return true if it wants to delay call to Create() until the popup is shown for the first time.
- virtual void OnComboDoubleClick ()

  The derived class may implement this to do something when the parent wxComboCtrl gets double-clicked.
- virtual void OnComboKeyEvent (wxKeyEvent &event)

  The derived class may implement this to receive key events from the parent wxComboCtrl.
- virtual void OnDismiss ()

  The derived class may implement this to do special processing when popup is hidden.
- virtual void OnPopup ()

  The derived class may implement this to do special processing when popup is shown.
- virtual void PaintComboControl (wxDC &dc, const wxRect &rect)

  The derived class may implement this to paint the parent wxComboCtrl.
- virtual void SetStringValue (const wxString &value)

  The derived class must implement this to receive string value changes from wxComboCtrl.

Protected Attributes

- wxComboCtrl * m_combo

  Parent wxComboCtrl.

21.111.2 Constructor & Destructor Documentation

wxComboPopup::wxComboPopup ( )

Default constructor.

It is recommended that internal variables are prepared in Init() instead (because m_combo is not valid in constructor).

21.111.3 Member Function Documentation

virtual bool wxComboPopup::Create (wxWindow * *parent*) [pure virtual]

The derived class must implement this to create the popup control.

Returns

true if the call succeeded, false otherwise.

virtual void wxComboPopup::DestroyPopup ( ) [virtual]

You only need to implement this member function if you create your popup class in non-standard way.

The default implementation can handle both multiple-inherited popup control (as seen in wxComboCtrl samples) and one allocated separately in heap.

If you do completely re-implement this function, make sure it calls Destroy() for the popup control and also deletes *this* object (usually as the last thing).

void wxComboPopup::Dismiss ( )

Utility function that hides the popup.

virtual bool wxComboPopup::FindItem (const wxString & *item,* wxString * *trueItem* = NULL) [virtual]

Implement to customize matching of value string to an item container entry.

Parameters

item	String entered, usually by user or from SetValue() call.
trueItem	When item matches an entry, but the entry's string representation is not exactly the same (case mismatch, for example), then the true item string should be written back to here, if it is not a NULL pointer.

Remarks

Default implementation always return true and does not alter trueItem.

virtual wxSize wxComboPopup::GetAdjustedSize (int *minWidth,* int *prefHeight,* int *maxHeight*) [virtual]

The derived class may implement this to return adjusted size for the popup control, according to the variables given.

Parameters

minWidth	Preferred minimum width.
prefHeight	Preferred height. May be -1 to indicate no preference.
maxHeight	Max height for window, as limited by screen size.

Remarks

This function is called each time popup is about to be shown.

wxComboCtrl* wxComboPopup::GetComboCtrl ( ) const

Returns pointer to the associated parent wxComboCtrl.

virtual wxWindow* wxComboPopup::GetControl ( ) [pure virtual]

The derived class must implement this to return pointer to the associated control created in Create().

virtual wxString wxComboPopup::GetStringValue ( ) const [pure virtual]

The derived class must implement this to return string representation of the value.

virtual void wxComboPopup::Init ( ) [virtual]

The derived class must implement this to initialize its internal variables.

This method is called immediately after construction finishes. m_combo member variable has been initialized before the call.

bool wxComboPopup::IsCreated ( ) const

Utility method that returns true if Create has been called.

Useful in conjunction with LazyCreate().

virtual bool wxComboPopup::LazyCreate ( ) [virtual]

The derived class may implement this to return true if it wants to delay call to Create() until the popup is shown for the first time.

It is more efficient, but on the other hand it is often more convenient to have the control created immediately.

Remarks

Base implementation returns false.

virtual void wxComboPopup::OnComboDoubleClick ( ) [virtual]

The derived class may implement this to do something when the parent wxComboCtrl gets double-clicked.

virtual void wxComboPopup::OnComboKeyEvent (wxKeyEvent & *event*) [virtual]

The derived class may implement this to receive key events from the parent wxComboCtrl.

Events not handled should be skipped, as usual.

virtual void wxComboPopup::OnDismiss ( ) [virtual]

The derived class may implement this to do special processing when popup is hidden.

virtual void wxComboPopup::OnPopup ( ) [virtual]

The derived class may implement this to do special processing when popup is shown.

virtual void wxComboPopup::PaintComboControl (wxDC & *dc*, const wxRect & *rect*) [virtual]

The derived class may implement this to paint the parent wxComboCtrl.

Default implementation draws value as string.

virtual void wxComboPopup::SetStringValue (const wxString & *value*) `[virtual]`

The derived class must implement this to receive string value changes from wxComboCtrl.

21.111.4 Member Data Documentation

wxComboCtrl* wxComboPopup::m_combo `[protected]`

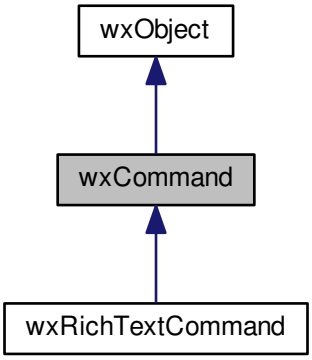
Parent wxComboCtrl.

This member variable is prepared automatically before Init() is called.

21.112 wxCommand Class Reference

`#include <wx/cmdproc.h>`

Inheritance diagram for wxCommand:



21.112.1 Detailed Description

wxCommand is a base class for modelling an application command, which is an action usually performed by selecting a menu item, pressing a toolbar button or any other means provided by the application to change the data or view.

Library: wxCore

Category: Document/View Framework

See also

wxCommand Overview

Public Member Functions

- wxCommand (bool canUndo=false, const wxString &name=wxEmptyString)

  Constructor.
- virtual ~wxCommand ()

  Destructor.
- virtual bool CanUndo () const

  Returns true if the command can be undone, false otherwise.
- virtual bool Do ()=0

  Override this member function to execute the appropriate action when called.
- virtual wxString GetName () const

  Returns the command name.
- virtual bool Undo ()=0

  Override this member function to un-execute a previous Do.

Additional Inherited Members

21.112.2 Constructor & Destructor Documentation

wxCommand::wxCommand (bool *canUndo* = `false`, const wxString & *name* = wxEmptyString)

Constructor.

wxCommand is an abstract class, so you will need to derive a new class and call this constructor from your own constructor.

Parameters

canUndo	Tells the command processor whether this command is undo-able. You can achieve the same functionality by overriding the CanUndo() member function (if for example the criteria for undoability is context-dependent).
name	Must be supplied for the command processor to display the command name in the application's edit menu.

virtual wxCommand::~wxCommand ( ) `[virtual]`

Destructor.

21.112.3 Member Function Documentation

virtual bool wxCommand::CanUndo ( ) const `[virtual]`

Returns true if the command can be undone, false otherwise.

virtual bool wxCommand::Do ( ) `[pure virtual]`

Override this member function to execute the appropriate action when called.

Returns

true to indicate that the action has taken place, false otherwise. Returning false will indicate to the command processor that the action is not undoable and should not be added to the command history.

Implemented in wxRichTextCommand.

virtual wxString wxCommand::GetName ( ) const [virtual]

Returns the command name.

virtual bool wxCommand::Undo ( ) [pure virtual]

Override this member function to un-execute a previous Do.

How you implement this command is totally application dependent, but typical strategies include:

- Perform an inverse operation on the last modified piece of data in the document. When redone, a copy of data stored in command is pasted back or some operation reapplied. This relies on the fact that you know the ordering of Undos; the user can never Undo at an arbitrary position in the command history.

- Restore the entire document state (perhaps using document transacting). Potentially very inefficient, but possibly easier to code if the user interface and data are complex, and an "inverse execute" operation is hard to write. The docview sample uses the first method, to remove or restore segments in the drawing.

Returns

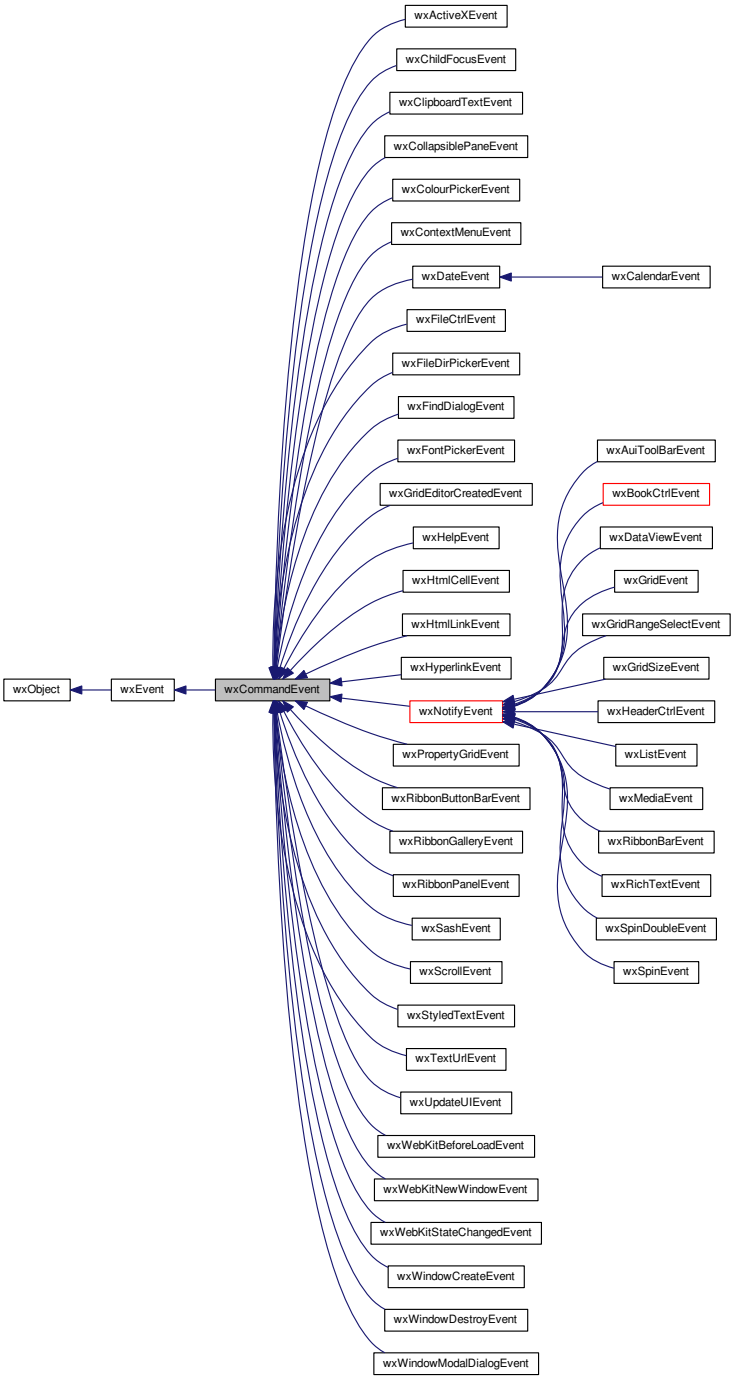
true to indicate that the action has taken place, false otherwise. Returning false will indicate to the command processor that the action is not redoable and no change should be made to the command history.

Implemented in wxRichTextCommand.

21.113 wxCommandEvent Class Reference

`#include <wx/event.h>`

Inheritance diagram for wxCommandEvent:



21.113.1 Detailed Description

This event class contains information about command events, which originate from a variety of simple controls.

Note that wxCommandEvents and wxCommandEvent-derived event classes by default and unlike other wxEvent-derived classes propagate upward from the source window (the window which emits the event) up to the first parent which processes the event. Be sure to read How Events Propagate Upwards.

More complex controls, such as wxTreeCtrl, have separate command event classes.

Events using this class

The following event handler macros redirect the events to member function handlers '**func**' with prototypes like: void handlerFuncName(wxCommandEvent& event)

Event macros:

- EVT_COMMAND(id, event, func): Process a command, supplying the window identifier, command event identifier, and member function.
- EVT_COMMAND_RANGE(id1, id2, event, func): Process a command for a range of window identifiers, supplying the minimum and maximum window identifiers, command event identifier, and member function.
- EVT_BUTTON(id, func): Process a `wxEVT_BUTTON` command, which is generated by a wxButton control.
- EVT_CHECKBOX(id, func): Process a `wxEVT_CHECKBOX` command, which is generated by a wxCheckBox control.
- EVT_CHOICE(id, func): Process a `wxEVT_CHOICE` command, which is generated by a wxChoice control.
- EVT_COMBOBOX(id, func): Process a `wxEVT_COMBOBOX` command, which is generated by a wxComboBox control.
- EVT_LISTBOX(id, func): Process a `wxEVT_LISTBOX` command, which is generated by a wxListBox control.
- EVT_LISTBOX_DCLICK(id, func): Process a `wxEVT_LISTBOX_DCLICK` command, which is generated by a wxListBox control.
- EVT_CHECKLISTBOX(id, func): Process a `wxEVT_CHECKLISTBOX` command, which is generated by a wxCheckListBox control.
- EVT_MENU(id, func): Process a `wxEVT_MENU` command, which is generated by a menu item.
- EVT_MENU_RANGE(id1, id2, func): Process a `wxEVT_MENU` command, which is generated by a range of menu items.
- EVT_CONTEXT_MENU(func): Process the event generated when the user has requested a popup menu to appear by pressing a special keyboard key (under Windows) or by right clicking the mouse.
- EVT_RADIOBOX(id, func): Process a `wxEVT_RADIOBOX` command, which is generated by a wxRadioBox control.
- EVT_RADIOBUTTON(id, func): Process a `wxEVT_RADIOBUTTON` command, which is generated by a wxRadioButton control.
- EVT_SCROLLBAR(id, func): Process a `wxEVT_SCROLLBAR` command, which is generated by a wxScrollBar control. This is provided for compatibility only; more specific scrollbar event macros should be used instead (see wxScrollEvent).
- EVT_SLIDER(id, func): Process a `wxEVT_SLIDER` command, which is generated by a wxSlider control.
- EVT_TEXT(id, func): Process a `wxEVT_TEXT` command, which is generated by a wxTextCtrl control.
- EVT_TEXT_ENTER(id, func): Process a `wxEVT_TEXT_ENTER` command, which is generated by a wxTextCtrl control. Note that you must use wxTE_PROCESS_ENTER flag when creating the control if you want it to generate such events.
- EVT_TEXT_MAXLEN(id, func): Process a `wxEVT_TEXT_MAXLEN` command, which is generated by a wxTextCtrl control when the user tries to enter more characters into it than the limit previously set with SetMaxLength().
- EVT_TOGGLEBUTTON(id, func): Process a `wxEVT_TOGGLEBUTTON` event.
- EVT_TOOL(id, func): Process a `wxEVT_TOOL` event (a synonym for `wxEVT_MENU`). Pass the id of the tool.

- EVT_TOOL_RANGE(id1, id2, func): Process a `wxEVT_TOOL` event for a range of identifiers. Pass the ids of the tools.
- EVT_TOOL_RCLICKED(id, func): Process a `wxEVT_TOOL_RCLICKED` event. Pass the id of the tool. (Not available on wxOSX.)
- EVT_TOOL_RCLICKED_RANGE(id1, id2, func): Process a `wxEVT_TOOL_RCLICKED` event for a range of ids. Pass the ids of the tools. (Not available on wxOSX.)
- EVT_TOOL_ENTER(id, func): Process a `wxEVT_TOOL_ENTER` event. Pass the id of the toolbar itself. The value of wxCommandEvent::GetSelection() is the tool id, or -1 if the mouse cursor has moved off a tool. (Not available on wxOSX.)
- EVT_COMMAND_LEFT_CLICK(id, func): Process a `wxEVT_COMMAND_LEFT_CLICK` command, which is generated by a control (wxMSW only).
- EVT_COMMAND_LEFT_DCLICK(id, func): Process a `wxEVT_COMMAND_LEFT_DCLICK` command, which is generated by a control (wxMSW only).
- EVT_COMMAND_RIGHT_CLICK(id, func): Process a `wxEVT_COMMAND_RIGHT_CLICK` command, which is generated by a control (wxMSW only).
- EVT_COMMAND_SET_FOCUS(id, func): Process a `wxEVT_COMMAND_SET_FOCUS` command, which is generated by a control (wxMSW only).
- EVT_COMMAND_KILL_FOCUS(id, func): Process a `wxEVT_COMMAND_KILL_FOCUS` command, which is generated by a control (wxMSW only).
- EVT_COMMAND_ENTER(id, func): Process a `wxEVT_COMMAND_ENTER` command, which is generated by a control.

Library: wxCore

Category: Events

Public Member Functions

- wxCommandEvent (wxEventType commandEventType=wxEVT_NULL, int id=0)

  Constructor.
- void * GetClientData () const

  Returns client data pointer for a listbox or choice selection event (not valid for a deselection).
- wxClientData * GetClientObject () const

  Returns client object pointer for a listbox or choice selection event (not valid for a deselection).
- long GetExtraLong () const

  Returns extra information dependent on the event objects type.
- int GetInt () const

  Returns the integer identifier corresponding to a listbox, choice or radiobox selection (only if the event was a selection, not a deselection), or a boolean value representing the value of a checkbox.
- int GetSelection () const

  Returns item index for a listbox or choice selection event (not valid for a deselection).
- wxString GetString () const

  Returns item string for a listbox or choice selection event.
- bool IsChecked () const

  This method can be used with checkbox and menu events: for the checkboxes, the method returns true for a selection event and false for a deselection one.
- bool IsSelection () const

For a listbox or similar event, returns true if it is a selection, false if it is a deselection.

- void SetClientData (void *clientData)

  Sets the client data for this event.

- void SetClientObject (wxClientData *clientObject)

  Sets the client object for this event.

- void SetExtraLong (long extraLong)

  *Sets the **m_extraLong** member.*

- void SetInt (int intCommand)

  *Sets the **m_commandInt** member.*

- void SetString (const wxString &string)

  *Sets the **m_commandString** member.*

Additional Inherited Members

21.113.2 Constructor & Destructor Documentation

wxCommandEvent::wxCommandEvent (wxEventType *commandEventType* = wxEVT_NULL, int *id* = 0)

Constructor.

21.113.3 Member Function Documentation

void* wxCommandEvent::GetClientData ( ) const

Returns client data pointer for a listbox or choice selection event (not valid for a deselection).

wxClientData* wxCommandEvent::GetClientObject ( ) const

Returns client object pointer for a listbox or choice selection event (not valid for a deselection).

long wxCommandEvent::GetExtraLong ( ) const

Returns extra information dependent on the event objects type.

If the event comes from a listbox selection, it is a boolean determining whether the event was a selection (true) or a deselection (false). A listbox deselection only occurs for multiple-selection boxes, and in this case the index and string values are indeterminate and the listbox must be examined by the application.

int wxCommandEvent::GetInt ( ) const

Returns the integer identifier corresponding to a listbox, choice or radiobox selection (only if the event was a selection, not a deselection), or a boolean value representing the value of a checkbox.

For a menu item, this method returns -1 if the item is not checkable or a boolean value (true or false) for checkable items indicating the new state of the item.

int wxCommandEvent::GetSelection ( ) const

Returns item index for a listbox or choice selection event (not valid for a deselection).

wxString wxCommandEvent::GetString ( ) const

Returns item string for a listbox or choice selection event.

If one or several items have been deselected, returns the index of the first deselected item. If some items have been selected and others deselected at the same time, it will return the index of the first selected item.

bool wxCommandEvent::IsChecked ( ) const

This method can be used with checkbox and menu events: for the checkboxes, the method returns true for a selection event and false for a deselection one.

For the menu events, this method indicates if the menu item just has become checked or unchecked (and thus only makes sense for checkable menu items).

Notice that this method cannot be used with wxCheckListBox currently.

bool wxCommandEvent::IsSelection ( ) const

For a listbox or similar event, returns true if it is a selection, false if it is a deselection.

If some items have been selected and others deselected at the same time, it will return true.

void wxCommandEvent::SetClientData (void * *clientData*)

Sets the client data for this event.

void wxCommandEvent::SetClientObject (wxClientData * *clientObject*)

Sets the client object for this event.

The client object is not owned by the event object and the event object will not delete the client object in its destructor.

The client object must be owned and deleted by another object (e.g. a control) that has longer life time than the event object.

void wxCommandEvent::SetExtraLong (long *extraLong*)

Sets the **m_extraLong** member.

void wxCommandEvent::SetInt (int *intCommand*)

Sets the **m_commandInt** member.

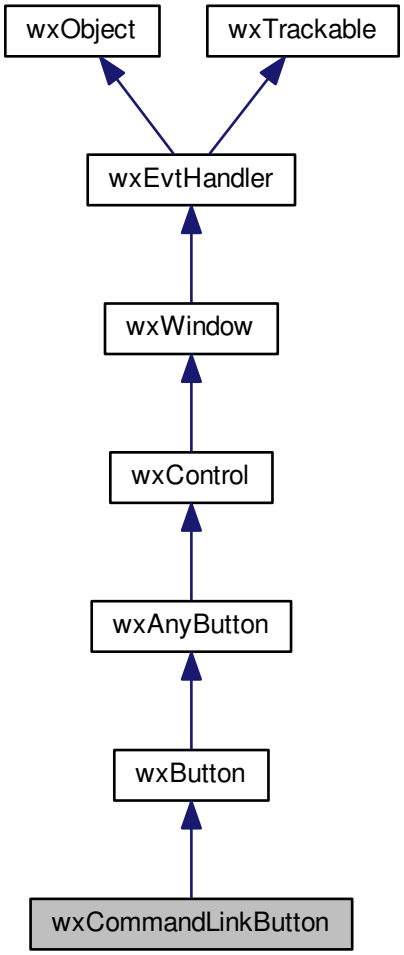
void wxCommandEvent::SetString (const wxString & *string*)

Sets the **m_commandString** member.

21.114 wxCommandLinkButton Class Reference

`#include <wx/commandlinkbutton.h>`

Inheritance diagram for wxCommandLinkButton:



21.114.1 Detailed Description

Objects of this class are similar in appearance to the normal wxButtons but are similar to the links in a web page in functionality.

Pressing such button usually results in switching to another window of the program and so they can be used as a replacement for the "Next" button in a multi-page dialog (such as wxWizard), for example.

Their advantage compared to the ordinary wxButtons is that they emphasize the action of switching the window and also that they allow to give more detailed explanation to the user because, in addition to the short button label, they also show a longer description string.

The short, title-like, part of the label is called the *main label* and the longer description is the *note*. Both of them can be set and queried independently using wxCommandLinkButton-specific methods such as SetMainLabel() or GetNote() or also via SetLabel() and GetLabel() methods inherited from wxButton. When using the latter, the main label and the note are concatenated into a single string using a new line character between them (notice that the note part can have more new lines in it).

wxCommandLinkButton generates the same event as wxButton but doesn't support any of wxButton-specific styles

nor adds any new styles of its own.

Currently this class uses native implementation under Windows Vista and later versions and a generic implementation for the other platforms and earlier Windows versions.

Since

2.9.2

Library: wxAdvanced

Category: Controls

wxButton, wxBitmapButton

Public Member Functions

- wxCommandLinkButton ()

  Default constructor.
- wxCommandLinkButton (wxWindow *parent, wxWindowID id, const wxString &mainLabel=wxEmptyString, const wxString &note=wxEmptyString, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, long style=0, const wxValidator &validator=wxDefaultValidator, const wxString &name=wxButtonNameStr)

  Constructor really creating a command Link button.
- bool Create (wxWindow *parent, wxWindowID id, const wxString &mainLabel=wxEmptyString, const wxString &note=wxEmptyString, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, long style=0, const wxValidator &validator=wxDefaultValidator, const wxString &name=wxButtonNameStr)

  Button creation function for two-step creation.
- void SetMainLabelAndNote (const wxString &mainLabel, const wxString &note)

  Sets a new main label and note for the button.
- virtual void SetLabel (const wxString &label)

  Sets the string label and note for the button.
- wxString GetLabel () const

  Returns the string label for the button.
- void SetMainLabel (const wxString &mainLabel)

  Changes the main label.
- void SetNote (const wxString &note)

  Changes the note.
- wxString GetMainLabel () const

  Returns the current main label.
- wxString GetNote () const

  Returns the currently used note.

Additional Inherited Members

21.114.2 Constructor & Destructor Documentation

wxCommandLinkButton::wxCommandLinkButton ( )

Default constructor.

Use Create() to really create the control.

wxCommandLinkButton::wxCommandLinkButton (wxWindow * *parent*, wxWindowID *id*, const wxString & *mainLabel* = wxEmptyString, const wxString & *note* = wxEmptyString, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, long *style* = 0, const wxValidator & *validator* = wxDefaultValidator, const wxString & *name* = wxButtonNameStr)

Constructor really creating a command Link button.

The button will be decorated with stock icons under GTK+ 2.

Parameters

parent	Parent window. Must not be NULL.
id	Button identifier. A value of wxID_ANY indicates a default value.
mainLabel	First line of text on the button, typically the label of an action that will be made when the button is pressed.
note	Second line of text describing the action performed when the button is pressed.
pos	Button position.
size	Button size. If the default size is specified then the button is sized appropriately for the text.
style	Window style. See wxButton class description.
validator	Window validator.
name	Window name.

See also

Create(), wxValidator

21.114.3 Member Function Documentation

bool wxCommandLinkButton::Create (wxWindow * *parent*, wxWindowID *id*, const wxString & *mainLabel* = wxEmptyString, const wxString & *note* = wxEmptyString, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, long *style* = 0, const wxValidator & *validator* = wxDefaultValidator, const wxString & *name* = wxButtonNameStr)

Button creation function for two-step creation.

For more details, see wxCommandLinkButton().

wxString wxCommandLinkButton::GetLabel ( ) const [virtual]

Returns the string label for the button.

See also

SetLabel()

Returns

A string with the main label and note concatenated together with a newline separating them.

Reimplemented from wxButton.

wxString wxCommandLinkButton::GetMainLabel ( ) const

Returns the current main label.

Returns

Main label currently displayed.

wxString wxCommandLinkButton::GetNote ( ) const

Returns the currently used note.

Returns

Note currently displayed.

virtual void wxCommandLinkButton::SetLabel (const wxString & *label*) [virtual]

Sets the string label and note for the button.

Parameters

label	The label and note to set, with the two separated by the first newline or none to set a blank note.

Reimplemented from wxButton.

void wxCommandLinkButton::SetMainLabel (const wxString & *mainLabel*)

Changes the main label.

Parameters

mainLabel	New main label to use.

void wxCommandLinkButton::SetMainLabelAndNote (const wxString & *mainLabel,* const wxString & *note*)

Sets a new main label and note for the button.

Neither of the arguments can be empty, if you need to change just the label or just the note, use SetMainLabel() or SetNote() instead of this function.

Parameters

mainLabel	New main label to use.
note	New note to use.

void wxCommandLinkButton::SetNote (const wxString & *note*)

Changes the note.

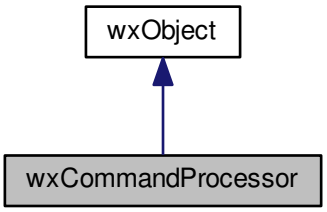
Parameters

note	New note to use.

21.115 wxCommandProcessor Class Reference

```
#include <wx/cmdproc.h>
```

Inheritance diagram for wxCommandProcessor:



21.115.1 Detailed Description

wxCommandProcessor is a class that maintains a history of wxCommands, with undo/redo functionality built-in.

Derive a new class from this if you want different behaviour.

Library: wxCore

Category: Document/View Framework

See also

wxCommandProcessor Overview, wxCommand

Public Member Functions

- wxCommandProcessor (int maxCommands=-1)

  Constructor.
- virtual ~wxCommandProcessor ()

  Destructor.
- virtual bool CanUndo () const

  Returns true if the currently-active command can be undone, false otherwise.
- virtual bool CanRedo () const

  Returns true if the currently-active command can be redone, false otherwise.
- virtual void ClearCommands ()

  Deletes all commands in the list and sets the current command pointer to NULL.
- wxList & GetCommands ()

  Returns the list of commands.
- wxCommand * GetCurrentCommand () const

  Returns the current command.
- wxMenu * GetEditMenu () const

  Returns the edit menu associated with the command processor.
- int GetMaxCommands () const

  Returns the maximum number of commands that the command processor stores.
- const wxString & GetRedoAccelerator () const

Returns the string that will be appended to the Redo menu item.

- wxString GetRedoMenuLabel () const

  Returns the string that will be shown for the redo menu item.
- const wxString & GetUndoAccelerator () const

  Returns the string that will be appended to the Undo menu item.
- wxString GetUndoMenuLabel () const

  Returns the string that will be shown for the undo menu item.
- virtual void Initialize ()

  Initializes the command processor, setting the current command to the last in the list (if any), and updating the edit menu (if one has been specified).
- virtual bool IsDirty () const

  Returns a boolean value that indicates if changes have been made since the last save operation.
- void MarkAsSaved ()

  You must call this method whenever the project is saved if you plan to use IsDirty().
- virtual bool Redo ()

  Executes (redoes) the current command (the command that has just been undone if any).
- void SetEditMenu (wxMenu *menu)

  Tells the command processor to update the Undo and Redo items on this menu as appropriate.
- virtual void SetMenuStrings ()

  Sets the menu labels according to the currently set menu and the current command state.
- void SetRedoAccelerator (const wxString &accel)

  Sets the string that will be appended to the Redo menu item.
- void SetUndoAccelerator (const wxString &accel)

  Sets the string that will be appended to the Undo menu item.
- virtual bool Submit (wxCommand *command, bool storeIt=true)

  Submits a new command to the command processor.
- virtual void Store (wxCommand *command)

  Just store the command without executing it.
- virtual bool Undo ()

  Undoes the last command executed.

Additional Inherited Members

21.115.2 Constructor & Destructor Documentation

wxCommandProcessor::wxCommandProcessor (int *maxCommands* = `-1`)

Constructor.

Parameters

maxCommands	May be set to a positive integer to limit the number of commands stored to it, otherwise (and by default) the list of commands can grow arbitrarily.

virtual wxCommandProcessor::~wxCommandProcessor ( ) `[virtual]`

Destructor.

21.115.3 Member Function Documentation

virtual bool wxCommandProcessor::CanRedo ( ) const `[virtual]`

Returns true if the currently-active command can be redone, false otherwise.

virtual bool wxCommandProcessor::CanUndo ( ) const `[virtual]`

Returns true if the currently-active command can be undone, false otherwise.

virtual void wxCommandProcessor::ClearCommands ( ) `[virtual]`

Deletes all commands in the list and sets the current command pointer to NULL.

wxList& wxCommandProcessor::GetCommands ( )

Returns the list of commands.

wxCommand* wxCommandProcessor::GetCurrentCommand ( ) const

Returns the current command.

wxMenu* wxCommandProcessor::GetEditMenu ( ) const

Returns the edit menu associated with the command processor.

int wxCommandProcessor::GetMaxCommands ( ) const

Returns the maximum number of commands that the command processor stores.

const wxString& wxCommandProcessor::GetRedoAccelerator ( ) const

Returns the string that will be appended to the Redo menu item.

wxString wxCommandProcessor::GetRedoMenuLabel ( ) const

Returns the string that will be shown for the redo menu item.

const wxString& wxCommandProcessor::GetUndoAccelerator ( ) const

Returns the string that will be appended to the Undo menu item.

wxString wxCommandProcessor::GetUndoMenuLabel ( ) const

Returns the string that will be shown for the undo menu item.

virtual void wxCommandProcessor::Initialize ( ) `[virtual]`

Initializes the command processor, setting the current command to the last in the list (if any), and updating the edit menu (if one has been specified).

virtual bool wxCommandProcessor::IsDirty ( ) const `[virtual]`

Returns a boolean value that indicates if changes have been made since the last save operation.

This only works if MarkAsSaved() is called whenever the project is saved.

void wxCommandProcessor::MarkAsSaved ( )

You must call this method whenever the project is saved if you plan to use IsDirty().

virtual bool wxCommandProcessor::Redo ( ) [virtual]

Executes (redoes) the current command (the command that has just been undone if any).

void wxCommandProcessor::SetEditMenu (wxMenu * *menu*)

Tells the command processor to update the Undo and Redo items on this menu as appropriate.

Set this to NULL if the menu is about to be destroyed and command operations may still be performed, or the command processor may try to access an invalid pointer.

virtual void wxCommandProcessor::SetMenuStrings ( ) [virtual]

Sets the menu labels according to the currently set menu and the current command state.

void wxCommandProcessor::SetRedoAccelerator (const wxString & *accel*)

Sets the string that will be appended to the Redo menu item.

void wxCommandProcessor::SetUndoAccelerator (const wxString & *accel*)

Sets the string that will be appended to the Undo menu item.

virtual void wxCommandProcessor::Store (wxCommand * *command*) [virtual]

Just store the command without executing it.

The command is stored in the history list, and the associated edit menu (if any) updated appropriately.

virtual bool wxCommandProcessor::Submit (wxCommand * *command*, bool *storeIt* = true) [virtual]

Submits a new command to the command processor.

The command processor calls wxCommand::Do() to execute the command; if it succeeds, the command is stored in the history list, and the associated edit menu (if any) updated appropriately. If it fails, the command is deleted immediately. Once Submit() has been called, the passed command should not be deleted directly by the application.

Parameters

command	The command to submit
storeIt	Indicates whether the successful command should be stored in the history list.

virtual bool wxCommandProcessor::Undo ( ) [virtual]

Undoes the last command executed.

21.116 wxCondition Class Reference

`#include <wx/thread.h>`

21.116.1 Detailed Description

wxCondition variables correspond to pthread conditions or to Win32 event objects.

They may be used in a multithreaded application to wait until the given condition becomes true which happens when the condition becomes signaled.

For example, if a worker thread is doing some long task and another thread has to wait until it is finished, the latter thread will wait on the condition object and the worker thread will signal it on exit (this example is not perfect because in this particular case it would be much better to just wxThread::Wait for the worker thread, but if there are several worker threads it already makes much more sense).

Note that a call to wxCondition::Signal may happen before the other thread calls wxCondition::Wait and, just as with the pthread conditions, the signal is then lost and so if you want to be sure that you don't miss it you must keep the mutex associated with the condition initially locked and lock it again before calling wxCondition::Signal. Of course, this means that this call is going to block until wxCondition::Wait is called by another thread.

21.116.2 Example

This example shows how a main thread may launch a worker thread which starts running and then waits until the main thread signals it to continue:

```
class MySignallingThread : public wxThread
{
public:
    MySignallingThread(wxMutex *mutex, wxCondition *condition)
    {
        m_mutex = mutex;
        m_condition = condition;
    }

    virtual ExitCode Entry()
    {
        ... do our job ...

        // tell the other(s) thread(s) that we're about to terminate: we must
        // lock the mutex first or we might signal the condition before the
        // waiting threads start waiting on it!
        wxMutexLocker lock(*m_mutex);
        m_condition->Broadcast(); // same as Signal() here -- one waiter only

        return 0;
    }

private:
    wxCondition *m_condition;
    wxMutex *m_mutex;
};

int main()
{
    wxMutex mutex;
    wxCondition condition(mutex);

    // the mutex should be initially locked
    mutex.Lock();

    // create and run the thread but notice that it won't be able to
    // exit (and signal its exit) before we unlock the mutex below
    MySignallingThread *thread = new MySignallingThread(&mutex, &condition);

    thread->Run();

    // wait for the thread termination: Wait() atomically unlocks the mutex
    // which allows the thread to continue and starts waiting
    condition.Wait();

    // now we can exit
    return 0;
}
```

Of course, here it would be much better to simply use a joinable thread and call wxThread::Wait on it, but this example does illustrate the importance of properly locking the mutex when using wxCondition.

Library: wxBase

wxThread, wxMutex

Public Member Functions

- wxCondition (wxMutex &mutex)
  Default and only constructor.
- ~wxCondition ()
  Destroys the wxCondition object.
- wxCondError Broadcast ()
  Broadcasts to all waiting threads, waking all of them up.
- bool IsOk () const
  Returns true if the object had been initialized successfully, false if an error occurred.
- wxCondError Signal ()
  Signals the object waking up at most one thread.
- wxCondError Wait ()
  Waits until the condition is signalled.
- template<typename Functor >
  wxCondError Wait (const Functor &predicate)
  Waits until the condition is signalled and the associated condition true.
- wxCondError WaitTimeout (unsigned long milliseconds)
  Waits until the condition is signalled or the timeout has elapsed.

21.116.3 Constructor & Destructor Documentation

wxCondition::wxCondition (wxMutex & *mutex*)

Default and only constructor.

The *mutex* must be locked by the caller before calling Wait() function. Use IsOk() to check if the object was successfully initialized.

wxCondition::~wxCondition ( )

Destroys the wxCondition object.

The destructor is not virtual so this class should not be used polymorphically.

21.116.4 Member Function Documentation

wxCondError wxCondition::Broadcast ( )

Broadcasts to all waiting threads, waking all of them up.

Note that this method may be called whether the mutex associated with this condition is locked or not.

See also

Signal()

bool wxCondition::IsOk ( ) const

Returns true if the object had been initialized successfully, false if an error occurred.

wxCondError wxCondition::Signal ( )

Signals the object waking up at most one thread.

If several threads are waiting on the same condition, the exact thread which is woken up is undefined. If no threads are waiting, the signal is lost and the condition would have to be signalled again to wake up any thread which may start waiting on it later.

Note that this method may be called whether the mutex associated with this condition is locked or not.

See also

Broadcast()

wxCondError wxCondition::Wait ( )

Waits until the condition is signalled.

This method atomically releases the lock on the mutex associated with this condition (this is why it must be locked prior to calling Wait()) and puts the thread to sleep until Signal() or Broadcast() is called. It then locks the mutex again and returns.

Note that even if Signal() had been called before Wait() without waking up any thread, the thread would still wait for another one and so it is important to ensure that the condition will be signalled after Wait() or the thread may sleep forever.

Returns

Returns wxCOND_NO_ERROR on success, another value if an error occurred.

See also

WaitTimeout()

template<typename Functor > wxCondError wxCondition::Wait (const Functor & *predicate*)

Waits until the condition is signalled and the associated condition true.

This is a convenience overload that may be used to ignore spurious awakenings while waiting for a specific condition to become true.

Equivalent to

```
while ( !predicate() )
{
    wxCondError e = Wait();
    if ( e != wxCOND_NO_ERROR )
        return e;
}
return wxCOND_NO_ERROR;
```

The predicate would typically be a C++11 lambda:

```
condvar.Wait([]{return value == 1;});
```

Since

3.0

wxCondError wxCondition::WaitTimeout (unsigned long *milliseconds*)

Waits until the condition is signalled or the timeout has elapsed.

This method is identical to Wait() except that it returns, with the return code of `wxCOND_TIMEOUT` as soon as the given timeout expires.

Parameters

milliseconds	Timeout in milliseconds

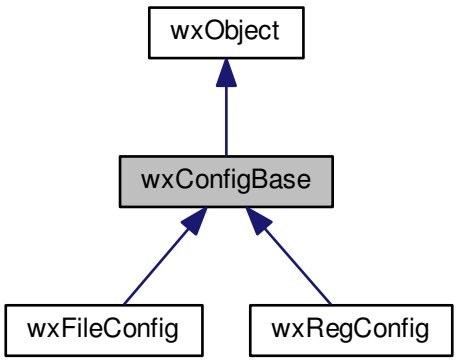
Returns

Returns wxCOND_NO_ERROR if the condition was signalled, wxCOND_TIMEOUT if the timeout elapsed before this happened or another error code from wxCondError enum.

21.117 wxConfigBase Class Reference

`#include <wx/config.h>`

Inheritance diagram for wxConfigBase:



21.117.1 Detailed Description

wxConfigBase defines the basic interface of all config classes.

It cannot be used by itself (it is an abstract base class) and you will always use one of its derivations: wxFileConfig, wxRegConfig or any other.

However, usually you don't even need to know the precise nature of the class you're working with but you would just use the wxConfigBase methods. This allows you to write the same code regardless of whether you're working with the registry under Windows or text-based config files under Unix. To make writing the portable code even easier, wxWidgets provides a typedef wxConfig which is mapped onto the native wxConfigBase implementation on the given platform: i.e. wxRegConfig under Windows and wxFileConfig otherwise.

See wxConfig Overview for a description of all features of this class.

It is highly recommended to use static functions Get() and/or Set(), so please have a look at them.

Related Include Files:

- <wx/config.h> - Let wxWidgets choose a wxConfig class for your platform.
- <wx/confbase.h> - Base config class.
- <wx/fileconf.h> - wxFileConfig class.
- <wx/msw/regconf.h> - wxRegConfig class, see also wxRegKey.

21.117.2 Example

Here is how you would typically use this class:

```
// using wxConfig instead of writing wxFileConfig or wxRegConfig enhances
// portability of the code
wxConfig *config = new wxConfig("MyAppName");

wxString str;
if ( config->Read("LastPrompt", &str) ) {
    // last prompt was found in the config file/registry and its value is
    // now in str
    // ...
}
else {
    // no last prompt...
}

// another example: using default values and the full path instead of just
// key name: if the key is not found , the value 17 is returned
long value = config->ReadLong("/LastRun/CalculatedValues/MaxValue", 17);

// at the end of the program we would save everything back
config->Write("LastPrompt", str);
config->Write("/LastRun/CalculatedValues/MaxValue", value);

// the changes will be written back automatically
delete config;
```

This basic example, of course, doesn't show all wxConfig features, such as enumerating, testing for existence and deleting the entries and groups of entries in the config file, its abilities to automatically store the default values or expand the environment variables on the fly. However, the main idea is that using this class is easy and that it should normally do what you expect it to.

Note

In the documentation of this class, the words "config file" also mean "registry hive" for wxRegConfig and, generally speaking, might mean any physical storage where a wxConfigBase-derived class stores its data.

21.117.3 Static Functions

The static functions provided deal with the "default" config object. Although its usage is not at all mandatory it may be convenient to use a global config object instead of creating and deleting the local config objects each time you need one (especially because creating a wxFileConfig object might be a time consuming operation). In this case, you may create this global config object in the very start of the program and Set() it as the default. Then, from anywhere in your program, you may access it using the Get() function. This global wxConfig object will be deleted by wxWidgets automatically if it exists. Note that this implies that if you do delete this object yourself (usually in wxApp::OnExit()) you must use Set(NULL) to prevent wxWidgets from deleting it the second time.

As it happens, you may even further simplify the procedure described above: you may forget about calling Set(). When Get() is called and there is no current object, it will create one using Create() function. To disable this behaviour DontCreateOnDemand() is provided.

Note

You should use either Set() or Get() because wxWidgets library itself would take advantage of it and could save various information in it. For example wxFontMapper or Unix version of wxFileDialog have the ability to use wxConfig class.

21.117.4 Path Management

As explained in the config overview, the config classes support a file system-like hierarchy of keys (files) and groups (directories). As in the file system case, to specify a key in the config class you must use a path to it. Config classes also support the notion of the current group, which makes it possible to use the relative paths. To clarify all this, here is an example (it is only for the sake of demonstration, it doesn't do anything sensible!):

```
wxConfig *config = new wxConfig("FooBarApp");

// right now the current path is '/'
conf->Write("RootEntry", 1);

// go to some other place: if the group(s) don't exist, they will be created
conf->SetPath("/Group/Subgroup");

// create an entry in subgroup
conf->Write("SubgroupEntry", 3);

// '..' is understood
conf->Write("../GroupEntry", 2);
conf->SetPath("..");

wxASSERT( conf->ReadLong("Subgroup/SubgroupEntry", 0) == 3 );

// use absolute path: it is allowed, too
wxASSERT( conf->ReadLong("/RootEntry", 0) == 1 );
```

It is highly recommended that you restore the path to its old value on function exit:

```
void foo(wxConfigBase *config)
{
    wxString strOldPath = config->GetPath();

    config->SetPath("/Foo/Data");
    // ...

    config->SetPath(strOldPath);
}
```

Otherwise the assert in the following example will surely fail (we suppose here that the foo() function is the same as above except that it doesn't save and restore the path):

```
void bar(wxConfigBase *config)
{
    config->Write("Test", 17);

    foo(config);

    // we're reading "/Foo/Data/Test" here! -1 will probably be returned...
    wxASSERT( config->ReadLong("Test", -1) == 17 );
}
```

Finally, the path separator in wxConfigBase and derived classes is always "/", regardless of the platform (i.e. it is not "\\" under Windows).

21.117.5 Enumeration

The enumeration functions allow you to enumerate all entries and groups in the config file. All functions here return false when there are no more items.

You must pass the same index to GetNext() and GetFirst() (don't modify it). Please note that it is not the index of the current item (you will have some great surprises with wxRegConfig if you assume this) and you shouldn't even

look at it: it is just a "cookie" which stores the state of the enumeration. It can't be stored inside the class because it would prevent you from running several enumerations simultaneously, that's why you must pass it explicitly.

Having said all this, enumerating the config entries/groups is very simple:

```
wxConfigBase *config = ...;
wxArrayString aNames;

// enumeration variables
wxString str;
long dummy;

// first enum all entries
bool bCont = config->GetFirstEntry(str, dummy);
while ( bCont ) {
    aNames.Add(str);

    bCont = config->GetNextEntry(str, dummy);
}

// ... we have all entry names in aNames...

// now all groups...
bCont = config->GetFirstGroup(str, dummy);
while ( bCont ) {
    aNames.Add(str);

    bCont = config->GetNextGroup(str, dummy);
}

// ... we have all group (and entry) names in aNames...
```

There are also functions to get the number of entries/subgroups without actually enumerating them, but you will probably never need them.

21.117.6 Key Access

The key access functions are the core of wxConfigBase class: they allow you to read and write config file data. All Read() functions take a default value which will be returned if the specified key is not found in the config file.

Currently, supported types of data are: wxString, `long`, `double`, `bool`, wxColour and any other types for which the functions wxToString() and wxFromString() are defined.

Try not to read long values into string variables and vice versa: although it just might work with wxFileConfig, you will get a system error with wxRegConfig because in the Windows registry the different types of entries are indeed used.

Final remark: the *szKey* parameter for all these functions can contain an arbitrary path (either relative or absolute), not just the key name.

wxConfigPathChanger

Public Types

- enum EntryType {
  Type_Unknown,
  Type_String,
  Type_Boolean,
  Type_Integer,
  Type_Float }

Public Member Functions

- wxConfigBase (const wxString &appName=wxEmptyString, const wxString &vendorName=wxEmptyString, const wxString &localFilename=wxEmptyString, const wxString &globalFilename=wxEmptyString, long style=0, const wxMBConv &conv=wxConvAuto())

  This is the default and only constructor of the wxConfigBase class, and derived classes.
- virtual ~wxConfigBase ()

  Empty but ensures that dtor of all derived classes is virtual.

Path Management

See Path Management

- virtual const wxString & GetPath () const =0

  Retrieve the current path (always as absolute path).
- virtual void SetPath (const wxString &strPath)=0

  Set current path: if the first character is '/', it is the absolute path, otherwise it is a relative path.

Enumeration

See Enumeration

- virtual bool GetFirstEntry (wxString &str, long &index) const =0

  Gets the first entry.
- virtual bool GetFirstGroup (wxString &str, long &index) const =0

  Gets the first group.
- virtual bool GetNextEntry (wxString &str, long &index) const =0

  Gets the next entry.
- virtual bool GetNextGroup (wxString &str, long &index) const =0

  Gets the next group.
- virtual size_t GetNumberOfEntries (bool bRecursive=false) const =0

  Get number of entries in the current group.
- virtual size_t GetNumberOfGroups (bool bRecursive=false) const =0

  Get number of entries/subgroups in the current group, with or without its subgroups.

Tests of Existence

- bool Exists (const wxString &strName) const
- virtual wxConfigBase::EntryType GetEntryType (const wxString &name) const

  Returns the type of the given entry or Unknown if the entry doesn't exist.
- virtual bool HasEntry (const wxString &strName) const =0
- virtual bool HasGroup (const wxString &strName) const =0

Miscellaneous Functions

- wxString GetAppName () const

  Returns the application name.
- wxString GetVendorName () const

  Returns the vendor name.

Key Access

See Key Access

- virtual bool Flush (bool bCurrentOnly=false)=0

  Permanently writes all changes (otherwise, they're only written from object's destructor).
- bool Read (const wxString &key, wxString *str) const

  Read a string from the key, returning true if the value was read.
- bool Read (const wxString &key, wxString *str, const wxString &defaultVal) const

  Read a string from the key.

- const wxString Read (const wxString &key, const wxString &defaultVal) const
  Another version of Read(), returning the string value directly.
- bool Read (const wxString &key, long *l) const
  Reads a long value, returning true if the value was found.
- bool Read (const wxString &key, long *l, long defaultVal) const
  Reads a long value, returning true if the value was found.
- bool Read (const wxString &key, double *d) const
  Reads a double value, returning true if the value was found.
- bool Read (const wxString &key, double *d, double defaultVal) const
  Reads a double value, returning true if the value was found.
- bool Read (const wxString &key, float *f) const
  Reads a float value, returning true if the value was found.
- bool Read (const wxString &key, float *f, float defaultVal) const
  Reads a float value, returning true if the value was found.
- bool Read (const wxString &key, bool *b) const
  Reads a boolean value, returning true if the value was found.
- bool Read (const wxString &key, bool *d, bool defaultVal) const
  Reads a boolean value, returning true if the value was found.
- bool Read (const wxString &key, wxMemoryBuffer *buf) const
  Reads a binary block, returning true if the value was found.
- bool Read (const wxString &key, T *value) const
  Reads a value of type T, for which function wxFromString() is defined, returning true if the value was found.
- bool Read (const wxString &key, T *value, const T &defaultVal) const
  Reads a value of type T, for which function wxFromString() is defined, returning true if the value was found.
- bool ReadBool (const wxString &key, bool defaultVal) const
  Reads a bool value from the key and returns it.
- double ReadDouble (const wxString &key, double defaultVal) const
  Reads a double value from the key and returns it.
- long ReadLong (const wxString &key, long defaultVal) const
  Reads a long value from the key and returns it.
- T ReadObject (const wxString &key, T const &defaultVal) const
  Reads a value of type T (for which the function wxFromString() must be defined) from the key and returns it.
- bool Write (const wxString &key, const wxString &value)
  Writes the wxString value to the config file and returns true on success.
- bool Write (const wxString &key, long value)
  Writes the long value to the config file and returns true on success.
- bool Write (const wxString &key, double value)
  Writes the double value to the config file and returns true on success.
- bool Write (const wxString &key, bool value)
  Writes the bool value to the config file and returns true on success.
- bool Write (const wxString &key, const wxMemoryBuffer &buf)
  Writes the wxMemoryBuffer value to the config file and returns true on success.
- bool Write (const wxString &key, T const &buf)
  Writes the specified value to the config file and returns true on success.

Rename Entries/Groups

These functions allow renaming entries or subgroups of the current group.

They will return false on error, typically because either the entry/group with the original name doesn't exist, because the entry/group with the new name already exists or because the function is not supported in this wxConfig implementation.

- virtual bool RenameEntry (const wxString &oldName, const wxString &newName)=0
  Renames an entry in the current group.
- virtual bool RenameGroup (const wxString &oldName, const wxString &newName)=0
  Renames a subgroup of the current group.

Delete Entries/Groups

These functions delete entries and/or groups of entries from the config file.

DeleteAll() is especially useful if you want to erase all traces of your program presence: for example, when you uninstall it.

- virtual bool DeleteAll ()=0
  Delete the whole underlying object (disk file, registry key, ...).
- virtual bool DeleteEntry (const wxString &key, bool bDeleteGroupIfEmpty=true)=0
  Deletes the specified entry and the group it belongs to if it was the last key in it and the second parameter is true.
- virtual bool DeleteGroup (const wxString &key)=0
  Delete the group (with all subgroups).

Options

Some aspects of wxConfigBase behaviour can be changed during run-time.

The first of them is the expansion of environment variables in the string values read from the config file: for example, if you have the following in your config file:

```
# config file for my program
UserData = $HOME/data

# the following syntax is valid only under Windows
UserData = %windir%\\data.dat
```

The call to Read("UserData") will return something like "`/home/zeitlin/data`" on linux for example.

Although this feature is very useful, it may be annoying if you read a value which contains '$' or '' symbols (% is used for environment variables expansion under Windows) which are not used for environment variable expansion. In this situation you may call SetExpandEnvVars(false) just before reading this value and SetExpandEnvVars(true) just after. Another solution would be to prefix the offending symbols with a backslash.

- bool IsExpandingEnvVars () const
  Returns true if we are expanding environment variables in key values.
- bool IsRecordingDefaults () const
  Returns true if we are writing defaults back to the config file.
- void SetExpandEnvVars (bool bDoIt=true)
  Determine whether we wish to expand environment variables in key values.
- void SetRecordDefaults (bool bDoIt=true)
  Sets whether defaults are recorded to the config file whenever an attempt to read the value which is not present in it is done.

Static Public Member Functions

- static wxConfigBase * Create ()
  Create a new config object and sets it as the current one.
- static void DontCreateOnDemand ()
  Calling this function will prevent Get() from automatically creating a new config object if the current one is NULL.
- static wxConfigBase * Get (bool CreateOnDemand=true)
  Get the current config object.
- static wxConfigBase * Set (wxConfigBase *pConfig)
  Sets the config object as the current one, returns the pointer to the previous current object (both the parameter and returned value may be NULL).

Additional Inherited Members

21.117.7 Member Enumeration Documentation

enum wxConfigBase::EntryType

Enumerator

Type_Unknown

Type_String

Type_Boolean

Type_Integer

Type_Float

21.117.8 Constructor & Destructor Documentation

wxConfigBase::wxConfigBase (const wxString & *appName* = wxEmptyString, const wxString & *vendorName* = wxEmptyString, const wxString & *localFilename* = wxEmptyString, const wxString & *globalFilename* = wxEmptyString, long *style* = 0, const wxMBConv & *conv* = wxConvAuto())

This is the default and only constructor of the wxConfigBase class, and derived classes.

Parameters

appName	The application name. If this is empty, the class will normally use wxApp::GetAppName() to set it. The application name is used in the registry key on Windows, and can be used to deduce the local filename parameter if that is missing.
vendorName	The vendor name. If this is empty, it is assumed that no vendor name is wanted, if this is optional for the current config class. The vendor name is appended to the application name for wxRegConfig.
localFilename	Some config classes require a local filename. If this is not present, but required, the application name will be used instead.
globalFilename	Some config classes require a global filename. If this is not present, but required, the application name will be used instead.
style	Can be one of wxCONFIG_USE_LOCAL_FILE and wxCONFIG_USE_GLOBAL_FILE. The style interpretation depends on the config class and is ignored by some implementations. For wxFileConfig, these styles determine whether a local or global config file is created or used: if wxCONFIG_USE_GLOBAL_FILE is used, then settings are read from the global config file and if wxCONFIG_USE_LOCAL_FILE is used, settings are read from and written to local config file (if they are both set, global file is read first, then local file, overwriting global settings). If the flag is present but the parameter is empty, the parameter will be set to a default. If the parameter is present but the style flag not, the relevant flag will be added to the style. For wxRegConfig, the GLOBAL flag refers to the HKLM key while LOCAL one is for the usual HKCU one. For wxFileConfig you can also add wxCONFIG_USE_RELATIVE_PATH by logically or'ing it to either of the _FILE options to tell wxFileConfig to use relative instead of absolute paths. On non-VMS Unix systems, the default local configuration file is "~/.appname". However, this path may be also used as user data directory (see wxStandardPaths::GetUserDataDir()) if the application has several data files. In this case wxCONFIG_USE_SUBDIR flag, which changes the default local configuration file to "~/.appname/appname" should be used. Notice that this flag is ignored if *localFilename* is provided. wxCONFIG_USE_SUBDIR is new since wxWidgets version 2.8.2. For wxFileConfig, you can also add wxCONFIG_USE_NO_ESCAPE_CHARACTERS which will turn off character escaping for the values of entries stored in the config file: for example a foo key with some backslash characters will be stored as "foo=C:\mydir" instead of the usual storage of "foo=C:\\mydir". The wxCONFIG_USE_NO_ESCAPE_CHARACTERS style can be helpful if your config file must be read or written to by a non-wxWidgets program (which might not understand the escape characters). Note, however, that if wxCONFIG_USE_NO_ESCAPE_CHARACTERS style is used, it is now your application's responsibility to ensure that there is no newline or other illegal characters in a value, before writing that value to the file.

conv	This parameter is only used by wxFileConfig when compiled in Unicode mode. It specifies the encoding in which the configuration file is written.

Remarks

By default, environment variable expansion is on and recording defaults is off.

virtual wxConfigBase::~wxConfigBase ( ) [virtual]

Empty but ensures that dtor of all derived classes is virtual.

21.117.9 Member Function Documentation

static wxConfigBase* wxConfigBase::Create ( ) [static]

Create a new config object and sets it as the current one.

This function will create the most appropriate implementation of wxConfig available for the current platform. By default this means that the system registry will be used for storing the configuration information under MSW and a file under the user home directory (see wxStandardPaths::GetUserConfigDir()) elsewhere.

If you prefer to use the configuration files everywhere, you can define `wxUSE_CONFIG_NATIVE` to 0 when compiling wxWidgets. Or you can simply always create wxFileConfig explicitly.

Finally, if you want to create a custom wxConfig subclass you may change this function behaviour by overriding wxAppTraits::CreateConfig() to create it. An example when this could be useful could be an application which could be installed either normally (in which case the default behaviour of using wxRegConfig is appropriate) or in a "portable" way in which case a wxFileConfig with a file in the program directory would be used and the choice would be done in CreateConfig() at run-time.

virtual bool wxConfigBase::DeleteAll ( ) [pure virtual]

Delete the whole underlying object (disk file, registry key, ...).

Primarily for use by uninstallation routine.

Implemented in wxFileConfig.

virtual bool wxConfigBase::DeleteEntry (const wxString & *key*, bool *bDeleteGroupIfEmpty* = `true`) [pure virtual]

Deletes the specified entry and the group it belongs to if it was the last key in it and the second parameter is true.

Implemented in wxFileConfig.

virtual bool wxConfigBase::DeleteGroup (const wxString & *key*) [pure virtual]

Delete the group (with all subgroups).

If the current path is under the group being deleted it is changed to its deepest still existing component. E.g. if the current path is `"/A/B/C/D"` and the group `C` is deleted, the path becomes `"/A/B"`.

Implemented in wxFileConfig.

static void wxConfigBase::DontCreateOnDemand ( ) [static]

Calling this function will prevent *Get()* from automatically creating a new config object if the current one is NULL.

It might be useful to call it near the program end to prevent "accidental" creation of a new config object.

bool wxConfigBase::Exists (const wxString & *strName*) const

Returns

true if either a group or an entry with a given name exists.

virtual bool wxConfigBase::Flush (bool *bCurrentOnly* = `false`) [pure virtual]

Permanently writes all changes (otherwise, they're only written from object's destructor).

Implemented in wxFileConfig.

static wxConfigBase* wxConfigBase::Get (bool *CreateOnDemand* = `true`) [static]

Get the current config object.

If there is no current object and *CreateOnDemand* is true, this creates one (using Create()) unless DontCreateOn↩Demand() was called previously.

wxString wxConfigBase::GetAppName ( ) const

Returns the application name.

virtual wxConfigBase::EntryType wxConfigBase::GetEntryType (const wxString & *name*) const [virtual]

Returns the type of the given entry or *Unknown* if the entry doesn't exist.

This function should be used to decide which version of Read() should be used because some of wxConfig implementations will complain about type mismatch otherwise: e.g., an attempt to read a string value from an integer key with wxRegConfig will fail.

virtual bool wxConfigBase::GetFirstEntry (wxString & *str,* long & *index*) const [pure virtual]

Gets the first entry.

wxPerl Note: In wxPerl this method takes no parameters and returns a 3-element list (continue_flag, string, index↩_for_getnextentry).

Implemented in wxFileConfig.

virtual bool wxConfigBase::GetFirstGroup (wxString & *str,* long & *index*) const [pure virtual]

Gets the first group.

wxPerl Note: In wxPerl this method takes no parameters and returns a 3-element list (continue_flag, string, index↩_for_getnextentry).

Implemented in wxFileConfig.

virtual bool wxConfigBase::GetNextEntry (wxString & *str,* long & *index*) const [pure virtual]

Gets the next entry.

wxPerl Note: In wxPerl this method only takes the *index* parameter and returns a 3-element list (continue_flag, string, index_for_getnextentry).

Implemented in wxFileConfig.

virtual bool wxConfigBase::GetNextGroup (wxString & *str,* long & *index*) const `[pure virtual]`

Gets the next group.

wxPerl Note: In wxPerl this method only takes the *index* parameter and returns a 3-element list (continue_flag, string, index_for_getnextentry).

Implemented in wxFileConfig.

virtual size_t wxConfigBase::GetNumberOfEntries (bool *bRecursive* = `false`) const `[pure virtual]`

Get number of entries in the current group.

Implemented in wxFileConfig.

virtual size_t wxConfigBase::GetNumberOfGroups (bool *bRecursive* = `false`) const `[pure virtual]`

Get number of entries/subgroups in the current group, with or without its subgroups.

Implemented in wxFileConfig.

virtual const wxString& wxConfigBase::GetPath ( ) const `[pure virtual]`

Retrieve the current path (always as absolute path).

Implemented in wxFileConfig.

wxString wxConfigBase::GetVendorName ( ) const

Returns the vendor name.

virtual bool wxConfigBase::HasEntry (const wxString & *strName*) const `[pure virtual]`

Returns

true if the entry by this name exists.

Implemented in wxFileConfig.

virtual bool wxConfigBase::HasGroup (const wxString & *strName*) const `[pure virtual]`

Returns

true if the group by this name exists.

Implemented in wxFileConfig.

bool wxConfigBase::IsExpandingEnvVars ( ) const

Returns true if we are expanding environment variables in key values.

bool wxConfigBase::IsRecordingDefaults ( ) const

Returns true if we are writing defaults back to the config file.

bool wxConfigBase::Read (const wxString & *key,* wxString * *str*) const

Read a string from the key, returning true if the value was read.

If the key was not found, *str* is not changed.

wxPerl Note: Not supported by wxPerl.

bool wxConfigBase::Read (const wxString & *key,* wxString * *str,* const wxString & *defaultVal*) const

Read a string from the key.

The default value is returned if the key was not found.

Returns

true if value was really read, false if the default was used.

wxPerl Note: Not supported by wxPerl.

const wxString wxConfigBase::Read (const wxString & *key,* const wxString & *defaultVal*) const

Another version of Read(), returning the string value directly.

wxPerl Note: In wxPerl, this can be called as:

- Read(key): returns the empty string if no key is found
- Read(key, default): returns the default value if no key is found

bool wxConfigBase::Read (const wxString & *key,* long * *l*) const

Reads a long value, returning true if the value was found.

If the value was not found, *l* is not changed.

wxPerl Note: Not supported by wxPerl.

bool wxConfigBase::Read (const wxString & *key,* long * *l,* long *defaultVal*) const

Reads a long value, returning true if the value was found.

If the value was not found, *defaultVal* is used instead.

wxPerl Note: In wxPerl, this can be called as:

- ReadInt(key): returns the 0 if no key is found
- ReadInt(key, default): returns the default value if no key is found

bool wxConfigBase::Read (const wxString & *key,* double * *d*) const

Reads a double value, returning true if the value was found.

If the value was not found, *d* is not changed.

wxPerl Note: Not supported by wxPerl.

bool wxConfigBase::Read (const wxString & *key,* double * *d,* double *defaultVal*) const

Reads a double value, returning true if the value was found.

If the value was not found, *defaultVal* is used instead.

wxPerl Note: In wxPerl, this can be called as:

- ReadFloat(key): returns the 0.0 if no key is found
- ReadFloat(key, default): returns the default value if no key is found

bool wxConfigBase::Read (const wxString & *key,* float * *f*) const

Reads a float value, returning true if the value was found.

If the value was not found, *f* is not changed.

Notice that the value is read as a double but must be in a valid range for floats for the function to return true.

Since

2.9.1

wxPerl Note: Not supported by wxPerl.

bool wxConfigBase::Read (const wxString & *key,* float * *f,* float *defaultVal*) const

Reads a float value, returning true if the value was found.

If the value was not found, *defaultVal* is used instead.

Notice that the value is read as a double but must be in a valid range for floats for the function to return true.

Since

2.9.1

wxPerl Note: Not supported by wxPerl.

bool wxConfigBase::Read (const wxString & *key,* bool * *b*) const

Reads a boolean value, returning true if the value was found.

If the value was not found, *b* is not changed.

Since

2.9.1

wxPerl Note: Not supported by wxPerl.

bool wxConfigBase::Read (const wxString & *key,* bool * *d,* bool *defaultVal*) const

Reads a boolean value, returning true if the value was found.

If the value was not found, *defaultVal* is used instead.

wxPerl Note: In wxPerl, this can be called as:

- ReadBool(key): returns false if no key is found
- ReadBool(key, default): returns the default value if no key is found

bool wxConfigBase::Read (const wxString & *key,* wxMemoryBuffer * *buf*) const

Reads a binary block, returning true if the value was found.

If the value was not found, *buf* is not changed.

bool wxConfigBase::Read (const wxString & *key,* T * *value*) const

Reads a value of type T, for which function wxFromString() is defined, returning true if the value was found.

If the value was not found, *value* is not changed.

bool wxConfigBase::Read (const wxString & *key,* T * *value,* const T & *defaultVal*) const

Reads a value of type T, for which function wxFromString() is defined, returning true if the value was found.

If the value was not found, *defaultVal* is used instead.

bool wxConfigBase::ReadBool (const wxString & *key,* bool *defaultVal*) const

Reads a bool value from the key and returns it.

defaultVal is returned if the key is not found.

double wxConfigBase::ReadDouble (const wxString & *key,* double *defaultVal*) const

Reads a double value from the key and returns it.

defaultVal is returned if the key is not found.

long wxConfigBase::ReadLong (const wxString & *key,* long *defaultVal*) const

Reads a long value from the key and returns it.

defaultVal is returned if the key is not found.

T wxConfigBase::ReadObject (const wxString & *key,* T const & *defaultVal*) const

Reads a value of type T (for which the function wxFromString() must be defined) from the key and returns it.

defaultVal is returned if the key is not found.

virtual bool wxConfigBase::RenameEntry (const wxString & *oldName,* const wxString & *newName*) [pure virtual]

Renames an entry in the current group.

The entries names (both the old and the new one) shouldn't contain backslashes, i.e. only simple names and not arbitrary paths are accepted by this function.

Returns

false if *oldName* doesn't exist or if *newName* already exists.

Implemented in wxFileConfig.

virtual bool wxConfigBase::RenameGroup (const wxString & *oldName,* const wxString & *newName*) [pure virtual]

Renames a subgroup of the current group.

The subgroup names (both the old and the new one) shouldn't contain backslashes, i.e. only simple names and not arbitrary paths are accepted by this function.

Returns

false if *oldName* doesn't exist or if *newName* already exists.

Implemented in wxFileConfig.

static wxConfigBase* wxConfigBase::Set (wxConfigBase * *pConfig*) [static]

Sets the config object as the current one, returns the pointer to the previous current object (both the parameter and returned value may be NULL).

void wxConfigBase::SetExpandEnvVars (bool *bDoIt* = true)

Determine whether we wish to expand environment variables in key values.

virtual void wxConfigBase::SetPath (const wxString & *strPath*) [pure virtual]

Set current path: if the first character is '/', it is the absolute path, otherwise it is a relative path.

'..' is supported. If *strPath* doesn't exist, it is created.

See also

wxConfigPathChanger

Implemented in wxFileConfig.

void wxConfigBase::SetRecordDefaults (bool *bDoIt* = true)

Sets whether defaults are recorded to the config file whenever an attempt to read the value which is not present in it is done.

If on (default is off) all default values for the settings used by the program are written back to the config file. This allows the user to see what config options may be changed and is probably useful only for wxFileConfig.

bool wxConfigBase::Write (const wxString & *key,* const wxString & *value*)

Writes the wxString value to the config file and returns true on success.

bool wxConfigBase::Write (const wxString & *key,* long *value*)

Writes the long value to the config file and returns true on success.

bool wxConfigBase::Write (const wxString & *key*, double *value*)

Writes the double value to the config file and returns true on success.

Notice that if floating point numbers are saved as strings (as is the case with the configuration files used by wxFileConfig), this function uses the C locale for writing out the number, i.e. it will always use a period as the decimal separator, irrespectively of the current locale. This behaviour is new since wxWidgets 2.9.1 as the current locale was used before, but the change should be transparent because both C and current locales are tried when reading the numbers back.

bool wxConfigBase::Write (const wxString & *key*, bool *value*)

Writes the bool value to the config file and returns true on success.

bool wxConfigBase::Write (const wxString & *key*, const wxMemoryBuffer & *buf*)

Writes the wxMemoryBuffer value to the config file and returns true on success.

bool wxConfigBase::Write (const wxString & *key*, T const & *buf*)

Writes the specified value to the config file and returns true on success.

The function wxToString() must be defined for type *T*.

21.118 wxConfigPathChanger Class Reference

`#include <wx/config.h>`

21.118.1 Detailed Description

A handy little class which changes the current path in a wxConfig object and restores it in dtor.

Declaring a local variable of this type, it's possible to work in a specific directory and ensure that the path is automatically restored when the function returns.

For example:

```
// this function loads somes settings from the given wxConfig object;
// the path selected inside it is left unchanged
bool LoadMySettings(wxConfigBase* cfg)
{
    wxConfigPathChanger changer(cfg, "/Foo/Data/SomeString");
    wxString str;
    if ( !config->Read("SomeString", &str) ) {
        wxLogError("Couldn't read SomeString!");
        return false;
            // NOTE: without wxConfigPathChanger it would be easy to forget to
            //       set the old path back into the wxConfig object before this return!
    }

    // do something useful with SomeString...

    return true;    // again: wxConfigPathChanger dtor will restore the original wxConfig path
}
```

Library: wxBase

Category: Application and System configuration

Public Member Functions

- wxConfigPathChanger (const wxConfigBase *pContainer, const wxString &strEntry)

  Changes the path of the given wxConfigBase object so that the key strEntry is accessible (for read or write).

- ~wxConfigPathChanger ()

  Restores the path selected, inside the wxConfig object passed to the ctor, to the path which was selected when the wxConfigPathChanger ctor was called.

- const wxString & Name () const

  Returns the name of the key which was passed to the ctor.

- void UpdateIfDeleted ()

  This method must be called if the original path inside the wxConfig object (i.e.

21.118.2 Constructor & Destructor Documentation

wxConfigPathChanger::wxConfigPathChanger (const wxConfigBase * *pContainer,* const wxString & *strEntry*)

Changes the path of the given wxConfigBase object so that the key *strEntry* is accessible (for read or write).

In other words, the ctor uses wxConfigBase::SetPath() with everything which precedes the last slash of *strEntry*, so that:

```
wxConfigPathChanger(wxConfigBase::Get(), "/MyProgram/SomeKeyName");
```

has the same effect of:

```
wxConfigPathChanger(wxConfigBase::Get(), "/MyProgram/");
```

wxConfigPathChanger::~wxConfigPathChanger ( )

Restores the path selected, inside the wxConfig object passed to the ctor, to the path which was selected when the wxConfigPathChanger ctor was called.

21.118.3 Member Function Documentation

const wxString& wxConfigPathChanger::Name ( ) const

Returns the name of the key which was passed to the ctor.

The "name" is just anything which follows the last slash of the string given to the ctor.

void wxConfigPathChanger::UpdateIfDeleted ( )

This method must be called if the original path inside the wxConfig object (i.e.

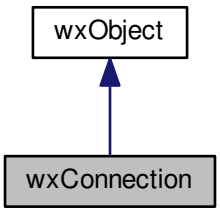
the current path at the moment of creation of this wxConfigPathChanger object) could have been deleted, thus preventing wxConfigPathChanger from restoring the not existing (any more) path.

If the original path doesn't exist any more, the path will be restored to the deepest still existing component of the old path.

21.119 wxConnection Class Reference

`#include <wx/ipc.h>`

Inheritance diagram for wxConnection:



21.119.1 Detailed Description

A wxConnection object represents the connection between a client and a server.

It is created by making a connection using a wxClient object, or by the acceptance of a connection by a wxServer object.

The bulk of a DDE-like (Dynamic Data Exchange) conversation is controlled by calling members in a **wxConnection** object or by overriding its members. The actual DDE-based implementation using wxDDEConnection is available on Windows only, but a platform-independent, socket-based version of this API is available using wxTCPConnection, which has the same API.

An application should normally derive a new connection class from wxConnection, in order to override the communication event handlers to do something interesting.

Library: wxBase

Category: Interprocess Communication

See also

wxClient, wxServer, Interprocess Communication

Public Member Functions

- bool Disconnect ()

  Called by the client or server application to disconnect from the other program; it causes the OnDisconnect() message to be sent to the corresponding connection object in the other program.
- virtual bool OnAdvise (const wxString &topic, const wxString &item, const void *data, size_t size, wxIPC↩ Format format)

  Message sent to the client application when the server notifies it of a change in the data associated with the given item, using Advise().
- virtual bool OnDisconnect ()

  Message sent to the client or server application when the other application notifies it to end the connection.
- virtual bool OnExec (const wxString &topic, const wxString &data)

Message sent to the server application when the client notifies it to execute the given data, using Execute().

- virtual bool OnPoke (const wxString &topic, const wxString &item, const void ∗data, size_t size, wxIPCFormat format)

  Message sent to the server application when the client notifies it to accept the given data.
- virtual const void ∗ OnRequest (const wxString &topic, const wxString &item, size_t ∗size, wxIPCFormat format)

  Message sent to the server application when the client calls Request().
- virtual bool OnStartAdvise (const wxString &topic, const wxString &item)

  Message sent to the server application by the client, when the client wishes to start an 'advise loop' for the given topic and item.
- virtual bool OnStopAdvise (const wxString &topic, const wxString &item)

  Message sent to the server application by the client, when the client wishes to stop an 'advise loop' for the given topic and item.
- const void ∗ Request (const wxString &item, size_t ∗size, wxIPCFormat format=wxIPC_TEXT)

  Called by the client application to request data from the server.
- bool StartAdvise (const wxString &item)

  Called by the client application to ask if an advise loop can be started with the server.
- bool StopAdvise (const wxString &item)

  Called by the client application to ask if an advise loop can be stopped.

- wxConnection ()

  Constructs a connection object.
- wxConnection (void ∗buffer, size_t size)

  Constructs a connection object.

- bool Advise (const wxString &item, const void ∗data, size_t size, wxIPCFormat format=wxIPC_PRIVATE)

  Called by the server application to advise the client of a change in the data associated with the given item.
- bool Advise (const wxString &item, const char ∗data)

  Called by the server application to advise the client of a change in the data associated with the given item.
- bool Advise (const wxString &item, const wchar_t ∗data)

  Called by the server application to advise the client of a change in the data associated with the given item.
- bool Advise (const wxString &item, const wxString data)

  Called by the server application to advise the client of a change in the data associated with the given item.

- bool Execute (const void ∗data, size_t size, wxIPCFormat format=wxIPC_PRIVATE)

  Called by the client application to execute a command on the server.
- bool Execute (const char ∗data)

  Called by the client application to execute a command on the server.
- bool Execute (const wchar_t ∗data)

  Called by the client application to execute a command on the server.
- bool Execute (const wxString data)

  Called by the client application to execute a command on the server.

- bool Poke (const wxString &item, const void ∗data, size_t size, wxIPCFormat format=wxIPC_PRIVATE)

  Called by the client application to poke data into the server.
- bool Poke (const wxString &item, const char ∗data)

  Called by the client application to poke data into the server.
- bool Poke (const wxString &item, const wchar_t ∗data)

  Called by the client application to poke data into the server.
- bool Poke (const wxString &item, const wxString data)

  Called by the client application to poke data into the server.

Static Public Member Functions

- static bool IsTextFormat (wxIPCFormat format)

  Returns true if the format is one of the text formats.
- static wxString GetTextFromData (const void ∗data, size_t size, wxIPCFormat format)

  Returns the data in any of the text formats as string.

Additional Inherited Members

21.119.2 Constructor & Destructor Documentation

wxConnection::wxConnection ( )

Constructs a connection object.

If no user-defined connection object is to be derived from wxConnection, then the constructor should not be called directly, since the default connection object will be provided on requesting (or accepting) a connection.

However, if the user defines his or her own derived connection object, the wxServer::OnAcceptConnection and/or wxClient::OnMakeConnection members should be replaced by functions which construct the new connection object.

If the arguments of the wxConnection constructor are void then the wxConnection object manages its own connection buffer, allocating memory as needed. A programmer-supplied buffer cannot be increased if necessary, and the program will assert if it is not large enough.

The programmer-supplied buffer is included mainly for backwards compatibility.

wxConnection::wxConnection (void ∗ *buffer,* size_t *size*)

Constructs a connection object.

If no user-defined connection object is to be derived from wxConnection, then the constructor should not be called directly, since the default connection object will be provided on requesting (or accepting) a connection.

However, if the user defines his or her own derived connection object, the wxServer::OnAcceptConnection and/or wxClient::OnMakeConnection members should be replaced by functions which construct the new connection object.

If the arguments of the wxConnection constructor are void then the wxConnection object manages its own connection buffer, allocating memory as needed. A programmer-supplied buffer cannot be increased if necessary, and the program will assert if it is not large enough.

The programmer-supplied buffer is included mainly for backwards compatibility.

21.119.3 Member Function Documentation

bool wxConnection::Advise (const wxString & *item,* const void ∗ *data,* size_t *size,* wxIPCFormat *format* = wxIPC_PRIVATE)

Called by the server application to advise the client of a change in the data associated with the given item.

Causes the client connection's OnAdvise() member to be called.

Returns

true if successful.

bool wxConnection::Advise (const wxString & *item,* const char ∗ *data*)

Called by the server application to advise the client of a change in the data associated with the given item.

Causes the client connection's OnAdvise() member to be called.

Returns

true if successful.

bool wxConnection::Advise (const wxString & *item,* const wchar_t * *data*)

Called by the server application to advise the client of a change in the data associated with the given item.

Causes the client connection's OnAdvise() member to be called.

Returns

true if successful.

bool wxConnection::Advise (const wxString & *item,* const wxString *data*)

Called by the server application to advise the client of a change in the data associated with the given item.

Causes the client connection's OnAdvise() member to be called.

Returns

true if successful.

bool wxConnection::Disconnect ( )

Called by the client or server application to disconnect from the other program; it causes the OnDisconnect() message to be sent to the corresponding connection object in the other program.

Returns true if successful or already disconnected. The application that calls Disconnect() must explicitly delete its side of the connection.

bool wxConnection::Execute (const void * *data,* size_t *size,* wxIPCFormat *format* = wxIPC_PRIVATE)

Called by the client application to execute a command on the server.

Can also be used to transfer arbitrary data to the server (similar to Poke() in that respect). Causes the server connection's OnExec() member to be called. Returns true if successful.

bool wxConnection::Execute (const char * *data*)

Called by the client application to execute a command on the server.

Can also be used to transfer arbitrary data to the server (similar to Poke() in that respect). Causes the server connection's OnExec() member to be called. Returns true if successful.

bool wxConnection::Execute (const wchar_t * *data*)

Called by the client application to execute a command on the server.

Can also be used to transfer arbitrary data to the server (similar to Poke() in that respect). Causes the server connection's OnExec() member to be called. Returns true if successful.

bool wxConnection::Execute (const wxString *data*)

Called by the client application to execute a command on the server.

Can also be used to transfer arbitrary data to the server (similar to Poke() in that respect). Causes the server connection's OnExec() member to be called. Returns true if successful.

static wxString wxConnection::GetTextFromData (const void * *data*, size_t *size*, wxIPCFormat *format*) [static]

Returns the data in any of the text formats as string.

Parameters

data	The raw data pointer as used with any of the other methods of this class.
size	The size of the data buffer pointed to by *data*.
format	The format of the data. It must be a text one, i.e. such that IsTextFormat() returns true for it.

Returns

The string representation of the data. If the format is not text, an assertion failure is triggered and empty string is returned.

static bool wxConnection::IsTextFormat (wxIPCFormat *format*) [static]

Returns true if the format is one of the text formats.

The text formats are wxIPC_TEXT, wxIPC_UNICODETEXT and wxIPC_UTF8TEXT.

virtual bool wxConnection::OnAdvise (const wxString & *topic*, const wxString & *item*, const void * *data*, size_t *size*, wxIPCFormat *format*) [virtual]

Message sent to the client application when the server notifies it of a change in the data associated with the given item, using Advise().

virtual bool wxConnection::OnDisconnect ( ) [virtual]

Message sent to the client or server application when the other application notifies it to end the connection.

The default behaviour is to delete the connection object and return true, so applications should generally override OnDisconnect() (finally calling the inherited method as well) so that they know the connection object is no longer available.

virtual bool wxConnection::OnExec (const wxString & *topic*, const wxString & *data*) [virtual]

Message sent to the server application when the client notifies it to execute the given data, using Execute().

Note that there is no item associated with this message.

virtual bool wxConnection::OnPoke (const wxString & *topic*, const wxString & *item*, const void * *data*, size_t *size*, wxIPCFormat *format*) [virtual]

Message sent to the server application when the client notifies it to accept the given data.

virtual const void* wxConnection::OnRequest (const wxString & *topic,* const wxString & *item,* size_t * *size,* wxIPCFormat *format*) [virtual]

Message sent to the server application when the client calls Request().

The server's OnRequest() method should respond by returning a character string, or NULL to indicate no data, and setting *size.

The character string must of course persist after the call returns.

virtual bool wxConnection::OnStartAdvise (const wxString & *topic,* const wxString & *item*) [virtual]

Message sent to the server application by the client, when the client wishes to start an 'advise loop' for the given topic and item.

The server can refuse to participate by returning false.

virtual bool wxConnection::OnStopAdvise (const wxString & *topic,* const wxString & *item*) [virtual]

Message sent to the server application by the client, when the client wishes to stop an 'advise loop' for the given topic and item.

The server can refuse to stop the advise loop by returning false, although this doesn't have much meaning in practice.

bool wxConnection::Poke (const wxString & *item,* const void * *data,* size_t *size,* wxIPCFormat *format =* wxIPC_PRIVATE)

Called by the client application to poke data into the server.

Can be used to transfer arbitrary data to the server. Causes the server connection's OnPoke() member to be called. If size is -1 the size is computed from the string length of data.

Returns true if successful.

bool wxConnection::Poke (const wxString & *item,* const char * *data*)

Called by the client application to poke data into the server.

Can be used to transfer arbitrary data to the server. Causes the server connection's OnPoke() member to be called. If size is -1 the size is computed from the string length of data.

Returns true if successful.

bool wxConnection::Poke (const wxString & *item,* const wchar_t * *data*)

Called by the client application to poke data into the server.

Can be used to transfer arbitrary data to the server. Causes the server connection's OnPoke() member to be called. If size is -1 the size is computed from the string length of data.

Returns true if successful.

bool wxConnection::Poke (const wxString & *item,* const wxString *data*)

Called by the client application to poke data into the server.

Can be used to transfer arbitrary data to the server. Causes the server connection's OnPoke() member to be called. If size is -1 the size is computed from the string length of data.

Returns true if successful.

const void* wxConnection::Request (const wxString & *item*, size_t * *size*, wxIPCFormat *format* = wxIPC_TEXT)

Called by the client application to request data from the server.

Causes the server connection's OnRequest() member to be called. Size may be NULL or a pointer to a variable to receive the size of the requested item.

Returns a character string (actually a pointer to the connection's buffer) if successful, NULL otherwise. This buffer does not need to be deleted.

bool wxConnection::StartAdvise (const wxString & *item*)

Called by the client application to ask if an advise loop can be started with the server.

Causes the server connection's OnStartAdvise() member to be called. Returns true if the server okays it, false otherwise.

bool wxConnection::StopAdvise (const wxString & *item*)

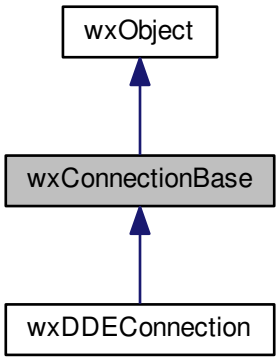
Called by the client application to ask if an advise loop can be stopped.

Causes the server connection's OnStopAdvise() member to be called. Returns true if the server okays it, false otherwise.

21.120 wxConnectionBase Class Reference

`#include <wx/ipcbase.h>`

Inheritance diagram for wxConnectionBase:



21.120.1 Detailed Description

Todo Document this class.

This class provides base, common functionality shared between wxDDEConnection, and wxTCPConnection.

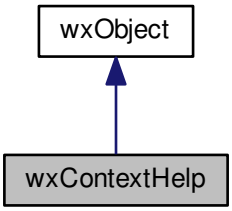
21.121 wxContextHelp Class Reference

`#include <wx/cshelp.h>`

Inheritance diagram for wxContextHelp:



21.121.1 Detailed Description

This class changes the cursor to a query and puts the application into a 'context-sensitive help mode'.

When the user left-clicks on a window within the specified window, a `wxEVT_HELP` event is sent to that control, and the application may respond to it by popping up some help.

For example:

```
wxContextHelp contextHelp(myWindow);
```

There are a couple of ways to invoke this behaviour implicitly:

- Use the wxDIALOG_EX_CONTEXTHELP style for a dialog (Windows only). This will put a question mark in the titlebar, and Windows will put the application into context-sensitive help mode automatically, with further programming.
- Create a wxContextHelpButton, whose predefined behaviour is to create a context help object. Normally you will write your application so that this button is only added to a dialog for non-Windows platforms (use wxDIALOG_EX_CONTEXTHELP on Windows).

Note that on Mac OS X, the cursor does not change when in context-sensitive help mode.

Library: wxCore

Category: Help

See also

wxHelpEvent, wxHelpController, wxContextHelpButton

Public Member Functions

- wxContextHelp (wxWindow *window=NULL, bool doNow=true)

  Constructs a context help object, calling BeginContextHelp() if doNow is true (the default).
- virtual ~wxContextHelp ()

  Destroys the context help object.
- bool BeginContextHelp (wxWindow *window)

  Puts the application into context-sensitive help mode.
- bool EndContextHelp ()

  Ends context-sensitive help mode.

Additional Inherited Members

21.121.2 Constructor & Destructor Documentation

wxContextHelp::wxContextHelp (wxWindow * *window* = `NULL`, bool *doNow* = `true`)

Constructs a context help object, calling BeginContextHelp() if *doNow* is true (the default).

If *window* is NULL, the top window is used.

virtual wxContextHelp::~wxContextHelp ( ) `[virtual]`

Destroys the context help object.

21.121.3 Member Function Documentation

bool wxContextHelp::BeginContextHelp (wxWindow * *window*)

Puts the application into context-sensitive help mode.

window is the window which will be used to catch events; if NULL, the top window will be used.

Returns true if the application was successfully put into context-sensitive help mode. This function only returns when the event loop has finished.

bool wxContextHelp::EndContextHelp ( )

Ends context-sensitive help mode.

Not normally called by the application.

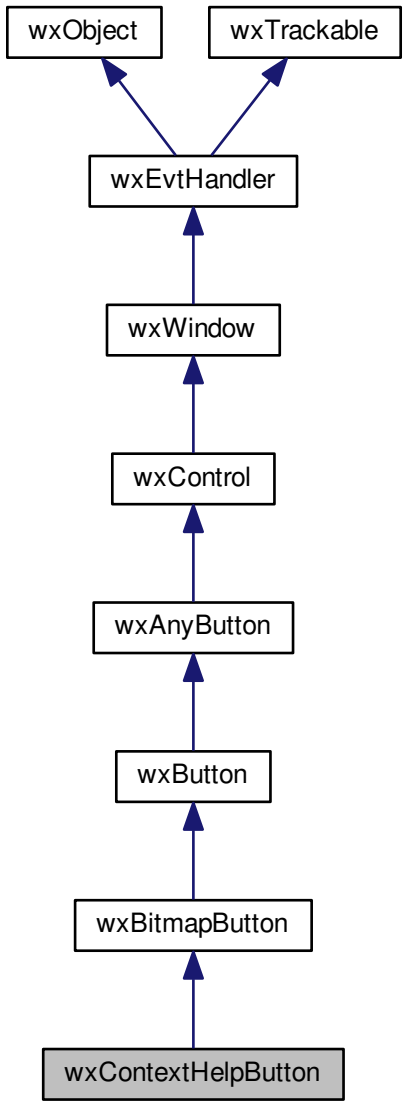
Inheritance diagram for wxContextHelpButton:



21.122.1 Detailed Description

Instances of this class may be used to add a question mark button that when pressed, puts the application into context-help mode.

It does this by creating a wxContextHelp object which itself generates a `wxEVT_HELP` event when the user clicks on a window.

On Windows, you may add a question-mark icon to a dialog by use of the wxDIALOG_EX_CONTEXTHELP extra style, but on other platforms you will have to add a button explicitly, usually next to OK, Cancel or similar buttons.

Library: wxCore

Category: Help

wxBitmapButton, wxContextHelp

Public Member Functions

- wxContextHelpButton (wxWindow *parent, wxWindowID id=wxID_CONTEXT_HELP, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, long style=wxBU_AUTODRAW)

  Constructor, creating and showing a context help button.

Additional Inherited Members

21.122.2 Constructor & Destructor Documentation

wxContextHelpButton::wxContextHelpButton (wxWindow * *parent*, wxWindowID *id* = wxID_CONTEXT_HELP, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, long *style* = wxBU_AUTODRAW)

Constructor, creating and showing a context help button.

Parameters

parent	Parent window. Must not be NULL.
id	Button identifier. Defaults to wxID_CONTEXT_HELP.
pos	Button position. If wxDefaultPosition is specified then a default position is chosen.
size	Button size. If wxDefaultSize is specified then the button is sized appropriately for the question mark bitmap.
style	Window style.

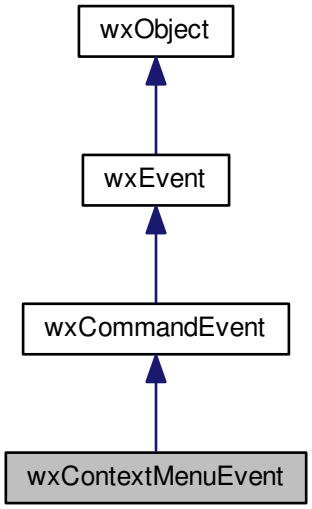
Remarks

Normally you only need pass the parent window to the constructor, and use the defaults for the remaining parameters.

21.123 wxContextMenuEvent Class Reference

`#include <wx/event.h>`

Inheritance diagram for wxContextMenuEvent:



21.123.1 Detailed Description

This class is used for context menu events, sent to give the application a chance to show a context (popup) menu for a wxWindow.

Note that if wxContextMenuEvent::GetPosition returns wxDefaultPosition, this means that the event originated from a keyboard context button event, and you should compute a suitable position yourself, for example by calling wx↩GetMousePosition().

Notice that the exact sequence of mouse events is different across the platforms. For example, under MSW the context menu event is generated after `EVT_RIGHT_UP` event and only if it was not handled but under GTK the context menu event is generated after `EVT_RIGHT_DOWN` event. This is correct in the sense that it ensures that the context menu is shown according to the current platform UI conventions and also means that you must not handle (or call wxEvent::Skip() in your handler if you do have one) neither right mouse down nor right mouse up event if you plan on handling `EVT_CONTEXT_MENU` event.

Events using this class

The following event handler macros redirect the events to member function handlers '**func**' with prototypes like: void handlerFuncName(wxContextMenuEvent& event)

Event macros:

- EVT_CONTEXT_MENU(func): A right click (or other context menu command depending on platform) has been detected.

Library: wxCore

Category: Events

wxCommandEvent, Events and Event Handling

Public Member Functions

- wxContextMenuEvent (wxEventType type=wxEVT_NULL, int id=0, const wxPoint &pos=wxDefaultPosition)

  Constructor.
- const wxPoint & GetPosition () const

  Returns the position in screen coordinates at which the menu should be shown.
- void SetPosition (const wxPoint &point)

  Sets the position at which the menu should be shown.

Additional Inherited Members

21.123.2 Constructor & Destructor Documentation

wxContextMenuEvent::wxContextMenuEvent (wxEventType *type* = wxEVT_NULL, int *id* = 0, const wxPoint & *pos* = wxDefaultPosition)

Constructor.

21.123.3 Member Function Documentation

const wxPoint& wxContextMenuEvent::GetPosition ( ) const

Returns the position in screen coordinates at which the menu should be shown.

Use wxWindow::ScreenToClient to convert to client coordinates.

You can also omit a position from wxWindow::PopupMenu in order to use the current mouse pointer position.

If the event originated from a keyboard event, the value returned from this function will be wxDefaultPosition.

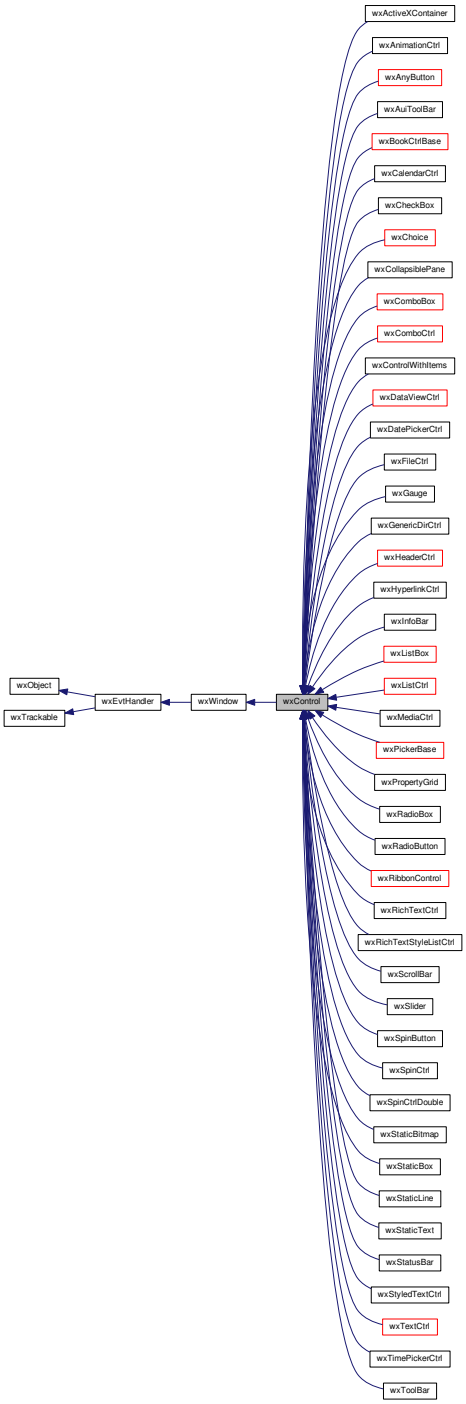
void wxContextMenuEvent::SetPosition (const wxPoint & *point*)

Sets the position at which the menu should be shown.

21.124 wxControl Class Reference

```
#include <wx/control.h>
```

Inheritance diagram for wxControl:



21.124.1 Detailed Description

This is the base class for a control or "widget".

A control is generally a small window which processes user input and/or displays one or more item of data.

Events emitted by this class

The following event handler macros redirect the events to member function handlers '**func**' with prototypes like: void handlerFuncName(wxClipboardTextEvent& event)

Event macros for events emitted by this class:

- EVT_TEXT_COPY(id, func): Some or all of the controls content was copied to the clipboard.
- EVT_TEXT_CUT(id, func): Some or all of the controls content was cut (i.e. copied and deleted).
- EVT_TEXT_PASTE(id, func): Clipboard content was pasted into the control.

Library: wxCore

Category: Controls

wxValidator

Public Member Functions

- wxControl (wxWindow *parent, wxWindowID id, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, long style=0, const wxValidator &validator=wxDefaultValidator, const wxString &name=wxControlNameStr)

  Constructs a control.
- wxControl ()

  Default constructor to allow 2-phase creation.
- bool Create (wxWindow *parent, wxWindowID id, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, long style=0, const wxValidator &validator=wxDefaultValidator, const wxString &name=wxControlNameStr)
- virtual void Command (wxCommandEvent &event)

  Simulates the effect of the user issuing a command to the item.
- wxString GetLabel () const

  Returns the control's label, as it was passed to SetLabel().
- wxString GetLabelText () const

  Returns the control's label without mnemonics.
- wxSize GetSizeFromTextSize (int xlen, int ylen=-1) const

  Determine the size needed by the control to leave the given area for its text.
- wxSize GetSizeFromTextSize (const wxSize &tsize) const

  This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.
- void SetLabel (const wxString &label)

  Sets the control's label.
- void SetLabelText (const wxString &text)

  Sets the control's label to exactly the given string.
- bool SetLabelMarkup (const wxString &markup)

  Sets the controls label to a string using markup.

Static Public Member Functions

- static wxString GetLabelText (const wxString &label)

  Returns the given label string without mnemonics ("&" characters).

- static wxString RemoveMnemonics (const wxString &str)

  Returns the given str string without mnemonics ("&" characters).

- static wxString EscapeMnemonics (const wxString &text)

  Escapes the special mnemonics characters ("&") in the given string.

- static wxString Ellipsize (const wxString &label, const wxDC &dc, wxEllipsizeMode mode, int maxWidth, int flags=wxELLIPSIZE_FLAGS_DEFAULT)

  Replaces parts of the label string with ellipsis, if needed, so that it fits into maxWidth pixels if possible.

Additional Inherited Members

21.124.2 Constructor & Destructor Documentation

wxControl::wxControl (wxWindow * *parent*, wxWindowID *id*, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, long *style* = 0, const wxValidator & *validator* = wxDefaultValidator, const wxString & *name* = wxControlNameStr)

Constructs a control.

Parameters

parent	Pointer to a parent window.
id	Control identifier. If wxID_ANY, will automatically create an identifier.
pos	Control position. wxDefaultPosition indicates that wxWidgets should generate a default position for the control.
size	Control size. wxDefaultSize indicates that wxWidgets should generate a default size for the window. If no suitable size can be found, the window will be sized to 20x20 pixels so that the window is visible but obviously not correctly sized.
style	Control style. For generic window styles, please see wxWindow.
validator	Control validator.
name	Control name.

wxControl::wxControl ( )

Default constructor to allow 2-phase creation.

21.124.3 Member Function Documentation

virtual void wxControl::Command (wxCommandEvent & *event*) [virtual]

Simulates the effect of the user issuing a command to the item.

See also

wxCommandEvent

Reimplemented in wxRichTextCtrl.

bool wxControl::Create (wxWindow * *parent*, wxWindowID *id*, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, long *style* = 0, const wxValidator & *validator* = wxDefaultValidator, const wxString & *name* = wxControlNameStr)

static wxString wxControl::Ellipsize (const wxString & *label*, const wxDC & *dc*, wxEllipsizeMode *mode*, int *maxWidth*, int *flags* = wxELLIPSIZE_FLAGS_DEFAULT) [static]

Replaces parts of the *label* string with ellipsis, if needed, so that it fits into *maxWidth* pixels if possible.

Note that this function does *not* guarantee that the returned string will always be shorter than *maxWidth*; if *maxWidth* is extremely small, ellipsized text may be larger.

Parameters

label	The string to ellipsize
dc	The DC used to retrieve the character widths through the wxDC::GetPartialTextExtents() function.
mode	The ellipsization mode. This is the setting which determines which part of the string should be replaced by the ellipsis. See wxEllipsizeMode enumeration values for more info.
maxWidth	The maximum width of the returned string in pixels. This argument determines how much characters of the string need to be removed (and replaced by ellipsis).
flags	One or more of the wxEllipsizeFlags enumeration values combined.

static wxString wxControl::EscapeMnemonics (const wxString & *text*) [static]

Escapes the special mnemonics characters ("&") in the given string.

This function can be helpful if you need to set the controls label to a user-provided string. If the string contains ampersands, they wouldn't appear on the display but be used instead to indicate that the character following the first of them can be used as a control mnemonic. While this can sometimes be desirable (e.g. to allow the user to configure mnemonics of the controls), more often you will want to use this function before passing a user-defined string to SetLabel(). Alternatively, if the label is entirely user-defined, you can just call SetLabelText() directly – but this function must be used if the label is a combination of a part defined by program containing the control mnemonics and a user-defined part.

Parameters

text	The string such as it should appear on the display.

Returns

The same string with the ampersands in it doubled.

wxString wxControl::GetLabel ( ) const [virtual]

Returns the control's label, as it was passed to SetLabel().

Note that the returned string may contains mnemonics ("&" characters) if they were passed to the SetLabel() function; use GetLabelText() if they are undesired.

Also note that the returned string is always the string which was passed to SetLabel() but may be different from the string passed to SetLabelText() (since this last one escapes mnemonic characters).

Reimplemented from wxWindow.

wxString wxControl::GetLabelText ( ) const

Returns the control's label without mnemonics.

Note that because of the stripping of the mnemonics the returned string may differ from the string which was passed to SetLabel() but should always be the same which was passed to SetLabelText().

static wxString wxControl::GetLabelText (const wxString & *label*) [static]

Returns the given *label* string without mnemonics ("&" characters).

wxSize wxControl::GetSizeFromTextSize (int *xlen*, int *ylen* = -1) const

Determine the size needed by the control to leave the given area for its text.

This function is mostly useful with control displaying short amounts of text that can be edited by the user, e.g. wxTextCtrl, wxComboBox, wxSearchCtrl etc. Typically it is used to size these controls for the maximal amount of input they are supposed to contain, for example:

```
// Create a control for post code entry.
wxTextCtrl* postcode = new wxTextCtrl(this, ...);

// And set its initial and minimal size to be big enough for
// entering 5 digits.
postcode->SetInitialSize(
    postcode->GetSizeFromTextSize(
        postcode->GetTextExtent("99999")));
```

Currently this method is only implemented for wxTextCtrl, wxComboBox and wxChoice in wxMSW and wxGTK.

Parameters

xlen	The horizontal extent of the area to leave for text, in pixels.
ylen	The vertical extent of the area to leave for text, in pixels. By default -1 meaning that the vertical component of the returned size should be the default height of this control.

Returns

The size that the control should have to leave the area of the specified size for its text. May return wxDefaultSize if this method is not implemented for this particular control under the current platform.

Since

2.9.5

wxSize wxControl::GetSizeFromTextSize (const wxSize & *tsize*) const

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.

static wxString wxControl::RemoveMnemonics (const wxString & *str*) [static]

Returns the given *str* string without mnemonics ("&" characters).

Note

This function is identical to GetLabelText() and is provided mostly for symmetry with EscapeMnemonics().

void wxControl::SetLabel (const wxString & *label*) `[virtual]`

Sets the control's label.

All "&" characters in the *label* are special and indicate that the following character is a *mnemonic* for this control and can be used to activate it from the keyboard (typically by using *Alt* key in combination with it). To insert a literal ampersand character, you need to double it, i.e. use "&&". If this behaviour is undesirable, use SetLabelText() instead.

Reimplemented from wxWindow.

bool wxControl::SetLabelMarkup (const wxString & *markup*)

Sets the controls label to a string using markup.

Simple markup supported by this function can be used to apply different fonts or colours to different parts of the control label when supported. If markup is not supported by the control or platform, it is simply stripped and SetLabel() is used with the resulting string.

For example,

```
wxStaticText *text;
...
text->SetLabelMarkup("<b>&amp;amp;Bed</b> &amp;amp;mp; "
                     "<span foreground='red'>breakfast</span> "
                     "available <big>HERE</big>");
```

would show the string using bold, red and big for the corresponding words under wxGTK but will simply show the string "Bed & breakfast available HERE" on the other platforms. In any case, the "B" of "Bed" will be underlined to indicate that it can be used as a mnemonic for this control.

The supported tags are:

Tag	Description
<b>	bold text
<big>	bigger text
<i>	italic text
<s>	strike-through text
<small>	smaller text
<tt>	monospaced text
<u>	underlined text
	generic formatter tag, see the table below for supported attributes.

Supported attributes:

Name	Description
foreground, fgcolor, color	Foreground text colour, can be a name or RGB value.
background, bgcolor	Background text colour, can be a name or RGB value.
font_family, face	Font face name.
font_weight, weight	Numeric value in 0..900 range or one of "ultralight", "light", "normal" (all meaning non-bold), "bold", "ultrabold" and "heavy" (all meaning bold).
font_style, style	Either "oblique" or "italic" (both with the same meaning) or "normal".
size	The font size can be specified either as "smaller" or "larger" relatively to the current font, as a CSS font size name ("xx-small", "x-small", "small", "medium", "large", "x-large" or "xx-large") or as a number giving font size in 1024th parts of a point, i.e. 10240 for a 10pt font.

This markup language is a strict subset of Pango markup (described at http://library.gnome.org/devel/pango/unstable/PangoMarkupFormat.html) and any tags and span attributes not

documented above can't be used under non-GTK platforms.

Also note that you need to escape the following special characters:

Special character	Escape as
&	& or as &&
'	&apos;
"	&quot;
<	&lt;
>	&gt;

The non-escaped ampersand & characters are interpreted as mnemonics as with wxControl::SetLabel.

Parameters

markup	String containing markup for the label. It may contain markup tags described above and newline characters but currently only wxGTK and wxOSX support multiline labels with markup, the generic implementation (also used in wxMSW) only handles single line markup labels. Notice that the string must be well-formed (e.g. all tags must be correctly closed) and won't be shown at all otherwise.

Returns

true if the new label was set (even if markup in it was ignored) or false if we failed to parse the markup. In this case the label remains unchanged.

Currently wxButton supports markup in all major ports (wxMSW, wxGTK and wxOSX/Cocoa) while wxStaticText supports it in wxGTK and wxOSX and its generic version (which can be used under MSW if markup support is required). Extending support to more controls is planned in the future.

Since

2.9.2

void wxControl::SetLabelText (const wxString & *text*)

Sets the control's label to exactly the given string.

Unlike SetLabel(), this function shows exactly the *text* passed to it in the control, without interpreting ampersands in it in any way. Notice that it means that the control can't have any mnemonic defined for it using this function.

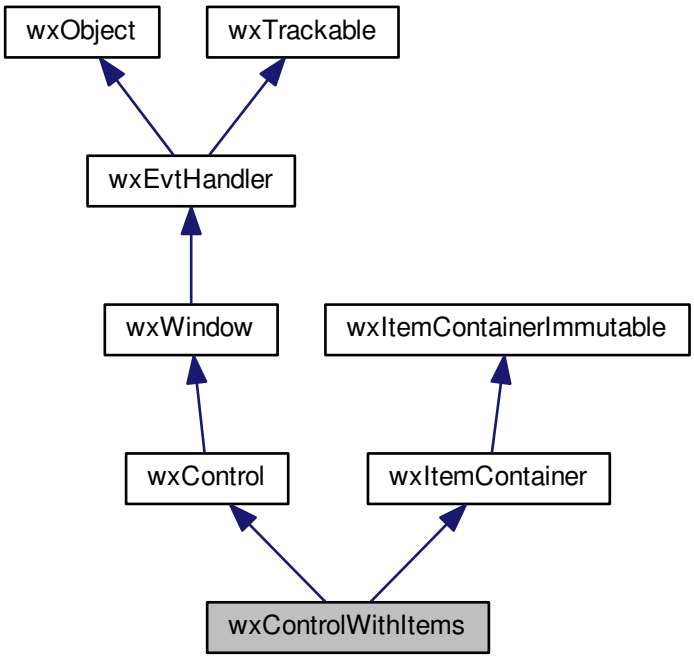
EscapeMnemonics()

21.125 wxControlWithItems Class Reference

`#include <wx/ctrlsub.h>`

Inheritance diagram for wxControlWithItems:



21.125.1 Detailed Description

This is convenience class that derives from both wxControl and wxItemContainer.

It is used as basis for some wxWidgets controls (wxChoice and wxListBox).

Library: wxCore

Category: Controls

See also

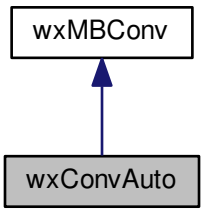
wxItemContainer, wxItemContainerImmutable

Additional Inherited Members

21.126 wxConvAuto Class Reference

`#include <wx/convauto.h>`

Inheritance diagram for wxConvAuto:



21.126.1 Detailed Description

This class implements a Unicode to/from multibyte converter capable of automatically recognizing the encoding of the multibyte text on input.

The logic used is very simple: the class uses the BOM (byte order mark) if it's present and tries to interpret the input as UTF-8 otherwise. If this fails, the input is interpreted as being in the default multibyte encoding which can be specified in the constructor of a wxConvAuto instance and, in turn, defaults to the value of GetFallbackEncoding() if not explicitly given.

For the conversion from Unicode to multibyte, the same encoding as was previously used for multibyte to Unicode conversion is reused. If there had been no previous multibyte to Unicode conversion, UTF-8 is used by default. Notice that once the multibyte encoding is automatically detected, it doesn't change any more, i.e. it is entirely determined by the first use of wxConvAuto object in the multibyte-to-Unicode direction. However creating a copy of wxConvAuto object, either via the usual copy constructor or assignment operator, or using wxMBConv::Clone(), resets the automatically detected encoding so that the new copy will try to detect the encoding of the input on first use.

This class is used by default in wxWidgets classes and functions reading text from files such as wxFile, wxFFile, wxTextFile, wxFileConfig and various stream classes so the encoding set with its SetFallbackEncoding() method will affect how these classes treat input files. In particular, use this method to change the fall-back multibyte encoding used to interpret the contents of the files whose contents isn't valid UTF-8 or to disallow it completely.

Library: wxBase

Category: Data Structures

See also

wxMBConv Overview

Public Member Functions

- wxConvAuto (wxFontEncoding enc=wxFONTENCODING_DEFAULT)

  Constructs a new wxConvAuto instance.

- wxBOM GetBOM () const

  Return the detected BOM type.
- const char * GetBOMChars (wxBOM bom, size_t *count)

  Return a pointer to the characters that makes up this BOM.

Static Public Member Functions

- static void DisableFallbackEncoding ()

  Disable the use of the fall back encoding: if the input doesn't have a BOM and is not valid UTF-8, the conversion will fail.
- static wxFontEncoding GetFallbackEncoding ()

  Returns the encoding used by default by wxConvAuto if no other encoding is explicitly specified in constructor.
- static void SetFallbackEncoding (wxFontEncoding enc)

  Changes the encoding used by default by wxConvAuto if no other encoding is explicitly specified in constructor.
- static wxBOM DetectBOM (const char *src, size_t srcLen)

  Return the BOM type of this buffer.

21.126.2 Constructor & Destructor Documentation

wxConvAuto::wxConvAuto (wxFontEncoding *enc* = wxFONTENCODING_DEFAULT)

Constructs a new wxConvAuto instance.

The object will try to detect the input of the multibyte text given to its wxMBConv::ToWChar() method automatically but if the automatic detection of Unicode encodings fails, the fall-back encoding *enc* will be used to interpret it as multibyte text.

The default value of *enc*, `wxFONTENCODING_DEFAULT`, means that the global default value (which can be set using SetFallbackEncoding()) should be used. As with that method, passing `wxFONTENCODING_MAX` inhibits using this encoding completely so the input multibyte text will always be interpreted as UTF-8 in the absence of BOM and the conversion will fail if the input doesn't form valid UTF-8 sequence.

Another special value is `wxFONTENCODING_SYSTEM` which means to use the encoding currently used on the user system, i.e. the encoding returned by wxLocale::GetSystemEncoding(). Any other encoding will be used as is, e.g. passing `wxFONTENCODING_ISO8859_1` ensures that non-UTF-8 input will be treated as latin1.

21.126.3 Member Function Documentation

static wxBOM wxConvAuto::DetectBOM (const char * *src*, size_t *srcLen*) `[static]`

Return the BOM type of this buffer.

This is a helper function which is normally only used internally by wxConvAuto but provided for convenience of the code that wants to detect the encoding of a stream by checking it for BOM presence on its own.

Since

2.9.3

static void wxConvAuto::DisableFallbackEncoding ( ) `[static]`

Disable the use of the fall back encoding: if the input doesn't have a BOM and is not valid UTF-8, the conversion will fail.

wxBOM wxConvAuto::GetBOM ( ) const

Return the detected BOM type.

The BOM type is detected after sufficiently many initial bytes have passed through this conversion object so it will always return wxBOM_Unknown immediately after the object creation but may return a different value later.

Since

2.9.3

const char* wxConvAuto::GetBOMChars (wxBOM *bom*, size_t * *count*)

Return a pointer to the characters that makes up this BOM.

The returned character count is 2, 3 or 4, or undefined if the return value is NULL.

Parameters

bom	A valid BOM type, i.e. not wxBOM_Unknown or wxBOM_None.
count	A non-NULL pointer receiving the number of characters in this BOM.

Returns

Pointer to characters composing the BOM or NULL if BOM is unknown or invalid. Notice that the returned string is not NUL-terminated and may contain embedded NULs so *count* must be used to handle it correctly.

Since

2.9.3

static wxFontEncoding wxConvAuto::GetFallbackEncoding ( ) [static]

Returns the encoding used by default by wxConvAuto if no other encoding is explicitly specified in constructor.

By default, returns `wxFONTENCODING_ISO8859_1` but can be changed using SetFallbackEncoding().

static void wxConvAuto::SetFallbackEncoding (wxFontEncoding *enc*) [static]

Changes the encoding used by default by wxConvAuto if no other encoding is explicitly specified in constructor.

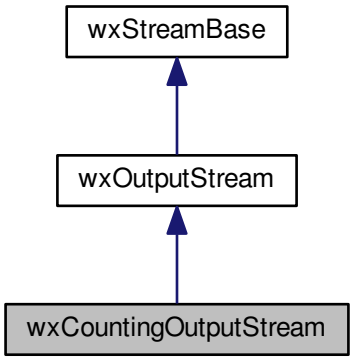
The default value, which can be retrieved using GetFallbackEncoding(), is `wxFONTENCODING_ISO8859_1`.

Special values of `wxFONTENCODING_SYSTEM` or `wxFONTENCODING_MAX` can be used for the *enc* parameter to use the encoding of the current user locale as fall back or not use any encoding for fall back at all, respectively (just as with the similar constructor parameter). However, `wxFONTENCODING_DEFAULT` can't be used here.

21.127 wxCountingOutputStream Class Reference

`#include <wx/stream.h>`

Inheritance diagram for wxCountingOutputStream:



21.127.1 Detailed Description

wxCountingOutputStream is a specialized output stream which does not write any data anywhere, instead it counts how many bytes would get written if this were a normal stream.

This can sometimes be useful or required if some data gets serialized to a stream or compressed by using stream compression and thus the final size of the stream cannot be known other than pretending to write the stream. One case where the resulting size would have to be known is if the data has to be written to a piece of memory and the memory has to be allocated before writing to it (which is probably always the case when writing to a memory stream).

Library: wxBase

Category: Streams

Public Member Functions

- wxCountingOutputStream ()

  Creates a wxCountingOutputStream object.
- virtual ~wxCountingOutputStream ()

  Destructor.
- virtual wxFileOffset GetLength () const

  Returns the current length of the stream.

Additional Inherited Members

21.127.2 Constructor & Destructor Documentation

wxCountingOutputStream::wxCountingOutputStream ( )

Creates a wxCountingOutputStream object.

virtual wxCountingOutputStream::~wxCountingOutputStream ( ) [virtual]

Destructor.

21.127.3 Member Function Documentation

virtual wxFileOffset wxCountingOutputStream::GetLength ( ) const [virtual]

Returns the current length of the stream.

This is the amount of data written to the stream so far, in bytes.

Reimplemented from wxStreamBase.

21.128 wxCriticalSection Class Reference

`#include <wx/thread.h>`

21.128.1 Detailed Description

A critical section object is used for exactly the same purpose as a wxMutex.

The only difference is that under Windows platform critical sections are only visible inside one process, while mutexes may be shared among processes, so using critical sections is slightly more efficient.

The terminology is also slightly different: mutex may be locked (or acquired) and unlocked (or released) while critical section is entered and left by the program.

Finally, you should try to use wxCriticalSectionLocker class whenever possible instead of directly using wxCriticalSection for the same reasons wxMutexLocker is preferable to wxMutex - please see wxMutex for an example.

Library: wxBase

Category: Threading

Note

Critical sections can be used before the wxWidgets library is fully initialized. In particular, it's safe to create global wxCriticalSection instances.

See also

wxThread, wxCondition, wxCriticalSectionLocker

Public Member Functions

- wxCriticalSection (wxCriticalSectionType critSecType=wxCRITSEC_DEFAULT)

  Default constructor initializes critical section object.
- ~wxCriticalSection ()

  Destructor frees the resources.
- void Enter ()

  Enter the critical section (same as locking a mutex): if another thread has already entered it, this call will block until the other thread calls Leave().

- bool TryEnter ()

  Try to enter the critical section (same as trying to lock a mutex).

- void Leave ()

  Leave the critical section allowing other threads use the global data protected by it.

21.128.2 Constructor & Destructor Documentation

wxCriticalSection::wxCriticalSection (wxCriticalSectionType *critSecType* = wxCRITSEC_DEFAULT)

Default constructor initializes critical section object.

By default critical sections are recursive under Unix and Windows.

wxCriticalSection::~wxCriticalSection ( )

Destructor frees the resources.

21.128.3 Member Function Documentation

void wxCriticalSection::Enter ( )

Enter the critical section (same as locking a mutex): if another thread has already entered it, this call will block until the other thread calls Leave().

There is no error return for this function.

After entering the critical section protecting a data variable, the thread running inside the critical section may safely use/modify it.

Note that entering the same critical section twice or more from the same thread doesn't result in a deadlock; in this case in fact this function will immediately return.

void wxCriticalSection::Leave ( )

Leave the critical section allowing other threads use the global data protected by it.

There is no error return for this function.

bool wxCriticalSection::TryEnter ( )

Try to enter the critical section (same as trying to lock a mutex).

If it can't, immediately returns false.

Since

2.9.3

21.129 wxCriticalSectionLocker Class Reference

`#include <wx/thread.h>`

21.129.1 Detailed Description

This is a small helper class to be used with wxCriticalSection objects.

A wxCriticalSectionLocker enters the critical section in the constructor and leaves it in the destructor making it much more difficult to forget to leave a critical section (which, in general, will lead to serious and difficult to debug problems).

Example of using it:

```
void Set Foo()
{
    // gs_critSect is some (global) critical section guarding access to the
    // object "foo"
    wxCriticalSectionLocker locker(gs_critSect);

    if ( ... )
    {
        // do something
        ...

        return;
    }

    // do something else
    ...

    return;
}
```

Without wxCriticalSectionLocker, you would need to remember to manually leave the critical section before each `return`.

Library: wxBase

Category: Threading

See also

wxCriticalSection, wxMutexLocker

Public Member Functions

- wxCriticalSectionLocker (wxCriticalSection &criticalsection)

  Constructs a wxCriticalSectionLocker object associated with given criticalsection and enters it.
- ~wxCriticalSectionLocker ()

  Destructor leaves the critical section.

21.129.2 Constructor & Destructor Documentation

wxCriticalSectionLocker::wxCriticalSectionLocker (wxCriticalSection & *criticalsection*)

Constructs a wxCriticalSectionLocker object associated with given *criticalsection* and enters it.

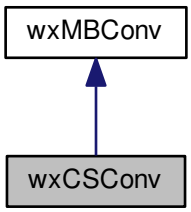
wxCriticalSectionLocker::~wxCriticalSectionLocker ( )

Destructor leaves the critical section.

21.130 wxCSConv Class Reference

`#include <wx/strconv.h>`

Inheritance diagram for wxCSConv:



21.130.1 Detailed Description

This class converts between any character set supported by the system and Unicode.

Please notice that this class uses system-provided conversion functions, e.g. `MultiByteToWideChar()` and `WideCharToMultiByte()` under MSW and `iconv(3)` under Unix systems and as such may support different encodings and different encoding names on different platforms (although all relatively common encodings are supported should be supported everywhere).

It has one predefined instance, **wxConvLocal**, for the default user character set.

Library: wxBase

Category: Text Conversion

wxMBConv, wxEncodingConverter, wxMBConv Overview

Public Member Functions

- wxCSConv (const wxString &charset)

  Constructor.
- wxCSConv (wxFontEncoding encoding)

  Constructor.
- bool IsOk () const

  Returns true if the charset (or the encoding) given at constructor is really available to use.

Additional Inherited Members

21.130.2 Constructor & Destructor Documentation

wxCSConv::wxCSConv (const wxString & *charset*)

Constructor.

You can specify the name of the character set you want to convert from/to. If the character set name is not recognized, ISO 8859-1 is used as fall back, use IsOk() to test for this.

Parameters

charset	The name of the encoding, shouldn't be empty.

wxCSConv::wxCSConv (wxFontEncoding *encoding*)

Constructor.

You can specify an encoding constant for the character set you want to convert from/to. Use IsOk() after construction to check whether the encoding is supported by the current system.

Parameters

encoding	Any valid (i.e. not wxFONTENCODING_MAX) font encoding.

21.130.3 Member Function Documentation

bool wxCSConv::IsOk ( ) const

Returns true if the charset (or the encoding) given at constructor is really available to use.

Returns false if ISO 8859-1 will be used instead.

Note this does not mean that a given string will be correctly converted. A malformed string may still make conversion functions return `wxCONV_FAILED`.

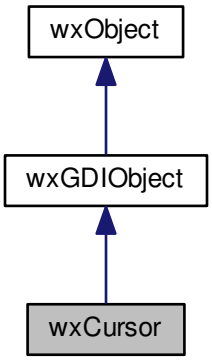
Since

2.8.2

21.131 wxCursor Class Reference

```
#include <wx/cursor.h>
```

Inheritance diagram for wxCursor:



21.131.1 Detailed Description

A cursor is a small bitmap usually used for denoting where the mouse pointer is, with a picture that might indicate the interpretation of a mouse click.

As with icons, cursors in X and MS Windows are created in a different manner. Therefore, separate cursors will be created for the different environments. Platform-specific methods for creating a wxCursor object are catered for, and this is an occasion where conditional compilation will probably be required (see wxIcon for an example).

A single cursor object may be used in many windows (any subwindow type). The wxWidgets convention is to set the cursor for a window, as in X, rather than to set it globally as in MS Windows, although a global wxSetCursor() function is also available for MS Windows use.

21.131.2 Creating a Custom Cursor

The following is an example of creating a cursor from 32x32 bitmap data (down_bits) and a mask (down_mask) where 1 is black and 0 is white for the bits, and 1 is opaque and 0 is transparent for the mask. It works on Windows and GTK+.

```
static char down_bits[] = { 255, 255, 255, 255, 31,
    255, 255, 255, 31, 255, 255, 255, 31, 255, 255, 255,
    31, 255, 255, 255, 31, 255, 255, 255, 31, 255, 255,
    255, 31, 255, 255, 255, 31, 255, 255, 255, 25, 243,
    255, 255, 19, 249, 255, 255, 7, 252, 255, 255, 15, 254,
    255, 255, 31, 255, 255, 255, 191, 255, 255, 255, 255,
    255, 255, 255, 255, 255, 255, 255, 255, 255, 255, 255,
    255, 255, 255, 255, 255, 255, 255, 255, 255, 255, 255,
    255, 255, 255, 255, 255, 255, 255, 255, 255, 255, 255,
    255, 255, 255, 255, 255, 255, 255, 255, 255, 255, 255,
    255, 255, 255, 255, 255, 255, 255, 255, 255, 255, 255,
    255, 255, 255, 255, 255, 255, 255, 255, 255, 255, 255,
    255 };

static char down_mask[] = { 240, 1, 0, 0, 240, 1,
    0, 0, 240, 1, 0, 0, 240, 1, 0, 0, 240, 1, 0, 0, 240, 1,
    0, 0, 240, 1, 0, 0, 240, 1, 0, 0, 255, 31, 0, 0, 255,
    31, 0, 0, 254, 15, 0, 0, 252, 7, 0, 0, 248, 3, 0, 0,
    240, 1, 0, 0, 224, 0, 0, 0, 64, 0, 0, 0, 0, 0, 0, 0, 0,
    0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0,
    0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0,
    0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0,
    0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0,
    0, 0, 0, 0, 0 };

#ifdef __WXMSW__
```

```
    wxBitmap down_bitmap(down_bits, 32, 32);
    wxBitmap down_mask_bitmap(down_mask, 32, 32);

    down_bitmap.SetMask(new wxMask(down_mask_bitmap));
    wxImage down_image = down_bitmap.ConvertToImage();
    down_image.SetOption(wxIMAGE_OPTION_CUR_HOTSPOT_X, 6);
    down_image.SetOption(wxIMAGE_OPTION_CUR_HOTSPOT_Y, 14);
    wxCursor down_cursor = wxCursor(down_image);
#elif defined(__WXGTK__) or defined(__WXMOTIF__)
    wxCursor down_cursor = wxCursor(down_bits, 32, 32, 6, 14,
                                    down_mask, wxWHITE, wxBLACK);
#endif
```

  Assignment operator, using reference counting.

Additional Inherited Members

21.131.3 Constructor & Destructor Documentation

wxCursor::wxCursor ( )

Default constructor.

wxCursor::wxCursor (const char *bits[],* int *width,* int *height,* int *hotSpotX* = `-1`, int *hotSpotY* = `-1`, const char *maskBits[]* = `NULL`)

Constructs a cursor by passing an array of bits (XBM data).

The parameters *fg* and *bg* have an effect only on GTK+, and force the cursor to use particular background and foreground colours.

If either *hotSpotX* or *hotSpotY* is -1, the hotspot will be the centre of the cursor image (Motif only).

Parameters

bits	An array of XBM data bits.
width	Cursor width.
height	Cursor height.
hotSpotX	Hotspot x coordinate (relative to the top left of the image).
hotSpotY	Hotspot y coordinate (relative to the top left of the image).
maskBits	Bits for a mask bitmap.

Availability: only available for the wxGTK, wxMotif ports.

wxPerl Note: In wxPerl use Wx::Cursor->newData(bits, width, height, hotSpotX = -1, hotSpotY = -1, maskBits = 0).

wxCursor::wxCursor (const wxString & *cursorName,* wxBitmapType *type* = `wxCURSOR_DEFAULT_TYPE`, int *hotSpotX* = `0`, int *hotSpotY* = `0`)

Constructs a cursor by passing a string resource name or filename.

The arguments *hotSpotX* and *hotSpotY* are only used when there's no hotspot info in the resource/image-file to load (e.g. when using `wxBITMAP_TYPE_ICO` under wxMSW or `wxBITMAP_TYPE_XPM` under wxGTK).

Parameters

cursorName	The name of the resource or the image file to load.
type	Icon type to load. It defaults to `wxCURSOR_DEFAULT_TYPE`, which is a #define associated to different values on different platforms: • under Windows, it defaults to `wxBITMAP_TYPE_CUR_RESOURCE`. Other permitted types under Windows are `wxBITMAP_TYPE_CUR` (to load a cursor from a .cur cursor file), `wxBITMAP_TYPE_ICO` (to load a cursor from a .ico icon file) and `wxBITMAP_TYPE_ANI` (to load a cursor from a .ani icon file). • under MacOS, it defaults to `wxBITMAP_TYPE_MACCURSOR_RESOURCE`; when specifying a string resource name, first the color cursors 'crsr' and then the black/white cursors 'CURS' in the resource chain are scanned through. Note that resource forks are deprecated on OS X so this is only available for legacy reasons and should not be used in new code. • under GTK, it defaults to `wxBITMAP_TYPE_XPM`. See the wxCursor(const wxImage& image) ctor for more info. • under X11, it defaults to `wxBITMAP_TYPE_XPM`. • under Motif, it defaults to `wxBITMAP_TYPE_XBM`.
hotSpotX	Hotspot x coordinate (relative to the top left of the image).
hotSpotY	Hotspot y coordinate (relative to the top left of the image).

wxCursor::wxCursor (**wxStockCursor** *cursorId*)

Constructs a cursor using a cursor identifier.

Parameters

cursorId	A stock cursor identifier. See wxStockCursor.

wxCursor::wxCursor (**const wxImage &** *image*)

Constructs a cursor from a wxImage.

If cursor are monochrome on the current platform, colors with the RGB elements all greater than 127 will be foreground, colors less than this background. The mask (if any) will be used to specify the transparent area.

In wxMSW the foreground will be white and the background black. If the cursor is larger than 32x32 it is resized.

In wxGTK, colour cursors and alpha channel are supported (starting from GTK+ 2.2). Otherwise the two most frequent colors will be used for foreground and background. In any case, the cursor will be displayed at the size of the image.

Under wxMac (Cocoa), large cursors are supported.

Notice that the *image* can define the cursor hot spot. To set it you need to use wxImage::SetOption() with `wxIMAGE_OPTION_CUR_HOTSPOT_X` or `wxIMAGE_OPTION_CUR_HOTSPOT_Y`, e.g.

```
image.SetOption(wxIMAGE_OPTION_CUR_HOTSPOT_X, hotSpotX);
image.SetOption(wxIMAGE_OPTION_CUR_HOTSPOT_X, hotSpotY);
```

wxCursor::wxCursor (**const wxCursor &** *cursor*)

Copy constructor, uses reference counting.

Parameters

cursor	Pointer or reference to a cursor to copy.

virtual wxCursor::~wxCursor ( ) [virtual]

Destroys the cursor.

See reference-counted object destruction for more info.

A cursor can be reused for more than one window, and does not get destroyed when the window is destroyed. wxWidgets destroys all cursors on application exit, although it is best to clean them up explicitly.

21.131.4 Member Function Documentation

wxPoint wxCursor::GetHotSpot ( ) const

Returns the coordinates of the cursor hot spot.

The hot spot is the point at which the mouse is actually considered to be when this cursor is used.

This method is currently only implemented in wxMSW and wxGTK2+ and simply returns wxDefaultPosition in the other ports.

Since

3.1.0

virtual bool wxCursor::IsOk ( ) const [virtual]

Returns true if cursor data is present.

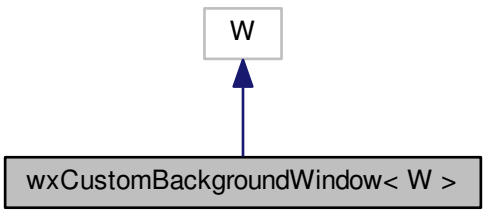
wxCursor& wxCursor::operator= (const wxCursor & *cursor*)

Assignment operator, using reference counting.

21.132 wxCustomBackgroundWindow< W > Class Template Reference

`#include <wx/custombgwin.h>`

Inheritance diagram for wxCustomBackgroundWindow< W >:



21.132.1 Detailed Description

template<class W>class wxCustomBackgroundWindow< W >

A helper class making it possible to use custom background for any window.

wxWindow itself only provides SetBackgroundColour() method taking a (solid) wxColour. This class extends it by allowing to use custom bitmap backgrounds with any window, provided that you inherit from it. Notice that the usual rule of not interfering with event handling or painting of native controls still applies, so you shouldn't try to use custom backgrounds with classes such as wxButton (even if this might work on some platforms, it's not guaranteed to work in general). But you can use this class in conjunction with wxWindow, wxPanel, wxFrame and other similar classes, e.g. the erase sample shows how to use it with wxScrolledWindow:

```
#include "wx/custombgwin.h"

class MyCanvas : public wxCustomBackgroundWindow<wxScrolledWindow>
{
public:
    MyCanvas(wxWindow* parent)
    {
        // Notice that we must explicitly call base class Create()
        // instead of using its ctor as wxCustomBackgroundWindow
        // doesn't define any non-default ctors.
        Create(parent, wxID_ANY);

        ...

        SetBackgroundBitmap(bitmap);
    }
};
```

Category: Miscellaneous Windows

Since

2.9.3

Public Member Functions

- wxCustomBackgroundWindow ()

  Trivial default constructor.
- void SetBackgroundBitmap (const wxBitmap &bmp)

  Set the background bitmap for this window.

21.132.2 Constructor & Destructor Documentation

template<class W > wxCustomBackgroundWindow< W >::wxCustomBackgroundWindow ( )

Trivial default constructor.

21.132.3 Member Function Documentation

template<class W > void wxCustomBackgroundWindow< W >::SetBackgroundBitmap (const wxBitmap & *bmp*)

Set the background bitmap for this window.

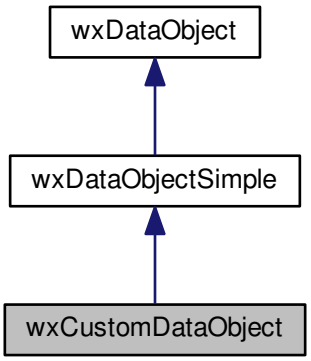
If *bmp* is a valid bitmap, this bitmap will be tiled over the panel background and show through any of its transparent children. Passing an invalid bitmap reverts to the default background appearance.

Notice that you must not prevent the base class EVT_ERASE_BACKGROUND handler from running (i.e. not to handle this event yourself) for this to work.

21.133 wxCustomDataObject Class Reference

`#include <wx/dataobj.h>`

Inheritance diagram for wxCustomDataObject:



21.133.1 Detailed Description

wxCustomDataObject is a specialization of wxDataObjectSimple for some application-specific data in arbitrary (either custom or one of the standard ones).

The only restriction is that it is supposed that this data can be copied bitwise (i.e. with `memcpy()`), so it would be a bad idea to make it contain a C++ object (though C struct is fine).

By default, wxCustomDataObject stores the data inside in a buffer. To put the data into the buffer you may use either SetData() or TakeData() depending on whether you want the object to make a copy of data or not.

This class may be used as is, but if you don't want store the data inside the object but provide it on demand instead, you should override GetSize(), GetData() and SetData() (or may be only the first two or only the last one if you only allow reading/writing the data).

Library: wxCore

Category: Clipboard and Drag & Drop

See also

wxDataObject

Public Member Functions

- wxCustomDataObject (const wxDataFormat &format=wxFormatInvalid)

  The constructor accepts a format argument which specifies the (single) format supported by this object.
- virtual ~wxCustomDataObject ()

  The destructor will free the data held by the object.
- virtual void * Alloc (size_t size)

This function is called to allocate size bytes of memory from SetData().

- virtual void Free ()

  This function is called when the data is freed, you may override it to anything you want (or may be nothing at all).

- virtual void * GetData () const

  Returns a pointer to the data.

- virtual size_t GetSize () const

  Returns the data size in bytes.

- virtual bool SetData (size_t size, const void *data)

  Set the data.

- void TakeData (size_t size, void *data)

  Like SetData(), but doesn't copy the data - instead the object takes ownership of the pointer.

Additional Inherited Members

21.133.2 Constructor & Destructor Documentation

wxCustomDataObject::wxCustomDataObject (const wxDataFormat & *format* = wxFormatInvalid)

The constructor accepts a *format* argument which specifies the (single) format supported by this object.

If it isn't set here, wxDataObjectSimple::SetFormat() should be used.

virtual wxCustomDataObject::~wxCustomDataObject ( ) [virtual]

The destructor will free the data held by the object.

Notice that although it calls the virtual Free() function, the base class version will always be called (C++ doesn't allow calling virtual functions from constructors or destructors), so if you override Free(), you should override the destructor in your class as well (which would probably just call the derived class' version of Free()).

21.133.3 Member Function Documentation

virtual void* wxCustomDataObject::Alloc (size_t *size*) [virtual]

This function is called to allocate *size* bytes of memory from SetData().

The default version just uses the operator new.

virtual void wxCustomDataObject::Free ( ) [virtual]

This function is called when the data is freed, you may override it to anything you want (or may be nothing at all).

The default version calls operator delete[] on the data.

virtual void* wxCustomDataObject::GetData ( ) const [virtual]

Returns a pointer to the data.

virtual size_t wxCustomDataObject::GetSize ( ) const [virtual]

Returns the data size in bytes.

virtual bool wxCustomDataObject::SetData (size_t *size*, const void * *data*) `[virtual]`

Set the data.

The data object will make an internal copy.

Reimplemented from wxDataObjectSimple.

void wxCustomDataObject::TakeData (size_t *size*, void * *data*)

Like SetData(), but doesn't copy the data - instead the object takes ownership of the pointer.

21.134 wxDataFormat Class Reference

`#include <wx/dataobj.h>`

21.134.1 Detailed Description

A wxDataFormat is an encapsulation of a platform-specific format handle which is used by the system for the clipboard and drag and drop operations.

The applications are usually only interested in, for example, pasting data from the clipboard only if the data is in a format the program understands and a data format is something which uniquely identifies this format.

On the system level, a data format is usually just a number (`CLIPFORMAT` under Windows or `Atom` under X11, for example) and the standard formats are, indeed, just numbers which can be implicitly converted to wxDataFormat. The standard formats are:

wxDF_INVALID	An invalid format - used as default argument for functions taking a wxDataFormat argument sometimes.
wxDF_TEXT	Text format (wxString).
wxDF_BITMAP	A bitmap (wxBitmap).
wxDF_METAFILE	A metafile (wxMetafile, Windows only).
wxDF_FILENAME	A list of filenames.
wxDF_HTML	An HTML string. This is currently only valid on Mac and MSW.

As mentioned above, these standard formats may be passed to any function taking wxDataFormat argument because wxDataFormat has an implicit conversion from them (or, to be precise from the type `wxDataFormat::NativeFormat` which is the type used by the underlying platform for data formats).

Aside the standard formats, the application may also use custom formats which are identified by their names (strings) and not numeric identifiers. Although internally custom format must be created (or *registered*) first, you shouldn't care about it because it is done automatically the first time the wxDataFormat object corresponding to a given format name is created. The only implication of this is that you should avoid having global wxDataFormat objects with non-default constructor because their constructors are executed before the program has time to perform all necessary initialisations and so an attempt to do clipboard format registration at this time will usually lead to a crash!

Library: wxCore

Category: Clipboard and Drag & Drop

Drag and Drop Overview, Drag & Drop Sample, wxDataObject

Public Member Functions

- wxDataFormat (wxDataFormatId format=wxDF_INVALID)

  Constructs a data format object for one of the standard data formats or an empty data object (use SetType() or SetId() later in this case).
- wxDataFormat (const wxString &format)

  Constructs a data format object for a custom format identified by its name format.
- wxString GetId () const

  Returns the name of a custom format (this function will fail for a standard format).
- wxDataFormatId GetType () const

  Returns the platform-specific number identifying the format.
- void SetId (const wxString &format)

  Sets the format to be the custom format identified by the given name.
- void SetType (wxDataFormatId type)

  Sets the format to the given value, which should be one of wxDF_XXX constants.
- bool operator!= (const wxDataFormat &format) const

  Returns true if the formats are different.
- bool operator!= (wxDataFormatId format) const

  Returns true if the formats are different.
- bool operator== (const wxDataFormat &format) const

  Returns true if the formats are equal.
- bool operator== (wxDataFormatId format) const

  Returns true if the formats are equal.

21.134.2 Constructor & Destructor Documentation

wxDataFormat::wxDataFormat (wxDataFormatId *format* = wxDF_INVALID)

Constructs a data format object for one of the standard data formats or an empty data object (use SetType() or SetId() later in this case).

wxPerl Note: In wxPerl use Wx::Bitmap->newNative(format).

wxDataFormat::wxDataFormat (const wxString & *format*)

Constructs a data format object for a custom format identified by its name *format*.

wxPerl Note: In wxPerl use Wx::Bitmap->newUser(format).

21.134.3 Member Function Documentation

wxString wxDataFormat::GetId ( ) const

Returns the name of a custom format (this function will fail for a standard format).

wxDataFormatId wxDataFormat::GetType ( ) const

Returns the platform-specific number identifying the format.

bool wxDataFormat::operator!= (const wxDataFormat & *format*) const

Returns true if the formats are different.

bool wxDataFormat::operator!= (wxDataFormatId *format*) const

Returns true if the formats are different.

bool wxDataFormat::operator== (const wxDataFormat & *format*) const

Returns true if the formats are equal.

bool wxDataFormat::operator== (wxDataFormatId *format*) const

Returns true if the formats are equal.

void wxDataFormat::SetId (const wxString & *format*)

Sets the format to be the custom format identified by the given name.

void wxDataFormat::SetType (wxDataFormatId *type*)

Sets the format to the given value, which should be one of wxDF_XXX constants.

21.135 wxDatagramSocket Class Reference

`#include <wx/socket.h>`

  Constructor.
- virtual ~wxDatagramSocket ()

  Destructor.
- wxDatagramSocket & SendTo (const wxSockAddress &address, const void *buffer, wxUint32 nbytes)

  Write a buffer of nbytes bytes to the socket.

Additional Inherited Members

21.135.2 Constructor & Destructor Documentation

wxDatagramSocket::wxDatagramSocket (const wxSockAddress & *addr,* wxSocketFlags *flags* = wxSOCKET_NONE)

Constructor.

Parameters

addr	The socket address.
flags	Socket flags (See wxSocketBase::SetFlags()).

virtual wxDatagramSocket::~wxDatagramSocket ( ) [virtual]

Destructor.

Please see wxSocketBase::Destroy().

21.135.3 Member Function Documentation

wxDatagramSocket& wxDatagramSocket::SendTo (const wxSockAddress & *address,* const void * *buffer,* wxUint32 *nbytes*)

Write a buffer of *nbytes* bytes to the socket.

Use wxSocketBase::LastWriteCount() to verify the number of bytes actually wrote. Use wxSocketBase::Error() to determine if the operation succeeded.

Parameters

address	The address of the destination peer for this data.
buffer	Buffer where read data is.
nbytes	Number of bytes.

Returns

Returns a reference to the current object.

See also

wxSocketBase::LastError(), wxSocketBase::SetFlags()

21.136 wxDataInputStream Class Reference

`#include <wx/datstrm.h>`

21.136.1 Detailed Description

This class provides functions that read binary data types in a portable way.

Please see wxDataOutputStream for the discussion of the format expected by this stream on input, notably for the floating point values.

If you want to read data from text files (or streams) use wxTextInputStream instead.

The ">>" operator is overloaded and you can use this class like a standard C++ iostream. Note, however, that the arguments are the fixed size types wxUint32, wxInt32 etc and on a typical 32-bit computer, none of these match to the "long" type (wxInt32 is defined as signed int on 32-bit architectures) so that you cannot use long. To avoid problems (here and elsewhere), make use of the wxInt32, wxUint32, etc types.

For example:

```
wxFileInputStream input( "mytext.dat" );
wxDataInputStream store( input );
wxUint8 i1;
float f2;
wxString line;

store >> i1;       // read a 8 bit integer.
store >> i1 >> f2; // read a 8 bit integer followed by float.
store >> line;     // read a text line
```

  Constructs a datastream object from an input stream.
- ~wxDataInputStream ()

  Destroys the wxDataInputStream object.
- void BigEndianOrdered (bool be_order)

  If be_order is true, all data will be read in big-endian order, such as written by programs on a big endian architecture (e.g.
- wxMBConv * GetConv () const

  Returns the current text conversion class used for reading strings.
- wxUint8 Read8 ()

  Reads a single byte from the stream.
- void Read8 (wxUint8 *buffer, size_t size)

  Reads bytes from the stream in a specified buffer.
- wxUint16 Read16 ()

  Reads a 16 bit unsigned integer from the stream.
- void Read16 (wxUint16 *buffer, size_t size)

  Reads 16 bit unsigned integers from the stream in a specified buffer.

- wxUint32 Read32 ()

  Reads a 32 bit unsigned integer from the stream.
- void Read32 (wxUint32 *buffer, size_t size)

  Reads 32 bit unsigned integers from the stream in a specified buffer.
- wxUint64 Read64 ()

  Reads a 64 bit unsigned integer from the stream.
- void Read64 (wxUint64 *buffer, size_t size)

  Reads 64 bit unsigned integers from the stream in a specified buffer.
- float ReadFloat ()

  Reads a float from the stream.
- void ReadFloat (float *buffer, size_t size)

  Reads float data from the stream in a specified buffer.
- double ReadDouble ()

  Reads a double from the stream.
- void ReadDouble (double *buffer, size_t size)

  Reads double data from the stream in a specified buffer.
- wxString ReadString ()

  Reads a string from a stream.
- void SetConv (const wxMBConv &conv)

  Sets the text conversion class used for reading strings.
- void UseBasicPrecisions ()

  Disables the use of extended precision format for floating point numbers.
- void UseExtendedPrecision ()

  Explicitly request the use of extended precision for floating point numbers.

21.136.2 Constructor & Destructor Documentation

wxDataInputStream::wxDataInputStream (wxInputStream & *stream*, const wxMBConv & *conv* = `wxConvUTF8`)

Constructs a datastream object from an input stream.

Only read methods will be available.

Note that the *conv* parameter is only available in Unicode builds of wxWidgets.

Parameters

stream	The input stream.
conv	Charset conversion object used to decode strings in Unicode mode (see ReadString() for a detailed description). Note that you must not destroy *conv* before you destroy this wxDataInputStream instance!

wxDataInputStream::~wxDataInputStream ( )

Destroys the wxDataInputStream object.

21.136.3 Member Function Documentation

void wxDataInputStream::BigEndianOrdered (bool *be_order*)

If *be_order* is true, all data will be read in big-endian order, such as written by programs on a big endian architecture (e.g.

Sparc) or written by Java-Streams (which always use big-endian order).

wxMBConv* wxDataInputStream::GetConv ( ) const

Returns the current text conversion class used for reading strings.

wxUint16 wxDataInputStream::Read16 ( )

Reads a 16 bit unsigned integer from the stream.

void wxDataInputStream::Read16 (wxUint16 * *buffer*, size_t *size*)

Reads 16 bit unsigned integers from the stream in a specified buffer.

The number of 16 bit unsigned integers to read is specified by the *size* variable.

wxUint32 wxDataInputStream::Read32 ( )

Reads a 32 bit unsigned integer from the stream.

void wxDataInputStream::Read32 (wxUint32 * *buffer*, size_t *size*)

Reads 32 bit unsigned integers from the stream in a specified buffer.

The number of 32 bit unsigned integers to read is specified by the *size* variable.

wxUint64 wxDataInputStream::Read64 ( )

Reads a 64 bit unsigned integer from the stream.

void wxDataInputStream::Read64 (wxUint64 * *buffer*, size_t *size*)

Reads 64 bit unsigned integers from the stream in a specified buffer.

The number of 64 bit unsigned integers to read is specified by the *size* variable.

wxUint8 wxDataInputStream::Read8 ( )

Reads a single byte from the stream.

void wxDataInputStream::Read8 (wxUint8 * *buffer*, size_t *size*)

Reads bytes from the stream in a specified buffer.

The number of bytes to read is specified by the *size* variable.

double wxDataInputStream::ReadDouble ( )

Reads a double from the stream.

The expected format is either 80 bit extended precision or, if UseBasicPrecisions() had been called, standard IEEE 754 64 bit double precision.

void wxDataInputStream::ReadDouble (double * *buffer,* size_t *size*)

Reads double data from the stream in a specified buffer.

The number of doubles to read is specified by the *size* variable.

float wxDataInputStream::ReadFloat ( )

Reads a float from the stream.

Notice that if UseBasicPrecisions() hadn't been called, this function simply reads a double and truncates it to float as by default the same (80 bit extended precision) representation is used for both float and double values.

Since

2.9.5

void wxDataInputStream::ReadFloat (float * *buffer,* size_t *size*)

Reads float data from the stream in a specified buffer.

The number of floats to read is specified by the *size* variable.

Since

2.9.5

wxString wxDataInputStream::ReadString ( )

Reads a string from a stream.

Actually, this function first reads a long integer specifying the length of the string (without the last null character) and then reads the string.

In Unicode build of wxWidgets, the function first reads multibyte (char*) string from the stream and then converts it to Unicode using the *conv* object passed to constructor and returns the result as wxString. You are responsible for using the same converter as when writing the stream.

See also

wxDataOutputStream::WriteString()

void wxDataInputStream::SetConv (const wxMBConv & *conv*)

Sets the text conversion class used for reading strings.

void wxDataInputStream::UseBasicPrecisions ( )

Disables the use of extended precision format for floating point numbers.

This method disables the use of 80 bit extended precision format for the `float` and `double` values read from the stream, which is used by default (unless `wxUSE_APPLE_IEEE` was set to `0` when building the library, in which case the extended format support is not available at all and this function does nothing).

After calling it, `float` values will be expected to appear in one of IEEE 754 "basic formats", i.e. 32 bit single precision format for floats and 64 bit double precision format for doubles in the input.

Since

2.9.5

void wxDataInputStream::UseExtendedPrecision ( )

Explicitly request the use of extended precision for floating point numbers.

This function allows the application code to explicitly request the use of 80 bit extended precision format for the floating point numbers. This is the case by default but using this function explicitly ensures that the compilation of code relying on reading the input containing numbers in extended precision format would fail when using a version of wxWidgets compiled with `wxUSE_APPLE_IEEE==0` and so not supporting this format at all.

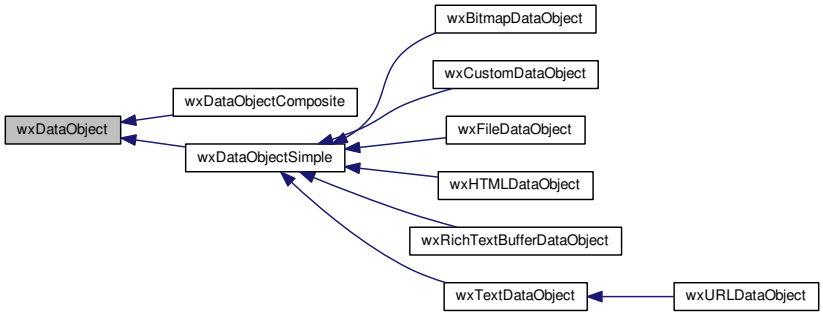
Since

2.9.5

21.137 wxDataObject Class Reference

`#include <wx/dataobj.h>`

Inheritance diagram for wxDataObject:



21.137.1 Detailed Description

A wxDataObject represents data that can be copied to or from the clipboard, or dragged and dropped.

The important thing about wxDataObject is that this is a 'smart' piece of data unlike 'dumb' data containers such as memory buffers or files. Being 'smart' here means that the data object itself should know what data formats it supports and how to render itself in each of its supported formats.

A supported format, incidentally, is exactly the format in which the data can be requested from a data object or from which the data object may be set. In the general case, an object may support different formats on 'input' and 'output', i.e. it may be able to render itself in a given format but not be created from data on this format or vice versa. wxDataObject defines the wxDataObject::Direction enumeration type which distinguishes between them.

See wxDataFormat documentation for more about formats.

Not surprisingly, being 'smart' comes at a price of added complexity. This is reasonable for the situations when you really need to support multiple formats, but may be annoying if you only want to do something simple like cut and paste text.

To provide a solution for both cases, wxWidgets has two predefined classes which derive from wxDataObject↩ : wxDataObjectSimple and wxDataObjectComposite. wxDataObjectSimple is the simplest wxDataObject possible

and only holds data in a single format (such as HTML or text) and wxDataObjectComposite is the simplest way to implement a wxDataObject that does support multiple formats because it achieves this by simply holding several wxDataObjectSimple objects.

So, you have several solutions when you need a wxDataObject class (and you need one as soon as you want to transfer data via the clipboard or drag and drop):

1. Use one of the built-in classes.
    - You may use wxTextDataObject, wxBitmapDataObject wxFileDataObject, wxURLDataObject in the simplest cases when you only need to support one format and your data is either text, bitmap or list of files.
2. Use wxDataObjectSimple
    - Deriving from wxDataObjectSimple is the simplest solution for custom data - you will only support one format and so probably won't be able to communicate with other programs, but data transfer will work in your program (or between different instances of it).
3. Use wxDataObjectComposite
    - This is a simple but powerful solution which allows you to support any number of formats (either standard or custom if you combine it with the previous solution).
4. Use wxDataObject directly
    - This is the solution for maximum flexibility and efficiency, but it is also the most difficult to implement.
