  Converts from multibyte encoding to Unicode by calling ToWChar() and allocating a temporary wxWCharBuffer to hold the result.
- const wxWCharBuffer cMB2WC (const wxCharBuffer &buf) const

  Converts a char buffer to wide char one.
- const wxCharBuffer cWC2MB (const wchar_t *in, size_t inLen, size_t *outLen) const

  Converts from Unicode to multibyte encoding by calling FromWChar() and allocating a temporary wxCharBuffer to hold the result.
- const wxCharBuffer cWC2MB (const wxWCharBuffer &buf) const

  Converts a wide char buffer to char one.
- virtual size_t MB2WC (wchar_t *out, const char *in, size_t outLen) const
- virtual size_t WC2MB (char *buf, const wchar_t *psz, size_t n) const

- const char * cMB2WX (const char *psz) const

  Converts from multibyte encoding to the current wxChar type (which depends on whether wxUSE_UNICODE is set to 1).
- const wxWCharBuffer cMB2WX (const char *psz) const

  Converts from multibyte encoding to the current wxChar type (which depends on whether wxUSE_UNICODE is set to 1).

- const wchar_t * cWC2WX (const wchar_t *psz) const

  Converts from Unicode to the current wxChar type.
- const wxCharBuffer cWC2WX (const wchar_t *psz) const

  Converts from Unicode to the current wxChar type.

- const char * cWX2MB (const wxChar *psz) const

  Converts from the current wxChar type to multibyte encoding.
- const wxCharBuffer cWX2MB (const wxChar *psz) const

  Converts from the current wxChar type to multibyte encoding.

- const wchar_t * cWX2WC (const wxChar *psz) const

  Converts from the current wxChar type to Unicode.
- const wxWCharBuffer cWX2WC (const wxChar *psz) const

  Converts from the current wxChar type to Unicode.

Static Public Member Functions

- static size_t GetMaxMBNulLen ()

  Returns the maximal value which can be returned by GetMBNulLen() for any conversion object.

21.447.2 Constructor & Destructor Documentation

wxMBConv::wxMBConv ( )

Trivial default constructor.

21.447.3 Member Function Documentation

virtual wxMBConv* wxMBConv::Clone ( ) const `[pure virtual]`

This pure virtual function is overridden in each of the derived classes to return a new copy of the object it is called on.

It is used for copying the conversion objects while preserving their dynamic type.

const wxWCharBuffer wxMBConv::cMB2WC (const char * *in*, size_t *inLen*, size_t * *outLen*) const

Converts from multibyte encoding to Unicode by calling ToWChar() and allocating a temporary wxWCharBuffer to hold the result.

This function is a convenient wrapper around ToWChar() as it takes care of allocating the buffer of the necessary size itself. Its parameters have the same meaning as for ToWChar(), in particular *inLen* can be specified explicitly in which case exactly that many characters are converted and *outLen* receives (if non-NULL) exactly the corresponding number of wide characters, whether the last one of them is `NUL` or not. However if `inLen` is `wxNO_LEN`, then `outLen` doesn't count the trailing `NUL` even if it is always present in this case.

Finally notice that if the conversion fails, the returned buffer is invalid and *outLen* is set to 0 (and not `wxCONV_FAILED` for compatibility concerns).

const wxWCharBuffer wxMBConv::cMB2WC (const wxCharBuffer & *buf*) const

Converts a char buffer to wide char one.

This is the most convenient and safest conversion function as you don't have to deal with the buffer lengths directly. Use it if the input buffer is known not to be empty or if you are sure that the conversion is going to succeed – otherwise, use the overload above to be able to distinguish between empty input and conversion failure.

Returns

The buffer containing the converted text, empty if the input was empty or if the conversion failed.

Since

2.9.1

const char* wxMBConv::cMB2WX (const char * *psz*) const

Converts from multibyte encoding to the current wxChar type (which depends on whether wxUSE_UNICODE is set to 1).

If wxChar is char, it returns the parameter unaltered. If wxChar is wchar_t, it returns the result in a wxWCharBuffer. The macro wxMB2WXbuf is defined as the correct return type (without const).

const wxWCharBuffer wxMBConv::cMB2WX (const char * *psz*) const

Converts from multibyte encoding to the current wxChar type (which depends on whether wxUSE_UNICODE is set to 1).

If wxChar is char, it returns the parameter unaltered. If wxChar is wchar_t, it returns the result in a wxWCharBuffer. The macro wxMB2WXbuf is defined as the correct return type (without const).

const wxCharBuffer wxMBConv::cWC2MB (const wchar_t * *in*, size_t *inLen*, size_t * *outLen*) const

Converts from Unicode to multibyte encoding by calling FromWChar() and allocating a temporary wxCharBuffer to hold the result.

This function is a convenient wrapper around FromWChar() as it takes care of allocating the buffer of necessary size itself.

Its parameters have the same meaning as the corresponding parameters of FromWChar(), please see the description of cMB2WC() for more details.

const wxCharBuffer wxMBConv::cWC2MB (const wxWCharBuffer & *buf*) const

Converts a wide char buffer to char one.

This is the most convenient and safest conversion function as you don't have to deal with the buffer lengths directly. Use it if the input buffer is known not to be empty or if you are sure that the conversion is going to succeed – otherwise, use the overload above to be able to distinguish between empty input and conversion failure.

Returns

The buffer containing the converted text, empty if the input was empty or if the conversion failed.

Since

2.9.1

const wchar_t* wxMBConv::cWC2WX (const wchar_t * *psz*) const

Converts from Unicode to the current wxChar type.

If wxChar is wchar_t, it returns the parameter unaltered. If wxChar is char, it returns the result in a wxCharBuffer. The macro wxWC2WXbuf is defined as the correct return type (without const).

const wxCharBuffer wxMBConv::cWC2WX (const wchar_t * *psz*) const

Converts from Unicode to the current wxChar type.

If wxChar is wchar_t, it returns the parameter unaltered. If wxChar is char, it returns the result in a wxCharBuffer. The macro wxWC2WXbuf is defined as the correct return type (without const).

const char* wxMBConv::cWX2MB (const wxChar * *psz*) const

Converts from the current wxChar type to multibyte encoding.

If wxChar is char, it returns the parameter unaltered. If wxChar is wchar_t, it returns the result in a wxCharBuffer. The macro wxWX2MBbuf is defined as the correct return type (without const).

const wxCharBuffer wxMBConv::cWX2MB (const wxChar * *psz*) const

Converts from the current wxChar type to multibyte encoding.

If wxChar is char, it returns the parameter unaltered. If wxChar is wchar_t, it returns the result in a wxCharBuffer. The macro wxWX2MBbuf is defined as the correct return type (without const).

const wchar_t* wxMBConv::cWX2WC (const wxChar * *psz*) const

Converts from the current wxChar type to Unicode.

If wxChar is wchar_t, it returns the parameter unaltered. If wxChar is char, it returns the result in a wxWCharBuffer. The macro wxWX2WCbuf is defined as the correct return type (without const).

const wxWCharBuffer wxMBConv::cWX2WC (const wxChar * *psz*) const

Converts from the current wxChar type to Unicode.

If wxChar is wchar_t, it returns the parameter unaltered. If wxChar is char, it returns the result in a wxWCharBuffer. The macro wxWX2WCbuf is defined as the correct return type (without const).

virtual size_t wxMBConv::FromWChar (char * *dst*, size_t *dstLen*, const wchar_t * *src*, size_t *srcLen* = `wxNO_LEN`) const `[virtual]`

Converts wide character string to multibyte.

This function has the same semantics as ToWChar() except that it converts a wide string to multibyte one. As with ToWChar(), it may be more convenient to use cWC2MB() when working with `NUL` terminated strings.

Parameters

dst	Pointer to output buffer of the size of at least *dstLen* or NULL.
dstLen	Maximal number of characters to be written to the output buffer if *dst* is non-NULL, unused otherwise.
src	Point to the source string, must not be NULL.
srcLen	The number of characters of the source string to convert or `wxNO_LEN` (default parameter) to convert everything up to and including the terminating `NUL` character.

Returns

The number of character written (or which would have been written if it were non-NULL) to *dst* or `wxCONV_FAILED` on error.

static size_t wxMBConv::GetMaxMBNulLen ( ) `[static]`

Returns the maximal value which can be returned by GetMBNulLen() for any conversion object.

Currently this value is 4.

This method can be used to allocate the buffer with enough space for the trailing `NUL` characters for any encoding.

virtual size_t wxMBConv::GetMBNulLen ( ) const `[virtual]`

This function returns 1 for most of the multibyte encodings in which the string is terminated by a single `NUL`, 2 for UTF-16 and 4 for UTF-32 for which the string is terminated with 2 and 4 `NUL` characters respectively.

The other cases are not currently supported and `wxCONV_FAILED` (defined as -1) is returned for them.

virtual size_t wxMBConv::MB2WC (wchar_t * *out*, const char * *in*, size_t *outLen*) const `[virtual]`

Deprecated This function is deprecated, please use ToWChar() instead.

Converts from a string *in* multibyte encoding to Unicode putting up to *outLen* characters into the buffer *out*.

If *out* is NULL, only the length of the string which would result from the conversion is calculated and returned. Note that this is the length and not size, i.e. the returned value does not include the trailing NUL. But when the function is called with a non-NULL *out* buffer, the *outLen* parameter should be one more to allow to properly NUL-terminate the string.

So to properly use this function you need to write:

```
size_t lenConv = conv.MB2WC(NULL, in, 0);
if ( lenConv == wxCONV_FAILED )
    ... handle error ...
// allocate 1 more character for the trailing NUL and also pass
// the size of the buffer to the function now
wchar_t *out = new wchar_t[lenConv + 1];
if ( conv.MB2WC(out, in, lenConv + 1) == wxCONV_FAILED )
    ... handle error ...
```

For this and other reasons, ToWChar() is strongly recommended as a replacement.

Parameters

out	The output buffer, may be NULL if the caller is only interested in the length of the resulting string
in	The NUL-terminated input string, cannot be NULL
outLen	The length of the output buffer but including NUL, ignored if out is NULL

Returns

The length of the converted string excluding the trailing NUL.

virtual size_t wxMBConv::ToWChar (wchar_t * *dst*, size_t *dstLen*, const char * *src*, size_t *srcLen* = wxNO_LEN) const [virtual]

Convert multibyte string to a wide character one.

This is the most general function for converting a multibyte string to a wide string, cMB2WC() may be often more convenient, however this function is the most efficient one as it allows to avoid any unnecessary copying.

The main case is when *dst* is not NULL and *srcLen* is not wxNO_LEN (which is defined as (size_t)-1): then the function converts exactly *srcLen* bytes starting at *src* into wide string which it output to *dst*. If the length of the resulting wide string is greater than *dstLen*, an error is returned. Note that if *srcLen* bytes don't include NUL characters, the resulting wide string is not NUL-terminated neither.

If *srcLen* is wxNO_LEN, the function supposes that the string is properly (i.e. as necessary for the encoding handled by this conversion) NUL-terminated and converts the entire string, including any trailing NUL bytes. In this case the wide string is also NUL-terminated.

Finally, if *dst* is NULL, the function returns the length of the needed buffer.

Example of use of this function:

```
size_t dstLen = conv.ToWChar(NULL, 0, src);
if ( dstLen == wxCONV_FAILED )
    ... handle error ...
wchar_t *dst = new wchar_t[dstLen];
if ( conv.ToWChar(dst, dstLen, src) == wxCONV_FAILED )
    ... handle error ...
```

Notice that when passing the explicit source length the output will *not* be NUL terminated if you pass strlen(str) as parameter. Either leave *srcLen* as default wxNO_LEN or add one to strlen result if you want the output to be NUL terminated.

Parameters

dst	Pointer to output buffer of the size of at least *dstLen* or NULL.
dstLen	Maximal number of characters to be written to the output buffer if *dst* is non-NULL, unused otherwise.
src	Point to the source string, must not be NULL.
srcLen	The number of characters of the source string to convert or `wxNO_LEN` (default parameter) to convert everything up to and including the terminating `NUL` character(s).

Returns

The number of character written (or which would have been written if it were non-NULL) to *dst* or `wxCONV_FAILED` on error.

virtual size_t wxMBConv::WC2MB (char * *buf*, const wchar_t * *psz*, size_t *n*) const `[virtual]`

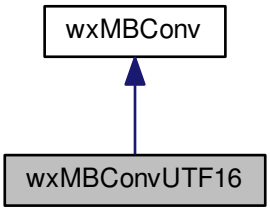
Deprecated This function is deprecated, please use FromWChar() instead.

Converts from Unicode to multibyte encoding. The semantics of this function (including the return value meaning) is the same as for wxMBConv::MB2WC. Notice that when the function is called with a non-NULL buffer, the *n* parameter should be the size of the buffer and so it should take into account the trailing `NUL`, which might take two or four bytes for some encodings (UTF-16 and UTF-32) and not one, i.e. GetMBNulLen().

21.448 wxMBConvUTF16 Class Reference

`#include <wx/strconv.h>`

Inheritance diagram for wxMBConvUTF16:



21.448.1 Detailed Description

This class is used to convert between multibyte encodings and UTF-16 Unicode encoding (also known as UCS-2).

Unlike UTF-8 encoding, UTF-16 uses words and not bytes and hence depends on the byte ordering: big or little endian. Hence this class is provided in two versions: wxMBConvUTF16LE and wxMBConvUTF16BE and wxMBConvUTF16 itself is just a typedef for one of them (native for the given platform, e.g. LE under Windows and BE under Mac).

Library: wxBase

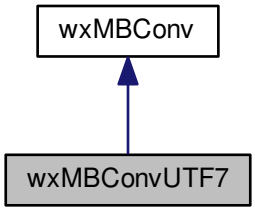
21.450 wxMBConvUTF7 Class Reference

`#include <wx/strconv.h>`

Inheritance diagram for wxMBConvUTF7:



21.450.1 Detailed Description

This class converts between the UTF-7 encoding and Unicode.

It has one predefined instance, **wxConvUTF7**.

Notice that, unlike all the other conversion objects, this converter is stateful, i.e. it remembers its state from the last call to its ToWChar() or FromWChar() and assumes it is called on the continuation of the same string when the same method is called again. This assumption is only made if an explicit length is specified as parameter to these functions as if an entire `NUL` terminated string is processed the state doesn't need to be remembered.

This also means that, unlike the other predefined conversion objects, **wxConvUTF7** is *not* thread-safe.

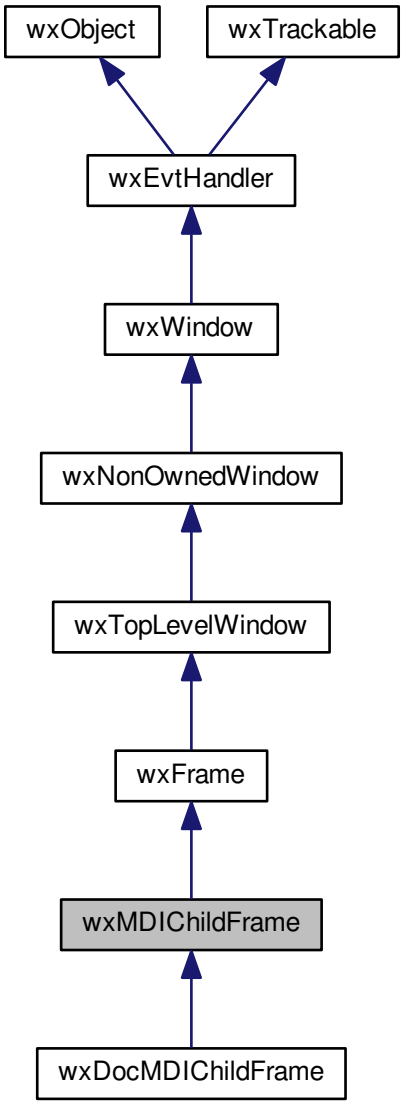
21.452 wxMDIChildFrame Class Reference

`#include <wx/mdi.h>`

Inheritance diagram for wxMDIChildFrame:



21.452.1 Detailed Description

An MDI child frame is a frame that can only exist inside a wxMDIClientWindow, which is itself a child of wxMDI↩ ParentFrame.

Styles

This class supports the following styles:

All of the standard wxFrame styles can be used but most of them are ignored by TDI-based MDI implementations.

Remarks

Although internally an MDI child frame is a child of the MDI client window, in wxWidgets you create it as a child of wxMDIParentFrame. In fact, you can usually forget that the client window exists. MDI child frames are clipped to the area of the MDI client window, and may be iconized on the client window. You can associate a menubar with a child frame as usual, although an MDI child doesn't display its menubar under its own title bar. The MDI parent frame's menubar will be changed to reflect the currently active child frame. If there are currently no children, the parent frame's own menubar will be displayed.

  Maximizes this MDI child frame.
- virtual void Restore ()

  Restores this MDI child frame (unmaximizes).

Additional Inherited Members

21.452.2 Constructor & Destructor Documentation

wxMDIChildFrame::wxMDIChildFrame ( )

Default constructor.

wxMDIChildFrame::wxMDIChildFrame (wxMDIParentFrame * *parent*, wxWindowID *id*, const wxString & *title*, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, long *style* = wxDEFAULT_FRAME_STYLE, const wxString & *name* = `wxFrameNameStr`)

Constructor, creating the window.

Parameters

parent	The window parent. This should not be NULL.
id	The window identifier. It may take a value of -1 to indicate a default value.
title	The caption to be displayed on the frame's title bar.
pos	The window position. The value wxDefaultPosition indicates a default position, chosen by either the windowing system or wxWidgets, depending on platform.
size	The window size. The value wxDefaultSize indicates a default size, chosen by either the windowing system or wxWidgets, depending on platform.
style	The window style. See wxMDIChildFrame.
name	The name of the window. This parameter is used to associate a name with the item, allowing the application user to set Motif resource values for individual windows.

Create()

virtual wxMDIChildFrame::~wxMDIChildFrame ( ) [virtual]

Destructor.

Destroys all child windows and menu bar if present.

21.452.3 Member Function Documentation

virtual void wxMDIChildFrame::Activate ( ) [virtual]

Activates this MDI child frame.

See also

Maximize(), Restore()

bool wxMDIChildFrame::Create (wxMDIParentFrame * *parent*, wxWindowID *id*, const wxString & *title*, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, long *style* = wxDEFAULT_FRAME_STYLE, const wxString & *name* = wxFrameNameStr)

Used in two-step frame construction.

See wxMDIChildFrame() for further details.

wxMDIParentFrame* wxMDIChildFrame::GetMDIParent ( ) const

Returns the MDI parent frame containing this child.

Notice that this may return a different object than GetParent() as the child frames may be created as children of the client window internally.

virtual bool wxMDIChildFrame::IsAlwaysMaximized ( ) const [virtual]

Returns true for MDI children in TDI implementations.

TDI-based implementations represent MDI children as pages in a wxNotebook and so they are always maximized and can't be restored or iconized.

See also

wxMDIParentFrame::IsTDI().

Reimplemented from wxTopLevelWindow.

virtual void wxMDIChildFrame::Maximize (bool *maximize* = `true`) `[virtual]`

Maximizes this MDI child frame.

This function doesn't do anything if IsAlwaysMaximized() returns true.

See also

Activate(), Restore()

Reimplemented from wxTopLevelWindow.

virtual void wxMDIChildFrame::Restore ( ) `[virtual]`

Restores this MDI child frame (unmaximizes).

This function doesn't do anything if IsAlwaysMaximized() returns true.

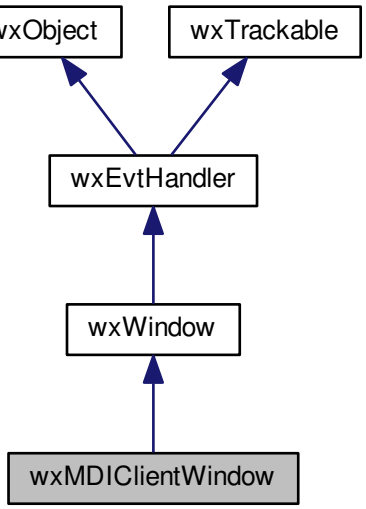
See also

Activate(), Maximize()

21.453 wxMDIClientWindow Class Reference

`#include <wx/mdi.h>`

Inheritance diagram for wxMDIClientWindow:



21.453.1 Detailed Description

An MDI client window is a child of wxMDIParentFrame, and manages zero or more wxMDIChildFrame objects.

Remarks

The client window is the area where MDI child windows exist. It doesn't have to cover the whole parent frame; other windows such as toolbars and a help window might coexist with it. There can be scrollbars on a client window, which are controlled by the parent window style.

The wxMDIClientWindow class is usually adequate without further derivation, and it is created automatically when the MDI parent frame is created. If the application needs to derive a new class, the function wxMDIParentFrame::OnCreateClient() must be overridden in order to give an opportunity to use a different class of client window.

Under wxMSW, the client window will automatically have a sunken border style when the active child is not maximized, and no border style when a child is maximized.

Public Member Functions

- wxMDIClientWindow ()

  Default constructor.
- virtual bool CreateClient (wxMDIParentFrame *parent, long style=0)

  Called by wxMDIParentFrame immediately after creating the client window.

Additional Inherited Members

21.453.2 Constructor & Destructor Documentation

wxMDIClientWindow::wxMDIClientWindow ( )

Default constructor.

Objects of this class are only created by wxMDIParentFrame which uses the default constructor and calls CreateClient() immediately afterwards.

21.453.3 Member Function Documentation

virtual bool wxMDIClientWindow::CreateClient (wxMDIParentFrame * *parent*, long *style* = 0) `[virtual]`

Called by wxMDIParentFrame immediately after creating the client window.

This function may be overridden in the derived class but the base class version must usually be called first to really create the window.

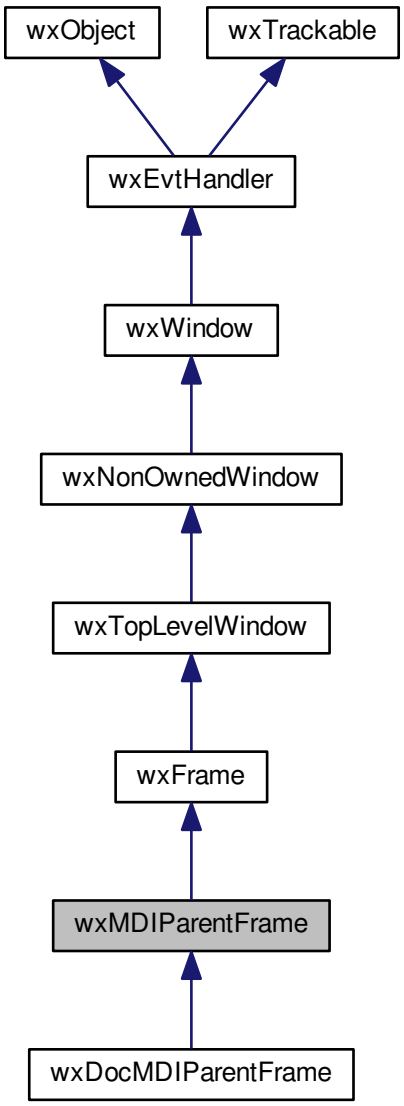
Parameters

parent	The window parent.
style	The window style. Only wxHSCROLL and wxVSCROLL bits are meaningful here.

21.454 wxMDIParentFrame Class Reference

`#include <wx/mdi.h>`

Inheritance diagram for wxMDIParentFrame:



21.454.1 Detailed Description

An MDI (Multiple Document Interface) parent frame is a window which can contain MDI child frames in its client area which emulates the full desktop.

MDI is a user-interface model in which all the window reside inside the single parent window as opposed to being separate from each other. It remains popular despite dire warnings from Microsoft itself (which popularized this model in the first model) that MDI is obsolete.

An MDI parent frame always has a wxMDIClientWindow associated with it, which is the parent for MDI child frames. In the simplest case, the client window takes up the entire parent frame area but it is also possible to resize it to be smaller in order to have other windows in the frame, a typical example is using a sidebar along one of the window edges.

The appearance of MDI applications differs between different ports. The classic MDI model, with child windows which can be independently moved, resized etc, is only available under MSW, which provides native support for it. In Mac ports, multiple top level windows are used for the MDI children too and the MDI parent frame itself is invisible, to accommodate the native look and feel requirements. In all the other ports, a tab-based MDI implementation (sometimes called TDI) is used and so at most one MDI child is visible at any moment (child frames are always maximized).

Remarks

Although it is possible to have multiple MDI parent frames, a typical MDI application has a single MDI parent frame window inside which multiple MDI child frames, i.e. objects of class wxMDIChildFrame, can be created.

Styles

This class supports the following styles:

There are no special styles for this class, all wxFrame styles apply to it in the usual way. The only exception is that wxHSCROLL and wxVSCROLL styles apply not to the frame itself but to the client window, so that using them enables horizontal and vertical scrollbars for this window and not the frame.

- virtual void ActivatePrevious ()

  Activates the MDI child preceding the currently active one.
- virtual void ArrangeIcons ()

  Arranges any iconized (minimized) MDI child windows.
- virtual void Cascade ()

  Arranges the MDI child windows in a cascade.
- bool Create (wxWindow *parent, wxWindowID id, const wxString &title, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, long style=wxDEFAULT_FRAME_STYLE|wxVSCROLL|wxHSCROLL, const wxString &name=wxFrameNameStr)

  Used in two-step frame construction.
- virtual wxMDIChildFrame * GetActiveChild () const

  Returns a pointer to the active MDI child, if there is one.
- wxMDIClientWindowBase * GetClientWindow () const

  Returns a pointer to the client window.
- wxMenu * GetWindowMenu () const

  Returns the current MDI Window menu.
- virtual wxMDIClientWindow * OnCreateClient ()

  Override this to return a different kind of client window.
- virtual void SetWindowMenu (wxMenu *menu)

  Replace the current MDI Window menu.
- virtual void Tile (wxOrientation orient=wxHORIZONTAL)

  Tiles the MDI child windows either horizontally or vertically depending on whether orient is `wxHORIZONTAL` or `wxVERTICAL`.

Static Public Member Functions

- static bool IsTDI ()

  Returns whether the MDI implementation is tab-based.

Additional Inherited Members

21.454.2 Constructor & Destructor Documentation

wxMDIParentFrame::wxMDIParentFrame ( )

Default constructor.

Use Create() for the objects created using this constructor.

wxMDIParentFrame::wxMDIParentFrame (wxWindow * *parent*, wxWindowID *id*, const wxString & *title*, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, long *style* = wxDEFAULT_FRAME_STYLE|wxVSCROLL|wxHSCROLL, const wxString & *name* = `wxFrameNameStr`)

Constructor, creating the window.

Notice that if you override virtual OnCreateClient() method you shouldn't be using this constructor but the default constructor and Create() as otherwise your overridden method is never going to be called because of the usual C++ virtual call resolution rules.

Parameters

parent	The window parent. Usually is NULL.
id	The window identifier. It may take a value of `wxID_ANY` to indicate a default value.
title	The caption to be displayed on the frame's title bar.
pos	The window position. The value wxDefaultPosition indicates a default position, chosen by either the windowing system or wxWidgets, depending on platform.
size	The window size. The value wxDefaultSize indicates a default size, chosen by either the windowing system or wxWidgets, depending on platform.
style	The window style. Default value includes wxHSCROLL and wxVSCROLL styles.
name	The name of the window. This parameter is used to associate a name with the item, allowing the application user to set Motif resource values for individual windows.

Remarks

Under wxMSW, the client window will automatically have a sunken border style when the active child is not maximized, and no border style when a child is maximized.

Tile(), ArrangeIcons()

bool wxMDIParentFrame::Create (wxWindow * *parent*, wxWindowID *id*, const wxString & *title*, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, long *style* = wxDEFAULT_FRAME_STYLE|wxVSCROLL|wxHSCROLL, const wxString & *name* = wxFrameNameStr)

Used in two-step frame construction.

See wxMDIParentFrame() for further details.

virtual wxMDIChildFrame* wxMDIParentFrame::GetActiveChild ( ) const [virtual]

Returns a pointer to the active MDI child, if there is one.

If there are any children at all this function returns a non-NULL pointer.

wxMDIClientWindowBase* wxMDIParentFrame::GetClientWindow ( ) const

Returns a pointer to the client window.

See also

OnCreateClient()

wxMenu* wxMDIParentFrame::GetWindowMenu ( ) const

Returns the current MDI Window menu.

Unless wxFRAME_NO_WINDOW_MENU style was used, a default menu listing all the currently active children and providing the usual operations (tile, cascade, ...) on them is created automatically by the library and this function can be used to retrieve it. Notice that the default menu can be replaced by calling SetWindowMenu().

This function is currently not available under OS X.

Returns

The current Window menu or NULL.

static bool wxMDIParentFrame::IsTDI ( ) [static]

Returns whether the MDI implementation is tab-based.

Currently only the MSW port uses the real MDI. In Mac ports the usual SDI is used, as common under this platforms, and all the other ports use TDI implementation.

TDI-based MDI applications have different appearance and functionality (e.g. child frames can't be minimized and only one of them is visible at any given time) so the application may need to adapt its interface somewhat depending on the return value of this function.

virtual wxMDIClientWindow* wxMDIParentFrame::OnCreateClient ( ) [virtual]

Override this to return a different kind of client window.

If you override this function, you must create your parent frame in two stages, or your function will never be called, due to the way C++ treats virtual functions called from constructors. For example:

```
frame = new MyParentFrame;
frame->Create(parent, myParentFrameId, "My Parent Frame");
```

Remarks

You might wish to derive from wxMDIClientWindow in order to implement different erase behaviour, for example, such as painting a bitmap on the background.

Note that it is probably impossible to have a client window that scrolls as well as painting a bitmap or pattern, since in **OnScroll**, the scrollbar positions always return zero.

See also

GetClientWindow(), wxMDIClientWindow

virtual void wxMDIParentFrame::SetWindowMenu (wxMenu * *menu*) [virtual]

Replace the current MDI Window menu.

Ownership of the menu object passes to the frame when you call this function, i.e. the menu will be deleted by it when it's no longer needed (usually when the frame itself is deleted or when SetWindowMenu() is called again).

To remove the window completely, you can use the wxFRAME_NO_WINDOW_MENU window style but this function also allows to do it by passing NULL pointer as *menu*.

The menu may include the items with the following standard identifiers (but may use arbitrary text and help strings and bitmaps for them):

- wxID_MDI_WINDOW_CASCADE
- wxID_MDI_WINDOW_TILE_HORZ
- wxID_MDI_WINDOW_TILE_VERT
- wxID_MDI_WINDOW_ARRANGE_ICONS
- wxID_MDI_WINDOW_PREV
- wxID_MDI_WINDOW_NEXT All of which are handled by wxMDIParentFrame itself. If any other commands are used in the menu, the derived frame should handle them.

This function is currently not available under OS X.

Parameters

menu	The menu to be used instead of the standard MDI Window menu or NULL.

virtual void wxMDIParentFrame::Tile (wxOrientation *orient* = wxHORIZONTAL) `[virtual]`

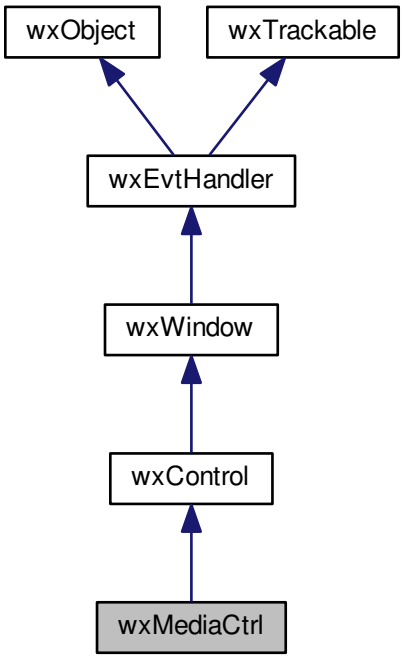
Tiles the MDI child windows either horizontally or vertically depending on whether *orient* is `wxHORIZONTAL` or `wxVERTICAL`.

This method is only implemented in MSW MDI implementation and does nothing under the other platforms.

21.455 wxMediaCtrl Class Reference

`#include <wx/mediactrl.h>`

Inheritance diagram for wxMediaCtrl:



21.455.1 Detailed Description

wxMediaCtrl is a class for displaying types of media, such as videos, audio files, natively through native codecs.

wxMediaCtrl uses native backends to render media, for example on Windows there is a ActiveMovie/DirectShow backend, and on Macintosh there is a QuickTime backend.

21.455.2 Rendering media

Depending upon the backend, wxMediaCtrl can render and display pretty much any kind of media that the native system can - such as an image, mpeg video, or mp3 (without license restrictions - since it relies on native system calls that may not technically have mp3 decoding available, for example, it falls outside the realm of licensing restrictions).

For general operation, all you need to do is call Load() to load the file you want to render, catch the EVT_MEDIA↩_LOADED event, and then call Play() to show the video/audio of the media in that event.

More complex operations are generally more heavily dependent on the capabilities of the backend. For example, QuickTime cannot set the playback rate of certain streaming media - while DirectShow is slightly more flexible in that regard.

21.455.3 Operation

When wxMediaCtrl plays a file, it plays until the stop position is reached (currently the end of the file/stream). Right before it hits the end of the stream, it fires off a EVT_MEDIA_STOP event to its parent window, at which point the event handler can choose to veto the event, preventing the stream from actually stopping.

Example:

```
//connect to the media event
this->Connect(wxMY_ID, wxEVT_MEDIA_STOP, (wxObjectEventFunction)
(wxEventFunction)(wxMediaEventFunction) &MyFrame::OnMediaStop);

//...
void MyFrame::OnMediaStop(const wxMediaEvent& evt)
{
    if(bUserWantsToSeek)
    {
        m_mediactrl->SetPosition(
            m_mediactrl->GetDuration() << 1
                                );
        evt.Veto();
    }
}
```

When wxMediaCtrl stops, either by the EVT_MEDIA_STOP not being vetoed, or by manually calling Stop(), where it actually stops is not at the beginning, rather, but at the beginning of the stream. That is, when it stops and play is called, playback is guaranteed to start at the beginning of the media. This is because some streams are not seekable, and when stop is called on them they return to the beginning, thus wxMediaCtrl tries to keep consistent for all types of media.

Note that when changing the state of the media through Play() and other methods, the media may not actually be in the wxMEDIASTATE_PLAYING, for example. If you are relying on the media being in certain state catch the event relevant to the state. See wxMediaEvent for the kinds of events that you can catch.

21.455.4 Video size

By default, wxMediaCtrl will scale the size of the video to the requested amount passed to either its constructor or Create(). After calling wxMediaCtrl::Load or performing an equivalent operation, you can subsequently obtain the "real" size of the video (if there is any) by calling wxMediaCtrl::GetBestSize(). Note that the actual result on the display will be slightly different when wxMediaCtrl::ShowPlayerControls is activated and the actual video size will be less than specified due to the extra controls provided by the native toolkit. In addition, the backend may modify wxMediaCtrl::GetBestSize() to include the size of the extra controls - so if you want the real size of the video just disable wxMediaCtrl::ShowPlayerControls().

The idea with setting wxMediaCtrl::GetBestSize() to the size of the video is that GetBestSize() is a wxWindow-derived function that is called when sizers on a window recalculate. What this means is that if you use sizers by default the video will show in its original size without any extra assistance needed from the user.

21.455.5 Player controls

Normally, when you use wxMediaCtrl it is just a window for the video to play in. However, some toolkits have their own media player interface. For example, QuickTime generally has a bar below the video with a slider. A special feature available to wxMediaCtrl, you can use the toolkits interface instead of making your own by using the ShowPlayerControls() function. There are several options for the flags parameter, with the two general flags being `wxMEDIACTRLPLAYERCONTROLS_NONE` which turns off the native interface, and `wxMEDIACTRLPLAYER↩CONTROLS_DEFAULT` which lets wxMediaCtrl decide what native controls on the interface. Be sure to review the caveats outlined in Video size before doing so.

21.455.6 Choosing a backend

Generally, you should almost certainly leave this part up to wxMediaCtrl - but if you need a certain backend for a particular reason, such as QuickTime for playing .mov files, all you need to do to choose a specific backend is to pass the name of the backend class to wxMediaCtrl::Create().

The following are valid backend identifiers:

- **wxMEDIABACKEND_DIRECTSHOW:** Use ActiveMovie/DirectShow. Uses the native ActiveMovie (I.E. DirectShow) control. Default backend on Windows and supported by nearly all Windows versions, even some Windows CE versions. May display a windows media player logo while inactive.
- **wxMEDIABACKEND_QUICKTIME:** Use QuickTime. Mac Only. WARNING: May not working correctly embedded in a wxNotebook.
- **wxMEDIABACKEND_GSTREAMER**, Use GStreamer. Unix Only. Requires GStreamer 0.8 along with at the very least the xvimagesink, xoverlay, and gst-play modules of gstreamer to function. You need the correct modules to play the relevant files, for example the mad module to play mp3s, etc.
- **wxMEDIABACKEND_WMP10**, Uses Windows Media Player 10 (Windows only) - works on mobile machines with Windows Media Player 10 and desktop machines with either Windows Media Player 9 or 10.

Note that other backends such as wxMEDIABACKEND_MCI can now be found at wxCode (`http://wxcode.↩sourceforge.net/`).

21.455.7 Creating a backend

Creating a backend for wxMediaCtrl is a rather simple process. Simply derive from wxMediaBackendCommonBase and implement the methods you want. The methods in wxMediaBackend correspond to those in wxMediaCtrl except for wxMediaCtrl::CreateControl which does the actual creation of the control, in cases where a custom control is not needed you may simply call wxControl::Create().

You need to make sure to use the `DECLARE_CLASS` and `IMPLEMENT_CLASS` macros.

The only real tricky part is that you need to make sure the file in compiled in, which if there are just backends in there will not happen and you may need to use a force link hack (see `http://www.wxwidgets.↩org/wiki/index.php/RTTI`).

This is a rather simple example of how to create a backend in the wxActiveXContainer documentation.

Library: wxMedia

wxMediaEvent

Public Member Functions

- wxMediaCtrl ()

  Default constructor - you MUST call Create() before calling any other methods of wxMediaCtrl.
- wxMediaCtrl (wxWindow *parent, wxWindowID id, const wxString &fileName=wxEmptyString, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, long style=0, const wxString &szBackend=wxEmptyString, const wxValidator &validator=wxDefaultValidator, const wxString &name="mediaCtrl")

  Constructor that calls Create().
- bool Create (wxWindow *parent, wxWindowID id, const wxString &fileName=wxEmptyString, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, long style=0, const wxString &szBackend=wxEmptyString, const wxValidator &validator=wxDefaultValidator, const wxString &name="mediaCtrl")

  Creates this control.
- wxSize GetBestSize () const

  Obtains the best size relative to the original/natural size of the video, if there is any.
- double GetPlaybackRate ()

  Obtains the playback rate, or speed of the media.
- wxMediaState GetState ()

  Obtains the state the playback of the media is in.
- double GetVolume ()

  Gets the volume of the media from a 0.0 to 1.0 range.
- wxFileOffset Length ()

  Obtains the length - the total amount of time the movie has in milliseconds.
- bool Load (const wxString &fileName)

  Loads the file that fileName refers to.
- bool Load (const wxURI &uri)

  Loads the location that uri refers to.
- bool Load (const wxURI &uri, const wxURI &proxy)

  Loads the location that `uri` refers to with the proxy `proxy`.
- bool LoadURI (const wxString &fileName)

  Same as Load(const wxURI& uri).
- bool LoadURIWithProxy (const wxString &fileName, const wxString &proxy)

  Same as Load(const wxURI& uri, const wxURI& proxy).
- bool Pause ()

  Pauses playback of the movie.
- bool Play ()

  Resumes playback of the movie.
- wxFileOffset Seek (wxFileOffset where, wxSeekMode mode=wxFromStart)

  Seeks to a position within the movie.
- bool SetPlaybackRate (double dRate)

  Sets the playback rate, or speed of the media, to that referred by dRate.
- bool SetVolume (double dVolume)

  Sets the volume of the media from a 0.0 to 1.0 range to that referred by `dVolume`.
- bool ShowPlayerControls (wxMediaCtrlPlayerControls flags=wxMEDIACTRLPLAYERCONTROLS_DEFAULT)

  A special feature to wxMediaCtrl.
- bool Stop ()

  Stops the media.
- wxFileOffset Tell ()

  Obtains the current position in time within the movie in milliseconds.

Additional Inherited Members

21.455.8 Constructor & Destructor Documentation

wxMediaCtrl::wxMediaCtrl ( )

Default constructor - you MUST call Create() before calling any other methods of wxMediaCtrl.

wxMediaCtrl::wxMediaCtrl (wxWindow * *parent*, wxWindowID *id*, const wxString & *fileName* = wxEmptyString, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, long *style* = 0, const wxString & *szBackend* = wxEmptyString, const wxValidator & *validator* = wxDefaultValidator, const wxString & *name* = "mediaCtrl")

Constructor that calls Create().

You may prefer to call Create() directly to check to see if wxMediaCtrl is available on the system.

Parameters

parent	parent of this control. Must not be NULL.
id	id to use for events
fileName	If not empty, the path of a file to open.
pos	Position to put control at.
size	Size to put the control at and to stretch movie to.
style	Optional styles.
szBackend	Name of backend you want to use, leave blank to make wxMediaCtrl figure it out.
validator	validator to use.
name	Window name.

21.455.9 Member Function Documentation

bool wxMediaCtrl::Create (wxWindow * *parent*, wxWindowID *id*, const wxString & *fileName* = wxEmptyString, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, long *style* = 0, const wxString & *szBackend* = wxEmptyString, const wxValidator & *validator* = wxDefaultValidator, const wxString & *name* = "mediaCtrl")

Creates this control.

Returns false if it can't load the movie located at *fileName* or it cannot load one of its native backends.

If you specify a file to open via *fileName* and you don't specify a backend to use, wxMediaCtrl tries each of its backends until one that can render the path referred to by *fileName* can be found.

Parameters

parent	parent of this control. Must not be NULL.
id	id to use for events
fileName	If not empty, the path of a file to open.
pos	Position to put control at.
size	Size to put the control at and to stretch movie to.
style	Optional styles.
szBackend	Name of backend you want to use, leave blank to make wxMediaCtrl figure it out.
validator	validator to use.
name	Window name.

wxSize wxMediaCtrl::GetBestSize ( ) const

Obtains the best size relative to the original/natural size of the video, if there is any.

See Video size for more information.

double wxMediaCtrl::GetPlaybackRate ( )

Obtains the playback rate, or speed of the media.

`1.0` represents normal speed, while `2.0` represents twice the normal speed of the media, for example. Not supported on the GStreamer (Unix) backend.

Returns

zero on failure.

wxMediaState wxMediaCtrl::GetState ( )

Obtains the state the playback of the media is in.

wxMEDIASTATE_STOPPED	The movie has stopped.
wxMEDIASTATE_PAUSED	The movie is paused.
wxMEDIASTATE_PLAYING	The movie is currently playing.

double wxMediaCtrl::GetVolume ( )

Gets the volume of the media from a 0.0 to 1.0 range.

Note

Due to rounding and other errors the value returned may not be the exact value sent to SetVolume().

wxFileOffset wxMediaCtrl::Length ( )

Obtains the length - the total amount of time the movie has in milliseconds.

bool wxMediaCtrl::Load (const wxString & *fileName*)

Loads the file that fileName refers to.

Returns false if loading fails.

bool wxMediaCtrl::Load (const wxURI & *uri*)

Loads the location that uri refers to.

Note that this is very implementation-dependent, although HTTP URI/URLs are generally supported, for example. Returns false if loading fails.

bool wxMediaCtrl::Load (const wxURI & *uri,* const wxURI & *proxy*)

Loads the location that `uri` refers to with the proxy `proxy`.

Not implemented on most backends so it should be called with caution. Returns false if loading fails.

bool wxMediaCtrl::LoadURI (const wxString & *fileName*)

Same as Load(const wxURI& uri).

Kept for wxPython compatibility.

bool wxMediaCtrl::LoadURIWithProxy (const wxString & *fileName,* const wxString & *proxy*)

Same as Load(const wxURI& uri, const wxURI& proxy).

Kept for wxPython compatibility.

bool wxMediaCtrl::Pause ( )

Pauses playback of the movie.

bool wxMediaCtrl::Play ( )

Resumes playback of the movie.

wxFileOffset wxMediaCtrl::Seek (wxFileOffset *where,* wxSeekMode *mode* = wxFromStart)

Seeks to a position within the movie.

Todo Document the wxSeekMode parameter *mode*, and perhaps also the wxFileOffset and wxSeekMode themselves.

bool wxMediaCtrl::SetPlaybackRate (double *dRate*)

Sets the playback rate, or speed of the media, to that referred by *dRate*.

`1.0` represents normal speed, while `2.0` represents twice the normal speed of the media, for example. Not supported on the GStreamer (Unix) backend. Returns true if successful.

bool wxMediaCtrl::SetVolume (double *dVolume*)

Sets the volume of the media from a 0.0 to 1.0 range to that referred by `dVolume`.

`1.0` represents full volume, while `0.5` represents half (50 percent) volume, for example.

Note

The volume may not be exact due to conversion and rounding errors, although setting the volume to full or none is always exact. Returns true if successful.

bool wxMediaCtrl::ShowPlayerControls (wxMediaCtrlPlayerControls *flags* = wxMEDIACTRLPLAYERCONTROLS_↩ DEFAULT)

A special feature to wxMediaCtrl.

Applications using native toolkits such as QuickTime usually have a scrollbar, play button, and more provided to them by the toolkit. By default wxMediaCtrl does not do this. However, on the directshow and quicktime backends you can show or hide the native controls provided by the underlying toolkit at will using ShowPlayerControls().

Simply calling the function with default parameters tells wxMediaCtrl to use the default controls provided by the toolkit. The function takes a wxMediaCtrlPlayerControls enumeration, please see available show modes there.

For more info see Player controls.

Currently only implemented on the QuickTime and DirectShow backends. The function returns true on success.

bool wxMediaCtrl::Stop ( )

Stops the media.

See Operation for an overview of how stopping works.

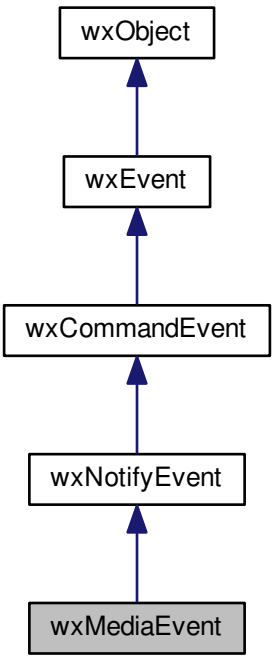
wxFileOffset wxMediaCtrl::Tell ( )

Obtains the current position in time within the movie in milliseconds.

21.456 wxMediaEvent Class Reference

`#include <wx/mediactrl.h>`

Inheritance diagram for wxMediaEvent:



21.456.1 Detailed Description

Event wxMediaCtrl uses.

Events using this class

The following event handler macros redirect the events to member function handlers '**func**' with prototypes like: void handlerFuncName(wxMediaEvent& event)

Event macros:

- EVT_MEDIA_LOADED(id, func): Sent when a media has loaded enough data that it can start playing. Processes a `wxEVT_MEDIA_LOADED` event type.
- EVT_MEDIA_STOP(id, func): Sent when a media has switched to the `wxMEDIASTATE_STOPPED` state. You may be able to Veto this event to prevent it from stopping, causing it to continue playing - even if it has reached that end of the media (note that this may not have the desired effect - if you want to loop the media, for example, catch the `EVT_MEDIA_FINISHED` and play there instead). Processes a `wxEVT_MEDIA_STOP` event type.
- EVT_MEDIA_FINISHED(id, func): Sent when a media has finished playing in a wxMediaCtrl. Processes a `wxEVT_MEDIA_FINISHED` event type.
- EVT_MEDIA_STATECHANGED(id, func): Sent when a media has switched its state (from any media state). Processes a `wxEVT_MEDIA_STATECHANGED` event type.
- EVT_MEDIA_PLAY(id, func): Sent when a media has switched to the `wxMEDIASTATE_PLAYING` state. Processes a `wxEVT_MEDIA_PLAY` event type.
- EVT_MEDIA_PAUSE(id, func): Sent when a media has switched to the `wxMEDIASTATE_PAUSED` state. Processes a `wxEVT_MEDIA_PAUSE` event type.

21.457 wxMemoryBuffer Class Reference

```
#include <wx/buffer.h>
```

21.457.1 Detailed Description

A **wxMemoryBuffer** is a useful data structure for storing arbitrary sized blocks of memory.

wxMemoryBuffer guarantees deletion of the memory block when the object is destroyed.

Library: wxBase

Category: Data Structures

Public Member Functions

- wxMemoryBuffer (const wxMemoryBuffer &src)

  Copy constructor, refcounting is used for performance, but wxMemoryBuffer is not a copy-on-write structure so changes made to one buffer effect all copies made from it.
- wxMemoryBuffer (size_t size=1024)

  Create a new buffer.
- void AppendByte (char data)

  Append a single byte to the buffer.
- void AppendData (const void *data, size_t len)

  Single call to append a data block to the buffer.
- void Clear ()

  Clear the buffer contents.
- void * GetAppendBuf (size_t sizeNeeded)

  Ensure that the buffer is big enough and return a pointer to the start of the empty space in the buffer.
- size_t GetBufSize () const

  Returns the size of the buffer.
- void * GetData () const

  Return a pointer to the data in the buffer.
- size_t GetDataLen () const

  Returns the length of the valid data in the buffer.
- void * GetWriteBuf (size_t sizeNeeded)

  Ensure the buffer is big enough and return a pointer to the buffer which can be used to directly write into the buffer up to sizeNeeded bytes.
- bool IsEmpty () const

  Returns true if the buffer contains no data.
- void SetBufSize (size_t size)

  Ensures the buffer has at least size bytes available.
- void SetDataLen (size_t size)

  Sets the length of the data stored in the buffer.
- void UngetAppendBuf (size_t sizeUsed)

  Update the length after completing a direct append, which you must have used GetAppendBuf() to initialise.
- void UngetWriteBuf (size_t sizeUsed)

  Update the buffer after completing a direct write, which you must have used GetWriteBuf() to initialise.

21.457.2 Constructor & Destructor Documentation

wxMemoryBuffer::wxMemoryBuffer (const wxMemoryBuffer & *src*)

Copy constructor, refcounting is used for performance, but wxMemoryBuffer is not a copy-on-write structure so changes made to one buffer effect all copies made from it.

See also

Reference Counting

wxMemoryBuffer::wxMemoryBuffer (size_t *size* = 1024)

Create a new buffer.

Parameters

size	size of the new buffer, 1KiB by default.

21.457.3 Member Function Documentation

void wxMemoryBuffer::AppendByte (char *data*)

Append a single byte to the buffer.

Parameters

data	New byte to append to the buffer.

void wxMemoryBuffer::AppendData (const void * *data,* size_t *len*)

Single call to append a data block to the buffer.

Parameters

data	Pointer to block to append to the buffer.
len	Length of data to append.

void wxMemoryBuffer::Clear ( )

Clear the buffer contents.

The buffer won't contain any data after this method is called.

See also

IsEmpty()

Since

2.9.4

void* wxMemoryBuffer::GetAppendBuf (size_t *sizeNeeded*)

Ensure that the buffer is big enough and return a pointer to the start of the empty space in the buffer.

This pointer can be used to directly write data into the buffer, this new data will be appended to the existing data.

Parameters

sizeNeeded	Amount of extra space required in the buffer for the append operation

size_t wxMemoryBuffer::GetBufSize ( ) const

Returns the size of the buffer.

void* wxMemoryBuffer::GetData ( ) const

Return a pointer to the data in the buffer.

size_t wxMemoryBuffer::GetDataLen ( ) const

Returns the length of the valid data in the buffer.

void* wxMemoryBuffer::GetWriteBuf (size_t *sizeNeeded*)

Ensure the buffer is big enough and return a pointer to the buffer which can be used to directly write into the buffer up to *sizeNeeded* bytes.

bool wxMemoryBuffer::IsEmpty ( ) const

Returns true if the buffer contains no data.

See also

Clear()

Since

2.9.4

void wxMemoryBuffer::SetBufSize (size_t *size*)

Ensures the buffer has at least *size* bytes available.

void wxMemoryBuffer::SetDataLen (size_t *size*)

Sets the length of the data stored in the buffer.

Mainly useful for truncating existing data.

Parameters

size	New length of the valid data in the buffer. This is distinct from the allocated size

void wxMemoryBuffer::UngetAppendBuf (size_t *sizeUsed*)

Update the length after completing a direct append, which you must have used GetAppendBuf() to initialise.

Parameters

sizeUsed	This is the amount of new data that has been appended.

void wxMemoryBuffer::UngetWriteBuf (size_t *sizeUsed*)

Update the buffer after completing a direct write, which you must have used GetWriteBuf() to initialise.

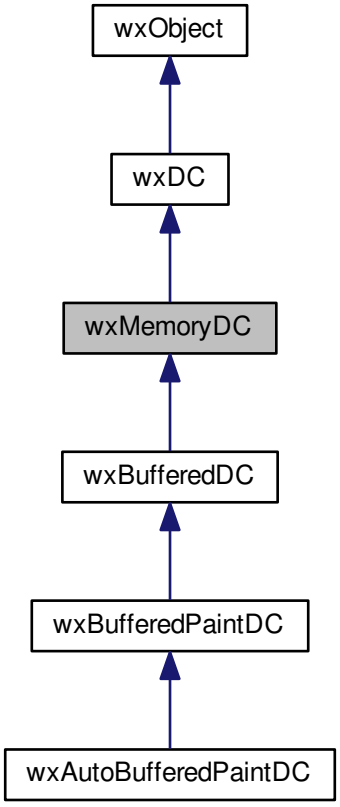
Parameters

sizeUsed	The amount of data written in to buffer by the direct write

21.458 wxMemoryDC Class Reference

`#include <wx/dcmemory.h>`

Inheritance diagram for wxMemoryDC:



21.458.1 Detailed Description

A memory device context provides a means to draw graphics onto a bitmap.

When drawing in to a mono-bitmap, using `wxWHITE`, `wxWHITE_PEN` and `wxWHITE_BRUSH` will draw the background colour (i.e. 0) whereas all other colours will draw the foreground colour (i.e. 1).

A bitmap must be selected into the new memory DC before it may be used for anything. Typical usage is as follows:

```
// Create a memory DC
wxMemoryDC temp_dc;
temp_dc.SelectObject(test_bitmap);

// We can now draw into the memory DC...
// Copy from this DC to another DC.
old_dc.Blit(250, 50, BITMAP_WIDTH, BITMAP_HEIGHT, temp_dc, 0, 0);
```

Note that the memory DC must be deleted (or the bitmap selected out of it) before a bitmap can be reselected into another memory DC.

And, before performing any other operations on the bitmap data, the bitmap must be selected out of the memory DC:

```
temp_dc.SelectObject(wxNullBitmap);
```

This happens automatically when wxMemoryDC object goes out of scope.

Library: wxCore

Category: Device Contexts

See also

wxBitmap, wxDC

Public Member Functions

- wxMemoryDC ()

  Constructs a new memory device context.
- wxMemoryDC (wxDC ∗dc)

  Constructs a new memory device context having the same characteristics as the given existing device context.
- wxMemoryDC (wxBitmap &bitmap)

  Constructs a new memory device context and calls SelectObject() with the given bitmap.
- void SelectObject (wxBitmap &bitmap)

  Works exactly like SelectObjectAsSource() but this is the function you should use when you select a bitmap because you want to modify it, e.g.
- void SelectObjectAsSource (const wxBitmap &bitmap)

  Selects the given bitmap into the device context, to use as the memory bitmap.

Additional Inherited Members

21.458.2 Constructor & Destructor Documentation

wxMemoryDC::wxMemoryDC ( )

Constructs a new memory device context.

Use the wxDC::IsOk() member to test whether the constructor was successful in creating a usable device context. Don't forget to select a bitmap into the DC before drawing on it.

wxMemoryDC::wxMemoryDC (wxDC ∗ *dc*)

Constructs a new memory device context having the same characteristics as the given existing device context.

This constructor creates a memory device context *compatible* with *dc* in wxMSW, the argument is ignored in the other ports. If *dc* is NULL, a device context compatible with the screen is created, just as with the default constructor.

wxMemoryDC::wxMemoryDC (wxBitmap & *bitmap*)

Constructs a new memory device context and calls SelectObject() with the given bitmap.

Use the wxDC::IsOk() member to test whether the constructor was successful in creating a usable device context.

21.458.3 Member Function Documentation

void wxMemoryDC::SelectObject (wxBitmap & *bitmap*)

Works exactly like SelectObjectAsSource() but this is the function you should use when you select a bitmap because you want to modify it, e.g.

drawing on this DC.

Using SelectObjectAsSource() when modifying the bitmap may incur some problems related to wxBitmap being a reference counted object (see Reference Counting).

Before using the updated bitmap data, make sure to select it out of context first either by selecting wxNullBitmap into the device context or destroying the device context entirely.

If the bitmap is already selected in this device context, nothing is done. If it is selected in another context, the function asserts and drawing on the bitmap won't work correctly.

See also

wxDC::DrawBitmap()

void wxMemoryDC::SelectObjectAsSource (const wxBitmap & *bitmap*)

Selects the given bitmap into the device context, to use as the memory bitmap.

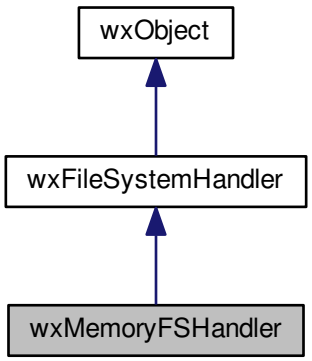
Selecting the bitmap into a memory DC allows you to draw into the DC (and therefore the bitmap) and also to use wxDC::Blit() to copy the bitmap to a window. For this purpose, you may find wxDC::DrawIcon() easier to use instead.

If the argument is wxNullBitmap (or some other uninitialised wxBitmap) the current bitmap is selected out of the device context, and the original bitmap restored, allowing the current bitmap to be destroyed safely.

21.459 wxMemoryFSHandler Class Reference

```
#include <wx/fs_mem.h>
```

Inheritance diagram for wxMemoryFSHandler:



21.459.1 Detailed Description

This wxFileSystem handler can store arbitrary data in memory stream and make them accessible via an URL.

It is particularly suitable for storing bitmaps from resources or included XPM files so that they can be used with wxHTML or wxWebView.

Filenames are prefixed with "memory:", e.g. "memory:myfile.html".

Example:

```
#ifndef __WXMSW__
#include "logo.xpm"
#endif

void MyFrame::OnAbout(wxCommandEvent&)
{
    wxFileSystem::AddHandler(new wxMemoryFSHandler);
    wxMemoryFSHandler::AddFile("logo.png", wxBITMAP(logo),
      wxBITMAP_TYPE_PNG);
    wxMemoryFSHandler::AddFile("about.htm",
                           "<html><body>About: "
                           "<img src=\"memory:logo.png\"></body></html>");

    wxDialog dlg(this, -1, wxString(_("About")));
    wxBoxSizer *topsizer;
    topsizer = new wxBoxSizer(wxVERTICAL);
#ifdef USE_WEBVIEW
    wxWebView* browser = wxWebView::New(&dlg, wxID_ANY,
      wxWebViewDefaultURLStr,
                            wxDefaultPosition, wxSize(380, 160));
    browser->RegisterHandler(wxSharedPtr<wxWebViewHandler>(new
      wxWebViewFSHandler("memory")));
    browser->LoadURL("memory:about.htm");
#else // Use wxHtml
    wxHtmlWindow *browser;
    browser = new wxHtmlWindow(&dlg, -1, wxDefaultPosition,
                               wxSize(380, 160), wxHW_SCROLLBAR_NEVER);
    browser->SetBorders(0);
    browser->LoadPage("memory:about.htm");
    browser->SetSize(browser->GetInternalRepresentation()->
      GetWidth(),
                 browser->GetInternalRepresentation()->
      GetHeight());
#endif
    topsizer->Add(browser, 1, wxALL, 10);
    topsizer->Add(new wxStaticLine(&dlg, -1), 0, wxEXPAND |
      wxLEFT | wxRIGHT, 10);
    topsizer->Add(new wxButton(&dlg, wxID_OK, "Ok"),
                 0, wxALL | wxALIGN_RIGHT, 15);
    dlg.SetAutoLayout(true);
    dlg.SetSizer(topsizer);
    topsizer->Fit(&dlg);
    dlg.Centre();
    dlg.ShowModal();

    wxMemoryFSHandler::RemoveFile("logo.png");
    wxMemoryFSHandler::RemoveFile("about.htm");
}
```

wxMemoryFSHandler::AddFileWithMimeType

Public Member Functions

- wxMemoryFSHandler ()

  Constructor.

Static Public Member Functions

- static void RemoveFile (const wxString &filename)

  Removes a file from memory FS and frees the occupied memory.

- static void AddFile (const wxString &filename, wxImage &image, wxBitmapType type)

  Adds a file to the list of the files stored in memory.

- static void AddFile (const wxString &filename, const wxBitmap &bitmap, wxBitmapType type)

  Adds a file to the list of the files stored in memory.

- static void AddFileWithMimeType (const wxString &filename, const wxString &textdata, const wxString &mimetype)

  Like AddFile(), but lets you explicitly specify added file's MIME type.

- static void AddFileWithMimeType (const wxString &filename, const void *binarydata, size_t size, const wxString &mimetype)

  Like AddFile(), but lets you explicitly specify added file's MIME type.

Additional Inherited Members

21.459.2 Constructor & Destructor Documentation

wxMemoryFSHandler::wxMemoryFSHandler ( )

Constructor.

21.459.3 Member Function Documentation

static void wxMemoryFSHandler::AddFile (const wxString & *filename,* wxImage & *image,* wxBitmapType *type*) `[static]`

Adds a file to the list of the files stored in memory.

Stored data (bitmap, text or raw data) will be copied into private memory stream and available under name "`memory:`" + *filename*.

Note

you must use a *type* value (aka image format) that wxWidgets can save (e.g. JPG, PNG, see wxImage documentation)!

See also

AddFileWithMimeType()

static void wxMemoryFSHandler::AddFile (const wxString & *filename,* const wxBitmap & *bitmap,* wxBitmapType *type*) `[static]`

Adds a file to the list of the files stored in memory.

Stored data (bitmap, text or raw data) will be copied into private memory stream and available under name "`memory:`" + *filename*.

Note

you must use a *type* value (aka image format) that wxWidgets can save (e.g. JPG, PNG, see wxImage documentation)!

AddFile()

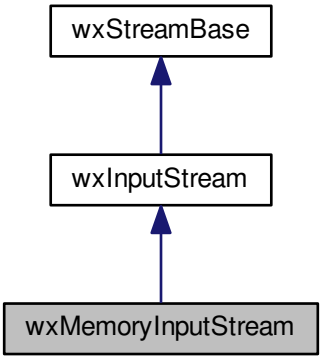
static void wxMemoryFSHandler::RemoveFile (const wxString & *filename*) [static]

Removes a file from memory FS and frees the occupied memory.

21.460 wxMemoryInputStream Class Reference

```
#include <wx/mstream.h>
```

Inheritance diagram for wxMemoryInputStream:



21.460.1 Detailed Description

This class allows to use all methods taking a wxInputStream reference to read in-memory data.

Example:

```
// we've got a block of memory containing a BMP image and we want
// to use wxImage to load it:
wxMemoryInputStream stream(my_memory_block, size);

wxImage theBitmap;
if (!theBitmap.LoadFile(stream, wxBITMAP_TYPE_BMP))
    return;

// we can now safely delete the original memory buffer as the data
// has been decoded by wxImage:
delete [] my_memory_block;
```

Library: wxBase

Category: Streams

See also

wxStreamBuffer, wxMemoryOutputStream

Public Member Functions

- wxMemoryInputStream (const void *data, size_t len)

  Initializes a new read-only memory stream which will use the specified buffer data of length len.
- wxMemoryInputStream (const wxMemoryOutputStream &stream)

  Creates a new read-only memory stream, initializing it with the data from the given output stream stream.
- wxMemoryInputStream (wxInputStream &stream, wxFileOffset len=wxInvalidOffset)

  Creates a new read-only memory stream, initializing it with the data from the given input stream stream.
- virtual ~wxMemoryInputStream ()

  Destructor.

- wxStreamBuffer * GetInputStreamBuffer () const

  Returns the pointer to the stream object used as an internal buffer for that stream.

Additional Inherited Members

21.460.2 Constructor & Destructor Documentation

wxMemoryInputStream::wxMemoryInputStream (const void * *data*, size_t *len*)

Initializes a new read-only memory stream which will use the specified buffer data of length len.

The stream does not take ownership of the buffer, i.e. the buffer will not be deleted in its destructor.

wxMemoryInputStream::wxMemoryInputStream (const wxMemoryOutputStream & *stream*)

Creates a new read-only memory stream, initializing it with the data from the given output stream *stream*.

wxMemoryInputStream::wxMemoryInputStream (wxInputStream & *stream*, wxFileOffset *len* = wxInvalidOffset)

Creates a new read-only memory stream, initializing it with the data from the given input stream *stream*.

The *len* argument specifies the amount of data to read from the *stream*. Setting it to wxInvalidOffset means that the *stream* is to be read entirely (i.e. till the EOF is reached).

virtual wxMemoryInputStream::~wxMemoryInputStream ( ) [virtual]

Destructor.

Does NOT free the buffer provided in the ctor.

21.460.3 Member Function Documentation

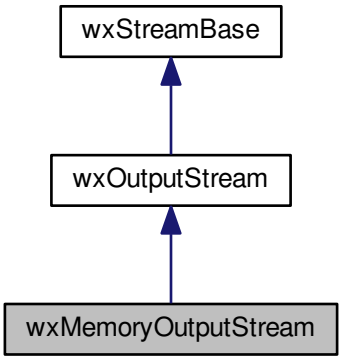
wxStreamBuffer* wxMemoryInputStream::GetInputStreamBuffer ( ) const

Returns the pointer to the stream object used as an internal buffer for that stream.

21.461 wxMemoryOutputStream Class Reference

`#include <wx/mstream.h>`

Inheritance diagram for wxMemoryOutputStream:



21.461.1 Detailed Description

This class allows to use all methods taking a wxOutputStream reference to write to in-memory data.

Example:

```
wxMemoryOutputStream stream;
if (!my_wxImage.SaveFile(stream))
    return;

// now we can access the saved image bytes:
wxStreamBuffer* theBuffer = stream.GetOutputStreamBuffer();
unsigned char byte;
if (theBuffer->Read(byte, 1) != 1)
    return;

// ... do something with 'byte'...

// remember that ~wxMemoryOutputStream will destroy the internal
// buffer since we didn't provide our own when constructing it
```

Library: wxBase

Category: Streams

See also

wxStreamBuffer

Public Member Functions

- wxMemoryOutputStream (void *data=NULL, size_t length=0)

  If data is NULL, then it will initialize a new empty buffer which will grow if required.
- virtual ~wxMemoryOutputStream ()

  Destructor.
- size_t CopyTo (void *buffer, size_t len) const

  Allows you to transfer data from the internal buffer of wxMemoryOutputStream to an external buffer.

- wxStreamBuffer * GetOutputStreamBuffer () const

  Returns the pointer to the stream object used as an internal buffer for this stream.

Additional Inherited Members

21.461.2 Constructor & Destructor Documentation

wxMemoryOutputStream::wxMemoryOutputStream (void * *data* = NULL, size_t *length* = 0)

If *data* is NULL, then it will initialize a new empty buffer which will grow if required.

Warning

If the buffer is created by wxMemoryOutputStream, it will be destroyed at the destruction of the stream.

virtual wxMemoryOutputStream::~wxMemoryOutputStream ( ) [virtual]

Destructor.

If the buffer wasn't provided by the user, it will be deleted here.

21.461.3 Member Function Documentation

size_t wxMemoryOutputStream::CopyTo (void * *buffer*, size_t *len*) const

Allows you to transfer data from the internal buffer of wxMemoryOutputStream to an external buffer.

len specifies the size of the buffer.

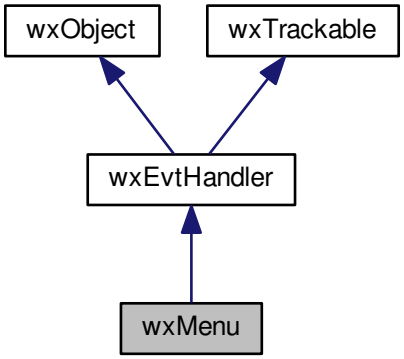
wxStreamBuffer* wxMemoryOutputStream::GetOutputStreamBuffer ( ) const

Returns the pointer to the stream object used as an internal buffer for this stream.

21.462 wxMenu Class Reference

```
#include <wx/menu.h>
```

Inheritance diagram for wxMenu:



21.462.1 Detailed Description

A menu is a popup (or pull down) list of items, one of which may be selected before the menu goes away (clicking elsewhere dismisses the menu).

Menus may be used to construct either menu bars or popup menus.

A menu item has an integer ID associated with it which can be used to identify the selection, or to change the menu item in some way. A menu item with a special identifier *wxID_SEPARATOR* is a separator item and doesn't have an associated command but just makes a separator line appear in the menu.

Note

> Please note that *wxID_ABOUT* and *wxID_EXIT* are predefined by wxWidgets and have a special meaning since entries using these IDs will be taken out of the normal menus under OS X and will be inserted into the system menu (following the appropriate OS X interface guideline).

Menu items may be either *normal* items, *check* items or *radio* items. Normal items don't have any special properties while the check items have a boolean flag associated to them and they show a checkmark in the menu when the flag is set. wxWidgets automatically toggles the flag value when the item is clicked and its value may be retrieved using either wxMenu::IsChecked method of wxMenu or wxMenuBar itself or by using wxEvent::IsChecked when you get the menu notification for the item in question.

The radio items are similar to the check items except that all the other items in the same radio group are unchecked when a radio item is checked. The radio group is formed by a contiguous range of radio items, i.e. it starts at the first item of this kind and ends with the first item of a different kind (or the end of the menu). Notice that because the radio groups are defined in terms of the item positions inserting or removing the items in the menu containing the radio items risks to not work correctly.

21.462.2 Allocation strategy

All menus must be created on the **heap** because all menus attached to a menubar or to another menu will be deleted by their parent when it is deleted. The only exception to this rule are the popup menus (i.e. menus used with wxWindow::PopupMenu()) as wxWidgets does not destroy them to allow reusing the same menu more than once. But the exception applies only to the menus themselves and not to any submenus of popup menus which are still destroyed by wxWidgets as usual and so must be heap-allocated.

As the frame menubar is deleted by the frame itself, it means that normally all menus used are deleted automatically.

21.462.3 Event handling

If the menu is part of a menubar, then wxMenuBar event processing is used.

With a popup menu (see wxWindow::PopupMenu), there is a variety of ways to handle a menu selection event (`wxEVT_MENU`):

- Provide `EVT_MENU` handlers in the window which pops up the menu, or in an ancestor of that window (the simplest method);
- Derive a new class from wxMenu and define event table entries using the `EVT_MENU` macro;
- Set a new event handler for wxMenu, through wxEvtHandler::SetNextHandler, specifying an object whose class has `EVT_MENU` entries;

Note that instead of static `EVT_MENU` macros you can also use dynamic connection; see Dynamic Event Handling.

Library: wxCore

Category: Menus

See also

wxMenuBar, wxWindow::PopupMenu, Events and Event Handling, wxFileHistory (most recently used files menu)

Public Member Functions

- wxMenu ()

  Constructs a wxMenu object.
- wxMenu (long style)

  Constructs a wxMenu object.
- wxMenu (const wxString &title, long style=0)

  Constructs a wxMenu object with a title.
- virtual ~wxMenu ()

  Destructor, destroying the menu.
- wxMenuItem * Append (int id, const wxString &item=wxEmptyString, const wxString &helpString=wxEmptyString, wxItemKind kind=wxITEM_NORMAL)

  Adds a menu item.
- wxMenuItem * Append (int id, const wxString &item, wxMenu *subMenu, const wxString &helpString=wxEmptyString)

  Adds a submenu.
- wxMenuItem * Append (wxMenuItem *menuItem)

  Adds a menu item object.
- wxMenuItem * AppendCheckItem (int id, const wxString &item, const wxString &help=wxEmptyString)

  Adds a checkable item to the end of the menu.
- wxMenuItem * AppendRadioItem (int id, const wxString &item, const wxString &help=wxEmptyString)

  Adds a radio item to the end of the menu.
- wxMenuItem * AppendSeparator ()

  Adds a separator to the end of the menu.
- wxMenuItem * AppendSubMenu (wxMenu *submenu, const wxString &text, const wxString &help=wxEmptyString)

  Adds the given submenu to this menu.

- virtual void Break ()

  Inserts a break in a menu, causing the next appended item to appear in a new column.
- void Check (int id, bool check)

  Checks or unchecks the menu item.
- bool Delete (int id)

  Deletes the menu item from the menu.
- bool Delete (wxMenuItem *item)

  Deletes the menu item from the menu.
- bool Destroy (int id)

  Deletes the menu item from the menu.
- bool Destroy (wxMenuItem *item)

  Deletes the menu item from the menu.
- void Enable (int id, bool enable)

  Enables or disables (greys out) a menu item.
- wxMenuItem * FindChildItem (int id, size_t *pos=NULL) const

  Finds the menu item object associated with the given menu item identifier and, optionally, the position of the item in the menu.
- virtual int FindItem (const wxString &itemString) const

  Finds the menu id for a menu item string.
- wxMenuItem * FindItem (int id, wxMenu **menu=NULL) const

  Finds the menu item object associated with the given menu item identifier and, optionally, the (sub)menu it belongs to.
- wxMenuItem * FindItemByPosition (size_t position) const

  Returns the wxMenuItem given a position in the menu.
- virtual wxString GetHelpString (int id) const

  Returns the help string associated with a menu item.
- wxString GetLabel (int id) const

  Returns a menu item label.
- wxString GetLabelText (int id) const

  Returns a menu item label, without any of the original mnemonics and accelerators.
- size_t GetMenuItemCount () const

  Returns the number of items in the menu.
- const wxString & GetTitle () const

  Returns the title of the menu.
- wxMenuItem * Insert (size_t pos, wxMenuItem *menuItem)

  Inserts the given item before the position pos.
- wxMenuItem * Insert (size_t pos, int id, const wxString &item=wxEmptyString, const wxString &help↩String=wxEmptyString, wxItemKind kind=wxITEM_NORMAL)

  Inserts the given item before the position pos.
- wxMenuItem * Insert (size_t pos, int id, const wxString &text, wxMenu *submenu, const wxString &help=wx↩EmptyString)

  Inserts the given submenu before the position pos.
- wxMenuItem * InsertCheckItem (size_t pos, int id, const wxString &item, const wxString &helpString=wx↩EmptyString)

  Inserts a checkable item at the given position.
- wxMenuItem * InsertRadioItem (size_t pos, int id, const wxString &item, const wxString &helpString=wx↩EmptyString)

  Inserts a radio item at the given position.
- wxMenuItem * InsertSeparator (size_t pos)

  Inserts a separator at the given position.
- bool IsChecked (int id) const

Determines whether a menu item is checked.

- bool IsEnabled (int id) const

  Determines whether a menu item is enabled.

- wxMenuItem * Prepend (wxMenuItem *item)

  Inserts the given item at position 0, i.e. before all the other existing items.

- wxMenuItem * Prepend (int id, const wxString &item=wxEmptyString, const wxString &helpString=wxEmptyString, wxItemKind kind=wxITEM_NORMAL)

  Inserts the given item at position 0, i.e. before all the other existing items.

- wxMenuItem * Prepend (int id, const wxString &text, wxMenu *submenu, const wxString &help=wxEmptyString)

  Inserts the given submenu at position 0.

- wxMenuItem * PrependCheckItem (int id, const wxString &item, const wxString &helpString=wxEmptyString)

  Inserts a checkable item at position 0.

- wxMenuItem * PrependRadioItem (int id, const wxString &item, const wxString &helpString=wxEmptyString)

  Inserts a radio item at position 0.

- wxMenuItem * PrependSeparator ()

  Inserts a separator at position 0.

- wxMenuItem * Remove (int id)

  Removes the menu item from the menu but doesn't delete the associated C++ object.

- wxMenuItem * Remove (wxMenuItem *item)

  Removes the menu item from the menu but doesn't delete the associated C++ object.

- virtual void SetHelpString (int id, const wxString &helpString)

  Sets an item's help string.

- void SetLabel (int id, const wxString &label)

  Sets the label of a menu item.

- virtual void SetTitle (const wxString &title)

  Sets the title of the menu.

- void UpdateUI (wxEvtHandler *source=NULL)

  Sends events to source (or owning window if NULL) to update the menu UI.

- void SetInvokingWindow (wxWindow *win)
- wxWindow * GetInvokingWindow () const
- wxWindow * GetWindow () const
- long GetStyle () const
- void SetParent (wxMenu *parent)
- wxMenu * GetParent () const
- virtual void Attach (wxMenuBar *menubar)
- virtual void Detach ()
- bool IsAttached () const

- wxMenuItemList & GetMenuItems ()

  Returns the list of items in the menu.

- const wxMenuItemList & GetMenuItems () const

  Returns the list of items in the menu.

Additional Inherited Members

21.462.4 Constructor & Destructor Documentation

wxMenu::wxMenu ( )

Constructs a wxMenu object.

wxMenu::wxMenu (long *style*)

Constructs a wxMenu object.

Parameters

style	If set to wxMENU_TEAROFF, the menu will be detachable (wxGTK and wxQT only).

wxMenu::wxMenu (const wxString & *title*, long *style* = 0)

Constructs a wxMenu object with a title.

Parameters

title	Title at the top of the menu (not always supported).
style	If set to wxMENU_TEAROFF, the menu will be detachable (wxGTK and wxQT only).

virtual wxMenu::~wxMenu ( ) [virtual]

Destructor, destroying the menu.

Note

Under Motif, a popup menu must have a valid parent (the window it was last popped up on) when being destroyed. Therefore, make sure you delete or re-use the popup menu *before* destroying the parent window. Re-use in this context means popping up the menu on a different window from last time, which causes an implicit destruction and recreation of internal data structures.

21.462.5 Member Function Documentation

wxMenuItem* wxMenu::Append (int *id*, const wxString & *item* = wxEmptyString, const wxString & *helpString* = wxEmptyString, wxItemKind *kind* = wxITEM_NORMAL)

Adds a menu item.

Parameters

id	The menu command identifier.
item	The string to appear on the menu item. See wxMenuItem::SetItemLabel() for more details.
helpString	An optional help string associated with the item. By default, the handler for the wxEVT_MENU_HIGHLIGHT event displays this string in the status line.
kind	May be wxITEM_SEPARATOR, wxITEM_NORMAL, wxITEM_CHECK or wxITEM_RADIO.

Example:

```
m_pFileMenu->Append(ID_NEW_FILE, "&New file\tCTRL+N", "Creates a new XYZ document");
```

or even better for stock menu items (see wxMenuItem::wxMenuItem):

```
m_pFileMenu->Append(wxID_NEW, "", "Creates a new XYZ document");
```

Remarks

This command can be used after the menu has been shown, as well as on initial creation of a menu or menubar.

See also

AppendSeparator(), AppendCheckItem(), AppendRadioItem(), AppendSubMenu(), Insert(), SetLabel(), GetHelpString(), SetHelpString(), wxMenuItem

wxMenuItem* wxMenu::Append (int *id,* const wxString & *item,* wxMenu * *subMenu,* const wxString & *helpString* = wxEmptyString)

Adds a submenu.

Deprecated This function is deprecated, use AppendSubMenu() instead.

Parameters

id	The menu command identifier.
item	The string to appear on the menu item.
subMenu	Pull-right submenu.
helpString	An optional help string associated with the item. By default, the handler for the `wxEVT_MENU_HIGHLIGHT` event displays this string in the status line.

See also

AppendSeparator(), AppendCheckItem(), AppendRadioItem(), AppendSubMenu(), Insert(), SetLabel(), GetHelpString(), SetHelpString(), wxMenuItem

wxMenuItem* wxMenu::Append (wxMenuItem * *menuItem*)

Adds a menu item object.

This is the most generic variant of Append() method because it may be used for both items (including separators) and submenus and because you can also specify various extra properties of a menu item this way, such as bitmaps and fonts.

Parameters

menuItem	A menuitem object. It will be owned by the wxMenu object after this function is called, so do not delete it yourself.

Remarks

See the remarks for the other Append() overloads.

See also

AppendSeparator(), AppendCheckItem(), AppendRadioItem(), AppendSubMenu(), Insert(), SetLabel(), GetHelpString(), SetHelpString(), wxMenuItem

wxMenuItem* wxMenu::AppendCheckItem (int *id,* const wxString & *item,* const wxString & *help* = wxEmptyString)

Adds a checkable item to the end of the menu.

See also

Append(), InsertCheckItem()

wxMenuItem* wxMenu::AppendRadioItem (int *id,* const wxString & *item,* const wxString & *help* = wxEmptyString)

Adds a radio item to the end of the menu.

All consequent radio items form a group and when an item in the group is checked, all the others are automatically unchecked.

Note

Radio items are not supported under wxMotif.

See also

Append(), InsertRadioItem()

wxMenuItem* wxMenu::AppendSeparator ( )

Adds a separator to the end of the menu.

See also

Append(), InsertSeparator()

wxMenuItem* wxMenu::AppendSubMenu (wxMenu * *submenu,* const wxString & *text,* const wxString & *help =* wxEmptyString)

Adds the given *submenu* to this menu.

text is the text shown in the menu for it and *help* is the help string shown in the status bar when the submenu item is selected.

See also

Insert(), Prepend()

virtual void wxMenu::Attach (wxMenuBar * *menubar*) [virtual]

virtual void wxMenu::Break ( ) [virtual]

Inserts a break in a menu, causing the next appended item to appear in a new column.

void wxMenu::Check (int *id,* bool *check*)

Checks or unchecks the menu item.

Parameters

id	The menu item identifier.
check	If true, the item will be checked, otherwise it will be unchecked.

See also

IsChecked()

bool wxMenu::Delete (int *id*)

Deletes the menu item from the menu.

If the item is a submenu, it will **not** be deleted. Use Destroy() if you want to delete a submenu.

Parameters

id	Id of the menu item to be deleted.

See also

FindItem(), Destroy(), Remove()

bool wxMenu::Delete (wxMenuItem * *item*)

Deletes the menu item from the menu.

If the item is a submenu, it will **not** be deleted. Use Destroy() if you want to delete a submenu.

Parameters

item	Menu item to be deleted.

See also

FindItem(), Destroy(), Remove()

bool wxMenu::Destroy (int *id*)

Deletes the menu item from the menu.

If the item is a submenu, it will be deleted. Use Remove() if you want to keep the submenu (for example, to reuse it later).

Parameters

id	Id of the menu item to be deleted.

See also

FindItem(), Delete(), Remove()

bool wxMenu::Destroy (wxMenuItem * *item*)

Deletes the menu item from the menu.

If the item is a submenu, it will be deleted. Use Remove() if you want to keep the submenu (for example, to reuse it later).

Parameters

item	Menu item to be deleted.

See also

FindItem(), Delete(), Remove()

virtual void wxMenu::Detach ( ) [virtual]

void wxMenu::Enable (int *id,* bool *enable*)

Enables or disables (greys out) a menu item.

Parameters

id	The menu item identifier.
enable	true to enable the menu item, false to disable it.

See also

IsEnabled()

wxMenuItem* wxMenu::FindChildItem (int *id*, size_t * *pos* = NULL) const

Finds the menu item object associated with the given menu item identifier and, optionally, the position of the item in the menu.

Unlike FindItem(), this function doesn't recurse but only looks at the direct children of this menu.

Parameters

id	The identifier of the menu item to find.
pos	If the pointer is not NULL, it is filled with the item's position if it was found or (size_t)wxNOT_FOUND otherwise.

Returns

Menu item object or NULL if not found.

virtual int wxMenu::FindItem (const wxString & *itemString*) const [virtual]

Finds the menu id for a menu item string.

Parameters

itemString	Menu item string to find.

Returns

Menu item identifier, or wxNOT_FOUND if none is found.

Remarks

Any special menu codes are stripped out of source and target strings before matching.

wxMenuItem* wxMenu::FindItem (int *id*, wxMenu ** *menu* = NULL) const

Finds the menu item object associated with the given menu item identifier and, optionally, the (sub)menu it belongs to.

Parameters

id	Menu item identifier.
menu	If the pointer is not NULL, it will be filled with the item's parent menu (if the item was found)

Returns

Menu item object or NULL if none is found.

wxMenuItem* wxMenu::FindItemByPosition (size_t *position*) const

Returns the wxMenuItem given a position in the menu.

virtual wxString wxMenu::GetHelpString (int *id*) const `[virtual]`

Returns the help string associated with a menu item.

Parameters

id	The menu item identifier.

Returns

The help string, or the empty string if there is no help string or the item was not found.

See also

SetHelpString(), Append()

wxWindow* wxMenu::GetInvokingWindow ( ) const

wxString wxMenu::GetLabel (int *id*) const

Returns a menu item label.

Parameters

id	The menu item identifier.

Returns

The item label, or the empty string if the item was not found.

See also

GetLabelText(), SetLabel()

wxString wxMenu::GetLabelText (int *id*) const

Returns a menu item label, without any of the original mnemonics and accelerators.

Parameters

id	The menu item identifier.

Returns

The item label, or the empty string if the item was not found.

See also

GetLabel(), SetLabel()

size_t wxMenu::GetMenuItemCount ( ) const

Returns the number of items in the menu.

wxMenuItemList& wxMenu::GetMenuItems ( )

Returns the list of items in the menu.

wxMenuItemList is a pseudo-template list class containing wxMenuItem pointers, see wxList.

const wxMenuItemList& wxMenu::GetMenuItems ( ) const

Returns the list of items in the menu.

wxMenuItemList is a pseudo-template list class containing wxMenuItem pointers, see wxList.

wxMenu* wxMenu::GetParent ( ) const

long wxMenu::GetStyle ( ) const

const wxString& wxMenu::GetTitle ( ) const

Returns the title of the menu.

See also

SetTitle()

wxWindow* wxMenu::GetWindow ( ) const

wxMenuItem* wxMenu::Insert (size_t *pos*, wxMenuItem * *menuItem*)

Inserts the given *item* before the position *pos*.

Inserting the item at position GetMenuItemCount() is the same as appending it.

See also

Append(), Prepend()

wxMenuItem* wxMenu::Insert (size_t *pos*, int *id*, const wxString & *item* = wxEmptyString, const wxString & *helpString* = wxEmptyString, wxItemKind *kind* = wxITEM_NORMAL)

Inserts the given *item* before the position *pos*.

Inserting the item at position GetMenuItemCount() is the same as appending it.

See also

Append(), Prepend()

wxMenuItem* wxMenu::Insert (size_t *pos*, int *id*, const wxString & *text*, wxMenu * *submenu*, const wxString & *help* = wxEmptyString)

Inserts the given *submenu* before the position *pos*.

text is the text shown in the menu for it and *help* is the help string shown in the status bar when the submenu item is selected.

See also

AppendSubMenu(), Prepend()

wxMenuItem* wxMenu::InsertCheckItem (size_t *pos*, int *id*, const wxString & *item*, const wxString & *helpString* = wxEmptyString)

Inserts a checkable item at the given position.

See also

Insert(), AppendCheckItem()

wxMenuItem* wxMenu::InsertRadioItem (size_t *pos*, int *id*, const wxString & *item*, const wxString & *helpString* = wxEmptyString)

Inserts a radio item at the given position.

See also

Insert(), AppendRadioItem()

wxMenuItem* wxMenu::InsertSeparator (size_t *pos*)

Inserts a separator at the given position.

See also

Insert(), AppendSeparator()

bool wxMenu::IsAttached ( ) const

bool wxMenu::IsChecked (int *id*) const

Determines whether a menu item is checked.

Parameters

id	The menu item identifier.

Returns

true if the menu item is checked, false otherwise.

See also

Check()

bool wxMenu::IsEnabled (int *id*) const

Determines whether a menu item is enabled.

Parameters

id	The menu item identifier.

Returns

true if the menu item is enabled, false otherwise.

See also

Enable()

wxMenuItem* wxMenu::Prepend (wxMenuItem * *item*)

Inserts the given *item* at position 0, i.e. before all the other existing items.

See also

Append(), Insert()

wxMenuItem* wxMenu::Prepend (int *id*, const wxString & *item* = wxEmptyString, const wxString & *helpString* = wxEmptyString, wxItemKind *kind* = wxITEM_NORMAL)

Inserts the given *item* at position 0, i.e. before all the other existing items.

See also

Append(), Insert()

wxMenuItem* wxMenu::Prepend (int *id*, const wxString & *text*, wxMenu * *submenu*, const wxString & *help* = wxEmptyString)

Inserts the given *submenu* at position 0.

See also

AppendSubMenu(), Insert()

wxMenuItem* wxMenu::PrependCheckItem (int *id*, const wxString & *item*, const wxString & *helpString* = wxEmptyString)

Inserts a checkable item at position 0.

See also

Prepend(), AppendCheckItem()

wxMenuItem* wxMenu::PrependRadioItem (int *id*, const wxString & *item*, const wxString & *helpString* = wxEmptyString)

Inserts a radio item at position 0.

See also

Prepend(), AppendRadioItem()

wxMenuItem* wxMenu::PrependSeparator ( )

Inserts a separator at position 0.

See also

Prepend(), AppendSeparator()

wxMenuItem* wxMenu::Remove (int *id*)

Removes the menu item from the menu but doesn't delete the associated C++ object.

This allows you to reuse the same item later by adding it back to the menu (especially useful with submenus).

Parameters

id	The identifier of the menu item to remove.

Returns

A pointer to the item which was detached from the menu.

wxMenuItem* wxMenu::Remove (wxMenuItem * *item*)

Removes the menu item from the menu but doesn't delete the associated C++ object.

This allows you to reuse the same item later by adding it back to the menu (especially useful with submenus).

Parameters

item	The menu item to remove.

Returns

A pointer to the item which was detached from the menu.

virtual void wxMenu::SetHelpString (int *id*, const wxString & *helpString*) [virtual]

Sets an item's help string.

Parameters

id	The menu item identifier.
helpString	The help string to set.

See also

GetHelpString()

void wxMenu::SetInvokingWindow (wxWindow * *win*)

void wxMenu::SetLabel (int *id*, const wxString & *label*)

Sets the label of a menu item.

Parameters

id	The menu item identifier.
label	The menu item label to set.

See also

Append(), GetLabel()

void wxMenu::SetParent (wxMenu * *parent*)

virtual void wxMenu::SetTitle (const wxString & *title*) [virtual]

Sets the title of the menu.

Parameters

title	The title to set.

Remarks

Notice that you can only call this method directly for the popup menus, to change the title of a menu that is part of a menu bar you need to use wxMenuBar::SetLabelTop().

See also

GetTitle()

void wxMenu::UpdateUI (wxEvtHandler * *source* = NULL)

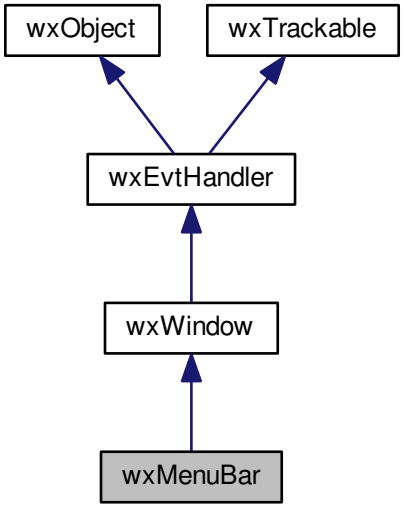
Sends events to *source* (or owning window if NULL) to update the menu UI.

This is called just before the menu is popped up with wxWindow::PopupMenu, but the application may call it at other times if required.

21.463 wxMenuBar Class Reference

```
#include <wx/menu.h>
```

Inheritance diagram for wxMenuBar:



21.463.1 Detailed Description

A menu bar is a series of menus accessible from the top of a frame.

Remarks

To respond to a menu selection, provide a handler for EVT_MENU, in the frame that contains the menu bar.

If you have a toolbar which uses the same identifiers as your EVT_MENU entries, events from the toolbar will also be processed by your EVT_MENU event handlers.

Tip: under Windows, if you discover that menu shortcuts (for example, Alt-F to show the file menu) are not working, check any EVT_CHAR events you are handling in child windows. If you are not calling event.Skip() for events that you don't process in these event handlers, menu shortcuts may cease to work.

Library: wxCore

Category: Menus

wxMenu, Events and Event Handling

Public Member Functions

- wxMenuBar (long style=0)

  Construct an empty menu bar.
- wxMenuBar (size_t n, wxMenu *menus[], const wxString titles[], long style=0)

  Construct a menu bar from arrays of menus and titles.

- virtual ~wxMenuBar ()

  Destructor, destroying the menu bar and removing it from the parent frame (if any).
- virtual bool Append (wxMenu *menu, const wxString &title)

  Adds the item to the end of the menu bar.
- void Check (int id, bool check)

  Checks or unchecks a menu item.
- void Enable (int id, bool enable)

  Enables or disables (greys out) a menu item.
- bool IsEnabledTop (size_t pos) const

  Returns true if the menu with the given index is enabled.
- virtual void EnableTop (size_t pos, bool enable)

  Enables or disables a whole menu.
- virtual wxMenuItem * FindItem (int id, wxMenu **menu=NULL) const

  Finds the menu item object associated with the given menu item identifier.
- int FindMenu (const wxString &title) const

  Returns the index of the menu with the given title or `wxNOT_FOUND` if no such menu exists in this menubar.
- virtual int FindMenuItem (const wxString &menuString, const wxString &itemString) const

  Finds the menu item id for a menu name/menu item string pair.
- wxString GetHelpString (int id) const

  Gets the help string associated with the menu item identifier.
- wxString GetLabel (int id) const

  Gets the label associated with a menu item.
- wxString GetLabelTop (size_t pos) const

  Returns the label of a top-level menu.
- wxMenu * GetMenu (size_t menuIndex) const

  Returns the menu at menuIndex (zero-based).
- size_t GetMenuCount () const

  Returns the number of menus in this menubar.
- virtual wxString GetMenuLabel (size_t pos) const

  Returns the label of a top-level menu.
- virtual wxString GetMenuLabelText (size_t pos) const

  Returns the label of a top-level menu.
- virtual bool Insert (size_t pos, wxMenu *menu, const wxString &title)

  Inserts the menu at the given position into the menu bar.
- bool IsChecked (int id) const

  Determines whether an item is checked.
- bool IsEnabled (int id) const

  Determines whether an item is enabled.
- virtual void Refresh (bool eraseBackground=true, const wxRect *rect=NULL)

  Redraw the menu bar.
- virtual wxMenu * Remove (size_t pos)

  Removes the menu from the menu bar and returns the menu object - the caller is responsible for deleting it.
- virtual wxMenu * Replace (size_t pos, wxMenu *menu, const wxString &title)

  Replaces the menu at the given position with another one.
- void SetHelpString (int id, const wxString &helpString)

  Sets the help string associated with a menu item.
- void SetLabel (int id, const wxString &label)

  Sets the label of a menu item.
- void SetLabelTop (size_t pos, const wxString &label)

  Sets the label of a top-level menu.
- virtual void SetMenuLabel (size_t pos, const wxString &label)

Sets the label of a top-level menu.

- wxMenu * OSXGetAppleMenu () const

  Returns the Apple menu.
- wxFrame * GetFrame () const
- bool IsAttached () const
- virtual void Attach (wxFrame *frame)
- virtual void Detach ()

Static Public Member Functions

- static void MacSetCommonMenuBar (wxMenuBar *menubar)

  Enables you to set the global menubar on Mac, that is, the menubar displayed when the app is running without any frames open.
- static wxMenuBar * MacGetCommonMenuBar ()

  Enables you to get the global menubar on Mac, that is, the menubar displayed when the app is running without any frames open.

Additional Inherited Members

21.463.2 Constructor & Destructor Documentation

wxMenuBar::wxMenuBar (long *style* = 0)

Construct an empty menu bar.

Parameters

style	If wxMB_DOCKABLE the menu bar can be detached (wxGTK only).

wxMenuBar::wxMenuBar (size_t *n*, wxMenu * *menus[]*, const wxString *titles[]*, long *style* = 0)

Construct a menu bar from arrays of menus and titles.

Parameters

n	The number of menus.
menus	An array of menus. Do not use this array again - it now belongs to the menu bar.
titles	An array of title strings. Deallocate this array after creating the menu bar.
style	If wxMB_DOCKABLE the menu bar can be detached (wxGTK only).

wxPerl Note: Not supported by wxPerl.

virtual wxMenuBar::~wxMenuBar ( ) [virtual]

Destructor, destroying the menu bar and removing it from the parent frame (if any).

21.463.3 Member Function Documentation

virtual bool wxMenuBar::Append (wxMenu * *menu*, const wxString & *title*) [virtual]

Adds the item to the end of the menu bar.

Parameters

menu	The menu to add. Do not deallocate this menu after calling Append().
title	The title of the menu, must be non-empty.

Returns

true on success, false if an error occurred.

See also

Insert()

virtual void wxMenuBar::Attach (wxFrame * *frame*) [virtual]

void wxMenuBar::Check (int *id*, bool *check*)

Checks or unchecks a menu item.

Parameters

id	The menu item identifier.
check	If true, checks the menu item, otherwise the item is unchecked.

Remarks

Only use this when the menu bar has been associated with a frame; otherwise, use the wxMenu equivalent call.

virtual void wxMenuBar::Detach ( ) [virtual]

void wxMenuBar::Enable (int *id*, bool *enable*)

Enables or disables (greys out) a menu item.

Parameters

id	The menu item identifier.
enable	true to enable the item, false to disable it.

Remarks

Only use this when the menu bar has been associated with a frame; otherwise, use the wxMenu equivalent call.

virtual void wxMenuBar::EnableTop (size_t *pos*, bool *enable*) [virtual]

Enables or disables a whole menu.

Parameters

pos	The position of the menu, starting from zero.
enable	true to enable the menu, false to disable it.

Remarks

Only use this when the menu bar has been associated with a frame.

virtual wxMenuItem* wxMenuBar::FindItem (int *id,* wxMenu ** *menu =* NULL) const [virtual]

Finds the menu item object associated with the given menu item identifier.

Parameters

id	Menu item identifier.
menu	If not NULL, menu will get set to the associated menu.

Returns

The found menu item object, or NULL if one was not found.

wxPerl Note: In wxPerl this method takes just the *id* parameter; in scalar context it returns the associated `Wx::MenuItem`, in list context it returns a 2-element list (item, submenu).

int wxMenuBar::FindMenu (const wxString & *title*) const

Returns the index of the menu with the given *title* or `wxNOT_FOUND` if no such menu exists in this menubar.

The *title* parameter may specify either the menu title (with accelerator characters, i.e. `"&File"`) or just the menu label (`"File"`) indifferently.

virtual int wxMenuBar::FindMenuItem (const wxString & *menuString,* const wxString & *itemString*) const [virtual]

Finds the menu item id for a menu name/menu item string pair.

Parameters

menuString	Menu title to find.
itemString	Item to find.

Returns

The menu item identifier, or wxNOT_FOUND if none was found.

Remarks

Any special menu codes are stripped out of source and target strings before matching.

wxFrame* wxMenuBar::GetFrame ( ) const

wxString wxMenuBar::GetHelpString (int *id*) const

Gets the help string associated with the menu item identifier.

Parameters

id	The menu item identifier.

Returns

The help string, or the empty string if there was no help string or the menu item was not found.

See also

SetHelpString()

wxString wxMenuBar::GetLabel (int *id*) const

Gets the label associated with a menu item.

Parameters

id	The menu item identifier.

Returns

The menu item label, or the empty string if the item was not found.

Remarks

Use only after the menubar has been associated with a frame.

wxString wxMenuBar::GetLabelTop (size_t *pos*) const

Returns the label of a top-level menu.

Note that the returned string does not include the accelerator characters which could have been specified in the menu title string during its construction.

Parameters

pos	Position of the menu on the menu bar, starting from zero.

Returns

The menu label, or the empty string if the menu was not found.

Remarks

Use only after the menubar has been associated with a frame.

Deprecated This function is deprecated in favour of GetMenuLabel() and GetMenuLabelText().

See also

SetLabelTop()

wxMenu* wxMenuBar::GetMenu (size_t *menuIndex*) const

Returns the menu at *menuIndex* (zero-based).

size_t wxMenuBar::GetMenuCount ( ) const

Returns the number of menus in this menubar.

virtual wxString wxMenuBar::GetMenuLabel (size_t *pos*) const [virtual]

Returns the label of a top-level menu.

Note that the returned string includes the accelerator characters that have been specified in the menu title string during its construction.

Parameters

pos	Position of the menu on the menu bar, starting from zero.

Returns

The menu label, or the empty string if the menu was not found.

Remarks

Use only after the menubar has been associated with a frame.

See also

GetMenuLabelText(), SetMenuLabel()

virtual wxString wxMenuBar::GetMenuLabelText (size_t *pos*) const [virtual]

Returns the label of a top-level menu.

Note that the returned string does not include any accelerator characters that may have been specified in the menu title string during its construction.

Parameters

pos	Position of the menu on the menu bar, starting from zero.

Returns

The menu label, or the empty string if the menu was not found.

Remarks

Use only after the menubar has been associated with a frame.

See also

GetMenuLabel(), SetMenuLabel()

virtual bool wxMenuBar::Insert (size_t *pos*, wxMenu * *menu*, const wxString & *title*) [virtual]

Inserts the menu at the given position into the menu bar.

Inserting menu at position 0 will insert it in the very beginning of it, inserting at position GetMenuCount() is the same as calling Append().

Parameters

pos	The position of the new menu in the menu bar
menu	The menu to add. wxMenuBar owns the menu and will free it.
title	The title of the menu.

Returns

true on success, false if an error occurred.

See also

Append()

bool wxMenuBar::IsAttached ( ) const

bool wxMenuBar::IsChecked (int *id*) const

Determines whether an item is checked.

Parameters

id	The menu item identifier.

Returns

true if the item was found and is checked, false otherwise.

bool wxMenuBar::IsEnabled (int *id*) const

Determines whether an item is enabled.

Parameters

id	The menu item identifier.

Returns

true if the item was found and is enabled, false otherwise.

bool wxMenuBar::IsEnabledTop (size_t *pos*) const

Returns true if the menu with the given index is enabled.

Parameters

pos	The menu position (0-based)

Since

2.9.4

static wxMenuBar* wxMenuBar::MacGetCommonMenuBar ( ) [static]

Enables you to get the global menubar on Mac, that is, the menubar displayed when the app is running without any frames open.

Returns

The global menubar.

Remarks

Only exists on Mac, other platforms do not have this method.

Availability: only available for the wxOSX port.

static void wxMenuBar::MacSetCommonMenuBar (wxMenuBar * *menubar*) [static]

Enables you to set the global menubar on Mac, that is, the menubar displayed when the app is running without any frames open.

Parameters

menubar	The menubar to set.

Remarks

Only exists on Mac, other platforms do not have this method.

Availability: only available for the wxOSX port.

wxMenu* wxMenuBar::OSXGetAppleMenu ( ) const

Returns the Apple menu.

This is the leftmost menu with application's name as its title. You shouldn't remove any items from it, but it is safe to insert extra menu items or submenus into it.

Availability: only available for the wxOSX port.

Since

3.0.1

virtual void wxMenuBar::Refresh (bool *eraseBackground* = `true`, const wxRect * *rect* = `NULL`) `[virtual]`

Redraw the menu bar.

Reimplemented from wxWindow.

virtual wxMenu* wxMenuBar::Remove (size_t *pos*) `[virtual]`

Removes the menu from the menu bar and returns the menu object - the caller is responsible for deleting it.

This function may be used together with Insert() to change the menubar dynamically.

See also

Replace()

virtual wxMenu* wxMenuBar::Replace (size_t *pos*, wxMenu * *menu*, const wxString & *title*) `[virtual]`

Replaces the menu at the given position with another one.

Parameters

pos	The position of the new menu in the menu bar
menu	The menu to add.
title	The title of the menu.

Returns

The menu which was previously at position pos. The caller is responsible for deleting it.

See also

Insert(), Remove()

void wxMenuBar::SetHelpString (int *id,* const wxString & *helpString*)

Sets the help string associated with a menu item.

Parameters

id	Menu item identifier.
helpString	Help string to associate with the menu item.

See also

GetHelpString()

void wxMenuBar::SetLabel (int *id,* const wxString & *label*)

Sets the label of a menu item.

Parameters

id	Menu item identifier.
label	Menu item label.

Remarks

Use only after the menubar has been associated with a frame.

See also

GetLabel()

void wxMenuBar::SetLabelTop (size_t *pos,* const wxString & *label*)

Sets the label of a top-level menu.

Parameters

pos	The position of a menu on the menu bar, starting from zero.
label	The menu label.

Remarks

Use only after the menubar has been associated with a frame.

Deprecated This function has been deprecated in favour of SetMenuLabel().

See also

GetLabelTop()

virtual void wxMenuBar::SetMenuLabel (size_t *pos,* const wxString & *label*) [virtual]

Sets the label of a top-level menu.

Parameters

pos	The position of a menu on the menu bar, starting from zero.
label	The menu label.

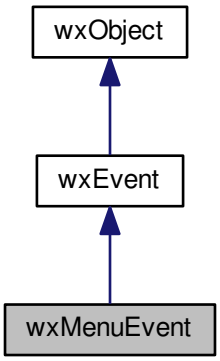
Remarks

Use only after the menubar has been associated with a frame.

21.464 wxMenuEvent Class Reference

`#include <wx/event.h>`

Inheritance diagram for wxMenuEvent:



21.464.1 Detailed Description

This class is used for a variety of menu-related events.

Note that these do not include menu command events, which are handled using wxCommandEvent objects.

Events of this class are generated by both menus that are part of a wxMenuBar, attached to wxFrame, and popup menus shown by wxWindow::PopupMenu(). They are sent to the following objects until one of them handles the event:

```
-# The menu object itself, as returned by GetMenu(), if any.
-# The wxMenuBar to which this menu is attached, if any.
-# The window associated with the menu, e.g. the one calling
PopupMenu() for the popup menus.
-# The top level parent of that window if it's different from the
window itself.
```

This is similar to command events generated by the menu items, but, unlike them, wxMenuEvent are only sent to the window itself and its top level parent but not any intermediate windows in the hierarchy.

The default handler for `wxEVT_MENU_HIGHLIGHT` in wxFrame displays help text in the status bar, see wxFrame::SetStatusBarPane().

Events using this class

The following event handler macros redirect the events to member function handlers '**func**' with prototypes like: void handlerFuncName(wxMenuEvent& event)

Event macros:

- EVT_MENU_OPEN(func): A menu is about to be opened. On Windows, this is only sent once for each navigation of the menubar (up until all menus have closed).
- EVT_MENU_CLOSE(func): A menu has been just closed. Notice that this event is currently being sent before the menu selection (`wxEVT_MENU`) event, if any.

- EVT_MENU_HIGHLIGHT(id, func): The menu item with the specified id has been highlighted: used to show help prompts in the status bar by wxFrame
- EVT_MENU_HIGHLIGHT_ALL(func): A menu item has been highlighted, i.e. the currently selected menu item has changed.

Library: wxCore

Category: Events

See also

wxCommandEvent, Events and Event Handling

Public Member Functions

- wxMenuEvent (wxEventType type=wxEVT_NULL, int id=0, wxMenu *menu=NULL)

  Constructor.
- wxMenu * GetMenu () const

  Returns the menu which is being opened or closed.
- int GetMenuId () const

  Returns the menu identifier associated with the event.
- bool IsPopup () const

  Returns true if the menu which is being opened or closed is a popup menu, false if it is a normal one.

Additional Inherited Members

21.464.2 Constructor & Destructor Documentation

wxMenuEvent::wxMenuEvent (wxEventType *type* = wxEVT_NULL, int *id* = 0, wxMenu * *menu* = NULL)

Constructor.

21.464.3 Member Function Documentation

wxMenu* wxMenuEvent::GetMenu ( ) const

Returns the menu which is being opened or closed.

This method can only be used with the OPEN and CLOSE events.

The returned value is never NULL in the ports implementing this function, which currently includes all the major ones.

int wxMenuEvent::GetMenuId ( ) const

Returns the menu identifier associated with the event.

This method should be only used with the HIGHLIGHT events.

bool wxMenuEvent::IsPopup ( ) const

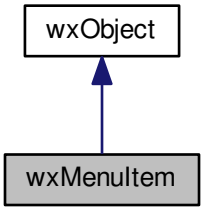
Returns true if the menu which is being opened or closed is a popup menu, false if it is a normal one.

This method should only be used with the `OPEN` and `CLOSE` events.

21.465 wxMenuItem Class Reference

`#include <wx/menuitem.h>`

Inheritance diagram for wxMenuItem:



21.465.1 Detailed Description

A menu item represents an item in a menu.

Note that you usually don't have to deal with it directly as wxMenu methods usually construct an object of this class for you.

Also please note that the methods related to fonts and bitmaps are currently only implemented for Windows, Mac and GTK+.

Events emitted by this class

The following event handler macros redirect the events to member function handlers '**func**' with prototypes like: void handlerFuncName(wxCommandEvent& event) or void handlerFuncName(wxMenuEvent& event)

Event macros for events emitted by this class:

- EVT_MENU(id, func): Process a `wxEVT_MENU` command, which is generated by a menu item. This type of event is sent as wxCommandEvent.
- EVT_MENU_RANGE(id1, id2, func): Process a `wxEVT_MENU` command, which is generated by a range of menu items. This type of event is sent as wxCommandEvent.
- EVT_MENU_OPEN(func): A menu is about to be opened. On Windows, this is only sent once for each navigation of the menubar (up until all menus have closed). This type of event is sent as wxMenuEvent.
- EVT_MENU_CLOSE(func): A menu has been just closed. This type of event is sent as wxMenuEvent.
- EVT_MENU_HIGHLIGHT(id, func): The menu item with the specified id has been highlighted: used to show help prompts in the status bar by wxFrame This type of event is sent as wxMenuEvent.
- EVT_MENU_HIGHLIGHT_ALL(func): A menu item has been highlighted, i.e. the currently selected menu item has changed. This type of event is sent as wxMenuEvent.

wxMenuBar, wxMenu

Getters

- wxColour & GetBackgroundColour () const

  Returns the background colour associated with the menu item.
- virtual const wxBitmap & GetBitmap (bool checked=true) const

  Returns the checked or unchecked bitmap.
- virtual const wxBitmap & GetDisabledBitmap () const

  Returns the bitmap to be used for disabled items.
- wxFont & GetFont () const

  Returns the font associated with the menu item.
- const wxString & GetHelp () const

  Returns the help string associated with the menu item.
- int GetId () const

  Returns the menu item identifier.
- virtual wxString GetItemLabel () const

  Returns the text associated with the menu item including any accelerator characters that were passed to the constructor or SetItemLabel().
- virtual wxString GetItemLabelText () const

  Returns the text associated with the menu item, without any accelerator characters.
- wxItemKind GetKind () const

  Returns the item kind, one of `wxITEM_SEPARATOR`*,* `wxITEM_NORMAL`*,* `wxITEM_CHECK` *or* `wxITEM_RADIO`*.*
- wxString GetLabel () const

  Returns the text associated with the menu item without any accelerator characters it might contain.
- int GetMarginWidth () const

  Gets the width of the menu item checkmark bitmap.
- wxMenu * GetMenu () const

  Returns the menu this menu item is in, or NULL if this menu item is not attached.
- wxString GetName () const

  Returns the text associated with the menu item.
- wxMenu * GetSubMenu () const

  Returns the submenu associated with the menu item, or NULL if there isn't one.
- const wxString & GetText () const

  Returns the text associated with the menu item, such as it was passed to the wxMenuItem constructor, i.e. with any accelerator characters it may contain.
- wxColour & GetTextColour () const

  Returns the text colour associated with the menu item.
- virtual wxAcceleratorEntry * GetAccel () const

  Get our accelerator or NULL (caller must delete the pointer)
- static wxAcceleratorEntry * GetAccelFromString (const wxString &label)

  Extract the accelerator from the given menu string, return NULL if none found.

Public Member Functions

- wxMenuItem (wxMenu *parentMenu=NULL, int id=wxID_SEPARATOR, const wxString &text=wxEmptyString, const wxString &helpString=wxEmptyString, wxItemKind kind=wxITEM_NORMAL, wxMenu *subMenu=NULL)

  Constructs a wxMenuItem object.
- virtual ~wxMenuItem ()

  Destructor.
- virtual void Check (bool check=true)

  Checks or unchecks the menu item.
- virtual void Enable (bool enable=true)

  Enables or disables the menu item.

Checkers

- bool IsCheck () const

  Returns true if the item is a check item.
- bool IsCheckable () const

  Returns true if the item is checkable.
- virtual bool IsChecked () const

  Returns true if the item is checked.
- virtual bool IsEnabled () const

  Returns true if the item is enabled.
- bool IsRadio () const

  Returns true if the item is a radio button.
- bool IsSeparator () const

  Returns true if the item is a separator.
- bool IsSubMenu () const

  Returns true if the item is a submenu.

Setters

- void SetBackgroundColour (const wxColour &colour)

  Sets the background colour associated with the menu item.
- virtual void SetBitmap (const wxBitmap &bmp, bool checked=true)

  Sets the bitmap for the menu item.
- void SetBitmaps (const wxBitmap &checked, const wxBitmap &unchecked=wxNullBitmap)

  Sets the checked/unchecked bitmaps for the menu item.
- void SetDisabledBitmap (const wxBitmap &disabled)

  Sets the to be used for disabled menu items.
- void SetFont (const wxFont &font)

  Sets the font associated with the menu item.
- void SetHelp (const wxString &helpString)

  Sets the help string.
- virtual void SetItemLabel (const wxString &label)

  Sets the label associated with the menu item.
- void SetMarginWidth (int width)

  Sets the width of the menu item checkmark bitmap.
- void SetMenu (wxMenu *menu)

  Sets the parent menu which will contain this menu item.
- void SetSubMenu (wxMenu *menu)

  Sets the submenu of this menu item.
- virtual void SetText (const wxString &text)

  Sets the text associated with the menu item.
- void SetTextColour (const wxColour &colour)

  Sets the text colour associated with the menu item.
- virtual void SetAccel (wxAcceleratorEntry *accel)

  Set the accel for this item - this may also be done indirectly with SetText()

Static Public Member Functions

- static wxString GetLabelFromText (const wxString &text)
- static wxString GetLabelText (const wxString &text)

  Strips all accelerator characters and mnemonics from the given text.

Additional Inherited Members

21.465.2 Constructor & Destructor Documentation

wxMenuItem::wxMenuItem (wxMenu * *parentMenu* = NULL, int *id* = wxID_SEPARATOR, const wxString & *text* = wxEmptyString, const wxString & *helpString* = wxEmptyString, wxItemKind *kind* = wxITEM_NORMAL, wxMenu * *subMenu* = NULL)

Constructs a wxMenuItem object.

Menu items can be standard, or "stock menu items", or custom. For the standard menu items (such as commands to open a file, exit the program and so on, see Stock Items for the full list) it is enough to specify just the stock ID and leave *text* and *helpString* empty. Some platforms (currently wxGTK only, and see the remark in SetBitmap() documentation) will also show standard bitmaps for stock menu items.

Leaving at least *text* empty for the stock menu items is actually strongly recommended as they will have appearance and keyboard interface (including standard accelerators) familiar to the user.

For the custom (non-stock) menu items, *text* must be specified and while *helpString* may be left empty, it's recommended to pass the item description (which is automatically shown by the library in the status bar when the menu item is selected) in this parameter.

Finally note that you can e.g. use a stock menu label without using its stock help string:

```
// use all stock properties:
helpMenu->Append(wxID_ABOUT);

// use the stock label and the stock accelerator but not the stock help string:
helpMenu->Append(wxID_ABOUT, "", "My custom help string");

// use all stock properties except for the bitmap:
wxMenuItem *mymenu = new wxMenuItem(helpMenu, wxID_ABOUT);
mymenu->SetBitmap(wxArtProvider::GetBitmap(
      wxART_WARNING));
helpMenu->Append(mymenu);
```

that is, stock properties are set independently one from the other.

Parameters

parentMenu	Menu that the menu item belongs to. Can be NULL if the item is going to be added to the menu later.
id	Identifier for this menu item. May be wxID_SEPARATOR, in which case the given kind is ignored and taken to be wxITEM_SEPARATOR instead.
text	Text for the menu item, as shown on the menu. See SetItemLabel() for more info.
helpString	Optional help string that will be shown on the status bar.
kind	May be wxITEM_SEPARATOR, wxITEM_NORMAL, wxITEM_CHECK or wxITEM_RADIO.
subMenu	If non-NULL, indicates that the menu item is a submenu.

virtual wxMenuItem::~wxMenuItem ( ) [virtual]

Destructor.

21.465.3 Member Function Documentation

virtual void wxMenuItem::Check (bool *check* = `true`) [virtual]

Checks or unchecks the menu item.

Note that this only works when the item is already appended to a menu.

virtual void wxMenuItem::Enable (bool *enable* = `true`) [virtual]

Enables or disables the menu item.

virtual wxAcceleratorEntry* wxMenuItem::GetAccel ( ) const [virtual]

Get our accelerator or NULL (caller must delete the pointer)

static wxAcceleratorEntry* wxMenuItem::GetAccelFromString (const wxString & *label*) [static]

Extract the accelerator from the given menu string, return NULL if none found.

wxColour& wxMenuItem::GetBackgroundColour ( ) const

Returns the background colour associated with the menu item.

Availability: only available for the wxMSW port.

virtual const wxBitmap& wxMenuItem::GetBitmap (bool *checked* = `true`) const [virtual]

Returns the checked or unchecked bitmap.

Availability: only available for the wxMSW port.

virtual const wxBitmap& wxMenuItem::GetDisabledBitmap ( ) const [virtual]

Returns the bitmap to be used for disabled items.

Availability: only available for the wxMSW port.

wxFont& wxMenuItem::GetFont ( ) const

Returns the font associated with the menu item.

Availability: only available for the wxMSW port.

const wxString& wxMenuItem::GetHelp ( ) const

Returns the help string associated with the menu item.

int wxMenuItem::GetId ( ) const

Returns the menu item identifier.

virtual wxString wxMenuItem::GetItemLabel ( ) const `[virtual]`

Returns the text associated with the menu item including any accelerator characters that were passed to the constructor or SetItemLabel().

See also

GetItemLabelText(), GetLabelText()

virtual wxString wxMenuItem::GetItemLabelText ( ) const `[virtual]`

Returns the text associated with the menu item, without any accelerator characters.

See also

GetItemLabel(), GetLabelText()

wxItemKind wxMenuItem::GetKind ( ) const

Returns the item kind, one of `wxITEM_SEPARATOR`, `wxITEM_NORMAL`, `wxITEM_CHECK` or `wxITEM_RADIO`.

wxString wxMenuItem::GetLabel ( ) const

Returns the text associated with the menu item without any accelerator characters it might contain.

Deprecated This function is deprecated in favour of GetItemLabelText().

See also

GetItemLabelText()

static wxString wxMenuItem::GetLabelFromText (const wxString & *text*) `[static]`

Deprecated This function is deprecated; please use GetLabelText() instead.

See also

GetLabelText()

static wxString wxMenuItem::GetLabelText (const wxString & *text*) `[static]`

Strips all accelerator characters and mnemonics from the given *text*.

For example:

```
wxMenuItem::GetLabelfromText("&Hello\tCtrl-h");
```

will return just `"Hello"`.

See also

GetItemLabelText(), GetItemLabel()

int wxMenuItem::GetMarginWidth ( ) const

Gets the width of the menu item checkmark bitmap.

Availability: only available for the wxMSW port.

wxMenu* wxMenuItem::GetMenu ( ) const

Returns the menu this menu item is in, or NULL if this menu item is not attached.

wxString wxMenuItem::GetName ( ) const

Returns the text associated with the menu item.

Deprecated This function is deprecated. Please use GetItemLabel() or GetItemLabelText() instead.

See also

GetItemLabel(), GetItemLabelText()

wxMenu* wxMenuItem::GetSubMenu ( ) const

Returns the submenu associated with the menu item, or NULL if there isn't one.

const wxString& wxMenuItem::GetText ( ) const

Returns the text associated with the menu item, such as it was passed to the wxMenuItem constructor, i.e. with any accelerator characters it may contain.

Deprecated This function is deprecated in favour of GetItemLabel().

See also

GetLabelFromText()

wxColour& wxMenuItem::GetTextColour ( ) const

Returns the text colour associated with the menu item.

Availability: only available for the wxMSW port.

bool wxMenuItem::IsCheck ( ) const

Returns true if the item is a check item.

Unlike IsCheckable() this doesn't return true for the radio buttons.

Since

2.9.5

bool wxMenuItem::IsCheckable ( ) const

Returns true if the item is checkable.

Notice that the radio buttons are considered to be checkable as well, so this method returns true for them too. Use IsCheck() if you want to test for the check items only.

virtual bool wxMenuItem::IsChecked ( ) const `[virtual]`

Returns true if the item is checked.

virtual bool wxMenuItem::IsEnabled ( ) const `[virtual]`

Returns true if the item is enabled.

bool wxMenuItem::IsRadio ( ) const

Returns true if the item is a radio button.

Since

2.9.5

bool wxMenuItem::IsSeparator ( ) const

Returns true if the item is a separator.

bool wxMenuItem::IsSubMenu ( ) const

Returns true if the item is a submenu.

virtual void wxMenuItem::SetAccel (wxAcceleratorEntry * *accel*) `[virtual]`

Set the accel for this item - this may also be done indirectly with SetText()

void wxMenuItem::SetBackgroundColour (const wxColour & *colour*)

Sets the background colour associated with the menu item.

Availability: only available for the wxMSW port.

virtual void wxMenuItem::SetBitmap (const wxBitmap & *bmp*, bool *checked* = `true`) `[virtual]`

Sets the bitmap for the menu item.

It is equivalent to wxMenuItem::SetBitmaps(bmp, wxNullBitmap) if *checked* is true (default value) or SetBitmaps(wxNullBitmap, bmp) otherwise.

SetBitmap() must be called before the item is appended to the menu, i.e. appending the item without a bitmap and setting one later is not guaranteed to work. But the bitmap can be changed or reset later if it had been set up initially.

Notice that GTK+ uses a global setting called `gtk-menu-images` to determine if the images should be shown in the menus at all. If it is off (which is the case in e.g. Gnome 2.28 by default), no images will be shown, consistently with the native behaviour.

Availability: only available for the wxMSW, wxOSX, wxGTK ports.

void wxMenuItem::SetBitmaps (const wxBitmap & *checked,* const wxBitmap & *unchecked* = wxNullBitmap)

Sets the checked/unchecked bitmaps for the menu item.

The first bitmap is also used as the single bitmap for uncheckable menu items.

Availability: only available for the wxMSW port.

void wxMenuItem::SetDisabledBitmap (const wxBitmap & *disabled*)

Sets the to be used for disabled menu items.

Availability: only available for the wxMSW port.

void wxMenuItem::SetFont (const wxFont & *font*)

Sets the font associated with the menu item.

Availability: only available for the wxMSW port.

void wxMenuItem::SetHelp (const wxString & *helpString*)

Sets the help string.

virtual void wxMenuItem::SetItemLabel (const wxString & *label*) `[virtual]`

Sets the label associated with the menu item.

Note that if the ID of this menu item corresponds to a stock ID, then it is not necessary to specify a label: wxWidgets will automatically use the stock item label associated with that ID. See the constructor for more info.

The label string for the normal menu items (not separators) may include the accelerator which can be used to activate the menu item from keyboard. An accelerator key can be specified using the ampersand `&` character. In order to embed an ampersand character in the menu item text, the ampersand must be doubled.

Optionally you can specify also an accelerator string appending a tab character `\t` followed by a valid key combination (e.g. `CTRL+V`). Its general syntax is any combination of `"CTRL"`, `"RAWCTRL"`, `"ALT"` and `"SHIFT"` strings (case doesn't matter) separated by either `'-'` or `'+'` characters and followed by the accelerator itself. Notice that `CTRL` corresponds to the "Ctrl" key on most platforms but not under Mac OS where it is mapped to "Cmd" key on Mac keyboard. Usually this is exactly what you want in portable code but if you really need to use the (rarely used for this purpose) "Ctrl" key even under Mac, you may use `RAWCTRL` to prevent this mapping. Under the other platforms `RAWCTRL` is the same as plain `CTRL`.

The accelerator may be any alphanumeric character, any function key (from F1 to F12) or one of the special characters listed in the table below (again, case doesn't matter):

- `DEL` or `DELETE`: Delete key
- `BACK` : Backspace key
- `INS` or `INSERT`: Insert key
- `ENTER` or `RETURN`: Enter key
- `PGUP`: PageUp key
- `PGDN`: PageDown key
- `LEFT`: Left cursor arrow key
- `RIGHT`: Right cursor arrow key

- `UP`: Up cursor arrow key
- `DOWN`: Down cursor arrow key
- `HOME`: Home key
- `END`: End key
- `SPACE`: Space
- `TAB`: Tab key
- `ESC` or `ESCAPE`: Escape key (Windows only)

Examples:

```
m_pMyMenuItem->SetItemLabel("My &item\tCTRL+I");
m_pMyMenuItem2->SetItemLabel("Clean && build\tF7");
m_pMyMenuItem3->SetItemLabel("Simple item");
m_pMyMenuItem4->SetItemLabel("Item with &accelerator");
```

Note

In wxGTK using `"SHIFT"` with non-alphabetic characters currently doesn't work, even in combination with other modifiers, due to GTK+ limitation. E.g. `Shift+Ctrl+A` works but `Shift+Ctrl+1` or `Shift+/` do not, so avoid using accelerators of this form in portable code.

See also

GetItemLabel(), GetItemLabelText()

void wxMenuItem::SetMarginWidth (int *width*)

Sets the width of the menu item checkmark bitmap.

Availability: only available for the wxMSW port.

void wxMenuItem::SetMenu (wxMenu * *menu*)

Sets the parent menu which will contain this menu item.

void wxMenuItem::SetSubMenu (wxMenu * *menu*)

Sets the submenu of this menu item.

virtual void wxMenuItem::SetText (const wxString & *text*) `[virtual]`

Sets the text associated with the menu item.

Deprecated This function is deprecated in favour of SetItemLabel().

See also

SetItemLabel().

void wxMenuItem::SetTextColour (const wxColour & *colour*)

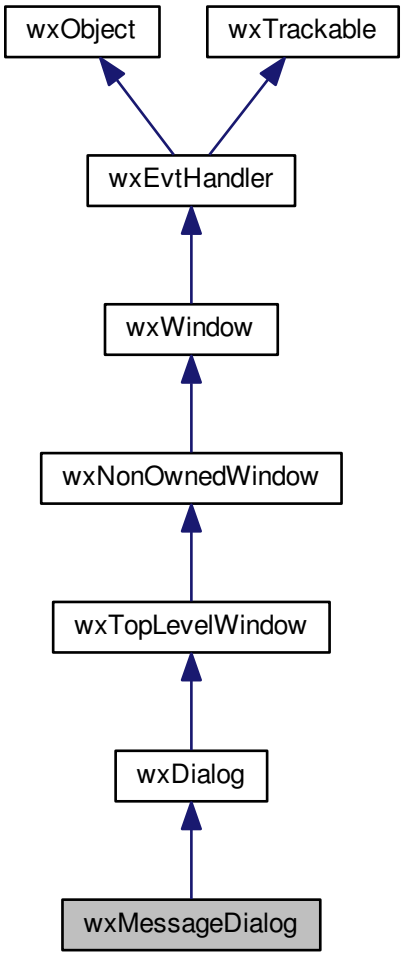
Sets the text colour associated with the menu item.

Availability: only available for the wxMSW port.

21.466 wxMessageDialog Class Reference

`#include <wx/msgdlg.h>`

Inheritance diagram for wxMessageDialog:



21.466.1 Detailed Description

This class represents a dialog that shows a single or multi-line message, with a choice of OK, Yes, No and Cancel buttons.

Styles

This class supports the following styles:

- wxOK: Puts an Ok button in the message box. May be combined with `wxCANCEL`.
- wxCANCEL: Puts a Cancel button in the message box. Must be combined with either `wxOK` or `wxYES_NO`.
- wxYES_NO: Puts Yes and No buttons in the message box. It is recommended to always use `wxCANCEL` with this style as otherwise the message box won't have a close button under wxMSW and the user will be forced to answer it.
- wxHELP: Puts a Help button to the message box. This button can have special appearance or be specially positioned if its label is not changed from the default one. Notice that using this button is not supported when showing a message box from non-main thread in wxOSX/Cocoa and it is not supported in wxOSX/Carbon at all. Available since wxWidgets 2.9.3.
- wxNO_DEFAULT: Makes the "No" button default, can only be used with `wxYES_NO`.
- wxCANCEL_DEFAULT: Makes the "Cancel" button default, can only be used with `wxCANCEL`. This style is currently not supported (and ignored) in wxOSX.
- wxYES_DEFAULT: Makes the "Yes" button default, this is the default behaviour and this flag exists solely for symmetry with `wxNO_DEFAULT`.
- wxOK_DEFAULT: Makes the "OK" button default, this is the default behaviour and this flag exists solely for symmetry with `wxCANCEL_DEFAULT`.
- wxICON_NONE: Displays no icon in the dialog if possible (an icon might still be displayed if the current platform mandates its use). This style may be used to prevent the dialog from using the default icon based on `wxYES_NO` presence as explained in `wxICON_QUESTION` and `wxICON_INFORMATION` documentation below.
- wxICON_EXCLAMATION: Displays an exclamation, or warning, icon in the dialog.
- wxICON_ERROR: Displays an error icon in the dialog.
- wxICON_HAND: Displays an error symbol, this is a MSW-inspired synonym for `wxICON_ERROR`.
- wxICON_QUESTION: Displays a question mark symbol. This icon is automatically used with `wxYES_NO` so it's usually unnecessary to specify it explicitly. This style is not supported for message dialogs under wxMSW when a task dialog is used to implement them (i.e. when running under Windows Vista or later) because `Microsoft guidelines` indicate that no icon should be used for routine confirmations. If it is specified, no icon will be displayed.
- wxICON_INFORMATION: Displays an information symbol. This icon is used by default if `wxYES_NO` is not given so it is usually unnecessary to specify it explicitly.
- wxICON_AUTH_NEEDED: Displays an authentication needed symbol. This style is only supported for message dialogs under wxMSW when a task dialog is used to implement them (i.e. when running under Windows Vista or later). In other cases the default icon selection logic will be used. Note this can be combined with other styles to provide a fallback. For instance, using wxICON_AUTH_NEEDED | wxICON_QUESTION will show a shield symbol on Windows Vista or above and a question symbol on other platforms. Available since wxWidgets 2.9.5
- wxSTAY_ON_TOP: Makes the message box stay on top of all other windows and not only just its parent (currently implemented only under MSW and GTK).
- wxCENTRE: Centre the message box on its parent or on the screen if parent is not specified. Setting this style under MSW makes no differences as the dialog is always centered on the parent.

Library: wxCore

Category: Common Dialogs

See also

wxMessageDialog Overview
wxRichMessageDialog

Classes

- class ButtonLabel

  Helper class allowing to use either stock id or string labels.

Public Member Functions

- wxMessageDialog (wxWindow *parent, const wxString &message, const wxString &caption=wxMessageBoxCaptionStr, long style=wxOK|wxCENTRE, const wxPoint &pos=wxDefaultPosition)

  Constructor specifying the message box properties.
- virtual void SetExtendedMessage (const wxString &extendedMessage)

  Sets the extended message for the dialog: this message is usually an extension of the short message specified in the constructor or set with SetMessage().
- virtual bool SetHelpLabel (const ButtonLabel &help)

  Sets the label for the Help button.
- virtual void SetMessage (const wxString &message)

  Sets the message shown by the dialog.
- virtual bool SetOKCancelLabels (const ButtonLabel &ok, const ButtonLabel &cancel)

  Overrides the default labels of the OK and Cancel buttons.
- virtual bool SetOKLabel (const ButtonLabel &ok)

  Overrides the default label of the OK button.
- virtual bool SetYesNoCancelLabels (const ButtonLabel &yes, const ButtonLabel &no, const ButtonLabel &cancel)

  Overrides the default labels of the Yes, No and Cancel buttons.
- virtual bool SetYesNoLabels (const ButtonLabel &yes, const ButtonLabel &no)

  Overrides the default labels of the Yes and No buttons.
- virtual int ShowModal ()

  Shows the dialog, returning one of wxID_OK, wxID_CANCEL, wxID_YES, wxID_NO or wxID_HELP.
- wxString GetCaption () const
- wxString GetMessage () const
- wxString GetExtendedMessage () const
- long GetMessageDialogStyle () const
- bool HasCustomLabels () const
- wxString GetYesLabel () const
- wxString GetNoLabel () const
- wxString GetOKLabel () const
- wxString GetCancelLabel () const
- wxString GetHelpLabel () const
- long GetEffectiveIcon () const

Additional Inherited Members

21.466.2 Constructor & Destructor Documentation

wxMessageDialog::wxMessageDialog (wxWindow * *parent*, const wxString & *message*, const wxString & *caption* = wxMessageBoxCaptionStr, long *style* = wxOK|wxCENTRE, const wxPoint & *pos* = wxDefaultPosition)

Constructor specifying the message box properties.

Use ShowModal() to show the dialog.

style may be a bit list of the identifiers described above.

Notice that not all styles are compatible: only one of `wxOK` and `wxYES_NO` may be specified (and one of them must be specified) and at most one default button style can be used and it is only valid if the corresponding button is shown in the message box.

Parameters

parent	Parent window.
message	Message to show in the dialog.
caption	The dialog title.
style	Combination of style flags described above.
pos	Dialog position (ignored under MSW).

21.466.3 Member Function Documentation

wxString wxMessageDialog::GetCancelLabel ( ) const

wxString wxMessageDialog::GetCaption ( ) const

long wxMessageDialog::GetEffectiveIcon ( ) const

wxString wxMessageDialog::GetExtendedMessage ( ) const

wxString wxMessageDialog::GetHelpLabel ( ) const

wxString wxMessageDialog::GetMessage ( ) const

long wxMessageDialog::GetMessageDialogStyle ( ) const

wxString wxMessageDialog::GetNoLabel ( ) const

wxString wxMessageDialog::GetOKLabel ( ) const

wxString wxMessageDialog::GetYesLabel ( ) const

bool wxMessageDialog::HasCustomLabels ( ) const

virtual void wxMessageDialog::SetExtendedMessage (const wxString & *extendedMessage*) `[virtual]`

Sets the extended message for the dialog: this message is usually an extension of the short message specified in the constructor or set with SetMessage().

If it is set, the main message appears highlighted – if supported – and this message appears beneath it in normal font. On the platforms which don't support extended messages, it is simply appended to the normal message with an empty line separating them.

Since

2.9.0

virtual bool wxMessageDialog::SetHelpLabel (const ButtonLabel & *help*) [virtual]

Sets the label for the Help button.

Please see the remarks in SetYesNoLabels() documentation.

Notice that changing the label of the help button resets its special status (if any, this depends on the platform) and it will be treated just like another button in this case.

Since

2.9.3

virtual void wxMessageDialog::SetMessage (const wxString & *message*) [virtual]

Sets the message shown by the dialog.

Since

2.9.0

virtual bool wxMessageDialog::SetOKCancelLabels (const ButtonLabel & *ok,* const ButtonLabel & *cancel*) [virtual]

Overrides the default labels of the OK and Cancel buttons.

Please see the remarks in SetYesNoLabels() documentation.

Since

2.9.0

virtual bool wxMessageDialog::SetOKLabel (const ButtonLabel & *ok*) [virtual]

Overrides the default label of the OK button.

Please see the remarks in SetYesNoLabels() documentation.

Since

2.9.0

virtual bool wxMessageDialog::SetYesNoCancelLabels (const ButtonLabel & *yes,* const ButtonLabel & *no,* const ButtonLabel & *cancel*) [virtual]

Overrides the default labels of the Yes, No and Cancel buttons.

Please see the remarks in SetYesNoLabels() documentation.

Since

2.9.0

virtual bool wxMessageDialog::SetYesNoLabels (const ButtonLabel & *yes*, const ButtonLabel & *no*) [virtual]

Overrides the default labels of the Yes and No buttons.

The arguments of this function can be either strings or one of the standard identifiers, such as wxID_APPLY or wxID_OPEN. Notice that even if the label is specified as an identifier, the return value of the dialog ShowModal() method still remains one of wxID_OK, wxID_CANCEL, wxID_YES or wxID_NO values, i.e. this identifier changes only the label appearance but not the return code generated by the button. It is possible to mix stock identifiers and string labels in the same function call, for example:

```
wxMessageDialog dlg(...);
dlg.SetYesNoLabels(wxID_SAVE, _("&Don't save"));
```

Also notice that this function is not currently available on all platforms (although as of wxWidgets 2.9.0 it is implemented in all major ports), so it may return false to indicate that the labels couldn't be changed. If it returns true, the labels were set successfully.

Typically, if the function was used successfully, the main dialog message may need to be changed, e.g.:

```
wxMessageDialog dlg(...);
if ( dlg.SetYesNoLabels(_("&Quit"), _("&Don't quit")) )
    dlg.SetMessage(_("What do you want to do?"));
else // buttons have standard "Yes"/"No" values, so rephrase the question
    dlg.SetMessage(_("Do you really want to quit?"));
```

Since

2.9.0

virtual int wxMessageDialog::ShowModal ( ) [virtual]

Shows the dialog, returning one of wxID_OK, wxID_CANCEL, wxID_YES, wxID_NO or wxID_HELP.

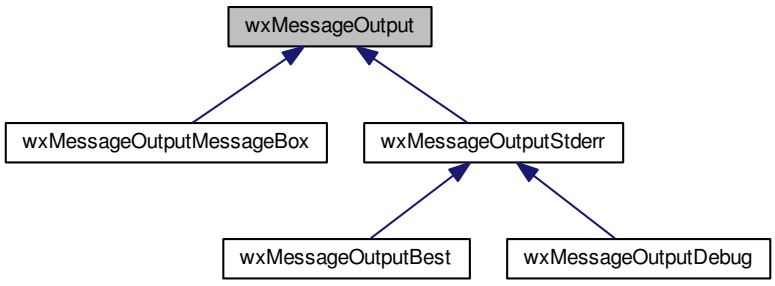
Notice that this method returns the identifier of the button which was clicked unlike wxMessageBox() function.

Reimplemented from wxDialog.

21.467 wxMessageOutput Class Reference

`#include <wx/msgout.h>`

Inheritance diagram for wxMessageOutput:



21.467.1 Detailed Description

Simple class allowing to write strings to various output channels.

wxMessageOutput is a low-level class and doesn't provide any of the conveniences of wxLog. It simply allows to write a message to some output channel: usually file or standard error but possibly also a message box. While use of wxLog and related functions is preferable in many cases sometimes this simple interface may be more convenient.

This class itself is an abstract base class for various concrete derived classes:

- wxMessageOutputStderr
- wxMessageOutputBest
- wxMessageOutputMessageBox
- wxMessageOutputLog

It also provides access to the global message output object which is created by wxAppTraits::CreateMessageOutput() which creates an object of class wxMessageOutputStderr in console applications and wxMessageOutputBest in the GUI ones but may be overridden in user-defined traits class.

Example of using this class:

```
wxMessageOutputDebug().Printf("name=%s, preparing to greet...", name);
wxMessageOutput::Get()->Printf("Hello, %s!", name);
```

Library: wxBase

Category: Logging

Public Member Functions

- void Printf (const wxString &format,...)

  Output a message.
- virtual void Output (const wxString &str)=0

  Method called by Printf() to really output the text.

Static Public Member Functions

- static wxMessageOutput * Get ()

  Return the global message output object.
- static wxMessageOutput * Set (wxMessageOutput *msgout)

  Sets the global message output object.

21.467.2 Member Function Documentation

static wxMessageOutput* wxMessageOutput::Get ( ) `[static]`

Return the global message output object.

This object is never NULL while the program is running but may be NULL during initialization (before wxApp object is instantiated) or shutdown.(after wxApp destruction).

See also

wxAppTraits::CreateMessageOutput()

virtual void wxMessageOutput::Output (const wxString & *str*) `[pure virtual]`

Method called by Printf() to really output the text.

This method is overridden in various derived classes and is also the one you should override if you implement a custom message output object.

It may also be called directly instead of Printf(). This is especially useful when outputting a user-defined string because it can be simply called with this string instead of using

```
msgout.Printf("%s", str);
```

(notice that passing user-defined string to Printf() directly is, of course, a security risk).

void wxMessageOutput::Printf (const wxString & *format, ...*)

Output a message.

This function uses the same conventions as standard `printf()`.

static wxMessageOutput* wxMessageOutput::Set (wxMessageOutput * *msgout*) `[static]`

Sets the global message output object.

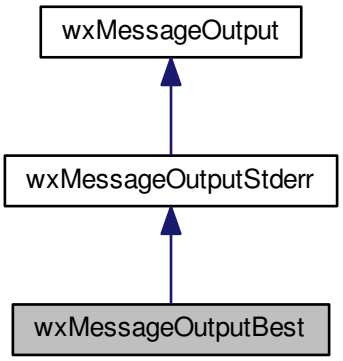
Using this function may be a simpler alternative to changing the message output object used for your program than overriding wxAppTraits::CreateMessageOutput().

Remember to delete the returned pointer or restore it later with another call to Set().

21.468 wxMessageOutputBest Class Reference

`#include <wx/msgout.h>`

Inheritance diagram for wxMessageOutputBest:



21.468.1 Detailed Description

Output messages in the best possible way.

Some systems (e.g. MSW) are capable of showing message boxes even from console programs. If this is the case, this class will use message box if standard error stream is not available (e.g. running console program not from console under Windows) or possibly even always, depending on the value of flags constructor argument.

Library: wxBase

Category: Logging

Public Member Functions

- wxMessageOutputBest (wxMessageOutputFlags flags=wxMSGOUT_PREFER_STDERR)

  Create a new message output object.

Additional Inherited Members

21.468.2 Constructor & Destructor Documentation

wxMessageOutputBest::wxMessageOutputBest (wxMessageOutputFlags *flags* = wxMSGOUT_PREFER_STDERR)

Create a new message output object.

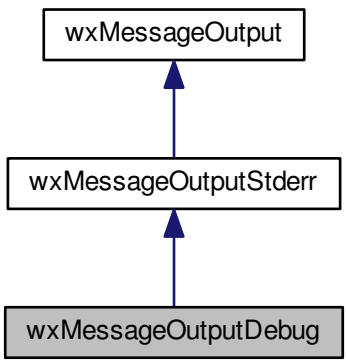
Parameters

flags	May be either `wxMSGOUT_PREFER_STDERR` (default) meaning that standard error will be used if it's available (e.g. program is being run from console under Windows) or `wxMSGOUT_PREFER_MSGBOX` meaning that a message box will always be used if the current system supports showing message boxes from console programs (currently only Windows does).

21.469 wxMessageOutputDebug Class Reference

`#include <wx/msgout.h>`

Inheritance diagram for wxMessageOutputDebug:



21.469.1 Detailed Description

Output messages to the system debug output channel.

Under MSW this class outputs messages to the so called debug output. Under the other systems it simply uses the standard error stream.

Library: wxBase

Category: Logging

Public Member Functions

- wxMessageOutputDebug ()

  Default constructor.

Additional Inherited Members

21.469.2 Constructor & Destructor Documentation

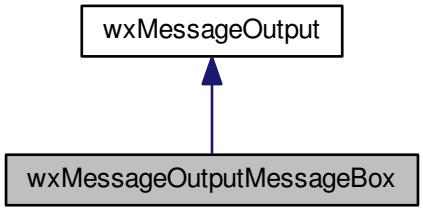
wxMessageOutputDebug::wxMessageOutputDebug ( )

Default constructor.

21.470 wxMessageOutputMessageBox Class Reference

```
#include <wx/msgout.h>
```

Inheritance diagram for wxMessageOutputMessageBox:



21.470.1 Detailed Description

Output messages by showing them in a message box.

This class is only available to GUI applications, unlike all the other wxMessageOutput-derived classes.

Library: wxCore

Category: Logging

Public Member Functions

- wxMessageOutputMessageBox ()

  Default constructor.

Additional Inherited Members

21.470.2 Constructor & Destructor Documentation

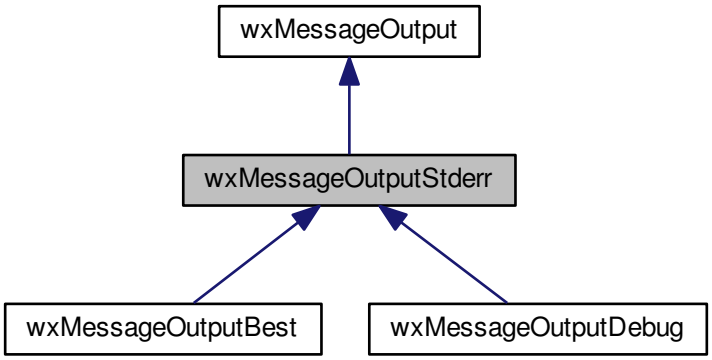
wxMessageOutputMessageBox::wxMessageOutputMessageBox ( )

Default constructor.

21.471 wxMessageOutputStderr Class Reference

`#include <wx/msgout.h>`

Inheritance diagram for wxMessageOutputStderr:



21.471.1 Detailed Description

Output messages to stderr or another STDIO file stream.

Implements wxMessageOutput by using stderr or specified file.

Library: wxBase

Category: Logging

Public Member Functions

- wxMessageOutputStderr (FILE *fp=stderr)

  Create a new message output object associated with standard error stream by default.

Additional Inherited Members

21.471.2 Constructor & Destructor Documentation

wxMessageOutputStderr::wxMessageOutputStderr (FILE * *fp* = `stderr`)

Create a new message output object associated with standard error stream by default.

Parameters

fp	Non-null STDIO file stream. Notice that this object does *not* take ownership of this pointer, i.e. the caller is responsible for both ensuring that its life-time is great er than life-time of this object and for deleting it if necessary.

21.472 wxMessageQueue< T > Class Template Reference

`#include <wx/msgqueue.h>`

21.472.1 Detailed Description

template<typename T>class wxMessageQueue< T >

wxMessageQueue allows passing messages between threads.

This class should be typically used to communicate between the main and worker threads. The main thread calls wxMessageQueue::Post and the worker thread calls wxMessageQueue::Receive.

Template Parameters

T	For this class a message is an object of arbitrary type T.

Notice that often there is a some special message indicating that the thread should terminate as there is no other way to gracefully shutdown a thread waiting on the message queue.

Since

2.9.0

Library: None; this class implementation is entirely header-based.

Category: Threading

See also

wxThread

Public Member Functions

- wxMessageQueue ()

  Default and only constructor.
- wxMessageQueueError Clear ()

  Remove all messages from the queue.
- bool IsOk () const

  Returns true if the object had been initialized successfully, false if an error occurred.
- wxMessageQueueError Post (T const &msg)

  Add a message to this queue and signal the threads waiting for messages (i.e.
- wxMessageQueueError Receive (T &msg)

  Block until a message becomes available in the queue.
- wxMessageQueueError ReceiveTimeout (long timeout, T &msg)

  Block until a message becomes available in the queue, but no more than timeout milliseconds has elapsed.

21.472.2 Constructor & Destructor Documentation

template<typename T > wxMessageQueue< T >::wxMessageQueue ( )

Default and only constructor.

Use wxMessageQueue::IsOk to check if the object was successfully initialized.

21.472.3 Member Function Documentation

template<typename T > wxMessageQueueError wxMessageQueue< T >::Clear ( )

Remove all messages from the queue.

This method is meant to be called from the same thread(s) that call Post() to discard any still pending requests if they became unnecessary.

Since

2.9.1

template<typename T > bool wxMessageQueue< T >::IsOk ( ) const

Returns true if the object had been initialized successfully, false if an error occurred.

template<typename T > wxMessageQueueError wxMessageQueue< T >::Post (T const & *msg*)

Add a message to this queue and signal the threads waiting for messages (i.e.

the threads which called wxMessageQueue::Receive or wxMessageQueue::ReceiveTimeout).

This method is safe to call from multiple threads in parallel.

template<typename T > wxMessageQueueError wxMessageQueue< T >::Receive (T & *msg*)

Block until a message becomes available in the queue.

Waits indefinitely long or until an error occurs.

The message is returned in *msg*.

template<typename T > wxMessageQueueError wxMessageQueue< T >::ReceiveTimeout (long *timeout*, T & *msg*)

Block until a message becomes available in the queue, but no more than *timeout* milliseconds has elapsed.

If no message is available after *timeout* milliseconds then returns **wxMSGQUEUE_TIMEOUT**.

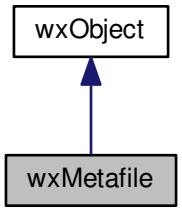
If *timeout* is 0 then checks for any messages present in the queue and returns immediately without waiting.

The message is returned in *msg*.

21.473 wxMetafile Class Reference

`#include <wx/metafile.h>`

Inheritance diagram for wxMetafile:



21.473.1 Detailed Description

A **wxMetafile** represents the MS Windows metafile object, so metafile operations have no effect in X.

In wxWidgets, only sufficient functionality has been provided for copying a graphic to the clipboard; this may be extended in a future version.

Presently, the only way of creating a metafile is to use a wxMetafileDC.

Availability: only available for the wxMSW port.

Library: wxCore

Category: Graphics Device Interface (GDI)

wxMetafileDC

Public Member Functions

- wxMetafile (const wxString &filename=wxEmptyString)

  Constructor.
- ~wxMetafile ()

  Destructor.

- bool IsOk ()

  Returns true if the metafile is valid.
- bool Play (wxDC *dc)

  Plays the metafile into the given device context, returning true if successful.
- bool SetClipboard (int width=0, int height=0)

  Passes the metafile data to the clipboard.

Additional Inherited Members

21.473.2 Constructor & Destructor Documentation

wxMetafile::wxMetafile (const wxString & *filename* = wxEmptyString)

Constructor.

If a filename is given, the Windows disk metafile is read in. Check whether this was performed successfully by using the IsOk() member.

wxMetafile::~wxMetafile ( )

Destructor.

See Object Destruction for more info.

21.473.3 Member Function Documentation

bool wxMetafile::IsOk ( )

Returns true if the metafile is valid.

bool wxMetafile::Play (wxDC * *dc*)

Plays the metafile into the given device context, returning true if successful.

bool wxMetafile::SetClipboard (int *width* = 0, int *height* = 0)

Passes the metafile data to the clipboard.

The metafile can no longer be used for anything, but the wxMetafile object must still be destroyed by the application.

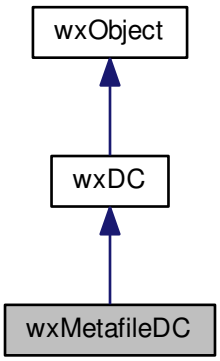
Below is a example of metafile, metafile device context and clipboard use from the `hello.cpp` example. Note the way the metafile dimensions are passed to the clipboard, making use of the device context's ability to keep track of the maximum extent of drawing commands.

```
wxMetafileDC dc;
if (dc.IsOk())
{
    Draw(dc, false);
    wxMetafile *mf = dc.Close();
    if (mf)
    {
        bool success = mf->SetClipboard((int)(dc.MaxX() + 10), (int)(dc.
      MaxY() + 10));
        delete mf;
    }
}
```

21.474 wxMetafileDC Class Reference

`#include <wx/metafile.h>`

Inheritance diagram for wxMetafileDC:



21.474.1 Detailed Description

This is a type of device context that allows a metafile object to be created (Windows only), and has most of the characteristics of a normal **wxDC**.

The wxMetafileDC::Close member must be called after drawing into the device context, to return a metafile. The only purpose for this at present is to allow the metafile to be copied to the clipboard (see wxMetafile).

Adding metafile capability to an application should be easy if you already write to a wxDC; simply pass the wxMetafileDC to your drawing function instead. You may wish to conditionally compile this code so it is not compiled under X (although no harm will result if you leave it in).

Note that a metafile saved to disk is in standard Windows metafile format, and cannot be imported into most applications. To make it importable, call the function wxMakeMetafilePlaceable after closing your disk-based metafile device context.

Library: wxCore

Category: Device Contexts

wxMetafile, wxDC

Public Member Functions

- wxMetafileDC (const wxString &filename=wxEmptyString)

  Constructor.
- ~wxMetafileDC ()

  Destructor.

- wxMetafile * Close ()

  This must be called after the device context is finished with.

Additional Inherited Members

21.474.2 Constructor & Destructor Documentation

wxMetafileDC::wxMetafileDC (const wxString & *filename* = wxEmptyString)

Constructor.

If no filename is passed, the metafile is created in memory.

wxMetafileDC::~wxMetafileDC ( )

Destructor.

21.474.3 Member Function Documentation

wxMetafile* wxMetafileDC::Close ( )

This must be called after the device context is finished with.

A metafile is returned, and ownership of it passes to the calling application (so it should be destroyed explicitly).

21.475 wxMimeTypesManager Class Reference

```
#include <wx/mimetype.h>
```

21.475.1 Detailed Description

This class allows the application to retrieve information about all known MIME types from a system-specific location and the filename extensions to the MIME types and vice versa.

MIME stands for "Multipurpose Internet Mail Extensions" and was originally used in mail protocols. It's standardized by several RFCs.

Under Windows, the MIME type information is queried from registry. Under Linux and Unix, it is queried from the XDG data directories.

Currently, wxMimeTypesManager is limited to *reading* MIME type information.

The application should not construct its own manager: it should use the object pointer wxTheMimeTypesManager. The functions GetFileTypeFromMimeType() and GetFileTypeFromExtension() return a wxFileType object which may be further queried for file description, icon and other attributes.

21.475.2 Helper functions

All of these functions are static (i.e. don't need a wxMimeTypesManager object to call them) and provide some useful operations for string representations of MIME types. Their usage is recommended instead of directly working with MIME types using wxString functions.

- wxMimeTypesManager::IsOfType()

21.475.3 Query database

These functions are the heart of this class: they allow to find a file type object from either file extension or MIME type. If the function is successful, it returns a pointer to the wxFileType object which must be deleted by the caller, otherwise NULL will be returned.

- wxMimeTypesManager::GetFileTypeFromMimeType()
- wxMimeTypesManager::GetFileTypeFromExtension()

Library: wxBase

Category: Application and System configuration

See also

wxFileType

Public Member Functions

- wxMimeTypesManager ()

  Constructor puts the object in the "working" state.
- ~wxMimeTypesManager ()

  Destructor is not virtual, so this class should not be derived from.
- void AddFallbacks (const wxFileTypeInfo *fallbacks)

  This function may be used to provide hard-wired fallbacks for the MIME types and extensions that might not be present in the system MIME database.
- wxFileType * GetFileTypeFromExtension (const wxString &extension)

  Gather information about the files with given extension and return the corresponding wxFileType object or NULL if the extension is unknown.
- wxFileType * GetFileTypeFromMimeType (const wxString &mimeType)

  Gather information about the files with given MIME type and return the corresponding wxFileType object or NULL if the MIME type is unknown.
- wxFileType * Associate (const wxFileTypeInfo &ftInfo)

  Create a new association using the fields of wxFileTypeInfo (at least the MIME type and the extension should be set).
- bool Unassociate (wxFileType *ft)

  Undo Associate().
- size_t EnumAllFileTypes (wxArrayString &mimetypes)

  Enumerate all known file types.

Static Public Member Functions

- static bool IsOfType (const wxString &mimeType, const wxString &wildcard)

  This function returns true if either the given mimeType is exactly the same as wildcard or if it has the same category and the subtype of wildcard is ''.*

21.475.4 Constructor & Destructor Documentation

wxMimeTypesManager::wxMimeTypesManager ( )

Constructor puts the object in the "working" state.

wxMimeTypesManager::~wxMimeTypesManager ( )

Destructor is not virtual, so this class should not be derived from.

21.475.5 Member Function Documentation

void wxMimeTypesManager::AddFallbacks (const wxFileTypeInfo * *fallbacks*)

This function may be used to provide hard-wired fallbacks for the MIME types and extensions that might not be present in the system MIME database.

Please see the typetest sample for an example of using it.

wxFileType* wxMimeTypesManager::Associate (const wxFileTypeInfo & *ftInfo*)

Create a new association using the fields of wxFileTypeInfo (at least the MIME type and the extension should be set).

size_t wxMimeTypesManager::EnumAllFileTypes (wxArrayString & *mimetypes*)

Enumerate all known file types.

Returns the number of retrieved items.

wxFileType* wxMimeTypesManager::GetFileTypeFromExtension (const wxString & *extension*)

Gather information about the files with given extension and return the corresponding wxFileType object or NULL if the extension is unknown.

The *extension* parameter may have, or not, the leading dot, if it has it, it is stripped automatically. It must not however be empty.

wxFileType* wxMimeTypesManager::GetFileTypeFromMimeType (const wxString & *mimeType*)

Gather information about the files with given MIME type and return the corresponding wxFileType object or NULL if the MIME type is unknown.

static bool wxMimeTypesManager::IsOfType (const wxString & *mimeType,* const wxString & *wildcard*) `[static]`

This function returns true if either the given *mimeType* is exactly the same as *wildcard* or if it has the same category and the subtype of *wildcard* is '*'.

Note that the '*' wildcard is not allowed in *mimeType* itself.

The comparison done by this function is case insensitive so it is not necessary to convert the strings to the same case before calling it.

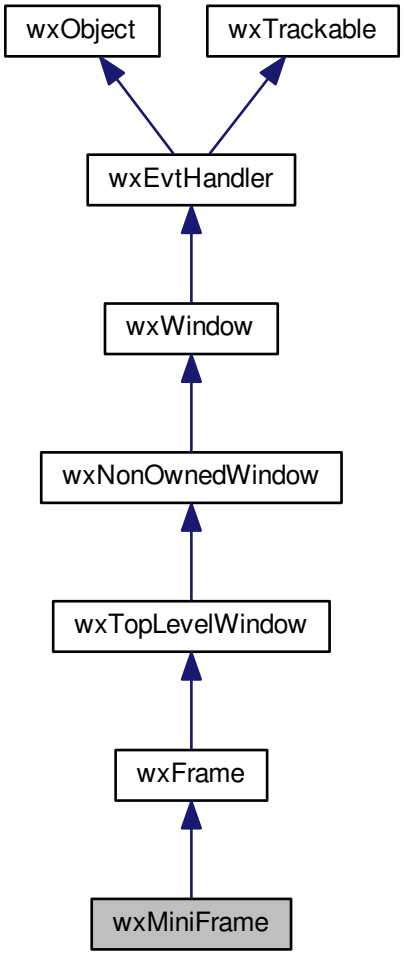
bool wxMimeTypesManager::Unassociate (wxFileType * *ft*)

Undo Associate().

21.476 wxMiniFrame Class Reference

```
#include <wx/minifram.h>
```

Inheritance diagram for wxMiniFrame:



21.476.1 Detailed Description

A miniframe is a frame with a small title bar.

It is suitable for floating toolbars that must not take up too much screen area.

An example of mini frame can be seen in the Dialogs Sample using the "Mini frame" command of the "Generic dialogs" submenu.

Styles

This class supports the following styles:

- wxICONIZE: Display the frame iconized (minimized) (Windows only).
- wxCAPTION: Puts a caption on the frame.
- wxMINIMIZE: Identical to wxICONIZE.

- wxMINIMIZE_BOX: Displays a minimize box on the frame (Windows and Motif only).
- wxMAXIMIZE: Displays the frame maximized (Windows only).
- wxMAXIMIZE_BOX: Displays a maximize box on the frame (Windows and Motif only).
- wxCLOSE_BOX: Displays a close box on the frame.
- wxSTAY_ON_TOP: Stay on top of other windows (Windows only).
- wxSYSTEM_MENU: Displays a system menu (Windows and Motif only).
- wxRESIZE_BORDER: Displays a resizable border around the window.

Remarks

This class has miniframe functionality under Windows and GTK, i.e. the presence of mini frame will not be noted in the task bar and focus behaviour is different. On other platforms, it behaves like a normal frame.

Library: wxCore

Public Member Functions

- wxMiniFrame ()

  Default ctor.
- wxMiniFrame (wxWindow *parent, wxWindowID id, const wxString &title, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, long style=wxCAPTION|wxRESIZE_BORDER, const wxString &name=wxFrameNameStr)

  Constructor, creating the window.
- virtual ~wxMiniFrame ()

  Destructor.
- bool Create (wxWindow *parent, wxWindowID id, const wxString &title, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, long style=wxCAPTION|wxRESIZE_BORDER, const wxString &name=wxFrameNameStr)

  Used in two-step frame construction.

Additional Inherited Members

21.476.2 Constructor & Destructor Documentation

wxMiniFrame::wxMiniFrame ( )

Default ctor.

wxMiniFrame::wxMiniFrame (wxWindow * *parent*, wxWindowID *id*, const wxString & *title*, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, long *style* = wxCAPTION|wxRESIZE_BORDER, const wxString & *name* = `wxFrameNameStr`)

Constructor, creating the window.

Parameters

parent	The window parent. This may be NULL. If it is non-NULL, the frame will always be displayed on top of the parent window on Windows.
id	The window identifier. It may take a value of -1 to indicate a default value.
title	The caption to be displayed on the frame's title bar.
pos	The window position. The value wxDefaultPosition indicates a default position, chosen by either the windowing system or wxWidgets, depending on platform.
size	The window size. The value wxDefaultSize indicates a default size, chosen by either the windowing system or wxWidgets, depending on platform.
style	The window style. See wxMiniFrame.
name	The name of the window. This parameter is used to associate a name with the item, allowing the application user to set Motif resource values for individual windows.

Remarks

The frame behaves like a normal frame on non-Windows platforms.

See also

Create()

virtual wxMiniFrame::~wxMiniFrame ( ) [virtual]

Destructor.

Destroys all child windows and menu bar if present.

21.476.3 Member Function Documentation

bool wxMiniFrame::Create (wxWindow * *parent*, wxWindowID *id*, const wxString & *title*, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, long *style* = wxCAPTION|wxRESIZE_BORDER, const wxString & *name* = wxFrameNameStr)

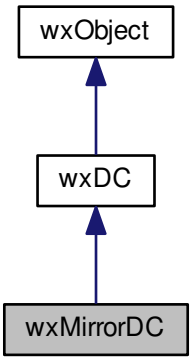
Used in two-step frame construction.

See wxMiniFrame() for further details.

21.477 wxMirrorDC Class Reference

`#include <wx/dcmirror.h>`

Inheritance diagram for wxMirrorDC:



21.477.1 Detailed Description

wxMirrorDC is a simple wrapper class which is always associated with a real wxDC object and either forwards all of its operations to it without changes (no mirroring takes place) or exchanges *x* and *y* coordinates which makes it possible to reuse the same code to draw a figure and its mirror – i.e.

reflection related to the diagonal line x == y.

Since

2.5.0

Library: wxCore

Category: Device Contexts

Public Member Functions

- wxMirrorDC (wxDC &dc, bool mirror)

  Creates a (maybe) mirrored DC associated with the real dc.

Additional Inherited Members

21.477.2 Constructor & Destructor Documentation

wxMirrorDC::wxMirrorDC (wxDC & *dc*, bool *mirror*)

Creates a (maybe) mirrored DC associated with the real *dc*.

Everything drawn on wxMirrorDC will appear (and maybe mirrored) on *dc*.

mirror specifies if we do mirror (if it is true) or not (if it is false).

21.478 wxModalDialogHook Class Reference

`#include <wx/modalhook.h>`

21.478.1 Detailed Description

Allows to intercept all modal dialog calls.

This class can be used to hook into normal modal dialog handling for some special needs. One of the most common use cases is for testing: as automatic tests can't continue if a modal dialog is shown while they run, this class can be used to avoid showing the modal dialogs during unattended execution. wxModalDialogHook can also be used for disabling some background operation while a modal dialog is shown.

To install a modal dialog hook, you need to derive your own class from this one and implement its pure virtual Enter() method. Then simply create an object of your class and call Register() on it to start receiving calls to your overridden Enter() (and possibly Exit()) methods:

```
class MyModalDialogHook : public wxModalDialogHook
{
protected:
    virtual int Enter(wxDialog* dialog)
    {
        // Just for demonstration purposes, intercept all uses of
        // wxFileDialog. Notice that this doesn't provide any real
        // sandboxing, of course, the program can still read and write
        // files by not using wxFileDialog to ask the user for their
        // names.
        if ( wxDynamicCast(dialog, wxFileDialog) )
        {
            wxLogError("Access to file system disallowed.");

            // Skip showing the file dialog entirely.
            return wxID_CANCEL;
        }

        m_lastEnter = wxDateTime::Now();

        // Allow the dialog to be shown as usual.
        return wxID_NONE;
    }

    virtual void Exit(wxDialog* dialog)
    {
        // Again, just for demonstration purposes, show how long did
        // the user take to dismiss the dialog. Notice that we
        // shouldn't use wxLogMessage() here as this would result in
        // another modal dialog call and hence infinite recursion. In
        // general, the hooks should be as unintrusive as possible.
        wxLogDebug("%s dialog took %s to be dismissed",
                   dialog->GetClassInfo()->GetClassName(),
                   (wxDateTime::Now() - m_lastEnter).Format());
    }
};

class MyApp : public wxApp
{
public:
    virtual bool OnInit()
    {
        ...
        m_myHook.Register();
        ...
    }

private:
    MyModalDialogHook m_myHook;
};
```

Since

2.9.5

Public Member Functions

- wxModalDialogHook ()

Default and trivial constructor.

- virtual ~wxModalDialogHook ()

  Destructor unregisters the hook if it's currently active.

- void Register ()

  Register this hook as being active.

- void Unregister ()

  Unregister this hook.

Protected Member Functions

- virtual int Enter (wxDialog *dialog)=0

  Called by wxWidgets before showing any modal dialogs.

- virtual void Exit (wxDialog *dialog)

  Called by wxWidgets after dismissing the modal dialog.

21.478.2 Constructor & Destructor Documentation

wxModalDialogHook::wxModalDialogHook ( )

Default and trivial constructor.

The constructor doesn't do anything, call Register() to make this hook active.

virtual wxModalDialogHook::~wxModalDialogHook ( ) [virtual]

Destructor unregisters the hook if it's currently active.

21.478.3 Member Function Documentation

virtual int wxModalDialogHook::Enter (wxDialog * *dialog*) [protected], [pure virtual]

Called by wxWidgets before showing any modal dialogs.

Override this to be notified whenever a modal dialog is about to be shown.

If the return value of this method is wxID_NONE, the dialog is shown as usual and Exit() will be called when it is dismissed. If the return value is anything else, the dialog is not shown at all and its wxDialog::ShowModal() simply returns with the given result. In this case, Exit() won't be called neither.

Parameters

dialog	The dialog about to be shown, never NULL.

Returns

wxID_NONE to continue with showing the dialog or anything else to skip showing the dialog and just return this value from its ShowModal().

virtual void wxModalDialogHook::Exit (wxDialog * *dialog*) [protected], [virtual]

Called by wxWidgets after dismissing the modal dialog.

Notice that it won't be called if Enter() hadn't been called because another modal hook, registered after this one, intercepted the dialog or if our Enter() was called but returned a value different from wxID_NONE.

Parameters

dialog	The dialog that was shown and dismissed, never NULL.

void wxModalDialogHook::Register ( )

Register this hook as being active.

After registering the hook, its Enter() and Exit() methods will be called whenever a modal dialog is shown.

Notice that the order of registration matters: the last hook registered is called first, and if its Enter() returns a value different from wxID_NONE, the subsequent hooks are skipped.

It is an error to register the same hook twice.

void wxModalDialogHook::Unregister ( )

Unregister this hook.

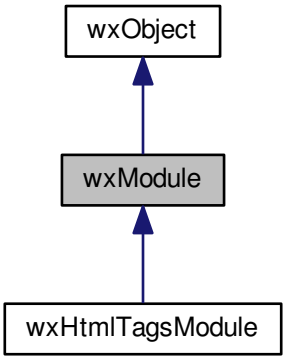
Notice that is done automatically from the destructor, so usually calling this method explicitly is unnecessary.

The hook must be currently registered.

21.479 wxModule Class Reference

`#include <wx/module.h>`

Inheritance diagram for wxModule:



21.479.1 Detailed Description

The module system is a very simple mechanism to allow applications (and parts of wxWidgets itself) to define initialization and cleanup functions that are automatically called on wxWidgets startup and exit.

To define a new kind of module, derive a class from wxModule, override the wxModule::OnInit and wxModule::On↩ Exit functions, and add the wxDECLARE_DYNAMIC_CLASS and wxIMPLEMENT_DYNAMIC_CLASS to header and implementation files (which can be the same file). On initialization, wxWidgets will find all classes derived from

wxModule, create an instance of each, and call each wxModule::OnInit function. On exit, wxWidgets will call the wxModule::OnExit function for each module instance.

Note that your module class does not have to be in a header file.

For example:

```
  // A module to allow DDE initialization/cleanup
// without calling these functions from app.cpp or from
// the user's application.
class wxDDEModule: public wxModule
{
public:
    wxDDEModule() { }
    virtual bool OnInit() { wxDDEInitialize(); return true; };
    virtual void OnExit() { wxDDECleanUp(); };

private:
    wxDECLARE_DYNAMIC_CLASS(wxDDEModule);
};

wxIMPLEMENT_DYNAMIC_CLASS(wxDDEModule, wxModule);

// Another module which uses DDE in its OnInit()
class MyModule: public wxModule
{
public:
    MyModule() { AddDependency(wxCLASSINFO(wxDDEModule)); }
    virtual bool OnInit() { ... code using DDE ... }
    virtual void OnExit() { ... }

private:
    wxDECLARE_DYNAMIC_CLASS(MyModule);
};

wxIMPLEMENT_DYNAMIC_CLASS(MyModule, wxModule);

// Another module which uses DDE in its OnInit()
// but uses a named dependency
class MyModule2: public wxModule
{
public:
    MyModule2() { AddDependency("wxDDEModule"); }
    virtual bool OnInit() { ... code using DDE ... }
    virtual void OnExit() { ... }

private:
    wxDECLARE_DYNAMIC_CLASS(MyModule2)
};

wxIMPLEMENT_DYNAMIC_CLASS(MyModule2, wxModule)
```

Library: wxBase

Category: Application and Process Management

Public Member Functions

- wxModule ()

  Constructs a wxModule object.
- virtual ~wxModule ()

  Destructor.
- virtual void OnExit ()=0

  Provide this function with appropriate cleanup for your module.
- virtual bool OnInit ()=0

  Provide this function with appropriate initialization for your module.

Protected Member Functions

- void AddDependency (wxClassInfo *dep)

Call this function from the constructor of the derived class.

- void AddDependency (const char *classname)

  Call this function from the constructor of the derived class.

Additional Inherited Members

21.479.2 Constructor & Destructor Documentation

wxModule::wxModule ( )

Constructs a wxModule object.

virtual wxModule::~wxModule ( ) [virtual]

Destructor.

21.479.3 Member Function Documentation

void wxModule::AddDependency (wxClassInfo * *dep*) [protected]

Call this function from the constructor of the derived class.

dep must be the wxCLASSINFO() of a wxModule-derived class and the corresponding module will be loaded before and unloaded after this module.

Parameters

dep	The class information object for the dependent module.

void wxModule::AddDependency (const char * *classname*) [protected]

Call this function from the constructor of the derived class.

This overload allows a dependency to be added by name without access to the class info.

This is useful when a module is declared entirely in a source file and there is no header for the declaration of the module needed by wxCLASSINFO(), however errors are not detected until run-time, instead of compile-time, then. Note that circular dependencies are detected and result in a fatal error.

Parameters

classname	The class name of the dependent module.

virtual void wxModule::OnExit ( ) [pure virtual]

Provide this function with appropriate cleanup for your module.

virtual bool wxModule::OnInit ( ) [pure virtual]

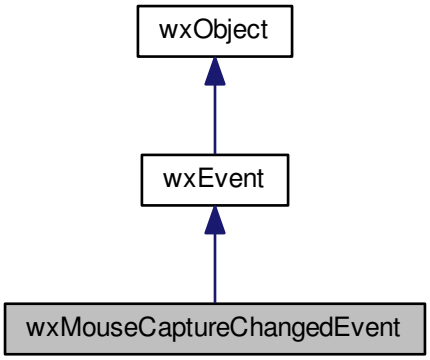
Provide this function with appropriate initialization for your module.

If the function returns false, wxWidgets will exit immediately.

21.480 wxMouseCaptureChangedEvent Class Reference

`#include <wx/event.h>`

Inheritance diagram for wxMouseCaptureChangedEvent:



21.480.1 Detailed Description

An mouse capture changed event is sent to a window that loses its mouse capture.

This is called even if wxWindow::ReleaseMouse was called by the application code. Handling this event allows an application to cater for unexpected capture releases which might otherwise confuse mouse handling code.

Availability: only available for the wxMSW port.

Events using this class

The following event handler macros redirect the events to member function handlers '**func**' with prototypes like: void handlerFuncName(wxMouseCaptureChangedEvent& event)

Event macros:

- EVT_MOUSE_CAPTURE_CHANGED(func): Process a `wxEVT_MOUSE_CAPTURE_CHANGED` event.

Library: wxCore

Category: Events

See also

wxMouseCaptureLostEvent, Events and Event Handling, wxWindow::CaptureMouse, wxWindow::Release↩ Mouse, wxWindow::GetCapture

Public Member Functions

- wxMouseCaptureChangedEvent (wxWindowID windowId=0, wxWindow *gainedCapture=NULL)

Constructor.

- wxWindow * GetCapturedWindow () const

  Returns the window that gained the capture, or NULL if it was a non-wxWidgets window.

Additional Inherited Members

21.480.2 Constructor & Destructor Documentation

wxMouseCaptureChangedEvent::wxMouseCaptureChangedEvent (wxWindowID *windowId* = 0, wxWindow * *gainedCapture* = NULL)

Constructor.

21.480.3 Member Function Documentation

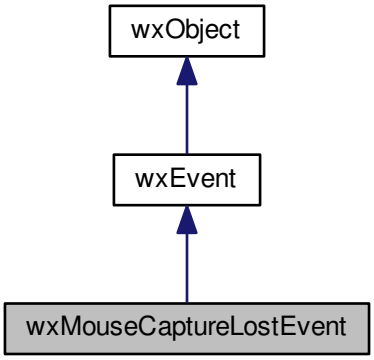
wxWindow* wxMouseCaptureChangedEvent::GetCapturedWindow ( ) const

Returns the window that gained the capture, or NULL if it was a non-wxWidgets window.

21.481 wxMouseCaptureLostEvent Class Reference

`#include <wx/event.h>`

Inheritance diagram for wxMouseCaptureLostEvent:



21.481.1 Detailed Description

A mouse capture lost event is sent to a window that had obtained mouse capture, which was subsequently lost due to an "external" event (for example, when a dialog box is shown or if another application captures the mouse).

If this happens, this event is sent to all windows that are on the capture stack (i.e. called CaptureMouse, but didn't call ReleaseMouse yet). The event is not sent if the capture changes because of a call to CaptureMouse or ReleaseMouse.

This event is currently emitted under Windows only.

Events using this class

The following event handler macros redirect the events to member function handlers '**func**' with prototypes like: void handlerFuncName(wxMouseCaptureLostEvent& event)

Event macros:

- EVT_MOUSE_CAPTURE_LOST(func): Process a `wxEVT_MOUSE_CAPTURE_LOST` event.

Availability: only available for the wxMSW port.

Library: wxCore

Category: Events

Public Member Functions

- wxMouseCaptureLostEvent (wxWindowID windowId=0)

  Constructor.

Additional Inherited Members

21.481.2 Constructor & Destructor Documentation

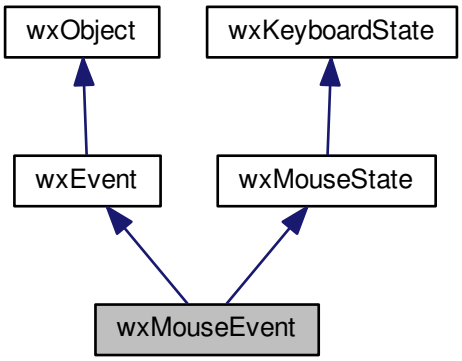
wxMouseCaptureLostEvent::wxMouseCaptureLostEvent (wxWindowID *windowId* = `0`)

Constructor.

21.482 wxMouseEvent Class Reference

```
#include <wx/event.h>
```

Inheritance diagram for wxMouseEvent:



21.482.1 Detailed Description

This event class contains information about the events generated by the mouse: they include mouse buttons press and release events and mouse move events.

All mouse events involving the buttons use `wxMOUSE_BTN_LEFT` for the left mouse button, `wxMOUSE_BTN_MIDDLE` for the middle one and `wxMOUSE_BTN_RIGHT` for the right one. And if the system supports more buttons, the `wxMOUSE_BTN_AUX1` and `wxMOUSE_BTN_AUX2` events can also be generated. Note that not all mice have even a middle button so a portable application should avoid relying on the events from it (but the right button click can be emulated using the left mouse button with the control key under Mac platforms with a single button mouse).

For the `wxEVT_ENTER_WINDOW` and `wxEVT_LEAVE_WINDOW` events purposes, the mouse is considered to be inside the window if it is in the window client area and not inside one of its children. In other words, the parent window receives `wxEVT_LEAVE_WINDOW` event not only when the mouse leaves the window entirely but also when it enters one of its children.

The position associated with a mouse event is expressed in the window coordinates of the window which generated the event, you can use wxWindow::ClientToScreen() to convert it to screen coordinates and possibly call wxWindow::ScreenToClient() next to convert it to window coordinates of another window.

Note

Note that under Windows CE mouse enter and leave events are not natively supported by the system but are generated by wxWidgets itself. This has several drawbacks: the LEAVE_WINDOW event might be received some time after the mouse left the window and the state variables for it may have changed during this time.
Note the difference between methods like wxMouseEvent::LeftDown and the inherited wxMouseState::LeftIsDown: the former returns true when the event corresponds to the left mouse button click while the latter returns true if the left mouse button is currently being pressed. For example, when the user is dragging the mouse you can use wxMouseEvent::LeftIsDown to test whether the left mouse button is (still) depressed. Also, by convention, if wxMouseEvent::LeftDown returns true, wxMouseEvent::LeftIsDown will also return true in wxWidgets whatever the underlying GUI behaviour is (which is platform-dependent). The same applies, of course, to other mouse buttons as well.

Events using this class

The following event handler macros redirect the events to member function handlers '**func**' with prototypes like: void handlerFuncName(wxMouseEvent& event)

Event macros:

- EVT_LEFT_DOWN(func): Process a `wxEVT_LEFT_DOWN` event. The handler of this event should normally call event.Skip() to allow the default processing to take place as otherwise the window under mouse wouldn't get the focus.
- EVT_LEFT_UP(func): Process a `wxEVT_LEFT_UP` event.
- EVT_LEFT_DCLICK(func): Process a `wxEVT_LEFT_DCLICK` event.
- EVT_MIDDLE_DOWN(func): Process a `wxEVT_MIDDLE_DOWN` event.
- EVT_MIDDLE_UP(func): Process a `wxEVT_MIDDLE_UP` event.
- EVT_MIDDLE_DCLICK(func): Process a `wxEVT_MIDDLE_DCLICK` event.
- EVT_RIGHT_DOWN(func): Process a `wxEVT_RIGHT_DOWN` event.
- EVT_RIGHT_UP(func): Process a `wxEVT_RIGHT_UP` event.
- EVT_RIGHT_DCLICK(func): Process a `wxEVT_RIGHT_DCLICK` event.
- EVT_MOUSE_AUX1_DOWN(func): Process a `wxEVT_AUX1_DOWN` event.
- EVT_MOUSE_AUX1_UP(func): Process a `wxEVT_AUX1_UP` event.
- EVT_MOUSE_AUX1_DCLICK(func): Process a `wxEVT_AUX1_DCLICK` event.
- EVT_MOUSE_AUX2_DOWN(func): Process a `wxEVT_AUX2_DOWN` event.
- EVT_MOUSE_AUX2_UP(func): Process a `wxEVT_AUX2_UP` event.
- EVT_MOUSE_AUX2_DCLICK(func): Process a `wxEVT_AUX2_DCLICK` event.
- EVT_MOTION(func): Process a `wxEVT_MOTION` event.
- EVT_ENTER_WINDOW(func): Process a `wxEVT_ENTER_WINDOW` event.
- EVT_LEAVE_WINDOW(func): Process a `wxEVT_LEAVE_WINDOW` event.
- EVT_MOUSEWHEEL(func): Process a `wxEVT_MOUSEWHEEL` event.
- EVT_MOUSE_EVENTS(func): Process all mouse events.
- EVT_MAGNIFY(func): Process a `wxEVT_MAGNIFY` event (new since wxWidgets 3.1.0).

Public Member Functions

- wxMouseEvent (wxEventType mouseEventType=wxEVT_NULL)

  Constructor.
- bool Aux1DClick () const

  Returns true if the event was a first extra button double click.
- bool Aux1Down () const

  Returns true if the first extra button mouse button changed to down.

- bool Aux1Up () const

  Returns true if the first extra button mouse button changed to up.
- bool Aux2DClick () const

  Returns true if the event was a second extra button double click.
- bool Aux2Down () const

  Returns true if the second extra button mouse button changed to down.
- bool Aux2Up () const

  Returns true if the second extra button mouse button changed to up.
- bool Button (wxMouseButton but) const

  Returns true if the event was generated by the specified button.
- bool ButtonDClick (wxMouseButton but=wxMOUSE_BTN_ANY) const

  If the argument is omitted, this returns true if the event was a mouse double click event.
- bool ButtonDown (wxMouseButton but=wxMOUSE_BTN_ANY) const

  If the argument is omitted, this returns true if the event was a mouse button down event.
- bool ButtonUp (wxMouseButton but=wxMOUSE_BTN_ANY) const

  If the argument is omitted, this returns true if the event was a mouse button up event.
- bool Dragging () const

  Returns true if this was a dragging event (motion while a button is depressed).
- bool Entering () const

  Returns true if the mouse was entering the window.
- int GetButton () const

  Returns the mouse button which generated this event or `wxMOUSE_BTN_NONE` if no button is involved (for mouse move, enter or leave event, for example).
- int GetClickCount () const

  Returns the number of mouse clicks for this event: 1 for a simple click, 2 for a double-click, 3 for a triple-click and so on.
- int GetLinesPerAction () const

  Returns the configured number of lines (or whatever) to be scrolled per wheel action.
- int GetColumnsPerAction () const

  Returns the configured number of columns (or whatever) to be scrolled per wheel action.
- wxPoint GetLogicalPosition (const wxDC &dc) const

  Returns the logical mouse position in pixels (i.e. translated according to the translation set for the DC, which usually indicates that the window has been scrolled).
- float GetMagnification () const

  For magnify (pinch to zoom) events: returns the change in magnification.
- int GetWheelDelta () const

  Get wheel delta, normally 120.
- int GetWheelRotation () const

  Get wheel rotation, positive or negative indicates direction of rotation.
- wxMouseWheelAxis GetWheelAxis () const

  Gets the axis the wheel operation concerns.
- bool IsButton () const

  Returns true if the event was a mouse button event (not necessarily a button down event - that may be tested using ButtonDown()).
- bool IsPageScroll () const

  Returns true if the system has been setup to do page scrolling with the mouse wheel instead of line scrolling.
- bool Leaving () const

  Returns true if the mouse was leaving the window.
- bool LeftDClick () const

  Returns true if the event was a left double click.
- bool LeftDown () const

Returns true if the left mouse button changed to down.

- bool LeftUp () const

  Returns true if the left mouse button changed to up.

- bool Magnify () const

  Returns true if the event is a magnify (i.e. pinch to zoom) event.

- bool MetaDown () const

  Returns true if the Meta key was down at the time of the event.

- bool MiddleDClick () const

  Returns true if the event was a middle double click.

- bool MiddleDown () const

  Returns true if the middle mouse button changed to down.

- bool MiddleUp () const

  Returns true if the middle mouse button changed to up.

- bool Moving () const

  Returns true if this was a motion event and no mouse buttons were pressed.

- bool RightDClick () const

  Returns true if the event was a right double click.

- bool RightDown () const

  Returns true if the right mouse button changed to down.

- bool RightUp () const

  Returns true if the right mouse button changed to up.

Additional Inherited Members

21.482.2 Constructor & Destructor Documentation

wxMouseEvent::wxMouseEvent (wxEventType *mouseEventType* = wxEVT_NULL)

Constructor.

Valid event types are:

- `wxEVT_ENTER_WINDOW`
- `wxEVT_LEAVE_WINDOW`
- `wxEVT_LEFT_DOWN`
- `wxEVT_LEFT_UP`
- `wxEVT_LEFT_DCLICK`
- `wxEVT_MIDDLE_DOWN`
- `wxEVT_MIDDLE_UP`
- `wxEVT_MIDDLE_DCLICK`
- `wxEVT_RIGHT_DOWN`
- `wxEVT_RIGHT_UP`
- `wxEVT_RIGHT_DCLICK`
- `wxEVT_AUX1_DOWN`
- `wxEVT_AUX1_UP`
- `wxEVT_AUX1_DCLICK`

- wxEVT_AUX2_DOWN
- wxEVT_AUX2_UP
- wxEVT_AUX2_DCLICK
- wxEVT_MOTION
- wxEVT_MOUSEWHEEL
- wxEVT_MAGNIFY

21.482.3 Member Function Documentation

bool wxMouseEvent::Aux1DClick ( ) const

Returns true if the event was a first extra button double click.

bool wxMouseEvent::Aux1Down ( ) const

Returns true if the first extra button mouse button changed to down.

bool wxMouseEvent::Aux1Up ( ) const

Returns true if the first extra button mouse button changed to up.

bool wxMouseEvent::Aux2DClick ( ) const

Returns true if the event was a second extra button double click.

bool wxMouseEvent::Aux2Down ( ) const

Returns true if the second extra button mouse button changed to down.

bool wxMouseEvent::Aux2Up ( ) const

Returns true if the second extra button mouse button changed to up.

bool wxMouseEvent::Button (wxMouseButton *but*) const

Returns true if the event was generated by the specified button.

See also

wxMouseState::ButtoinIsDown()

bool wxMouseEvent::ButtonDClick (wxMouseButton *but* = wxMOUSE_BTN_ANY) const

If the argument is omitted, this returns true if the event was a mouse double click event.

Otherwise the argument specifies which double click event was generated (see Button() for the possible values).

bool wxMouseEvent::ButtonDown (wxMouseButton *but* = wxMOUSE_BTN_ANY) const

If the argument is omitted, this returns true if the event was a mouse button down event.

Otherwise the argument specifies which button-down event was generated (see Button() for the possible values).

bool wxMouseEvent::ButtonUp (wxMouseButton *but* = wxMOUSE_BTN_ANY) const

If the argument is omitted, this returns true if the event was a mouse button up event.

Otherwise the argument specifies which button-up event was generated (see Button() for the possible values).

bool wxMouseEvent::Dragging ( ) const

Returns true if this was a dragging event (motion while a button is depressed).

See also

Moving()

bool wxMouseEvent::Entering ( ) const

Returns true if the mouse was entering the window.

See also

Leaving()

int wxMouseEvent::GetButton ( ) const

Returns the mouse button which generated this event or `wxMOUSE_BTN_NONE` if no button is involved (for mouse move, enter or leave event, for example).

Otherwise `wxMOUSE_BTN_LEFT` is returned for the left button down, up and double click events, `wxMOUSE_BTN_MIDDLE` and `wxMOUSE_BTN_RIGHT` for the same events for the middle and the right buttons respectively.

int wxMouseEvent::GetClickCount ( ) const

Returns the number of mouse clicks for this event: 1 for a simple click, 2 for a double-click, 3 for a triple-click and so on.

Currently this function is implemented only in wxMac and returns -1 for the other platforms (you can still distinguish simple clicks from double-clicks as they generate different kinds of events however).

Since

2.9.0

int wxMouseEvent::GetColumnsPerAction ( ) const

Returns the configured number of columns (or whatever) to be scrolled per wheel action.

Default value under most platforms is three.

See also

GetLinesPerAction()

Since

2.9.5

int wxMouseEvent::GetLinesPerAction ( ) const

Returns the configured number of lines (or whatever) to be scrolled per wheel action.

Default value under most platforms is three.

See also

GetColumnsPerAction()

wxPoint wxMouseEvent::GetLogicalPosition (const wxDC & *dc*) const

Returns the logical mouse position in pixels (i.e. translated according to the translation set for the DC, which usually indicates that the window has been scrolled).

float wxMouseEvent::GetMagnification ( ) const

For magnify (pinch to zoom) events: returns the change in magnification.

A value of 0 means no change, a positive value means we should enlarge (or zoom in), a negative value means we should shrink (or zoom out).

This method is only valid to call for `wxEVT_MAGNIFY` events which are currently only generated under OS X.

See also

Magnify()

Since

3.1.0

wxMouseWheelAxis wxMouseEvent::GetWheelAxis ( ) const

Gets the axis the wheel operation concerns.

Usually the mouse wheel is used to scroll vertically so `wxMOUSE_WHEEL_VERTICAL` is returned but some mice (and most trackpads) also allow to use the wheel to scroll horizontally in which case `wxMOUSE_WHEEL_HORIZ↩ ONTAL` is returned.

Notice that before wxWidgets 2.9.4 this method returned `int`.

int wxMouseEvent::GetWheelDelta ( ) const

Get wheel delta, normally 120.

This is the threshold for action to be taken, and one such action (for example, scrolling one increment) should occur for each delta.

int wxMouseEvent::GetWheelRotation ( ) const

Get wheel rotation, positive or negative indicates direction of rotation.

Current devices all send an event when rotation is at least +/-WheelDelta, but finer resolution devices can be created in the future.

Because of this you shouldn't assume that one event is equal to 1 line, but you should be able to either do partial line scrolling or wait until several events accumulate before scrolling.

bool wxMouseEvent::IsButton ( ) const

Returns true if the event was a mouse button event (not necessarily a button down event - that may be tested using ButtonDown()).

bool wxMouseEvent::IsPageScroll ( ) const

Returns true if the system has been setup to do page scrolling with the mouse wheel instead of line scrolling.

bool wxMouseEvent::Leaving ( ) const

Returns true if the mouse was leaving the window.

See also

Entering().

bool wxMouseEvent::LeftDClick ( ) const

Returns true if the event was a left double click.

bool wxMouseEvent::LeftDown ( ) const

Returns true if the left mouse button changed to down.

bool wxMouseEvent::LeftUp ( ) const

Returns true if the left mouse button changed to up.

bool wxMouseEvent::Magnify ( ) const

Returns true if the event is a magnify (i.e. pinch to zoom) event.

Such events are currently generated only under OS X.

See also

GetMagnification()

Since

3.1.0

bool wxMouseEvent::MetaDown ( ) const

Returns true if the Meta key was down at the time of the event.

bool wxMouseEvent::MiddleDClick ( ) const

Returns true if the event was a middle double click.

bool wxMouseEvent::MiddleDown ( ) const

Returns true if the middle mouse button changed to down.

bool wxMouseEvent::MiddleUp ( ) const

Returns true if the middle mouse button changed to up.

bool wxMouseEvent::Moving ( ) const

Returns true if this was a motion event and no mouse buttons were pressed.

If any mouse button is held pressed, then this method returns false and Dragging() returns true.

bool wxMouseEvent::RightDClick ( ) const

Returns true if the event was a right double click.

bool wxMouseEvent::RightDown ( ) const

Returns true if the right mouse button changed to down.

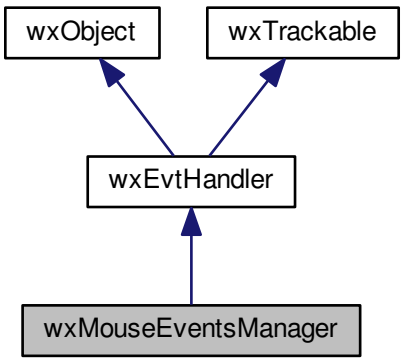
bool wxMouseEvent::RightUp ( ) const

Returns true if the right mouse button changed to up.

21.483 wxMouseEventsManager Class Reference

`#include <wx/mousemanager.h>`

Inheritance diagram for wxMouseEventsManager:



21.483.1 Detailed Description

Helper for handling mouse input events in windows containing multiple items.

This class handles mouse events and synthesizes high-level notifications such as clicks and drag events from low level mouse button presses and mouse movement events. It is useful because handling the mouse events is less obvious than might seem at a first glance: for example, clicks on an object should only be generated if the mouse was both pressed and released over it and not just released (so it requires storing the previous state) and dragging shouldn't start before the mouse moves away far enough.

This class encapsulates all these dull details for controls containing multiple items which can be identified by a positive integer index and you just need to implement its pure virtual functions to use it.

Notice that this class supposes that all items can be identified by an integer "index" but it doesn't need to be an ordinal index of the item (although this is the most common case) – it can be any value which can be used to uniquely identify an item.

Library: wxCore

Category: Events

Public Member Functions

- wxMouseEventsManager ()

  Default constructor.
- wxMouseEventsManager (wxWindow *win)

  Constructor creates the manager for the window.
- bool Create (wxWindow *win)

  Finishes initialization of the object created using default constructor.

Protected Member Functions

- virtual int MouseHitTest (const wxPoint &pos)=0

Must be overridden to return the item at the given position.

- virtual bool MouseClicked (int item)=0

  Must be overridden to react to mouse clicks.
- virtual bool MouseDragBegin (int item, const wxPoint &pos)=0

  Must be overridden to allow or deny dragging of the item.
- virtual void MouseDragging (int item, const wxPoint &pos)=0

  Must be overridden to provide feed back while an item is being dragged.
- virtual void MouseDragEnd (int item, const wxPoint &pos)=0

  Must be overridden to handle item drop.
- virtual void MouseDragCancelled (int item)=0

  Must be overridden to handle cancellation of mouse dragging.
- virtual void MouseClickBegin (int item)

  May be overridden to update the state of an item when it is pressed.
- virtual void MouseClickCancelled (int item)

  Must be overridden to reset the item appearance changed by MouseClickBegin().

Additional Inherited Members

21.483.2 Constructor & Destructor Documentation

wxMouseEventsManager::wxMouseEventsManager ( )

Default constructor.

You must call Create() to finish initializing the mouse events manager. If possible, avoid the use of this constructor in favour of the other one which fully initializes the mouse events manager immediately.

wxMouseEventsManager::wxMouseEventsManager (wxWindow * *win*)

Constructor creates the manager for the window.

A mouse event manager is always associated with a window and must be destroyed by the window when it is destroyed (it doesn't need to be allocated on the heap however).

21.483.3 Member Function Documentation

bool wxMouseEventsManager::Create (wxWindow * *win*)

Finishes initialization of the object created using default constructor.

Currently always returns true.

virtual void wxMouseEventsManager::MouseClickBegin (int *item*) `[protected], [virtual]`

May be overridden to update the state of an item when it is pressed.

This method is called when the item is becomes pressed and can be used to change its appearance when this happens. It is mostly useful for button-like items and doesn't need to be overridden if the items shouldn't change their appearance when pressed.

Parameters

item	The item being pressed.

virtual void wxMouseEventsManager::MouseClickCancelled (int *item*) `[protected], [virtual]`

Must be overridden to reset the item appearance changed by MouseClickBegin().

This method is called if the mouse capture was lost while the item was pressed and must be overridden to restore the default item appearance if it was changed in MouseClickBegin().

See also

MouseDragCancelled(), wxMouseCaptureLostEvent

virtual bool wxMouseEventsManager::MouseClicked (int *item*) `[protected], [pure virtual]`

Must be overridden to react to mouse clicks.

This method is called when the user clicked (i.e. pressed and released mouse over the *same* item) and should normally generate a notification about this click and return true if it was handled or false otherwise, determining whether the original mouse event is skipped or not.

Parameters

item	The item which was clicked.

Returns

true if the mouse event was processed and false otherwise.

virtual bool wxMouseEventsManager::MouseDragBegin (int *item*, const wxPoint & *pos*) `[protected], [pure virtual]`

Must be overridden to allow or deny dragging of the item.

This method is called when the user attempts to start dragging the given item.

Parameters

item	The item which is going to be dragged.
pos	The position from where it is being dragged.

Returns

true to allow the item to be dragged (in which case MouseDragging() and MouseDragEnd() will be called later, unless MouseDragCancelled() is called instead) or false to forbid it.

virtual void wxMouseEventsManager::MouseDragCancelled (int *item*) `[protected], [pure virtual]`

Must be overridden to handle cancellation of mouse dragging.

This method is called when mouse capture is lost while dragging the item and normally should remove the visual feedback drawn by MouseDragging() as well as reset any internal variables set in MouseDragBegin().

See also

wxMouseCaptureLostEvent

virtual void wxMouseEventsManager::MouseDragEnd (int *item,* const wxPoint & *pos*) `[protected], [pure virtual]`

Must be overridden to handle item drop.

This method is called when the mouse is released after dragging the item. Normally the item should be positioned at the new location.

Parameters

item	The item which was dragged and now dropped.
pos	The position at which the item was dropped.

See also

MouseDragBegin(), MouseDragging()

virtual void wxMouseEventsManager::MouseDragging (int *item,* const wxPoint & *pos*) `[protected], [pure virtual]`

Must be overridden to provide feed back while an item is being dragged.

This method is called while the item is being dragged and should normally update the feedback shown on screen (usually this is done using wxOverlay).

Notice that this method will never be called for the items for which MouseDragBegin() returns false. Consequently, if MouseDragBegin() always returns false you can do nothing in this method.

Parameters

item	The item being dragged.
pos	The current position of the item.

See also

MouseDragEnd()

virtual int wxMouseEventsManager::MouseHitTest (const wxPoint & *pos*) `[protected], [pure virtual]`

Must be overridden to return the item at the given position.

Parameters

pos	The position to test, in physical coordinates.

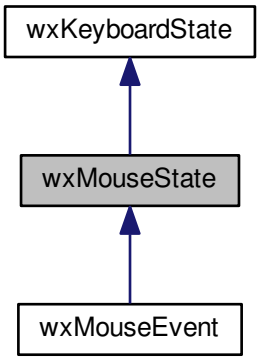
Returns

The index of the item at the given position or wxNOT_FOUND if there is no item there.

21.484 wxMouseState Class Reference

`#include <wx/mousestate.h>`

Inheritance diagram for wxMouseState:



21.484.1 Detailed Description

Represents the mouse state.

This class is used as a base class by wxMouseEvent and so its methods may be used to obtain information about the mouse state for the mouse events. It also inherits from wxKeyboardState and so carries information about the keyboard state and not only the mouse one.

This class is implemented entirely inline in <wx/mousestate.h> and thus has no linking requirements.

Library: None; this class implementation is entirely header-based.

Category: Events

wxMouseState::wxMouseState ( )

Default constructor.

21.484.3 Member Function Documentation

bool wxMouseState::Aux1IsDown ( ) const

Returns true if the first extra button mouse button is currently down.

bool wxMouseState::Aux2IsDown ( ) const

Returns true if the second extra button mouse button is currently down.

wxPoint wxMouseState::GetPosition ( ) const

Returns the physical mouse position.

void wxMouseState::GetPosition (int * *x*, int * *y*) const

Returns the physical mouse position.

wxCoord wxMouseState::GetX ( ) const

Returns X coordinate of the physical mouse event position.

wxCoord wxMouseState::GetY ( ) const

Returns Y coordinate of the physical mouse event position.

bool wxMouseState::LeftIsDown ( ) const

Returns true if the left mouse button is currently down.

bool wxMouseState::MiddleIsDown ( ) const

Returns true if the middle mouse button is currently down.

bool wxMouseState::RightIsDown ( ) const

Returns true if the right mouse button is currently down.

void wxMouseState::SetAux1Down (bool *down*)

void wxMouseState::SetAux2Down (bool *down*)

void wxMouseState::SetLeftDown (bool *down*)

void wxMouseState::SetMiddleDown (bool *down*)

void wxMouseState::SetPosition (wxPoint *pos*)

void wxMouseState::SetRightDown (bool *down*)

void wxMouseState::SetState (const wxMouseState & *state*)

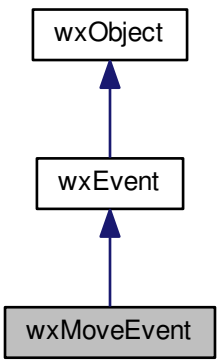
void wxMouseState::SetX (wxCoord *x*)

void wxMouseState::SetY (wxCoord *y*)

21.485 wxMoveEvent Class Reference

`#include <wx/event.h>`

Inheritance diagram for wxMoveEvent:



21.485.1 Detailed Description

A move event holds information about wxTopLevelWindow move change events.

These events are currently only generated by wxMSW port.

Events using this class

The following event handler macros redirect the events to member function handlers '**func**' with prototypes like: void handlerFuncName(wxMoveEvent& event)

Event macros:

- EVT_MOVE(func): Process a `wxEVT_MOVE` event, which is generated when a window is moved.
- EVT_MOVE_START(func): Process a `wxEVT_MOVE_START` event, which is generated when the user starts to move or size a window. wxMSW only.
- EVT_MOVING(func): Process a `wxEVT_MOVING` event, which is generated while the user is moving the window. wxMSW only.
- EVT_MOVE_END(func): Process a `wxEVT_MOVE_END` event, which is generated when the user stops moving or sizing a window. wxMSW only.

Library: wxCore

21.486 wxMsgCatalog Class Reference

`#include <wx/translation.h>`

21.486.1 Detailed Description

Represents a loaded translations message catalog.

This class should only be used directly by wxTranslationsLoader implementations.

Since

2.9.1

Static Public Member Functions

- static wxMsgCatalog * CreateFromFile (const wxString &filename, const wxString &domain)

  Creates catalog loaded from a MO file.
- static wxMsgCatalog * CreateFromData (const wxScopedCharBuffer &data, const wxString &domain)

  Creates catalog from MO file data in memory buffer.

21.486.2 Member Function Documentation

static wxMsgCatalog* wxMsgCatalog::CreateFromData (const wxScopedCharBuffer & *data,* const wxString & *domain*) [static]

Creates catalog from MO file data in memory buffer.

Parameters

data	Data in MO file format.
domain	Catalog's domain. This typically matches the *filename*.

Returns

Successfully loaded catalog or NULL on failure.

static wxMsgCatalog* wxMsgCatalog::CreateFromFile (const wxString & *filename,* const wxString & *domain*) [static]

Creates catalog loaded from a MO file.

Parameters

filename	Path to the MO file to load.

domain	Catalog's domain. This typically matches the *filename*.

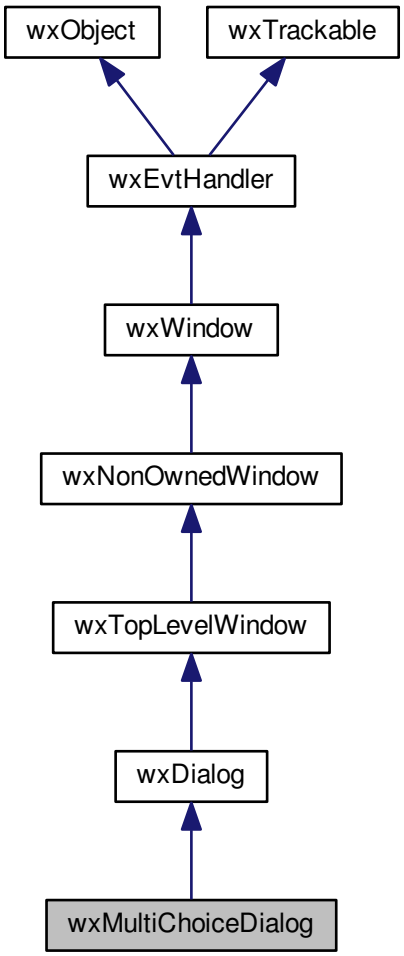
Returns

Successfully loaded catalog or NULL on failure.

21.487 wxMultiChoiceDialog Class Reference

`#include <wx/choicdlg.h>`

Inheritance diagram for wxMultiChoiceDialog:



21.487.1 Detailed Description

This class represents a dialog that shows a list of strings, and allows the user to select one or more.

Styles

This class supports the following styles:

- wxOK: Show an OK button.
- wxCANCEL: Show a Cancel button.
- wxCENTRE: Centre the message. Not Windows.

Library: wxBase

Category: Common Dialogs

See also

wxMultiChoiceDialog Overview, wxSingleChoiceDialog

Public Member Functions

- wxArrayInt GetSelections () const

  Returns array with indexes of selected items.
- void SetSelections (const wxArrayInt &selections)

  Sets selected items from the array of selected items' indexes.
- int ShowModal ()

  Shows the dialog, returning either wxID_OK or wxID_CANCEL.

- wxMultiChoiceDialog (wxWindow *parent, const wxString &message, const wxString &caption, int n, const wxString *choices, long style=wxCHOICEDLG_STYLE, const wxPoint &pos=wxDefaultPosition)

  Constructor taking an array of wxString choices.
- wxMultiChoiceDialog (wxWindow *parent, const wxString &message, const wxString &caption, const wxArrayString &choices, long style=wxCHOICEDLG_STYLE, const wxPoint &pos=wxDefaultPosition)

  Constructor taking an array of wxString choices.

Additional Inherited Members

21.487.2 Constructor & Destructor Documentation

wxMultiChoiceDialog::wxMultiChoiceDialog (wxWindow * *parent*, const wxString & *message*, const wxString & *caption*, int *n*, const wxString * *choices*, long *style* = wxCHOICEDLG_STYLE, const wxPoint & *pos* = wxDefaultPosition)

Constructor taking an array of wxString choices.

Parameters

parent	Parent window.
message	Message to show on the dialog.
caption	The dialog caption.
n	The number of choices.

choices	An array of strings, or a string list, containing the choices.
style	A dialog style (bitlist) containing flags chosen from standard dialog styles and the ones listed in the class documentation. The default value is equivalent to wxDEFAULT_DIALOG_STYLE | wxRESIZE_BORDER | wxOK | wxCANCEL | wxCENTRE.
pos	Dialog position. Not Windows.

Remarks

Use ShowModal() to show the dialog.

wxPerl Note: Not supported by wxPerl.

wxMultiChoiceDialog::wxMultiChoiceDialog (wxWindow * *parent*, const wxString & *message*, const wxString & *caption*, const wxArrayString & *choices*, long *style* = wxCHOICEDLG_STYLE, const wxPoint & *pos* = wxDefaultPosition)

Constructor taking an array of wxString choices.

Parameters

parent	Parent window.
message	Message to show on the dialog.
caption	The dialog caption.
choices	An array of strings, or a string list, containing the choices.
style	A dialog style (bitlist) containing flags chosen from standard dialog styles and the ones listed in the class documentation. The default value is equivalent to wxDEFAULT_DIALOG_STYLE | wxRESIZE_BORDER | wxOK | wxCANCEL | wxCENTRE.
pos	Dialog position. Not Windows.

Remarks

Use ShowModal() to show the dialog.

wxPerl Note: Use an array reference for the *choices* parameter.

21.487.3 Member Function Documentation

wxArrayInt wxMultiChoiceDialog::GetSelections ( ) const

Returns array with indexes of selected items.

void wxMultiChoiceDialog::SetSelections (const wxArrayInt & *selections*)

Sets selected items from the array of selected items' indexes.

int wxMultiChoiceDialog::ShowModal ( ) [virtual]

Shows the dialog, returning either wxID_OK or wxID_CANCEL.

Reimplemented from wxDialog.

21.488 wxMutex Class Reference

```
#include <wx/thread.h>
```

21.488.1 Detailed Description

A mutex object is a synchronization object whose state is set to signaled when it is not owned by any thread, and nonsignaled when it is owned.

Its name comes from its usefulness in coordinating mutually-exclusive access to a shared resource as only one thread at a time can own a mutex object.

Mutexes may be recursive in the sense that a thread can lock a mutex which it had already locked before (instead of dead locking the entire process in this situation by starting to wait on a mutex which will never be released while the thread is waiting) but using them is not recommended under Unix and they are **not** recursive by default. The reason for this is that recursive mutexes are not supported by all Unix flavours and, worse, they cannot be used with wxCondition.

For example, when several threads use the data stored in the linked list, modifications to the list should only be allowed to one thread at a time because during a new node addition the list integrity is temporarily broken (this is also called *program invariant*).

```
// this variable has an "s_" prefix because it is static: seeing an "s_" in
// a multithreaded program is in general a good sign that you should use a
// mutex (or a critical section)
static wxMutex *s_mutexProtectingTheGlobalData;

// we store some numbers in this global array which is presumably used by
// several threads simultaneously
wxArrayInt s_data;

void MyThread::AddNewNode(int num)
{
    // ensure that no other thread accesses the list
    s_mutexProtectingTheGlobalList->Lock();

    s_data.Add(num);

    s_mutexProtectingTheGlobalList->Unlock();
}

// return true if the given number is greater than all array elements
bool MyThread::IsGreater(int num)
{
    // before using the list we must acquire the mutex
    wxMutexLocker lock(s_mutexProtectingTheGlobalData);

    size_t count = s_data.Count();
    for ( size_t n = 0; n < count; n++ )
    {
        if ( s_data[n] > num )
            return false;
    }

    return true;
}
```

Notice how wxMutexLocker was used in the second function to ensure that the mutex is unlocked in any case: whether the function returns true or false (because the destructor of the local object *lock* is always called). Using this class instead of directly using wxMutex is, in general, safer and is even more so if your program uses C++ exceptions.

Library: wxBase

Category: Threading

wxThread, wxCondition, wxMutexLocker, wxCriticalSection

Public Member Functions

- wxMutex (wxMutexType type=wxMUTEX_DEFAULT)

Default constructor.

- ~wxMutex ()

  Destroys the wxMutex object.

- wxMutexError Lock ()

  Locks the mutex object.

- wxMutexError LockTimeout (unsigned long msec)

  Try to lock the mutex object during the specified time interval.

- wxMutexError TryLock ()

  Tries to lock the mutex object.

- wxMutexError Unlock ()

  Unlocks the mutex object.

21.488.2 Constructor & Destructor Documentation

wxMutex::wxMutex (wxMutexType *type* = wxMUTEX_DEFAULT)

Default constructor.

wxMutex::~wxMutex ( )

Destroys the wxMutex object.

21.488.3 Member Function Documentation

wxMutexError wxMutex::Lock ( )

Locks the mutex object.

This is equivalent to LockTimeout() with infinite timeout.

Note that if this mutex is already locked by the caller thread, this function doesn't block but rather immediately returns.

Returns

One of: `wxMUTEX_NO_ERROR`, `wxMUTEX_DEAD_LOCK`.

wxMutexError wxMutex::LockTimeout (unsigned long *msec*)

Try to lock the mutex object during the specified time interval.

Returns

One of: `wxMUTEX_NO_ERROR`, `wxMUTEX_DEAD_LOCK`, `wxMUTEX_TIMEOUT`.

wxMutexError wxMutex::TryLock ( )

Tries to lock the mutex object.

If it can't, returns immediately with an error.

Returns

One of: `wxMUTEX_NO_ERROR`, `wxMUTEX_BUSY`.

wxMutexError wxMutex::Unlock ( )

Unlocks the mutex object.

Returns

One of: `wxMUTEX_NO_ERROR`, `wxMUTEX_UNLOCKED`.

21.489 wxMutexLocker Class Reference

```
#include <wx/thread.h>
```

21.489.1 Detailed Description

This is a small helper class to be used with wxMutex objects.

A wxMutexLocker acquires a mutex lock in the constructor and releases (or unlocks) the mutex in the destructor making it much more difficult to forget to release a mutex (which, in general, will promptly lead to serious problems). See wxMutex for an example of wxMutexLocker usage.

Library: wxBase

Category: Threading

wxMutex, wxCriticalSectionLocker

Public Member Functions

- wxMutexLocker (wxMutex &mutex)

  Constructs a wxMutexLocker object associated with mutex and locks it.
- ~wxMutexLocker ()

  Destructor releases the mutex if it was successfully acquired in the ctor.
- bool IsOk () const

  Returns true if mutex was acquired in the constructor, false otherwise.

21.489.2 Constructor & Destructor Documentation

wxMutexLocker::wxMutexLocker (wxMutex & *mutex*)

Constructs a wxMutexLocker object associated with mutex and locks it.

Call IsOk() to check if the mutex was successfully locked.

wxMutexLocker::~wxMutexLocker ( )

Destructor releases the mutex if it was successfully acquired in the ctor.

21.489.3 Member Function Documentation

bool wxMutexLocker::IsOk ( ) const

Returns true if mutex was acquired in the constructor, false otherwise.

21.490 wxNativeFontInfo Class Reference

```
#include <wx/fontutil.h>
```

21.490.1 Detailed Description

wxNativeFontInfo is platform-specific font representation: this class should be considered as an opaque font description only used by the native functions, the user code can only get the objects of this type from somewhere and pass it somewhere else (possibly save them somewhere using ToString() and restore them using FromString())

Library: wxCore

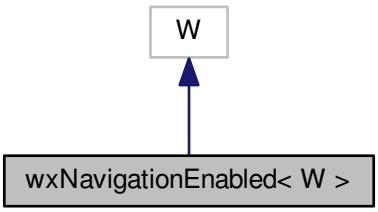
21.491 wxNavigationEnabled< W > Class Template Reference

`#include <wx/containr.h>`

Inheritance diagram for wxNavigationEnabled< W >:



21.491.1 Detailed Description

template<class W>class wxNavigationEnabled< W >

A helper class implementing TAB navigation among the window children.

This class contains the functionality needed to correctly implement TAB navigation among the children of the window. Its exact contents is not important and is intentionally not documented as the only way to use this class is to inherit from it instead of inheriting from the usual base class directly. For example, if some class needs to inherit from wxControl but contains multiple sub-windows and needs to support keyboard navigation, it is enough to declare it in the following way:

```
class MyControlWithSubChildren :
    public wxNavigationEnabled<wxControl>
{
public:
    // Default constructor is implemented in the same way as always.
    MyControlWithSubChildren() { }

    // Non-default constructor can't use wxControl ctor any more as
    // wxControl is not its direct base class, but it can use Create().
    MyControlWithSubChildren(wxWindow *parent, wxWindowID winid)
    {
        wxControl::Create(parent, winid);

        // More creation code...
    }

    // Everything else as usual ...
};
```

Library: wxCore

Since

2.9.3

Public Types

- typedef W BaseWindowClass

  The name of the real base window class that this class derives from.

Public Member Functions

- wxNavigationEnabled ()

  Default constructor.

21.491.2 Member Typedef Documentation

template<class W > typedef W wxNavigationEnabled< W >::BaseWindowClass

The name of the real base window class that this class derives from.

21.491.3 Constructor & Destructor Documentation

template<class W > wxNavigationEnabled< W >::wxNavigationEnabled ( )

Default constructor.

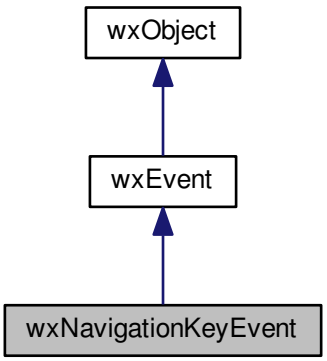
This class provides only the default constructor as it's not possible, in general, to provide all the constructors of the real base class BaseWindowClass.

This is however not usually a problem for wxWindow-derived classes as, by convention, they always define a Create() method such that calling it on an object initialized using the default constructor is equivalent to using a non-default constructor directly. So the classes inheriting from wxNavigationEnabled<W> should simply call W::↩ Create() in their constructors.

21.492 wxNavigationKeyEvent Class Reference

`#include <wx/event.h>`

Inheritance diagram for wxNavigationKeyEvent:



21.492.1 Detailed Description

This event class contains information about navigation events, generated by navigation keys such as tab and page down.

This event is mainly used by wxWidgets implementations. A wxNavigationKeyEvent handler is automatically provided by wxWidgets when you enable keyboard navigation inside a window by inheriting it from wxNavigationEnabled<>.

Events using this class

The following event handler macros redirect the events to member function handlers '**func**' with prototypes like: void handlerFuncName(wxNavigationKeyEvent& event)

Event macros:

- EVT_NAVIGATION_KEY(func): Process a navigation key event.

Library: wxCore

Category: Events

See also

wxWindow::Navigate, wxWindow::NavigateIn

Public Types

- enum wxNavigationKeyEventFlags {
  IsBackward = 0x0000,
  IsForward = 0x0001,
  WinChange = 0x0002,
  FromTab = 0x0004 }

  Flags which can be used with wxNavigationKeyEvent.

Public Member Functions

- wxNavigationKeyEvent ()
- wxNavigationKeyEvent (const wxNavigationKeyEvent &event)
- wxWindow * GetCurrentFocus () const

  Returns the child that has the focus, or NULL.
- bool GetDirection () const

  Returns true if the navigation was in the forward direction.
- bool IsFromTab () const

  Returns true if the navigation event was from a tab key.
- bool IsWindowChange () const

  Returns true if the navigation event represents a window change (for example, from Ctrl-Page Down in a notebook).
- void SetCurrentFocus (wxWindow *currentFocus)

  Sets the current focus window member.
- void SetDirection (bool direction)

  Sets the direction to forward if direction is true, or backward if false.
- void SetFlags (long flags)

Sets the flags for this event.

- void SetFromTab (bool fromTab)

  Marks the navigation event as from a tab key.

- void SetWindowChange (bool windowChange)

  Marks the event as a window change event.

Additional Inherited Members

21.492.2 Member Enumeration Documentation

enum wxNavigationKeyEvent::wxNavigationKeyEventFlags

Flags which can be used with wxNavigationKeyEvent.

Enumerator

IsBackward

IsForward

WinChange

FromTab

21.492.3 Constructor & Destructor Documentation

wxNavigationKeyEvent::wxNavigationKeyEvent ( )

wxNavigationKeyEvent::wxNavigationKeyEvent (const wxNavigationKeyEvent & *event*)

21.492.4 Member Function Documentation

wxWindow* wxNavigationKeyEvent::GetCurrentFocus ( ) const

Returns the child that has the focus, or NULL.

bool wxNavigationKeyEvent::GetDirection ( ) const

Returns true if the navigation was in the forward direction.

bool wxNavigationKeyEvent::IsFromTab ( ) const

Returns true if the navigation event was from a tab key.

This is required for proper navigation over radio buttons.

bool wxNavigationKeyEvent::IsWindowChange ( ) const

Returns true if the navigation event represents a window change (for example, from Ctrl-Page Down in a notebook).

void wxNavigationKeyEvent::SetCurrentFocus (wxWindow * *currentFocus*)

Sets the current focus window member.

void wxNavigationKeyEvent::SetDirection (bool *direction*)

Sets the direction to forward if *direction* is true, or backward if false.

void wxNavigationKeyEvent::SetFlags (long *flags*)

Sets the flags for this event.

The *flags* can be a combination of the wxNavigationKeyEvent::wxNavigationKeyEventFlags values.

void wxNavigationKeyEvent::SetFromTab (bool *fromTab*)

Marks the navigation event as from a tab key.

void wxNavigationKeyEvent::SetWindowChange (bool *windowChange*)

Marks the event as a window change event.

21.493 wxNode< T > Class Template Reference

`#include <wx/list.h>`

21.493.1 Detailed Description

template<typename T>class wxNode< T >

wxNode<T> is the node structure used in linked lists (see wxList) and derived classes.

You should never use wxNode<T> class directly, however, because it works with untyped (`void *`) data and this is unsafe. Use wxNode<T>-derived classes which are automatically defined by WX_DECLARE_LIST and WX_DEFINE_LIST macros instead as described in wxList documentation (see example there).

Also note that although there is a class called wxNode, it is defined for backwards compatibility only and usage of this class is strongly deprecated.

In the documentation below, the type `T` should be thought of as a "template" parameter: this is the type of data stored in the linked list or, in other words, the first argument of WX_DECLARE_LIST macro. Also, wxNode is written as wxNodeT even though it isn't really a template class – but it helps to think of it as if it were.

Template Parameters

T	The type stored in the wxNode.

Library: wxBase

Category: Data Structures

See also

wxList<T>, wxHashTable

Public Member Functions

- T * GetData () const

Retrieves the client data pointer associated with the node.

- wxNode< T > * GetNext () const

  Retrieves the next node or NULL if this node is the last one.

- wxNode< T > * GetPrevious ()

  Retrieves the previous node or NULL if this node is the first one in the list.

- int IndexOf ()

  Returns the zero-based index of this node within the list.

- void SetData (T *data)

  Sets the data associated with the node (usually the pointer will have been set when the node was created).

21.493.2 Member Function Documentation

template<typename T > T* wxNode< T >::GetData ( ) const

Retrieves the client data pointer associated with the node.

template<typename T > wxNode<T>* wxNode< T >::GetNext ( ) const

Retrieves the next node or NULL if this node is the last one.

template<typename T > wxNode<T>* wxNode< T >::GetPrevious ( )

Retrieves the previous node or NULL if this node is the first one in the list.

template<typename T > int wxNode< T >::IndexOf ( )

Returns the zero-based index of this node within the list.

The return value will be `wxNOT_FOUND` if the node has not been added to a list yet.

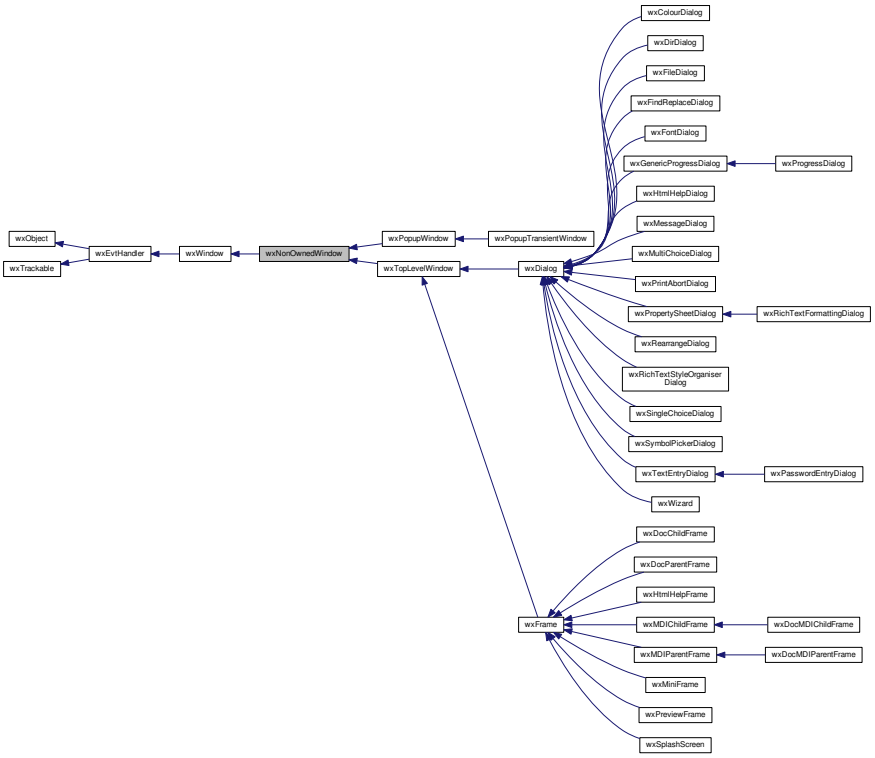
template<typename T > void wxNode< T >::SetData (T * *data*)

Sets the data associated with the node (usually the pointer will have been set when the node was created).

21.494 wxNonOwnedWindow Class Reference

`#include <wx/nonownedwnd.h>`

Inheritance diagram for wxNonOwnedWindow:



21.494.1 Detailed Description

Common base class for all non-child windows.

This is the common base class of wxTopLevelWindow and wxPopupWindow and is not used directly.

Currently the only additional functionality it provides, compared to base wxWindow class, is the ability to set the window shape.

Since

2.9.3

Public Member Functions

- bool SetShape (const wxRegion &region)

  If the platform supports it, sets the shape of the window to that depicted by region.
- bool SetShape (const wxGraphicsPath &path)

  Set the window shape to the given path.

Additional Inherited Members

21.494.2 Member Function Documentation

bool wxNonOwnedWindow::SetShape (const wxRegion & *region*)

If the platform supports it, sets the shape of the window to that depicted by *region*.

The system will not display or respond to any mouse event for the pixels that lie outside of the region. To reset the window to the normal rectangular shape simply call SetShape() again with an empty wxRegion. Returns true if the operation is successful.

This method is available in this class only since wxWidgets 2.9.3, previous versions only provided it in wxTopLevelWindow.

bool wxNonOwnedWindow::SetShape (const wxGraphicsPath & *path*)

Set the window shape to the given path.

Set the window shape to the interior of the given path and also draw the window border along the specified path.

For example, to make a clock-like circular window you could use

```
wxSize size = GetSize();
wxGraphicsPath
    path = wxGraphicsRenderer::GetDefaultRenderer()->
      CreatePath();
path.AddCircle(size.x/2, size.y/2, 30);
SetShape(path);
```

As the overload above, this method is not guaranteed to work on all platforms but currently does work in wxMSW, wxOSX/Cocoa and wxGTK (with the appropriate but almost always present X11 extensions) ports.

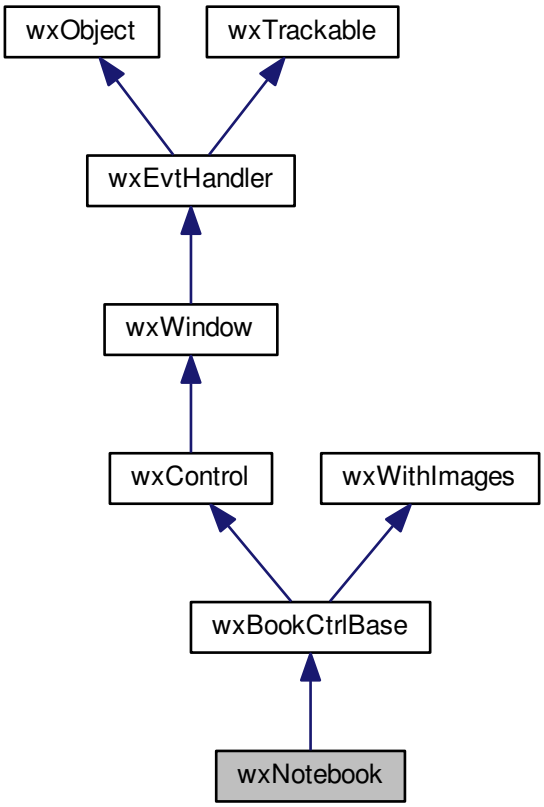
Since

2.9.3

21.495 wxNotebook Class Reference

```
#include <wx/notebook.h>
```

Inheritance diagram for wxNotebook:



21.495.1 Detailed Description

This class represents a notebook control, which manages multiple windows with associated tabs.

To use the class, create a wxNotebook object and call wxNotebook::AddPage or wxNotebook::InsertPage, passing a window to be used as the page. Do not explicitly delete the window for a page that is currently managed by wxNotebook.

wxNotebookPage is a typedef for wxWindow.

Styles

This class supports the following styles:

- wxNB_TOP: Place tabs on the top side.
- wxNB_LEFT: Place tabs on the left side.
- wxNB_RIGHT: Place tabs on the right side.
- wxNB_BOTTOM: Place tabs under instead of above the notebook pages.
- wxNB_FIXEDWIDTH: (Windows only) All tabs will have same width.

- wxNB_MULTILINE: (Windows only) There can be several rows of tabs.
- wxNB_NOPAGETHEME: (Windows only) Display a solid colour on notebook pages, and not a gradient, which can reduce performance.
- wxNB_FLAT: (Windows CE only) Show tabs in a flat style.

The styles wxNB_LEFT, RIGHT and BOTTOM are not supported under Microsoft Windows XP when using visual themes.

Events emitted by this class

The following event handler macros redirect the events to member function handlers '**func**' with prototypes like: void handlerFuncName(wxBookCtrlEvent& event)

Event macros for events emitted by this class:

- EVT_NOTEBOOK_PAGE_CHANGED(id, func): The page selection was changed. Processes a `wxEVT_NOTEBOOK_PAGE_CHANGED` event.
- EVT_NOTEBOOK_PAGE_CHANGING(id, func): The page selection is about to be changed. Processes a `wxEVT_NOTEBOOK_PAGE_CHANGING` event. This event can be vetoed.

21.495.2 Page backgrounds

On Windows XP, the default theme paints a gradient on the notebook's pages. If you wish to suppress this theme, for aesthetic or performance reasons, there are three ways of doing it. You can use `wxNB_NOPAGETHEME` to disable themed drawing for a particular notebook, you can call wxSystemOptions::SetOption to disable it for the whole application, or you can disable it for individual pages by using SetBackgroundColour().

To disable themed pages globally:

```
wxSystemOptions::SetOption("msw.notebook.themed-background", 0);
```

Set the value to 1 to enable it again. To give a single page a solid background that more or less fits in with the overall theme, use:

```
wxColour col = notebook->GetThemeBackgroundColour();
if (col.IsOk())
{
    page->SetBackgroundColour(col);
}
```

On platforms other than Windows, or if the application is not using Windows themes, GetThemeBackgroundColour() will return an uninitialised colour object, and the above code will therefore work on all platforms.

Library: wxCore

Category: Book Controls

See also

wxBookCtrl, wxBookCtrlEvent, wxImageList, Notebook Sample

Public Member Functions

- wxNotebook ()

  Constructs a notebook control.
- wxNotebook (wxWindow *parent, wxWindowID id, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, long style=0, const wxString &name=wxNotebookNameStr)

  Constructs a notebook control.
- virtual ~wxNotebook ()

  Destroys the wxNotebook object.
- bool Create (wxWindow *parent, wxWindowID id, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, long style=0, const wxString &name=wxNotebookNameStr)

  Creates a notebook control.
- virtual int GetRowCount () const

  Returns the number of rows in the notebook control.
- virtual wxColour GetThemeBackgroundColour () const

  If running under Windows and themes are enabled for the application, this function returns a suitable colour for painting the background of a notebook page, and can be passed to SetBackgroundColour().
- void OnSelChange (wxBookCtrlEvent &event)

  An event handler function, called when the page selection is changed.
- virtual void SetPadding (const wxSize &padding)

  Sets the amount of space around each page's icon and label, in pixels.
- virtual int GetPageImage (size_t nPage) const

  Returns the image index for the given page.
- virtual bool SetPageImage (size_t page, int image)

  Sets the image index for the given page.
- virtual wxString GetPageText (size_t nPage) const

  Returns the string for the given page.
- virtual bool SetPageText (size_t page, const wxString &text)

  Sets the text for the given page.
- virtual int GetSelection () const

  Returns the currently selected page, or `wxNOT_FOUND` if none was selected.
- virtual int SetSelection (size_t page)

  Sets the selection to the given page, returning the previous selection.
- virtual int ChangeSelection (size_t page)

  Changes the selection to the given page, returning the previous selection.
- virtual bool InsertPage (size_t index, wxWindow *page, const wxString &text, bool select=false, int image↩ Id=NO_IMAGE)

  Inserts a new page at the specified position.

Additional Inherited Members

21.495.3 Constructor & Destructor Documentation

wxNotebook::wxNotebook ( )

Constructs a notebook control.

wxNotebook::wxNotebook (wxWindow * *parent*, wxWindowID *id*, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, long *style* = `0`, const wxString & *name* = `wxNotebookNameStr`)

Constructs a notebook control.

Note that sometimes you can reduce flicker by passing the wxCLIP_CHILDREN window style.

Parameters

parent	The parent window. Must be non-NULL.
id	The window identifier.
pos	The window position.
size	The window size.
style	The window style. See wxNotebook.
name	The name of the control.

virtual wxNotebook::~wxNotebook ( ) [virtual]

Destroys the wxNotebook object.

21.495.4 Member Function Documentation

virtual int wxNotebook::ChangeSelection (size_t *page*) [virtual]

Changes the selection to the given page, returning the previous selection.

This function behaves as SetSelection() but does *not* generate the page changing events.

See User Generated Events vs Programmatically Generated Events for more information.

Implements wxBookCtrlBase.

bool wxNotebook::Create (wxWindow * *parent*, wxWindowID *id*, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, long *style* = 0, const wxString & *name* = wxNotebookNameStr)

Creates a notebook control.

See wxNotebook() for a description of the parameters.

virtual int wxNotebook::GetPageImage (size_t *nPage*) const [virtual]

Returns the image index for the given page.

Implements wxBookCtrlBase.

virtual wxString wxNotebook::GetPageText (size_t *nPage*) const [virtual]

Returns the string for the given page.

Implements wxBookCtrlBase.

virtual int wxNotebook::GetRowCount ( ) const [virtual]

Returns the number of rows in the notebook control.

virtual int wxNotebook::GetSelection ( ) const [virtual]

Returns the currently selected page, or wxNOT_FOUND if none was selected.

Note that this method may return either the previously or newly selected page when called from the EVT_BOOKCTRL_PAGE_CHANGED handler depending on the platform and so wxBookCtrlEvent::GetSelection should be used instead in this case.

Implements wxBookCtrlBase.

virtual wxColour wxNotebook::GetThemeBackgroundColour ( ) const `[virtual]`

If running under Windows and themes are enabled for the application, this function returns a suitable colour for painting the background of a notebook page, and can be passed to SetBackgroundColour().

Otherwise, an uninitialised colour will be returned.

virtual bool wxNotebook::InsertPage (size_t *index*, wxWindow * *page*, const wxString & *text*, bool *select* = `false`, int *imageId* = NO_IMAGE) `[virtual]`

Inserts a new page at the specified position.

Parameters

index	Specifies the position for the new page.
page	Specifies the new page.
text	Specifies the text for the new page.
select	Specifies whether the page should be selected.
imageId	Specifies the optional image index for the new page.

Returns

true if successful, false otherwise.

Remarks

Do not delete the page, it will be deleted by the book control.

See also

AddPage()

Implements wxBookCtrlBase.

void wxNotebook::OnSelChange (wxBookCtrlEvent & *event*)

An event handler function, called when the page selection is changed.

See also

wxBookCtrlEvent

virtual void wxNotebook::SetPadding (const wxSize & *padding*) `[virtual]`

Sets the amount of space around each page's icon and label, in pixels.

Note

The vertical padding cannot be changed in wxGTK.

virtual bool wxNotebook::SetPageImage (size_t *page*, int *image*) `[virtual]`

Sets the image index for the given page.

image is an index into the image list which was set with SetImageList().

Implements wxBookCtrlBase.

virtual bool wxNotebook::SetPageText (size_t *page,* const wxString & *text*) `[virtual]`

Sets the text for the given page.

Implements wxBookCtrlBase.

virtual int wxNotebook::SetSelection (size_t *page*) `[virtual]`

Sets the selection to the given page, returning the previous selection.

Notice that the call to this function generates the page changing events, use the ChangeSelection() function if you don't want these events to be generated.

See also

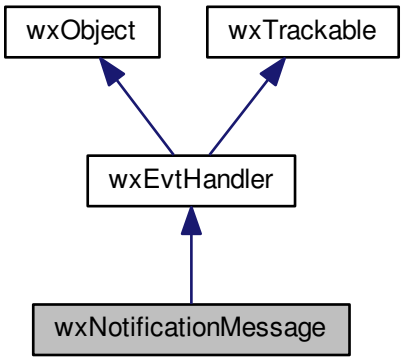
GetSelection()

Implements wxBookCtrlBase.

21.496 wxNotificationMessage Class Reference

`#include <wx/notifmsg.h>`

Inheritance diagram for wxNotificationMessage:



21.496.1 Detailed Description

This class allows to show the user a message non intrusively.

Currently it is implemented natively for Windows and GTK and uses (non-modal) dialogs for the display of the notifications under the other platforms.

Notice that this class is not a window and so doesn't derive from wxWindow.

Library: wxAdvanced

Category: Miscellaneous

Public Types

- enum {
  Timeout_Auto = -1,
  Timeout_Never = 0 }

  Possible values for Show() timeout.

Public Member Functions

- wxNotificationMessage ()

  Default constructor, use SetParent(), SetTitle() and SetMessage() to initialize the object before showing it.
- wxNotificationMessage (const wxString &title, const wxString &message=wxEmptyString, wxWindow *parent=NULL, int flags=wxICON_INFORMATION)

  Create a notification object with the given attributes.
- virtual ~wxNotificationMessage ()

  Destructor does not hide the notification.
- virtual bool Close ()

  Hides the notification.
- void SetFlags (int flags)

  This parameter can be currently used to specify the icon to show in the notification.
- void SetMessage (const wxString &message)

  Set the main text of the notification.
- void SetParent (wxWindow *parent)

  Set the parent for this notification: the notification will be associated with the top level parent of this window or, if this method is not called, with the main application window by default.
- void SetTitle (const wxString &title)

  Set the title, it must be a concise string (not more than 64 characters), use SetMessage() to give the user more details.
- virtual bool Show (int timeout=Timeout_Auto)

  Show the notification to the user and hides it after timeout seconds are elapsed.

Additional Inherited Members

21.496.2 Member Enumeration Documentation

anonymous enum

Possible values for Show() timeout.

Enumerator

Timeout_Auto Notification will be hidden automatically.

Timeout_Never Notification will never time out.

21.496.3 Constructor & Destructor Documentation

wxNotificationMessage::wxNotificationMessage ( )

Default constructor, use SetParent(), SetTitle() and SetMessage() to initialize the object before showing it.

wxNotificationMessage::wxNotificationMessage (const wxString & *title*, const wxString & *message* = wxEmptyString, wxWindow * *parent* = NULL, int *flags* = wxICON_INFORMATION)

Create a notification object with the given attributes.

See SetTitle(), SetMessage(), SetParent() and SetFlags() for the description of the corresponding parameters.

virtual wxNotificationMessage::~wxNotificationMessage ( ) [virtual]

Destructor does not hide the notification.

The notification can continue to be shown even after the C++ object was destroyed, call Close() explicitly if it needs to be hidden.

21.496.4 Member Function Documentation

virtual bool wxNotificationMessage::Close ( ) [virtual]

Hides the notification.

Returns true if it was hidden or false if it couldn't be done (e.g. on some systems automatically hidden notifications can't be hidden manually).

void wxNotificationMessage::SetFlags (int *flags*)

This parameter can be currently used to specify the icon to show in the notification.

Valid values are wxICON_INFORMATION, wxICON_WARNING and wxICON_ERROR (notice that wxICON_QUESTION is not allowed here). Some implementations of this class may not support the icons.

void wxNotificationMessage::SetMessage (const wxString & *message*)

Set the main text of the notification.

This should be a more detailed description than the title but still limited to reasonable length (not more than 256 characters).

void wxNotificationMessage::SetParent (wxWindow * *parent*)

Set the parent for this notification: the notification will be associated with the top level parent of this window or, if this method is not called, with the main application window by default.

void wxNotificationMessage::SetTitle (const wxString & *title*)

Set the title, it must be a concise string (not more than 64 characters), use SetMessage() to give the user more details.

virtual bool wxNotificationMessage::Show (int *timeout* = Timeout_Auto) [virtual]

Show the notification to the user and hides it after *timeout* seconds are elapsed.

Special values Timeout_Auto and Timeout_Never can be used here, notice that you shouldn't rely on *timeout* being exactly respected because the current platform may only support default timeout value and also because the user may be able to close the notification.

Note

When using native notifications in wxGTK, the timeout is ignored for the notifications with `wxICON_WARNING` or `wxICON_ERROR` flags, they always remain shown unless they're explicitly hidden by the user, i.e. behave as if Timeout_Auto were given.

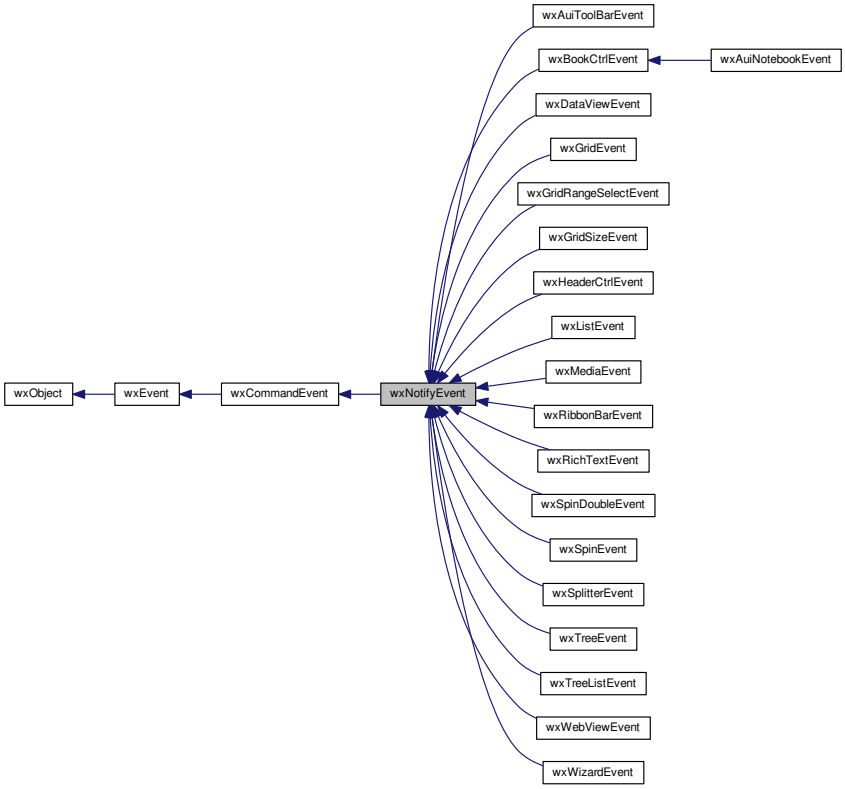
Returns

false if an error occurred.

21.497 wxNotifyEvent Class Reference

`#include <wx/event.h>`

Inheritance diagram for wxNotifyEvent:



21.497.1 Detailed Description

This class is not used by the event handlers by itself, but is a base class for other event classes (such as wxBookCtrlEvent).

It (or an object of a derived class) is sent when the controls state is being changed and allows the program to wxNotifyEvent::Veto() this change if it wants to prevent it from happening.

Library: wxCore

Category: Events

See also

wxBookCtrlEvent

Public Member Functions

- wxNotifyEvent (wxEventType eventType=wxEVT_NULL, int id=0)

  Constructor (used internally by wxWidgets only).
- void Allow ()

  This is the opposite of Veto(): it explicitly allows the event to be processed.
- bool IsAllowed () const

  Returns true if the change is allowed (Veto() hasn't been called) or false otherwise (if it was).
- void Veto ()

  Prevents the change announced by this event from happening.

Additional Inherited Members

21.497.2 Constructor & Destructor Documentation

wxNotifyEvent::wxNotifyEvent (wxEventType *eventType* = wxEVT_NULL, int *id* = 0)

Constructor (used internally by wxWidgets only).

21.497.3 Member Function Documentation

void wxNotifyEvent::Allow ( )

This is the opposite of Veto(): it explicitly allows the event to be processed.

For most events it is not necessary to call this method as the events are allowed anyhow but some are forbidden by default (this will be mentioned in the corresponding event description).

bool wxNotifyEvent::IsAllowed ( ) const

Returns true if the change is allowed (Veto() hasn't been called) or false otherwise (if it was).

void wxNotifyEvent::Veto ( )

Prevents the change announced by this event from happening.

It is in general a good idea to notify the user about the reasons for vetoing the change because otherwise the applications behaviour (which just refuses to do what the user wants) might be quite surprising.

21.498 wxNumberFormatter Class Reference

```
#include <wx/numformatter.h>
```

21.498.1 Detailed Description

Helper class for formatting and parsing numbers with thousands separators.

This class contains only static functions, so users must not create instances but directly call the member functions.

Since

2.9.2

Library: wxBase

Public Types

- enum Style {
  Style_None = 0x00,
  Style_WithThousandsSep = 0x01,
  Style_NoTrailingZeroes = 0x02 }
  Bit masks used with ToString().

Static Public Member Functions

- static wxString ToString (long val, int flags=Style_WithThousandsSep)
  Returns string representation of an integer number.
- static wxString ToString (double val, int precision, int flags=Style_WithThousandsSep)
  Returns string representation of a floating point number.
- static wxChar GetDecimalSeparator ()
  Get the decimal separator for the current locale.
- static bool GetThousandsSeparatorIfUsed (wxChar *sep)
  Get the thousands separator if grouping of the digits is used by the current locale.
- static bool FromString (wxString s, long *val)
  Parse a string representation of a number possibly including thousands separators.
- static bool FromString (wxString s, double *val)
  Parse a string representation of a number possibly including thousands separators.

21.498.2 Member Enumeration Documentation

enum wxNumberFormatter::Style

Bit masks used with ToString().

Enumerator

Style_None This flag can be used to indicate absence of any other flags below.

Style_WithThousandsSep If this flag is given, thousands separators will be inserted in the number string representation as defined by the current locale.

Style_NoTrailingZeroes If this flag is given, trailing zeroes in a floating point number string representation will be omitted. If the number is actually integer, the decimal separator will be omitted as well. To give an example, formatting the number `1.23` with precision 5 will normally yield "1.23000" but with this flag it would return "1.23". And formatting `123` with this flag will return just "123" for any precision.

This flag can't be used with ToString() overload taking the integer value.

21.498.3 Member Function Documentation

static bool wxNumberFormatter::FromString (wxString *s,* long * *val*) [static]

Parse a string representation of a number possibly including thousands separators.

These functions parse number representation in the current locale. On success they return true and store the result at the location pointed to by *val* (which can't be NULL), otherwise false is returned.

See also

wxString::ToLong(), wxString::ToDouble()

static bool wxNumberFormatter::FromString (wxString *s,* double * *val*) [static]

Parse a string representation of a number possibly including thousands separators.

These functions parse number representation in the current locale. On success they return true and store the result at the location pointed to by *val* (which can't be NULL), otherwise false is returned.

See also

wxString::ToLong(), wxString::ToDouble()

static wxChar wxNumberFormatter::GetDecimalSeparator ( ) [static]

Get the decimal separator for the current locale.

Decimal separators is always defined and we fall back to returning '.' in case of an error.

static bool wxNumberFormatter::GetThousandsSeparatorIfUsed (wxChar * *sep*) [static]

Get the thousands separator if grouping of the digits is used by the current locale.

The value returned in *sep* should be only used if the function returns true, otherwise no thousands separator should be used at all.

Parameters

sep	Points to the variable receiving the thousands separator character if it is used by the current locale. May be NULL if only the function return value is needed.

static wxString wxNumberFormatter::ToString (long *val,* int *flags* = Style_WithThousandsSep) [static]

Returns string representation of an integer number.

By default, the string will use thousands separators if appropriate for the current locale. This can be avoided by passing Style_None as *flags* in which case the call to the function has exactly the same effect as `wxString::Format("%ld", val)`.

Notice that calling ToString() with a value of type `int` and non-default flags results in ambiguity between this overload and the one below. To resolve it, you need to cast the value to `long`.

Parameters

val	The variable to convert to a string.
flags	Combination of values from the Style enumeration (except for Style_NoTrailingZeroes which can't be used with this overload).

static wxString wxNumberFormatter::ToString (double *val,* int *precision,* int *flags* = Style_WithThousandsSep) `[static]`

Returns string representation of a floating point number.

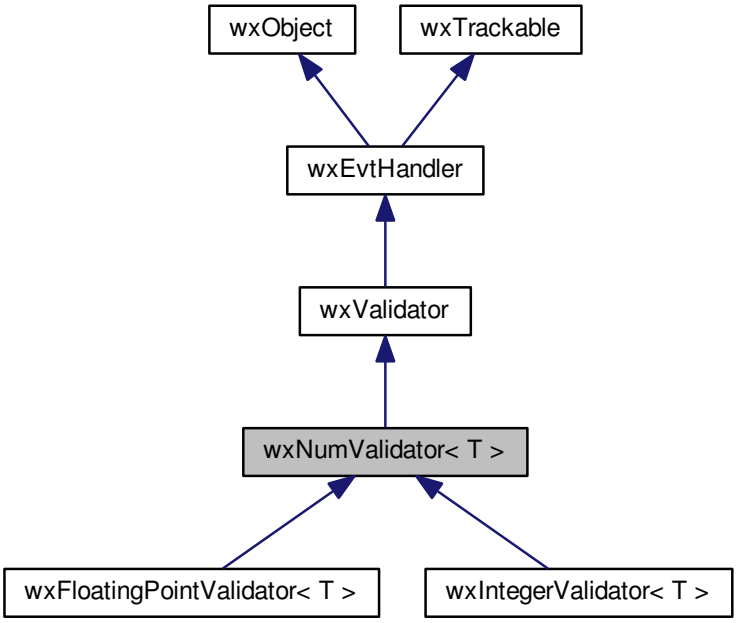
Parameters

val	The variable to convert to a string.
precision	Number of decimals to write in formatted string.
flags	Combination of values from the Style enumeration.

21.499 wxNumValidator< T > Class Template Reference

`#include <wx/valnum.h>`

Inheritance diagram for wxNumValidator< T >:



21.499.1 Detailed Description

template<typename T>class wxNumValidator< T >

wxNumValidator is the common base class for numeric validator classes.

This class is never used directly, but only as a base class for wxIntegerValidator and wxFloatingPointValidator.

Template Parameters

T	Type of the values used with this validator.

Category: Validators

Since

2.9.2

Public Types

- typedef T ValueType

  Type of the values this validator is used with.

Public Member Functions

- void SetMin (ValueType min)

  Sets the minimal value accepted by the validator.
- void SetMax (ValueType max)

  Sets the maximal value accepted by the validator.
- void SetRange (ValueType min, ValueType max)

  Sets both minimal and maximal values accepted by the validator.
- void SetStyle (int style)

  Change the validator style.
- virtual bool TransferToWindow ()

  Override base class method to format the control contents.
- virtual bool TransferFromWindow ()

  Override base class method to validate the control contents.

Additional Inherited Members

21.499.2 Member Typedef Documentation

template<typename T > typedef T wxNumValidator< T >::ValueType

Type of the values this validator is used with.

21.499.3 Member Function Documentation

template<typename T > void wxNumValidator< T >::SetMax (ValueType *max*)

Sets the maximal value accepted by the validator.

This value is inclusive, i.e. the value equal to *max* is accepted.

template<typename T > void wxNumValidator< T >::SetMin (ValueType *min*)

Sets the minimal value accepted by the validator.

This value is inclusive, i.e. the value equal to *min* is accepted.

template<typename T > void wxNumValidator< T >::SetRange (ValueType *min,* ValueType *max*)

Sets both minimal and maximal values accepted by the validator.

Calling this is equivalent to calling both SetMin() and SetMax().

template<typename T > void wxNumValidator< T >::SetStyle (int *style*)

Change the validator style.

Can be used to change the style of the validator after its creation. The *style* parameter must be a combination of the values from wxNumValidatorStyle enum.

template<typename T > virtual bool wxNumValidator< T >::TransferFromWindow ( ) [virtual]

Override base class method to validate the control contents.

This method is called to check the correctness of user input and fill the associated variable with the controls numeric value. It returns false if it is not a number in the configured range or if the control contents is empty for a validator without wxNUM_VAL_ZERO_AS_BLANK style.

It does nothing if there is no associated variable.

Reimplemented from wxValidator.

template<typename T > virtual bool wxNumValidator< T >::TransferToWindow ( ) [virtual]

Override base class method to format the control contents.

This method is called when the associated window is shown and it fills it with the contents of the associated variable, if any, formatted according to the validator style.

It does nothing if there is no associated variable.

Reimplemented from wxValidator.

21.500 wxObject Class Reference

`#include <wx/object.h>`

Inherited by wxAcceleratorTable, wxAccessible, wxAnimation, wxArchiveClassFactory, wxArchiveEntry, wxArtProvider, wxAutomationObject, wxBitmapHandler, wxClient, wxClipboard, wxColour, wxColourData, wxCommand, wxCommandProcessor, wxConfigBase, wxConnection, wxConnectionBase, wxContextHelp, wxDataViewIconText, wxDataViewRenderer, wxDC, wxDDEClient, wxDocTemplate, wxDragImage, wxEncodingConverter, wxEvent, wxEvtHandler, wxFileHistory, wxFileSystem, wxFileSystemHandler, wxFilterClassFactory, wxFindReplaceData, wxFontData, wxFSFile, wxGDIObject, wxGLContext, wxGraphicsObject, wxGraphicsRenderer, wxGridTableBase, wxHashTable, wxHelpControllerBase, wxHtmlCell, wxHtmlDCRenderer, wxHtmlEasyPrinting, wxHtmlFilter, wxHtmlHelpData, wxHtmlLinkInfo, wxHtmlTagHandler, wxImage, wxImageHandler, wxImageList, wxIndividualLayoutConstraint, wxJoystick, wxLayoutAlgorithm, wxLayoutConstraints, wxListItem, wxMask, wxMenuItem, wxMetafile, wxModule, wxPageSetupDialog, wxPageSetupDialogData, wxPGCell, wxPGEditor, wxPGProperty, wxPrintData, wxPrintDialog, wxPrintDialogData, wxPrinter, wxPrintout, wxPrintPreview, wxQuantize, wxRegionIterator, wxRichTextAction, wxRichTextDrawingContext, wxRichTextDrawingHandler, wxRichTextFieldType, wxRichTextFileHandler, wxRichTextFontTable, wxRichTextFormattingDialogFactory, wxRichTextHeaderFooterData, wxRichTextImageBlock, wxRichTextObject, wxRichTextPrinting, wxRichTextProperties, wxRichTextRenderer, wxRichTextStyleDefinition, wxRichTextStyleSheet, wxSizer, wxSizerItem, wxSockAddress, wxSocketBase, wxSound, wxStringTokenizer, wxSystemOptions, wxSystemSettings, wxTCPClient, wxTCPConnection, wxTCPServer, wxToolBarToolBase, wxToolTip, wxURI, wxVariant, wxWebViewFactory, wxXmlDocument, wxXmlResource, and wxXmlResourceHandler.

21.500.1 Detailed Description

This is the root class of many of the wxWidgets classes.

It declares a virtual destructor which ensures that destructors get called for all derived class objects where necessary.

wxObject is the hub of a dynamic object creation scheme, enabling a program to create instances of a class only knowing its string class name, and to query the class hierarchy.

The class contains optional debugging versions of **new** and **delete**, which can help trace memory allocation and deallocation problems.

wxObject can be used to implement reference counted objects, such as wxPen, wxBitmap and others (see this list). See wxRefCounter and Reference Counting for more info about reference counting.

Library: wxBase

Category: Runtime Type Information (RTTI)

See also

wxClassInfo, Debugging, Reference Counting, wxObjectDataRef, wxObjectDataPtr<T>

Public Member Functions

- wxObject ()

  Default ctor; initializes to NULL the internal reference data.
- wxObject (const wxObject &other)

  Copy ctor.
- virtual ~wxObject ()

  Destructor.
- virtual wxClassInfo * GetClassInfo () const

  This virtual function is redefined for every class that requires run-time type information, when using the wxDECLARE_CLASS macro (or similar).
- wxObjectRefData * GetRefData () const

  Returns the wxObject::m_refData pointer, i.e. the data referenced by this object.
- bool IsKindOf (const wxClassInfo *info) const

  Determines whether this class is a subclass of (or the same class as) the given class.
- bool IsSameAs (const wxObject &obj) const

  Returns true if this object has the same data pointer as obj.
- void Ref (const wxObject &clone)

  Makes this object refer to the data in clone.
- void SetRefData (wxObjectRefData *data)

  Sets the wxObject::m_refData pointer.
- void UnRef ()

  Decrements the reference count in the associated data, and if it is zero, deletes the data.
- void UnShare ()

  This is the same of AllocExclusive() but this method is public.
- void operator delete (void *buf)

  *The delete operator is defined for debugging versions of the library only, when the identifier **WXDEBUG** is defined.*
- void * operator new (size_t size, const wxString &filename=NULL, int lineNum=0)

  *The new operator is defined for debugging versions of the library only, when the identifier **WXDEBUG** is defined.*

Protected Member Functions

- void AllocExclusive ()

  Ensure that this object's data is not shared with any other object.
- virtual wxObjectRefData * CreateRefData () const

  Creates a new instance of the wxObjectRefData-derived class specific to this object and returns it.
- virtual wxObjectRefData * CloneRefData (const wxObjectRefData *data) const

  Creates a new instance of the wxObjectRefData-derived class specific to this object and initializes it copying data.

Protected Attributes

- wxObjectRefData * m_refData

  Pointer to an object which is the object's reference-counted data.

21.500.2 Constructor & Destructor Documentation

wxObject::wxObject ( )

Default ctor; initializes to NULL the internal reference data.

wxObject::wxObject (const wxObject & *other*)

Copy ctor.

Sets the internal wxObject::m_refData pointer to point to the same instance of the wxObjectRefData-derived class pointed by `other` and increments the refcount of wxObject::m_refData.

virtual wxObject::~wxObject ( ) [virtual]

Destructor.

Performs dereferencing, for those objects that use reference counting.

21.500.3 Member Function Documentation

void wxObject::AllocExclusive ( ) [protected]

Ensure that this object's data is not shared with any other object.

If we have no data, it is created using CreateRefData(); if we have shared data (i.e. data with a reference count greater than 1), it is copied using CloneRefData(); otherwise nothing is done (the data is already present and is not shared by other object instances).

If you use this function you should make sure that you override the CreateRefData() and CloneRefData() functions in your class otherwise an assertion will fail at runtime.

virtual wxObjectRefData* wxObject::CloneRefData (const wxObjectRefData * *data*) const [protected], [virtual]

Creates a new instance of the wxObjectRefData-derived class specific to this object and initializes it copying *data*.

This is usually implemented as a one-line call:

```
wxObjectRefData *MyObject::CloneRefData(const wxObjectRefData *data) const
{
    // rely on the MyObjectRefData copy ctor:
    return new MyObjectRefData(*(MyObjectRefData *)data);
}
```

virtual wxObjectRefData* wxObject::CreateRefData ( ) const [protected], [virtual]

Creates a new instance of the wxObjectRefData-derived class specific to this object and returns it.

This is usually implemented as a one-line call:

```
wxObjectRefData *MyObject::CreateRefData() const
{
    return new MyObjectRefData;
}
```

virtual wxClassInfo* wxObject::GetClassInfo ( ) const [virtual]

This virtual function is redefined for every class that requires run-time type information, when using the wxDECLARE_CLASS macro (or similar).

wxObjectRefData* wxObject::GetRefData ( ) const

Returns the wxObject::m_refData pointer, i.e. the data referenced by this object.

See also

Ref(), UnRef(), wxObject::m_refData, SetRefData(), wxObjectRefData

bool wxObject::IsKindOf (const wxClassInfo * *info*) const

Determines whether this class is a subclass of (or the same class as) the given class.

Example:

```
bool tmp = obj->IsKindOf(wxCLASSINFO(wxFrame));
```

Parameters

info	A pointer to a class information object, which may be obtained by using the wxCLASSINFO macro.

Returns

true if the class represented by info is the same class as this one or is derived from it.

bool wxObject::IsSameAs (const wxObject & *obj*) const

Returns true if this object has the same data pointer as *obj*.

Notice that true is returned if the data pointers are NULL in both objects.

This function only does a *shallow* comparison, i.e. it doesn't compare the objects pointed to by the data pointers of these objects.

See also

Reference Counting

void wxObject::operator delete (void * *buf*)

The *delete* operator is defined for debugging versions of the library only, when the identifier **WXDEBUG** is defined.

It takes over memory deallocation, allowing wxDebugContext operations.

void* wxObject::operator new (size_t *size*, const wxString & *filename* = NULL, int *lineNum* = 0)

The *new* operator is defined for debugging versions of the library only, when the identifier **WXDEBUG** is defined.

It takes over memory allocation, allowing wxDebugContext operations.

void wxObject::Ref (const wxObject & *clone*)

Makes this object refer to the data in *clone*.

Parameters

clone	The object to 'clone'.

Remarks

First this function calls UnRef() on itself to decrement (and perhaps free) the data it is currently referring to. It then sets its own wxObject::m_refData to point to that of *clone*, and increments the reference count inside the data.

See also

UnRef(), SetRefData(), GetRefData(), wxObjectRefData

void wxObject::SetRefData (wxObjectRefData * *data*)

Sets the wxObject::m_refData pointer.

See also

Ref(), UnRef(), GetRefData(), wxObjectRefData

void wxObject::UnRef ( )

Decrements the reference count in the associated data, and if it is zero, deletes the data.

The wxObject::m_refData member is set to NULL.

See also

Ref(), SetRefData(), GetRefData(), wxObjectRefData

void wxObject::UnShare ( )

This is the same of AllocExclusive() but this method is public.

21.500.4 Member Data Documentation

wxObjectRefData* wxObject::m_refData [protected]

Pointer to an object which is the object's reference-counted data.

See also

Ref(), UnRef(), SetRefData(), GetRefData(), wxObjectRefData

21.501 wxObjectDataPtr< T > Class Template Reference

`#include <wx/object.h>`

21.501.1 Detailed Description

template<class T>class wxObjectDataPtr< T >

This is an helper template class primarily written to avoid memory leaks because of missing calls to wxRefCounter::DecRef() and wxObjectRefData::DecRef().

Despite the name this template can actually be used as a smart pointer for any class implementing the reference counting interface which only consists of the two methods **T::IncRef()** and **T::DecRef()**.

The difference to wxSharedPtr<T> is that wxObjectDataPtr<T> relies on the reference counting to be in the class pointed to, where instead wxSharedPtr<T> implements the reference counting itself.

Below is an example illustrating how to implement reference counted data using wxRefCounter and wxObjectDataPtr<T> with copy-on-write semantics.

21.501.2 Example

```
class MyCarRefData: public wxRefCounter
{
public:
    MyCarRefData( int price = 0 ) : m_price(price) { }
    MyCarRefData( const MyCarRefData& data ) : m_price(data.m_price) { }

    void SetPrice( int price )  { m_price = price; }
    int GetPrice() const        { return m_price; }

protected:
    int m_price;
};

class MyCar
{
public:
    // initializes this MyCar assigning to the
    // internal data pointer a new instance of MyCarRefData
    MyCar( int price = 0 ) : m_data( new MyCarRefData(price) )
    {
    }

    MyCar& operator =( const MyCar& tocopy )
    {
        // shallow copy: this is just a fast copy of pointers; the real
        // memory-consuming data which typically is stored inside
        // MyCarRefData is not copied here!
        m_data = tocopy.m_data;
        return *this;
    }

    bool operator == ( const MyCar& other ) const
    {
        if (m_data.get() == other.m_data.get())
            return true; // this instance and the 'other' one share the
                         // same MyCarRefData data...
```

```
        return (m_data.GetPrice() == other.m_data.GetPrice());
    }

    void SetPrice( int price )
    {
        // make sure changes to this class do not affect other instances
        // currently sharing our same refcounted data:
        UnShare();

        m_data->SetPrice( price );
    }

    int GetPrice() const
    {
       return m_data->GetPrice();
    }

    wxObjectDataPtr<MyCarRefData> m_data;

protected:
    void UnShare()
    {
        if (m_data->GetRefCount() == 1)
            return;

        m_data.reset( new MyCarRefData( *m_data ) );
    }
};
```

Library: wxBase

Category: Runtime Type Information (RTTI), Smart Pointers

See also

wxObject, wxObjectRefData, Reference Counting, wxSharedPtr<T>, wxScopedPtr<T>, wxWeakRef<T>

Public Member Functions

- wxObjectDataPtr (T *ptr=NULL)

  Constructor.
- wxObjectDataPtr (const wxObjectDataPtr< T > &tocopy)

  This copy constructor increases the count of the reference counted object to which tocopy points and then this class will point to, as well.
- ~wxObjectDataPtr ()

  Decreases the reference count of the object to which this class points.
- T * get () const

  Gets a pointer to the reference counted object to which this class points.
- void reset (T *ptr)

  Reset this class to ptr which points to a reference counted object and calls T::DecRef() on the previously owned object.
- operator unspecified_bool_type () const

  Conversion to a boolean expression (in a variant which is not convertable to anything but a boolean expression).
- T & operator* () const

  Returns a reference to the object.
- T * operator-> () const

  Returns a pointer to the reference counted object to which this class points.

- wxObjectDataPtr< T > & operator= (const wxObjectDataPtr< T > &tocopy)

  Assignment operator.
- wxObjectDataPtr< T > & operator= (T *ptr)

  Assignment operator.

21.501.3 Constructor & Destructor Documentation

template<class T > wxObjectDataPtr< T >::wxObjectDataPtr (T * *ptr* = NULL)

Constructor.

ptr is a pointer to the reference counted object to which this class points. If *ptr* is not NULL **T::IncRef()** will be called on the object.

template<class T > wxObjectDataPtr< T >::wxObjectDataPtr (const wxObjectDataPtr< T > & *tocopy*)

This copy constructor increases the count of the reference counted object to which *tocopy* points and then this class will point to, as well.

template<class T > wxObjectDataPtr< T >::~wxObjectDataPtr ( )

Decreases the reference count of the object to which this class points.

21.501.4 Member Function Documentation

template<class T > T* wxObjectDataPtr< T >::get ( ) const

Gets a pointer to the reference counted object to which this class points.

template<class T > wxObjectDataPtr< T >::operator unspecified_bool_type ( ) const

Conversion to a boolean expression (in a variant which is not convertable to anything but a boolean expression).

If this class contains a valid pointer it will return true, if it contains a NULL pointer it will return false.

template<class T > T& wxObjectDataPtr< T >::operator* ( ) const

Returns a reference to the object.

If the internal pointer is NULL this method will cause an assert in debug mode.

template<class T > T* wxObjectDataPtr< T >::operator-> ( ) const

Returns a pointer to the reference counted object to which this class points.

If this the internal pointer is NULL, this method will assert in debug mode.

template<class T > wxObjectDataPtr<T>& wxObjectDataPtr< T >::operator= (const wxObjectDataPtr< T > & *tocopy*)

Assignment operator.

template<class T > wxObjectDataPtr<T>& wxObjectDataPtr< T >::operator= (T * *ptr*)

Assignment operator.

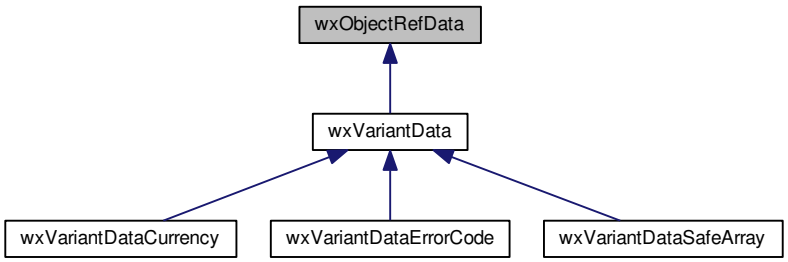
template<class T > void wxObjectDataPtr< T >::reset (T * *ptr*)

Reset this class to ptr which points to a reference counted object and calls T::DecRef() on the previously owned object.

21.502 wxObjectRefData Class Reference

`#include <wx/object.h>`

Inheritance diagram for wxObjectRefData:



21.502.1 Detailed Description

This class is just a typedef to wxRefCounter and is used by wxObject.

Derive classes from this to store your own data in wxObject-derived classes. When retrieving information from a wxObject's reference data, you will need to cast to your own derived class.

Below is an example illustrating how to store reference counted data in a class derived from wxObject including copy-on-write semantics.

21.502.2 Example

```
// include file
// ------------

class MyCar : public wxObject
{
public:
    MyCar() { }
    MyCar( int price );

    bool IsOk() const { return m_refData != NULL; }

    bool operator == ( const MyCar& car ) const;
    bool operator != (const MyCar& car) const { return !(*this == car); }

    void SetPrice( int price );
    int GetPrice() const;

protected:
    virtual wxObjectRefData *CreateRefData() const;
    virtual wxObjectRefData *CloneRefData(const wxObjectRefData *data) const;

    wxDECLARE_DYNAMIC_CLASS(MyCar)
};

// implementation
// --------------
```

```
// the reference data class is typically a private class only visible in the
// implementation source file of the refcounted class.
class MyCarRefData : public wxObjectRefData
{
public:
    MyCarRefData()
    {
        m_price = 0;
    }

    MyCarRefData( const MyCarRefData& data )
        : wxObjectRefData()
    {
        // copy refcounted data; this is usually a time- and memory-consuming operation
        // and is only done when two (or more) MyCar instances need to unshare a
        // common instance of MyCarRefData
        m_price = data.m_price;
    }

    bool operator == (const MyCarRefData& data) const
    {
        return m_price == data.m_price;
    }

private:
    // in real world, reference counting is usually used only when
    // the wxObjectRefData-derived class holds data very memory-consuming;
    // in this example the various MyCar instances may share a MyCarRefData
    // instance which however only takes 4 bytes for this integer!
    int m_price;
};

#define M_CARDATA ((MyCarRefData *)m_refData)
wxIMPLEMENT_DYNAMIC_CLASS(MyCar, wxObject);

MyCar::MyCar( int price )
{
    // here we init the MyCar internal data:
    m_refData = new MyCarRefData();
    M_CARDATA->m_price = price;
}

wxObjectRefData *MyCar::CreateRefData() const
{
    return new MyCarRefData;
}

wxObjectRefData *MyCar::CloneRefData(const wxObjectRefData *data) const
{
    return new MyCarRefData(*(MyCarRefData *)data);
}

bool MyCar::operator == ( const MyCar& car ) const
{
    if (m_refData == car.m_refData)
        return true;
    if (!m_refData || !car.m_refData)
        return false;

    // here we use the MyCarRefData::operator==() function.
    // Note however that this comparison may be very slow if the
    // reference data contains a lot of data to be compared.
    return ( *(MyCarRefData*)m_refData == *(MyCarRefData*)car.m_refData );
}

void MyCar::SetPrice( int price )
{
    // since this function modifies one of the MyCar internal property,
    // we need to be sure that the other MyCar instances which share the
    // same MyCarRefData instance are not affected by this call.
    // I.e. it's very important to call UnShare() in all setters of
    // refcounted classes!
    UnShare();

    M_CARDATA->m_price = price;
}

int MyCar::GetPrice() const
{
    wxCHECK_MSG( IsOk(), -1, "invalid car" );

    return M_CARDATA->m_price;
}
```

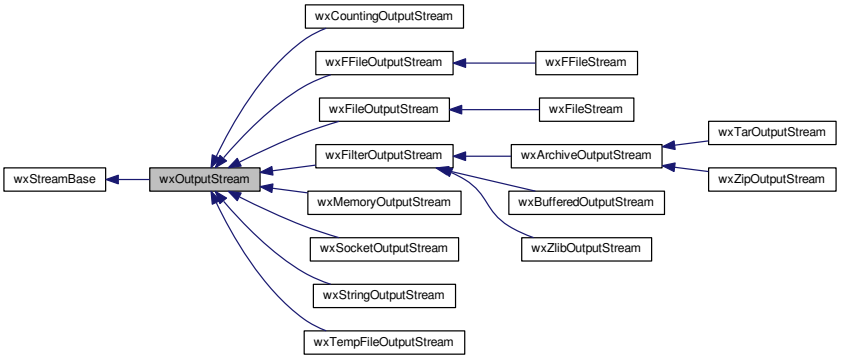
21.503 wxOutputStream Class Reference

`#include <wx/stream.h>`

Inheritance diagram for wxOutputStream:



21.503.1 Detailed Description

wxOutputStream is an abstract base class which may not be used directly.

It is the base class of all streams which provide a Write() function, i.e. which can be used to output data (e.g. to a file, to a socket, etc).

If you want to create your own output stream, you'll need to derive from this class and implement the protected OnSysWrite() function only.

Library: wxBase

Category: Streams

Public Member Functions

- wxOutputStream ()

  Creates a dummy wxOutputStream object.
- virtual ~wxOutputStream ()

  Destructor.
- virtual bool Close ()

  Closes the stream, returning false if an error occurs.

- virtual size_t LastWrite () const

  Returns the number of bytes written during the last Write().
- void PutC (char c)

  Puts the specified character in the output queue and increments the stream position.
- virtual wxFileOffset SeekO (wxFileOffset pos, wxSeekMode mode=wxFromStart)

  Changes the stream current position.
- virtual wxFileOffset TellO () const

  Returns the current stream position.
- virtual wxOutputStream & Write (const void ∗buffer, size_t size)

  Writes up to the specified amount of bytes using the data of buffer.
- wxOutputStream & Write (wxInputStream &stream_in)

  Reads data from the specified input stream and stores them in the current stream.
- bool WriteAll (const void ∗buffer, size_t size)

  Writes exactly the specified number of bytes from the buffer.

Protected Member Functions

- size_t OnSysWrite (const void ∗buffer, size_t bufsize)

  Internal function.

21.503.2 Constructor & Destructor Documentation

wxOutputStream::wxOutputStream ( )

Creates a dummy wxOutputStream object.

virtual wxOutputStream::∼wxOutputStream ( ) [virtual]

Destructor.

21.503.3 Member Function Documentation

virtual bool wxOutputStream::Close ( ) [virtual]

Closes the stream, returning false if an error occurs.

The stream is closed implicitly in the destructor if Close() is not called explicitly.

If this stream wraps another stream or some other resource such as a file, then the underlying resource is closed too if it is owned by this stream, or left open otherwise.

Reimplemented in wxZipOutputStream, wxTarOutputStream, and wxArchiveOutputStream.

virtual size_t wxOutputStream::LastWrite ( ) const [virtual]

Returns the number of bytes written during the last Write().

It may return 0 even if there is no error on the stream if it is only temporarily impossible to write to it.

size_t wxOutputStream::OnSysWrite (const void * *buffer*, size_t *bufsize*) `[protected]`

Internal function.

It is called when the stream wants to write data of the specified size *bufsize* into the given *buffer*.

It should return the size that was actually wrote (which maybe zero if *bufsize* is zero or if an error occurred; in this last case the internal variable `m_lasterror` should be appropriately set).

void wxOutputStream::PutC (char *c*)

Puts the specified character in the output queue and increments the stream position.

virtual wxFileOffset wxOutputStream::SeekO (wxFileOffset *pos*, wxSeekMode *mode* = wxFromStart) `[virtual]`

Changes the stream current position.

Parameters

pos	Offset to seek to.
mode	One of wxFromStart, wxFromEnd, wxFromCurrent.

Returns

The new stream position or wxInvalidOffset on error.

Reimplemented in wxBufferedOutputStream.

virtual wxFileOffset wxOutputStream::TellO ( ) const `[virtual]`

Returns the current stream position.

virtual wxOutputStream& wxOutputStream::Write (const void * *buffer*, size_t *size*) `[virtual]`

Writes up to the specified amount of bytes using the data of buffer.

Note that not all data can always be written so you must check the number of bytes really written to the stream using LastWrite() when this function returns.

In some cases (for example a write end of a pipe which is currently full) it is even possible that there is no errors and zero bytes have been written. This function returns a reference on the current object, so the user can test any states of the stream right away.

wxOutputStream& wxOutputStream::Write (wxInputStream & *stream_in*)

Reads data from the specified input stream and stores them in the current stream.

The data is read until an error is raised by one of the two streams.

bool wxOutputStream::WriteAll (const void * *buffer*, size_t *size*)

Writes exactly the specified number of bytes from the buffer.

Returns true if exactly *size* bytes were written. Otherwise, returns false and LastWrite() should be used to retrieve the exact amount of the data written if necessary.

This method uses repeated calls to Write() (which may return writing only part of the data) if necessary.

Since

2.9.5

21.504 wxOverlay Class Reference

`#include <wx/overlay.h>`

21.504.1 Detailed Description

Creates an overlay over an existing window, allowing for manipulations like rubberbanding, etc.

On wxOSX the overlay is implemented with native platform APIs, on the other platforms it is simulated using wxMemoryDC.

Library: wxCore

See also

wxDCOverlay, wxDC

Public Member Functions

- wxOverlay ()
- ~wxOverlay ()
- void Reset ()

  Clears the overlay without restoring the former state.

21.504.2 Constructor & Destructor Documentation

wxOverlay::wxOverlay ( )

wxOverlay::~wxOverlay ( )

21.504.3 Member Function Documentation

void wxOverlay::Reset ( )

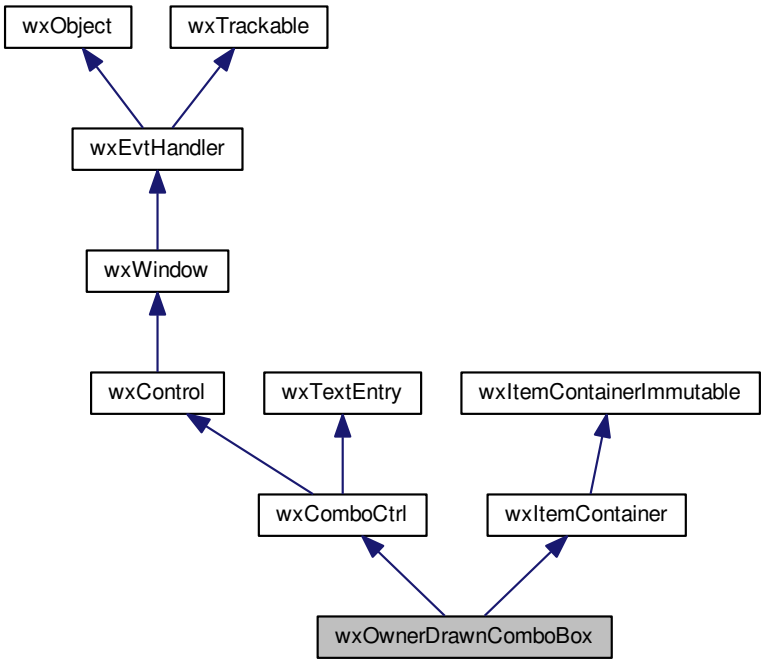
Clears the overlay without restoring the former state.

To be done, for example, when the window content has been changed and repainted.

21.505 wxOwnerDrawnComboBox Class Reference

`#include <wx/odcombo.h>`

Inheritance diagram for wxOwnerDrawnComboBox:



21.505.1 Detailed Description

wxOwnerDrawnComboBox is a combobox with owner-drawn list items.

In essence, it is a wxComboCtrl with wxVListBox popup and wxControlWithItems interface.

Implementing item drawing and measuring is similar to wxVListBox. Application needs to subclass wxOwnerDrawnComboBox and implement OnDrawItem(), OnMeasureItem() and OnMeasureItemWidth().

Styles

This class supports the following styles:

- wxODCB_DCLICK_CYCLES: Double-clicking cycles item if wxCB_READONLY is also used. Synonymous with wxCC_SPECIAL_DCLICK.
- wxODCB_STD_CONTROL_PAINT: Control itself is not custom painted using OnDrawItem. Even if this style is not used, writable wxOwnerDrawnComboBox is never custom painted unless SetCustomPaintWidth() is called.

See also

wxComboCtrl window styles and Window Styles.

Events emitted by this class

The following event handler macros redirect the events to member function handlers '**func**' with prototypes like: void handlerFuncName(wxCommandEvent& event)

Event macros for events emitted by this class:

- EVT_COMBOBOX(id, func): Process a wxEVT_COMBOBOX event, when an item on the list is selected. Note that calling GetValue() returns the new value of selection.

See also

Events emitted by wxComboCtrl.

Library: wxAdvanced

Category: Controls

wxComboCtrl, wxComboBox, wxVListBox, wxCommandEvent

Public Member Functions

- wxOwnerDrawnComboBox ()

  Default constructor.
- wxOwnerDrawnComboBox (wxWindow *parent, wxWindowID id, const wxString &value=wxEmptyString, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, int n=0, const wxString choices[]=NULL, long style=0, const wxValidator &validator=wxDefaultValidator, const wxString &name="comboBox")

  Constructor, creating and showing a owner-drawn combobox.
- wxOwnerDrawnComboBox (wxWindow *parent, wxWindowID id, const wxString &value, const wxPoint &pos, const wxSize &size, const wxArrayString &choices, long style=0, const wxValidator &validator=wxDefaultValidator, const wxString &name="comboBox")

  Constructor, creating and showing a owner-drawn combobox.
- virtual ~wxOwnerDrawnComboBox ()

  Destructor, destroying the owner-drawn combobox.
- bool IsEmpty () const

  IsEmpty() is not available in this class.
- bool IsListEmpty () const

  Returns true if the list of combobox choices is empty.
- bool IsTextEmpty () const

  Returns true if the text of the combobox is empty.
- virtual int GetWidestItem ()

  Returns index to the widest item in the list.
- virtual int GetWidestItemWidth ()

  Returns width of the widest item in the list.

- bool Create (wxWindow *parent, wxWindowID id, const wxString &value=wxEmptyString, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, long style=0, const wxValidator &validator=wxDefaultValidator, const wxString &name=wxComboBoxNameStr)

  Creates the combobox for two-step construction.
- bool Create (wxWindow *parent, wxWindowID id, const wxString &value, const wxPoint &pos, const wxSize &size, int n, const wxString choices[], long style=0, const wxValidator &validator=wxDefaultValidator, const wxString &name=wxComboBoxNameStr)

  Creates the combobox for two-step construction.
- bool Create (wxWindow *parent, wxWindowID id, const wxString &value, const wxPoint &pos, const wxSize &size, const wxArrayString &choices, long style=0, const wxValidator &validator=wxDefaultValidator, const wxString &name=wxComboBoxNameStr)

  Creates the combobox for two-step construction.

Protected Member Functions

- virtual void OnDrawBackground (wxDC &dc, const wxRect &rect, int item, int flags) const

  This method is used to draw the items background and, maybe, a border around it.
- virtual void OnDrawItem (wxDC &dc, const wxRect &rect, int item, int flags) const

  The derived class may implement this function to actually draw the item with the given index on the provided DC.
- virtual wxCoord OnMeasureItem (size_t item) const

  The derived class may implement this method to return the height of the specified item (in pixels).
- virtual wxCoord OnMeasureItemWidth (size_t item) const

  The derived class may implement this method to return the width of the specified item (in pixels).

Additional Inherited Members

21.505.2 Constructor & Destructor Documentation

wxOwnerDrawnComboBox::wxOwnerDrawnComboBox ( )

Default constructor.

wxOwnerDrawnComboBox::wxOwnerDrawnComboBox (wxWindow * *parent*, wxWindowID *id*, const wxString & *value* = wxEmptyString, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, int *n* = 0, const wxString *choices[]* = NULL, long *style* = 0, const wxValidator & *validator* = wxDefaultValidator, const wxString & *name* = "comboBox")

Constructor, creating and showing a owner-drawn combobox.

Parameters

parent	Parent window. Must not be NULL.
id	Window identifier. The value wxID_ANY indicates a default value.
value	Initial selection string. An empty string indicates no selection.
pos	Window position.
size	Window size. If wxDefaultSize is specified then the window is sized appropriately.
n	Number of strings with which to initialise the control.
choices	An array of strings with which to initialise the control.
style	Window style. See wxOwnerDrawnComboBox.
validator	Window validator.
name	Window name.

See also

Create(), wxValidator

wxOwnerDrawnComboBox::wxOwnerDrawnComboBox (wxWindow * *parent*, wxWindowID *id*, const wxString & *value*, const wxPoint & *pos*, const wxSize & *size*, const wxArrayString & *choices*, long *style* = 0, const wxValidator & *validator* = wxDefaultValidator, const wxString & *name* = "comboBox")

Constructor, creating and showing a owner-drawn combobox.

Parameters

parent	Parent window. Must not be NULL.
id	Window identifier. The value `wxID_ANY` indicates a default value.
value	Initial selection string. An empty string indicates no selection.
pos	Window position.
size	Window size. If wxDefaultSize is specified then the window is sized appropriately.
choices	An array of strings with which to initialise the control.
style	Window style. See wxOwnerDrawnComboBox.
validator	Window validator.
name	Window name.

See also

Create(), wxValidator

virtual wxOwnerDrawnComboBox::~wxOwnerDrawnComboBox ( ) [virtual]

Destructor, destroying the owner-drawn combobox.

21.505.3 Member Function Documentation

bool wxOwnerDrawnComboBox::Create (wxWindow * *parent*, wxWindowID *id*, const wxString & *value* = wxEmptyString, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, long *style* = 0, const wxValidator & *validator* = wxDefaultValidator, const wxString & *name* = wxComboBoxNameStr)

Creates the combobox for two-step construction.

See wxOwnerDrawnComboBox() for further details.

Remarks

Derived classes should call or replace this function.

bool wxOwnerDrawnComboBox::Create (wxWindow * *parent*, wxWindowID *id*, const wxString & *value*, const wxPoint & *pos*, const wxSize & *size*, int *n*, const wxString *choices[]*, long *style* = 0, const wxValidator & *validator* = wxDefaultValidator, const wxString & *name* = wxComboBoxNameStr)

Creates the combobox for two-step construction.

See wxOwnerDrawnComboBox() for further details.

Remarks

Derived classes should call or replace this function.

bool wxOwnerDrawnComboBox::Create (wxWindow * *parent*, wxWindowID *id*, const wxString & *value*, const wxPoint & *pos*, const wxSize & *size*, const wxArrayString & *choices*, long *style* = 0, const wxValidator & *validator* = wxDefaultValidator, const wxString & *name* = wxComboBoxNameStr)

Creates the combobox for two-step construction.

See wxOwnerDrawnComboBox() for further details.

Remarks

Derived classes should call or replace this function.

virtual int wxOwnerDrawnComboBox::GetWidestItem ( ) [virtual]

Returns index to the widest item in the list.

virtual int wxOwnerDrawnComboBox::GetWidestItemWidth ( ) [virtual]

Returns width of the widest item in the list.

bool wxOwnerDrawnComboBox::IsEmpty ( ) const [virtual]

IsEmpty() is not available in this class.

This method is documented here only to notice that it can't be used with this class because of the ambiguity between the methods with the same name inherited from wxItemContainer and wxTextEntry base classes.

Because of this, any attempt to call it results in a compilation error and you should use either IsListEmpty() or IsTextEmpty() depending on what exactly do you want to test.

Reimplemented from wxTextEntry.

bool wxOwnerDrawnComboBox::IsListEmpty ( ) const

Returns true if the list of combobox choices is empty.

Use this method instead of (not available in this class) IsEmpty() to test if the list of items is empty.

Since

3.1.0

bool wxOwnerDrawnComboBox::IsTextEmpty ( ) const

Returns true if the text of the combobox is empty.

Use this method instead of (not available in this class) IsEmpty() to test if the text currently entered into the combobox is empty.

Since

3.1.0

virtual void wxOwnerDrawnComboBox::OnDrawBackground (wxDC & *dc,* const wxRect & *rect,* int *item,* int *flags*) const [protected], [virtual]

This method is used to draw the items background and, maybe, a border around it.

The base class version implements a reasonable default behaviour which consists in drawing the selected item with the standard background colour and drawing a border around the item if it is either selected or current.

Remarks

flags has the same meaning as with OnDrawItem().

virtual void wxOwnerDrawnComboBox::OnDrawItem (wxDC & *dc,* const wxRect & *rect,* int *item,* int *flags*) const `[protected], [virtual]`

The derived class may implement this function to actually draw the item with the given index on the provided DC.

If function is not implemented, the item text is simply drawn, as if the control was a normal combobox.

Parameters

dc	The device context to use for drawing
rect	The bounding rectangle for the item being drawn (DC clipping region is set to this rectangle before calling this function)
item	The index of the item to be drawn
flags	A combination of the wxOwnerDrawnComboBoxPaintingFlags enumeration values.

virtual wxCoord wxOwnerDrawnComboBox::OnMeasureItem (size_t *item*) const `[protected], [virtual]`

The derived class may implement this method to return the height of the specified item (in pixels).

The default implementation returns text height, as if this control was a normal combobox.

virtual wxCoord wxOwnerDrawnComboBox::OnMeasureItemWidth (size_t *item*) const `[protected], [virtual]`

The derived class may implement this method to return the width of the specified item (in pixels).

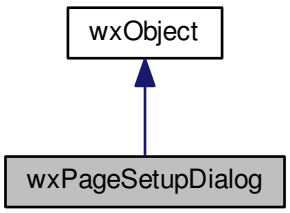
If -1 is returned, then the item text width is used.

The default implementation returns -1.

21.506 wxPageSetupDialog Class Reference

`#include <wx/printdlg.h>`

Inheritance diagram for wxPageSetupDialog:



21.506.1 Detailed Description

This class represents the page setup common dialog.

The page setup dialog contains controls for paper size (letter, A4, A5 etc.), orientation (landscape or portrait), and, only under Windows currently, controls for setting left, top, right and bottom margin sizes in millimetres.

The exact appearance of this dialog varies among the platforms as a native dialog is used when available (currently the case for all major platforms).

When the dialog has been closed, you need to query the wxPageSetupDialogData object associated with the dialog.

Note that the OK and Cancel buttons do not destroy the dialog; this must be done by the application.

Library: wxCore

Category: Printing Framework

See also

Printing Framework Overview, wxPrintDialog, wxPageSetupDialogData

Public Member Functions

- wxPageSetupDialog (wxWindow *parent, wxPageSetupDialogData *data=NULL)

  Constructor.
- virtual ~wxPageSetupDialog ()

  Destructor.
- wxPageSetupDialogData & GetPageSetupData ()

  Returns the wxPageSetupDialogData object associated with the dialog.
- int ShowModal ()

  Shows the dialog, returning `wxID_OK` if the user pressed OK, and `wxID_CANCEL` otherwise.

Additional Inherited Members

21.506.2 Constructor & Destructor Documentation

wxPageSetupDialog::wxPageSetupDialog (wxWindow * *parent*, wxPageSetupDialogData * *data* = `NULL`)

Constructor.

Pass a parent window, and optionally a pointer to a block of page setup data, which will be copied to the print dialog's internal data.

virtual wxPageSetupDialog::~wxPageSetupDialog ( ) `[virtual]`

Destructor.

21.506.3 Member Function Documentation

wxPageSetupDialogData& wxPageSetupDialog::GetPageSetupData ( )

Returns the wxPageSetupDialogData object associated with the dialog.

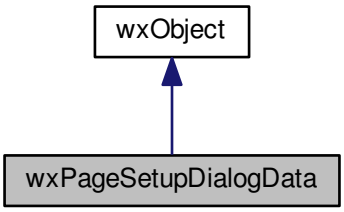
int wxPageSetupDialog::ShowModal ( )

Shows the dialog, returning `wxID_OK` if the user pressed OK, and `wxID_CANCEL` otherwise.

21.507 wxPageSetupDialogData Class Reference

```
#include <wx/cmndata.h>
```

Inheritance diagram for wxPageSetupDialogData:



21.507.1 Detailed Description

This class holds a variety of information related to wxPageSetupDialog.

It contains a wxPrintData member which is used to hold basic printer configuration data (as opposed to the user-interface configuration settings stored by wxPageSetupDialogData).

Library: wxCore

Category: Printing Framework, Data Structures

See also

Printing Framework Overview, wxPageSetupDialog

Public Member Functions

- wxPageSetupDialogData ()

  Default constructor.
- wxPageSetupDialogData (const wxPageSetupDialogData &data)

  Copy constructor.
- wxPageSetupDialogData (const wxPrintData &printData)

  Construct an object from a print data object.
- virtual ~wxPageSetupDialogData ()

  Destructor.
- void EnableHelp (bool flag)

  Enables or disables the "Help" button (Windows only).
- void EnableMargins (bool flag)

  Enables or disables the margin controls (Windows only).
- void EnableOrientation (bool flag)

  Enables or disables the orientation control (Windows only).
- void EnablePaper (bool flag)

  Enables or disables the paper size control (Windows only).
- void EnablePrinter (bool flag)

  Enables or disables the "Printer" button, which invokes a printer setup dialog.

- bool GetDefaultInfo () const

  Returns true if the dialog will simply return default printer information (such as orientation) instead of showing a dialog (Windows only).
- bool GetDefaultMinMargins () const

  Returns true if the page setup dialog will take its minimum margin values from the currently selected printer properties (Windows only).
- bool GetEnableHelp () const

  Returns true if the printer setup button is enabled.
- bool GetEnableMargins () const

  Returns true if the margin controls are enabled (Windows only).
- bool GetEnableOrientation () const

  Returns true if the orientation control is enabled (Windows only).
- bool GetEnablePaper () const

  Returns true if the paper size control is enabled (Windows only).
- bool GetEnablePrinter () const

  Returns true if the printer setup button is enabled.
- wxPoint GetMarginBottomRight () const

  Returns the right (x) and bottom (y) margins in millimetres.
- wxPoint GetMarginTopLeft () const

  Returns the left (x) and top (y) margins in millimetres.
- wxPoint GetMinMarginBottomRight () const

  Returns the right (x) and bottom (y) minimum margins the user can enter (Windows only).
- wxPoint GetMinMarginTopLeft () const

  Returns the left (x) and top (y) minimum margins the user can enter (Windows only).
- wxPaperSize GetPaperId () const

  Returns the paper id (stored in the internal wxPrintData object).
- wxSize GetPaperSize () const

  Returns the paper size in millimetres.
- wxPrintData & GetPrintData ()

  Returns a reference to the print data associated with this object.
- const wxPrintData & GetPrintData () const
- bool IsOk () const

  Returns true if the print data associated with the dialog data is valid.
- void SetDefaultInfo (bool flag)

  Pass true if the dialog will simply return default printer information (such as orientation) instead of showing a dialog (Windows only).
- void SetDefaultMinMargins (bool flag)

  Pass true if the page setup dialog will take its minimum margin values from the currently selected printer properties (Windows only).
- void SetMarginBottomRight (const wxPoint &pt)

  Sets the right (x) and bottom (y) margins in millimetres.
- void SetMarginTopLeft (const wxPoint &pt)

  Sets the left (x) and top (y) margins in millimetres.
- void SetMinMarginBottomRight (const wxPoint &pt)

  Sets the right (x) and bottom (y) minimum margins the user can enter (Windows only).
- void SetMinMarginTopLeft (const wxPoint &pt)

  Sets the left (x) and top (y) minimum margins the user can enter (Windows only).
- void SetPaperId (wxPaperSize id)

  Sets the paper size id.
- void SetPaperSize (const wxSize &size)

  Sets the paper size in millimetres.

- void SetPrintData (const wxPrintData &printData)

  Sets the print data associated with this object.
- wxPageSetupDialogData & operator= (const wxPrintData &data)

  Assigns print data to this object.
- wxPageSetupDialogData & operator= (const wxPageSetupDialogData &data)

  Assigns page setup data to this object.

Additional Inherited Members

21.507.2 Constructor & Destructor Documentation

wxPageSetupDialogData::wxPageSetupDialogData ( )

Default constructor.

wxPageSetupDialogData::wxPageSetupDialogData (const wxPageSetupDialogData & *data*)

Copy constructor.

wxPageSetupDialogData::wxPageSetupDialogData (const wxPrintData & *printData*)

Construct an object from a print data object.

virtual wxPageSetupDialogData::~wxPageSetupDialogData ( ) [virtual]

Destructor.

21.507.3 Member Function Documentation

void wxPageSetupDialogData::EnableHelp (bool *flag*)

Enables or disables the "Help" button (Windows only).

void wxPageSetupDialogData::EnableMargins (bool *flag*)

Enables or disables the margin controls (Windows only).

void wxPageSetupDialogData::EnableOrientation (bool *flag*)

Enables or disables the orientation control (Windows only).

void wxPageSetupDialogData::EnablePaper (bool *flag*)

Enables or disables the paper size control (Windows only).

void wxPageSetupDialogData::EnablePrinter (bool *flag*)

Enables or disables the "Printer" button, which invokes a printer setup dialog.

bool wxPageSetupDialogData::GetDefaultInfo ( ) const

Returns true if the dialog will simply return default printer information (such as orientation) instead of showing a dialog (Windows only).

bool wxPageSetupDialogData::GetDefaultMinMargins ( ) const

Returns true if the page setup dialog will take its minimum margin values from the currently selected printer properties (Windows only).

bool wxPageSetupDialogData::GetEnableHelp ( ) const

Returns true if the printer setup button is enabled.

bool wxPageSetupDialogData::GetEnableMargins ( ) const

Returns true if the margin controls are enabled (Windows only).

bool wxPageSetupDialogData::GetEnableOrientation ( ) const

Returns true if the orientation control is enabled (Windows only).

bool wxPageSetupDialogData::GetEnablePaper ( ) const

Returns true if the paper size control is enabled (Windows only).

bool wxPageSetupDialogData::GetEnablePrinter ( ) const

Returns true if the printer setup button is enabled.

wxPoint wxPageSetupDialogData::GetMarginBottomRight ( ) const

Returns the right (x) and bottom (y) margins in millimetres.

wxPoint wxPageSetupDialogData::GetMarginTopLeft ( ) const

Returns the left (x) and top (y) margins in millimetres.

wxPoint wxPageSetupDialogData::GetMinMarginBottomRight ( ) const

Returns the right (x) and bottom (y) minimum margins the user can enter (Windows only).

Units are in millimetres.

wxPoint wxPageSetupDialogData::GetMinMarginTopLeft ( ) const

Returns the left (x) and top (y) minimum margins the user can enter (Windows only).

Units are in millimetres.

wxPaperSize wxPageSetupDialogData::GetPaperId ( ) const

Returns the paper id (stored in the internal wxPrintData object).

See also

wxPrintData::SetPaperId()

wxSize wxPageSetupDialogData::GetPaperSize ( ) const

Returns the paper size in millimetres.

wxPrintData& wxPageSetupDialogData::GetPrintData ( )

Returns a reference to the print data associated with this object.

const wxPrintData& wxPageSetupDialogData::GetPrintData ( ) const

bool wxPageSetupDialogData::IsOk ( ) const

Returns true if the print data associated with the dialog data is valid.

This can return false on Windows if the current printer is not set, for example. On all other platforms, it returns true.

wxPageSetupDialogData& wxPageSetupDialogData::operator= (const wxPrintData & *data*)

Assigns print data to this object.

wxPageSetupDialogData& wxPageSetupDialogData::operator= (const wxPageSetupDialogData & *data*)

Assigns page setup data to this object.

void wxPageSetupDialogData::SetDefaultInfo (bool *flag*)

Pass true if the dialog will simply return default printer information (such as orientation) instead of showing a dialog (Windows only).

void wxPageSetupDialogData::SetDefaultMinMargins (bool *flag*)

Pass true if the page setup dialog will take its minimum margin values from the currently selected printer properties (Windows only).

Units are in millimetres.

void wxPageSetupDialogData::SetMarginBottomRight (const wxPoint & *pt*)

Sets the right (x) and bottom (y) margins in millimetres.

void wxPageSetupDialogData::SetMarginTopLeft (const wxPoint & *pt*)

Sets the left (x) and top (y) margins in millimetres.

void wxPageSetupDialogData::SetMinMarginBottomRight (const wxPoint & *pt*)

Sets the right (x) and bottom (y) minimum margins the user can enter (Windows only).

Units are in millimetres.

void wxPageSetupDialogData::SetMinMarginTopLeft (const wxPoint & *pt*)

Sets the left (x) and top (y) minimum margins the user can enter (Windows only).

Units are in millimetres.

void wxPageSetupDialogData::SetPaperId (wxPaperSize *id*)

Sets the paper size id.

Calling this function overrides the explicit paper dimensions passed in SetPaperSize().

See also

wxPrintData::SetPaperId()

void wxPageSetupDialogData::SetPaperSize (const wxSize & *size*)

Sets the paper size in millimetres.

If a corresponding paper id is found, it will be set in the internal wxPrintData object, otherwise the paper size overrides the paper id.

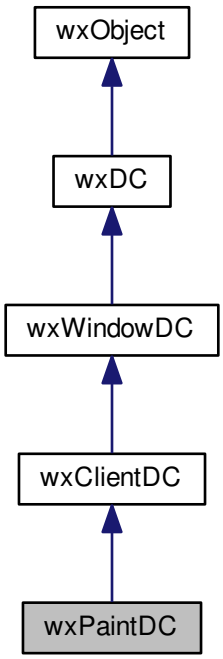
void wxPageSetupDialogData::SetPrintData (const wxPrintData & *printData*)

Sets the print data associated with this object.

21.508 wxPaintDC Class Reference

```
#include <wx/dcclient.h>
```

Inheritance diagram for wxPaintDC:



21.508.1 Detailed Description

A wxPaintDC must be constructed if an application wishes to paint on the client area of a window from within an EVT_PAINT() event handler.

This should normally be constructed as a temporary stack object; don't store a wxPaintDC object. If you have an EVT_PAINT() handler, you *must* create a wxPaintDC object within it even if you don't actually use it.

Using wxPaintDC within your EVT_PAINT() handler is important because it automatically sets the clipping area to the damaged area of the window. Attempts to draw outside this area do not appear.

To draw on a window from outside your EVT_PAINT() handler, construct a wxClientDC object.

To draw on the whole window including decorations, construct a wxWindowDC object (Windows only).

A wxPaintDC object is initialized to use the same font and colours as the window it is associated with.

Library: wxCore

21.508.2 Constructor & Destructor Documentation

wxPaintDC::wxPaintDC (wxWindow * *window*)

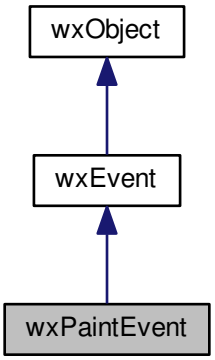
Constructor.

Pass a pointer to the window on which you wish to paint.

21.509 wxPaintEvent Class Reference

`#include <wx/event.h>`

Inheritance diagram for wxPaintEvent:



21.509.1 Detailed Description

A paint event is sent when a window's contents needs to be repainted.

The handler of this event must create a wxPaintDC object and use it for painting the window contents. For example:

```
void MyWindow::OnPaint(wxPaintEvent& event)
{
    wxPaintDC dc(this);

    DrawMyDocument(dc);
}
```

Notice that you must *not* create other kinds of wxDC (e.g. wxClientDC or wxWindowDC) in EVT_PAINT handlers and also don't create wxPaintDC outside of this event handlers.

You can optimize painting by retrieving the rectangles that have been damaged and only repainting these. The rectangles are in terms of the client area, and are unscrolled, so you will need to do some calculations using the current view position to obtain logical, scrolled units. Here is an example of using the wxRegionIterator class:

```
// Called when window needs to be repainted.
void MyWindow::OnPaint(wxPaintEvent& event)
{
    wxPaintDC dc(this);

    // Find Out where the window is scrolled to
    int vbX,vbY;                    // Top left corner of client
    GetViewStart(&vbX,&vbY);

    int vX,vY,vW,vH;                // Dimensions of client area in pixels
    wxRegionIterator upd(GetUpdateRegion()); // get the update rect list

    while (upd)
    {
        vX = upd.GetX();
        vY = upd.GetY();
        vW = upd.GetW();
        vH = upd.GetH();

        // Alternatively we can do this:
        // wxRect rect(upd.GetRect());

        // Repaint this rectangle
        ...some code...

        upd ++ ;
    }
}
```

Remarks

Please notice that in general it is impossible to change the drawing of a standard control (such as wxButton) and so you shouldn't attempt to handle paint events for them as even if it might work on some platforms, this is inherently not portable and won't work everywhere.

Events using this class

The following event handler macros redirect the events to member function handlers '**func**' with prototypes like: void handlerFuncName(wxPaintEvent& event)

Event macros:

- EVT_PAINT(func): Process a `wxEVT_PAINT` event.

Library: wxCore

Category: Events

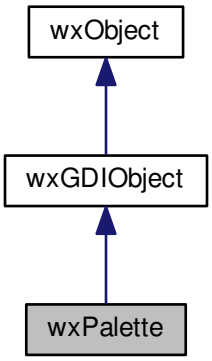
wxPaintEvent::wxPaintEvent (int *id* = 0)

Constructor.

21.510 wxPalette Class Reference

```
#include <wx/palette.h>
```

Inheritance diagram for wxPalette:



21.510.1 Detailed Description

A palette is a table that maps pixel values to RGB colours.

It allows the colours of a low-depth bitmap, for example, to be mapped to the available colours in a display. The notion of palettes is becoming more and more obsolete nowadays and only the MSW port is still using a native palette. All other ports use generic code which is basically just an array of colours.

It is likely that in the future the only use for palettes within wxWidgets will be for representing colour indices from images (such as GIF or PNG). The image handlers for these formats have been modified to create a palette if there is such information in the original image file (usually 256 or less colour images). See wxImage for more information.

Library: wxCore

Category: Graphics Device Interface (GDI)

Predefined objects/pointers: wxNullPalette

See also

wxDC::SetPalette(), wxBitmap

Public Member Functions

- wxPalette ()

  Default constructor.
- wxPalette (const wxPalette &palette)

  Copy constructor, uses Reference Counting.
- wxPalette (int n, const unsigned char *red, const unsigned char *green, const unsigned char *blue)

  Creates a palette from arrays of size n, one for each red, blue or green component.
- virtual ~wxPalette ()

  Destructor.
- bool Create (int n, const unsigned char *red, const unsigned char *green, const unsigned char *blue)

  Creates a palette from arrays of size n, one for each red, blue or green component.
- virtual int GetColoursCount () const

  Returns number of entries in palette.
- int GetPixel (unsigned char red, unsigned char green, unsigned char blue) const

  Returns a pixel value (index into the palette) for the given RGB values.
- bool GetRGB (int pixel, unsigned char *red, unsigned char *green, unsigned char *blue) const

  Returns RGB values for a given palette index.
- virtual bool IsOk () const

  Returns true if palette data is present.
- wxPalette & operator= (const wxPalette &palette)

  Assignment operator, using Reference Counting.

Additional Inherited Members

21.510.2 Constructor & Destructor Documentation

wxPalette::wxPalette ( )

Default constructor.

wxPalette::wxPalette (const wxPalette & *palette*)

Copy constructor, uses Reference Counting.

Parameters

palette	A reference to the palette to copy.

wxPalette::wxPalette (int *n*, const unsigned char * *red*, const unsigned char * *green*, const unsigned char * *blue*)

Creates a palette from arrays of size *n*, one for each red, blue or green component.

Parameters

n	The number of indices in the palette.
red	An array of red values.
green	An array of green values.
blue	An array of blue values.

wxPerl Note: In wxPerl this method takes as parameters 3 array references (they must be of the same length).

See also

Create()

virtual wxPalette::~wxPalette ( ) [virtual]

Destructor.

See also

reference-counted object destruction

21.510.3 Member Function Documentation

bool wxPalette::Create (int *n*, const unsigned char * *red*, const unsigned char * *green*, const unsigned char * *blue*)

Creates a palette from arrays of size *n*, one for each red, blue or green component.

Parameters

n	The number of indices in the palette.
red	An array of red values.
green	An array of green values.
blue	An array of blue values.

Returns

true if the creation was successful, false otherwise.

See also

wxPalette()

virtual int wxPalette::GetColoursCount ( ) const [virtual]

Returns number of entries in palette.

int wxPalette::GetPixel (unsigned char *red*, unsigned char *green*, unsigned char *blue*) const

Returns a pixel value (index into the palette) for the given RGB values.

Parameters

red	Red value.
green	Green value.
blue	Blue value.

Returns

The nearest palette index or `wxNOT_FOUND` for unexpected errors.

See also

GetRGB()

bool wxPalette::GetRGB (int *pixel*, unsigned char * *red*, unsigned char * *green*, unsigned char * *blue*) const

Returns RGB values for a given palette index.

Parameters

pixel	The palette index.
red	Receives the red value.
green	Receives the green value.
blue	Receives the blue value.

Returns

true if the operation was successful.

wxPerl Note: In wxPerl this method takes only the *pixel* parameter and returns a 3-element list (or the empty list upon failure).

See also

GetPixel()

virtual bool wxPalette::IsOk ( ) const `[virtual]`

Returns true if palette data is present.

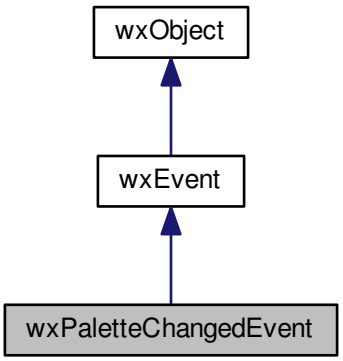
wxPalette& wxPalette::operator= (const wxPalette & *palette*)

Assignment operator, using Reference Counting.

21.511 wxPaletteChangedEvent Class Reference

`#include <wx/event.h>`

Inheritance diagram for wxPaletteChangedEvent:



Public Member Functions

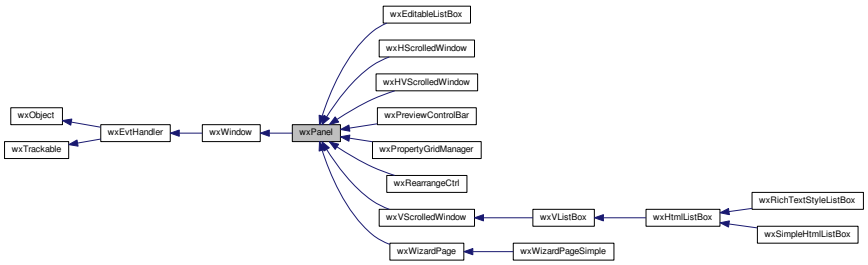
wxWindow* wxPaletteChangedEvent::GetChangedWindow ( ) const

void wxPaletteChangedEvent::SetChangedWindow (wxWindow * *win*)

21.512 wxPanel Class Reference

`#include <wx/panel.h>`

Inheritance diagram for wxPanel:



21.512.1 Detailed Description

A panel is a window on which controls are placed.

It is usually placed within a frame. Its main feature over its parent class wxWindow is code for handling child windows and TAB traversal, which is implemented natively if possible (e.g. in wxGTK) or by wxWidgets itself otherwise.

Note

Tab traversal is implemented through an otherwise undocumented intermediate wxControlContainer class from which any class can derive in addition to the normal wxWindow base class. Please see `wx/containr.h` and `wx/panel.h` to find out how this is achieved.
if not all characters are being intercepted by your OnKeyDown or OnChar handler, it may be because you are using the `wxTAB_TRAVERSAL` style, which grabs some keypresses for use by child controls.

Remarks

By default, a panel has the same colouring as a dialog.

Events emitted by this class

The following event handler macros redirect the events to member function handlers '**func**' with prototypes like: void handlerFuncName(wxNavigationKeyEvent& event)

Event macros for events emitted by this class:

- EVT_NAVIGATION_KEY(func): Process a navigation key event.

Library: wxCore

Category: Miscellaneous Windows

See also

wxDialog

Public Member Functions

- wxPanel ()

  Default constructor.
- wxPanel (wxWindow *parent, wxWindowID id=wxID_ANY, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, long style=wxTAB_TRAVERSAL, const wxString &name=wxPanelNameStr)

  Constructor.
- virtual ~wxPanel ()

  Destructor.
- bool AcceptsFocus () const

  This method is overridden from wxWindow::AcceptsFocus() and returns true only if there is no child window in the panel which can accept the focus.
- bool Create (wxWindow *parent, wxWindowID id=wxID_ANY, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, long style=wxTAB_TRAVERSAL, const wxString &name=wxPanelNameStr)

  Used for two-step panel construction.
- virtual void InitDialog ()

  Sends a wxInitDialogEvent, which in turn transfers data to the dialog via validators.
- virtual bool Layout ()

  See wxWindow::SetAutoLayout(): when auto layout is on, this function gets called automatically when the window is resized.
- void OnSysColourChanged (wxSysColourChangedEvent &event)

  The default handler for `wxEVT_SYS_COLOUR_CHANGED`.
- virtual void SetFocus ()

  Overrides wxWindow::SetFocus().
- void SetFocusIgnoringChildren ()

  In contrast to SetFocus() (see above) this will set the focus to the panel even if there are child windows in the panel.

Additional Inherited Members

21.512.2 Constructor & Destructor Documentation

wxPanel::wxPanel ( )

Default constructor.

wxPanel::wxPanel (wxWindow * *parent*, wxWindowID *id* = wxID_ANY, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, long *style* = wxTAB_TRAVERSAL, const wxString & *name* = `wxPanelNameStr`)

Constructor.

Parameters

parent	The parent window.
id	An identifier for the panel. `wxID_ANY` is taken to mean a default.
pos	The panel position. The value wxDefaultPosition indicates a default position, chosen by either the windowing system or wxWidgets, depending on platform.
size	The panel size. The value wxDefaultSize indicates a default size, chosen by either the windowing system or wxWidgets, depending on platform.
style	The window style. See wxPanel.
name	Window name.

See also

Create()

virtual wxPanel::~wxPanel ( ) [virtual]

Destructor.

Deletes any child windows before deleting the physical window.

21.512.3 Member Function Documentation

bool wxPanel::AcceptsFocus ( ) const [virtual]

This method is overridden from wxWindow::AcceptsFocus() and returns true only if there is no child window in the panel which can accept the focus.

This is reevaluated each time a child window is added or removed from the panel.

Reimplemented from wxWindow.

bool wxPanel::Create (wxWindow * *parent*, wxWindowID *id* = wxID_ANY, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, long *style* = wxTAB_TRAVERSAL, const wxString & *name* = `wxPanelNameStr`)

Used for two-step panel construction.

See wxPanel() for details.

virtual void wxPanel::InitDialog ( ) [virtual]

Sends a wxInitDialogEvent, which in turn transfers data to the dialog via validators.

See also

wxInitDialogEvent

Reimplemented from wxWindow.

virtual bool wxPanel::Layout ( ) [virtual]

See wxWindow::SetAutoLayout(): when auto layout is on, this function gets called automatically when the window is resized.

Reimplemented from wxWindow.

void wxPanel::OnSysColourChanged (wxSysColourChangedEvent & *event*)

The default handler for `wxEVT_SYS_COLOUR_CHANGED`.

Parameters

event	The colour change event.

Remarks

Changes the panel's colour to conform to the current settings (Windows only). Add an event table entry for your panel class if you wish the behaviour to be different (such as keeping a user-defined background colour). If you do override this function, call wxEvent::Skip() to propagate the notification to child windows and controls.

See also

wxSysColourChangedEvent

virtual void wxPanel::SetFocus ( ) [virtual]

Overrides wxWindow::SetFocus().

This method uses the (undocumented) mix-in class wxControlContainer which manages the focus and TAB logic for controls which usually have child controls.

In practice, if you call this method and the control has at least one child window, the focus will be given to the child window.

See also

wxFocusEvent, wxWindow::SetFocus()

Reimplemented from wxWindow.

void wxPanel::SetFocusIgnoringChildren ( )

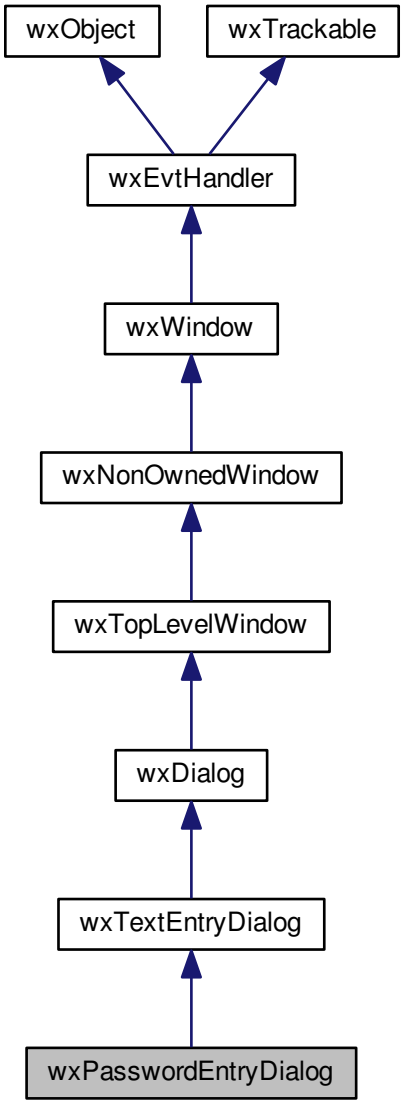
In contrast to SetFocus() (see above) this will set the focus to the panel even if there are child windows in the panel.

This is only rarely needed.

21.513 wxPasswordEntryDialog Class Reference

```
#include <wx/textdlg.h>
```

Inheritance diagram for wxPasswordEntryDialog:



21.513.1 Detailed Description

This class represents a dialog that requests a one-line password string from the user.

It is implemented as a generic wxWidgets dialog.

Library: wxCore

Category: Common Dialogs

See also

wxPasswordEntryDialog Overview

Public Member Functions

- wxPasswordEntryDialog (wxWindow *parent, const wxString &message, const wxString &caption=wxGetPasswordFromUserPromptStr, const wxString &defaultValue=wxEmptyString, long style=wxTextEntryDialogStyle, const wxPoint &pos=wxDefaultPosition)

  Constructor.

Additional Inherited Members

21.513.2 Constructor & Destructor Documentation

wxPasswordEntryDialog::wxPasswordEntryDialog (wxWindow * *parent*, const wxString & *message*, const wxString & *caption* = wxGetPasswordFromUserPromptStr, const wxString & *defaultValue* = wxEmptyString, long *style* = wxTextEntryDialogStyle, const wxPoint & *pos* = wxDefaultPosition)

Constructor.

Use wxTextEntryDialog::ShowModal to show the dialog.

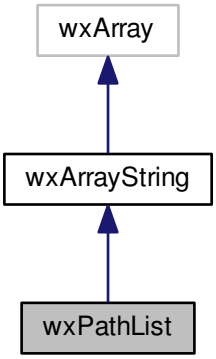
Parameters

parent	Parent window.
message	Message to show on the dialog.
caption	The caption of the dialog.
defaultValue	The default value, which may be the empty string.
style	A dialog style, specifying the buttons (wxOK, wxCANCEL) and an optional wxCENTRE style. You do not need to specify the wxTE_PASSWORD style, it is always applied.
pos	Dialog position.

21.514 wxPathList Class Reference

```
#include <wx/filefn.h>
```

Inheritance diagram for wxPathList:



21.514.1 Detailed Description

The path list is a convenient way of storing a number of directories, and when presented with a filename without a directory, searching for an existing file in those directories.

Be sure to look also at wxStandardPaths if you only want to search files in some standard paths.

Library: wxBase

Category: File Handling

See also

wxArrayString, wxStandardPaths, wxFileName

Public Member Functions

- wxPathList ()

  Standard constructor.
- wxPathList (const wxArrayString &arr)

  Constructs the object calling the Add() function.
- bool Add (const wxString &path)

  Adds the given directory to the path list, if the path is not already in the list.
- void Add (const wxArrayString &arr)

  Adds all elements of the given array as paths.
- void AddEnvList (const wxString &env_variable)

  Finds the value of the given environment variable, and adds all paths to the path list.
- bool EnsureFileAccessible (const wxString &filename)

  Given a full filename (with path), calls Add() with the path of the file.
- wxString FindAbsoluteValidPath (const wxString &file) const

  Like FindValidPath() but this function always returns an absolute path (eventually prepending the current working directory to the value returned wxPathList::FindValidPath()) or an empty string.

- wxString FindValidPath (const wxString &file) const

  Searches the given file in all paths stored in this class.

Additional Inherited Members

21.514.2 Constructor & Destructor Documentation

wxPathList::wxPathList ( )

Standard constructor.

wxPathList::wxPathList (const wxArrayString & *arr*)

Constructs the object calling the Add() function.

21.514.3 Member Function Documentation

bool wxPathList::Add (const wxString & *path*)

Adds the given directory to the path list, if the *path* is not already in the list.

If the path cannot be normalized for some reason, it returns false.

The *path* is always considered to be a directory but no existence checks will be done on it (because if it doesn't exist, it could be created later and thus result a valid path when FindValidPath() is called).

Note

if the given path is relative, it won't be made absolute before adding it (this is why FindValidPath() may return relative paths).

void wxPathList::Add (const wxArrayString & *arr*)

Adds all elements of the given array as paths.

void wxPathList::AddEnvList (const wxString & *env_variable*)

Finds the value of the given environment variable, and adds all paths to the path list.

Useful for finding files in the `PATH` variable, for example.

bool wxPathList::EnsureFileAccessible (const wxString & *filename*)

Given a full filename (with path), calls Add() with the path of the file.

wxString wxPathList::FindAbsoluteValidPath (const wxString & *file*) const

Like FindValidPath() but this function always returns an absolute path (eventually prepending the current working directory to the value returned wxPathList::FindValidPath()) or an empty string.

wxString wxPathList::FindValidPath (const wxString & *file*) const

Searches the given file in all paths stored in this class.

The first path which concatenated to the given string points to an existing file (see wxFileExists()) is returned.

If the file wasn't found in any of the stored paths, an empty string is returned.

The given string must be a file name, eventually with a path prefix (if the path prefix is absolute, only its name will be searched); i.e. it must not end with a directory separator (see wxFileName::GetPathSeparator) otherwise an assertion will fail.

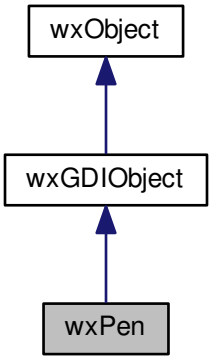
The returned path may be relative to the current working directory.

Note in fact that wxPathList can be used to store both relative and absolute paths so that if you added relative paths, then the current working directory (see wxGetCwd() and wxSetWorkingDirectory()) may affect the value returned by this function!

21.515 wxPen Class Reference

`#include <wx/pen.h>`

Inheritance diagram for wxPen:



21.515.1 Detailed Description

A pen is a drawing tool for drawing outlines.

It is used for drawing lines and painting the outline of rectangles, ellipses, etc. It has a colour, a width and a style.

Note

On a monochrome display, wxWidgets shows all non-white pens as black.

Do not initialize objects on the stack before the program commences, since other required structures may not have been set up yet. Instead, define global pointers to objects and create them in wxApp::OnInit() or when required.

An application may wish to dynamically create pens with different characteristics, and there is the consequent danger that a large number of duplicate pens will be created. Therefore an application may wish to get a pointer to a pen by using the global list of pens wxThePenList, and calling the member function wxPenList::FindOrCreatePen(). See wxPenList for more info.

This class uses reference counting and copy-on-write internally so that assignments between two instances of this class are very cheap. You can therefore use actual objects instead of pointers without efficiency problems. If an instance of this class is changed it will create its own data internally so that other instances, which previously shared the data using the reference counting, are not affected.

Library: wxCore

Category: Graphics Device Interface (GDI)

Predefined objects/pointers:

- wxNullPen
- wxBLACK_DASHED_PEN
- wxBLACK_PEN
- wxBLUE_PEN
- wxCYAN_PEN
- wxGREEN_PEN
- wxYELLOW_PEN
- wxGREY_PEN
- wxLIGHT_GREY_PEN
- wxMEDIUM_GREY_PEN
- wxRED_PEN
- wxTRANSPARENT_PEN
- wxWHITE_PEN

See also

wxPenList, wxDC, wxDC::SetPen()

Public Member Functions

- wxPen ()

  Default constructor.
- wxPen (const wxColour &colour, int width=1, wxPenStyle style=wxPENSTYLE_SOLID)

  Constructs a pen from a colour object, pen width and style.
- wxPen (const wxBitmap &stipple, int width)

  Constructs a stippled pen from a stipple bitmap and a width.
- wxPen (const wxPen &pen)

  Copy constructor, uses Reference Counting.
- virtual ~wxPen ()

  Destructor.
- virtual wxPenCap GetCap () const

  Returns the pen cap style, which may be one of `wxCAP_ROUND`, `wxCAP_PROJECTING` *and* `wxCAP_BUTT`.
- virtual wxColour GetColour () const

  Returns a reference to the pen colour.
- virtual int GetDashes (wxDash **dashes) const

Gets an array of dashes (defined as `char` in X, `DWORD` under Windows).

- virtual wxPenJoin GetJoin () const

  Returns the pen join style, which may be one of `wxJOIN_BEVEL`, `wxJOIN_ROUND` and `wxJOIN_MITER`.
- virtual wxBitmap * GetStipple () const

  Gets a pointer to the stipple bitmap.
- virtual wxPenStyle GetStyle () const

  Returns the pen style.
- virtual int GetWidth () const

  Returns the pen width.
- virtual bool IsOk () const

  Returns true if the pen is initialised.
- bool IsNonTransparent () const

  Returns true if the pen is a valid non-transparent pen.
- bool IsTransparent () const

  Returns true if the pen is transparent.
- virtual void SetCap (wxPenCap capStyle)

  Sets the pen cap style, which may be one of `wxCAP_ROUND`, `wxCAP_PROJECTING` and `wxCAP_BUTT`.
- virtual void SetDashes (int n, const wxDash *dash)

  Associates an array of dash values (defined as `char` in X, `DWORD` under Windows) with the pen.
- virtual void SetJoin (wxPenJoin join_style)

  Sets the pen join style, which may be one of `wxJOIN_BEVEL`, `wxJOIN_ROUND` and `wxJOIN_MITER`.
- virtual void SetStipple (const wxBitmap &stipple)

  Sets the bitmap for stippling.
- virtual void SetStyle (wxPenStyle style)

  Set the pen style.
- virtual void SetWidth (int width)

  Sets the pen width.
- bool operator!= (const wxPen &pen) const

  Inequality operator.
- wxPen & operator= (const wxPen &pen)

  Assignment operator, using Reference Counting.
- bool operator== (const wxPen &pen) const

  Equality operator.

- virtual void SetColour (wxColour &colour)

  The pen's colour is changed to the given colour.
- virtual void SetColour (unsigned char red, unsigned char green, unsigned char blue)

  The pen's colour is changed to the given colour.

Additional Inherited Members

21.515.2 Constructor & Destructor Documentation

wxPen::wxPen ( )

Default constructor.

The pen will be uninitialised, and IsOk() will return false.

wxPen::wxPen (const wxColour & *colour*, int *width* = 1, wxPenStyle *style* = wxPENSTYLE_SOLID)

Constructs a pen from a colour object, pen width and style.

Parameters

colour	A colour object.
width	Pen width. Under Windows, the pen width cannot be greater than 1 if the style is `wxPENS↩TYLE_DOT`, `wxPENSTYLE_LONG_DASH`, `wxPENSTYLE_SHORT_DASH`, `wxPENSTY↩LE_DOT_DASH`, or `wxPENSTYLE_USER_DASH`.
style	The style may be one of the wxPenStyle values.

Remarks

Different versions of Windows and different versions of other platforms support very different subsets of the styles above

- there is no similarity even between Windows95 and Windows98 - so handle with care.

See also

SetStyle(), SetColour(), SetWidth()

wxPen::wxPen (const wxBitmap & *stipple,* int *width*)

Constructs a stippled pen from a stipple bitmap and a width.

Parameters

width	Pen width. Under Windows, the pen width cannot be greater than 1 if the style is `wxPENS↩TYLE_DOT`, `wxPENSTYLE_LONG_DASH`, `wxPENSTYLE_SHORT_DASH`, `wxPENSTY↩LE_DOT_DASH`, or `wxPENSTYLE_USER_DASH`.
stipple	A stipple bitmap.

Availability: only available for the wxMSW, wxOSX ports.

See also

SetWidth(), SetStipple()

wxPen::wxPen (const wxPen & *pen*)

Copy constructor, uses Reference Counting.

Parameters

pen	A pointer or reference to a pen to copy.

virtual wxPen::~wxPen ( ) [virtual]

Destructor.

See also

reference-counted object destruction

Remarks

Although all remaining pens are deleted when the application exits, the application should try to clean up all pens itself. This is because wxWidgets cannot know if a pointer to the pen object is stored in an application data structure, and there is a risk of double deletion.

21.515.3 Member Function Documentation

virtual wxPenCap wxPen::GetCap ( ) const `[virtual]`

Returns the pen cap style, which may be one of `wxCAP_ROUND`, `wxCAP_PROJECTING` and `wxCAP_BUTT`.

The default is `wxCAP_ROUND`.

See also

SetCap()

virtual wxColour wxPen::GetColour ( ) const `[virtual]`

Returns a reference to the pen colour.

See also

SetColour()

virtual int wxPen::GetDashes (wxDash ** *dashes*) const `[virtual]`

Gets an array of dashes (defined as `char` in X, `DWORD` under Windows).

dashes is a pointer to the internal array. Do not deallocate or store this pointer.

Returns

The number of dashes associated with this pen.

See also

SetDashes()

virtual wxPenJoin wxPen::GetJoin ( ) const `[virtual]`

Returns the pen join style, which may be one of `wxJOIN_BEVEL`, `wxJOIN_ROUND` and `wxJOIN_MITER`.

The default is `wxJOIN_ROUND`.

See also

SetJoin()

virtual wxBitmap* wxPen::GetStipple ( ) const `[virtual]`

Gets a pointer to the stipple bitmap.

See also

SetStipple()

virtual wxPenStyle wxPen::GetStyle ( ) const `[virtual]`

Returns the pen style.

See also

wxPen(), SetStyle()

virtual int wxPen::GetWidth ( ) const `[virtual]`

Returns the pen width.

See also

SetWidth()

bool wxPen::IsNonTransparent ( ) const

Returns true if the pen is a valid non-transparent pen.

This method returns true if the pen object is initialized and has a non-transparent style. Notice that this should be used instead of simply testing whether GetStyle() returns a style different from wxPENSTYLE_TRANSPARENT if the pen may be invalid as GetStyle() would assert in this case.

See also

IsTransparent()

Since

2.9.2.

virtual bool wxPen::IsOk ( ) const `[virtual]`

Returns true if the pen is initialised.

Notice that an uninitialized pen object can't be queried for any pen properties and all calls to the accessor methods on it will result in an assert failure.

bool wxPen::IsTransparent ( ) const

Returns true if the pen is transparent.

A transparent pen is simply a pen with wxPENSTYLE_TRANSPARENT style.

Notice that this function works even for non-initialized pens (for which it returns false) unlike tests of the form `GetStyle() == wxPENSTYLE_TRANSPARENT` which would assert if the pen is invalid.

See also

IsNonTransparent()

Since

2.9.2.

bool wxPen::operator!= (const wxPen & *pen*) const

Inequality operator.

See reference-counted object comparison for more info.

wxPen& wxPen::operator= (const wxPen & *pen*)

Assignment operator, using Reference Counting.

bool wxPen::operator== (const wxPen & *pen*) const

Equality operator.

See reference-counted object comparison for more info.

virtual void wxPen::SetCap (wxPenCap *capStyle*) [virtual]

Sets the pen cap style, which may be one of `wxCAP_ROUND`, `wxCAP_PROJECTING` and `wxCAP_BUTT`.

The default is `wxCAP_ROUND`.

See also

GetCap()

virtual void wxPen::SetColour (wxColour & *colour*) [virtual]

The pen's colour is changed to the given colour.

See also

GetColour()

virtual void wxPen::SetColour (unsigned char *red,* unsigned char *green,* unsigned char *blue*) [virtual]

The pen's colour is changed to the given colour.

See also

GetColour()

virtual void wxPen::SetDashes (int *n,* const wxDash * *dash*) [virtual]

Associates an array of dash values (defined as `char` in X, `DWORD` under Windows) with the pen.

The array is not deallocated by wxPen, but neither must it be deallocated by the calling application until the pen is deleted or this function is called with a NULL array.

See also

GetDashes()

virtual void wxPen::SetJoin (wxPenJoin *join_style*) `[virtual]`

Sets the pen join style, which may be one of `wxJOIN_BEVEL`, `wxJOIN_ROUND` and `wxJOIN_MITER`.

The default is `wxJOIN_ROUND`.

See also

GetJoin()

virtual void wxPen::SetStipple (const wxBitmap & *stipple*) `[virtual]`

Sets the bitmap for stippling.

See also

GetStipple()

virtual void wxPen::SetStyle (wxPenStyle *style*) `[virtual]`

Set the pen style.

See also

wxPen()

virtual void wxPen::SetWidth (int *width*) `[virtual]`

Sets the pen width.

See also

GetWidth()

21.516 wxPenList Class Reference

`#include <wx/pen.h>`

21.516.1 Detailed Description

There is only one instance of this class: wxThePenList.

Use this object to search for a previously created pen of the desired type and create it if not already found. In some windowing systems, the pen may be a scarce resource, so it can pay to reuse old resources if possible. When an application finishes, all pens will be deleted and their resources freed, eliminating the possibility of 'memory leaks'. However, it is best not to rely on this automatic cleanup because it can lead to double deletion in some circumstances.

There are two mechanisms in recent versions of wxWidgets which make the pen list less useful than it once was. Under Windows, scarce resources are cleaned up internally if they are not being used. Also, a referencing counting mechanism applied to all GDI objects means that some sharing of underlying resources is possible. You don't have to keep track of pointers, working out when it is safe delete a pen, because the referencing counting does it for you. For example, you can set a pen in a device context, and then immediately delete the pen you passed, because the pen is 'copied'.

So you may find it easier to ignore the pen list, and instead create and copy pens as you see fit. If your Windows resource meter suggests your application is using too many resources, you can resort to using GDI lists to share objects explicitly.

The only compelling use for the pen list is for wxWidgets to keep track of pens in order to clean them up on exit. It is also kept for backward compatibility with earlier versions of wxWidgets.

Library: wxCore

Category: Graphics Device Interface (GDI)

Predefined objects/pointers: wxThePenList

See also

wxPen

Public Member Functions

- wxPenList ()

  Constructor.
- wxPen * FindOrCreatePen (const wxColour &colour, int width=1, wxPenStyle style=wxPENSTYLE_SOLID)

  Finds a pen with the specified attributes and returns it, else creates a new pen, adds it to the pen list, and returns it.

21.516.2 Constructor & Destructor Documentation

wxPenList::wxPenList ( )

Constructor.

The application should not construct its own pen list: use the object pointer wxThePenList.

21.516.3 Member Function Documentation

wxPen* wxPenList::FindOrCreatePen (const wxColour & *colour*, int *width* = 1, wxPenStyle *style* = wxPENSTYLE_SOLID)

Finds a pen with the specified attributes and returns it, else creates a new pen, adds it to the pen list, and returns it.

Parameters

colour	Colour object.
width	Width of pen.
style	Pen style. See wxPenStyle for a list of styles.

21.517 wxPersistenceManager Class Reference

```
#include <wx/persist.h>
```

21.517.1 Detailed Description

Provides support for automatically saving and restoring object properties to persistent storage.

This class is the central element of wxWidgets persistence framework, see Persistent Objects Overview for its overview.

This is a singleton class and its unique instance can be retrieved using Get() method.

Since

2.9.0

Library: wxCore

Public Member Functions

- void DisableSaving ()

  Globally disable saving the persistence object properties.
- void DisableRestoring ()

  Globally disable restoring the persistence object properties.
- template<class T >
  wxPersistentObject * Register (T *obj)

  Register an object with the manager automatically creating a persistence adapter for it.
- wxPersistentObject * Register (void *obj, wxPersistentObject *po)

  Register an object with the manager.
- wxPersistentObject * Find (void *obj) const

  Check if the object is registered and return the associated wxPersistentObject if it is or NULL otherwise.
- void Unregister (void *obj)

  Unregister the object and delete the associated wxPersistentObject.
- void Save (void *obj)

  Save the object properties to persistent storage.
- bool Restore (void *obj)

  Restore the object properties previously saved by Save().
- void SaveAndUnregister (void *obj)

  Combines both Save() and Unregister() calls.
- template<class T >
  bool RegisterAndRestore (T *obj)

  Combines both Register() and Restore() calls.
- bool RegisterAndRestore (void *obj, wxPersistentObject *po)

  Combines both Register() and Restore() calls.

Static Public Member Functions

- static void Set (wxPersistenceManager &manager)

  Set the global persistence manager to use.
- static wxPersistenceManager & Get ()

  Returns the unique persistence manager object.

Protected Member Functions

- wxPersistenceManager ()

  Protected default constructor.
- virtual wxConfigBase * GetConfig () const

  Return the config object to use.
- virtual wxString GetKey (const wxPersistentObject &who, const wxString &name) const

  Return the path to use for saving the setting with the given name for the specified object.

21.517.2 Constructor & Destructor Documentation

wxPersistenceManager::wxPersistenceManager ( ) [protected]

Protected default constructor.

This constructor is only provided for the derived classes, to use an object of this class static Get() method should be called.

21.517.3 Member Function Documentation

void wxPersistenceManager::DisableRestoring ( )

Globally disable restoring the persistence object properties.

By default, restoring properties in Restore() is enabled but this function allows to disable it. This is mostly useful for testing.

See also

DisableSaving()

void wxPersistenceManager::DisableSaving ( )

Globally disable saving the persistence object properties.

By default, saving properties in Save() is enabled but the program may wish to disable if, for example, it detects that it is running on a system which shouldn't be modified in any way and so configuration file (or Windows registry) shouldn't be written to.

See also

DisableRestoring()

wxPersistentObject* wxPersistenceManager::Find (void * *obj*) const

Check if the object is registered and return the associated wxPersistentObject if it is or NULL otherwise.

static wxPersistenceManager& wxPersistenceManager::Get ( ) [static]

Returns the unique persistence manager object.

If Set() hadn't been called before, a default persistence manager implementation is returned.

virtual **wxConfigBase*** **wxPersistenceManager::GetConfig** ( ) **const** [protected], [virtual]

Return the config object to use.

By default the global wxConfig, returned by wxConfigBase::Get(), is used but a derived class could override this function to return a different one if necessary.

Since

2.9.3

virtual **wxString** **wxPersistenceManager::GetKey** (**const wxPersistentObject &** *who,* **const wxString &** *name*) **const** [protected], [virtual]

Return the path to use for saving the setting with the given name for the specified object.

Notice that the *name* argument is the name of the setting, not the name of the object itself which can be retrieved with its GetName() method.

This method can be overridden by a derived class to change where in wxConfig the different options are stored. By default, all settings of the persistent controls are stored under "Persistent_Options" group and grouped by control type (e.g. "Window" for top level windows or "Splitter") and name, so that the position of a splitter called "sep" could be stored under "Persistent_Options/Splitter/sep/Position" key.

Since

2.9.3

template<class T> **wxPersistentObject*** **wxPersistenceManager::Register** (**T** * *obj*)

Register an object with the manager automatically creating a persistence adapter for it.

This is equivalent to calling Register(void *, wxPersistentObject *) with wxCreatePersistentObject(obj) as the second argument.

Parameters

obj	The object to register. wxCreatePersistentObject() overload must be defined for the objects of this class.

wxPersistentObject* **wxPersistenceManager::Register** (**void** * *obj,* **wxPersistentObject** * *po*)

Register an object with the manager.

Note that registering the object doesn't do anything except allowing to call Restore() for it later. If you want to register the object and restore its properties, use RegisterAndRestore().

The manager takes ownership of *po* and will delete it when it is unregistered.

Parameters

obj	The object to register.
po	The wxPersistentObject to use for saving and restoring this object properties.

template<class T> **bool** **wxPersistenceManager::RegisterAndRestore** (**T** * *obj*)

Combines both Register() and Restore() calls.

bool wxPersistenceManager::RegisterAndRestore (void * *obj*, wxPersistentObject * *po*)

Combines both Register() and Restore() calls.

bool wxPersistenceManager::Restore (void * *obj*)

Restore the object properties previously saved by Save().

This method does nothing if DisableRestoring() had been called.

Parameters

obj	An object previously registered with Register().

Returns

true if the object properties were restored or false if nothing was found to restore or the saved settings were invalid.

See also

RegisterAndRestore()

void wxPersistenceManager::Save (void * *obj*)

Save the object properties to persistent storage.

This method does nothing if DisableSaving() had been called.

Parameters

obj	An object previously registered with Register().

See also

SaveAndUnregister()

void wxPersistenceManager::SaveAndUnregister (void * *obj*)

Combines both Save() and Unregister() calls.

static void wxPersistenceManager::Set (wxPersistenceManager & *manager*) `[static]`

Set the global persistence manager to use.

Call this method to specify a non-default persistence manager to use. It should usually be called very early (e.g. in wxApp-derived class constructor or in the beginning of overridden wxApp::OnInit()) to affect creation of all persistent controls and the object passed to it must have a lifetime long enough to be still alive when the persistent controls are destroyed and need it to save their state so typically this would be a global or a wxApp member.

Since

2.9.3

void wxPersistenceManager::Unregister (void * *obj*)

Unregister the object and delete the associated wxPersistentObject.

For the persistent windows this is done automatically (via SaveAndUnregister()) when the window is destroyed so you only need to call this function explicitly if you are using custom persistent objects or if you want to prevent the object properties from being saved.

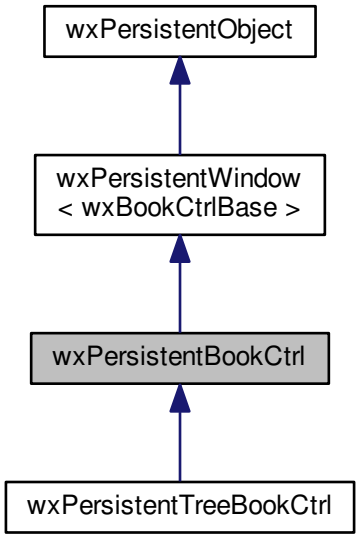
Parameters

obj	An object previously registered with Register().

21.518 wxPersistentBookCtrl Class Reference

`#include <wx/persist/bookctrl.h>`

Inheritance diagram for wxPersistentBookCtrl:



21.518.1 Detailed Description

Persistence adapter for wxBookCtrlBase.

This adapter handles the selected page of wxBookCtrlBase, i.e. it saves its value when the associated book control is destroyed and restores it when it is recreated.

See also

wxPersistentTreeBookCtrl

Public Member Functions

- wxPersistentBookCtrl (wxBookCtrlBase *book)

Constructor.

- virtual void Save () const

  Save the currently selected page index.

- virtual bool Restore ()

  Restore the selected page index.

Additional Inherited Members

21.518.2 Constructor & Destructor Documentation

wxPersistentBookCtrl::wxPersistentBookCtrl (wxBookCtrlBase * *book*)

Constructor.

Parameters

book	The associated book control.

21.518.3 Member Function Documentation

virtual bool wxPersistentBookCtrl::Restore ( ) [virtual]

Restore the selected page index.

The book control must be initialized before calling this function, i.e. all of its pages should be already added to it – otherwise restoring the selection has no effect.

Implements wxPersistentObject.

Reimplemented in wxPersistentTreeBookCtrl.

virtual void wxPersistentBookCtrl::Save ( ) const [virtual]

Save the currently selected page index.

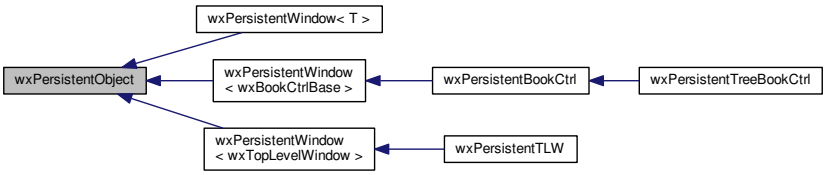
Implements wxPersistentObject.

Reimplemented in wxPersistentTreeBookCtrl.

21.519 wxPersistentObject Class Reference

```
#include <wx/persist.h>
```

Inheritance diagram for wxPersistentObject:



21.519.1 Detailed Description

Base class for persistent object adapters.

wxWidgets persistence framework is non-intrusive, i.e. can work with the classes which have no relationship to nor knowledge of it. To allow this, an intermediate persistence adapter is used: this is just a simple object which provides the methods used by wxPersistenceManager to save and restore the object properties and implements them using the concrete class methods.

You may derive your own classes from wxPersistentObject to implement persistence support for your common classes, see Defining Custom Persistent Windows.

See also

wxPersistentWindow<>

Public Member Functions

- wxPersistentObject (void *obj)

  Constructor takes the object which we're associated with.
- virtual ~wxPersistentObject ()

  Trivial but virtual destructor.
- void * GetObject () const

  Return the associated object.

Methods to be implemented in the derived classes.

Notice that these methods are only used by wxPersistenceManager normally and shouldn't be called directly.

- virtual void Save () const =0

  Save the object properties.
- virtual bool Restore ()=0

  Restore the object properties.
- virtual wxString GetKind () const =0

  Returns the string uniquely identifying the objects supported by this adapter.
- virtual wxString GetName () const =0

  Returns the string uniquely identifying the object we're associated with among all the other objects of the same type.

Protected Member Functions

- template<typename T >
  bool SaveValue (const wxString &name, T value) const

  Save the specified value using the given name.
- template<typename T >
  bool RestoreValue (const wxString &name, T *value)

  Restore the value saved by Save().

21.519.2 Constructor & Destructor Documentation

wxPersistentObject::wxPersistentObject (void * *obj*)

Constructor takes the object which we're associated with.

This object must have life-time greater than ours as we keep a pointer to it.

virtual wxPersistentObject::~wxPersistentObject ( ) [virtual]

Trivial but virtual destructor.

21.519.3 Member Function Documentation

virtual wxString wxPersistentObject::GetKind ( ) const [pure virtual]

Returns the string uniquely identifying the objects supported by this adapter.

This method is called from SaveValue() and RestoreValue() and normally returns some short (but not too cryptic) strings, e.g. `"Checkbox"`.

virtual wxString wxPersistentObject::GetName ( ) const [pure virtual]

Returns the string uniquely identifying the object we're associated with among all the other objects of the same type.

This method is used together with GetKind() to construct the unique full name of the object in e.g. a configuration file.

Implemented in wxPersistentWindow< T >, wxPersistentWindow< wxBookCtrlBase >, and wxPersistentWindow< wxTopLevelWindow >.

void* wxPersistentObject::GetObject ( ) const

Return the associated object.

virtual bool wxPersistentObject::Restore ( ) [pure virtual]

Restore the object properties.

The implementation of this method should use RestoreValue().

Implemented in wxPersistentBookCtrl, wxPersistentTreeBookCtrl, and wxPersistentTLW.

template<typename T > bool wxPersistentObject::RestoreValue (const wxString & *name*, T * *value*) [protected]

Restore the value saved by Save().

Parameters

name	The same name as was used by Save().
value	Non-NULL pointer which will be filled with the value if it was read successfully or not modified if it wasn't.

Returns

true if the value was successfully read or false if it was not found or an error occurred.

virtual void wxPersistentObject::Save ( ) const [pure virtual]

Save the object properties.

The implementation of this method should use SaveValue().

Implemented in wxPersistentBookCtrl, wxPersistentTLW, and wxPersistentTreeBookCtrl.

template<typename T > bool wxPersistentObject::SaveValue (const wxString & *name,* T *value*) const [protected]

Save the specified value using the given name.

Parameters

name	The name of the value in the configuration file.
value	The value to save, currently must be a type supported by wxConfig.

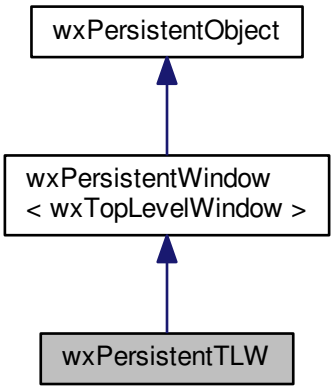
Returns

true if the value was saved or false if an error occurred.

21.520 wxPersistentTLW Class Reference

`#include <wx/persist/toplevel.h>`

Inheritance diagram for wxPersistentTLW:



21.520.1 Detailed Description

Persistence adapter for wxTopLevelWindow.

This adapter saves and restores the geometry (i.e. position and size) and the state (iconized, maximized or normal) of top level windows. It can be used with both wxFrame and wxDialog.

Note that it does *not* save nor restore the window visibility.

Public Member Functions

- wxPersistentTLW (wxTopLevelWindow *book)

  Constructor.

- virtual void Save () const

  Save the current window geometry.

- virtual bool Restore ()

  Restore the window geometry.

Additional Inherited Members

21.520.2 Constructor & Destructor Documentation

wxPersistentTLW::wxPersistentTLW (wxTopLevelWindow * *book*)

Constructor.

Parameters

book	The associated window.

21.520.3 Member Function Documentation

virtual bool wxPersistentTLW::Restore ( ) [virtual]

Restore the window geometry.

Implements wxPersistentObject.

virtual void wxPersistentTLW::Save ( ) const [virtual]

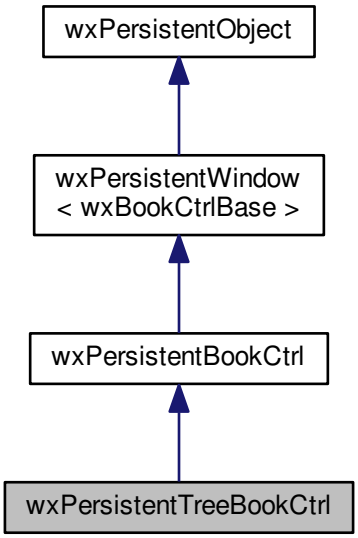
Save the current window geometry.

Implements wxPersistentObject.

21.521 wxPersistentTreeBookCtrl Class Reference

`#include <wx/persist/treebook.h>`

Inheritance diagram for wxPersistentTreeBookCtrl:



21.521.1 Detailed Description

Persistence adapter for wxTreebook.

This adapter saves and restores the expanded branches of the wxTreeCtrl used by wxTreebook, in addition to saving and restoring the selection as implemented by the base wxPersistentBookCtrl class.

Public Member Functions

- wxPersistentTreeBookCtrl (wxTreebook *book)

  Constructor.

- virtual void Save () const

  Save the currently opened branches.

- virtual bool Restore ()

  Restore the opened branches.

Additional Inherited Members

21.521.2 Constructor & Destructor Documentation

wxPersistentTreeBookCtrl::wxPersistentTreeBookCtrl (wxTreebook * *book*)

Constructor.

Parameters

book	The associated tree book control.

21.521.3 Member Function Documentation

virtual bool wxPersistentTreeBookCtrl::Restore ( ) [virtual]

Restore the opened branches.

The book control must be initialized before calling this function, i.e. all of its pages should be already added to it.

Reimplemented from wxPersistentBookCtrl.

virtual void wxPersistentTreeBookCtrl::Save ( ) const [virtual]

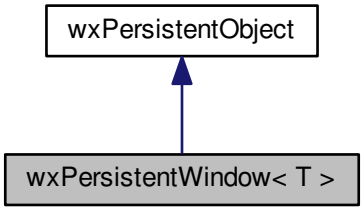
Save the currently opened branches.

Reimplemented from wxPersistentBookCtrl.

21.522 wxPersistentWindow< T > Class Template Reference

`#include <wx/persist/window.h>`

Inheritance diagram for wxPersistentWindow< T >:



21.522.1 Detailed Description

template<class T>class wxPersistentWindow< T >

Base class for persistent windows.

Compared to wxPersistentObject this class does three things:

- Most importantly, wxPersistentWindow catches wxWindowDestroyEvent generated when the window is destroyed and saves its properties automatically when it happens.
- It implements GetName() using wxWindow::GetName() so that the derived classes don't need to do it.
- It adds a convenient wxPersistentWindow::Get() accessor returning the window object of the correct type.

Public Types

- typedef T WindowType

  The type of the associated window.

Public Member Functions

- wxPersistentWindow (WindowType *win)

  Constructor for a persistent window object.
- WindowType * Get () const
- virtual wxString GetName () const

  Implements the base class pure virtual method using wxWindow::GetName().

Additional Inherited Members

21.522.2 Member Typedef Documentation

template<class T> typedef T wxPersistentWindow< T >::WindowType

The type of the associated window.

21.522.3 Constructor & Destructor Documentation

template<class T> wxPersistentWindow< T >::wxPersistentWindow (WindowType * *win*)

Constructor for a persistent window object.

The constructor uses wxEvtHandler::Connect() to catch wxWindowDestroyEvent generated when the window is destroyed and call wxPersistenceManager::SaveAndUnregister() when this happens. This ensures that the window properties are saved and that this object itself is deleted when the window is.

21.522.4 Member Function Documentation

template<class T> WindowType* wxPersistentWindow< T >::Get ( ) const `[inline]`

template<class T> virtual wxString wxPersistentWindow< T >::GetName ( ) const `[virtual]`

Implements the base class pure virtual method using wxWindow::GetName().

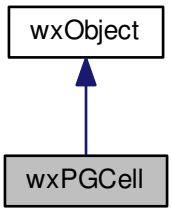
Notice that window names are usually not unique while this function must return a unique (at least among the objects of this type) string. Because of this you need to specify a non-default window name in its constructor when creating it or explicitly call wxWindow::SetName() before saving or restoring persistent properties.

Implements wxPersistentObject.

21.523 wxPGCell Class Reference

`#include <wx/propgrid/property.h>`

Inheritance diagram for wxPGCell:



21.523.1 Detailed Description

Base class for wxPropertyGrid cell information.

Library: wxPropertyGrid

Category: wxPropertyGrid

Public Member Functions

- wxPGCell ()
- wxPGCell (const wxPGCell &other)
- wxPGCell (const wxString &text, const wxBitmap &bitmap=wxNullBitmap, const wxColour &fgCol=wxNull↩ Colour, const wxColour &bgCol=wxNullColour)
- virtual ∼wxPGCell ()
- const wxPGCellData ∗ GetData () const
- bool HasText () const

  Returns true if this cell has custom text stored within.
- void MergeFrom (const wxPGCell &srcCell)

  Merges valid data from srcCell into this.
- void SetText (const wxString &text)
- void SetBitmap (const wxBitmap &bitmap)
- void SetFgCol (const wxColour &col)
- void SetFont (const wxFont &font)

  Sets font of the cell.
- void SetBgCol (const wxColour &col)
- const wxString & GetText () const
- const wxBitmap & GetBitmap () const
- const wxColour & GetFgCol () const
- const wxFont & GetFont () const

  Returns font of the cell.
- const wxColour & GetBgCol () const
- wxPGCell & operator= (const wxPGCell &other)

Additional Inherited Members

21.523.2 Constructor & Destructor Documentation

wxPGCell::wxPGCell ( )

wxPGCell::wxPGCell (const wxPGCell & *other*)

wxPGCell::wxPGCell (const wxString & *text*, const wxBitmap & *bitmap* = wxNullBitmap, const wxColour & *fgCol* = wxNullColour, const wxColour & *bgCol* = wxNullColour)

virtual wxPGCell::∼wxPGCell ( ) `[virtual]`

21.523.3 Member Function Documentation

const wxColour& wxPGCell::GetBgCol ( ) const

const wxBitmap& wxPGCell::GetBitmap ( ) const

const wxPGCellData∗ wxPGCell::GetData ( ) const

const wxColour& wxPGCell::GetFgCol ( ) const

const wxFont& wxPGCell::GetFont ( ) const

Returns font of the cell.

If no specific font is set for this cell, then the font will be invalid.

const wxString& wxPGCell::GetText ( ) const

bool wxPGCell::HasText ( ) const

Returns true if this cell has custom text stored within.

void wxPGCell::MergeFrom (const wxPGCell & *srcCell*)

Merges valid data from srcCell into this.

wxPGCell& wxPGCell::operator= (const wxPGCell & *other*)

void wxPGCell::SetBgCol (const wxColour & *col*)

void wxPGCell::SetBitmap (const wxBitmap & *bitmap*)

void wxPGCell::SetFgCol (const wxColour & *col*)

void wxPGCell::SetFont (const wxFont & *font*)

Sets font of the cell.

Remarks

Because wxPropertyGrid does not support rows of different height, it makes little sense to change size of the font. Therefore it is recommended to use return value of wxPropertyGrid::GetFont() or wxPropertyGrid::GetCaptionFont() as a basis for the font that, after modifications, is passed to this member function.

void wxPGCell::SetText (const wxString & *text*)

21.524 wxPGChoices Class Reference

`#include <wx/propgrid/property.h>`

21.524.1 Detailed Description

Helper class for managing choices of wxPropertyGrid properties.

Each entry can have label, value, bitmap, text colour, and background colour.

wxPGChoices uses reference counting, similar to other wxWidgets classes. This means that assignment operator and copy constructor only copy the reference and not the actual data. Use Copy() member function to create a real copy.

Remarks

If you do not specify value for entry, index is used.

Library: wxPropertyGrid

Category: wxPropertyGrid

Public Types

- typedef long ValArrItem

Public Member Functions

- wxPGChoices ()

  Default constructor.
- wxPGChoices (const wxPGChoices &a)

  Copy constructor, uses reference counting.
- wxPGChoices (const wxChar **labels, const long *values=NULL)

  Constructor.
- wxPGChoices (const wxArrayString &labels, const wxArrayInt &values=wxArrayInt())

  Constructor.
- wxPGChoices (wxPGChoicesData *data)

  Constructor.
- ~wxPGChoices ()

  Destructor.
- void Add (const wxChar **labels, const ValArrItem *values=NULL)

  Adds to current.
- void Add (const wxArrayString &arr, const wxArrayInt &arrint)

  Version that works with wxArrayString and wxArrayInt.
- wxPGChoiceEntry & Add (const wxString &label, int value=wxPG_INVALID_VALUE)

  Adds single item.
- wxPGChoiceEntry & Add (const wxString &label, const wxBitmap &bitmap, int value=wxPG_INVALID_VA↩ LUE)

  Adds a single item, with bitmap.
- wxPGChoiceEntry & Add (const wxPGChoiceEntry &entry)

  Adds a single item with full entry information.
- wxPGChoiceEntry & AddAsSorted (const wxString &label, int value=wxPG_INVALID_VALUE)

  Adds single item, sorted.
- void Assign (const wxPGChoices &a)

  Assigns choices data, using reference counting.
- void AssignData (wxPGChoicesData *data)

  Assigns data from another set of choices.
- void Clear ()

  Deletes all items.
- wxPGChoices Copy () const

  Returns a real copy of the choices.
- const wxString & GetLabel (unsigned int ind) const

  Returns label of item.
- unsigned int GetCount () const

  Returns number of items.
- int GetValue (unsigned int ind) const

  Returns value of item;.
- wxArrayInt GetValuesForStrings (const wxArrayString &strings) const

  Returns array of values matching the given strings.
- wxArrayInt GetIndicesForStrings (const wxArrayString &strings, wxArrayString *unmatched=NULL) const

  Returns array of indices matching given strings.
- int Index (const wxString &label) const

  Returns index of item with given label.

- int Index (int val) const

  Returns index of item with given value.
- wxPGChoiceEntry & Insert (const wxString &label, int index, int value=wxPG_INVALID_VALUE)

  Inserts single item.
- wxPGChoiceEntry & Insert (const wxPGChoiceEntry &entry, int index)

  Inserts a single item with full entry information.
- bool IsOk () const

  Returns false if this is a constant empty set of choices, which should not be modified.
- const wxPGChoiceEntry & Item (unsigned int i) const

  Returns item at given index.
- wxPGChoiceEntry & Item (unsigned int i)

  Returns item at given index.
- void RemoveAt (size_t nIndex, size_t count=1)

  Removes count items starting at position nIndex.
- void Set (const wxChar **labels, const long *values=NULL)

  Sets contents from lists of strings and values.
- void Set (const wxArrayString &labels, const wxArrayInt &values=wxArrayInt())

  Sets contents from lists of strings and values.
- void AllocExclusive ()

  Creates exclusive copy of current choices.
- wxArrayString GetLabels () const

  Returns array of choice labels.
- void operator= (const wxPGChoices &a)
- wxPGChoiceEntry & operator[] (unsigned int i)
- const wxPGChoiceEntry & operator[] (unsigned int i) const

21.524.2 Member Typedef Documentation

typedef long wxPGChoices::ValArrItem

21.524.3 Constructor & Destructor Documentation

wxPGChoices::wxPGChoices ( )

Default constructor.

wxPGChoices::wxPGChoices (const wxPGChoices & *a*)

Copy constructor, uses reference counting.

To create a real copy, use Copy() member function instead.

wxPGChoices::wxPGChoices (const wxChar ** *labels*, const long * *values* = NULL)

Constructor.

wxPGChoices::wxPGChoices (const wxArrayString & *labels*, const wxArrayInt & *values* = wxArrayInt())

Constructor.

wxPGChoices::wxPGChoices (wxPGChoicesData * *data*)

Constructor.

wxPGChoices::~wxPGChoices ( )

Destructor.

21.524.4 Member Function Documentation

void wxPGChoices::Add (const wxChar ** *labels*, const wxArrItem * *values* = NULL)

Adds to current.

If did not have own copies, creates them now. If was empty, identical to set except that creates copies.

void wxPGChoices::Add (const wxArrayString & *arr*, const wxArrayInt & *arrint*)

Version that works with wxArrayString and wxArrayInt.

wxPGChoiceEntry& wxPGChoices::Add (const wxString & *label*, int *value* = wxPG_INVALID_VALUE)

Adds single item.

wxPGChoiceEntry& wxPGChoices::Add (const wxString & *label*, const wxBitmap & *bitmap*, int *value* = wxPG_INVALID_VALUE)

Adds a single item, with bitmap.

wxPGChoiceEntry& wxPGChoices::Add (const wxPGChoiceEntry & *entry*)

Adds a single item with full entry information.

wxPGChoiceEntry& wxPGChoices::AddAsSorted (const wxString & *label*, int *value* = wxPG_INVALID_VALUE)

Adds single item, sorted.

void wxPGChoices::AllocExclusive ( )

Creates exclusive copy of current choices.

void wxPGChoices::Assign (const wxPGChoices & *a*)

Assigns choices data, using reference counting.

To create a real copy, use Copy() member function instead.

void wxPGChoices::AssignData (wxPGChoicesData * *data*)

Assigns data from another set of choices.

void wxPGChoices::Clear ( )

Deletes all items.

wxPGChoices wxPGChoices::Copy ( ) const

Returns a real copy of the choices.

unsigned int wxPGChoices::GetCount ( ) const

Returns number of items.

wxArrayInt wxPGChoices::GetIndicesForStrings (const wxArrayString & *strings,* wxArrayString * *unmatched* = NULL) const

Returns array of indices matching given strings.

Unmatching strings are added to 'unmatched', if not NULL.

const wxString& wxPGChoices::GetLabel (unsigned int *ind*) const

Returns label of item.

wxArrayString wxPGChoices::GetLabels ( ) const

Returns array of choice labels.

int wxPGChoices::GetValue (unsigned int *ind*) const

Returns value of item;.

wxArrayInt wxPGChoices::GetValuesForStrings (const wxArrayString & *strings*) const

Returns array of values matching the given strings.

Unmatching strings result in wxPG_INVALID_VALUE entry in array.

int wxPGChoices::Index (const wxString & *label*) const

Returns index of item with given label.

int wxPGChoices::Index (int *val*) const

Returns index of item with given value.

wxPGChoiceEntry& wxPGChoices::Insert (const wxString & *label,* int *index,* int *value* = wxPG_INVALID_VALUE)

Inserts single item.

wxPGChoiceEntry& wxPGChoices::Insert (const wxPGChoiceEntry & *entry,* int *index*)

Inserts a single item with full entry information.

bool wxPGChoices::IsOk ( ) const

Returns false if this is a constant empty set of choices, which should not be modified.

const wxPGChoiceEntry& wxPGChoices::Item (unsigned int *i*) const

Returns item at given index.

wxPGChoiceEntry& wxPGChoices::Item (unsigned int *i*)

Returns item at given index.

void wxPGChoices::operator= (const wxPGChoices & *a*)

wxPGChoiceEntry& wxPGChoices::operator[] (unsigned int *i*)

const wxPGChoiceEntry& wxPGChoices::operator[] (unsigned int *i*) const

void wxPGChoices::RemoveAt (size_t *nIndex,* size_t *count* = `1`)

Removes count items starting at position nIndex.

void wxPGChoices::Set (const wxChar ** *labels,* const long * *values* = `NULL`)**

Sets contents from lists of strings and values.

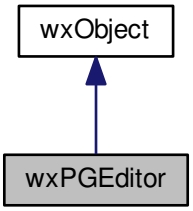
void wxPGChoices::Set (const wxArrayString & *labels,* const wxArrayInt & *values* = wxArrayInt `()`)

Sets contents from lists of strings and values.

21.525 wxPGEditor Class Reference

`#include <wx/propgrid/editors.h>`

Inheritance diagram for wxPGEditor:



21.525.1 Detailed Description

Base class for custom wxPropertyGrid editors.

Remarks

- Names of built-in property editors are: TextCtrl, Choice, ComboBox, CheckBox, TextCtrlAndButton, and ChoiceAndButton. Additional editors include SpinCtrl and DatePickerCtrl, but using them requires calling wxPropertyGrid::RegisterAdditionalEditors() prior use.
- Pointer to built-in editor is available as wxPGEditor_EditorName (eg. wxPGEditor_TextCtrl).
- Before you start using new editor you just created, you need to register it using static function wxPropertyGrid::RegisterEditorClass(), with code like this:

```
wxPGEditor* editorPointer = wxPropertyGrid::RegisterEditorClass
      (new MyEditorClass(), "MyEditor");
```

  After that, wxPropertyGrid will take ownership of the given object, but you should still store editorPointer somewhere, so you can pass it to wxPGProperty::SetEditor(), or return it from wxPGEditor::DoGetEditorClass().

Library: wxPropertyGrid

Category: wxPropertyGrid

Public Member Functions

- wxPGEditor ()

  Constructor.
- virtual ~wxPGEditor ()

  Destructor.
- virtual wxString GetName () const

  Returns pointer to the name of the editor.
- virtual wxPGWindowList CreateControls (wxPropertyGrid *propgrid, wxPGProperty *property, const wxPoint &pos, const wxSize &size) const =0

  Instantiates editor controls.
- virtual void UpdateControl (wxPGProperty *property, wxWindow *ctrl) const =0

  Loads value from property to the control.

- virtual void DrawValue (wxDC &dc, const wxRect &rect, wxPGProperty *property, const wxString &text) const

  Draws value for given property.
- virtual bool OnEvent (wxPropertyGrid *propgrid, wxPGProperty *property, wxWindow *wnd_primary, wxEvent &event) const =0

  Handles events.
- virtual bool GetValueFromControl (wxVariant &variant, wxPGProperty *property, wxWindow *ctrl) const

  Returns value from control, via parameter 'variant'.
- virtual void SetValueToUnspecified (wxPGProperty *property, wxWindow *ctrl) const =0

  Sets value in control to unspecified.
- virtual void SetControlAppearance (wxPropertyGrid *pg, wxPGProperty *property, wxWindow *ctrl, const wxPGCell &appearance, const wxPGCell &oldAppearance, bool unspecified) const

  Called by property grid to set new appearance for the control.
- virtual void SetControlStringValue (wxPGProperty *property, wxWindow *ctrl, const wxString &txt) const

  Sets control's value specifically from string.
- virtual void SetControlIntValue (wxPGProperty *property, wxWindow *ctrl, int value) const

  Sets control's value specifically from int (applies to choice etc.).
- virtual int InsertItem (wxWindow *ctrl, const wxString &label, int index) const

  Inserts item to existing control.
- virtual void DeleteItem (wxWindow *ctrl, int index) const

  Deletes item from existing control.
- virtual void OnFocus (wxPGProperty *property, wxWindow *wnd) const

  Extra processing when control gains focus.
- virtual bool CanContainCustomImage () const

  Returns true if control itself can contain the custom image.

Additional Inherited Members

21.525.2 Constructor & Destructor Documentation

wxPGEditor::wxPGEditor ( )

Constructor.

virtual wxPGEditor::~wxPGEditor ( ) `[virtual]`

Destructor.

21.525.3 Member Function Documentation

virtual bool wxPGEditor::CanContainCustomImage ( ) const `[virtual]`

Returns true if control itself can contain the custom image.

Default implementation returns false.

virtual wxPGWindowList wxPGEditor::CreateControls (wxPropertyGrid * *propgrid*, wxPGProperty * *property*, const wxPoint & *pos*, const wxSize & *size*) const `[pure virtual]`

Instantiates editor controls.

Parameters

propgrid	wxPropertyGrid to which the property belongs (use as parent for control).
property	Property for which this method is called.
pos	Position, inside wxPropertyGrid, to create control(s) to.
size	Initial size for control(s).

Remarks

- Primary control shall use id wxPG_SUBID1, and secondary (button) control shall use wxPG_SUBID2.
- Unlike in previous version of wxPropertyGrid, it is no longer necessary to call wxEvtHandler::Connect() for interesting editor events. Instead, all events from control are now automatically forwarded to wxPGEditor::OnEvent() and wxPGProperty::OnEvent().

virtual void wxPGEditor::DeleteItem (wxWindow * *ctrl,* int *index*) const `[virtual]`

Deletes item from existing control.

Default implementation does nothing.

virtual void wxPGEditor::DrawValue (wxDC & *dc,* const wxRect & *rect,* wxPGProperty * *property,* const wxString & *text*) const `[virtual]`

Draws value for given property.

virtual wxString wxPGEditor::GetName ( ) const `[virtual]`

Returns pointer to the name of the editor.

For example, wxPGEditor_TextCtrl has name "TextCtrl". If you dont' need to access your custom editor by string name, then you do not need to implement this function.

virtual bool wxPGEditor::GetValueFromControl (wxVariant & *variant,* wxPGProperty * *property,* wxWindow * *ctrl*) const `[virtual]`

Returns value from control, via parameter 'variant'.

Usually ends up calling property's StringToValue() or IntToValue(). Returns true if value was different.

virtual int wxPGEditor::InsertItem (wxWindow * *ctrl,* const wxString & *label,* int *index*) const `[virtual]`

Inserts item to existing control.

Index -1 means end of list. Default implementation does nothing. Returns index of item added.

virtual bool wxPGEditor::OnEvent (wxPropertyGrid * *propgrid,* wxPGProperty * *property,* wxWindow * *wnd_primary,* wxEvent & *event*) const `[pure virtual]`

Handles events.

Returns true if value in control was modified (see wxPGProperty::OnEvent() for more information).

Remarks

wxPropertyGrid will automatically unfocus the editor when `wxEVT_TEXT_ENTER` is received and when it results in property value being modified. This happens regardless of editor type (ie. behaviour is same for any wxTextCtrl and wxComboBox based editor).

virtual void wxPGEditor::OnFocus (wxPGProperty * *property,* wxWindow * *wnd*) const `[virtual]`

Extra processing when control gains focus.

For example, wxTextCtrl based controls should select all text.

virtual void wxPGEditor::SetControlAppearance (wxPropertyGrid * *pg,* wxPGProperty * *property,* wxWindow * *ctrl,* const wxPGCell & *appearance,* const wxPGCell & *oldAppearance,* bool *unspecified*) const `[virtual]`

Called by property grid to set new appearance for the control.

Default implementation sets foreground colour, background colour, font, plus text for wxTextCtrl and wxComboCtrl.

The parameter *appearance* represents the new appearance to be applied.

The parameter *oldAppearance* is the previously applied appearance. Used to detect which control attributes need to be changed (e.g. so we only change background colour if really needed).

Finally, the parameter *unspecified* if true tells this function that the new appearance represents an unspecified property value.

virtual void wxPGEditor::SetControlIntValue (wxPGProperty * *property,* wxWindow * *ctrl,* int *value*) const `[virtual]`

Sets control's value specifically from int (applies to choice etc.).

virtual void wxPGEditor::SetControlStringValue (wxPGProperty * *property,* wxWindow * *ctrl,* const wxString & *txt*) const `[virtual]`

Sets control's value specifically from string.

virtual void wxPGEditor::SetValueToUnspecified (wxPGProperty * *property,* wxWindow * *ctrl*) const `[pure virtual]`

Sets value in control to unspecified.

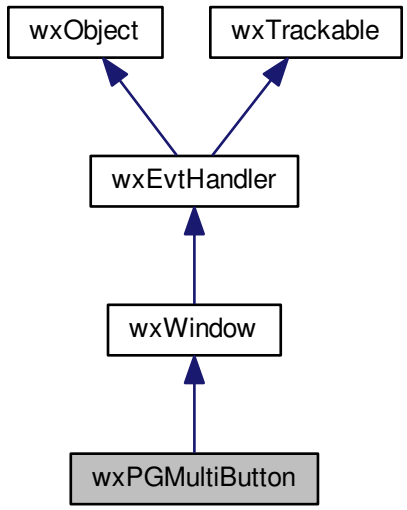
virtual void wxPGEditor::UpdateControl (wxPGProperty * *property,* wxWindow * *ctrl*) const `[pure virtual]`

Loads value from property to the control.

21.526 wxPGMultiButton Class Reference

`#include <wx/propgrid/editors.h>`

Inheritance diagram for wxPGMultiButton:



21.526.1 Detailed Description

This class can be used to have multiple buttons in a property editor.

You will need to create a new property editor class, override CreateControls, and have it return wxPGMultiButton instance in wxPGWindowList::SetSecondary().

For instance, here we add three buttons to a TextCtrl editor:

```
#include <wx/propgrid/editors.h>

class wxSampleMultiButtonEditor : public wxPGTextCtrlEditor
{
    wxDECLARE_DYNAMIC_CLASS(wxSampleMultiButtonEditor);

public:
    wxSampleMultiButtonEditor() {}
    virtual ~wxSampleMultiButtonEditor() {}

    virtual wxString GetName() const { return "SampleMultiButtonEditor"; }

    virtual wxPGWindowList CreateControls( wxPropertyGrid* propGrid,
                                           wxPGProperty* property,
                                           const wxPoint& pos,
                                           const wxSize& sz ) const;
    virtual bool OnEvent( wxPropertyGrid* propGrid,
                          wxPGProperty* property,
                          wxWindow* ctrl,
                          wxEvent& event ) const;
};

wxIMPLEMENT_DYNAMIC_CLASS(wxSampleMultiButtonEditor, wxPGTextCtrlEditor);

wxPGWindowList wxSampleMultiButtonEditor::CreateControls( wxPropertyGrid* propGrid,
                                                          wxPGProperty* property,
                                                          const wxPoint& pos,
                                                          const wxSize& sz ) const
{
    // Create and populate buttons-subwindow
    wxPGMultiButton* buttons = new wxPGMultiButton( propGrid, sz );

    // Add two regular buttons
    buttons->Add( "..." );
    buttons->Add( "A" );
```

```
    // Add a bitmap button
    buttons->Add( wxArtProvider::GetBitmap(
      wxART_FOLDER) );

    // Create the 'primary' editor control (textctrl in this case)
    wxPGWindowList wndList = wxPGTextCtrlEditor::CreateControls
                             ( propGrid, property, pos,
                               buttons->GetPrimarySize() );

    // Finally, move buttons-subwindow to correct position and make sure
    // returned wxPGWindowList contains our custom button list.
    buttons->Finalize(propGrid, pos);

    wndList.SetSecondary( buttons );
    return wndList;
}

bool wxSampleMultiButtonEditor::OnEvent( wxPropertyGrid* propGrid,
                                         wxPGProperty* property,
                                         wxWindow* ctrl,
                                         wxEvent& event ) const
{
    if ( event.GetEventType() == wxEVT_BUTTON )
    {
        wxPGMultiButton* buttons = (wxPGMultiButton*) propGrid->
      GetEditorControlSecondary();

        if ( event.GetId() == buttons->GetButtonId(0) )
        {
            // Do something when the first button is pressed
            // Return true if the action modified the value in editor.
            ...
        }
        if ( event.GetId() == buttons->GetButtonId(1) )
        {
            // Do something when the second button is pressed
            ...
        }
        if ( event.GetId() == buttons->GetButtonId(2) )
        {
            // Do something when the third button is pressed
            ...
        }
    }
    return wxPGTextCtrlEditor::OnEvent(propGrid, property, ctrl, event);
}
```

Further to use this editor, code like this can be used:

```
// Register editor class - needs only to be called once
wxPGEditor* multiButtonEditor = new wxSampleMultiButtonEditor();
wxPropertyGrid::RegisterEditorClass( multiButtonEditor );

// Insert the property that will have multiple buttons
propGrid->Append( new wxLongStringProperty("MultipleButtons", wxPG_LABEL) );

// Change property to use editor created in the previous code segment
propGrid->SetPropertyEditor( "MultipleButtons", multiButtonEditor );
```

Library: wxPropertyGrid

Category: wxPropertyGrid

Public Member Functions

- wxPGMultiButton (wxPropertyGrid *pg, const wxSize &sz)

  Constructor.
- virtual ~wxPGMultiButton ()

  Destructor.
- void Add (const wxString &label, int id=-2)

  Adds new button, with given label.
- void Add (const wxBitmap &bitmap, int id=-2)

Adds new bitmap button.

- void Finalize (wxPropertyGrid *propGrid, const wxPoint &pos)

  Call this in CreateControls() of your custom editor class after all buttons have been added.
- wxWindow * GetButton (unsigned int i)

  Returns pointer to one of the buttons.
- int GetButtonId (unsigned int i) const

  Returns Id of one of the buttons.
- unsigned int GetCount ()

  Returns number of buttons.
- wxSize GetPrimarySize () const

  Returns size of primary editor control, as appropriately reduced by number of buttons present.

Additional Inherited Members

21.526.2 Constructor & Destructor Documentation

wxPGMultiButton::wxPGMultiButton (wxPropertyGrid * *pg*, const wxSize & *sz*)

Constructor.

virtual wxPGMultiButton::~wxPGMultiButton ( ) [inline], [virtual]

Destructor.

21.526.3 Member Function Documentation

void wxPGMultiButton::Add (const wxString & *label*, int *id* = -2)

Adds new button, with given label.

void wxPGMultiButton::Add (const wxBitmap & *bitmap*, int *id* = -2)

Adds new bitmap button.

void wxPGMultiButton::Finalize (wxPropertyGrid * *propGrid*, const wxPoint & *pos*)

Call this in CreateControls() of your custom editor class after all buttons have been added.

Parameters

propGrid	wxPropertyGrid given in CreateControls().
pos	wxPoint given in CreateControls().

wxWindow* wxPGMultiButton::GetButton (unsigned int *i*)

Returns pointer to one of the buttons.

int wxPGMultiButton::GetButtonId (unsigned int *i*) const

Returns Id of one of the buttons.

This is utility function to be used in event handlers.

unsigned int wxPGMultiButton::GetCount ( )

Returns number of buttons.

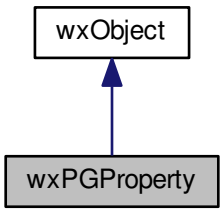
wxSize wxPGMultiButton::GetPrimarySize ( ) const

Returns size of primary editor control, as appropriately reduced by number of buttons present.

21.527 wxPGProperty Class Reference

`#include <wx/propgrid/property.h>`

Inheritance diagram for wxPGProperty:



21.527.1 Detailed Description

wxPGProperty is base class for all wxPropertyGrid properties.

In sections below we cover few related topics.

- Supplied Ready-to-use Property Classes
- Creating Custom Properties

21.527.2 Supplied Ready-to-use Property Classes

Here is a list and short description of supplied fully-functional property classes. They are located in either props.h or advprops.h.

- wxArrayStringProperty
- wxBoolProperty
- wxColourProperty
- wxCursorProperty
- wxDateProperty
- wxDirProperty
- wxEditEnumProperty

- wxEnumProperty
- wxFileProperty
- wxFlagsProperty
- wxFloatProperty
- wxFontProperty
- wxImageFileProperty
- wxIntProperty
- wxLongStringProperty
- wxMultiChoiceProperty
- wxPropertyCategory
- wxStringProperty
- wxSystemColourProperty
- wxUIntProperty

wxPropertyCategory

Not an actual property per se, but a header for a group of properties. Regardless inherits from wxPGProperty, and supports displaying 'labels' for columns other than the first one. Easiest way to set category's label for second column is to call wxPGProperty::SetValue() with string argument.

wxStringProperty

Simple string property. wxPG_STRING_PASSWORD attribute may be used to echo value as asterisks and use wxTE_PASSWORD for wxTextCtrl. wxPG_ATTR_AUTOCOMPLETE attribute may be used to enable auto-completion (use a wxArrayString value), and is also supported by any property that happens to use a wxTextCtrl-based editor.

Remarks

wxStringProperty has a special trait: if it has value of "<composed>", and also has child properties, then its displayed value becomes composition of child property values, similar as with wxFontProperty, for instance.

wxIntProperty

Like wxStringProperty, but converts text to a signed long integer. wxIntProperty seamlessly supports 64-bit integers (ie. wxLongLong). To safely convert variant to integer, use code like this:

```
wxLongLong ll;
ll << property->GetValue();

// or
wxLongLong ll = propertyGrid->GetPropertyValueAsLong(property);
```

wxUIntProperty

Like wxIntProperty, but displays value as unsigned int. To set the prefix used globally, manipulate wxPG_UINT_PREFIX string attribute. To set the globally used base, manipulate wxPG_UINT_BASE int attribute. Regardless of current prefix, understands (hex) values starting with both "0x" and "$". Like wxIntProperty, wxUIntProperty seamlessly supports 64-bit unsigned integers (ie. wxULongLong). Same wxVariant safety rules apply.

wxFloatProperty

Like wxStringProperty, but converts text to a double-precision floating point. Default float-to-text precision is 6 decimals, but this can be changed by modifying wxPG_FLOAT_PRECISION attribute.

Note that when displaying the value, sign is omitted if the resulting textual representation is effectively zero (for example, -0.0001 with precision of 3 will become 0.0 instead of -0.0). This behaviour is unlike what C standard library does, but should result in better end-user experience in almost all cases.

wxBoolProperty

Represents a boolean value. wxChoice is used as editor control, by the default. wxPG_BOOL_USE_CHECKBOX attribute can be set to true in order to use check box instead.

wxLongStringProperty

Like wxStringProperty, but has a button that triggers a small text editor dialog. Note that in long string values, tabs are represented by "\t" and line break by "\n".

To display custom dialog on button press, you can subclass wxLongStringProperty and implement OnButtonClick, like this:

```
virtual bool OnButtonClick( wxPropertyGrid* propGrid, wxString& value )
{
    wxSize dialogSize(...size of your dialog...);

    wxPoint dlgPos = propGrid->GetGoodEditorDialogPosition(this,
                                                           dialogSize)

    // Create dialog dlg at dlgPos. Use value as initial string
    // value.
    ...

    if ( dlg.ShowModal() == wxID_OK )
    {
        value = dlg.GetStringValue);
        return true;
    }
    return false;
}
```

Also, if you wish not to have line breaks and tabs translated to escape sequences, then do following in constructor of your subclass:

```
m_flags |= wxPG_PROP_NO_ESCAPE;
```

wxDirProperty

Like wxLongStringProperty, but the button triggers dir selector instead. Supported properties (all with string value): wxPG_DIR_DIALOG_MESSAGE.

wxFileProperty

Like wxLongStringProperty, but the button triggers file selector instead. Default wildcard is "All files..." but this can be changed by setting wxPG_FILE_WILDCARD attribute (see wxFileDialog for format details). Attribute wxPG_F↩ ILE_SHOW_FULL_PATH can be set to false in order to show only the filename, not the entire path.

wxEnumProperty

Represents a single selection from a list of choices - wxOwnerDrawnComboBox is used to edit the value.

wxFlagsProperty

Represents a bit set that fits in a long integer. wxBoolProperty sub- properties are created for editing individual bits. Textctrl is created to manually edit the flags as a text; a continuous sequence of spaces, commas and semicolons are considered as a flag id separator.

Note: When changing "choices" (ie. flag labels) of wxFlagsProperty, you will need to use wxPGProperty::SetChoices() - otherwise they will not get updated properly.

wxFlagsProperty supports the same attributes as wxBoolProperty.

wxArrayStringProperty

Allows editing of a list of strings in wxTextCtrl and in a separate dialog. Supports "Delimiter" attribute, which defaults to comma (','').

wxDateProperty

wxDateTime property. Default editor is DatePickerCtrl, although TextCtrl should work as well. wxPG_DATE_FORMAT attribute can be used to change string wxDateTime::Format uses (although default is recommended as it is locale-dependent), and wxPG_DATE_PICKER_STYLE allows changing window style given to DatePickerCtrl (default is wxDP_DEFAULT|wxDP_SHOWCENTURY). Using wxDP_ALLOWNONE will enable better unspecified value support.

wxEditEnumProperty

Represents a string that can be freely edited or selected from list of choices - custom combobox control is used to edit the value.

wxMultiChoiceProperty

Allows editing a multiple selection from a list of strings. This is property is pretty much built around concept of wxMultiChoiceDialog. It uses wxArrayString value.

wxImageFileProperty

Like wxFileProperty, but has thumbnail of the image in front of the filename and autogenerates wildcard from available image handlers.

wxColourProperty

Useful alternate editor: Choice.

Represents wxColour. wxButton is used to trigger a colour picker dialog. There are various sub-classing opportunities with this class. See below in wxSystemColourProperty section for details.

Setting "HasAlpha" attribute to true for this property allows user to edit the alpha colour component.

wxFontProperty

Represents wxFont. Various sub-properties are used to edit individual subvalues.

wxSystemColourProperty

Represents wxColour and a system colour index. wxChoice is used to edit the value. Drop-down list has color images. Note that value type is wxColourPropertyValue instead of wxColour (which wxColourProperty uses).

```
class wxColourPropertyValue : public wxObject
{
public:
    //  An integer value relating to the colour, and which exact
    //  meaning depends on the property with which it is used.
    //
    //  For wxSystemColourProperty:
    //  Any of wxSYS_COLOUR_XXX, or any web-colour ( use wxPG_TO_WEB_COLOUR
    //  macro - (currently unsupported) ), or wxPG_COLOUR_CUSTOM.
    wxUint32    m_type;

    // Resulting colour. Should be correct regardless of type.
    wxColour    m_colour;
};
```

in wxSystemColourProperty, and its derived class wxColourProperty, there are various sub-classing features. To set a basic list of colour names, call wxPGProperty::SetChoices().

```
// Override in derived class to customize how colours are translated
// to strings.
virtual wxString ColourToString( const wxColour& col, int index ) const;

// Returns index of entry that triggers colour picker dialog
// (default is last).
virtual int GetCustomColourIndex() const;

// Helper function to show the colour dialog
bool QueryColourFromUser( wxVariant& variant ) const;

// Returns colour for given choice.
// Default function returns wxSystemSettings::GetColour(index).
virtual wxColour GetColour( int index ) const;
```

wxCursorProperty

Represents a wxCursor. wxChoice is used to edit the value. Drop-down list has cursor images under some (wxM↩ SW) platforms.

21.527.3 Creating Custom Properties

New properties can be created by subclassing wxPGProperty or one of the provided property classes, and (re)implementing necessary member functions. Below, each virtual member function has ample documentation about its purpose and any odd details which to keep in mind.

Here is a very simple 'template' code:

```
class MyProperty : public wxPGProperty
{
public:
    // Default constructor
    MyProperty() { }

    // All arguments of this ctor must have a default value -
    // use wxPG_LABEL for label and name
    MyProperty( const wxString& label = wxPG_LABEL,
                const wxString& name = wxPG_LABEL,
                const wxString& value = wxEmptyString )
        : wxPGProperty(label, name)
    {
        // m_value is wxVariant
        m_value = value;
    }

    virtual ~MyProperty() { }

    const wxPGEditor* DoGetEditorClass() const
    {
        // Determines editor used by property.
```

```
        // You can replace 'TextCtrl' below with any of these
        // builtin-in property editor identifiers: Choice, ComboBox,
        // TextCtrlAndButton, ChoiceAndButton, CheckBox, SpinCtrl,
        // DatePickerCtrl.
        return wxPGEditor_TextCtrl;
    }

    virtual wxString ValueToString( wxVariant& value,
                                    int argFlags ) const
    {
        // TODO: Convert given property value to a string
    }

    virtual bool StringToValue( wxVariant& variant, const
      wxString& text, int argFlags )
    {
        // TODO: Adapt string to property value.
    }

protected:
};
```

Since wxPGProperty derives from wxObject, you can use standard wxDECLARE_DYNAMIC_CLASS and wxI↩MPLEMENT_DYNAMIC_CLASS macros. From the above example they were omitted for sake of simplicity, and besides, they are only really needed if you need to use wxRTTI with your property class.

You can change the 'value type' of a property by simply assigning different type of variant with SetValue. **It is mandatory to implement wxVariantData class for all data types used as property values.** You can use macros declared in wxPropertyGrid headers. For instance:

```
// In header file:
// (If you need to have export declaration, use version of macros
// with _EXPORTED postfix)
WX_PG_DECLARE_VARIANT_DATA(MyDataClass)

// In sources file:
WX_PG_IMPLEMENT_VARIANT_DATA(MyDataClass)

// Or, if you don't have valid == operator:
WX_PG_IMPLEMENT_VARIANT_DATA_DUMMY_EQ(MyDataClass)
```

Library: wxPropertyGrid

Category: wxPropertyGrid

Public Types

- typedef wxUint32 FlagType

Public Member Functions

- wxPGProperty ()

  Default constructor.
- wxPGProperty (const wxString &label, const wxString &name)

  Constructor.
- virtual ~wxPGProperty ()

  Virtual destructor.
- virtual void OnSetValue ()

  This virtual function is called after m_value has been set.
- virtual wxVariant DoGetValue () const

  Override this to return something else than m_value as the value.
- virtual bool ValidateValue (wxVariant &value, wxPGValidationInfo &validationInfo) const

  Implement this function in derived class to check the value.

- virtual bool StringToValue (wxVariant &variant, const wxString &text, int argFlags=0) const

  Converts text into wxVariant value appropriate for this property.
- virtual bool IntToValue (wxVariant &variant, int number, int argFlags=0) const

  Converts integer (possibly a choice selection) into wxVariant value appropriate for this property.
- virtual wxString ValueToString (wxVariant &value, int argFlags=0) const

  Converts property value into a text representation.
- bool SetValueFromString (const wxString &text, int flags=0)

  Converts string to a value, and if successful, calls SetValue() on it.
- bool SetValueFromInt (long value, int flags=0)

  Converts integer to a value, and if successful, calls SetValue() on it.
- virtual wxSize OnMeasureImage (int item=-1) const

  Returns size of the custom painted image in front of property.
- virtual bool OnEvent (wxPropertyGrid *propgrid, wxWindow *wnd_primary, wxEvent &event)

  Events received by editor widgets are processed here.
- virtual wxVariant ChildChanged (wxVariant &thisValue, int childIndex, wxVariant &childValue) const

  Called after value of a child property has been altered.
- virtual const wxPGEditor * DoGetEditorClass () const

  Returns pointer to an instance of used editor.
- virtual wxValidator * DoGetValidator () const

  Returns pointer to the wxValidator that should be used with the editor of this property (NULL for no validator).
- virtual void OnCustomPaint (wxDC &dc, const wxRect &rect, wxPGPaintData &paintdata)

  Override to paint an image in front of the property value text or drop-down list item (but only if wxPGProperty::OnMeasureImage is overridden as well).
- virtual wxPGCellRenderer * GetCellRenderer (int column) const

  Returns used wxPGCellRenderer instance for given property column (label=0, value=1).
- virtual int GetChoiceSelection () const

  Returns which choice is currently selected.
- virtual void RefreshChildren ()

  Refresh values of child properties.
- virtual bool DoSetAttribute (const wxString &name, wxVariant &value)

  Reimplement this member function to add special handling for attributes of this property.
- virtual wxVariant DoGetAttribute (const wxString &name) const

  Returns value of an attribute.
- virtual wxPGEditorDialogAdapter * GetEditorDialog () const

  Returns instance of a new wxPGEditorDialogAdapter instance, which is used when user presses the (optional) button next to the editor control;.
- virtual void OnValidationFailure (wxVariant &pendingValue)

  Called whenever validation has failed with given pending value.
- int AddChoice (const wxString &label, int value=wxPG_INVALID_VALUE)

  Append a new choice to property's list of choices.
- wxDEPRECATED (void AddChild(wxPGProperty *prop))

  Adds a private child property.
- void AddPrivateChild (wxPGProperty *prop)

  Adds a private child property.
- void AdaptListToValue (wxVariant &list, wxVariant *value) const

  Adapts list variant into proper value using consecutive ChildChanged() calls.
- wxPGProperty * AppendChild (wxPGProperty *childProperty)

  Use this member function to add independent (ie.
- bool AreAllChildrenSpecified (wxVariant *pendingList=NULL) const

  Determines, recursively, if all children are not unspecified.
- bool AreChildrenComponents () const

Returns true if children of this property are component values (for instance, points size, face name, and is_underlined are component values of a font).

- void ChangeFlag (wxPGPropertyFlags flag, bool set)

  Sets or clears given property flag.
- void DeleteChildren ()

  Deletes children of the property.
- void DeleteChoice (int index)

  Removes entry from property's wxPGChoices and editor control (if it is active).
- void Enable (bool enable=true)

  Enables or disables the property.
- wxString GenerateComposedValue () const

  Composes text from values of child properties.
- wxVariant GetAttribute (const wxString &name) const

  Returns property attribute value, null variant if not found.
- wxString GetAttribute (const wxString &name, const wxString &defVal) const

  Returns named attribute, as string, if found.
- long GetAttributeAsLong (const wxString &name, long defVal) const

  Returns named attribute, as long, if found.
- double GetAttributeAsDouble (const wxString &name, double defVal) const

  Returns named attribute, as double, if found.
- wxVariant GetAttributesAsList () const

  Returns attributes as list wxVariant.
- const wxPGEditor * GetColumnEditor (int column) const

  Returns editor used for given column.
- const wxString & GetBaseName () const

  Returns property's base name (ie.
- const wxPGCell & GetCell (unsigned int column) const

  Returns wxPGCell of given column.
- wxPGCell & GetCell (unsigned int column)

  Returns wxPGCell of given column, creating one if necessary.
- wxPGCell & GetOrCreateCell (unsigned int column)

  Returns wxPGCell of given column, creating one if necessary.
- unsigned int GetChildCount () const

  Returns number of child properties.
- int GetChildrenHeight (int lh, int iMax=-1) const

  Returns height of children, recursively, and by taking expanded/collapsed status into account.
- const wxPGChoices & GetChoices () const

  Returns read-only reference to property's list of choices.
- void * GetClientData () const

  Returns client data (void) of a property.*
- wxClientData * GetClientObject () const

  Sets managed client object of a property.
- wxVariant GetDefaultValue () const

  Returns property's default value.
- wxString GetDisplayedString () const

  Returns property's displayed text.
- const wxPGEditor * GetEditorClass () const

  Returns wxPGEditor that will be used and created when property becomes selected.
- FlagType GetFlags () const

  Returns property flags.
- wxPropertyGrid * GetGrid () const

Returns property grid where property lies.

- wxPropertyGrid * GetGridIfDisplayed () const

  Returns owner wxPropertyGrid, but only if one is currently on a page displaying this property.
- const wxString & GetHelpString () const

  Returns property's help or description text.
- unsigned int GetIndexInParent () const

  Returns position in parent's array.
- const wxString & GetLabel () const

  Returns property's label.
- const wxPGProperty * GetLastVisibleSubItem () const

  Returns last visible child property, recursively.
- wxPGProperty * GetMainParent () const

  Returns highest level non-category, non-root parent.
- int GetMaxLength () const

  Returns maximum allowed length of property's text value.
- wxString GetName () const

  Returns property's name with all (non-category, non-root) parents.
- wxPGProperty * GetParent () const

  Return parent of property.
- wxPGProperty * GetPropertyByName (const wxString &name) const

  Returns (direct) child property with given name (or NULL if not found).
- wxValidator * GetValidator () const

  Gets assignable version of property's validator.
- wxVariant GetValue () const

  Returns property's value.
- wxBitmap * GetValueImage () const

  Returns bitmap that appears next to value text.
- virtual wxString GetValueAsString (int argFlags=0) const

  Returns text representation of property's value.
- wxDEPRECATED (wxString GetValueString(int argFlags=0) const)

  Synonymous to GetValueAsString().
- wxString GetValueType () const

  Returns value type used by this property.
- int GetY () const

  Returns coordinate to the top y of the property.
- FlagType HasFlag (wxPGPropertyFlags flag) const

  Returns non-zero if property has given flag set.
- bool HasVisibleChildren () const

  Returns true if property has even one visible child.
- bool Hide (bool hide, int flags=wxPG_RECURSE)

  Hides or reveals the property.
- int Index (const wxPGProperty *p) const

  Returns index of given child property.
- wxPGProperty * InsertChild (int index, wxPGProperty *childProperty)

  Use this member function to add independent (ie.
- int InsertChoice (const wxString &label, int index, int value=wxPG_INVALID_VALUE)

  Inserts a new choice to property's list of choices.
- bool IsCategory () const

  Returns true if this property is actually a wxPropertyCategory.
- bool IsEnabled () const

  Returns true if property is enabled.

- bool IsExpanded () const

  Returns true if property has visible children.
- bool IsRoot () const

  Returns true if this property is actually a wxRootProperty.
- bool IsSomeParent (wxPGProperty *candidateParent) const

  Returns true if candidateParent is some parent of this property.
- bool IsTextEditable () const

  Returns true if property has editable wxTextCtrl when selected.
- bool IsValueUnspecified () const

  Returns true if property's value is considered unspecified.
- bool IsVisible () const

  Returns true if all parents expanded.
- wxPGProperty * Item (unsigned int i) const

  Returns child property at index i.
- void RefreshEditor ()

  If property's editor is active, then update it's value.
- void SetAttribute (const wxString &name, wxVariant value)

  Sets an attribute for this property.
- void SetAutoUnspecified (bool enable=true)

  Set if user can change the property's value to unspecified by modifying the value of the editor control (usually by clearing it).
- void SetBackgroundColour (const wxColour &colour, int flags=wxPG_RECURSE)

  Sets property's background colour.
- void SetEditor (const wxPGEditor *editor)

  Sets editor for a property.
- void SetEditor (const wxString &editorName)

  Sets editor for a property, by editor name.
- void SetCell (int column, const wxPGCell &cell)

  Sets cell information for given column.
- bool SetChoices (wxPGChoices &choices)

  Sets new set of choices for the property.
- void SetClientData (void *clientData)

  Sets client data (void) of a property.*
- void SetClientObject (wxClientData *clientObject)

  Returns client object of a property.
- void SetChoiceSelection (int newValue)

  Sets selected choice and changes property value.
- void SetDefaultValue (wxVariant &value)

  Set default value of a property.
- void SetFlagRecursively (wxPGPropertyFlags flag, bool set)

  Sets or clears given property flag, recursively.
- void SetHelpString (const wxString &helpString)

  Sets property's help string, which is shown, for example, in wxPropertyGridManager's description text box.
- void SetLabel (const wxString &label)

  Sets property's label.
- bool SetMaxLength (int maxLen)

  Set max length of text in text editor.
- void SetModifiedStatus (bool modified)

  Sets property's "is it modified?" flag.
- void SetName (const wxString &newName)

  Sets new (base) name for property.

- void SetParentalType (int flag)

  Changes what sort of parent this property is for its children.
- void SetTextColour (const wxColour &colour, int flags=wxPG_RECURSE)

  Sets property's text colour.
- void SetValidator (const wxValidator &validator)

  Sets wxValidator for a property.
- void SetValue (wxVariant value, wxVariant *pList=NULL, int flags=wxPG_SETVAL_REFRESH_EDITOR)

  Call this to set value of the property.
- void SetValueImage (wxBitmap &bmp)

  Set wxBitmap in front of the value.
- void SetValueInEvent (wxVariant value) const

  Call this function in OnEvent(), OnButtonClick() etc.
- void SetValueToUnspecified ()

  Sets property's value to unspecified (ie.
- void SetWasModified (bool set=true)

  Call with false in OnSetValue() to cancel value changes after all (ie.
- wxPGProperty * UpdateParentValues ()

  Updates composed values of parent non-category properties, recursively.
- bool UsesAutoUnspecified () const

  Returns true if containing grid uses wxPG_EX_AUTO_UNSPECIFIED_VALUES.

Protected Member Functions

- void Empty ()

  Deletes all child properties.

Additional Inherited Members

21.527.4 Member Typedef Documentation

typedef wxUint32 wxPGProperty::FlagType

21.527.5 Constructor & Destructor Documentation

wxPGProperty::wxPGProperty ( )

Default constructor.

wxPGProperty::wxPGProperty (const wxString & *label*, const wxString & *name*)

Constructor.

Non-abstract property classes should have constructor of this style:

```
MyProperty( const wxString& label, const wxString& name, const T& value )
    : wxPGProperty(label, name)
{
    // Generally recommended way to set the initial value
    // (as it should work in pretty much 100% of cases).
    wxVariant variant;
    variant << value;
    SetValue(variant);

    // If has private child properties then create them here.
    // For example:
    //     AddPrivateChild( new wxStringProperty("Subprop 1",
    //                                           wxPG_LABEL,
    //                                           value.GetSubProp1()));
}
```

virtual wxPGProperty::~wxPGProperty ( ) [virtual]

Virtual destructor.

It is customary for derived properties to implement this.

21.527.6 Member Function Documentation

void wxPGProperty::AdaptListToValue (wxVariant & *list*, wxVariant * *value*) const

Adapts list variant into proper value using consecutive ChildChanged() calls.

int wxPGProperty::AddChoice (const wxString & *label*, int *value* = wxPG_INVALID_VALUE)

Append a new choice to property's list of choices.

Parameters

label	Label for added choice.
value	Value for new choice. Do not specify if you wish this to equal choice index.

Returns

Index to added choice.

void wxPGProperty::AddPrivateChild (wxPGProperty * *prop*)

Adds a private child property.

If you use this instead of wxPropertyGridInterface::Insert() or wxPropertyGridInterface::AppendIn(), then property's parental type will automatically be set up to wxPG_PROP_AGGREGATE. In other words, all properties of this property will become private.

wxPGProperty* wxPGProperty::AppendChild (wxPGProperty * *childProperty*)

Use this member function to add independent (ie.

regular) children to a property.

Returns

Appended childProperty.

Remarks

wxPropertyGrid is not automatically refreshed by this function.

See also

InsertChild(), AddPrivateChild()

bool wxPGProperty::AreAllChildrenSpecified (wxVariant * *pendingList* = NULL) const

Determines, recursively, if all children are not unspecified.

Parameters

pendingList	Assumes members in this wxVariant list as pending replacement values.

bool wxPGProperty::AreChildrenComponents ( ) const

Returns true if children of this property are component values (for instance, points size, face name, and is_↩ underlined are component values of a font).

void wxPGProperty::ChangeFlag (wxPGPropertyFlags *flag,* bool *set*)

Sets or clears given property flag.

Mainly for internal use.

Remarks

Setting a property flag never has any side-effect, and is intended almost exclusively for internal use. So, for example, if you want to disable a property, call Enable(false) instead of setting wxPG_PROP_DISABLED flag.

See also

HasFlag(), GetFlags()

virtual wxVariant wxPGProperty::ChildChanged (wxVariant & *thisValue,* int *childIndex,* wxVariant & *childValue*) const [virtual]

Called after value of a child property has been altered.

Must return new value of the whole property (after any alterations warranted by child's new value).

Note that this function is usually called at the time that value of this property, or given child property, is still pending for change, and as such, result of GetValue() or m_value should not be relied on.

Sample pseudo-code implementation:

```
wxVariant MyProperty::ChildChanged( wxVariant& thisValue,
                                    int childIndex,
                                    wxVariant& childValue ) const
{
    // Acquire reference to actual type of data stored in variant
    // (TFromVariant only exists if wxPropertyGrid's wxVariant-macros
    // were used to create the variant class).
    T& data = TFromVariant(thisValue);

    // Copy childValue into data.
    switch ( childIndex )
    {
        case 0:
            data.SetSubProp1( childvalue.GetLong() );
            break;
        case 1:
            data.SetSubProp2( childvalue.GetString() );
            break;
        ...
    }

    // Return altered data
    return data;
}
```

Parameters

thisValue	Value of this property. Changed value should be returned (in previous versions of wxPropertyGrid it was only necessary to write value back to this argument).
childIndex	Index of child changed (you can use Item(childIndex) to get child property).
childValue	(Pending) value of the child property.

Returns

Modified value of the whole property.

void wxPGProperty::DeleteChildren ( )

Deletes children of the property.

void wxPGProperty::DeleteChoice (int *index*)

Removes entry from property's wxPGChoices and editor control (if it is active).

If selected item is deleted, then the value is set to unspecified.

virtual wxVariant wxPGProperty::DoGetAttribute (const wxString & *name*) const [virtual]

Returns value of an attribute.

Override if custom handling of attributes is needed.

Default implementation simply return NULL variant.

virtual const wxPGEditor* wxPGProperty::DoGetEditorClass ( ) const [virtual]

Returns pointer to an instance of used editor.

virtual wxValidator* wxPGProperty::DoGetValidator ( ) const [virtual]

Returns pointer to the wxValidator that should be used with the editor of this property (NULL for no validator).

Setting validator explicitly via SetPropertyValidator will override this.

In most situations, code like this should work well (macros are used to maintain one actual validator instance, so on the second call the function exits within the first macro):

```
wxValidator* wxMyPropertyClass::DoGetValidator () const
{
    WX_PG_DOGETVALIDATOR_ENTRY()

    wxMyValidator* validator = new wxMyValidator(...);

    ... prepare validator...

    WX_PG_DOGETVALIDATOR_EXIT(validator)
}
```

Remarks

You can get common filename validator by returning wxFileProperty::GetClassValidator(). wxDirProperty, for example, uses it.

virtual wxVariant wxPGProperty::DoGetValue ( ) const `[virtual]`

Override this to return something else than m_value as the value.

virtual bool wxPGProperty::DoSetAttribute (const wxString & *name*, wxVariant & *value*) `[virtual]`

Reimplement this member function to add special handling for attributes of this property.

Returns

Return false to have the attribute automatically stored in m_attributes. Default implementation simply does that and nothing else.

Remarks

To actually set property attribute values from the application, use wxPGProperty::SetAttribute() instead.

void wxPGProperty::Empty ( ) `[protected]`

Deletes all child properties.

void wxPGProperty::Enable (bool *enable* = `true`)

Enables or disables the property.

Disabled property usually appears as having grey text.

Parameters

enable	If false, property is disabled instead.

See also

wxPropertyGridInterface::EnableProperty()

wxString wxPGProperty::GenerateComposedValue ( ) const

Composes text from values of child properties.

wxVariant wxPGProperty::GetAttribute (const wxString & *name*) const

Returns property attribute value, null variant if not found.

wxString wxPGProperty::GetAttribute (const wxString & *name*, const wxString & *defVal*) const

Returns named attribute, as string, if found.

Otherwise defVal is returned.

double wxPGProperty::GetAttributeAsDouble (const wxString & *name*, double *defVal*) const

Returns named attribute, as double, if found.

Otherwise defVal is returned.

long wxPGProperty::GetAttributeAsLong (const wxString & *name,* long *defVal*) const

Returns named attribute, as long, if found.

Otherwise defVal is returned.

wxVariant wxPGProperty::GetAttributesAsList ( ) const

Returns attributes as list wxVariant.

const wxString& wxPGProperty::GetBaseName ( ) const

Returns property's base name (ie.

parent's name is not added in any case)

const wxPGCell& wxPGProperty::GetCell (unsigned int *column*) const

Returns wxPGCell of given column.

Remarks

const version of this member function returns 'default' wxPGCell object if the property itself didn't hold cell data.

wxPGCell& wxPGProperty::GetCell (unsigned int *column*)

Returns wxPGCell of given column, creating one if necessary.

virtual wxPGCellRenderer* wxPGProperty::GetCellRenderer (int *column*) const `[virtual]`

Returns used wxPGCellRenderer instance for given property column (label=0, value=1).

Default implementation returns editor's renderer for all columns.

unsigned int wxPGProperty::GetChildCount ( ) const

Returns number of child properties.

int wxPGProperty::GetChildrenHeight (int *lh,* int *iMax* = `-1`) const

Returns height of children, recursively, and by taking expanded/collapsed status into account.

Parameters

lh	Line height. Pass result of GetGrid()->GetRowHeight() here.
iMax	Only used (internally) when finding property y-positions.

const wxPGChoices& wxPGProperty::GetChoices ( ) const

Returns read-only reference to property's list of choices.

virtual int wxPGProperty::GetChoiceSelection ( ) const `[virtual]`

Returns which choice is currently selected.

Only applies to properties which have choices.

Needs to reimplemented in derived class if property value does not map directly to a choice. Integer as index, bool, and string usually do.

void* wxPGProperty::GetClientData ( ) const

Returns client data (void*) of a property.

wxClientData* wxPGProperty::GetClientObject ( ) const

Sets managed client object of a property.

const wxPGEditor* wxPGProperty::GetColumnEditor (int *column*) const

Returns editor used for given column.

NULL for no editor.

wxVariant wxPGProperty::GetDefaultValue ( ) const

Returns property's default value.

If property's value type is not a built-in one, and "DefaultValue" attribute is not defined, then this function usually returns Null variant.

wxString wxPGProperty::GetDisplayedString ( ) const

Returns property's displayed text.

const wxPGEditor* wxPGProperty::GetEditorClass ( ) const

Returns wxPGEditor that will be used and created when property becomes selected.

Returns more accurate value than DoGetEditorClass().

virtual wxPGEditorDialogAdapter* wxPGProperty::GetEditorDialog ( ) const `[virtual]`

Returns instance of a new wxPGEditorDialogAdapter instance, which is used when user presses the (optional) button next to the editor control;.

Default implementation returns NULL (ie. no action is generated when button is pressed).

FlagType wxPGProperty::GetFlags ( ) const

Returns property flags.

wxPropertyGrid* wxPGProperty::GetGrid ( ) const

Returns property grid where property lies.

wxPropertyGrid* wxPGProperty::GetGridIfDisplayed ( ) const

Returns owner wxPropertyGrid, but only if one is currently on a page displaying this property.

const wxString& wxPGProperty::GetHelpString ( ) const

Returns property's help or description text.

See also

SetHelpString()

unsigned int wxPGProperty::GetIndexInParent ( ) const

Returns position in parent's array.

const wxString& wxPGProperty::GetLabel ( ) const

Returns property's label.

const wxPGProperty* wxPGProperty::GetLastVisibleSubItem ( ) const

Returns last visible child property, recursively.

wxPGProperty* wxPGProperty::GetMainParent ( ) const

Returns highest level non-category, non-root parent.

Useful when you have nested properties with children.

Remarks

If immediate parent is root or category, this will return the property itself.

int wxPGProperty::GetMaxLength ( ) const

Returns maximum allowed length of property's text value.

wxString wxPGProperty::GetName ( ) const

Returns property's name with all (non-category, non-root) parents.

wxPGCell& wxPGProperty::GetOrCreateCell (unsigned int *column*)

Returns wxPGCell of given column, creating one if necessary.

wxPGProperty* wxPGProperty::GetParent ( ) const

Return parent of property.

wxPGProperty* wxPGProperty::GetPropertyByName (const wxString & *name*) const

Returns (direct) child property with given name (or NULL if not found).

wxValidator* wxPGProperty::GetValidator ( ) const

Gets assignable version of property's validator.

wxVariant wxPGProperty::GetValue ( ) const

Returns property's value.

virtual wxString wxPGProperty::GetValueAsString (int *argFlags* = 0) const [virtual]

Returns text representation of property's value.

Parameters

argFlags	If 0 (default value), then displayed string is returned. If wxPG_FULL_VALUE is set, returns complete, storable string value instead of displayable. If wxPG_EDITABLE_VALUE is set, returns string value that must be editable in textctrl. If wxPG_COMPOSITE_FRAGMENT is set, returns text that is appropriate to display as a part of string property's composite text representation.

Remarks

In older versions, this function used to be overridden to convert property's value into a string representation. This function is now handled by ValueToString(), and overriding this function now will result in run-time assertion failure.

wxBitmap* wxPGProperty::GetValueImage ( ) const

Returns bitmap that appears next to value text.

Only returns non-NULL bitmap if one was set with SetValueImage().

wxString wxPGProperty::GetValueType ( ) const

Returns value type used by this property.

int wxPGProperty::GetY ( ) const

Returns coordinate to the top y of the property.

Note that the position of scrollbars is not taken into account.

FlagType wxPGProperty::HasFlag (wxPGPropertyFlags *flag*) const

Returns non-zero if property has given flag set.

See also

propgrid_propflags

bool wxPGProperty::HasVisibleChildren ( ) const

Returns true if property has even one visible child.

bool wxPGProperty::Hide (bool *hide*, int *flags* = wxPG_RECURSE)

Hides or reveals the property.

Parameters

hide	true for hide, false for reveal.
flags	By default changes are applied recursively. Set this parameter wxPG_DONT_RECURSE to prevent this.

int wxPGProperty::Index (const wxPGProperty * *p*) const

Returns index of given child property.

wxNOT_FOUND if given property is not child of this.

wxPGProperty* wxPGProperty::InsertChild (int *index*, wxPGProperty * *childProperty*)

Use this member function to add independent (ie.

regular) children to a property.

Returns

Inserted childProperty.

Remarks

wxPropertyGrid is not automatically refreshed by this function.

See also

AppendChild(), AddPrivateChild()

int wxPGProperty::InsertChoice (const wxString & *label*, int *index*, int *value* = wxPG_INVALID_VALUE)

Inserts a new choice to property's list of choices.

Parameters

label	Text for new choice
index	Insertion position. Use wxNOT_FOUND to append.
value	Value for new choice. Do not specify if you wish this to equal choice index.

virtual bool wxPGProperty::IntToValue (wxVariant & *variant*, int *number*, int *argFlags* = 0) const [virtual]

Converts integer (possibly a choice selection) into wxVariant value appropriate for this property.

Parameters

variant	On function entry this is the old value (should not be wxNullVariant in normal cases). Translated value must be assigned back to it.
number	Integer to be translated into variant.
argFlags	If wxPG_FULL_VALUE is set, returns complete, storable value instead of displayable one.

Returns

Returns true if resulting wxVariant value was different.

Remarks

- If property is not supposed to use choice or spinctrl or other editor with int-based value, it is not necessary to implement this method.
- Default implementation simply assign given int to m_value.
- If property uses choice control, and displays a dialog on some choice items, then it is preferred to display that dialog in IntToValue instead of OnEvent.
- You might want to take into account that m_value is Mull variant if property value is unspecified (which is usually only case if you explicitly enabled that sort behaviour).

bool wxPGProperty::IsCategory ( ) const

Returns true if this property is actually a wxPropertyCategory.

bool wxPGProperty::IsEnabled ( ) const

Returns true if property is enabled.

bool wxPGProperty::IsExpanded ( ) const

Returns true if property has visible children.

bool wxPGProperty::IsRoot ( ) const

Returns true if this property is actually a wxRootProperty.

bool wxPGProperty::IsSomeParent (wxPGProperty * *candidateParent*) const

Returns true if candidateParent is some parent of this property.

bool wxPGProperty::IsTextEditable ( ) const

Returns true if property has editable wxTextCtrl when selected.

Remarks

Although disabled properties do not displayed editor, they still return true here as being disabled is considered a temporary condition (unlike being read-only or having limited editing enabled).

bool wxPGProperty::IsValueUnspecified ( ) const

Returns true if property's value is considered unspecified.

This usually means that value is Null variant.

bool wxPGProperty::IsVisible ( ) const

Returns true if all parents expanded.

wxPGProperty* wxPGProperty::Item (unsigned int *i*) const

Returns child property at index i.

virtual void wxPGProperty::OnCustomPaint (wxDC & *dc*, const wxRect & *rect*, wxPGPaintData & *paintdata*) [virtual]

Override to paint an image in front of the property value text or drop-down list item (but only if wxPGProperty::OnMeasureImage is overridden as well).

If property's OnMeasureImage() returns size that has height != 0 but less than row height (< 0 has special meanings), wxPropertyGrid calls this method to draw a custom image in a limited area in front of the editor control or value text/graphics, and if control has drop-down list, then the image is drawn there as well (even in the case OnMeasureImage() returned higher height than row height).

NOTE: Following applies when OnMeasureImage() returns a "flexible" height (using wxPG_FLEXIBLE_SIZE(W,H) macro), which implies variable height items: If rect.x is < 0, then this is a measure item call, which means that dc is invalid and only thing that should be done is to set paintdata.m_drawnHeight to the height of the image of item at index paintdata.m_choiceItem. This call may be done even as often as once every drop-down popup show.

Parameters

dc	wxDC to paint on.
rect	Box reserved for custom graphics. Includes surrounding rectangle, if any. If x is < 0, then this is a measure item call (see above).

paintdata	wxPGPaintData structure with much useful data about painted item.
	
	`struct wxPGPaintData`
	`{`
	`  // wxPropertyGrid.`
	`  const wxPropertyGrid*  m_parent;`
	
	`  // Normally -1, otherwise index to drop-down list item that has to be drawn.`
	`  int  m_choiceItem;`
	
	`  // Set to drawn width in OnCustomPaint (optional).`
	`  int  m_drawnWidth;`
	
	`  // In a measure item call, set this to the height of item at m_choiceItem index`
	`  int  m_drawnHeight;`
	`};`

Remarks

- You can actually exceed rect width, but if you do so then paintdata.m_drawnWidth must be set to the full width drawn in pixels.
- Due to technical reasons, rect's height will be default even if custom height was reported during measure call.
- Brush is guaranteed to be default background colour. It has been already used to clear the background of area being painted. It can be modified.
- Pen is guaranteed to be 1-wide 'black' (or whatever is the proper colour) pen for drawing framing rectangle. It can be changed as well.

See also

ValueToString()

virtual bool wxPGProperty::OnEvent (wxPropertyGrid * *propgrid*, wxWindow * *wnd_primary*, wxEvent & *event*) [virtual]

Events received by editor widgets are processed here.

Note that editor class usually processes most events. Some, such as button press events of TextCtrlAndButton class, can be handled here. Also, if custom handling for regular events is desired, then that can also be done (for example, wxSystemColourProperty custom handles `wxEVT_CHOICE` to display colour picker dialog when 'custom' selection is made).

If the event causes value to be changed, SetValueInEvent() should be called to set the new value.

The parameter *event* is the associated wxEvent.

Return values

Should	return true if any changes in value should be reported.

Remarks

- If property uses choice control, and displays a dialog on some choice items, then it is preferred to display that dialog in IntToValue instead of OnEvent.

virtual wxSize wxPGProperty::OnMeasureImage (int *item* = -1) const [virtual]

Returns size of the custom painted image in front of property.

This method must be overridden to return non-default value if OnCustomPaint is to be called.

Parameters

item	Normally -1, but can be an index to the property's list of items.

Remarks

- Default behaviour is to return wxSize(0,0), which means no image.
- Default image width or height is indicated with dimension -1.
- You can also return wxPG_DEFAULT_IMAGE_SIZE which equals wxSize(-1, -1).

virtual void wxPGProperty::OnSetValue ( ) [virtual]

This virtual function is called after m_value has been set.

Remarks

- If m_value was set to Null variant (ie. unspecified value), OnSetValue() will not be called.
- m_value may be of any variant type. Typically properties internally support only one variant type, and as such OnSetValue() provides a good opportunity to convert supported values into internal type.
- Default implementation does nothing.

virtual void wxPGProperty::OnValidationFailure (wxVariant & *pendingValue*) `[virtual]`

Called whenever validation has failed with given pending value.

Remarks

If you implement this in your custom property class, please remember to call the baser implementation as well, since they may use it to revert property into pre-change state.

virtual void wxPGProperty::RefreshChildren ( ) `[virtual]`

Refresh values of child properties.

Automatically called after value is set.

void wxPGProperty::RefreshEditor ( )

If property's editor is active, then update it's value.

void wxPGProperty::SetAttribute (const wxString & *name,* wxVariant *value*)

Sets an attribute for this property.

Parameters

name	Text identifier of attribute. See wxPropertyGrid Property Attribute Identifiers.
value	Value of attribute.

Remarks

Setting attribute's value to Null variant will simply remove it from property's set of attributes.

void wxPGProperty::SetAutoUnspecified (bool *enable* = `true`)

Set if user can change the property's value to unspecified by modifying the value of the editor control (usually by clearing it).

Currently, this can work with following properties: wxIntProperty, wxUIntProperty, wxFloatProperty, wxEditEnum↩ Property.

Parameters

enable	Whether to enable or disable this behaviour (it is disabled by default).

void wxPGProperty::SetBackgroundColour (const wxColour & *colour,* int *flags* = `wxPG_RECURSE`)

Sets property's background colour.

Parameters

colour	Background colour to use.
flags	Default is wxPG_RECURSE which causes colour to be set recursively. Omit this flag to only set colour for the property in question and not any of its children.

void wxPGProperty::SetCell (int *column,* const wxPGCell & *cell*)

Sets cell information for given column.

bool wxPGProperty::SetChoices (wxPGChoices & *choices*)

Sets new set of choices for the property.

Remarks

This operation deselects the property and clears its value.

void wxPGProperty::SetChoiceSelection (int *newValue*)

Sets selected choice and changes property value.

Tries to retain value type, although currently if it is not string, then it is forced to integer.

void wxPGProperty::SetClientData (void * *clientData*)

Sets client data (void*) of a property.

Remarks

This untyped client data has to be deleted manually.

void wxPGProperty::SetClientObject (wxClientData * *clientObject*)

Returns client object of a property.

void wxPGProperty::SetDefaultValue (wxVariant & *value*)

Set default value of a property.

Synonymous to

```
SetAttribute("DefaultValue", value);
```

void wxPGProperty::SetEditor (const wxPGEditor * *editor*)

Sets editor for a property.

Parameters

editor	For builtin editors, use wxPGEditor_X, where X is builtin editor's name (TextCtrl, Choice, etc. see wxPGEditor documentation for full list).

For custom editors, use pointer you received from wxPropertyGrid::RegisterEditorClass().

void wxPGProperty::SetEditor (const wxString & *editorName*)

Sets editor for a property, by editor name.

void wxPGProperty::SetFlagRecursively (wxPGPropertyFlags *flag,* bool *set*)

Sets or clears given property flag, recursively.

This function is primarily intended for internal use.

See also

ChangeFlag()

void wxPGProperty::SetHelpString (const wxString & *helpString*)

Sets property's help string, which is shown, for example, in wxPropertyGridManager's description text box.

void wxPGProperty::SetLabel (const wxString & *label*)

Sets property's label.

Remarks

Properties under same parent may have same labels. However, property names must still remain unique.

bool wxPGProperty::SetMaxLength (int *maxLen*)

Set max length of text in text editor.

void wxPGProperty::SetModifiedStatus (bool *modified*)

Sets property's "is it modified?" flag.

Affects children recursively.

void wxPGProperty::SetName (const wxString & *newName*)

Sets new (base) name for property.

void wxPGProperty::SetParentalType (int *flag*)

Changes what sort of parent this property is for its children.

Parameters

flag	Use one of the following values: wxPG_PROP_MISC_PARENT (for generic parents), wxPG_PROP_CATEGORY (for categories), or wxPG_PROP_AGGREGATE (for derived property classes with private children).

Remarks

You generally do not need to call this function.

void wxPGProperty::SetTextColour (const wxColour & *colour,* int *flags* = `wxPG_RECURSE`)

Sets property's text colour.

Parameters

colour	Text colour to use.
flags	Default is wxPG_RECURSE which causes colour to be set recursively. Omit this flag to only set colour for the property in question and not any of its children.

void wxPGProperty::SetValidator (const wxValidator & *validator*)

Sets wxValidator for a property.

void wxPGProperty::SetValue (wxVariant *value*, wxVariant * *pList* = NULL, int *flags* = wxPG_SETVAL_REFRESH_EDITOR)

Call this to set value of the property.

Unlike methods in wxPropertyGrid, this does not automatically update the display.

Remarks

Use wxPropertyGrid::ChangePropertyValue() instead if you need to run through validation process and send property change event.

If you need to change property value in event, based on user input, use SetValueInEvent() instead.

Parameters

value	The value to set.
pList	Pointer to list variant that contains child values. Used to indicate which children should be marked as modified. Usually you just use NULL.
flags	wxPG_SETVAL_REFRESH_EDITOR is set by default, to refresh editor and redraw properties.

bool wxPGProperty::SetValueFromInt (long *value*, int *flags* = 0)

Converts integer to a value, and if successful, calls SetValue() on it.

Default behaviour is to do nothing.

Parameters

value	Int to get the value from.
flags	If has wxPG_FULL_VALUE, then the value given is a actual value and not an index.

Returns

true if value was changed.

bool wxPGProperty::SetValueFromString (const wxString & *text*, int *flags* = 0)

Converts string to a value, and if successful, calls SetValue() on it.

Default behaviour is to do nothing.

Parameters

text	String to get the value from.
flags	

Todo docme

Returns

true if value was changed.

void wxPGProperty::SetValueImage (wxBitmap & *bmp*)

Set wxBitmap in front of the value.

This bitmap may be ignored by custom cell renderers.

void wxPGProperty::SetValueInEvent (wxVariant *value*) const

Call this function in OnEvent(), OnButtonClick() etc.

to change the property value based on user input.

Remarks

This method is const since it doesn't actually modify value, but posts given variant as pending value, stored in wxPropertyGrid.

void wxPGProperty::SetValueToUnspecified ( )

Sets property's value to unspecified (ie.

Null variant).

void wxPGProperty::SetWasModified (bool *set* = `true`)

Call with false in OnSetValue() to cancel value changes after all (ie.

cancel true returned by StringToValue() or IntToValue()).

virtual bool wxPGProperty::StringToValue (wxVariant & *variant*, const wxString & *text*, int *argFlags* = `0`) const `[virtual]`

Converts text into wxVariant value appropriate for this property.

Parameters

variant	On function entry this is the old value (should not be wxNullVariant in normal cases). Translated value must be assigned back to it.
text	Text to be translated into variant.
argFlags	If wxPG_FULL_VALUE is set, returns complete, storable value instead of displayable one (they may be different). If wxPG_COMPOSITE_FRAGMENT is set, text is interpreted as a part of composite property string value (as generated by ValueToString() called with this same flag).

Returns

Returns true if resulting wxVariant value was different.

Remarks

Default implementation converts semicolon delimited tokens into child values. Only works for properties with children.

You might want to take into account that m_value is Null variant if property value is unspecified (which is usually only case if you explicitly enabled that sort behaviour).

wxPGProperty* wxPGProperty::UpdateParentValues ( )

Updates composed values of parent non-category properties, recursively.

Returns topmost property updated.

bool wxPGProperty::UsesAutoUnspecified ( ) const

Returns true if containing grid uses wxPG_EX_AUTO_UNSPECIFIED_VALUES.

virtual bool wxPGProperty::ValidateValue (wxVariant & *value*, wxPGValidationInfo & *validationInfo*) const [virtual]

Implement this function in derived class to check the value.

Return true if it is ok. Returning false prevents property change events from occurring.

Remarks

- Default implementation always returns true.

virtual wxString wxPGProperty::ValueToString (wxVariant & *value*, int *argFlags* = 0) const [virtual]

Converts property value into a text representation.

Parameters

value	Value to be converted.
argFlags	If 0 (default value), then displayed string is returned. If wxPG_FULL_VALUE is set, returns complete, storable string value instead of displayable. If wxPG_EDITABLE_VALUE is set, returns string value that must be editable in textctrl. If wxPG_COMPOSITE_FRAGMENT is set, returns text that is appropriate to display as a part of string property's composite text representation.

Remarks

Default implementation calls GenerateComposedValue().

wxPGProperty::wxDEPRECATED (void *AddChildwxPGProperty* *prop)

Adds a private child property.

Deprecated Use AddPrivateChild() instead.

See also

AddPrivateChild()

wxPGProperty::wxDEPRECATED (wxString GetValueString(int argFlags=0) *const*)

Synonymous to GetValueAsString().

Deprecated Use GetValueAsString() instead.

See also

GetValueAsString()

21.528 wxPGValidationInfo Class Reference

`#include <wx/propgrid/propgrid.h>`

21.528.1 Detailed Description

wxPGValidationInfo

Used to convey validation information to and from functions that actually perform validation. Mostly used in custom property classes.

Public Member Functions

- wxPGVFBFlags GetFailureBehavior ()
- const wxString & GetFailureMessage () const

  Returns current failure message.
- wxVariant & GetValue ()

  Returns reference to pending value.
- void SetFailureBehavior (wxPGVFBFlags failureBehavior)

  Set validation failure behaviour.
- void SetFailureMessage (const wxString &message)

  Set current failure message.

21.528.2 Member Function Documentation

wxPGVFBFlags wxPGValidationInfo::GetFailureBehavior ( )

Returns

Returns failure behaviour which is a combination of wxPropertyGrid Validation Failure behaviour Flags.

const wxString& wxPGValidationInfo::GetFailureMessage ( ) const

Returns current failure message.

wxVariant& wxPGValidationInfo::GetValue ( )

Returns reference to pending value.

void wxPGValidationInfo::SetFailureBehavior (wxPGVFBFlags *failureBehavior*)

Set validation failure behaviour.

Parameters

failureBehavior	Mixture of wxPropertyGrid Validation Failure behaviour Flags.

void wxPGValidationInfo::SetFailureMessage (const wxString & *message*)

Set current failure message.

21.529 wxPGVIterator Class Reference

`#include <wx/propgrid/propgridpagestate.h>`

21.529.1 Detailed Description

21.529.2 wxPGVIterator

Abstract implementation of a simple iterator. Can only be used to iterate in forward order, and only through the entire container. Used to have functions dealing with all properties work with both wxPropertyGrid and wxPropertyGrid↩ Manager.

Public Member Functions

- wxPGVIterator ()
- wxPGVIterator (wxPGVIteratorBase ∗obj)

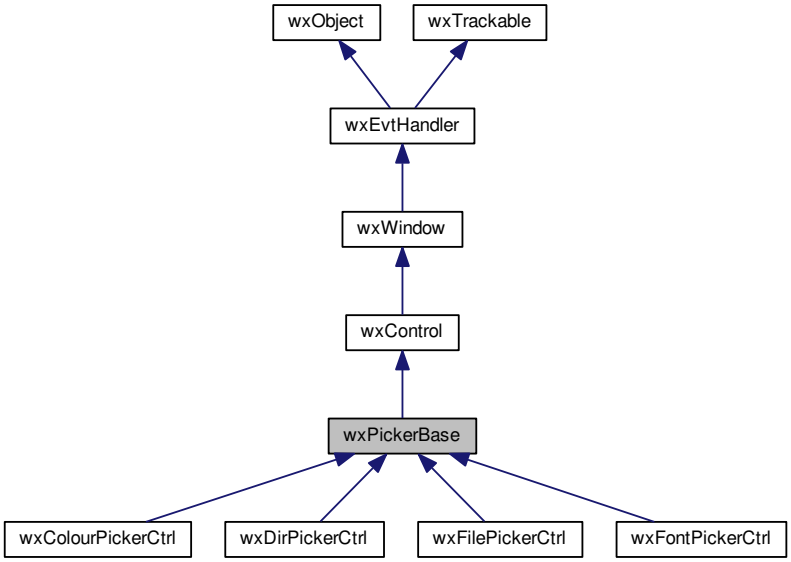
21.530 wxPickerBase Class Reference

`#include <wx/pickerbase.h>`

Inheritance diagram for wxPickerBase:



21.530.1 Detailed Description

Base abstract class for all pickers which support an auxiliary text control.

This class handles all positioning and sizing of the text control like a an horizontal wxBoxSizer would do, with the text control on the left of the picker button.

The proportion (see wxSizer documentation for more info about proportion values) of the picker control defaults to 1 when there isn't a text control associated (see `wxPB_USE_TEXTCTRL` style) and to 0 otherwise.

Styles

This class supports the following styles:

- wxPB_USE_TEXTCTRL: Creates a text control to the left of the picker which is completely managed by this wxPickerBase class.

Library: wxCore

Category: Picker Controls

See also

wxColourPickerCtrl

Public Member Functions

- wxPickerBase ()
- virtual ~wxPickerBase ()
- bool CreateBase (wxWindow *parent, wxWindowID id, const wxString &text=wxEmptyString, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, long style=0, const wxValidator &validator=wxDefaultValidator, const wxString &name=wxButtonNameStr)
- int GetInternalMargin () const

  Returns the margin (in pixel) between the picker and the text control.
- int GetPickerCtrlProportion () const

  Returns the proportion value of the picker.
- wxTextCtrl * GetTextCtrl ()

  Returns a pointer to the text control handled by this window or NULL if the `wxPB_USE_TEXTCTRL` style was not specified when this control was created.
- wxControl * GetPickerCtrl ()

  Returns the native implementation of the real picker control.
- int GetTextCtrlProportion () const

  Returns the proportion value of the text control.
- bool HasTextCtrl () const

  Returns true if this window has a valid text control (i.e. if the `wxPB_USE_TEXTCTRL` style was given when creating this control).
- bool IsPickerCtrlGrowable () const

  Returns true if the picker control is growable.
- bool IsTextCtrlGrowable () const

  Returns true if the text control is growable.
- void SetInternalMargin (int margin)

  Sets the margin (in pixel) between the picker and the text control.
- void SetPickerCtrlGrowable (bool grow=true)

  Sets the picker control as growable when `grow` is true.
- void SetPickerCtrlProportion (int prop)

  Sets the proportion value of the picker.
- void SetTextCtrlGrowable (bool grow=true)

  Sets the text control as growable when `grow` is true.

- void SetTextCtrlProportion (int prop)

  Sets the proportion value of the text control.
- void SetTextCtrl (wxTextCtrl *text)
- void SetPickerCtrl (wxControl *picker)
- virtual void UpdatePickerFromTextCtrl ()=0
- virtual void UpdateTextCtrlFromPicker ()=0

Protected Member Functions

- virtual long GetTextCtrlStyle (long style) const
- virtual long GetPickerStyle (long style) const
- void PostCreation ()

Additional Inherited Members

21.530.2 Constructor & Destructor Documentation

wxPickerBase::wxPickerBase ( )

virtual wxPickerBase::~wxPickerBase ( ) `[virtual]`

21.530.3 Member Function Documentation

bool wxPickerBase::CreateBase (wxWindow * *parent*, wxWindowID *id*, const wxString & *text* = wxEmptyString, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, long *style* = 0, const wxValidator & *validator* = wxDefaultValidator, const wxString & *name* = wxButtonNameStr)

int wxPickerBase::GetInternalMargin ( ) const

Returns the margin (in pixel) between the picker and the text control.

This function can be used only when HasTextCtrl() returns true.

wxControl* wxPickerBase::GetPickerCtrl ( )

Returns the native implementation of the real picker control.

Note

The returned control in the generic implementation of wxFilePickerCtrl, wxDirPickerCtrl, wxFontPickerCtrl and wxColourPickerCtrl is a specialized wxButton class so that you can change its label doing, e.g.:

```
#ifdef __WXMSW__
    // wxMSW is one of the platforms where the generic implementation
    // of wxFilePickerCtrl is used...

    wxButton *pButt = wx_static_cast(wxButton*, myFilePickerCtrl->
      GetPickerCtrl());
    if (pButt)
        pButt->SetLabel("Custom browse string");
#endif
```

int wxPickerBase::GetPickerCtrlProportion ( ) const

Returns the proportion value of the picker.

virtual long wxPickerBase::GetPickerStyle (long *style*) const `[protected], [virtual]`

wxTextCtrl* wxPickerBase::GetTextCtrl ( )

Returns a pointer to the text control handled by this window or NULL if the `wxPB_USE_TEXTCTRL` style was not specified when this control was created.

Remarks

The contents of the text control could be an invalid representation of the entity which can be chosen through the picker (e.g. when the user enters an invalid colour syntax because of a typo). Thus you should never parse the content of the textctrl to get the user's input; rather use the derived-class getter (e.g. wxColourPickerCtrl::GetColour(), wxFilePickerCtrl::GetPath(), etc).

int wxPickerBase::GetTextCtrlProportion ( ) const

Returns the proportion value of the text control.

This function can be used only when HasTextCtrl() returns true.

virtual long wxPickerBase::GetTextCtrlStyle (long *style*) const `[protected], [virtual]`

bool wxPickerBase::HasTextCtrl ( ) const

Returns true if this window has a valid text control (i.e. if the `wxPB_USE_TEXTCTRL` style was given when creating this control).

bool wxPickerBase::IsPickerCtrlGrowable ( ) const

Returns true if the picker control is growable.

bool wxPickerBase::IsTextCtrlGrowable ( ) const

Returns true if the text control is growable.

This function can be used only when HasTextCtrl() returns true.

void wxPickerBase::PostCreation ( ) `[protected]`

void wxPickerBase::SetInternalMargin (int *margin*)

Sets the margin (in pixel) between the picker and the text control.

This function can be used only when HasTextCtrl() returns true.

void wxPickerBase::SetPickerCtrl (wxControl * *picker*)

void wxPickerBase::SetPickerCtrlGrowable (bool *grow* = `true`)

Sets the picker control as growable when `grow` is true.

void wxPickerBase::SetPickerCtrlProportion (int *prop*)

Sets the proportion value of the picker.

Look at the detailed description of wxPickerBase for more info.

void wxPickerBase::SetTextCtrl (wxTextCtrl * *text*)

void wxPickerBase::SetTextCtrlGrowable (bool *grow* = `true`)

Sets the text control as growable when `grow` is true.

This function can be used only when HasTextCtrl() returns true.

void wxPickerBase::SetTextCtrlProportion (int *prop*)

Sets the proportion value of the text control.

Look at the detailed description of wxPickerBase for more info.

This function can be used only when HasTextCtrl() returns true.

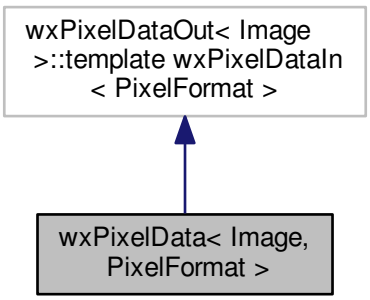
virtual void wxPickerBase::UpdatePickerFromTextCtrl ( ) [pure virtual]

virtual void wxPickerBase::UpdateTextCtrlFromPicker ( ) [pure virtual]

21.531 wxPixelData< Image, PixelFormat > Class Template Reference

`#include <wx/rawbmp.h>`

Inheritance diagram for wxPixelData< Image, PixelFormat >:



21.531.1 Detailed Description

template<class Image, class PixelFormat = wxPixelFormatFor<Image>>class wxPixelData< Image, PixelFormat >

A class template with ready to use implementations for getting direct and efficient access to wxBitmap's internal data and wxImage's internal data through a standard interface.

It is possible to extend this class (interface) to other types of image content.

Implemented on Windows, GTK+ and OS X:

- wxNativePixelData: Class to access to wxBitmap's internal data without alpha channel (RGB).
- wxAlphaPixelData: Class to access to wxBitmap's internal data with alpha channel (RGBA).

Implemented everywhere:

- wxImagePixelData: Class to access to wxImage's internal data with alpha channel (RGBA).

wxMSW note: efficient access is only possible to the bits of the so called device independent bitmaps (DIB) under MSW. To ensure that wxBitmap uses a DIB internally and not a device dependent bitmap (DDB), you need to pass an explicit depth to its ctor, i.e. either 24 or 32, as by default wxBitmap creates a DDB of the screen depth.

Example:

```
wxBitmap bmp(width, size, 24); // explicit depth important under MSW
wxNativePixelData data(bmp);
if ( !data )
{
    // ... raw access to bitmap data unavailable, do something else ...
    return;
}

if ( data.GetWidth() < 20 || data.GetHeight() < 20 )
{
    // ... complain: the bitmap it too small ...
    return;
}

wxNativePixelData::Iterator p(data);

// we draw a (10, 10)-(20, 20) rect manually using the given r, g, b
p.Offset(data, 10, 10);

for ( int y = 0; y < 10; ++y )
{
    wxNativePixelData::Iterator rowStart = p;

    for ( int x = 0; x < 10; ++x, ++p )
    {
        p.Red() = r;
        p.Green() = g;
        p.Blue() = b;
    }

    p = rowStart;
    p.OffsetY(data, 1);
}
```

Library: wxCore

Category: Graphics Device Interface (GDI)

wxBitmap, wxImage

Classes

- class Iterator

  The iterator of class wxPixelData.

Public Types

- typedef Image ImageType

  The type of the class we're working with.

Public Member Functions

- wxPixelData (Image &image)

  Create pixel data object representing the entire image.
- wxPixelData (Image &i, const wxRect &rect)

  Create pixel data object representing the area of the image defined by rect.
- wxPixelData (Image &i, const wxPoint &pt, const wxSize &sz)

  Create pixel data object representing the area of the image defined by pt and sz.
- operator bool () const

  Return true of if we could get access to bitmap data successfully.
- Iterator GetPixels () const

  Return the iterator pointing to the origin of the image.
- wxPoint GetOrigin () const

  Returns origin of the rectangular region this wxPixelData represents.
- int GetWidth () const

  Return width of the region this wxPixelData represents.
- int GetHeight () const

  Return height of the region this wxPixelData represents.
- wxSize GetSize () const

  Return the area which this wxPixelData represents in the image.
- int GetRowStride () const

  Return the distance between two rows.

21.531.2 Member Typedef Documentation

template<class Image , class PixelFormat = wxPixelFormatFor<Image>> typedef Image wxPixelData< Image, PixelFormat >::ImageType

The type of the class we're working with.

21.531.3 Constructor & Destructor Documentation

template<class Image , class PixelFormat = wxPixelFormatFor<Image>> wxPixelData< Image, PixelFormat >::wxPixelData (Image & *image*)

Create pixel data object representing the entire image.

template<class Image , class PixelFormat = wxPixelFormatFor<Image>> wxPixelData< Image, PixelFormat >::wxPixelData (Image & *i,* const wxRect & *rect*)

Create pixel data object representing the area of the image defined by *rect*.

template<class Image , class PixelFormat = wxPixelFormatFor<Image>> wxPixelData< Image, PixelFormat >::wxPixelData (Image & *i,* const wxPoint & *pt,* const wxSize & *sz*)

Create pixel data object representing the area of the image defined by *pt* and *sz*.

21.531.4 Member Function Documentation

template<class Image , class PixelFormat = wxPixelFormatFor<Image>> int wxPixelData< Image, PixelFormat >::GetHeight ( ) const

Return height of the region this wxPixelData represents.

template<class Image , class PixelFormat = wxPixelFormatFor<Image>> wxPoint wxPixelData< Image, PixelFormat >::GetOrigin ( ) const

Returns origin of the rectangular region this wxPixelData represents.

template<class Image , class PixelFormat = wxPixelFormatFor<Image>> Iterator wxPixelData< Image, PixelFormat >::GetPixels ( ) const

Return the iterator pointing to the origin of the image.

template<class Image , class PixelFormat = wxPixelFormatFor<Image>> int wxPixelData< Image, PixelFormat >::GetRowStride ( ) const

Return the distance between two rows.

template<class Image , class PixelFormat = wxPixelFormatFor<Image>> wxSize wxPixelData< Image, PixelFormat >::GetSize ( ) const

Return the area which this wxPixelData represents in the image.

template<class Image , class PixelFormat = wxPixelFormatFor<Image>> int wxPixelData< Image, PixelFormat >::GetWidth ( ) const

Return width of the region this wxPixelData represents.

template<class Image , class PixelFormat = wxPixelFormatFor<Image>> wxPixelData< Image, PixelFormat >::operator bool ( ) const

Return true of if we could get access to bitmap data successfully.

21.532 wxPlatformInfo Class Reference

`#include <wx/platinfo.h>`

21.532.1 Detailed Description

This class holds information about the operating system, the toolkit and the basic architecture of the machine where the application is currently running.

This class does not only have *getters* for the information above, it also has *setters*. This allows you to e.g. save the current platform information in a data file (maybe in string form) so that when you later load it, you can easily retrieve (see the static getters for string->enum conversion functions) and store inside a wxPlatformInfo instance (using its setters) the signature of the system which generated it.

In general however you only need to use the static Get() function and then access the various information for the current platform:

```
wxLogMessage("This application is running under %s.",
             wxPlatformInfo::Get().GetOperatingSystemIdName());
```

Library: wxBase

Category: Application and System configuration

See also

wxGetOsVersion(), wxIsPlatformLittleEndian(), wxIsPlatform64Bit(), wxAppTraits, Network, User and OS

Public Member Functions

- wxPlatformInfo ()

  Initializes the instance with the values corresponding to the currently running platform.
- wxPlatformInfo (wxPortId pid, int tkMajor=-1, int tkMinor=-1, wxOperatingSystemId id=wxOS_UNKNOWN, int osMajor=-1, int osMinor=-1, wxArchitecture arch=wxARCH_INVALID, wxEndianness endian=wxENDIAN_↩ INVALID)

  Initializes the object using given values.
- bool CheckOSVersion (int major, int minor) const

  Returns true if the OS version is at least `major.minor`.
- bool CheckToolkitVersion (int major, int minor) const

  Returns true if the toolkit version is at least `major.minor`.
- bool IsOk () const

  Returns true if this instance is fully initialized with valid values.
- bool IsUsingUniversalWidgets () const

  Returns true if this wxPlatformInfo describes wxUniversal build.
- bool operator!= (const wxPlatformInfo &t) const

  Inequality operator.
- bool operator== (const wxPlatformInfo &t) const

  Equality operator.

Getters

- wxArchitecture GetArchitecture () const

  Returns the architecture ID of this wxPlatformInfo instance.
- wxEndianness GetEndianness () const

  Returns the endianness ID of this wxPlatformInfo instance.
- int GetOSMajorVersion () const

  Returns the run-time major version of the OS associated with this wxPlatformInfo instance.
- int GetOSMinorVersion () const

  Returns the run-time minor version of the OS associated with this wxPlatformInfo instance.
- wxOperatingSystemId GetOperatingSystemId () const

  Returns the operating system ID of this wxPlatformInfo instance.
- wxString GetOperatingSystemDescription () const

  Returns the description of the operating system of this wxPlatformInfo instance.
- wxPortId GetPortId () const

  Returns the wxWidgets port ID associated with this wxPlatformInfo instance.
- wxLinuxDistributionInfo GetLinuxDistributionInfo () const

  Returns the Linux distribution info associated with this wxPlatformInfo instance.
- wxString GetDesktopEnvironment () const

Returns the desktop environment associated with this wxPlatformInfo instance.

- int GetToolkitMajorVersion () const

  Returns the run-time major version of the toolkit associated with this wxPlatformInfo instance.
- int GetToolkitMinorVersion () const

  Returns the run-time minor version of the toolkit associated with this wxPlatformInfo instance.

String-form getters

- wxString GetArchName () const

  Returns the name for the architecture of this wxPlatformInfo instance.
- wxString GetEndiannessName () const

  Returns the name for the endianness of this wxPlatformInfo instance.
- wxString GetOperatingSystemFamilyName () const

  Returns the operating system family name of the OS associated with this wxPlatformInfo instance.
- wxString GetOperatingSystemIdName () const

  Returns the operating system name of the OS associated with this wxPlatformInfo instance.
- wxString GetPortIdName () const

  Returns the name of the wxWidgets port ID associated with this wxPlatformInfo instance.
- wxString GetPortIdShortName () const

  Returns the short name of the wxWidgets port ID associated with this wxPlatformInfo instance.

Setters

- void SetArchitecture (wxArchitecture n)

  Sets the architecture enum value associated with this wxPlatformInfo instance.
- void SetEndianness (wxEndianness n)

  Sets the endianness enum value associated with this wxPlatformInfo instance.
- void SetOSVersion (int major, int minor)

  Sets the version of the operating system associated with this wxPlatformInfo instance.
- void SetOperatingSystemId (wxOperatingSystemId n)

  Sets the operating system associated with this wxPlatformInfo instance.
- void SetPortId (wxPortId n)

  Sets the wxWidgets port ID associated with this wxPlatformInfo instance.
- void SetToolkitVersion (int major, int minor)

  Sets the version of the toolkit associated with this wxPlatformInfo instance.
- void SetOperatingSystemDescription (const wxString &desc)

  Sets the operating system description associated with this wxPlatformInfo instance.
- void SetDesktopEnvironment (const wxString &de)

  Sets the desktop environment associated with this wxPlatformInfo instance.
- void SetLinuxDistributionInfo (const wxLinuxDistributionInfo &di)

  Sets the linux distribution info associated with this wxPlatformInfo instance.

Static Public Member Functions

- static const wxPlatformInfo & Get ()

  Returns the global wxPlatformInfo object, initialized with the values for the currently running platform.

Static enum getters

These getters allow for easy string-to-enumeration-value conversion.

- static wxArchitecture GetArch (const wxString &arch)

  Converts the given string to a wxArchitecture enum value or to `wxARCH_INVALID` if the given string is not a valid architecture string (i.e.
- static wxEndianness GetEndianness (const wxString &end)

  Converts the given string to a wxEndianness enum value or to `wxENDIAN_INVALID` if the given string is not a valid endianness string (i.e.
- static wxOperatingSystemId GetOperatingSystemId (const wxString &name)

Converts the given string to a wxOperatingSystemId enum value or to `wxOS_UNKNOWN` if the given string is not a valid operating system name.

- static wxPortId GetPortId (const wxString &portname)

  Converts the given string to a wxWidgets port ID value or to `wxPORT_UNKNOWN` if the given string does not match any of the wxWidgets canonical name ports ("wxGTK", "wxMSW", etc) nor any of the short wxWidgets name ports ("gtk", "msw", etc).

Static string-form getters

These getters allow for easy enumeration-value-to-string conversion.

- static wxString GetArchName (wxArchitecture arch)

  Returns the name for the given wxArchitecture enumeration value.
- static wxString GetEndiannessName (wxEndianness end)

  Returns name for the given wxEndianness enumeration value.
- static wxString GetOperatingSystemFamilyName (wxOperatingSystemId os)

  Returns the operating system family name for the given wxOperatingSystemId enumeration value: `Unix` for `wxOS_UNIX`, `Macintosh` for `wxOS_MAC`, `Windows` for `wxOS_WINDOWS`, `DOS` for `wxOS_DOS`, `OS/2` for `wxOS_OS2`.
- static wxString GetOperatingSystemIdName (wxOperatingSystemId os)

  Returns the name for the given operating system ID value.
- static wxString GetPortIdName (wxPortId port, bool usingUniversal)

  Returns the name of the given wxWidgets port ID value.
- static wxString GetPortIdShortName (wxPortId port, bool usingUniversal)

  Returns the short name of the given wxWidgets port ID value.
- static wxString GetOperatingSystemDirectory ()

  Returns the operating system directory.

21.532.2 Constructor & Destructor Documentation

wxPlatformInfo::wxPlatformInfo ( )

Initializes the instance with the values corresponding to the currently running platform.

This is a fast operation because it only requires to copy the values internally cached for the currently running platform.

See also

Get()

wxPlatformInfo::wxPlatformInfo (wxPortId *pid*, int *tkMajor* = −1, int *tkMinor* = −1, wxOperatingSystemId *id* = wxOS_UNKNOWN, int *osMajor* = −1, int *osMinor* = −1, wxArchitecture *arch* = wxARCH_INVALID, wxEndianness *endian* = wxENDIAN_INVALID)

Initializes the object using given values.

21.532.3 Member Function Documentation

bool wxPlatformInfo::CheckOSVersion (int *major*, int *minor*) const

Returns true if the OS version is at least `major.minor`.

See also

GetOSMajorVersion(), GetOSMinorVersion(), CheckToolkitVersion()

bool wxPlatformInfo::CheckToolkitVersion (int *major,* int *minor*) const

Returns true if the toolkit version is at least `major.minor`.

See also

GetToolkitMajorVersion(), GetToolkitMinorVersion(), CheckOSVersion()

static const wxPlatformInfo& wxPlatformInfo::Get ( ) [static]

Returns the global wxPlatformInfo object, initialized with the values for the currently running platform.

static wxArchitecture wxPlatformInfo::GetArch (const wxString & *arch*) [static]

Converts the given string to a wxArchitecture enum value or to `wxARCH_INVALID` if the given string is not a valid architecture string (i.e.

does not contain nor `32` nor `64` strings).

wxArchitecture wxPlatformInfo::GetArchitecture ( ) const

Returns the architecture ID of this wxPlatformInfo instance.

static wxString wxPlatformInfo::GetArchName (wxArchitecture *arch*) [static]

Returns the name for the given wxArchitecture enumeration value.

wxString wxPlatformInfo::GetArchName ( ) const

Returns the name for the architecture of this wxPlatformInfo instance.

wxString wxPlatformInfo::GetDesktopEnvironment ( ) const

Returns the desktop environment associated with this wxPlatformInfo instance.

See wxAppTraits::GetDesktopEnvironment() for more info.

static wxEndianness wxPlatformInfo::GetEndianness (const wxString & *end*) [static]

Converts the given string to a wxEndianness enum value or to `wxENDIAN_INVALID` if the given string is not a valid endianness string (i.e.

does not contain nor little nor big strings).

wxEndianness wxPlatformInfo::GetEndianness ( ) const

Returns the endianness ID of this wxPlatformInfo instance.

static wxString wxPlatformInfo::GetEndiannessName (wxEndianness *end*) [static]

Returns name for the given wxEndianness enumeration value.

wxString wxPlatformInfo::GetEndiannessName ( ) const

Returns the name for the endianness of this wxPlatformInfo instance.

wxLinuxDistributionInfo wxPlatformInfo::GetLinuxDistributionInfo ( ) const

Returns the Linux distribution info associated with this wxPlatformInfo instance.

See wxGetLinuxDistributionInfo() for more info.

wxString wxPlatformInfo::GetOperatingSystemDescription ( ) const

Returns the description of the operating system of this wxPlatformInfo instance.

See wxGetOSDescription() for more info.

static wxString wxPlatformInfo::GetOperatingSystemDirectory ( ) [static]

Returns the operating system directory.

See wxGetOSDirectory() for more info.

static wxString wxPlatformInfo::GetOperatingSystemFamilyName (wxOperatingSystemId *os*) [static]

Returns the operating system family name for the given wxOperatingSystemId enumeration value: `Unix` for `wxOS_UNIX`, `Macintosh` for `wxOS_MAC`, `Windows` for `wxOS_WINDOWS`, `DOS` for `wxOS_DOS`, `OS/2` for `wxOS_OS2`.

wxString wxPlatformInfo::GetOperatingSystemFamilyName ( ) const

Returns the operating system family name of the OS associated with this wxPlatformInfo instance.

static wxOperatingSystemId wxPlatformInfo::GetOperatingSystemId (const wxString & *name*) [static]

Converts the given string to a wxOperatingSystemId enum value or to `wxOS_UNKNOWN` if the given string is not a valid operating system name.

wxOperatingSystemId wxPlatformInfo::GetOperatingSystemId ( ) const

Returns the operating system ID of this wxPlatformInfo instance.

See wxGetOsVersion() for more info.

static wxString wxPlatformInfo::GetOperatingSystemIdName (wxOperatingSystemId *os*) [static]

Returns the name for the given operating system ID value.

This can be a long name (e.g. `Microsoft Windows NT`); use GetOperatingSystemFamilyName() to retrieve a short, generic name.

wxString wxPlatformInfo::GetOperatingSystemIdName ( ) const

Returns the operating system name of the OS associated with this wxPlatformInfo instance.

int wxPlatformInfo::GetOSMajorVersion ( ) const

Returns the run-time major version of the OS associated with this wxPlatformInfo instance.

See also

wxGetOsVersion(), CheckOSVersion()

int wxPlatformInfo::GetOSMinorVersion ( ) const

Returns the run-time minor version of the OS associated with this wxPlatformInfo instance.

See also

wxGetOsVersion(), CheckOSVersion()

static wxPortId wxPlatformInfo::GetPortId (const wxString & *portname*) [static]

Converts the given string to a wxWidgets port ID value or to `wxPORT_UNKNOWN` if the given string does not match any of the wxWidgets canonical name ports ("wxGTK", "wxMSW", etc) nor any of the short wxWidgets name ports ("gtk", "msw", etc).

wxPortId wxPlatformInfo::GetPortId ( ) const

Returns the wxWidgets port ID associated with this wxPlatformInfo instance.

static wxString wxPlatformInfo::GetPortIdName (wxPortId *port*, bool *usingUniversal*) [static]

Returns the name of the given wxWidgets port ID value.

The *usingUniversal* argument specifies whether the port is in its native or wxUniversal variant.

The returned string always starts with the "wx" prefix and is a mixed-case string.

wxString wxPlatformInfo::GetPortIdName ( ) const

Returns the name of the wxWidgets port ID associated with this wxPlatformInfo instance.

static wxString wxPlatformInfo::GetPortIdShortName (wxPortId *port*, bool *usingUniversal*) [static]

Returns the short name of the given wxWidgets port ID value.

The *usingUniversal* argument specifies whether the port is in its native or wxUniversal variant.

The returned string does not start with the "wx" prefix and is always lower case.

wxString wxPlatformInfo::GetPortIdShortName ( ) const

Returns the short name of the wxWidgets port ID associated with this wxPlatformInfo instance.

int wxPlatformInfo::GetToolkitMajorVersion ( ) const

Returns the run-time major version of the toolkit associated with this wxPlatformInfo instance.

Note that if GetPortId() returns `wxPORT_BASE`, then this value is zero (unless externally modified with SetToolkitVersion()); that is, no native toolkit is in use. See wxAppTraits::GetToolkitVersion() for more info.

See also

CheckToolkitVersion()

int wxPlatformInfo::GetToolkitMinorVersion ( ) const

Returns the run-time minor version of the toolkit associated with this wxPlatformInfo instance.

Note that if GetPortId() returns `wxPORT_BASE`, then this value is zero (unless externally modified with SetToolkitVersion()); that is, no native toolkit is in use. See wxAppTraits::GetToolkitVersion() for more info.

See also

CheckToolkitVersion()

bool wxPlatformInfo::IsOk ( ) const

Returns true if this instance is fully initialized with valid values.

bool wxPlatformInfo::IsUsingUniversalWidgets ( ) const

Returns true if this wxPlatformInfo describes wxUniversal build.

bool wxPlatformInfo::operator!= (const wxPlatformInfo & *t*) const

Inequality operator.

Tests all class' internal variables.

bool wxPlatformInfo::operator== (const wxPlatformInfo & *t*) const

Equality operator.

Tests all class' internal variables.

void wxPlatformInfo::SetArchitecture (wxArchitecture *n*)

Sets the architecture enum value associated with this wxPlatformInfo instance.

void wxPlatformInfo::SetDesktopEnvironment (const wxString & *de*)

Sets the desktop environment associated with this wxPlatformInfo instance.

void wxPlatformInfo::SetEndianness (wxEndianness *n*)

Sets the endianness enum value associated with this wxPlatformInfo instance.

void wxPlatformInfo::SetLinuxDistributionInfo (const wxLinuxDistributionInfo & *di*)

Sets the linux distribution info associated with this wxPlatformInfo instance.

void wxPlatformInfo::SetOperatingSystemDescription (const wxString & *desc*)

Sets the operating system description associated with this wxPlatformInfo instance.

void wxPlatformInfo::SetOperatingSystemId (wxOperatingSystemId *n*)

Sets the operating system associated with this wxPlatformInfo instance.

void wxPlatformInfo::SetOSVersion (int *major,* int *minor*)

Sets the version of the operating system associated with this wxPlatformInfo instance.

void wxPlatformInfo::SetPortId (wxPortId *n*)

Sets the wxWidgets port ID associated with this wxPlatformInfo instance.

void wxPlatformInfo::SetToolkitVersion (int *major,* int *minor*)

Sets the version of the toolkit associated with this wxPlatformInfo instance.

21.533 wxPoint Class Reference

```
#include <wx/gdicmn.h>
```

21.533.1 Detailed Description

A wxPoint is a useful data structure for graphics operations.

It contains integer *x* and *y* members. See wxRealPoint for a floating point version.

Note that the width and height stored inside a wxPoint object may be negative and that wxPoint functions do not perform any check against negative values (this is used to e.g. store the special -1 value in wxDefaultPosition instance).

Library: wxCore

Category: Data Structures

Predefined objects/pointers: wxDefaultPosition

See also

wxRealPoint

Public Member Functions

- wxPoint ()

  Constructs a point.
- wxPoint (int x, int y)

  Initializes the point object with the given x and y coordinates.
- wxPoint (const wxRealPoint &pt)

  Converts the given wxRealPoint (with floating point coordinates) to a wxPoint instance.

Miscellaneous operators

Note that these operators are documented as class members (to make them easier to find) but, as their prototype shows, they are implemented as global operators; note that this is transparent to the user but it helps to understand why the following functions are documented to take the wxPoint they operate on as an explicit argument.

- wxPoint & operator= (const wxPoint &pt)
- bool operator== (const wxPoint &p1, const wxPoint &p2)
- bool operator!= (const wxPoint &p1, const wxPoint &p2)
- wxPoint operator+ (const wxPoint &p1, const wxPoint &p2)
- wxPoint operator- (const wxPoint &p1, const wxPoint &p2)
- wxPoint & operator+= (const wxPoint &pt)
- wxPoint & operator-= (const wxPoint &pt)
- wxPoint operator+ (const wxPoint &pt, const wxSize &sz)
- wxPoint operator- (const wxPoint &pt, const wxSize &sz)
- wxPoint operator+ (const wxSize &sz, const wxPoint &pt)
- wxPoint operator- (const wxSize &sz, const wxPoint &pt)
- wxPoint & operator+= (const wxSize &sz)
- wxPoint & operator-= (const wxSize &sz)
- wxSize operator/ (const wxPoint &sz, int factor)
- wxSize operator* (const wxPoint &sz, int factor)
- wxSize operator* (int factor, const wxSize &sz)
- wxSize & operator/= (int factor)
- wxSize & operator*= (int factor)

Defaults handling.

Test for and set non-specified wxPoint components.

Although a wxPoint is always initialized to (0, 0), wxWidgets commonly uses wxDefaultCoord (defined as `-1`) to indicate that a point hasn't been initialized or specified. In particular, wxDefaultPosition is used in many places with this meaning.

- bool IsFullySpecified () const

  Returns true if neither of the point components is equal to wxDefaultCoord.
- void SetDefaults (const wxPoint &pt)

  Combine this object with another one replacing the uninitialized values.

Public Attributes

- int x

  x member.
- int y

  y member.

21.533.2 Constructor & Destructor Documentation

wxPoint::wxPoint ( )

Constructs a point.

Initializes the internal x and y coordinates to zero.

wxPoint::wxPoint (int *x*, int *y*)

Initializes the point object with the given *x* and *y* coordinates.

wxPoint::wxPoint (const wxRealPoint & *pt*)

Converts the given wxRealPoint (with floating point coordinates) to a wxPoint instance.

Notice that this truncates the floating point values of *pt* components, if you want to round them instead you need to do it manually, e.g.

```
#include <wx/math.h>    // for wxRound()

wxRealPoint rp = ...;
wxPoint p(wxRound(rp.x), wxRound(rp.y));
```

21.533.3 Member Function Documentation

bool wxPoint::IsFullySpecified ( ) const

Returns true if neither of the point components is equal to wxDefaultCoord.

This method is typically used before calling SetDefaults().

Since

2.9.2

bool wxPoint::operator!= (const wxPoint & *p1*, const wxPoint & *p2*)

wxSize wxPoint::operator* (const wxPoint & *sz*, int *factor*)

wxSize wxPoint::operator* (int *factor*, const wxSize & *sz*)

wxSize& wxPoint::operator*= (int *factor*)

wxPoint wxPoint::operator+ (const wxPoint & *p1*, const wxPoint & *p2*)

wxPoint wxPoint::operator+ (const wxPoint & *pt*, const wxSize & *sz*)

wxPoint wxPoint::operator+ (const wxSize & *sz*, const wxPoint & *pt*)

wxPoint& wxPoint::operator+= (const wxPoint & *pt*)

wxPoint& wxPoint::operator+= (const wxSize & *sz*)

wxPoint wxPoint::operator- (const wxPoint & *p1*, const wxPoint & *p2*)

wxPoint wxPoint::operator- (const wxPoint & *pt*, const wxSize & *sz*)

wxPoint wxPoint::operator- (const wxSize & *sz*, const wxPoint & *pt*)

wxPoint& wxPoint::operator-= (const wxPoint & *pt*)

wxPoint& wxPoint::operator-= (const wxSize & *sz*)

wxSize wxPoint::operator/ (const wxPoint & *sz,* int *factor*)

wxSize& wxPoint::operator/= (int *factor*)

wxPoint& wxPoint::operator= (const wxPoint & *pt*)

bool wxPoint::operator== (const wxPoint & *p1,* const wxPoint & *p2*)

void wxPoint::SetDefaults (const wxPoint & *pt*)

Combine this object with another one replacing the uninitialized values.

It is typically used like this:

```
if ( !pos.IsFullySpecified() )
{
    pos.SetDefaults(GetDefaultPosition());
}
```

See also

IsFullySpecified()

Since

2.9.2

21.533.4 Member Data Documentation

int wxPoint::x

x member.

int wxPoint::y

y member.

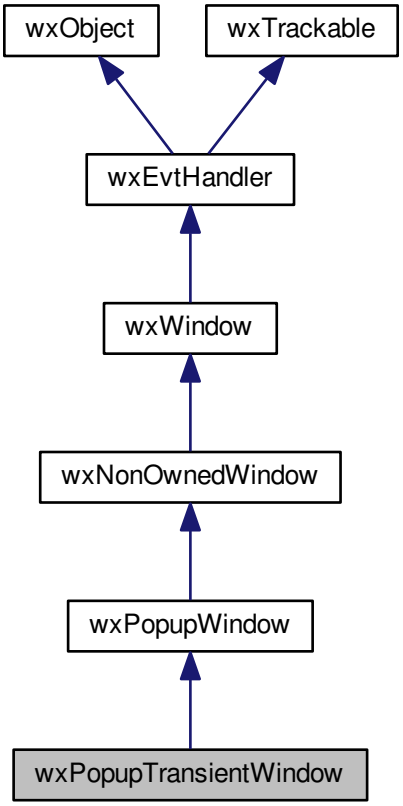
21.536 wxPopupTransientWindow Class Reference

`#include <wx/popupwin.h>`

Inheritance diagram for wxPopupTransientWindow:



21.536.1 Detailed Description

A wxPopupWindow which disappears automatically when the user clicks mouse outside it or if it loses focus in any other way.

This window can be useful for implementing custom combobox-like controls for example.

Library: wxCore

Category: Managed Windows

See also

wxPopupWindow

Public Member Functions

- wxPopupTransientWindow ()

  Default constructor.

- wxPopupTransientWindow (wxWindow *parent, int flags=wxBORDER_NONE)
  Constructor.
- virtual void Popup (wxWindow *focus=NULL)
  Popup the window (this will show it too).
- virtual void Dismiss ()
  Hide the window.
- virtual bool ProcessLeftDown (wxMouseEvent &event)
  Called when a mouse is pressed while the popup is shown.

Protected Member Functions

- virtual void OnDismiss ()
  This is called when the popup is disappeared because of anything else but direct call to Dismiss().

Additional Inherited Members

21.536.2 Constructor & Destructor Documentation

wxPopupTransientWindow::wxPopupTransientWindow ( )

Default constructor.

wxPopupTransientWindow::wxPopupTransientWindow (wxWindow * *parent,* int *flags* = wxBORDER_NONE)

Constructor.

21.536.3 Member Function Documentation

virtual void wxPopupTransientWindow::Dismiss ( ) [virtual]

Hide the window.

virtual void wxPopupTransientWindow::OnDismiss ( ) [protected], [virtual]

This is called when the popup is disappeared because of anything else but direct call to Dismiss().

virtual void wxPopupTransientWindow::Popup (wxWindow * *focus* = NULL) [virtual]

Popup the window (this will show it too).

If *winFocus* is non-NULL, it will be kept focused while this window is shown, otherwise this window itself will receive focus. In any case, the popup will disappear automatically if it loses focus because of a user action.

See also

Dismiss()

virtual bool wxPopupTransientWindow::ProcessLeftDown (wxMouseEvent & *event*) [virtual]

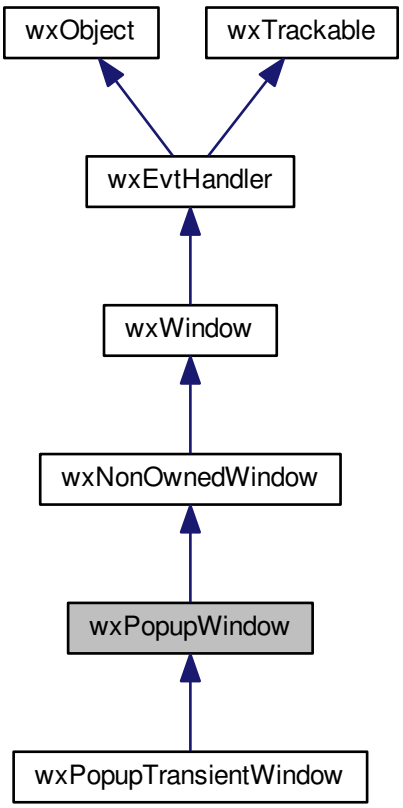
Called when a mouse is pressed while the popup is shown.

Return true from here to prevent its normal processing by the popup (which consists in dismissing it if the mouse is clicked outside it).

21.537 wxPopupWindow Class Reference

`#include <wx/popupwin.h>`

Inheritance diagram for wxPopupWindow:



21.537.1 Detailed Description

A special kind of top level window used for popup menus, combobox popups and such.

Library: wxCore

Category: Managed Windows

wxDialog, wxFrame

Public Member Functions

- wxPopupWindow ()

Default constructor.

- wxPopupWindow (wxWindow *parent, int flags=wxBORDER_NONE)

  Constructor.

- bool Create (wxWindow *parent, int flags=wxBORDER_NONE)

  Create method for two-step creation.

- virtual void Position (const wxPoint &ptOrigin, const wxSize &sizePopup)

  Move the popup window to the right position, i.e. such that it is entirely visible.

Additional Inherited Members

21.537.2 Constructor & Destructor Documentation

wxPopupWindow::wxPopupWindow ( )

Default constructor.

wxPopupWindow::wxPopupWindow (wxWindow * *parent,* int *flags* = wxBORDER_NONE)

Constructor.

21.537.3 Member Function Documentation

bool wxPopupWindow::Create (wxWindow * *parent,* int *flags* = wxBORDER_NONE)

Create method for two-step creation.

virtual void wxPopupWindow::Position (const wxPoint & *ptOrigin,* const wxSize & *sizePopup*) `[virtual]`

Move the popup window to the right position, i.e. such that it is entirely visible.

The popup is positioned at ptOrigin + size if it opens below and to the right (default), at ptOrigin - sizePopup if it opens above and to the left etc.

Parameters

ptOrigin	Must be given in screen coordinates!
sizePopup	The size of the popup window

21.538 wxPosition Class Reference

`#include <wx/position.h>`

21.538.1 Detailed Description

This class represents the position of an item in any kind of grid of rows and columns such as wxGridBagSizer, or wxHVScrolledWindow.

Library: wxBase

Category: Data Structures

See also

wxPoint, wxSize

Public Member Functions

- wxPosition ()

  Construct a new wxPosition, setting the row and column to the default value of (0, 0).
- wxPosition (int row, int col)

  Construct a new wxPosition, setting the row and column to the value of (row, col).
- int GetCol () const

  A synonym for GetColumn().
- int GetColumn () const

  Get the current row value.
- int GetRow () const

  Get the current row value.
- void SetCol (int column)

  A synonym for SetColumn().
- void SetColumn (int column)

  Set a new column value.
- void SetRow (int row)

  Set a new row value.

Miscellaneous operators

- bool operator== (const wxPosition &pos) const
- bool operator!= (const wxPosition &pos) const
- wxPosition & operator+= (const wxPosition &pos)
- wxPosition & operator-= (const wxPosition &pos)
- wxPosition & operator+= (const wxSize &size)
- wxPosition & operator-= (const wxSize &size)
- wxPosition operator+ (const wxPosition &pos) const
- wxPosition operator- (const wxPosition &pos) const
- wxPosition operator+ (const wxSize &size) const
- wxPosition operator- (const wxSize &size) const

21.538.2 Constructor & Destructor Documentation

wxPosition::wxPosition ( )

Construct a new wxPosition, setting the row and column to the default value of (0, 0).

wxPosition::wxPosition (int *row,* int *col*)

Construct a new wxPosition, setting the row and column to the value of (*row*, *col*).

21.538.3 Member Function Documentation

int wxPosition::GetCol ( ) const

A synonym for GetColumn().

int wxPosition::GetColumn ( ) const

Get the current row value.

int wxPosition::GetRow ( ) const

Get the current row value.

bool wxPosition::operator!= (const wxPosition & *pos*) const

wxPosition wxPosition::operator+ (const wxPosition & *pos*) const

wxPosition wxPosition::operator+ (const wxSize & *size*) const

wxPosition& wxPosition::operator+= (const wxPosition & *pos*)

wxPosition& wxPosition::operator+= (const wxSize & *size*)

wxPosition wxPosition::operator- (const wxPosition & *pos*) const

wxPosition wxPosition::operator- (const wxSize & *size*) const

wxPosition& wxPosition::operator-= (const wxPosition & *pos*)

wxPosition& wxPosition::operator-= (const wxSize & *size*)

bool wxPosition::operator== (const wxPosition & *pos*) const

void wxPosition::SetCol (int *column*)

A synonym for SetColumn().

void wxPosition::SetColumn (int *column*)

Set a new column value.

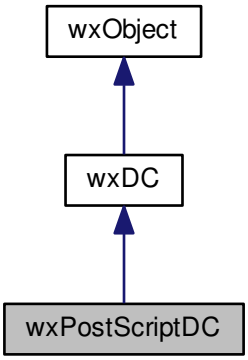
void wxPosition::SetRow (int *row*)

Set a new row value.

21.539 wxPostScriptDC Class Reference

`#include <wx/dcps.h>`

Inheritance diagram for wxPostScriptDC:



21.539.1 Detailed Description

This defines the wxWidgets Encapsulated PostScript device context, which can write PostScript files on any platform.

See wxDC for descriptions of the member functions.

Library: wxBase

Category: Device Contexts

Public Member Functions

- wxPostScriptDC ()
- wxPostScriptDC (const wxPrintData &printData)

  Constructs a PostScript printer device context from a wxPrintData object.

Additional Inherited Members

21.539.2 Constructor & Destructor Documentation

wxPostScriptDC::wxPostScriptDC ( )

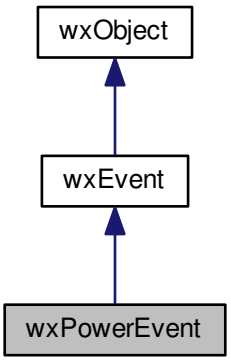
wxPostScriptDC::wxPostScriptDC (const wxPrintData & *printData*)

Constructs a PostScript printer device context from a wxPrintData object.

21.540 wxPowerEvent Class Reference

```
#include <wx/power.h>
```

Inheritance diagram for wxPowerEvent:



21.540.1 Detailed Description

The power events are generated when the system power state changes, e.g.

the system is suspended, hibernated, plugged into or unplugged from the wall socket and so on. wxPowerEvents are emitted by wxWindows.

Notice that currently only suspend and resume events are generated and only under MS Windows platform. To avoid the need to change the code using this event later when these events are implemented on the other platforms please use the test `ifdef wxHAS_POWER_EVENTS` instead of directly testing for the platform in your code: this symbol will be defined for all platforms supporting the power events.

Events using this class

The following event handler macros redirect the events to member function handlers '**func**' with prototypes like: void handlerFuncName(wxPowerEvent& event)

Event macros:

- EVT_POWER_SUSPENDING(func):

  Warning

  > This event and the possibility to veto suspend was removed from MSW systems starting from Windows Vista. wxPowerResourceBlocker can be used to prevent the system from suspending under both XP and later systems, use it instead of handling this event.

  System is about to be suspended, this event can be vetoed to prevent suspend from taking place.

- EVT_POWER_SUSPENDED(func): System is about to suspend: normally the application should quickly (i.e. without user intervention) close all the open files and network connections here, possibly remembering them to reopen them later when the system is resumed.
- EVT_POWER_SUSPEND_CANCEL(func): System suspension was cancelled because some application vetoed it.
- EVT_POWER_RESUME(func): System resumed from suspend: normally the application should restore the state in which it had been before the suspension.

Library: wxBase

Category: Events

See also

wxGetPowerType(), wxGetBatteryState()

Public Member Functions

- wxPowerEvent ()
- wxPowerEvent (wxEventType evtType)
- void Veto ()

  Call this to prevent suspend from taking place in `wxEVT_POWER_SUSPENDING` handler (it is ignored for all the others).
- bool IsVetoed () const

  Returns whether Veto has been called.

Additional Inherited Members

21.540.2 Constructor & Destructor Documentation

wxPowerEvent::wxPowerEvent ( )

wxPowerEvent::wxPowerEvent (wxEventType *evtType*)

21.540.3 Member Function Documentation

bool wxPowerEvent::IsVetoed ( ) const

Returns whether Veto has been called.

void wxPowerEvent::Veto ( )

Call this to prevent suspend from taking place in `wxEVT_POWER_SUSPENDING` handler (it is ignored for all the others).

21.541 wxPowerResource Class Reference

```
#include <wx/power.h>
```

21.541.1 Detailed Description

Helper functions for acquiring and releasing the given power resource.

If an application performs a long running task without user interaction it is often necessary to prevent the system from automatically suspending or powering off the screen and Acquire() method can be used to do this.

Notice that currently this functionality is only implemented for MSW and OSX and on the latter only wxPOWER_↩ RESOURCE_SYSTEM is supported for versions earlier than 10.9.

If possible, use wxPowerResourceBlocker class to ensure that Release() is called instead of calling it manually.

Since

3.1.0

Library: wxBase

Category: Miscellaneous

See also

wxPowerResourceBlocker

Static Public Member Functions

- static bool Acquire (wxPowerResourceKind kind, const wxString &reason=wxString())

  Acquire a power resource for the application.
- static void Release (wxPowerResourceKind kind)

  Release a previously acquired power resource.

21.541.2 Member Function Documentation

static bool wxPowerResource::Acquire (wxPowerResourceKind *kind,* const wxString & *reason* = wxString ()) `[static]`

Acquire a power resource for the application.

If successful, the system will not automatically power of the screen or suspend until Release() is called.

Every call to Acquire **must** be matched by a corresponding call to Release() or the system will not suspend until the application ends, use wxPowerResourceBlocker to ensure that this happens.

Parameters

kind	Power resource required, either wxPOWER_RESOURCE_SCREEN or wxPOWER_RESOURCE_SYSTEM.
reason	Optional reason may be specified which might be used on some platforms to inform the user what is preventing power saving. It should usually describe the operation requiring the resource and specifying it is strongly recommended.

Returns

Returns true if the acquisition was successful.

See also

Release()

static void wxPowerResource::Release (wxPowerResourceKind *kind*) `[static]`

Release a previously acquired power resource.

Release **must** be called for every Acquire() call made to restore normal power saving behaviour

Parameters

kind	Power resource to be released.

See also

Acquire()

21.542 wxPowerResourceBlocker Class Reference

`#include <wx/power.h>`

21.542.1 Detailed Description

Helper RAII class ensuring that power resources are released.

A wxPowerResourceBlocker object acquires a power resource in the constructor and releases it in the destructor making it impossible to to forget to release the power resource (which would prevent suspending or screen power off until the application ends).

Example:

```
void MyWindow::DoSomething()
{
    wxPowerResourceBlocker
        blocker(wxPOWER_RESOURCE_SYSTEM, "Downloading something important");

    if ( !blocker.IsInEffect() )
    {
        // If the resource could not be acquired, tell the user that he has
        // to keep the system alive
        wxLogMessage("Warning: system may suspend while downloading.");
    }

    // Run an important download and the system will not suspend while downloading
    for ( int i = 0; i < download.size(); ++i )
        download.readByte();

    // wxPOWER_RESOURCE_SYSTEM automatically released here.
}
```

Since

3.1.0

Library: wxBase

Category: Miscellaneous

See also

wxPowerResource

Public Member Functions

- wxPowerResourceBlocker (wxPowerResourceKind kind, const wxString &reason=wxString())

  Acquires the power resource.
- bool IsInEffect () const

  Returns whether the power resource could be acquired.
- ~wxPowerResourceBlocker ()

  Releases the power resource.

21.542.2 Constructor & Destructor Documentation

wxPowerResourceBlocker::wxPowerResourceBlocker (wxPowerResourceKind *kind,* const wxString & *reason =* wxString ()) [explicit]

Acquires the power resource.

Uses the same parameters as wxPowerResource::Acquire().

wxPowerResourceBlocker::~wxPowerResourceBlocker ( )

Releases the power resource.

See also

wxPowerResource::Release()

21.542.3 Member Function Documentation

bool wxPowerResourceBlocker::IsInEffect ( ) const

Returns whether the power resource could be acquired.

This can be used to inform the user that the application will not prevent automatic suspending.

See also

wxPowerResource::Acquire()

21.543 wxPreferencesEditor Class Reference

```
#include <wx/preferences.h>
```

21.543.1 Detailed Description

Manage preferences dialog.

This class encapsulates the differences – both in appearance and behaviour – between preferences dialogs on different platforms. In particular, OS X preferences look very different from the typical notebook control used on other platforms, and both OS X and GTK+ preferences windows are modeless unlike Windows options dialogs that are typically modal.

wxPreferencesEditor is able to hide the differences by hiding the creation of preferences window from the API. Instead, you create an instance of wxPreferencesEditor and add page descriptions in the form of wxPreferences↩ Page using its AddPage() method. After setting up the editor object, you must call Show() to present preferences to the user.

Note

Notice that this class is not derived from wxWindow and hence doesn't represent a window, even if its Show() method does create one internally.

Library: wxCore

Since

2.9.5

Public Member Functions

- wxPreferencesEditor (const wxString &title=wxString())

  Constructor.
- ~wxPreferencesEditor ()

  Destructor.
- void AddPage (wxPreferencesPage *page)

  Add a new page to the editor.
- virtual void Show (wxWindow *parent)

  Show the preferences dialog or bring it to the top if it's already shown.
- void Dismiss ()

  Hide the currently shown dialog, if any.

Static Public Member Functions

- static bool ShouldApplyChangesImmediately () static bool ShownModally()

  Returns whether changes to values in preferences pages should be applied immediately or only when the user clicks the OK button.

21.543.2 Constructor & Destructor Documentation

wxPreferencesEditor::wxPreferencesEditor (const wxString & *title* = wxString ( ))

Constructor.

Creates an empty editor, use AddPage() to add controls to it.

Parameters

title	The title overriding the default title of the top level window used by the editor. It is recommended to not specify this parameter to use the native convention for the preferences dialogs instead.

wxPreferencesEditor::~wxPreferencesEditor ( )

Destructor.

Destroying this object hides the associated preferences window if it is open at the moment.

The destructor is non-virtual as this class is not supposed to be derived from.

21.543.3 Member Function Documentation

void wxPreferencesEditor::AddPage (wxPreferencesPage * *page*)

Add a new page to the editor.

The editor takes ownership of the page and will delete it from its destructor (but not sooner).

See also

wxPreferencesPage, wxStockPreferencesPage

void wxPreferencesEditor::Dismiss ( )

Hide the currently shown dialog, if any.

This is typically called to dismiss the dialog if the object whose preferences it is editing was closed.

static bool wxPreferencesEditor::ShouldApplyChangesImmediately ( ) [static]

Returns whether changes to values in preferences pages should be applied immediately or only when the user clicks the OK button.

Currently, changes are applied immediately on OS X and GTK+.

The preprocessor macro `wxHAS_PREF_EDITOR_APPLY_IMMEDIATELY` is defined in this case as well. Returns whether the preferences dialog is shown modally.

If this method returns false, as it currently does in wxGTK and wxOSX, Show() simply makes the dialog visible and returns immediately. If it returns true, as it does in wxMSW and under the other platforms, then the dialog is shown modally, i.e. Show() blocks until the user dismisses it.

Notice that it isn't necessary to test the return value of this method to use this class normally, its interface is designed to work in both cases. However it can sometimes be necessary to call it if the program needs to handle modal dialogs specially, e.g. perhaps to block some periodic background update operation while a modal dialog is shown.

virtual void wxPreferencesEditor::Show (wxWindow * *parent*) [virtual]

Show the preferences dialog or bring it to the top if it's already shown.

Notice that this method may or may not block depending on the platform, i.e. depending on whether the dialog is modal or not.

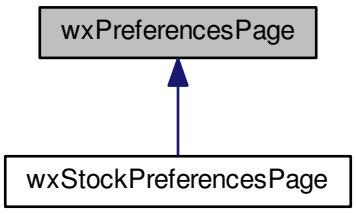
Parameters

parent	The window that invokes the preferences. Call Dismiss() before it's destroyed.

21.544 wxPreferencesPage Class Reference

`#include <wx/preferences.h>`

Inheritance diagram for wxPreferencesPage:



21.544.1 Detailed Description

One page of preferences dialog.

This is the base class for implementation of application's preferences. Its methods return various properties of the page, such as title or icon. The actual page is created by CreateWindow().

See also

wxStockPreferencesPage

Library: wxCore

Since

2.9.5

Public Member Functions

- wxPreferencesPage ()
  Constructor.
- virtual ~wxPreferencesPage ()
  Destructor.
- virtual wxString GetName () const =0
  Return name of the page.
- virtual wxBitmap GetLargeIcon () const =0
  Return 32x32 icon used for the page on some platforms.
- virtual wxWindow * CreateWindow (wxWindow *parent)=0
  Create a window for this page.

21.544.2 Constructor & Destructor Documentation

wxPreferencesPage::wxPreferencesPage ( )

Constructor.

virtual wxPreferencesPage::~wxPreferencesPage ( ) [virtual]

Destructor.

21.544.3 Member Function Documentation

virtual wxWindow* wxPreferencesPage::CreateWindow (wxWindow * *parent*) [pure virtual]

Create a window for this page.

The window will be placed into the preferences dialog in platform-specific manner. Depending on the platform, this method may be called before showing the preferences window, when switching to its tab or even more than once. Don't make assumptions about the number of times or the specific time when it is called.

The caller takes ownership of the window.

wxPanel is usually used, but doesn't have to be.

Parameters

parent	Parent window to use.

virtual wxBitmap wxPreferencesPage::GetLargeIcon ( ) const `[pure virtual]`

Return 32x32 icon used for the page on some platforms.

Currently only used on OS X.

Note

This method is only pure virtual on platforms that require it (OS X). On other platforms, it has default implementation that returns an invalid bitmap. The preprocessor symbol `wxHAS_PREF_EDITOR_ICONS` is defined if this method must be implemented.

Implemented in wxStockPreferencesPage.

virtual wxString wxPreferencesPage::GetName ( ) const `[pure virtual]`

Return name of the page.

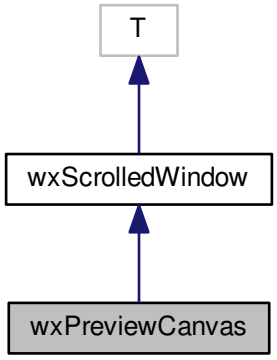
The name is used for notebook tab's label, icon label etc., depending on the platform.

Implemented in wxStockPreferencesPage.

21.545 wxPreviewCanvas Class Reference

`#include <wx/print.h>`

Inheritance diagram for wxPreviewCanvas:



21.545.1 Detailed Description

A preview canvas is the default canvas used by the print preview system to display the preview.

Library: wxCore

Category: Printing Framework

See also

wxPreviewFrame, wxPreviewControlBar, wxPrintPreview

Public Member Functions

- wxPreviewCanvas (wxPrintPreview *preview, wxWindow *parent, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, long style=0, const wxString &name="canvas")

  Constructor.

- virtual ~wxPreviewCanvas ()

  Destructor.

- void OnPaint (wxPaintEvent &event)

  Calls wxPrintPreview::PaintPage() to refresh the canvas.

Additional Inherited Members

21.545.2 Constructor & Destructor Documentation

wxPreviewCanvas::wxPreviewCanvas (wxPrintPreview * *preview*, wxWindow * *parent*, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, long *style* = 0, const wxString & *name* = "canvas")

Constructor.

virtual wxPreviewCanvas::~wxPreviewCanvas ( ) [virtual]

Destructor.

21.545.3 Member Function Documentation

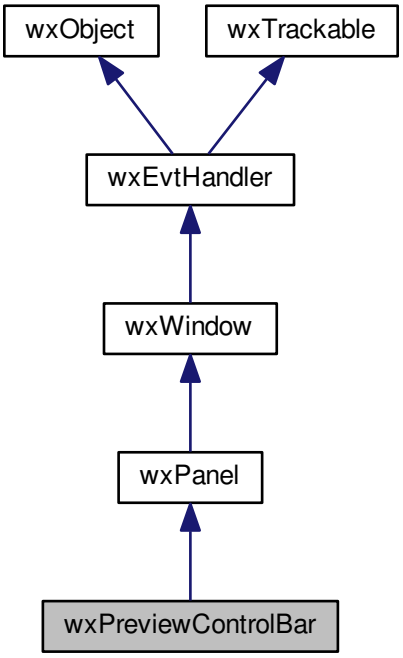
void wxPreviewCanvas::OnPaint (wxPaintEvent & *event*)

Calls wxPrintPreview::PaintPage() to refresh the canvas.

21.546 wxPreviewControlBar Class Reference

```
#include <wx/print.h>
```

Inheritance diagram for wxPreviewControlBar:



21.546.1 Detailed Description

This is the default implementation of the preview control bar, a panel with buttons and a zoom control.

You can derive a new class from this and override some or all member functions to change the behaviour and appearance; or you can leave it as it is.

Library: wxCore

Category: Printing Framework

See also

wxPreviewFrame, wxPreviewCanvas, wxPrintPreview

Public Member Functions

- wxPreviewControlBar (wxPrintPreview *preview, long buttons, wxWindow *parent, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, long style=0, const wxString &name="panel")

  Constructor.
- virtual ~wxPreviewControlBar ()

  Destructor.
- virtual void CreateButtons ()

Creates buttons, according to value of the button style flags.

- virtual wxPrintPreviewBase * GetPrintPreview () const

  Gets the print preview object associated with the control bar.

- virtual int GetZoomControl ()

  Gets the current zoom setting in percent.

- virtual void SetZoomControl (int percent)

  Sets the zoom control.

Additional Inherited Members

21.546.2 Constructor & Destructor Documentation

wxPreviewControlBar::wxPreviewControlBar (wxPrintPreview * *preview,* long *buttons,* wxWindow * *parent,* const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, long *style* = `0`, const wxString & *name* = `"panel"`)

Constructor.

The *buttons* parameter may be a combination of the following, using the bitwise 'or' operator:

- wxPREVIEW_PRINT: Create a print button.
- wxPREVIEW_NEXT: Create a next page button.
- wxPREVIEW_PREVIOUS: Create a previous page button.
- wxPREVIEW_ZOOM: Create a zoom control.
- wxPREVIEW_DEFAULT: Equivalent to a combination of `wxPREVIEW_PREVIOUS`, `wxPREVIEW_NEXT` and `wxPREVIEW_ZOOM`.

virtual wxPreviewControlBar::~wxPreviewControlBar ( ) `[virtual]`

Destructor.

21.546.3 Member Function Documentation

virtual void wxPreviewControlBar::CreateButtons ( ) `[virtual]`

Creates buttons, according to value of the button style flags.

Todo which flags??

virtual wxPrintPreviewBase* wxPreviewControlBar::GetPrintPreview ( ) const `[virtual]`

Gets the print preview object associated with the control bar.

virtual int wxPreviewControlBar::GetZoomControl ( ) `[virtual]`

Gets the current zoom setting in percent.

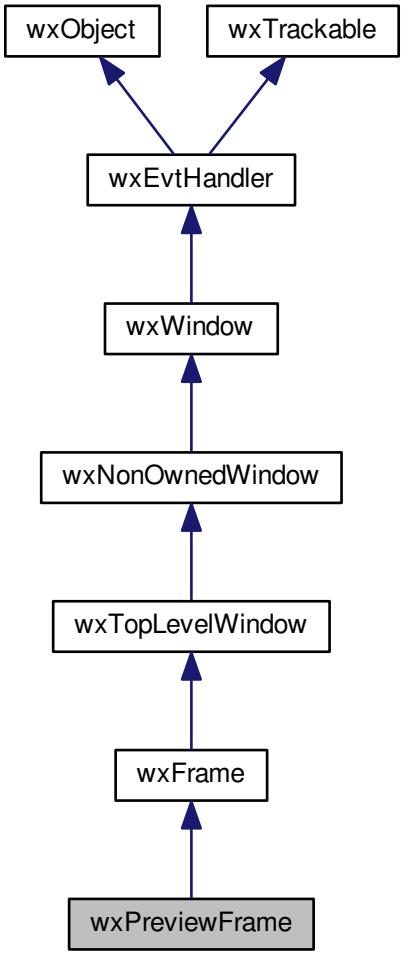
virtual void wxPreviewControlBar::SetZoomControl (int *percent*) `[virtual]`

Sets the zoom control.

21.547 wxPreviewFrame Class Reference

`#include <wx/print.h>`

Inheritance diagram for wxPreviewFrame:



21.547.1 Detailed Description

This class provides the default method of managing the print preview interface.

Member functions may be overridden to replace functionality, or the class may be used without derivation.

Library: wxCore

Category: Printing Framework

See also

wxPreviewCanvas, wxPreviewControlBar, wxPrintPreview

Public Member Functions

- wxPreviewFrame (wxPrintPreviewBase *preview, wxWindow *parent, const wxString &title="Print Preview", const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, long style=wxDEFAULT_FRAME_STYLE, const wxString &name=wxFrameNameStr)

  Constructor.
- virtual ~wxPreviewFrame ()

  Destructor.
- virtual void CreateCanvas ()

  Creates a wxPreviewCanvas.
- virtual void CreateControlBar ()

  Creates a wxPreviewControlBar.
- virtual void Initialize ()

  Initializes the frame elements and prepares for showing it.
- virtual void InitializeWithModality (wxPreviewFrameModalityKind kind)

  Initializes the frame elements and prepares for showing it with the given modality kind.
- void OnCloseWindow (wxCloseEvent &event)

  Enables any disabled frames in the application, and deletes the print preview object, implicitly deleting any printout objects associated with the print preview object.

Additional Inherited Members

21.547.2 Constructor & Destructor Documentation

wxPreviewFrame::wxPreviewFrame (wxPrintPreviewBase * *preview*, wxWindow * *parent*, const wxString & *title* = `"Print Preview"`, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, long *style* = wxDEFAULT_FRAME_STYLE, const wxString & *name* = `wxFrameNameStr`)

Constructor.

Pass a print preview object plus other normal frame arguments. The print preview object will be destroyed by the frame when it closes.

virtual wxPreviewFrame::~wxPreviewFrame ( ) `[virtual]`

Destructor.

21.547.3 Member Function Documentation

virtual void wxPreviewFrame::CreateCanvas ( ) `[virtual]`

Creates a wxPreviewCanvas.

Override this function to allow a user-defined preview canvas object to be created.

virtual void wxPreviewFrame::CreateControlBar ( ) [virtual]

Creates a wxPreviewControlBar.

Override this function to allow a user-defined preview control bar object to be created.

virtual void wxPreviewFrame::Initialize ( ) [virtual]

Initializes the frame elements and prepares for showing it.

Calling this method is equivalent to calling InitializeWithModality() with wxPreviewFrame_AppModal argument, please see its documentation for more details.

Please notice that this function is virtual mostly for backwards compatibility only, there is no real need to override it as it's never called by wxWidgets itself.

virtual void wxPreviewFrame::InitializeWithModality (wxPreviewFrameModalityKind *kind*) [virtual]

Initializes the frame elements and prepares for showing it with the given modality kind.

This method creates the frame elements by calling CreateCanvas() and CreateControlBar() methods (which may be overridden to customize them) and prepares to show the frame according to the value of *kind* parameter:

- If it is wxPreviewFrame_AppModal, all the other application windows will be disabled when this frame is shown. This is the same behaviour as that of simple Initialize().
- If it is wxPreviewFrame_WindowModal, only the parent window of the preview frame will be disabled when it is shown.
- And if it is wxPreviewFrame_NonModal, no windows at all will be disabled while the preview is shown.

Notice that this function (or Initialize()) must be called by the application prior to showing the frame but you still must call `Show(true)` to actually show it afterwards.

Parameters

kind	The modality kind of preview frame.

Since

2.9.2

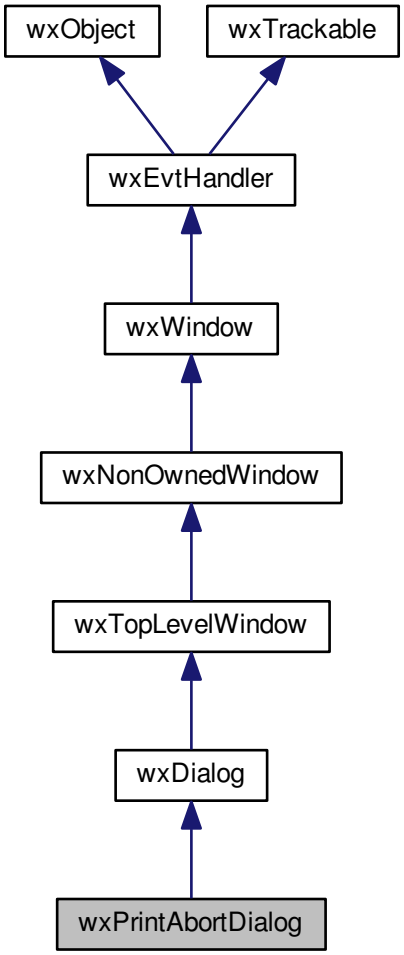
void wxPreviewFrame::OnCloseWindow (wxCloseEvent & *event*)

Enables any disabled frames in the application, and deletes the print preview object, implicitly deleting any printout objects associated with the print preview object.

21.548 wxPrintAbortDialog Class Reference

`#include <wx/print.h>`

Inheritance diagram for wxPrintAbortDialog:



21.548.1 Detailed Description

The dialog created by default by the print framework that enables aborting the printing process.

Public Member Functions

- wxPrintAbortDialog (wxWindow *parent, const wxString &documentTitle, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, long style=wxDEFAULT_DIALOG_STYLE, const wxString &name="dialog")
- void SetProgress (int currentPage, int totalPages, int currentCopy, int totalCopies)

21.548.2 Constructor & Destructor Documentation

wxPrintAbortDialog::wxPrintAbortDialog (wxWindow * *parent*, const wxString & *documentTitle*, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, long *style* = wxDEFAULT_DIALOG_STYLE, const wxString & *name* = "dialog")

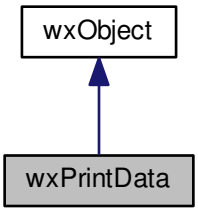
21.548.3 Member Function Documentation

void wxPrintAbortDialog::SetProgress (int *currentPage*, int *totalPages*, int *currentCopy*, int *totalCopies*)

21.549 wxPrintData Class Reference

`#include <wx/cmndata.h>`

Inheritance diagram for wxPrintData:



21.549.1 Detailed Description

This class holds a variety of information related to printers and printer device contexts.

This class is used to create a wxPrinterDC and a wxPostScriptDC. It is also used as a data member of wxPrintDialogData and wxPageSetupDialogData, as part of the mechanism for transferring data between the print dialogs and the application.

Library: wxCore

Category: Printing Framework, Data Structures

See also

Printing Framework Overview, wxPrintDialog, wxPageSetupDialog, wxPrintDialogData, wxPageSetupDialogData, wxPrintDialog Overview, wxPrinterDC, wxPostScriptDC

Public Member Functions

- wxPrintData ()

  Default constructor.
- wxPrintData (const wxPrintData &data)

  Copy constructor.
- virtual ~wxPrintData ()

  Destructor.

- wxPrintBin GetBin () const

  Returns the current bin (papersource).
- bool GetCollate () const

  Returns true if collation is on.
- bool GetColour () const

  Returns true if colour printing is on.
- wxDuplexMode GetDuplex () const

  Returns the duplex mode.
- int GetNoCopies () const

  Returns the number of copies requested by the user.
- wxPrintOrientation GetOrientation () const

  Gets the orientation.
- wxPaperSize GetPaperId () const

  Returns the paper size id.
- const wxString & GetPrinterName () const

  Returns the printer name.
- wxPrintQuality GetQuality () const

  Returns the current print quality.
- bool IsOk () const

  Returns true if the print data is valid for using in print dialogs.
- void SetBin (wxPrintBin flag)

  Sets the current bin.
- void SetCollate (bool flag)

  Sets collation to on or off.
- void SetColour (bool flag)

  Sets colour printing on or off.
- void SetDuplex (wxDuplexMode mode)

  Returns the duplex mode.
- void SetNoCopies (int n)

  Sets the default number of copies to be printed out.
- void SetOrientation (wxPrintOrientation orientation)

  Sets the orientation.
- void SetPaperId (wxPaperSize paperId)

  Sets the paper id.
- void SetPrinterName (const wxString &printerName)

  Sets the printer name.
- void SetQuality (wxPrintQuality quality)

  Sets the desired print quality.
- wxPrintData & operator= (const wxPrintData &data)

  Assigns print data to this object.
- wxString GetFilename () const
- void SetFilename (const wxString &filename)
- wxPrintMode GetPrintMode () const
- void SetPrintMode (wxPrintMode printMode)

Additional Inherited Members

21.549.2 Constructor & Destructor Documentation

wxPrintData::wxPrintData ( )

Default constructor.

wxPrintData::wxPrintData (const wxPrintData & *data*)

Copy constructor.

virtual wxPrintData::~wxPrintData ( ) [virtual]

Destructor.

21.549.3 Member Function Documentation

wxPrintBin wxPrintData::GetBin ( ) const

Returns the current bin (papersource).

By default, the system is left to select the bin (`wxPRINTBIN_DEFAULT` is returned).

See SetBin() for the full list of bin values.

bool wxPrintData::GetCollate ( ) const

Returns true if collation is on.

bool wxPrintData::GetColour ( ) const

Returns true if colour printing is on.

wxDuplexMode wxPrintData::GetDuplex ( ) const

Returns the duplex mode.

One of wxDUPLEX_SIMPLEX, wxDUPLEX_HORIZONTAL, wxDUPLEX_VERTICAL.

wxString wxPrintData::GetFilename ( ) const

int wxPrintData::GetNoCopies ( ) const

Returns the number of copies requested by the user.

wxPrintOrientation wxPrintData::GetOrientation ( ) const

Gets the orientation.

This can be wxLANDSCAPE or wxPORTRAIT.

wxPaperSize wxPrintData::GetPaperId ( ) const

Returns the paper size id.

See also

SetPaperId()

const wxString& wxPrintData::GetPrinterName ( ) const

Returns the printer name.

If the printer name is the empty string, it indicates that the default printer should be used.

wxPrintMode wxPrintData::GetPrintMode ( ) const

wxPrintQuality wxPrintData::GetQuality ( ) const

Returns the current print quality.

This can be a positive integer, denoting the number of dots per inch, or one of the following identifiers:

- wxPRINT_QUALITY_HIGH
- wxPRINT_QUALITY_MEDIUM
- wxPRINT_QUALITY_LOW
- wxPRINT_QUALITY_DRAFT

On input you should pass one of these identifiers, but on return you may get back a positive integer indicating the current resolution setting.

bool wxPrintData::IsOk ( ) const

Returns true if the print data is valid for using in print dialogs.

This can return false on Windows if the current printer is not set, for example. On all other platforms, it returns true.

wxPrintData& wxPrintData::operator= (const wxPrintData & *data*)

Assigns print data to this object.

void wxPrintData::SetBin (wxPrintBin *flag*)

Sets the current bin.

void wxPrintData::SetCollate (bool *flag*)

Sets collation to on or off.

void wxPrintData::SetColour (bool *flag*)

Sets colour printing on or off.

void wxPrintData::SetDuplex (wxDuplexMode *mode*)

Returns the duplex mode.

One of wxDUPLEX_SIMPLEX, wxDUPLEX_HORIZONTAL, wxDUPLEX_VERTICAL.

void wxPrintData::SetFilename (const wxString & *filename*)

void wxPrintData::SetNoCopies (int *n*)

Sets the default number of copies to be printed out.

void wxPrintData::SetOrientation (wxPrintOrientation *orientation*)

Sets the orientation.

This can be wxLANDSCAPE or wxPORTRAIT.

void wxPrintData::SetPaperId (wxPaperSize *paperId*)

Sets the paper id.

This indicates the type of paper to be used. For a mapping between paper id, paper size and string name, see wxPrintPaperDatabase in "paper.h" (not yet documented).

void wxPrintData::SetPrinterName (const wxString & *printerName*)

Sets the printer name.

This can be the empty string to indicate that the default printer should be used.

void wxPrintData::SetPrintMode (wxPrintMode *printMode*)

void wxPrintData::SetQuality (wxPrintQuality *quality*)

Sets the desired print quality.

This can be a positive integer, denoting the number of dots per inch, or one of the following identifiers:

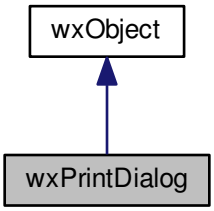
- wxPRINT_QUALITY_HIGH
- wxPRINT_QUALITY_MEDIUM
- wxPRINT_QUALITY_LOW
- wxPRINT_QUALITY_DRAFT

On input you should pass one of these identifiers, but on return you may get back a positive integer indicating the current resolution setting.

21.550 wxPrintDialog Class Reference

#include <wx/printdlg.h>

Inheritance diagram for wxPrintDialog:



21.550.1 Detailed Description

This class represents the print and print setup common dialogs.

You may obtain a wxPrinterDC device context from a successfully dismissed print dialog.

Library: wxCore

Category: Printing Framework

Printing Framework Overview, wxPrintDialog Overview

Public Member Functions

- wxPrintDialog (wxWindow *parent, wxPrintDialogData *data=NULL)

  Constructor.
- wxPrintDialog (wxWindow *parent, wxPrintData *data)
- virtual ~wxPrintDialog ()

  Destructor.
- virtual wxDC * GetPrintDC ()

  Returns the device context created by the print dialog, if any.
- virtual wxPrintDialogData & GetPrintDialogData ()

  Returns the print dialog data associated with the print dialog.
- virtual wxPrintData & GetPrintData ()

  Returns the print data associated with the print dialog.
- virtual int ShowModal ()

  Shows the dialog, returning `wxID_OK` if the user pressed OK, and `wxID_CANCEL` otherwise.

Additional Inherited Members

21.550.2 Constructor & Destructor Documentation

wxPrintDialog::wxPrintDialog (wxWindow * *parent,* wxPrintDialogData * *data* = NULL)

Constructor.

Pass a parent window, and optionally a pointer to a block of print data, which will be copied to the print dialog's print data.

See also

wxPrintDialogData

wxPrintDialog::wxPrintDialog (wxWindow * *parent,* wxPrintData * *data*)

virtual wxPrintDialog::~wxPrintDialog ( ) [virtual]

Destructor.

If GetPrintDC() has not been called, the device context obtained by the dialog (if any) will be deleted.

21.550.3 Member Function Documentation

virtual wxPrintData& wxPrintDialog::GetPrintData ( ) [virtual]

Returns the print data associated with the print dialog.

virtual wxDC* wxPrintDialog::GetPrintDC ( ) [virtual]

Returns the device context created by the print dialog, if any.

When this function has been called, the ownership of the device context is transferred to the application, so it must then be deleted explicitly.

virtual wxPrintDialogData& wxPrintDialog::GetPrintDialogData ( ) [virtual]

Returns the print dialog data associated with the print dialog.

virtual int wxPrintDialog::ShowModal ( ) [virtual]

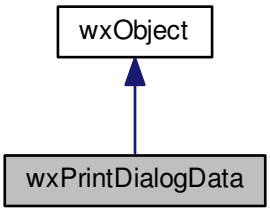
Shows the dialog, returning wxID_OK if the user pressed OK, and wxID_CANCEL otherwise.

After this function is called, a device context may be retrievable using GetPrintDC().

21.551 wxPrintDialogData Class Reference

```
#include <wx/cmndata.h>
```

Inheritance diagram for wxPrintDialogData:



21.551.1 Detailed Description

This class holds information related to the visual characteristics of wxPrintDialog.

It contains a wxPrintData object with underlying printing settings.

Library: wxCore

Category: Printing Framework, Common Dialogs, Data Structures

Printing Framework Overview, wxPrintDialog, wxPrintDialog Overview

Public Member Functions

- wxPrintDialogData ()

  Default constructor.
- wxPrintDialogData (const wxPrintDialogData &dialogData)

  Copy constructor.
- wxPrintDialogData (const wxPrintData &printData)

  Construct an object from a print dialog data object.
- virtual ~wxPrintDialogData ()

  Destructor.
- void EnableHelp (bool flag)

  Enables or disables the "Help" button.
- void EnablePageNumbers (bool flag)

  Enables or disables the "Page numbers" controls.
- void EnablePrintToFile (bool flag)

  Enables or disables the "Print to file" checkbox.
- void EnableSelection (bool flag)

  Enables or disables the "Selection" radio button.
- bool GetAllPages () const

  Returns true if the user requested that all pages be printed.
- bool GetCollate () const

Returns true if the user requested that the document(s) be collated.

- int GetFromPage () const

  Returns the from page number, as entered by the user.
- int GetMaxPage () const

  Returns the maximum page number.
- int GetMinPage () const

  Returns the minimum page number.
- int GetNoCopies () const

  Returns the number of copies requested by the user.
- wxPrintData & GetPrintData ()

  Returns a reference to the internal wxPrintData object.
- bool GetPrintToFile () const

  Returns true if the user has selected printing to a file.
- bool GetSelection () const

  Returns true if the user requested that the selection be printed (where "selection" is a concept specific to the application).
- int GetToPage () const

  Returns the "print to" page number, as entered by the user.
- bool IsOk () const

  Returns true if the print data is valid for using in print dialogs.
- void SetCollate (bool flag)

  Sets the "Collate" checkbox to true or false.
- void SetFromPage (int page)

  Sets the from page number.
- void SetMaxPage (int page)

  Sets the maximum page number.
- void SetMinPage (int page)

  Sets the minimum page number.
- void SetNoCopies (int n)

  Sets the default number of copies the user has requested to be printed out.
- void SetPrintData (const wxPrintData &printData)

  Sets the internal wxPrintData.
- void SetPrintToFile (bool flag)

  Sets the "Print to file" checkbox to true or false.
- void SetSelection (bool flag)

  Selects the "Selection" radio button.
- void SetSetupDialog (bool flag)
- void SetToPage (int page)

  Sets the "print to" page number.
- void operator= (const wxPrintData &data)

  Assigns print data to this object.
- void operator= (const wxPrintDialogData &data)

  Assigns another print dialog data object to this object.

Additional Inherited Members

21.551.2 Constructor & Destructor Documentation

wxPrintDialogData::wxPrintDialogData ( )

Default constructor.

wxPrintDialogData::wxPrintDialogData (const wxPrintDialogData & *dialogData*)

Copy constructor.

wxPrintDialogData::wxPrintDialogData (const wxPrintData & *printData*)

Construct an object from a print dialog data object.

virtual wxPrintDialogData::~wxPrintDialogData ( ) [virtual]

Destructor.

21.551.3 Member Function Documentation

void wxPrintDialogData::EnableHelp (bool *flag*)

Enables or disables the "Help" button.

void wxPrintDialogData::EnablePageNumbers (bool *flag*)

Enables or disables the "Page numbers" controls.

void wxPrintDialogData::EnablePrintToFile (bool *flag*)

Enables or disables the "Print to file" checkbox.

void wxPrintDialogData::EnableSelection (bool *flag*)

Enables or disables the "Selection" radio button.

bool wxPrintDialogData::GetAllPages ( ) const

Returns true if the user requested that all pages be printed.

bool wxPrintDialogData::GetCollate ( ) const

Returns true if the user requested that the document(s) be collated.

int wxPrintDialogData::GetFromPage ( ) const

Returns the *from* page number, as entered by the user.

int wxPrintDialogData::GetMaxPage ( ) const

Returns the *maximum* page number.

int wxPrintDialogData::GetMinPage ( ) const

Returns the *minimum* page number.

int wxPrintDialogData::GetNoCopies ( ) const

Returns the number of copies requested by the user.

wxPrintData& wxPrintDialogData::GetPrintData ( )

Returns a reference to the internal wxPrintData object.

bool wxPrintDialogData::GetPrintToFile ( ) const

Returns true if the user has selected printing to a file.

bool wxPrintDialogData::GetSelection ( ) const

Returns true if the user requested that the selection be printed (where "selection" is a concept specific to the application).

int wxPrintDialogData::GetToPage ( ) const

Returns the *"print to"* page number, as entered by the user.

bool wxPrintDialogData::IsOk ( ) const

Returns true if the print data is valid for using in print dialogs.

This can return false on Windows if the current printer is not set, for example. On all other platforms, it returns true.

void wxPrintDialogData::operator= (const wxPrintData & *data*)

Assigns print data to this object.

void wxPrintDialogData::operator= (const wxPrintDialogData & *data*)

Assigns another print dialog data object to this object.

void wxPrintDialogData::SetCollate (bool *flag*)

Sets the "Collate" checkbox to true or false.

void wxPrintDialogData::SetFromPage (int *page*)

Sets the *from* page number.

void wxPrintDialogData::SetMaxPage (int *page*)

Sets the *maximum* page number.

void wxPrintDialogData::SetMinPage (int *page*)

Sets the *minimum* page number.

void wxPrintDialogData::SetNoCopies (int *n*)

Sets the default number of copies the user has requested to be printed out.

void wxPrintDialogData::SetPrintData (const wxPrintData & *printData*)

Sets the internal wxPrintData.

void wxPrintDialogData::SetPrintToFile (bool *flag*)

Sets the "Print to file" checkbox to true or false.

void wxPrintDialogData::SetSelection (bool *flag*)

Selects the "Selection" radio button.

The effect of printing the selection depends on how the application implements this command, if at all.

void wxPrintDialogData::SetSetupDialog (bool *flag*)

Deprecated This function has been deprecated since version 2.5.4.

Determines whether the dialog to be shown will be the Print dialog (pass false) or Print Setup dialog (pass true).

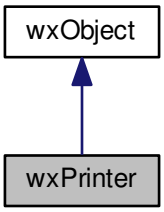
void wxPrintDialogData::SetToPage (int *page*)

Sets the *"print to"* page number.

21.552 wxPrinter Class Reference

`#include <wx/print.h>`

Inheritance diagram for wxPrinter:



21.552.1 Detailed Description

This class represents the Windows or PostScript printer, and is the vehicle through which printing may be launched by an application.

Printing can also be achieved through using of lower functions and classes, but this and associated classes provide a more convenient and general method of printing.

Library: wxCore

Category: Printing Framework

Printing Framework Overview, wxPrinterDC, wxPrintDialog, wxPrintout, wxPrintPreview

Public Member Functions

- wxPrinter (wxPrintDialogData *data=NULL)

  Constructor.
- virtual wxPrintAbortDialog * CreateAbortWindow (wxWindow *parent, wxPrintout *printout)

  Creates the default printing abort window, with a cancel button.
- bool GetAbort () const

  Returns true if the user has aborted the print job.
- virtual wxPrintDialogData & GetPrintDialogData () const

  Returns the print data associated with the printer object.
- virtual bool Print (wxWindow *parent, wxPrintout *printout, bool prompt=true)

  Starts the printing process.
- virtual wxDC * PrintDialog (wxWindow *parent)

  Invokes the print dialog.
- virtual void ReportError (wxWindow *parent, wxPrintout *printout, const wxString &message)

  Default error-reporting function.
- virtual bool Setup (wxWindow *parent)

  Invokes the print setup dialog.

Static Public Member Functions

- static wxPrinterError GetLastError ()

  Return last error.

Additional Inherited Members

21.552.2 Constructor & Destructor Documentation

wxPrinter::wxPrinter (wxPrintDialogData * *data* = `NULL`)

Constructor.

Pass an optional pointer to a block of print dialog data, which will be copied to the printer object's local data.

See also

wxPrintDialogData, wxPrintData

21.552.3 Member Function Documentation

virtual wxPrintAbortDialog* wxPrinter::CreateAbortWindow (wxWindow * *parent*, wxPrintout * *printout*) [virtual]

Creates the default printing abort window, with a cancel button.

bool wxPrinter::GetAbort ( ) const

Returns true if the user has aborted the print job.

static wxPrinterError wxPrinter::GetLastError ( ) [static]

Return last error.

Valid after calling Print(), PrintDialog() or wxPrintPreview::Print().

These functions set last error to `wxPRINTER_NO_ERROR` if no error happened.

Returned value is one of the following:

wxPRINTER_NO_ERROR	No error happened.
wxPRINTER_CANCELLED	The user cancelled printing.
wxPRINTER_ERROR	There was an error during printing.

virtual wxPrintDialogData& wxPrinter::GetPrintDialogData ( ) const [virtual]

Returns the print data associated with the printer object.

virtual bool wxPrinter::Print (wxWindow * *parent*, wxPrintout * *printout*, bool *prompt* = `true`) [virtual]

Starts the printing process.

Provide a parent window, a user-defined wxPrintout object which controls the printing of a document, and whether the print dialog should be invoked first.

Print() could return false if there was a problem initializing the printer device context (current printer not set, for example) or the user cancelled printing. Call GetLastError() to get detailed information about the kind of the error.

virtual wxDC* wxPrinter::PrintDialog (wxWindow * *parent*) [virtual]

Invokes the print dialog.

If successful (the user did not press Cancel and no error occurred), a suitable device context will be returned; otherwise NULL is returned; call GetLastError() to get detailed information about the kind of the error.

Remarks

The application must delete this device context to avoid a memory leak.

virtual void wxPrinter::ReportError (wxWindow * *parent*, wxPrintout * *printout*, const wxString & *message*) [virtual]

Default error-reporting function.

virtual bool wxPrinter::Setup (wxWindow * *parent*) [virtual]

Invokes the print setup dialog.

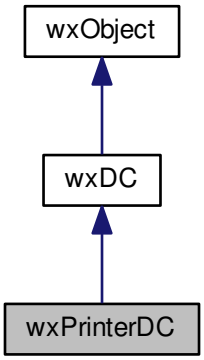
Remarks

The setup dialog is obsolete from Windows 95, though retained for backward compatibility.

21.553 wxPrinterDC Class Reference

`#include <wx/dcprint.h>`

Inheritance diagram for wxPrinterDC:



21.553.1 Detailed Description

A printer device context is specific to MSW and Mac, and allows access to any printer with a Windows or Macintosh driver.

See wxDC for further information on device contexts, and wxDC::GetSize() for advice on achieving the correct scaling for the page.

Library: wxCore

Category: Printing Framework

See also

Printing Framework Overview, wxDC

Public Member Functions

- wxPrinterDC (const wxPrintData &printData)

  Constructor.

- wxRect GetPaperRect () const

  Return the rectangle in device coordinates that corresponds to the full paper area, including the nonprinting regions of the paper.

Additional Inherited Members

21.553.2 Constructor & Destructor Documentation

wxPrinterDC::wxPrinterDC (const wxPrintData & *printData*)

Constructor.

Pass a wxPrintData object with information necessary for setting up a suitable printer device context. This is the recommended way to construct a wxPrinterDC. Make sure you specify a reference to a wxPrintData object, not a pointer - you may not even get a warning if you pass a pointer instead.

21.553.3 Member Function Documentation

wxRect wxPrinterDC::GetPaperRect ( ) const

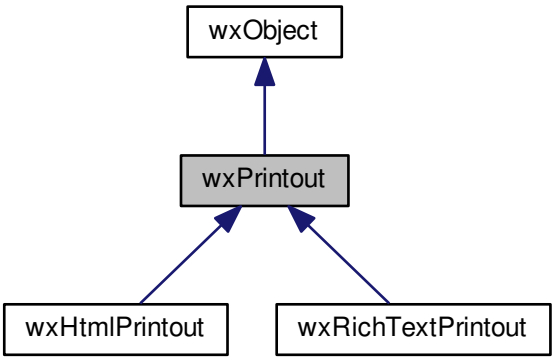
Return the rectangle in device coordinates that corresponds to the full paper area, including the nonprinting regions of the paper.

The point (0,0) in device coordinates is the top left corner of the page rectangle, which is the printable area on MSW and Mac. The coordinates of the top left corner of the paper rectangle will therefore have small negative values, while the bottom right coordinates will be somewhat larger than the values returned by wxDC::GetSize().

21.554 wxPrintout Class Reference

`#include <wx/print.h>`

Inheritance diagram for wxPrintout:



21.554.1 Detailed Description

This class encapsulates the functionality of printing out an application document.

A new class must be derived and members overridden to respond to calls such as OnPrintPage() and HasPage() and to render the print image onto an associated wxDC. Instances of this class are passed to wxPrinter::Print() or to a wxPrintPreview object to initiate printing or previewing.

Your derived wxPrintout is responsible for drawing both the preview image and the printed page. If your windows' drawing routines accept an arbitrary DC as an argument, you can re-use those routines within your wxPrintout subclass to draw the printout image. You may also add additional drawing elements within your wxPrintout subclass, like headers, footers, and/or page numbers. However, the image on the printed page will often differ from the image drawn on the screen, as will the print preview image – not just in the presence of headers and footers, but typically in scale. A high-resolution printer presents a much larger drawing surface (i.e., a higher-resolution DC); a zoomed-out preview image presents a much smaller drawing surface (lower-resolution DC). By using the routines FitThisSize↩ ToXXX() and/or MapScreenSizeToXXX() within your wxPrintout subclass to set the user scale and origin of the associated DC, you can easily use a single drawing routine to draw on your application's windows, to create the print preview image, and to create the printed paper image, and achieve a common appearance to the preview image and the printed page.

Library: wxCore

Category: Printing Framework

See also

Printing Framework Overview, wxPrinterDC, wxPrintDialog, wxPageSetupDialog, wxPrinter, wxPrintPreview

Public Member Functions

- wxPrintout (const wxString &title="Printout")

  Constructor.
- virtual ~wxPrintout ()

  Destructor.
- void FitThisSizeToPage (const wxSize &imageSize)

  Set the user scale and device origin of the wxDC associated with this wxPrintout so that the given image size fits entirely within the page rectangle and the origin is at the top left corner of the page rectangle.
- void FitThisSizeToPageMargins (const wxSize &imageSize, const wxPageSetupDialogData &pageSetup↩ Data)

  Set the user scale and device origin of the wxDC associated with this wxPrintout so that the given image size fits entirely within the page margins set in the given wxPageSetupDialogData object.
- void FitThisSizeToPaper (const wxSize &imageSize)

  Set the user scale and device origin of the wxDC associated with this wxPrintout so that the given image size fits entirely within the paper and the origin is at the top left corner of the paper.
- wxDC * GetDC () const

  Returns the device context associated with the printout (given to the printout at start of printing or previewing).
- wxRect GetLogicalPageMarginsRect (const wxPageSetupDialogData &pageSetupData) const

  Return the rectangle corresponding to the page margins specified by the given wxPageSetupDialogData object in the associated wxDC's logical coordinates for the current user scale and device origin.
- wxRect GetLogicalPageRect () const

  Return the rectangle corresponding to the page in the associated wxDC 's logical coordinates for the current user scale and device origin.
- wxRect GetLogicalPaperRect () const

  Return the rectangle corresponding to the paper in the associated wxDC 's logical coordinates for the current user scale and device origin.

- void GetPPIPrinter (int *w, int *h) const

  Returns the number of pixels per logical inch of the printer device context.
- void GetPPIScreen (int *w, int *h) const

  Returns the number of pixels per logical inch of the screen device context.
- virtual void GetPageInfo (int *minPage, int *maxPage, int *pageFrom, int *pageTo)

  Called by the framework to obtain information from the application about minimum and maximum page values that the user can select, and the required page range to be printed.
- void GetPageSizeMM (int *w, int *h) const

  Returns the size of the printer page in millimetres.
- void GetPageSizePixels (int *w, int *h) const

  Returns the size of the printer page in pixels, called the page rectangle.
- wxRect GetPaperRectPixels () const

  Returns the rectangle that corresponds to the entire paper in pixels, called the paper rectangle.
- virtual wxString GetTitle () const

  Returns the title of the printout.
- virtual bool HasPage (int pageNum)

  Should be overridden to return true if the document has this page, or false if not.
- virtual bool IsPreview () const

  Returns true if the printout is currently being used for previewing.
- wxPrintPreview * GetPreview () const

  Returns the associated preview object if any.
- void MapScreenSizeToDevice ()

  Set the user scale and device origin of the wxDC associated with this wxPrintout so that one screen pixel maps to one device pixel on the DC.
- void MapScreenSizeToPage ()

  This sets the user scale of the wxDC associated with this wxPrintout to the same scale as MapScreenSizeToPaper() but sets the logical origin to the top left corner of the page rectangle.
- void MapScreenSizeToPageMargins (const wxPageSetupDialogData &pageSetupData)

  This sets the user scale of the wxDC associated with this wxPrintout to the same scale as MapScreenSizeToPage↩ Margins() but sets the logical origin to the top left corner of the page margins specified by the given wxPageSetup↩ DialogData object.
- void MapScreenSizeToPaper ()

  Set the user scale and device origin of the wxDC associated with this wxPrintout so that the printed page matches the screen size as closely as possible and the logical origin is in the top left corner of the paper rectangle.
- void OffsetLogicalOrigin (wxCoord xoff, wxCoord yoff)

  Shift the device origin by an amount specified in logical coordinates.
- virtual bool OnBeginDocument (int startPage, int endPage)

  Called by the framework at the start of document printing.
- virtual void OnBeginPrinting ()

  Called by the framework at the start of printing.
- virtual void OnEndDocument ()

  Called by the framework at the end of document printing.
- virtual void OnEndPrinting ()

  Called by the framework at the end of printing.
- virtual void OnPreparePrinting ()

  Called once by the framework before any other demands are made of the wxPrintout object.
- virtual bool OnPrintPage (int pageNum)=0

  Called by the framework when a page should be printed.
- void SetLogicalOrigin (wxCoord x, wxCoord y)

  Set the device origin of the associated wxDC so that the current logical point becomes the new logical origin.

Additional Inherited Members

21.554.2 Constructor & Destructor Documentation

wxPrintout::wxPrintout (const wxString & *title* = "Printout")

Constructor.

Pass an optional title argument - the current filename would be a good idea. This will appear in the printing list (at least in MSW)

virtual wxPrintout::~wxPrintout ( ) [virtual]

Destructor.

21.554.3 Member Function Documentation

void wxPrintout::FitThisSizeToPage (const wxSize & *imageSize*)

Set the user scale and device origin of the wxDC associated with this wxPrintout so that the given image size fits entirely within the page rectangle and the origin is at the top left corner of the page rectangle.

On MSW and Mac, the page rectangle is the printable area of the page. On other platforms and PostScript printing, the page rectangle is the entire paper.

Use this if you want your printed image as large as possible, but with the caveat that on some platforms, portions of the image might be cut off at the edges.

void wxPrintout::FitThisSizeToPageMargins (const wxSize & *imageSize,* const wxPageSetupDialogData & *pageSetupData*)

Set the user scale and device origin of the wxDC associated with this wxPrintout so that the given image size fits entirely within the page margins set in the given wxPageSetupDialogData object.

This function provides the greatest consistency across all platforms because it does not depend on having access to the printable area of the paper.

Remarks

On Mac, the native wxPageSetupDialog does not let you set the page margins; you'll have to provide your own mechanism, or you can use the Mac-only class wxMacPageMarginsDialog.

void wxPrintout::FitThisSizeToPaper (const wxSize & *imageSize*)

Set the user scale and device origin of the wxDC associated with this wxPrintout so that the given image size fits entirely within the paper and the origin is at the top left corner of the paper.

Use this if you're managing your own page margins.

Note

With most printers, the region around the edges of the paper are not printable so that the edges of the image could be cut off.

wxDC* wxPrintout::GetDC ( ) const

Returns the device context associated with the printout (given to the printout at start of printing or previewing).

The application can use GetDC() to obtain a device context to draw on.

This will be a wxPrinterDC if printing under Windows or Mac, a wxPostScriptDC if printing on other platforms, and a wxMemoryDC if previewing.

wxRect wxPrintout::GetLogicalPageMarginsRect (const wxPageSetupDialogData & *pageSetupData*) const

Return the rectangle corresponding to the page margins specified by the given wxPageSetupDialogData object in the associated wxDC's logical coordinates for the current user scale and device origin.

The page margins are specified with respect to the edges of the paper on all platforms.

wxRect wxPrintout::GetLogicalPageRect ( ) const

Return the rectangle corresponding to the page in the associated wxDC 's logical coordinates for the current user scale and device origin.

On MSW and Mac, this will be the printable area of the paper. On other platforms and PostScript printing, this will be the full paper rectangle.

wxRect wxPrintout::GetLogicalPaperRect ( ) const

Return the rectangle corresponding to the paper in the associated wxDC 's logical coordinates for the current user scale and device origin.

virtual void wxPrintout::GetPageInfo (int * *minPage,* int * *maxPage,* int * *pageFrom,* int * *pageTo*) [virtual]

Called by the framework to obtain information from the application about minimum and maximum page values that the user can select, and the required page range to be printed.

By default this returns (1, 32000) for the page minimum and maximum values, and (1, 1) for the required page range.

minPage must be greater than zero and *maxPage* must be greater than *minPage*.

Reimplemented in wxRichTextPrintout.

void wxPrintout::GetPageSizeMM (int * *w,* int * *h*) const

Returns the size of the printer page in millimetres.

wxPerl Note: In wxPerl this method takes no arguments and returns a 2-element list (w, h).

void wxPrintout::GetPageSizePixels (int * *w,* int * *h*) const

Returns the size of the printer page in pixels, called the page rectangle.

The page rectangle has a top left corner at (0,0) and a bottom right corner at (w,h). These values may not be the same as the values returned from wxDC::GetSize(); if the printout is being used for previewing, a memory device context is used, which uses a bitmap size reflecting the current preview zoom. The application must take this discrepancy into account if previewing is to be supported.

wxRect wxPrintout::GetPaperRectPixels ( ) const

Returns the rectangle that corresponds to the entire paper in pixels, called the paper rectangle.

This distinction between paper rectangle and page rectangle reflects the fact that most printers cannot print all the way to the edge of the paper. The page rectangle is a rectangle whose top left corner is at (0,0) and whose width and height are given by wxDC::GetPageSizePixels().

On MSW and Mac, the page rectangle gives the printable area of the paper, while the paper rectangle represents the entire paper, including non-printable borders. Thus, the rectangle returned by wxDC::GetPaperRectPixels() will have a top left corner whose coordinates are small negative numbers and the bottom right corner will have values somewhat larger than the width and height given by wxDC::GetPageSizePixels().

On other platforms and for PostScript printing, the paper is treated as if its entire area were printable, so this function will return the same rectangle as the page rectangle.

void wxPrintout::GetPPIPrinter (int * *w*, int * *h*) const

Returns the number of pixels per logical inch of the printer device context.

Dividing the printer PPI by the screen PPI can give a suitable scaling factor for drawing text onto the printer.

Remember to multiply this by a scaling factor to take the preview DC size into account. Or you can just use the FitThisSizeToXXX() and MapScreenSizeToXXX routines below, which do most of the scaling calculations for you.

wxPerl Note: In wxPerl this method takes no arguments and returns a 2-element list (w, h).

void wxPrintout::GetPPIScreen (int * *w*, int * *h*) const

Returns the number of pixels per logical inch of the screen device context.

Dividing the printer PPI by the screen PPI can give a suitable scaling factor for drawing text onto the printer.

If you are doing your own scaling, remember to multiply this by a scaling factor to take the preview DC size into account.

wxPerl Note: In wxPerl this method takes no arguments and returns a 2-element list (w, h).

wxPrintPreview* wxPrintout::GetPreview ( ) const

Returns the associated preview object if any.

If this printout object is used for previewing, returns the associated wxPrintPreview. Otherwise returns NULL.

The returned pointer is not owned by the printout and must not be deleted.

See also

IsPreview()

Since

2.9.1.

virtual wxString wxPrintout::GetTitle ( ) const `[virtual]`

Returns the title of the printout.

Todo the python note here was wrong

virtual bool wxPrintout::HasPage (int *pageNum*) `[virtual]`

Should be overridden to return true if the document has this page, or false if not.

Returning false signifies the end of the document. By default, HasPage behaves as if the document has only one page.

Reimplemented in wxRichTextPrintout.

virtual bool wxPrintout::IsPreview ( ) const `[virtual]`

Returns true if the printout is currently being used for previewing.

See also

GetPreview()

void wxPrintout::MapScreenSizeToDevice ( )

Set the user scale and device origin of the wxDC associated with this wxPrintout so that one screen pixel maps to one device pixel on the DC.

That is, the user scale is set to (1,1) and the device origin is set to (0,0).

Use this if you want to do your own scaling prior to calling wxDC drawing calls, for example, if your underlying model is floating-point and you want to achieve maximum drawing precision on high-resolution printers.

You can use the GetLogicalXXXRect() routines below to obtain the paper rectangle, page rectangle, or page margins rectangle to perform your own scaling.

Note

While the underlying drawing model of Mac OS X is floating-point, wxWidgets's drawing model scales from integer coordinates.

void wxPrintout::MapScreenSizeToPage ( )

This sets the user scale of the wxDC associated with this wxPrintout to the same scale as MapScreenSizeToPaper() but sets the logical origin to the top left corner of the page rectangle.

void wxPrintout::MapScreenSizeToPageMargins (const wxPageSetupDialogData & *pageSetupData*)

This sets the user scale of the wxDC associated with this wxPrintout to the same scale as MapScreenSizeToPage↩ Margins() but sets the logical origin to the top left corner of the page margins specified by the given wxPageSetup↩ DialogData object.

void wxPrintout::MapScreenSizeToPaper ( )

Set the user scale and device origin of the wxDC associated with this wxPrintout so that the printed page matches the screen size as closely as possible and the logical origin is in the top left corner of the paper rectangle.

That is, a 100-pixel object on screen should appear at the same size on the printed page. (It will, of course, be larger or smaller in the preview image, depending on the zoom factor.)

Use this if you want WYSIWYG behaviour, e.g., in a text editor.

void wxPrintout::OffsetLogicalOrigin (wxCoord *xoff*, wxCoord *yoff*)

Shift the device origin by an amount specified in logical coordinates.

virtual bool wxPrintout::OnBeginDocument (int *startPage*, int *endPage*) [virtual]

Called by the framework at the start of document printing.

Return false from this function cancels the print job.

OnBeginDocument() is called once for every copy printed.

Remarks

The base OnBeginDocument() must be called (and the return value checked) from within the overridden function, since it calls wxDC::StartDoc().

virtual void wxPrintout::OnBeginPrinting ( ) [virtual]

Called by the framework at the start of printing.

OnBeginPrinting() is called once for every print job (regardless of how many copies are being printed).

virtual void wxPrintout::OnEndDocument ( ) [virtual]

Called by the framework at the end of document printing.

OnEndDocument() is called once for every copy printed.

Remarks

The base OnEndDocument() must be called from within the overridden function, since it calls wxDC::EndDoc().

virtual void wxPrintout::OnEndPrinting ( ) [virtual]

Called by the framework at the end of printing.

OnEndPrinting is called once for every print job (regardless of how many copies are being printed).

virtual void wxPrintout::OnPreparePrinting ( ) [virtual]

Called once by the framework before any other demands are made of the wxPrintout object.

This gives the object an opportunity to calculate the number of pages in the document, for example.

Reimplemented in wxRichTextPrintout.

virtual bool wxPrintout::OnPrintPage (int *pageNum*) [pure virtual]

Called by the framework when a page should be printed.

Returning false cancels the print job.

Implemented in wxRichTextPrintout.

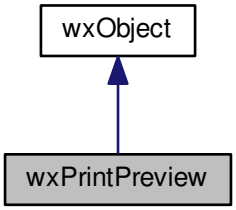
void wxPrintout::SetLogicalOrigin (wxCoord *x*, wxCoord *y*)

Set the device origin of the associated wxDC so that the current logical point becomes the new logical origin.

21.555 wxPrintPreview Class Reference

`#include <wx/print.h>`

Inheritance diagram for wxPrintPreview:



21.555.1 Detailed Description

Objects of this class manage the print preview process.

The object is passed a wxPrintout object, and the wxPrintPreview object itself is passed to a wxPreviewFrame object. Previewing is started by initializing and showing the preview frame. Unlike wxPrinter::Print(), flow of control returns to the application immediately after the frame is shown.

Note

The preview shown is only exact on Windows. On other platforms, the wxDC used for preview is different from what is used for printing and the results may be significantly different, depending on how is the output created. In particular, printing code relying on wxDC::GetTextExtent() heavily (for example, wxHtmlEasyPrinting and other wxHTML classes do) is affected. It is recommended to use native preview functionality on platforms that offer it (OS X, GTK+).

Library: wxCore

Category: Printing Framework

Printing Framework Overview, wxPrinterDC, wxPrintDialog, wxPrintout, wxPrinter, wxPreviewCanvas, wxPreviewControlBar, wxPreviewFrame

Public Member Functions

- wxPrintPreview (wxPrintout *printout, wxPrintout *printoutForPrinting=NULL, wxPrintDialogData *data=NULL)

Constructor.

- wxPrintPreview (wxPrintout *printout, wxPrintout *printoutForPrinting, wxPrintData *data)
- ~wxPrintPreview ()

  Destructor.
- virtual wxPreviewCanvas * GetCanvas () const

  Gets the preview window used for displaying the print preview image.
- virtual int GetCurrentPage () const

  Gets the page currently being previewed.
- virtual wxFrame * GetFrame () const

  Gets the frame used for displaying the print preview canvas and control bar.
- virtual int GetMaxPage () const

  Returns the maximum page number.
- virtual int GetMinPage () const

  Returns the minimum page number.
- virtual wxPrintout * GetPrintout () const

  Gets the preview printout object associated with the wxPrintPreview object.
- virtual wxPrintout * GetPrintoutForPrinting () const

  Gets the printout object to be used for printing from within the preview interface, or NULL if none exists.
- virtual bool IsOk () const

  Returns true if the wxPrintPreview is valid, false otherwise.
- virtual bool PaintPage (wxPreviewCanvas *canvas, wxDC &dc)

  This refreshes the preview window with the preview image.
- virtual bool Print (bool prompt)

  Invokes the print process using the second wxPrintout object supplied in the wxPrintPreview constructor.
- virtual bool RenderPage (int pageNum)

  Renders a page into a wxMemoryDC.
- virtual void SetCanvas (wxPreviewCanvas *window)

  Sets the window to be used for displaying the print preview image.
- virtual bool SetCurrentPage (int pageNum)

  Sets the current page to be previewed.
- virtual void SetFrame (wxFrame *frame)

  Sets the frame to be used for displaying the print preview canvas and control bar.
- virtual void SetPrintout (wxPrintout *printout)

  Associates a printout object with the wxPrintPreview object.
- virtual void SetZoom (int percent)

  Sets the percentage preview zoom, and refreshes the preview canvas accordingly.

Additional Inherited Members

21.555.2 Constructor & Destructor Documentation

wxPrintPreview::wxPrintPreview (wxPrintout * *printout,* wxPrintout * *printoutForPrinting* = NULL, wxPrintDialogData * *data* = NULL)

Constructor.

Pass a printout object, an optional printout object to be used for actual printing, and the address of an optional block of printer data, which will be copied to the print preview object's print data.

If *printoutForPrinting* is non-NULL, a **"Print..."** button will be placed on the preview frame so that the user can print directly from the preview interface.

Remarks

Do not explicitly delete the printout objects once this constructor has been called, since they will be deleted in the wxPrintPreview destructor. The same does not apply to the *data* argument.

Use IsOk() to check whether the wxPrintPreview object was created correctly.

wxPrintPreview::wxPrintPreview (wxPrintout * *printout,* wxPrintout * *printoutForPrinting,* wxPrintData * *data*)

wxPrintPreview::~wxPrintPreview ( )

Destructor.

Deletes both print preview objects, so do not destroy these objects in your application.

21.555.3 Member Function Documentation

virtual wxPreviewCanvas* wxPrintPreview::GetCanvas ( ) const `[virtual]`

Gets the preview window used for displaying the print preview image.

virtual int wxPrintPreview::GetCurrentPage ( ) const `[virtual]`

Gets the page currently being previewed.

virtual wxFrame* wxPrintPreview::GetFrame ( ) const `[virtual]`

Gets the frame used for displaying the print preview canvas and control bar.

virtual int wxPrintPreview::GetMaxPage ( ) const `[virtual]`

Returns the maximum page number.

virtual int wxPrintPreview::GetMinPage ( ) const `[virtual]`

Returns the minimum page number.

virtual wxPrintout* wxPrintPreview::GetPrintout ( ) const `[virtual]`

Gets the preview printout object associated with the wxPrintPreview object.

virtual wxPrintout* wxPrintPreview::GetPrintoutForPrinting ( ) const `[virtual]`

Gets the printout object to be used for printing from within the preview interface, or NULL if none exists.

virtual bool wxPrintPreview::IsOk ( ) const `[virtual]`

Returns true if the wxPrintPreview is valid, false otherwise.

It could return false if there was a problem initializing the printer device context (current printer not set, for example).

virtual bool wxPrintPreview::PaintPage (wxPreviewCanvas * *canvas*, wxDC & *dc*) [virtual]

This refreshes the preview window with the preview image.

It must be called from the preview window's OnPaint member.

The implementation simply blits the preview bitmap onto the canvas, creating a new preview bitmap if none exists.

virtual bool wxPrintPreview::Print (bool *prompt*) [virtual]

Invokes the print process using the second wxPrintout object supplied in the wxPrintPreview constructor.

Will normally be called by the **Print**... panel item on the preview frame's control bar.

Returns false in case of error – call wxPrinter::GetLastError() to get detailed information about the kind of the error.

virtual bool wxPrintPreview::RenderPage (int *pageNum*) [virtual]

Renders a page into a wxMemoryDC.

Used internally by wxPrintPreview.

virtual void wxPrintPreview::SetCanvas (wxPreviewCanvas * *window*) [virtual]

Sets the window to be used for displaying the print preview image.

virtual bool wxPrintPreview::SetCurrentPage (int *pageNum*) [virtual]

Sets the current page to be previewed.

virtual void wxPrintPreview::SetFrame (wxFrame * *frame*) [virtual]

Sets the frame to be used for displaying the print preview canvas and control bar.

virtual void wxPrintPreview::SetPrintout (wxPrintout * *printout*) [virtual]

Associates a printout object with the wxPrintPreview object.

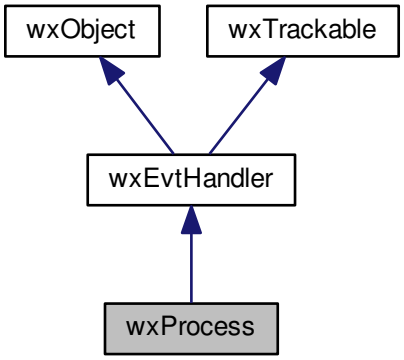
virtual void wxPrintPreview::SetZoom (int *percent*) [virtual]

Sets the percentage preview zoom, and refreshes the preview canvas accordingly.

21.556 wxProcess Class Reference

`#include <wx/process.h>`

Inheritance diagram for wxProcess:



21.556.1 Detailed Description

The objects of this class are used in conjunction with the wxExecute() function.

When a wxProcess object is passed to wxExecute(), its OnTerminate() virtual method is called when the process terminates. This allows the program to be (asynchronously) notified about the process termination and also retrieve its exit status which is unavailable from wxExecute() in the case of asynchronous execution.

Note

If the `wxEVT_END_PROCESS` event sent after termination is processed by the parent, then it is responsible for deleting the wxProcess object which sent it. However, if it is not processed, the object will **delete itself** and so the library users should only delete those objects whose notifications have been processed (and call wxProcess::Detach for others). This also means that unless you're going to process the `wxEVT_END_PROCESS` event, you **must** allocate the wxProcess class on the heap.

wxProcess also supports IO redirection of the child process. For this, you have to call its Redirect() method before passing it to wxExecute(). If the child process was launched successfully, GetInputStream(), GetOutputStream() and GetErrorStream() can then be used to retrieve the streams corresponding to the child process standard output, input and error output respectively.

Events emitted by this class

The following event handler macros redirect the events to member function handlers '**func**' with prototypes like: void handlerFuncName(wxProcessEvent& event)

Event macros for events emitted by this class:

- EVT_END_PROCESS(id, func): Process a `wxEVT_END_PROCESS` event, sent by wxProcess::OnTerminate upon the external process termination.

Library: wxBase

Category: Application and Process Management

wxPerl Note: In wxPerl this class has an additional `Destroy` method, for explicit destruction.

See also

wxExecute(), External Program Execution Sample

Public Member Functions

- wxProcess (wxEvtHandler *parent=NULL, int id=-1)

  Constructs a process object.
- wxProcess (int flags)

  Creates an object without any associated parent (and hence no id neither) but allows to specify the flags which can have the value of `wxPROCESS_DEFAULT` or `wxPROCESS_REDIRECT`.
- virtual ~wxProcess ()

  Destroys the wxProcess object.
- void CloseOutput ()

  Closes the output stream (the one connected to the stdin of the child process).
- void Detach ()

  Detaches this event handler from the parent specified in the constructor (see wxEvtHandler::Unlink() for a similar but not identical function).
- wxInputStream * GetErrorStream () const

  Returns an input stream which corresponds to the standard error output (stderr) of the child process.
- wxInputStream * GetInputStream () const

  It returns an input stream corresponding to the standard output stream of the subprocess.
- wxOutputStream * GetOutputStream () const

  It returns an output stream corresponding to the input stream of the subprocess.
- long GetPid () const

  Returns the process ID of the process launched by Open() or set by wxExecute() (if you passed this wxProcess as argument).
- bool IsErrorAvailable () const

  Returns true if there is data to be read on the child process standard error stream.
- bool IsInputAvailable () const

  Returns true if there is data to be read on the child process standard output stream.
- bool IsInputOpened () const

  Returns true if the child process standard output stream is opened.
- virtual void OnTerminate (int pid, int status)

  It is called when the process with the pid pid finishes.
- void Redirect ()

  Turns on redirection.
- void SetPriority (unsigned priority)

  Sets the priority of the process, between 0 (lowest) and 100 (highest).

Static Public Member Functions

- static bool Exists (int pid)

  Returns true if the given process exists in the system.
- static wxKillError Kill (int pid, wxSignal sig=wxSIGTERM, int flags=wxKILL_NOCHILDREN)

  Send the specified signal to the given process.
- static wxProcess * Open (const wxString &cmd, int flags=wxEXEC_ASYNC)

  This static method replaces the standard `popen()` function: it launches the process specified by the cmd parameter and returns the wxProcess object which can be used to retrieve the streams connected to the standard input, output and error output of the child process.

Additional Inherited Members

21.556.2 Constructor & Destructor Documentation

wxProcess::wxProcess (wxEvtHandler * *parent* = NULL, int *id* = -1)

Constructs a process object.

id is only used in the case you want to use wxWidgets events. It identifies this object, or another window that will receive the event.

If the *parent* parameter is different from NULL, it will receive a wxEVT_END_PROCESS notification event (you should insert EVT_END_PROCESS macro in the event table of the parent to handle it) with the given *id*.

Parameters

parent	The event handler parent.
id	id of an event.

wxProcess::wxProcess (int *flags*)

Creates an object without any associated parent (and hence no id neither) but allows to specify the *flags* which can have the value of wxPROCESS_DEFAULT or wxPROCESS_REDIRECT.

Specifying the former value has no particular effect while using the latter one is equivalent to calling Redirect().

virtual wxProcess::~wxProcess ( ) [virtual]

Destroys the wxProcess object.

21.556.3 Member Function Documentation

void wxProcess::CloseOutput ( )

Closes the output stream (the one connected to the stdin of the child process).

This function can be used to indicate to the child process that there is no more data to be read - usually, a filter program will only terminate when the input stream is closed.

Notice that GetOutputStream() will return NULL after the output stream is closed.

void wxProcess::Detach ( )

Detaches this event handler from the parent specified in the constructor (see wxEvtHandler::Unlink() for a similar but not identical function).

Normally, a wxProcess object is deleted by its parent when it receives the notification about the process termination.

However, it might happen that the parent object is destroyed before the external process is terminated (e.g. a window from which this external process was launched is closed by the user) and in this case it **should** not delete the wxProcess object, but **should** call Detach() instead.

After the wxProcess object is detached from its parent, no notification events will be sent to the parent and the object will delete itself upon reception of the process termination notification.

static bool wxProcess::Exists (int *pid*) [static]

Returns true if the given process exists in the system.

See also

Kill(), Exec sample

wxInputStream* wxProcess::GetErrorStream ( ) const

Returns an input stream which corresponds to the standard error output (stderr) of the child process.

wxInputStream* wxProcess::GetInputStream ( ) const

It returns an input stream corresponding to the standard output stream of the subprocess.

If it is NULL, you have not turned on the redirection.

See also

Redirect().

wxOutputStream* wxProcess::GetOutputStream ( ) const

It returns an output stream corresponding to the input stream of the subprocess.

If it is NULL, you have not turned on the redirection or already called CloseOutput().

See also

Redirect().

long wxProcess::GetPid ( ) const

Returns the process ID of the process launched by Open() or set by wxExecute() (if you passed this wxProcess as argument).

bool wxProcess::IsErrorAvailable ( ) const

Returns true if there is data to be read on the child process standard error stream.

See also

IsInputAvailable()

bool wxProcess::IsInputAvailable ( ) const

Returns true if there is data to be read on the child process standard output stream.

This allows to write simple (and extremely inefficient) polling-based code waiting for a better mechanism in future wxWidgets versions. See the exec sample for an example of using this function.

See also

IsInputOpened()

bool wxProcess::IsInputOpened ( ) const

Returns true if the child process standard output stream is opened.

static wxKillError wxProcess::Kill (int *pid*, wxSignal *sig* = wxSIGTERM, int *flags* = wxKILL_NOCHILDREN) [static]

Send the specified signal to the given process.

Possible signal values can be one of the wxSignal enumeration values.

`wxSIGNONE`, `wxSIGKILL` and `wxSIGTERM` have the same meaning under both Unix and Windows but all the other signals are equivalent to `wxSIGTERM` under Windows.

The *flags* parameter can be `wxKILL_NOCHILDREN` (the default), or `wxKILL_CHILDREN`, in which case the child processes of this process will be killed too. Note that under Unix, for `wxKILL_CHILDREN` to work you should have created the process passing `wxEXEC_MAKE_GROUP_LEADER`.

Returns the element of wxKillError enum.

See also

Exists(), wxKill(), Exec sample

virtual void wxProcess::OnTerminate (int *pid*, int *status*) [virtual]

It is called when the process with the pid *pid* finishes.

It raises a wxWidgets event when it isn't overridden.

Note that this function won't be called if you Kill() the process.

Parameters

pid	The pid of the process which has just terminated.
status	The exit code of the process.

static wxProcess* wxProcess::Open (const wxString & *cmd*, int *flags* = wxEXEC_ASYNC) [static]

This static method replaces the standard `popen()` function: it launches the process specified by the *cmd* parameter and returns the wxProcess object which can be used to retrieve the streams connected to the standard input, output and error output of the child process.

If the process couldn't be launched, NULL is returned.

Remarks

In any case the returned pointer should **not** be deleted, rather the process object will be destroyed automatically when the child process terminates. This does mean that the child process should be told to quit before the main program exits to avoid memory leaks.

Parameters

cmd	The command to execute, including optional arguments.
flags	The flags to pass to wxExecute(). Note: `wxEXEC_SYNC` should not be used.

Returns

A pointer to new wxProcess object or NULL on error.

See also

wxExecute()

void wxProcess::Redirect ( )

Turns on redirection.

wxExecute() will try to open a couple of pipes to catch the subprocess stdio. The caught input stream is returned by GetOutputStream() as a non-seekable stream. The caught output stream is returned by GetInputStream() as a non-seekable stream.

void wxProcess::SetPriority (unsigned *priority*)

Sets the priority of the process, between 0 (lowest) and 100 (highest).

It can only be set before the process is created.

The following symbolic constants can be used in addition to raw values in 0..100 range:

- **wxPRIORITY_MIN:** 0
- **wxPRIORITY_DEFAULT:** 50
- **wxPRIORITY_MAX:** 100

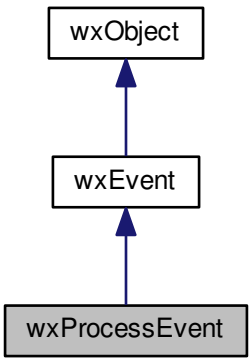
Since

2.9.5

21.557 wxProcessEvent Class Reference

`#include <wx/process.h>`

Inheritance diagram for wxProcessEvent:



21.557.1 Detailed Description

A process event is sent to the wxEvtHandler specified to wxProcess when a process is terminated.

Events using this class

The following event handler macros redirect the events to member function handlers '**func**' with prototypes like: void handlerFuncName(wxProcessEvent& event)

Event macros:

- EVT_END_PROCESS(id, func): Process a `wxEVT_END_PROCESS` event. *id* is the identifier of the process object (the id passed to the wxProcess constructor) or a window to receive the event.

Library: wxBase

Category: Events

See also

wxProcess, Events and Event Handling

Public Member Functions

- wxProcessEvent (int id=0, int pid=0, int exitcode=0)

  Constructor.
- int GetExitCode ()

  Returns the exist status.
- int GetPid ()

  Returns the process id.

Additional Inherited Members

21.557.2 Constructor & Destructor Documentation

wxProcessEvent::wxProcessEvent (int *id* = `0`, int *pid* = `0`, int *exitcode* = `0`)

Constructor.

Takes a wxProcessObject or window id, a process id and an exit status.

21.557.3 Member Function Documentation

int wxProcessEvent::GetExitCode ( )

Returns the exist status.

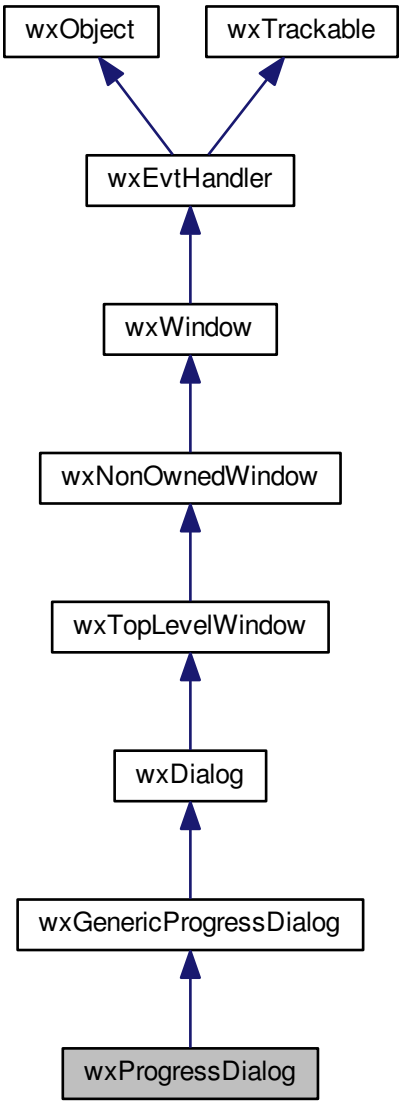
int wxProcessEvent::GetPid ( )

Returns the process id.

21.558 wxProgressDialog Class Reference

```
#include <wx/progdlg.h>
```

Inheritance diagram for wxProgressDialog:



21.558.1 Detailed Description

If supported by the platform this class will provide the platform's native progress dialog, else it will simply be the *wxGenericProgressDialog*.

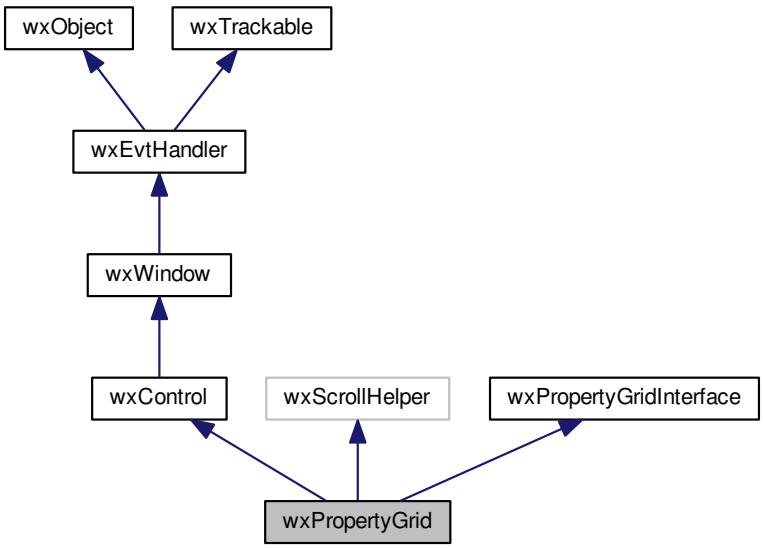
21.561 wxPropertyGrid Class Reference

`#include <wx/propgrid/propgrid.h>`

Inheritance diagram for wxPropertyGrid:



21.561.1 Detailed Description

wxPropertyGrid is a specialized grid for editing properties - in other words name = value pairs.

List of ready-to-use property classes include strings, numbers, flag sets, fonts, colours and many others. It is possible, for example, to categorize properties, set up a complete tree-hierarchy, add more than two columns, and set arbitrary per-property attributes.

Please note that most member functions are inherited and as such not documented on this page. This means you will probably also want to read wxPropertyGridInterface class reference.

See also wxPropertyGrid Overview.

21.561.2 Window Styles

See wxPropertyGrid Window Styles.

21.561.3 Event Handling

To process input from a property grid control, use these event handler macros to direct input to member functions that take a wxPropertyGridEvent argument.

Events emitted by this class

The following event handler macros redirect the events to member function handlers '**func**' with prototypes like: void handlerFuncName(wxPropertyGridEvent& event)

Event macros for events emitted by this class:

- EVT_PG_SELECTED (id, func): Respond to `wxEVT_PG_SELECTED` event, generated when a property selection has been changed, either by user action or by indirect program function. For instance, collaps-

ing a parent property programmatically causes any selected child property to become unselected, and may therefore cause this event to be generated.

- EVT_PG_CHANGED(id, func): Respond to `wxEVT_PG_CHANGED` event, generated when property value has been changed by the user.
- EVT_PG_CHANGING(id, func): Respond to `wxEVT_PG_CHANGING` event, generated when property value is about to be changed by user. Use wxPropertyGridEvent::GetValue() to take a peek at the pending value, and wxPropertyGridEvent::Veto() to prevent change from taking place, if necessary.
- EVT_PG_HIGHLIGHTED(id, func): Respond to `wxEVT_PG_HIGHLIGHTED` event, which occurs when mouse moves over a property. Event's property is NULL if hovered area does not belong to any property.
- EVT_PG_RIGHT_CLICK(id, func): Respond to `wxEVT_PG_RIGHT_CLICK` event, which occurs when property is clicked on with right mouse button.
- EVT_PG_DOUBLE_CLICK(id, func): Respond to `wxEVT_PG_DOUBLE_CLICK` event, which occurs when property is double-clicked on with left mouse button.
- EVT_PG_ITEM_COLLAPSED(id, func): Respond to `wxEVT_PG_ITEM_COLLAPSED` event, generated when user collapses a property or category.
- EVT_PG_ITEM_EXPANDED(id, func): Respond to `wxEVT_PG_ITEM_EXPANDED` event, generated when user expands a property or category.
- EVT_PG_LABEL_EDIT_BEGIN(id, func): Respond to `wxEVT_PG_LABEL_EDIT_BEGIN` event, generated when user is about to begin editing a property label. You can veto this event to prevent the action.
- EVT_PG_LABEL_EDIT_ENDING(id, func): Respond to `wxEVT_PG_LABEL_EDIT_ENDING` event, generated when user is about to end editing of a property label. You can veto this event to prevent the action.
- EVT_PG_COL_BEGIN_DRAG(id, func): Respond to `wxEVT_PG_COL_BEGIN_DRAG` event, generated when user starts resizing a column - can be vetoed.
- EVT_PG_COL_DRAGGING, (id, func): Respond to `wxEVT_PG_COL_DRAGGING`, event, generated when a column resize by user is in progress. This event is also generated when user double-clicks the splitter in order to recenter it.
- EVT_PG_COL_END_DRAG(id, func): Respond to `wxEVT_PG_COL_END_DRAG` event, generated after column resize by user has finished.

Remarks

Use Freeze() and Thaw() respectively to disable and enable drawing. This will also delay sorting etc. miscellaneous calculations to the last possible moment.

Library: wxPropertyGrid

Category: wxPropertyGrid

Public Member Functions

- wxPropertyGrid ()

  Two step constructor.
- wxPropertyGrid (wxWindow *parent, wxWindowID id=wxID_ANY, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, long style=wxPG_DEFAULT_STYLE, const wxString &name=wx↩PropertyGridNameStr)

  Constructor.
- virtual ~wxPropertyGrid ()

Destructor.

- void AddActionTrigger (int action, int keycode, int modifiers=0)

  Adds given key combination to trigger given action.
- bool AddToSelection (wxPGPropArg id)

  Adds given property into selection.
- void BeginLabelEdit (unsigned int colIndex=0)

  Creates label editor wxTextCtrl for given column, for property that is currently selected.
- bool ChangePropertyValue (wxPGPropArg id, wxVariant newValue)

  Changes value of a property, as if from an editor.
- void CenterSplitter (bool enableAutoResizing=false)

  Centers the splitter.
- virtual void Clear ()

  Deletes all properties.
- void ClearActionTriggers (int action)

  Clears action triggers for given action.
- virtual bool CommitChangesFromEditor (wxUint32 flags=0)

  Forces updating the value of property from the editor control.
- bool Create (wxWindow *parent, wxWindowID id=wxID_ANY, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, long style=wxPG_DEFAULT_STYLE, const wxString &name=wxPropertyGridNameStr)

  Two step creation.
- void DedicateKey (int keycode)

  Dedicates a specific keycode to wxPropertyGrid.
- bool EnableCategories (bool enable)

  Enables or disables (shows/hides) categories according to parameter enable.
- void EndLabelEdit (bool commit=true)

  Destroys label editor wxTextCtrl, if any.
- bool EnsureVisible (wxPGPropArg id)

  Scrolls and/or expands items to ensure that the given item is visible.
- wxSize FitColumns ()

  Reduces column sizes to minimum possible, while still retaining fully visible grid contents (labels, images).
- wxTextCtrl * GetLabelEditor () const

  Returns currently active label editor, NULL if none.
- wxWindow * GetPanel ()

  Returns wxWindow that the properties are painted on, and which should be used as the parent for editor controls.
- wxColour GetCaptionBackgroundColour () const

  Returns current category caption background colour.
- wxFont & GetCaptionFont ()

  Returns current category caption font.
- wxColour GetCaptionForegroundColour () const

  Returns current category caption text colour.
- wxColour GetCellBackgroundColour () const

  Returns current cell background colour.
- wxColour GetCellDisabledTextColour () const

  Returns current cell text colour when disabled.
- wxColour GetCellTextColour () const

  Returns current cell text colour.
- unsigned int GetColumnCount () const

  Returns number of columns currently on grid.
- wxColour GetEmptySpaceColour () const

  Returns colour of empty space below properties.

- int GetFontHeight () const

  Returns height of highest characters of used font.
- wxPropertyGrid * GetGrid ()

  Returns pointer to itself.
- wxRect GetImageRect (wxPGProperty *property, int item) const

  Returns rectangle of custom paint image.
- wxSize GetImageSize (wxPGProperty *property=NULL, int item=-1) const

  Returns size of the custom paint image in front of property.
- wxPGProperty * GetLastItem (int flags=wxPG_ITERATE_DEFAULT)

  Returns last item which could be iterated using given flags.
- wxColour GetLineColour () const

  Returns colour of lines between cells.
- wxColour GetMarginColour () const

  Returns background colour of margin.
- wxPGProperty * GetRoot () const

  Returns "root property".
- int GetRowHeight () const

  Returns height of a single grid row (in pixels).
- wxPGProperty * GetSelectedProperty () const

  Returns currently selected property.
- wxPGProperty * GetSelection () const

  Returns currently selected property.
- wxColour GetSelectionBackgroundColour () const

  Returns current selection background colour.
- wxColour GetSelectionForegroundColour () const

  Returns current selection text colour.
- wxPGSortCallback GetSortFunction () const

  Returns the property sort function (default is NULL).
- int GetSplitterPosition (unsigned int splitterIndex=0) const

  Returns current splitter x position.
- wxTextCtrl * GetEditorTextCtrl () const

  Returns wxTextCtrl active in currently selected property, if any.
- const wxPGCell & GetUnspecifiedValueAppearance () const

  Returns current appearance of unspecified value cells.
- wxString GetUnspecifiedValueText (int argFlags=0) const

  Returns (visual) text representation of the unspecified property value.
- int GetVerticalSpacing () const

  Returns current vertical spacing.
- wxPropertyGridHitTestResult HitTest (const wxPoint &pt) const

  Returns information about arbitrary position in the grid.
- bool IsAnyModified () const

  Returns true if any property has been modified by the user.
- bool IsEditorFocused () const

  Returns true if a property editor control has focus.
- bool IsFrozen () const

  Returns true if updating is frozen (ie.
- void MakeColumnEditable (unsigned int column, bool editable=true)

  Makes given column editable by user.
- void OnTLPChanging (wxWindow *newTLP)

  It is recommended that you call this function any time your code causes wxPropertyGrid's top-level parent to change.
- void RefreshEditor ()

Refreshes any active editor control.

- virtual void RefreshProperty (wxPGProperty *p)

  Redraws given property.
- void ResetColours ()

  Resets all colours to the original system values.
- void ResetColumnSizes (bool enableAutoResizing=false)

  Resets column sizes and splitter positions, based on proportions.
- bool RemoveFromSelection (wxPGPropArg id)

  Removes given property from selection.
- bool SelectProperty (wxPGPropArg id, bool focus=false)

  Selects a property.
- void SetCaptionBackgroundColour (const wxColour &col)

  Sets category caption background colour.
- void SetCaptionTextColour (const wxColour &col)

  Sets category caption text colour.
- void SetCellBackgroundColour (const wxColour &col)

  Sets default cell background colour - applies to property cells.
- void SetCellDisabledTextColour (const wxColour &col)

  Sets cell text colour for disabled properties.
- void SetCellTextColour (const wxColour &col)

  Sets default cell text colour - applies to property name and value text.
- void SetColumnCount (int colCount)

  Set number of columns (2 or more).
- void SetCurrentCategory (wxPGPropArg id)

  Sets the 'current' category - Append will add non-category properties under it.
- void SetEmptySpaceColour (const wxColour &col)

  Sets colour of empty space below properties.
- void SetLineColour (const wxColour &col)

  Sets colour of lines between cells.
- void SetMarginColour (const wxColour &col)

  Sets background colour of margin.
- void SetSelection (const wxArrayPGProperty &newSelection)

  Set entire new selection from given list of properties.
- void SetSelectionBackgroundColour (const wxColour &col)

  Sets selection background colour - applies to selected property name background.
- void SetSelectionTextColour (const wxColour &col)

  Sets selection foreground colour - applies to selected property name text.
- void SetSortFunction (wxPGSortCallback sortFunction)

  Sets the property sorting function.
- void SetSplitterPosition (int newxpos, int col=0)

  Sets x coordinate of the splitter.
- void SetSplitterLeft (bool privateChildrenToo=false)

  Moves splitter as left as possible, while still allowing all labels to be shown in full.
- void SetUnspecifiedValueAppearance (const wxPGCell &cell)

  Sets appearance of value cells representing an unspecified property value.
- void SetVerticalSpacing (int vspacing)

  Sets vertical spacing.

wxPropertyGrid customization

Reimplement these member functions in derived class for better control over wxPropertyGrid behaviour.

- virtual void DoShowPropertyError (wxPGProperty *property, const wxString &msg)
  Override in derived class to display error messages in custom manner (these message usually only result from validation failure).
- virtual void DoHidePropertyError (wxPGProperty *property)
  Override in derived class to hide an error displayed by DoShowPropertyError().
- virtual wxStatusBar * GetStatusBar ()
  Return wxStatusBar that is used by this wxPropertyGrid.

Property development functions

These member functions are usually only called when creating custom user properties.

- void EditorsValueWasModified ()
  Call when editor widget's contents is modified.
- void EditorsValueWasNotModified ()
  Reverse of EditorsValueWasModified().
- wxVariant GetUncommittedPropertyValue ()
  Returns most up-to-date value of selected property.
- bool IsEditorsValueModified () const
  Returns true if editor's value was marked modified.
- void ShowPropertyError (wxPGPropArg id, const wxString &msg)
  Shows an brief error message that is related to a property.
- bool WasValueChangedInEvent () const
  You can use this member function, for instance, to detect in wxPGProperty::OnEvent() if wxPGProperty::SetValueInEvent() was already called in wxPGEditor::OnEvent().

Static Public Member Functions

- static void AutoGetTranslation (bool enable)
  This static function enables or disables automatic use of wxGetTranslation() for following strings: wxEnumProperty list labels, wxFlagsProperty child property labels.
- static wxPGEditor * RegisterEditorClass (wxPGEditor *editor, bool noDefCheck=false)
  Forwards to DoRegisterEditorClass with empty name.
- static wxPGEditor * DoRegisterEditorClass (wxPGEditor *editor, const wxString &name, bool noDefCheck=false)
  Registers a new editor class.

Additional Inherited Members

21.561.4 Constructor & Destructor Documentation

wxPropertyGrid::wxPropertyGrid ( )

Two step constructor.

Call Create() when this constructor is called to build up the wxPropertyGrid

wxPropertyGrid::wxPropertyGrid (wxWindow * *parent*, wxWindowID *id* = wxID_ANY, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, long *style* = wxPG_DEFAULT_STYLE, const wxString & *name* = `wxPropertyGridNameStr`)

Constructor.

The styles to be used are styles valid for the wxWindow.

See also

wxPropertyGrid Window Styles.

virtual wxPropertyGrid::~wxPropertyGrid ( ) [virtual]

Destructor.

21.561.5 Member Function Documentation

void wxPropertyGrid::AddActionTrigger (int *action,* int *keycode,* int *modifiers* = 0)

Adds given key combination to trigger given action.

Here is a sample code to make Enter key press move focus to the next property.

```
propGrid->AddActionTrigger(wxPG_ACTION_NEXT_PROPERTY,
                           WXK_RETURN);
propGrid->DedicateKey(WXK_RETURN);
```

Parameters

action	Which action to trigger. See wxPropertyGrid Action Identifiers.
keycode	Which keycode triggers the action.
modifiers	Which key event modifiers, in addition to keycode, are needed to trigger the action.

bool wxPropertyGrid::AddToSelection (wxPGPropArg *id*)

Adds given property into selection.

If wxPG_EX_MULTIPLE_SELECTION extra style is not used, then this has same effect as calling SelectProperty().

Remarks

Multiple selection is not supported for categories. This means that if you have properties selected, you cannot add category to selection, and also if you have category selected, you cannot add other properties to selection. This member function will fail silently in these cases, even returning true.

static void wxPropertyGrid::AutoGetTranslation (bool *enable*) [static]

This static function enables or disables automatic use of wxGetTranslation() for following strings: wxEnumProperty list labels, wxFlagsProperty child property labels.

Default is false.

void wxPropertyGrid::BeginLabelEdit (unsigned int *colIndex* = 0)

Creates label editor wxTextCtrl for given column, for property that is currently selected.

When multiple selection is enabled, this applies to whatever property GetSelection() returns.

Parameters

colIndex	Which column's label to edit. Note that you should not use value 1, which is reserved for property value column.

See also

EndLabelEdit(), MakeColumnEditable()

void wxPropertyGrid::CenterSplitter (bool *enableAutoResizing* = `false`)

Centers the splitter.

Parameters

enableAuto↩ Resizing	If true, automatic column resizing is enabled (only applicapple if window style wxPG_SPLI↩ TTER_AUTO_CENTER is used).

bool wxPropertyGrid::ChangePropertyValue (wxPGPropArg *id*, wxVariant *newValue*)

Changes value of a property, as if from an editor.

Use this instead of SetPropertyValue() if you need the value to run through validation process, and also send the property change event.

Returns

Returns true if value was successfully changed.

virtual void wxPropertyGrid::Clear ( ) [virtual]

Deletes all properties.

Implements wxPropertyGridInterface.

void wxPropertyGrid::ClearActionTriggers (int *action*)

Clears action triggers for given action.

Parameters

action	Which action to trigger. wxPropertyGrid Action Identifiers.

virtual bool wxPropertyGrid::CommitChangesFromEditor (wxUint32 *flags* = 0) [virtual]

Forces updating the value of property from the editor control.

Note that `wxEVT_PG_CHANGING` and `wxEVT_PG_CHANGED` are dispatched using ProcessEvent, meaning your event handlers will be called immediately.

Returns

Returns true if anything was changed.

bool wxPropertyGrid::Create (wxWindow * *parent*, wxWindowID *id* = wxID_ANY, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, long *style* = wxPG_DEFAULT_STYLE, const wxString & *name* = `wxPropertyGridNameStr`)

Two step creation.

Whenever the control is created without any parameters, use Create to actually create it. Don't access the control's public methods before this is called

See also

wxPropertyGrid Window Styles.

void wxPropertyGrid::DedicateKey (int *keycode*)

Dedicates a specific keycode to wxPropertyGrid.

This means that such key presses will not be redirected to editor controls.

Using this function allows, for example, navigation between properties using arrow keys even when the focus is in the editor control.

virtual void wxPropertyGrid::DoHidePropertyError (wxPGProperty * *property*) [virtual]

Override in derived class to hide an error displayed by DoShowPropertyError().

See also

DoShowPropertyError()

static wxPGEditor* wxPropertyGrid::DoRegisterEditorClass (wxPGEditor * *editor,* const wxString & *name,* bool *noDefCheck* = false) [static]

Registers a new editor class.

Returns

Returns pointer to the editor class instance that should be used.

virtual void wxPropertyGrid::DoShowPropertyError (wxPGProperty * *property,* const wxString & *msg*) [virtual]

Override in derived class to display error messages in custom manner (these message usually only result from validation failure).

Remarks

If you implement this, then you also need to implement DoHidePropertyError() - possibly to do nothing, if error does not need hiding (e.g. it was logged or shown in a message box).

See also

DoHidePropertyError()

void wxPropertyGrid::EditorsValueWasModified ( )

Call when editor widget's contents is modified.

For example, this is called when changes text in wxTextCtrl (used in wxStringProperty and wxIntProperty).

Remarks

This function should only be called by custom properties.

See also

wxPGProperty::OnEvent()

void wxPropertyGrid::EditorsValueWasNotModified ( )

Reverse of EditorsValueWasModified().

Remarks

This function should only be called by custom properties.

bool wxPropertyGrid::EnableCategories (bool *enable*)

Enables or disables (shows/hides) categories according to parameter enable.

Remarks

This functions deselects selected property, if any. Validation failure option wxPG_VFB_STAY_IN_PROPERTY is not respected, ie. selection is cleared even if editor had invalid value.

void wxPropertyGrid::EndLabelEdit (bool *commit* = `true`)

Destroys label editor wxTextCtrl, if any.

Parameters

commit	Use true (default) to store edited label text in property cell data.

See also

BeginLabelEdit(), MakeColumnEditable()

bool wxPropertyGrid::EnsureVisible (wxPGPropArg *id*)

Scrolls and/or expands items to ensure that the given item is visible.

Returns

Returns true if something was actually done.

wxSize wxPropertyGrid::FitColumns ( )

Reduces column sizes to minimum possible, while still retaining fully visible grid contents (labels, images).

Returns

Minimum size for the grid to still display everything.

Remarks

Does not work well with wxPG_SPLITTER_AUTO_CENTER window style.

```
This function only works properly if grid size prior to call was
already fairly large.

Note that you can also get calculated column widths by calling
GetState->GetColumnWidth() immediately after this function
returns.
```

wxColour wxPropertyGrid::GetCaptionBackgroundColour ( ) const

Returns current category caption background colour.

wxFont& wxPropertyGrid::GetCaptionFont ( )

Returns current category caption font.

wxColour wxPropertyGrid::GetCaptionForegroundColour ( ) const

Returns current category caption text colour.

wxColour wxPropertyGrid::GetCellBackgroundColour ( ) const

Returns current cell background colour.

wxColour wxPropertyGrid::GetCellDisabledTextColour ( ) const

Returns current cell text colour when disabled.

wxColour wxPropertyGrid::GetCellTextColour ( ) const

Returns current cell text colour.

unsigned int wxPropertyGrid::GetColumnCount ( ) const

Returns number of columns currently on grid.

wxTextCtrl* wxPropertyGrid::GetEditorTextCtrl ( ) const

Returns wxTextCtrl active in currently selected property, if any.

Takes wxOwnerDrawnComboBox into account.

wxColour wxPropertyGrid::GetEmptySpaceColour ( ) const

Returns colour of empty space below properties.

int wxPropertyGrid::GetFontHeight ( ) const

Returns height of highest characters of used font.

wxPropertyGrid* wxPropertyGrid::GetGrid ( )

Returns pointer to itself.

Dummy function that enables same kind of code to use wxPropertyGrid and wxPropertyGridManager.

wxRect wxPropertyGrid::GetImageRect (wxPGProperty * *property*, int *item*) const

Returns rectangle of custom paint image.

Parameters

property	Return image rectangle for this property.
item	Which choice of property to use (each choice may have different image).

wxSize wxPropertyGrid::GetImageSize (wxPGProperty * *property* = NULL, int *item* = -1) const

Returns size of the custom paint image in front of property.

Parameters

property	Return image rectangle for this property. If this argument is NULL, then preferred size is returned.
item	Which choice of property to use (each choice may have different image).

wxTextCtrl* wxPropertyGrid::GetLabelEditor ( ) const

Returns currently active label editor, NULL if none.

wxPGProperty* wxPropertyGrid::GetLastItem (int *flags* = wxPG_ITERATE_DEFAULT)

Returns last item which could be iterated using given flags.

Parameters

flags	See wxPropertyGridIterator Flags.

wxColour wxPropertyGrid::GetLineColour ( ) const

Returns colour of lines between cells.

wxColour wxPropertyGrid::GetMarginColour ( ) const

Returns background colour of margin.

wxWindow* wxPropertyGrid::GetPanel ( )

Returns wxWindow that the properties are painted on, and which should be used as the parent for editor controls.

wxPGProperty* wxPropertyGrid::GetRoot ( ) const

Returns "root property".

It does not have name, etc. and it is not visible. It is only useful for accessing its children.

int wxPropertyGrid::GetRowHeight ( ) const

Returns height of a single grid row (in pixels).

wxPGProperty* wxPropertyGrid::GetSelectedProperty ( ) const

Returns currently selected property.

wxPGProperty* wxPropertyGrid::GetSelection ( ) const

Returns currently selected property.

wxColour wxPropertyGrid::GetSelectionBackgroundColour ( ) const

Returns current selection background colour.

wxColour wxPropertyGrid::GetSelectionForegroundColour ( ) const

Returns current selection text colour.

wxPGSortCallback wxPropertyGrid::GetSortFunction ( ) const

Returns the property sort function (default is NULL).

See also

SetSortFunction

int wxPropertyGrid::GetSplitterPosition (unsigned int *splitterIndex* = 0) const

Returns current splitter x position.

virtual wxStatusBar* wxPropertyGrid::GetStatusBar ( ) [virtual]

Return wxStatusBar that is used by this wxPropertyGrid.

You can reimplement this member function in derived class to override the default behaviour of using the top-level wxFrame's status bar, if any.

wxVariant wxPropertyGrid::GetUncommittedPropertyValue ( )

Returns most up-to-date value of selected property.

This will return value different from GetSelectedProperty()->GetValue() only when text editor is activate and string edited by user represents valid, uncommitted property value.

const wxPGCell& wxPropertyGrid::GetUnspecifiedValueAppearance ( ) const

Returns current appearance of unspecified value cells.

See also

SetUnspecifiedValueAppearance()

wxString wxPropertyGrid::GetUnspecifiedValueText (int *argFlags* = 0) const

Returns (visual) text representation of the unspecified property value.

Parameters

argFlags	For internal use only.

int wxPropertyGrid::GetVerticalSpacing ( ) const

Returns current vertical spacing.

wxPropertyGridHitTestResult wxPropertyGrid::HitTest (const wxPoint & *pt*) const

Returns information about arbitrary position in the grid.

Parameters

pt	Coordinates in the virtual grid space. You may need to use wxScrolled<T>::CalcScrolled↩ Position() for translating wxPropertyGrid client coordinates into something this member function can use.

bool wxPropertyGrid::IsAnyModified ( ) const

Returns true if any property has been modified by the user.

bool wxPropertyGrid::IsEditorFocused ( ) const

Returns true if a property editor control has focus.

bool wxPropertyGrid::IsEditorsValueModified ( ) const

Returns true if editor's value was marked modified.

bool wxPropertyGrid::IsFrozen ( ) const

Returns true if updating is frozen (ie.

Freeze() called but not yet Thaw()).

void wxPropertyGrid::MakeColumnEditable (unsigned int *column*, bool *editable* = `true`)

Makes given column editable by user.

Parameters

column	The index of the column to make editable.
editable	Using false here will disable column from being editable.

See also

BeginLabelEdit(), EndLabelEdit()

void wxPropertyGrid::OnTLPChanging (wxWindow * *newTLP*)

It is recommended that you call this function any time your code causes wxPropertyGrid's top-level parent to change.

wxPropertyGrid's OnIdle() handler should be able to detect most changes, but it is not perfect.

Parameters

newTLP	New top-level parent that is about to be set. Old top-level parent window should still exist as the current one.

Remarks

This function is automatically called from wxPropertyGrid:: Reparent() and wxPropertyGridManager::↩ Reparent(). You only need to use it if you reparent wxPropertyGrid indirectly.

void wxPropertyGrid::RefreshEditor ( )

Refreshes any active editor control.

virtual void wxPropertyGrid::RefreshProperty (wxPGProperty * *p*) [virtual]

Redraws given property.

static wxPGEditor* wxPropertyGrid::RegisterEditorClass (wxPGEditor * *editor,* bool *noDefCheck* = false) [static]

Forwards to DoRegisterEditorClass with empty name.

bool wxPropertyGrid::RemoveFromSelection (wxPGPropArg *id*)

Removes given property from selection.

If property is not selected, an assertion failure will occur.

void wxPropertyGrid::ResetColours ( )

Resets all colours to the original system values.

void wxPropertyGrid::ResetColumnSizes (bool *enableAutoResizing* = false)

Resets column sizes and splitter positions, based on proportions.

Parameters

enableAuto↩ Resizing	If true, automatic column resizing is enabled (only applicapple if window style wxPG_SPLI↩ TTER_AUTO_CENTER is used).

See also

wxPropertyGridInterface::SetColumnProportion()

bool wxPropertyGrid::SelectProperty (wxPGPropArg *id,* bool *focus* = false)

Selects a property.

Editor widget is automatically created, but not focused unless focus is true.

Parameters

id	Property to select (name or pointer).
focus	If true, move keyboard focus to the created editor right away.

Returns

returns true if selection finished successfully. Usually only fails if current value in editor is not valid.

Remarks

In wxPropertyGrid 1.4, this member function used to generate `wxEVT_PG_SELECTED`. In wxWidgets 2.9 and later, it no longer does that.
This clears any previous selection.

See also

wxPropertyGridInterface::ClearSelection()

void wxPropertyGrid::SetCaptionBackgroundColour (const wxColour & *col*)

Sets category caption background colour.

void wxPropertyGrid::SetCaptionTextColour (const wxColour & *col*)

Sets category caption text colour.

void wxPropertyGrid::SetCellBackgroundColour (const wxColour & *col*)

Sets default cell background colour - applies to property cells.

Note that appearance of editor widgets may not be affected.

void wxPropertyGrid::SetCellDisabledTextColour (const wxColour & *col*)

Sets cell text colour for disabled properties.

void wxPropertyGrid::SetCellTextColour (const wxColour & *col*)

Sets default cell text colour - applies to property name and value text.

Note that appearance of editor widgets may not be affected.

void wxPropertyGrid::SetColumnCount (int *colCount*)

Set number of columns (2 or more).

void wxPropertyGrid::SetCurrentCategory (wxPGPropArg *id*)

Sets the 'current' category - Append will add non-category properties under it.

void wxPropertyGrid::SetEmptySpaceColour (const wxColour & *col*)

Sets colour of empty space below properties.

void wxPropertyGrid::SetLineColour (const wxColour & *col*)

Sets colour of lines between cells.

void wxPropertyGrid::SetMarginColour (const wxColour & *col*)

Sets background colour of margin.

void wxPropertyGrid::SetSelection (const wxArrayPGProperty & *newSelection*)

Set entire new selection from given list of properties.

void wxPropertyGrid::SetSelectionBackgroundColour (const wxColour & *col*)

Sets selection background colour - applies to selected property name background.

void wxPropertyGrid::SetSelectionTextColour (const wxColour & *col*)

Sets selection foreground colour - applies to selected property name text.

void wxPropertyGrid::SetSortFunction (wxPGSortCallback *sortFunction*)

Sets the property sorting function.

Parameters

sortFunction	The sorting function to be used. It should return a value greater than 0 if position of p1 is after p2. So, for instance, when comparing property names, you can use following implementation:

```
int MyPropertySortFunction(wxPropertyGrid* propGrid,
                           wxPGProperty* p1,
                           wxPGProperty* p2)
{
    return p1->GetBaseName().compare( p2->GetBaseName() );
}
```

Remarks

Default property sort function sorts properties by their labels (case-insensitively).

See also

GetSortFunction, wxPropertyGridInterface::Sort, wxPropertyGridInterface::SortChildren

void wxPropertyGrid::SetSplitterLeft (bool *privateChildrenToo* = `false`)

Moves splitter as left as possible, while still allowing all labels to be shown in full.

Parameters

privateChildren↩ Too	If false, will still allow private children to be cropped.

void wxPropertyGrid::SetSplitterPosition (int *newxpos,* int *col* = 0)

Sets x coordinate of the splitter.

Remarks

Splitter position cannot exceed grid size, and therefore setting it during form creation may fail as initial grid size is often smaller than desired splitter position, especially when sizers are being used.

void wxPropertyGrid::SetUnspecifiedValueAppearance (const wxPGCell & *cell*)

Sets appearance of value cells representing an unspecified property value.

Default appearance is blank.

Remarks

If you set the unspecified value to have any textual representation, then that will override "InlineHelp" attribute.

See also

wxPGProperty::SetValueToUnspecified(), wxPGProperty::IsValueUnspecified()

void wxPropertyGrid::SetVerticalSpacing (int *vspacing*)

Sets vertical spacing.

Can be 1, 2, or 3 - a value relative to font height. Value of 2 should be default on most platforms.

void wxPropertyGrid::ShowPropertyError (wxPGPropArg *id,* const wxString & *msg*)

Shows an brief error message that is related to a property.

bool wxPropertyGrid::WasValueChangedInEvent ( ) const

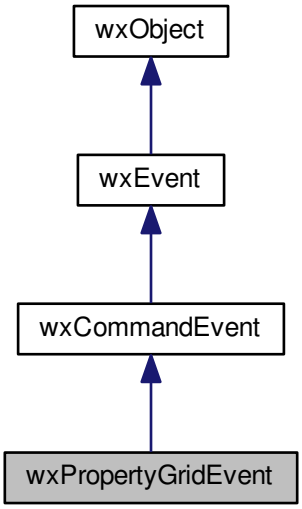
You can use this member function, for instance, to detect in wxPGProperty::OnEvent() if wxPGProperty::SetValue↩ InEvent() was already called in wxPGEditor::OnEvent().

It really only detects if was value was changed using wxPGProperty::SetValueInEvent(), which is usually used when a 'picker' dialog is displayed. If value was written by "normal means" in wxPGProperty::StringToValue() or IntTo↩ Value(), then this function will return false (on the other hand, wxPGProperty::OnEvent() is not even called in those cases).

21.562 wxPropertyGridEvent Class Reference

`#include <wx/propgrid/propgrid.h>`

Inheritance diagram for wxPropertyGridEvent:



21.562.1 Detailed Description

A property grid event holds information about events associated with wxPropertyGrid objects.

Library: wxPropertyGrid

Category: wxPropertyGrid

Public Member Functions

- wxPropertyGridEvent (wxEventType commandType=0, int id=0)

  Constructor.
- wxPropertyGridEvent (const wxPropertyGridEvent &event)

  Copy constructor.
- ~wxPropertyGridEvent ()

  Destructor.
- bool CanVeto () const

  Returns true if you can veto the action that the event is signaling.
- unsigned int GetColumn () const

  Returns the column index associated with this event.
- wxPGProperty * GetMainParent () const

  Returns highest level non-category, non-root parent of property for which event occurred.
- wxPGProperty * GetProperty () const

  Returns property associated with this event.
- wxPGVFBFlags GetValidationFailureBehavior () const

  Returns current validation failure flags.

- wxString GetPropertyName () const

  Returns name of the associated property.
- wxVariant GetPropertyValue () const wxVariant GetValue() const

  Returns value of the associated property.
- void SetCanVeto (bool canVeto)

  Set if event can be vetoed.
- void SetProperty (wxPGProperty *p)

  Changes the property associated with this event.
- void SetValidationFailureBehavior (wxPGVFBFlags flags)

  Set override validation failure behaviour.
- void SetValidationFailureMessage (const wxString &message)

  Sets custom failure message for this time only.
- void Veto (bool veto=true)

  Call this from your event handler to veto action that the event is signaling.
- bool WasVetoed () const

  Returns true if event was vetoed.

Additional Inherited Members

21.562.2 Constructor & Destructor Documentation

wxPropertyGridEvent::wxPropertyGridEvent (wxEventType *commandType* = 0, int *id* = 0)

Constructor.

wxPropertyGridEvent::wxPropertyGridEvent (const wxPropertyGridEvent & *event*)

Copy constructor.

wxPropertyGridEvent::~wxPropertyGridEvent ( )

Destructor.

21.562.3 Member Function Documentation

bool wxPropertyGridEvent::CanVeto ( ) const

Returns true if you can veto the action that the event is signaling.

unsigned int wxPropertyGridEvent::GetColumn ( ) const

Returns the column index associated with this event.

For the column dragging events, it is the column to the left of the splitter being dragged

wxPGProperty* wxPropertyGridEvent::GetMainParent ( ) const

Returns highest level non-category, non-root parent of property for which event occurred.

Useful when you have nested properties with children.

Remarks

If immediate parent is root or category, this will return the property itself.

wxPGProperty* wxPropertyGridEvent::GetProperty ( ) const

Returns property associated with this event.

Remarks

You should assume that this property can always be NULL. For instance, `wxEVT_PG_SELECTED` is emitted not only when a new property is selected, but also when selection is cleared by user activity.

wxString wxPropertyGridEvent::GetPropertyName ( ) const

Returns name of the associated property.

Remarks

Property name is stored in event, so it remains accessible even after the associated property or the property grid has been deleted.

wxVariant wxPropertyGridEvent::GetPropertyValue ( ) const

Returns value of the associated property.

Works for all event types, but for `wxEVT_PG_CHANGING` this member function returns the value that is pending, so you can call Veto() if the value is not satisfactory.

Remarks

Property value is stored in event, so it remains accessible even after the associated property or the property grid has been deleted.

See also

GetPropertyValue()

wxPGVFBFlags wxPropertyGridEvent::GetValidationFailureBehavior ( ) const

Returns current validation failure flags.

void wxPropertyGridEvent::SetCanVeto (bool *canVeto*)

Set if event can be vetoed.

void wxPropertyGridEvent::SetProperty (wxPGProperty * *p*)

Changes the property associated with this event.

void wxPropertyGridEvent::SetValidationFailureBehavior (wxPGVFBFlags *flags*)

Set override validation failure behaviour.

Only effective if Veto() was also called, and only allowed if event type is `wxEVT_PG_CHANGING`.

void wxPropertyGridEvent::SetValidationFailureMessage (const wxString & *message*)

Sets custom failure message for this time only.

Only applies if wxPG_VFB_SHOW_MESSAGE is set in validation failure flags.

void wxPropertyGridEvent::Veto (bool *veto* = `true`)

Call this from your event handler to veto action that the event is signaling.

You can only veto a shutdown if wxPropertyGridEvent::CanVeto() returns true.

Remarks

Currently only `wxEVT_PG_CHANGING` supports vetoing.

bool wxPropertyGridEvent::WasVetoed ( ) const

Returns true if event was vetoed.

21.563 wxPropertyGridHitTestResult Struct Reference

`#include <wx/propgrid/propgridpagestate.h>`

21.563.1 Detailed Description

21.563.2 wxPropertyGridHitTestResult

A return value from wxPropertyGrid::HitTest(), contains all you need to know about an arbitrary location on the grid.

Public Member Functions

- wxPGProperty * GetProperty () const

Public Attributes

- int column

  Column.
- int splitter

  Index of splitter hit, -1 for none.
- int splitterHitOffset

  If splitter hit, offset to that.

Private Attributes

- wxPGProperty * property

  Property.

21.563.3 Member Function Documentation

wxPGProperty* wxPropertyGridHitTestResult::GetProperty ( ) const `[inline]`

21.563.4 Member Data Documentation

int wxPropertyGridHitTestResult::column

Column.

-1 for margin.

wxPGProperty* wxPropertyGridHitTestResult::property `[private]`

Property.

NULL if empty space below properties was hit

int wxPropertyGridHitTestResult::splitter

Index of splitter hit, -1 for none.

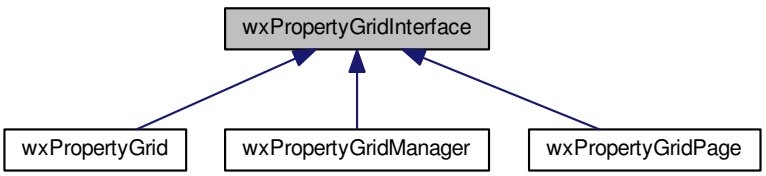
int wxPropertyGridHitTestResult::splitterHitOffset

If splitter hit, offset to that.

21.564 wxPropertyGridInterface Class Reference

`#include <wx/propgrid/propgridiface.h>`

Inheritance diagram for wxPropertyGridInterface:



21.564.1 Detailed Description

Most of the shared property manipulation interface shared by wxPropertyGrid, wxPropertyGridPage, and wx↩ PropertyGridManager is defined in this class.

Remarks

- In separate wxPropertyGrid component this class was known as wxPropertyContainerMethods.
- wxPropertyGridInterface's property operation member functions all accept a special wxPGPropArg id argument, using which you can refer to properties either by their pointer (for performance) or by their name (for conveniency).

Library: wxPropertyGrid

Category: wxPropertyGrid

Public Types

- enum EditableStateFlags {
  SelectionState = 0x01,
  ExpandedState = 0x02,
  ScrollPosState = 0x04,
  PageState = 0x08,
  SplitterPosState = 0x10,
  DescBoxState = 0x20,
  AllStates }

Public Member Functions

- virtual ~wxPropertyGridInterface ()

  Destructor.
- wxPGProperty * Append (wxPGProperty *property)

  Appends property to the list.
- wxPGProperty * AppendIn (wxPGPropArg id, wxPGProperty *newProperty)

  Same as Append(), but appends under given parent property.
- void BeginAddChildren (wxPGPropArg id)

  In order to add new items into a property with private children (for instance, wxFlagsProperty), you need to call this method.
- virtual void Clear ()=0

  Deletes all properties.
- bool ClearSelection (bool validation=false)

  Clears current selection, if any.
- void ClearModifiedStatus ()

  Resets modified status of all properties.
- bool Collapse (wxPGPropArg id)

  Collapses given category or property with children.
- bool CollapseAll ()

  Collapses all items that can be collapsed.
- bool ChangePropertyValue (wxPGPropArg id, wxVariant newValue)

  Changes value of a property, as if by user.
- void DeleteProperty (wxPGPropArg id)

  Removes and deletes a property and any children.
- bool DisableProperty (wxPGPropArg id)

  Disables a property.
- bool EditorValidate ()

  Returns true if all property grid data changes have been committed.
- bool EnableProperty (wxPGPropArg id, bool enable=true)

  Enables or disables property.
- void EndAddChildren (wxPGPropArg id)

  Called after population of property with fixed children has finished.
- bool Expand (wxPGPropArg id)

  Expands given category or property with children.

- bool ExpandAll (bool expand=true)

  Expands all items that can be expanded.
- int GetColumnProportion (unsigned int column) const

  Returns auto-resize proportion of the given column.
- wxPGProperty * GetFirstChild (wxPGPropArg id)

  Returns id of first child of given property.
- wxPGProperty * GetFirst (int flags=wxPG_ITERATE_ALL)

  Returns id of first item that matches given criteria.
- wxPGProperty * GetProperty (const wxString &name) const

  Returns pointer to a property with given name (case-sensitive).
- void GetPropertiesWithFlag (wxArrayPGProperty *targetArr, wxPGProperty::FlagType flags, bool inverse=false, int iterFlags=(wxPG_ITERATE_PROPERTIES|wxPG_ITERATE_HIDDEN|wxPG_ITERATE_CATEGORIES)) const

  Adds to 'targetArr' pointers to properties that have given flags 'flags' set.
- wxVariant GetPropertyAttribute (wxPGPropArg id, const wxString &attrName) const

  Returns value of given attribute.
- wxColour GetPropertyBackgroundColour (wxPGPropArg id) const

  Returns background colour of first cell of a property.
- wxPropertyCategory * GetPropertyCategory (wxPGPropArg id) const

  Returns pointer of property's nearest parent category.
- void * GetPropertyClientData (wxPGPropArg id) const

  Returns client data (void) of a property.*
- wxPGProperty * GetPropertyByLabel (const wxString &label) const

  Returns first property which label matches given string.
- wxPGProperty * GetPropertyByName (const wxString &name) const

  Returns pointer to a property with given name (case-sensitive).
- wxPGProperty * GetPropertyByName (const wxString &name, const wxString &subname) const

  Returns child property 'subname' of property 'name'.
- const wxPGEditor * GetPropertyEditor (wxPGPropArg id) const

  Returns property's editor.
- wxString GetPropertyHelpString (wxPGPropArg id) const

  Returns help string associated with a property.
- wxBitmap * GetPropertyImage (wxPGPropArg id) const

  Returns property's custom value image (NULL of none).
- const wxString & GetPropertyLabel (wxPGPropArg id)

  Returns label of a property.
- wxString GetPropertyName (wxPGProperty *property)

  Returns property's name, by which it is globally accessible.
- wxColour GetPropertyTextColour (wxPGPropArg id) const

  Returns text colour of first cell of a property.
- wxValidator * GetPropertyValidator (wxPGPropArg id)

  Returns validator of a property as a reference, which you can pass to any number of SetPropertyValidator.
- wxVariant GetPropertyValue (wxPGPropArg id)

  Returns property's value as wxVariant.
- wxArrayInt GetPropertyValueAsArrayInt (wxPGPropArg id) const

  Return's property's value as wxArrayInt.
- wxArrayString GetPropertyValueAsArrayString (wxPGPropArg id) const

  Returns property's value as wxArrayString.
- bool GetPropertyValueAsBool (wxPGPropArg id) const

  Returns property's value as bool.
- wxDateTime GetPropertyValueAsDateTime (wxPGPropArg id) const

Return's property's value as wxDateTime.

- double GetPropertyValueAsDouble (wxPGPropArg id) const

  Returns property's value as double-precision floating point number.
- int GetPropertyValueAsInt (wxPGPropArg id) const

  Returns property's value as integer.
- long GetPropertyValueAsLong (wxPGPropArg id) const

  Returns property's value as integer.
- wxLongLong_t GetPropertyValueAsLongLong (wxPGPropArg id) const

  Returns property's value as native signed 64-bit integer.
- wxString GetPropertyValueAsString (wxPGPropArg id) const

  Returns property's value as wxString.
- unsigned long GetPropertyValueAsULong (wxPGPropArg id) const

  Returns property's value as unsigned integer.
- wxULongLong_t GetPropertyValueAsULongLong (wxPGPropArg id) const

  Returns property's value as native unsigned 64-bit integer.
- wxVariant GetPropertyValues (const wxString &listname=wxEmptyString, wxPGProperty *baseparent=NU↩ LL, long flags=0) const

  Returns a wxVariant list containing wxVariant versions of all property values.
- const wxArrayPGProperty & GetSelectedProperties () const

  Returns list of currently selected properties.
- wxPGProperty * GetSelection () const

  Returns currently selected property.
- virtual wxPGVIterator GetVIterator (int flags) const

  Similar to GetIterator(), but instead returns wxPGVIterator instance, which can be useful for forward-iterating through arbitrary property containers.
- bool HideProperty (wxPGPropArg id, bool hide=true, int flags=wxPG_RECURSE)

  Hides or reveals a property.
- wxPGProperty * Insert (wxPGPropArg priorThis, wxPGProperty *newProperty)

  Inserts property to the property container.
- wxPGProperty * Insert (wxPGPropArg parent, int index, wxPGProperty *newProperty)

  Inserts property to the property container.
- bool IsPropertyCategory (wxPGPropArg id) const

  Returns true if property is a category.
- bool IsPropertyEnabled (wxPGPropArg id) const

  Returns true if property is enabled.
- bool IsPropertyExpanded (wxPGPropArg id) const

  Returns true if given property is expanded.
- bool IsPropertyModified (wxPGPropArg id) const

  Returns true if property has been modified after value set or modify flag clear by software.
- virtual bool IsPropertySelected (wxPGPropArg id) const

  Returns true if property is selected.
- bool IsPropertyShown (wxPGPropArg id) const

  Returns true if property is shown (ie.
- bool IsPropertyValueUnspecified (wxPGPropArg id) const

  Returns true if property value is set to unspecified.
- void LimitPropertyEditing (wxPGPropArg id, bool limit=true)

  Disables (limit = true) or enables (limit = false) wxTextCtrl editor of a property, if it is not the sole mean to edit the value.
- wxPGProperty * RemoveProperty (wxPGPropArg id)

  Removes a property.
- wxPGProperty * ReplaceProperty (wxPGPropArg id, wxPGProperty *property)

Replaces property with id with newly created one.

- bool RestoreEditableState (const wxString &src, int restoreStates=AllStates)

  Restores user-editable state.
- wxString SaveEditableState (int includedStates=AllStates) const

  Used to acquire user-editable state (selected property, expanded properties, scrolled position, splitter positions).
- bool SetColumnProportion (unsigned int column, int proportion)

  Set proportion of a auto-stretchable column.
- void SetPropertyAttribute (wxPGPropArg id, const wxString &attrName, wxVariant value, long argFlags=0)

  Sets an attribute for this property.
- void SetPropertyAttributeAll (const wxString &attrName, wxVariant value)

  Sets property attribute for all applicapple properties.
- void SetPropertyBackgroundColour (wxPGPropArg id, const wxColour &colour, int flags=wxPG_RECURSE)

  Sets background colour of a property.
- void SetPropertyCell (wxPGPropArg id, int column, const wxString &text=wxEmptyString, const wxBitmap &bitmap=wxNullBitmap, const wxColour &fgCol=wxNullColour, const wxColour &bgCol=wxNullColour)

  Sets text, bitmap, and colours for given column's cell.
- void SetPropertyClientData (wxPGPropArg id, void ∗clientData)

  Sets client data (void∗) of a property.
- void SetPropertyColoursToDefault (wxPGPropArg id)

  Resets text and background colours of given property.
- void SetPropertyEditor (wxPGPropArg id, const wxPGEditor ∗editor)

  Sets editor for a property.
- void SetPropertyEditor (wxPGPropArg id, const wxString &editorName)

  Sets editor control of a property.
- void SetPropertyLabel (wxPGPropArg id, const wxString &newproplabel)

  Sets label of a property.
- void SetPropertyName (wxPGPropArg id, const wxString &newName)

  Sets name of a property.
- void SetPropertyReadOnly (wxPGPropArg id, bool set=true, int flags=wxPG_RECURSE)

  Sets property (and, recursively, its children) to have read-only value.
- void SetPropertyValueUnspecified (wxPGPropArg id)

  Sets property's value to unspecified.
- void SetPropertyValues (const wxVariantList &list, wxPGPropArg defaultCategory=wxNullProperty)

  Sets property values from a list of wxVariants.
- void SetPropertyValues (const wxVariant &list, wxPGPropArg defaultCategory=wxNullProperty)

  Sets property values from a list of wxVariants.
- void SetPropertyHelpString (wxPGPropArg id, const wxString &helpString)

  Associates the help string with property.
- void SetPropertyImage (wxPGPropArg id, wxBitmap &bmp)

  Set wxBitmap in front of the value.
- bool SetPropertyMaxLength (wxPGPropArg id, int maxLen)

  Sets max length of property's text.
- void SetPropertyTextColour (wxPGPropArg id, const wxColour &colour, int flags=wxPG_RECURSE)

  Sets text colour of a property.
- void SetPropertyValidator (wxPGPropArg id, const wxValidator &validator)

  Sets validator of a property.
- void SetPropertyValue (wxPGPropArg id, long value)

  Sets value (integer) of a property.
- void SetPropertyValue (wxPGPropArg id, int value)

  Sets value (integer) of a property.
- void SetPropertyValue (wxPGPropArg id, double value)

Sets value (floating point) of a property.

- void SetPropertyValue (wxPGPropArg id, bool value)

  Sets value (bool) of a property.
- void SetPropertyValue (wxPGPropArg id, const wxString &value)

  Sets value (string) of a property.
- void SetPropertyValue (wxPGPropArg id, const wxArrayString &value)

  Sets value (wxArrayString) of a property.
- void SetPropertyValue (wxPGPropArg id, const wxDateTime &value)

  Sets value (wxDateTime) of a property.
- void SetPropertyValue (wxPGPropArg id, wxObject *value)

  Sets value (wxObject) of a property.*
- void SetPropertyValue (wxPGPropArg id, wxObject &value)

  Sets value (wxObject&) of a property.
- void SetPropertyValue (wxPGPropArg id, wxLongLong_t value)

  Sets value (native 64-bit int) of a property.
- void SetPropertyValue (wxPGPropArg id, wxULongLong_t value)

  Sets value (native 64-bit unsigned int) of a property.
- void SetPropertyValue (wxPGPropArg id, const wxArrayInt &value)

  Sets value (wxArrayInt&) of a property.
- void SetPropertyValueString (wxPGPropArg id, const wxString &value)

  Sets value (wxString) of a property.
- void SetPropertyValue (wxPGPropArg id, wxVariant value)

  Sets value (wxVariant&) of a property.
- void SetValidationFailureBehavior (int vfbFlags)

  Adjusts how wxPropertyGrid behaves when invalid value is entered in a property.
- void Sort (int flags=0)

  Sorts all properties recursively.
- void SortChildren (wxPGPropArg id, int flags=0)

  Sorts children of a property.

- wxPropertyGridIterator GetIterator (int flags=wxPG_ITERATE_DEFAULT, wxPGProperty *firstProp=NULL)

  Returns iterator class instance.
- wxPropertyGridConstIterator GetIterator (int flags=wxPG_ITERATE_DEFAULT, wxPGProperty *firstProp=NULL) const

  Returns iterator class instance.

- wxPropertyGridIterator GetIterator (int flags, int startPos)

  Returns iterator class instance.
- wxPropertyGridConstIterator GetIterator (int flags, int startPos) const

  Returns iterator class instance.

Static Public Member Functions

- static void InitAllTypeHandlers ()

  Initializes all property types.
- static void RegisterAdditionalEditors ()

  Initializes additional property editors (SpinCtrl etc.).
- static void SetBoolChoices (const wxString &trueChoice, const wxString &falseChoice)

  Sets strings listed in the choice dropdown of a wxBoolProperty.
- static wxPGEditor * GetEditorByName (const wxString &editorName)

  Returns editor pointer of editor with given name;.

21.564.2 Member Enumeration Documentation

enum wxPropertyGridInterface::EditableStateFlags

Flags for wxPropertyGridInterface::SaveEditableState() and wxPropertyGridInterface::RestoreEditableState().

Enumerator

SelectionState Include selected property.

ExpandedState Include expanded/collapsed property information.

ScrollPosState Include scrolled position.

PageState Include selected page information. Only applies to wxPropertyGridManager.

SplitterPosState Include splitter position. Stored for each page.

DescBoxState Include description box size. Only applies to wxPropertyGridManager.

AllStates Include all supported user editable state information. This is usually the default value.

21.564.3 Constructor & Destructor Documentation

virtual wxPropertyGridInterface::~wxPropertyGridInterface ( ) [inline], [virtual]

Destructor.

21.564.4 Member Function Documentation

wxPGProperty* wxPropertyGridInterface::Append (wxPGProperty * *property*)

Appends property to the list.

wxPropertyGrid assumes ownership of the object. Becomes child of most recently added category.

Remarks

- wxPropertyGrid takes the ownership of the property pointer.
- If appending a category with name identical to a category already in the wxPropertyGrid, then newly created category is deleted, and most recently added category (under which properties are appended) is set to the one with same name. This allows easier adding of items to same categories in multiple passes.
- Does not automatically redraw the control, so you may need to call Refresh() when calling this function after control has been shown for the first time.
- This functions deselects selected property, if any. Validation failure option wxPG_VFB_STAY_IN_PR↩ OPERTY is not respected, ie. selection is cleared even if editor had invalid value.

wxPGProperty* wxPropertyGridInterface::AppendIn (wxPGPropArg *id*, wxPGProperty * *newProperty*)

Same as Append(), but appends under given parent property.

Parameters

id	Name or pointer to parent property.
newProperty	Property to be added.

void wxPropertyGridInterface::BeginAddChildren (wxPGPropArg *id*)

In order to add new items into a property with private children (for instance, wxFlagsProperty), you need to call this method.

After populating has been finished, you need to call EndAddChildren().

See also

EndAddChildren()

bool wxPropertyGridInterface::ChangePropertyValue (wxPGPropArg *id,* wxVariant *newValue*)

Changes value of a property, as if by user.

Use this instead of SetPropertyValue() if you need the value to run through validation process, and also send the property change event.

Returns

Returns true if value was successfully changed.

virtual void wxPropertyGridInterface::Clear ( ) [pure virtual]

Deletes all properties.

Remarks

This functions deselects selected property, if any. Validation failure option wxPG_VFB_STAY_IN_PROPERTY is not respected, ie. selection is cleared even if editor had invalid value.

Implemented in wxPropertyGrid, wxPropertyGridManager, and wxPropertyGridPage.

void wxPropertyGridInterface::ClearModifiedStatus ( )

Resets modified status of all properties.

bool wxPropertyGridInterface::ClearSelection (bool *validation* = false)

Clears current selection, if any.

Parameters

validation	If set to false, deselecting the property will always work, even if its editor had invalid value in it.

Returns

Returns true if successful or if there was no selection. May fail if validation was enabled and active editor had invalid value.

Remarks

In wxPropertyGrid 1.4, this member function used to send wxPG_EVT_SELECTED. In wxWidgets 2.9 and later, it no longer does that.

See also

wxPropertyGrid::SelectProperty()

bool wxPropertyGridInterface::Collapse (wxPGPropArg *id*)

Collapses given category or property with children.

Returns

Returns true if actually collapsed.

Remarks

This function may deselect selected property, if any. Validation failure option wxPG_VFB_STAY_IN_PROPERTY is not respected, ie. selection is cleared even if editor had invalid value.

bool wxPropertyGridInterface::CollapseAll ( )

Collapses all items that can be collapsed.

Remarks

This functions clears selection. Validation failure option wxPG_VFB_STAY_IN_PROPERTY is not respected, ie. selection is cleared even if editor had invalid value.

void wxPropertyGridInterface::DeleteProperty (wxPGPropArg *id*)

Removes and deletes a property and any children.

Parameters

id	Pointer or name of a property.

Remarks

If you delete a property in a wxPropertyGrid event handler, the actual deletion is postponed until the next idle event.

This functions deselects selected property, if any. Validation failure option wxPG_VFB_STAY_IN_PROPERTY is not respected, ie. selection is cleared even if editor had invalid value.

bool wxPropertyGridInterface::DisableProperty (wxPGPropArg *id*)

Disables a property.

See also

EnableProperty(), wxPGProperty::Enable()

bool wxPropertyGridInterface::EditorValidate ( )

Returns true if all property grid data changes have been committed.

Usually only returns false if value in active editor has been invalidated by a wxValidator.

bool wxPropertyGridInterface::EnableProperty (wxPGPropArg *id,* bool *enable* = `true`)

Enables or disables property.

Disabled property usually appears as having grey text.

Parameters

id	Name or pointer to a property.
enable	If false, property is disabled instead.

See also

wxPGProperty::Enable()

void wxPropertyGridInterface::EndAddChildren (wxPGPropArg *id*)

Called after population of property with fixed children has finished.

See also

BeginAddChildren()

bool wxPropertyGridInterface::Expand (wxPGPropArg *id*)

Expands given category or property with children.

Returns

Returns true if actually expanded.

Remarks

This function may deselect selected property, if any. Validation failure option wxPG_VFB_STAY_IN_PROPERTY is not respected, ie. selection is cleared even if editor had invalid value.

bool wxPropertyGridInterface::ExpandAll (bool *expand* = `true`)

Expands all items that can be expanded.

Remarks

This functions clears selection. Validation failure option wxPG_VFB_STAY_IN_PROPERTY is not respected, ie. selection is cleared even if editor had invalid value.

int wxPropertyGridInterface::GetColumnProportion (unsigned int *column*) const

Returns auto-resize proportion of the given column.

See also

SetColumnProportion()

static wxPGEditor* wxPropertyGridInterface::GetEditorByName (const wxString & *editorName*) `[static]`

Returns editor pointer of editor with given name;.

wxPGProperty* wxPropertyGridInterface::GetFirst (int *flags* = wxPG_ITERATE_ALL)

Returns id of first item that matches given criteria.

Parameters

flags	See wxPropertyGridIterator Flags.

wxPGProperty∗ wxPropertyGridInterface::GetFirstChild (wxPGPropArg *id*)

Returns id of first child of given property.

Remarks

Does not return private children!

wxPropertyGridIterator wxPropertyGridInterface::GetIterator (int *flags* = wxPG_ITERATE_DEFAULT, wxPGProperty ∗ *firstProp* = NULL)

Returns iterator class instance.

Parameters

flags	See wxPropertyGridIterator Flags. Value wxPG_ITERATE_DEFAULT causes iteration over everything except private child properties.
firstProp	Property to start iteration from. If NULL, then first child of root is used.

wxPropertyGridConstIterator wxPropertyGridInterface::GetIterator (int *flags* = wxPG_ITERATE_DEFAULT, wxPGProperty ∗ *firstProp* = NULL) const

Returns iterator class instance.

Parameters

flags	See wxPropertyGridIterator Flags. Value wxPG_ITERATE_DEFAULT causes iteration over everything except private child properties.
firstProp	Property to start iteration from. If NULL, then first child of root is used.

wxPropertyGridIterator wxPropertyGridInterface::GetIterator (int *flags*, int *startPos*)

Returns iterator class instance.

Parameters

flags	See wxPropertyGridIterator Flags. Value wxPG_ITERATE_DEFAULT causes iteration over everything except private child properties.
startPos	Either wxTOP or wxBOTTOM. wxTOP will indicate that iterations start from the first property from the top, and wxBOTTOM means that the iteration will instead begin from bottommost valid item.

wxPropertyGridConstIterator wxPropertyGridInterface::GetIterator (int *flags*, int *startPos*) const

Returns iterator class instance.

Parameters

flags	See wxPropertyGridIterator Flags. Value wxPG_ITERATE_DEFAULT causes iteration over everything except private child properties.
startPos	Either wxTOP or wxBOTTOM. wxTOP will indicate that iterations start from the first property from the top, and wxBOTTOM means that the iteration will instead begin from bottommost valid item.

void wxPropertyGridInterface::GetPropertiesWithFlag (wxArrayPGProperty * *targetArr*, wxPGProperty::FlagType *flags*, bool *inverse* = `false`, int *iterFlags* = (wxPG_ITERATE_PROPERTIES|wxPG_ITERATE_HIDDEN|wxPG_ITERATE_CATEGORIES)) const

Adds to 'targetArr' pointers to properties that have given flags 'flags' set.

However, if *'inverse'* is set to true, then only properties without given flags are stored.

Parameters

targetArr	

Todo docme

Parameters

flags	Property flags to use.
inverse	

docme

Parameters

iterFlags	Iterator flags to use. Default is everything expect private children. See wxPropertyGridIterator Flags.

wxPGProperty* wxPropertyGridInterface::GetProperty (const wxString & *name*) const

Returns pointer to a property with given name (case-sensitive).

If there is no property with such name, NULL pointer is returned.

Remarks

Properties which have non-category, non-root parent cannot be accessed globally by their name. Instead, use "<property>.<subproperty>" instead of "<subproperty>".

wxVariant wxPropertyGridInterface::GetPropertyAttribute (wxPGPropArg *id*, const wxString & *attrName*) const

Returns value of given attribute.

If none found, returns wxNullVariant.

wxColour wxPropertyGridInterface::GetPropertyBackgroundColour (wxPGPropArg *id*) const

Returns background colour of first cell of a property.

wxPGProperty* wxPropertyGridInterface::GetPropertyByLabel (const wxString & *label*) const

Returns first property which label matches given string.

NULL if none found. Note that this operation is very slow when compared to GetPropertyByName().

wxPGProperty* wxPropertyGridInterface::GetPropertyByName (const wxString & *name*) const

Returns pointer to a property with given name (case-sensitive).

If there is no property with such name, NULL pointer is returned.

Remarks

Properties which have non-category, non-root parent cannot be accessed globally by their name. Instead, use "<property>.<subproperty>" instead of "<subproperty>".

wxPGProperty* wxPropertyGridInterface::GetPropertyByName (const wxString & *name,* const wxString & *subname*) const

Returns child property 'subname' of property 'name'.

Same as calling GetPropertyByName("name.subname"), albeit slightly faster.

wxPropertyCategory* wxPropertyGridInterface::GetPropertyCategory (wxPGPropArg *id*) const

Returns pointer of property's nearest parent category.

If no category found, returns NULL.

void* wxPropertyGridInterface::GetPropertyClientData (wxPGPropArg *id*) const

Returns client data (void*) of a property.

const wxPGEditor* wxPropertyGridInterface::GetPropertyEditor (wxPGPropArg *id*) const

Returns property's editor.

wxString wxPropertyGridInterface::GetPropertyHelpString (wxPGPropArg *id*) const

Returns help string associated with a property.

wxBitmap* wxPropertyGridInterface::GetPropertyImage (wxPGPropArg *id*) const

Returns property's custom value image (NULL of none).

const wxString& wxPropertyGridInterface::GetPropertyLabel (wxPGPropArg *id*)

Returns label of a property.

wxString wxPropertyGridInterface::GetPropertyName (wxPGProperty * *property*)

Returns property's name, by which it is globally accessible.

wxColour wxPropertyGridInterface::GetPropertyTextColour (wxPGPropArg *id*) const

Returns text colour of first cell of a property.

wxValidator* wxPropertyGridInterface::GetPropertyValidator (wxPGPropArg *id*)

Returns validator of a property as a reference, which you can pass to any number of SetPropertyValidator.

wxVariant wxPropertyGridInterface::GetPropertyValue (wxPGPropArg *id*)

Returns property's value as wxVariant.

If property value is unspecified, Null variant is returned.

wxArrayInt wxPropertyGridInterface::GetPropertyValueAsArrayInt (wxPGPropArg *id*) const

Return's property's value as wxArrayInt.

wxArrayString wxPropertyGridInterface::GetPropertyValueAsArrayString (wxPGPropArg *id*) const

Returns property's value as wxArrayString.

bool wxPropertyGridInterface::GetPropertyValueAsBool (wxPGPropArg *id*) const

Returns property's value as bool.

wxDateTime wxPropertyGridInterface::GetPropertyValueAsDateTime (wxPGPropArg *id*) const

Return's property's value as wxDateTime.

double wxPropertyGridInterface::GetPropertyValueAsDouble (wxPGPropArg *id*) const

Returns property's value as double-precision floating point number.

int wxPropertyGridInterface::GetPropertyValueAsInt (wxPGPropArg *id*) const

Returns property's value as integer.

long wxPropertyGridInterface::GetPropertyValueAsLong (wxPGPropArg *id*) const

Returns property's value as integer.

wxLongLong_t wxPropertyGridInterface::GetPropertyValueAsLongLong (wxPGPropArg *id*) const

Returns property's value as native signed 64-bit integer.

wxString wxPropertyGridInterface::GetPropertyValueAsString (wxPGPropArg *id*) const

Returns property's value as wxString.

If property does not use string value type, then its value is converted using wxPGProperty::GetValueAsString().

unsigned long wxPropertyGridInterface::GetPropertyValueAsULong (wxPGPropArg *id*) const

Returns property's value as unsigned integer.

wxULongLong_t wxPropertyGridInterface::GetPropertyValueAsULongLong (wxPGPropArg *id*) const

Returns property's value as native unsigned 64-bit integer.

wxVariant wxPropertyGridInterface::GetPropertyValues (const wxString & *listname* = wxEmptyString, wxPGProperty * *baseparent* = NULL, long *flags* = 0) const

Returns a wxVariant list containing wxVariant versions of all property values.

Order is not guaranteed.

Parameters

listname	

Todo docme

Parameters

baseparent	

docme

Parameters

flags	Use wxPG_KEEP_STRUCTURE to retain category structure; each sub category will be its own wxVariantList of wxVariant.

```
Use wxPG_INC_ATTRIBUTES to include property attributes as well.
Each attribute will be stored as list variant named
"@@<propname>@@attr."
```

const wxArrayPGProperty& wxPropertyGridInterface::GetSelectedProperties ( ) const

Returns list of currently selected properties.

Remarks

wxArrayPGProperty should be compatible with std::vector API.

wxPGProperty* wxPropertyGridInterface::GetSelection ( ) const

Returns currently selected property.

NULL if none.

Remarks

When wxPG_EX_MULTIPLE_SELECTION extra style is used, this member function returns the focused property, that is the one which can have active editor.

virtual wxPGVIterator wxPropertyGridInterface::GetVIterator (int *flags*) const [virtual]

Similar to GetIterator(), but instead returns wxPGVIterator instance, which can be useful for forward-iterating through arbitrary property containers.

Parameters

flags	See wxPropertyGridIterator Flags.

Reimplemented in wxPropertyGridManager.

bool wxPropertyGridInterface::HideProperty (wxPGPropArg *id*, bool *hide* = true, int *flags* = wxPG_RECURSE)

Hides or reveals a property.

Parameters

id	

Todo docme

Parameters

hide	If true, hides property, otherwise reveals it.
flags	By default changes are applied recursively. Set this parameter wxPG_DONT_RECURSE to prevent this.

static void wxPropertyGridInterface::InitAllTypeHandlers ( ) [static]

Initializes *all* property types.

Causes references to most object files in the library, so calling this may cause significant increase in executable size when linking with static library.

wxPGProperty* wxPropertyGridInterface::Insert (wxPGPropArg *priorThis*, wxPGProperty * *newProperty*)

Inserts property to the property container.

Parameters

priorThis	New property is inserted just prior to this. Available only in the first variant. There are two versions of this function to allow this parameter to be either an id or name to a property.
newProperty	Pointer to the inserted property. wxPropertyGrid will take ownership of this object.

Returns

Returns newProperty.

Remarks

- wxPropertyGrid takes the ownership of the property pointer.
- While Append may be faster way to add items, make note that when both types of data storage (categoric and non-categoric) are active, Insert becomes even more slow. This is especially true if current mode is non-categoric.
- This functions deselects selected property, if any. Validation failure option wxPG_VFB_STAY_IN_PROPE↩ RTY is not respected, ie. selection is cleared even if editor had invalid value.

Example of use:

```
// append category
wxPGProperty* my_cat_id = propertygrid->Append( new wxPropertyCategory("My Category") );

...

// insert into category - using second variant
wxPGProperty* my_item_id_1 = propertygrid->Insert( my_cat_id, 0, new wxStringProperty("My
       String 1") );

// insert before to first item - using first variant
wxPGProperty* my_item_id_2 = propertygrid->Insert( my_item_id, new wxStringProperty("My String
       2") );
```

wxPGProperty* **wxPropertyGridInterface::Insert** (**wxPGPropArg** *parent,* **int** *index,* **wxPGProperty** * *newProperty*)

Inserts property to the property container.

See the other overload for more details.

Parameters

parent	New property is inserted under this category. Available only in the second variant. There are two versions of this function to allow this parameter to be either an id or name to a property.
index	Index under category. Available only in the second variant. If index is < 0, property is appended in category.
newProperty	Pointer to the inserted property. wxPropertyGrid will take ownership of this object.

Returns

Returns newProperty.

bool wxPropertyGridInterface::IsPropertyCategory (wxPGPropArg *id*) const

Returns true if property is a category.

bool wxPropertyGridInterface::IsPropertyEnabled (wxPGPropArg *id*) const

Returns true if property is enabled.

bool wxPropertyGridInterface::IsPropertyExpanded (wxPGPropArg *id*) const

Returns true if given property is expanded.

Naturally, always returns false for properties that cannot be expanded.

bool wxPropertyGridInterface::IsPropertyModified (wxPGPropArg *id*) const

Returns true if property has been modified after value set or modify flag clear by software.

virtual bool wxPropertyGridInterface::IsPropertySelected (wxPGPropArg *id*) const `[virtual]`

Returns true if property is selected.

Reimplemented in wxPropertyGridManager.

bool wxPropertyGridInterface::IsPropertyShown (wxPGPropArg *id*) const

Returns true if property is shown (ie.

HideProperty() with true not called for it).

bool wxPropertyGridInterface::IsPropertyValueUnspecified (wxPGPropArg *id*) const

Returns true if property value is set to unspecified.

void wxPropertyGridInterface::LimitPropertyEditing (wxPGPropArg *id*, bool *limit* = `true`)

Disables (limit = true) or enables (limit = false) wxTextCtrl editor of a property, if it is not the sole mean to edit the value.

static void wxPropertyGridInterface::RegisterAdditionalEditors ( ) [static]

Initializes additional property editors (SpinCtrl etc.).

Causes references to most object files in the library, so calling this may cause significant increase in executable size when linking with static library.

wxPGProperty* wxPropertyGridInterface::RemoveProperty (wxPGPropArg *id*)

Removes a property.

Does not delete the property object, but instead returns it.

Parameters

id	Pointer or name of a property.

Remarks

Removed property cannot have any children.

```
Also, if you remove property in a wxPropertyGrid event
handler, the actual removal is postponed until the next
idle event.
```

wxPGProperty* wxPropertyGridInterface::ReplaceProperty (wxPGPropArg *id,* wxPGProperty * *property*)

Replaces property with id with newly created one.

For example, this code replaces existing property named "Flags" with one that will have different set of items:

```
pg->ReplaceProperty("Flags",
    wxFlagsProperty("Flags", wxPG_LABEL, newItems))
```

See also

Insert()

bool wxPropertyGridInterface::RestoreEditableState (const wxString & *src,* int *restoreStates* = AllStates)

Restores user-editable state.

See also wxPropertyGridInterface::SaveEditableState().

Parameters

src	String generated by SaveEditableState.
restoreStates	Which parts to restore from source string. See list of editable state flags.

Returns

Returns false if there was problem reading the string.

Remarks

If some parts of state (such as scrolled or splitter position) fail to restore correctly, please make sure that you call this function after wxPropertyGrid size has been set (this may sometimes be tricky when sizers are used).

wxString wxPropertyGridInterface::SaveEditableState (int *includedStates* = AllStates) const

Used to acquire user-editable state (selected property, expanded properties, scrolled position, splitter positions).

Parameters

includedStates	Which parts of state to include. See list of editable state flags.

static void wxPropertyGridInterface::SetBoolChoices (const wxString & *trueChoice*, const wxString & *falseChoice*) [static]

Sets strings listed in the choice dropdown of a wxBoolProperty.

Defaults are "True" and "False", so changing them to, say, "Yes" and "No" may be useful in some less technical applications.

bool wxPropertyGridInterface::SetColumnProportion (unsigned int *column*, int *proportion*)

Set proportion of a auto-stretchable column.

wxPG_SPLITTER_AUTO_CENTER window style needs to be used to indicate that columns are auto- resizable.

Returns

Returns false on failure.

Remarks

You should call this for individual pages of wxPropertyGridManager (if used).

See also

GetColumnProportion()

void wxPropertyGridInterface::SetPropertyAttribute (wxPGPropArg *id*, const wxString & *attrName*, wxVariant *value*, long *argFlags* = 0)

Sets an attribute for this property.

Parameters

id	

Todo docme

Parameters

attrName	Text identifier of attribute. See wxPropertyGrid Property Attribute Identifiers.
value	Value of attribute.
argFlags	Optional. Use wxPG_RECURSE to set the attribute to child properties recursively.

Remarks

Setting attribute's value to Null variant will simply remove it from property's set of attributes.

void wxPropertyGridInterface::SetPropertyAttributeAll (const wxString & *attrName*, wxVariant *value*)

Sets property attribute for all applicapple properties.

Be sure to use this method only after all properties have been added to the grid.

void wxPropertyGridInterface::SetPropertyBackgroundColour (wxPGPropArg *id,* const wxColour & *colour,* int *flags =* `wxPG_RECURSE`)

Sets background colour of a property.

Parameters

id	Property name or pointer.
colour	New background colour.
flags	Default is wxPG_RECURSE which causes colour to be set recursively. Omit this flag to only set colour for the property in question and not any of its children.

void wxPropertyGridInterface::SetPropertyCell (wxPGPropArg *id*, int *column*, const wxString & *text* = wxEmptyString, const wxBitmap & *bitmap* = wxNullBitmap, const wxColour & *fgCol* = wxNullColour, const wxColour & *bgCol* = wxNullColour)

Sets text, bitmap, and colours for given column's cell.

Remarks

- You can set label cell by using column 0.
- You can use wxPG_LABEL as text to use default text for column.

void wxPropertyGridInterface::SetPropertyClientData (wxPGPropArg *id*, void * *clientData*)

Sets client data (void*) of a property.

Remarks

This untyped client data has to be deleted manually.

void wxPropertyGridInterface::SetPropertyColoursToDefault (wxPGPropArg *id*)

Resets text and background colours of given property.

void wxPropertyGridInterface::SetPropertyEditor (wxPGPropArg *id*, const wxPGEditor * *editor*)

Sets editor for a property.

Parameters

id	

Todo docme

Parameters

editor	For builtin editors, use wxPGEditor_X, where X is builtin editor's name (TextCtrl, Choice, etc. see wxPGEditor documentation for full list).

For custom editors, use pointer you received from wxPropertyGrid::RegisterEditorClass().

void wxPropertyGridInterface::SetPropertyEditor (wxPGPropArg *id*, const wxString & *editorName*)

Sets editor control of a property.

As editor argument, use editor name string, such as "TextCtrl" or "Choice".

void wxPropertyGridInterface::SetPropertyHelpString (wxPGPropArg *id,* const wxString & *helpString*)

Associates the help string with property.

Remarks

By default, text is shown either in the manager's "description" text box or in the status bar. If extra window style wxPG_EX_HELP_AS_TOOLTIPS is used, then the text will appear as a tooltip.

void wxPropertyGridInterface::SetPropertyImage (wxPGPropArg *id,* wxBitmap & *bmp*)

Set wxBitmap in front of the value.

Remarks

Bitmap will be scaled to a size returned by wxPropertyGrid::GetImageSize();

void wxPropertyGridInterface::SetPropertyLabel (wxPGPropArg *id,* const wxString & *newproplabel*)

Sets label of a property.

Remarks

- Properties under same parent may have same labels. However, property names must still remain unique.

bool wxPropertyGridInterface::SetPropertyMaxLength (wxPGPropArg *id,* int *maxLen*)

Sets max length of property's text.

void wxPropertyGridInterface::SetPropertyName (wxPGPropArg *id,* const wxString & *newName*)

Sets name of a property.

Parameters

id	Name or pointer of property which name to change.
newName	New name for property.

void wxPropertyGridInterface::SetPropertyReadOnly (wxPGPropArg *id,* bool *set* = `true`, int *flags* = `wxPG_RECURSE`)

Sets property (and, recursively, its children) to have read-only value.

In other words, user cannot change the value in the editor, but they can still copy it.

Parameters

id	Property name or pointer.
set	Use true to enable read-only, false to disable it.
flags	By default changes are applied recursively. Set this parameter wxPG_DONT_RECURSE to prevent this.

Remarks

This is mainly for use with textctrl editor. Only some other editors fully support it.

void wxPropertyGridInterface::SetPropertyTextColour (wxPGPropArg *id,* const wxColour & *colour,* int *flags =* `wxPG_RECURSE`)

Sets text colour of a property.

Parameters

id	Property name or pointer.
colour	New background colour.
flags	Default is wxPG_RECURSE which causes colour to be set recursively. Omit this flag to only set colour for the property in question and not any of its children.

void wxPropertyGridInterface::SetPropertyValidator (wxPGPropArg *id,* const wxValidator & *validator*)

Sets validator of a property.

void wxPropertyGridInterface::SetPropertyValue (wxPGPropArg *id,* long *value*)

Sets value (integer) of a property.

void wxPropertyGridInterface::SetPropertyValue (wxPGPropArg *id,* int *value*)

Sets value (integer) of a property.

void wxPropertyGridInterface::SetPropertyValue (wxPGPropArg *id,* double *value*)

Sets value (floating point) of a property.

void wxPropertyGridInterface::SetPropertyValue (wxPGPropArg *id,* bool *value*)

Sets value (bool) of a property.

void wxPropertyGridInterface::SetPropertyValue (wxPGPropArg *id,* const wxString & *value*)

Sets value (string) of a property.

void wxPropertyGridInterface::SetPropertyValue (wxPGPropArg *id,* const wxArrayString & *value*)

Sets value (wxArrayString) of a property.

void wxPropertyGridInterface::SetPropertyValue (wxPGPropArg *id,* const wxDateTime & *value*)

Sets value (wxDateTime) of a property.

void wxPropertyGridInterface::SetPropertyValue (wxPGPropArg *id,* wxObject * *value*)

Sets value (wxObject*) of a property.

void wxPropertyGridInterface::SetPropertyValue (wxPGPropArg *id,* wxObject & *value*)

Sets value (wxObject&) of a property.

void wxPropertyGridInterface::SetPropertyValue (wxPGPropArg *id,* wxLongLong_t *value*)

Sets value (native 64-bit int) of a property.

void wxPropertyGridInterface::SetPropertyValue (wxPGPropArg *id,* wxULongLong_t *value*)

Sets value (native 64-bit unsigned int) of a property.

void wxPropertyGridInterface::SetPropertyValue (wxPGPropArg *id,* const wxArrayInt & *value*)

Sets value (wxArrayInt&) of a property.

void wxPropertyGridInterface::SetPropertyValue (wxPGPropArg *id,* wxVariant *value*)

Sets value (wxVariant&) of a property.

Remarks

Use wxPropertyGrid::ChangePropertyValue() instead if you need to run through validation process and send property change event.

void wxPropertyGridInterface::SetPropertyValues (const wxVariantList & *list,* wxPGPropArg *defaultCategory* = wxNullProperty)

Sets property values from a list of wxVariants.

void wxPropertyGridInterface::SetPropertyValues (const wxVariant & *list,* wxPGPropArg *defaultCategory* = wxNullProperty)

Sets property values from a list of wxVariants.

void wxPropertyGridInterface::SetPropertyValueString (wxPGPropArg *id,* const wxString & *value*)

Sets value (wxString) of a property.

Remarks

This method uses wxPGProperty::SetValueFromString(), which all properties should implement. This means that there should not be a type error, and instead the string is converted to property's actual value type.

void wxPropertyGridInterface::SetPropertyValueUnspecified (wxPGPropArg *id*)

Sets property's value to unspecified.

If it has children (it may be category), then the same thing is done to them.

void wxPropertyGridInterface::SetValidationFailureBehavior (int *vfbFlags*)

Adjusts how wxPropertyGrid behaves when invalid value is entered in a property.

Parameters

vfbFlags	See wxPropertyGrid Validation Failure behaviour Flags for possible values.

void wxPropertyGridInterface::Sort (int *flags* = 0)

Sorts all properties recursively.

Parameters

flags	This can contain any of the following options: wxPG_SORT_TOP_LEVEL_ONLY: Only sort categories and their immediate children. Sorting done by wxPG_AUTO_SORT option uses this.

See also

SortChildren, wxPropertyGrid::SetSortFunction

void wxPropertyGridInterface::SortChildren (wxPGPropArg *id*, int *flags* = 0)

Sorts children of a property.

Parameters

id	Name or pointer to a property.
flags	This can contain any of the following options: wxPG_RECURSE: Sorts recursively.

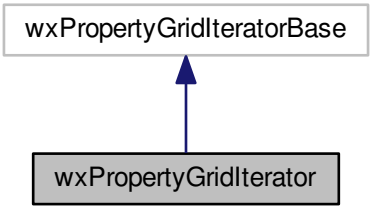
See also

Sort, wxPropertyGrid::SetSortFunction

21.565 wxPropertyGridIterator Class Reference

`#include <wx/propgrid/propgridpagestate.h>`

Inheritance diagram for wxPropertyGridIterator:



21.565.1 Detailed Description

21.565.2 wxPropertyGridIterator

Preferable way to iterate through contents of wxPropertyGrid, wxPropertyGridManager, and wxPropertyGridPage.

See wxPropertyGridInterface::GetIterator() for more information about usage.

Library: wxPropertyGrid

Category: wxPropertyGrid

Public Member Functions

- void Assign (const wxPropertyGridIteratorBase &it)
- bool AtEnd () const
- wxPGProperty * GetProperty () const

  Get current property.
- void Next (bool iterateChildren=true)

  Iterate to the next property.
- void Prev ()

  Iterate to the previous property.

21.565.3 Member Function Documentation

void wxPropertyGridIterator::Assign (const wxPropertyGridIteratorBase & *it*)

bool wxPropertyGridIterator::AtEnd ( ) const `[inline]`

wxPGProperty* wxPropertyGridIterator::GetProperty ( ) const `[inline]`

Get current property.

void wxPropertyGridIterator::Next (bool *iterateChildren* = `true`)

Iterate to the next property.

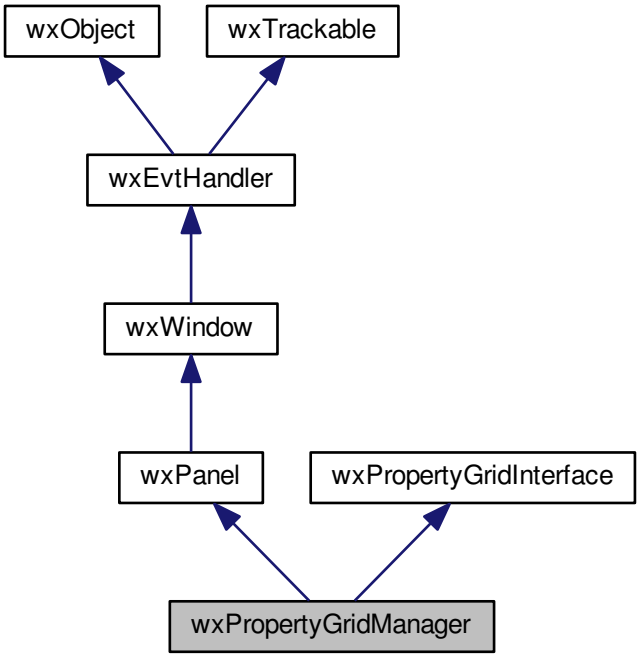
void wxPropertyGridIterator::Prev ( )

Iterate to the previous property.

21.566 wxPropertyGridManager Class Reference

`#include <wx/propgrid/manager.h>`

Inheritance diagram for wxPropertyGridManager:



21.566.1 Detailed Description

wxPropertyGridManager is an efficient multi-page version of wxPropertyGrid, which can optionally have toolbar for mode and page selection, a help text box, and a header.

wxPropertyGridManager inherits from wxPropertyGridInterface, and as such it has most property manipulation functions. However, only some of them affect properties on all pages (eg. GetPropertyByName() and ExpandAll()), while some (eg. Append()) only apply to the currently selected page.

To operate explicitly on properties on specific page, use wxPropertyGridManager::GetPage() to obtain pointer to page's wxPropertyGridPage object.

Visual methods, such as SetCellBackgroundColour() are only available in wxPropertyGrid. Use wxPropertyGrid↩ Manager::GetGrid() to obtain pointer to it.

Non-virtual iterators will not work in wxPropertyGridManager. Instead, you must acquire the internal grid (GetGrid()) or wxPropertyGridPage object (GetPage()).

wxPropertyGridManager constructor has exact same format as wxPropertyGrid constructor, and basically accepts same extra window style flags (albeit also has some extra ones).

Here's some example code for creating and populating a wxPropertyGridManager:

```
wxPropertyGridManager* pgMan = new wxPropertyGridManager(this,
      PGID,
    wxDefaultPosition, wxDefaultSize,
    // These and other similar styles are automatically
    // passed to the embedded wxPropertyGrid.
    wxPG_BOLD_MODIFIED|wxPG_SPLITTER_AUTO_CENTER|
    // Include toolbar.
    wxPG_TOOLBAR |
    // Include description box.
    wxPG_DESCRIPTION |
```

```
    // Plus defaults.
    wxPGMAN_DEFAULT_STYLE
   );

wxPropertyGridPage* page;

page = pgMan->AddPage("First Page");

page->Append( new wxPropertyCategory("Category A1") );

page->Append( new wxIntProperty("Number",wxPG_LABEL,1) );

page->Append( new wxColourProperty("Colour",wxPG_LABEL,*wxWHITE) );

page = pgMan->AddPage("Second Page");

page->Append( "Text",wxPG_LABEL,"(no text)" );

page->Append( new wxFontProperty("Font",wxPG_LABEL) );

// Display a header above the grid
pgMan->ShowHeader();
```

21.566.2 Window Styles

See wxPropertyGrid Window Styles.

21.566.3 Event Handling

See wxPropertyGrid Event Handling for more information.

Library: wxPropertyGrid

Category: wxPropertyGrid

Public Member Functions

- wxPropertyGridPage * AddPage (const wxString &label=wxEmptyString, const wxBitmap &bmp=wxPG_NULL_BITMAP, wxPropertyGridPage *pageObj=NULL)

  Creates new property page.
- virtual void Clear ()

  Deletes all properties and all pages.
- void ClearPage (int page)

  Deletes all properties on given page.
- bool CommitChangesFromEditor (wxUint32 flags=0)

  Forces updating the value of property from the editor control.
- bool Create (wxWindow *parent, wxWindowID id=wxID_ANY, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, long style=wxPGMAN_DEFAULT_STYLE, const wxString &name=wxPropertyGridManagerNameStr)

  Two step creation.
- bool EnableCategories (bool enable)

  Enables or disables (shows/hides) categories according to parameter enable.
- bool EnsureVisible (wxPGPropArg id)

  Selects page, scrolls and/or expands items to ensure that the given item is visible.
- int GetColumnCount (int page=-1) const

  Returns number of columns on given page.
- int GetDescBoxHeight () const

  Returns height of the description text box.

- wxPropertyGrid * GetGrid ()

  Returns pointer to the contained wxPropertyGrid.
- virtual wxPGVIterator GetVIterator (int flags) const

  Similar to GetIterator, but instead returns wxPGVIterator instance, which can be useful for forward-iterating through arbitrary property containers.
- wxPropertyGridPage * GetCurrentPage () const

  Returns currently selected page.
- wxPropertyGridPage * GetPage (unsigned int ind) const

  Returns page object for given page index.
- wxPropertyGridPage * GetPage (const wxString &name) const

  Returns page object for given page name.
- int GetPageByName (const wxString &name) const

  Returns index for a page name.
- size_t GetPageCount () const

  Returns number of managed pages.
- const wxString & GetPageName (int index) const

  Returns name of given page.
- wxPGProperty * GetPageRoot (int index) const

  Returns "root property" of the given page.
- int GetSelectedPage () const

  Returns index to currently selected page.
- wxPGProperty * GetSelectedProperty () const

  Alias for GetSelection().
- wxPGProperty * GetSelection () const

  Shortcut for GetGrid()->GetSelection().
- wxToolBar * GetToolBar () const

  Returns a pointer to the toolbar currently associated with the wxPropertyGridManager (if any).
- virtual wxPropertyGridPage * InsertPage (int index, const wxString &label, const wxBitmap &bmp=wxNull↩ Bitmap, wxPropertyGridPage *pageObj=NULL)

  Creates new property page.
- bool IsAnyModified () const

  Returns true if any property on any page has been modified by the user.
- bool IsFrozen () const

  Returns true if updating is frozen (ie.
- bool IsPageModified (size_t index) const

  Returns true if any property on given page has been modified by the user.
- virtual bool IsPropertySelected (wxPGPropArg id) const

  Returns true if property is selected.
- virtual bool RemovePage (int page)

  Removes a page.
- void SelectPage (int index)

  Select and displays a given page.
- void SelectPage (const wxString &label)

  Select and displays a given page (by label).
- void SelectPage (wxPropertyGridPage *page)

  Select and displays a given page.
- bool SelectProperty (wxPGPropArg id, bool focus=false)

  Select a property.
- void SetColumnCount (int colCount, int page=-1)

  Sets number of columns on given page (default is current page).
- void SetColumnTitle (int idx, const wxString &title)

Sets a column title.

- void SetDescription (const wxString &label, const wxString &content)

  Sets label and text in description box.
- void SetDescBoxHeight (int ht, bool refresh=true)

  Sets y coordinate of the description box splitter.
- void SetSplitterLeft (bool subProps=false, bool allPages=true)

  Moves splitter as left as possible, while still allowing all labels to be shown in full.
- void SetPageSplitterLeft (int page, bool subProps=false)

  Moves splitter as left as possible on an individual page, while still allowing all labels to be shown in full.
- void SetPageSplitterPosition (int page, int pos, int column=0)

  Sets splitter position on individual page.
- void SetSplitterPosition (int pos, int column=0)

  Sets splitter position for all pages.
- void ShowHeader (bool show=true)

  Show or hide the property grid header control.

Protected Member Functions

- virtual wxPropertyGrid * CreatePropertyGrid () const

  Creates property grid for the manager.

Additional Inherited Members

21.566.4 Member Function Documentation

wxPropertyGridPage* wxPropertyGridManager::AddPage (const wxString & *label* = wxEmptyString, const wxBitmap & *bmp* = `wxPG_NULL_BITMAP`, wxPropertyGridPage * *pageObj* = `NULL`)

Creates new property page.

Note that the first page is not created automatically.

Parameters

label	A label for the page. This may be shown as a toolbar tooltip etc.
bmp	Bitmap image for toolbar. If wxNullBitmap is used, then a built-in default image is used.
pageObj	wxPropertyGridPage instance. Manager will take ownership of this object. NULL indicates that a default page instance should be created.

Returns

Returns pointer to created property grid page.

Remarks

If toolbar is used, it is highly recommended that the pages are added when the toolbar is not turned off using window style flag switching. Otherwise toolbar buttons might not be added properly.

virtual void wxPropertyGridManager::Clear ( ) `[virtual]`

Deletes all properties and all pages.

Implements wxPropertyGridInterface.

void wxPropertyGridManager::ClearPage (int *page*)

Deletes all properties on given page.

bool wxPropertyGridManager::CommitChangesFromEditor (wxUint32 *flags* = 0)

Forces updating the value of property from the editor control.

Returns

Returns true if value was actually updated.

bool wxPropertyGridManager::Create (wxWindow * *parent*, wxWindowID *id* = wxID_ANY, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, long *style* = wxPGMAN_DEFAULT_STYLE, const wxString & *name* = wxPropertyGridManagerNameStr)

Two step creation.

Whenever the control is created without any parameters, use Create to actually create it. Don't access the control's public methods before this is called.

See also

wxPropertyGrid Window Styles

virtual wxPropertyGrid* wxPropertyGridManager::CreatePropertyGrid ( ) const [protected], [virtual]

Creates property grid for the manager.

Reimplement in derived class to use subclassed wxPropertyGrid. However, if you do this then you must also use the two-step construction (ie. default constructor and Create() instead of constructor with arguments) when creating the manager.

bool wxPropertyGridManager::EnableCategories (bool *enable*)

Enables or disables (shows/hides) categories according to parameter enable.

Remarks

Calling his may not properly update toolbar buttons.

bool wxPropertyGridManager::EnsureVisible (wxPGPropArg *id*)

Selects page, scrolls and/or expands items to ensure that the given item is visible.

Returns

Returns true if something was actually done.

int wxPropertyGridManager::GetColumnCount (int *page* = -1) const

Returns number of columns on given page.

By the default, returns number of columns on current page.

wxPropertyGridPage* wxPropertyGridManager::GetCurrentPage ( ) const

Returns currently selected page.

int wxPropertyGridManager::GetDescBoxHeight ( ) const

Returns height of the description text box.

wxPropertyGrid* wxPropertyGridManager::GetGrid ( )

Returns pointer to the contained wxPropertyGrid.

This does not change after wxPropertyGridManager has been created, so you can safely obtain pointer once and use it for the entire lifetime of the manager instance.

wxPropertyGridPage* wxPropertyGridManager::GetPage (unsigned int *ind*) const

Returns page object for given page index.

wxPropertyGridPage* wxPropertyGridManager::GetPage (const wxString & *name*) const

Returns page object for given page name.

int wxPropertyGridManager::GetPageByName (const wxString & *name*) const

Returns index for a page name.

If no match is found, wxNOT_FOUND is returned.

size_t wxPropertyGridManager::GetPageCount ( ) const

Returns number of managed pages.

const wxString& wxPropertyGridManager::GetPageName (int *index*) const

Returns name of given page.

wxPGProperty* wxPropertyGridManager::GetPageRoot (int *index*) const

Returns "root property" of the given page.

It does not have name, etc. and it is not visible. It is only useful for accessing its children.

int wxPropertyGridManager::GetSelectedPage ( ) const

Returns index to currently selected page.

wxPGProperty* wxPropertyGridManager::GetSelectedProperty ( ) const

Alias for GetSelection().

wxPGProperty* wxPropertyGridManager::GetSelection ( ) const

Shortcut for GetGrid()->GetSelection().

wxToolBar* wxPropertyGridManager::GetToolBar ( ) const

Returns a pointer to the toolbar currently associated with the wxPropertyGridManager (if any).

virtual wxPGVIterator wxPropertyGridManager::GetVIterator (int *flags*) const `[virtual]`

Similar to GetIterator, but instead returns wxPGVIterator instance, which can be useful for forward-iterating through arbitrary property containers.

Reimplemented from wxPropertyGridInterface.

virtual wxPropertyGridPage* wxPropertyGridManager::InsertPage (int *index*, const wxString & *label*, const wxBitmap & *bmp* = wxNullBitmap, wxPropertyGridPage * *pageObj* = NULL) `[virtual]`

Creates new property page.

Note that the first page is not created automatically.

Parameters

index	Add to this position. -1 will add as the last item.
label	A label for the page. This may be shown as a toolbar tooltip etc.
bmp	Bitmap image for toolbar. If wxNullBitmap is used, then a built-in default image is used.
pageObj	wxPropertyGridPage instance. Manager will take ownership of this object. If NULL, default page object is constructed.

Returns

Returns pointer to created page.

bool wxPropertyGridManager::IsAnyModified ( ) const

Returns true if any property on any page has been modified by the user.

bool wxPropertyGridManager::IsFrozen ( ) const

Returns true if updating is frozen (ie.

Freeze() called but not yet Thaw()).

bool wxPropertyGridManager::IsPageModified (size_t *index*) const

Returns true if any property on given page has been modified by the user.

virtual bool wxPropertyGridManager::IsPropertySelected (wxPGPropArg *id*) const `[virtual]`

Returns true if property is selected.

Since selection is page based, this function checks every page in the manager.

Reimplemented from wxPropertyGridInterface.

virtual bool wxPropertyGridManager::RemovePage (int *page*) [virtual]

Removes a page.

Returns

Returns false if it was not possible to remove page in question.

void wxPropertyGridManager::SelectPage (int *index*)

Select and displays a given page.

Parameters

index	Index of page being seleced. Can be -1 to select nothing.

void wxPropertyGridManager::SelectPage (const wxString & *label*)

Select and displays a given page (by label).

void wxPropertyGridManager::SelectPage (wxPropertyGridPage * *page*)

Select and displays a given page.

bool wxPropertyGridManager::SelectProperty (wxPGPropArg *id,* bool *focus* = false)

Select a property.

See also

wxPropertyGrid::SelectProperty(), wxPropertyGridInterface::ClearSelection()

void wxPropertyGridManager::SetColumnCount (int *colCount,* int *page* = -1)

Sets number of columns on given page (default is current page).

Remarks

If you use header, then you should always use this member function to set the column count, instead of ones present in wxPropertyGrid or wxPropertyGridPage.

void wxPropertyGridManager::SetColumnTitle (int *idx,* const wxString & *title*)

Sets a column title.

Default title for column 0 is "Property", and "Value" for column 1.

Remarks

If header is not shown yet, then calling this member function will make it visible.

void wxPropertyGridManager::SetDescBoxHeight (int *ht,* bool *refresh* = true)

Sets y coordinate of the description box splitter.

void wxPropertyGridManager::SetDescription (const wxString & *label,* const wxString & *content*)

Sets label and text in description box.

void wxPropertyGridManager::SetPageSplitterLeft (int *page,* bool *subProps* = `false`)

Moves splitter as left as possible on an individual page, while still allowing all labels to be shown in full.

void wxPropertyGridManager::SetPageSplitterPosition (int *page,* int *pos,* int *column* = `0`)

Sets splitter position on individual page.

Remarks

If you use header, then you should always use this member function to set the splitter position, instead of ones present in wxPropertyGrid or wxPropertyGridPage.

void wxPropertyGridManager::SetSplitterLeft (bool *subProps* = `false`, bool *allPages* = `true`)

Moves splitter as left as possible, while still allowing all labels to be shown in full.

Parameters

subProps	If false, will still allow sub-properties (ie. properties which parent is not root or category) to be cropped.
allPages	If true, takes labels on all pages into account.

void wxPropertyGridManager::SetSplitterPosition (int *pos,* int *column* = `0`)

Sets splitter position for all pages.

Remarks

Splitter position cannot exceed grid size, and therefore setting it during form creation may fail as initial grid size is often smaller than desired splitter position, especially when sizers are being used.

If you use header, then you should always use this member function to set the splitter position, instead of ones present in wxPropertyGrid or wxPropertyGridPage.

void wxPropertyGridManager::ShowHeader (bool *show* = `true`)

Show or hide the property grid header control.

It is hidden by the default.

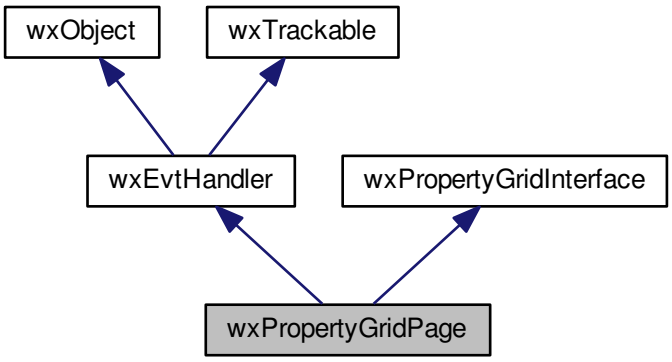
Remarks

Grid may look better if you use wxPG_NO_INTERNAL_BORDER window style when showing a header.

21.567 wxPropertyGridPage Class Reference

`#include <wx/propgrid/manager.h>`

Inheritance diagram for wxPropertyGridPage:



21.567.1 Detailed Description

Holder of property grid page information.

You can subclass this and give instance in wxPropertyGridManager::AddPage. It inherits from wxEvtHandler and can be used to process events specific to this page (id of events will still be same as manager's). If you don't want to use it to process all events of the page, you need to return false in the derived wxPropertyGridPage::IsHandling↩ AllEvents.

Please note that wxPropertyGridPage lacks many non-const property manipulation functions found in wxProperty↩ GridManager. Please use parent manager (m_manager member variable) when needed.

Please note that most member functions are inherited and as such not documented on this page. This means you will probably also want to read wxPropertyGridInterface class reference.

21.567.2 Event Handling

wxPropertyGridPage receives events emitted by its wxPropertyGridManager, but only those events that are specific to that page. If wxPropertyGridPage:: IsHandlingAllEvents returns false, then unhandled events are sent to the manager's parent, as usual.

See wxPropertyGrid Event Handling for more information.

Library: wxPropertyGrid

Category: wxPropertyGrid

Public Member Functions

- wxPropertyGridPage ()
- virtual ~wxPropertyGridPage ()
- virtual void Clear ()

  Deletes all properties on page.

- wxSize FitColumns ()

  Reduces column sizes to minimum possible that contents are still visibly (naturally some margin space will be applied as well).
- int GetIndex () const

  Returns page index in manager;.
- wxPGProperty * GetRoot () const

  Returns "root property".
- int GetSplitterPosition (int col=0) const

  Returns x-coordinate position of splitter on a page.
- int GetToolId () const

  Returns id of the tool bar item that represents this page on wxPropertyGridManager's wxToolBar.
- virtual void Init ()

  Do any member initialization in this method.
- virtual bool IsHandlingAllEvents () const

  Return false here to indicate unhandled events should be propagated to manager's parent, as normal.
- virtual void OnShow ()

  Called every time page is about to be shown.
- virtual void RefreshProperty (wxPGProperty *p)

  Refreshes given property on page.
- void SetSplitterPosition (int splitterPos, int col=0)

  Sets splitter position on page.

wxPropertyGridPage::wxPropertyGridPage ( )

virtual wxPropertyGridPage::~wxPropertyGridPage ( ) [virtual]

21.567.4 Member Function Documentation

virtual void wxPropertyGridPage::Clear ( ) [virtual]

Deletes all properties on page.

Implements wxPropertyGridInterface.

wxSize wxPropertyGridPage::FitColumns ( )

Reduces column sizes to minimum possible that contents are still visibly (naturally some margin space will be applied as well).

Returns

Returns minimum size for the page to still display everything.

Remarks

This function only works properly if size of containing grid was already fairly large.

Note that you can also get calculated column widths by calling GetColumnWidth() immediately after this function returns.

int wxPropertyGridPage::GetIndex ( ) const `[inline]`

Returns page index in manager;.

wxPGProperty* wxPropertyGridPage::GetRoot ( ) const

Returns "root property".

It does not have name, etc. and it is not visible. It is only useful for accessing its children.

int wxPropertyGridPage::GetSplitterPosition (int *col* = 0) const

Returns x-coordinate position of splitter on a page.

int wxPropertyGridPage::GetToolId ( ) const

Returns id of the tool bar item that represents this page on wxPropertyGridManager's wxToolBar.

virtual void wxPropertyGridPage::Init ( ) `[virtual]`

Do any member initialization in this method.

Remarks

- Called every time the page is added into a manager.
  - You can add properties to the page here.

virtual bool wxPropertyGridPage::IsHandlingAllEvents ( ) const `[virtual]`

Return false here to indicate unhandled events should be propagated to manager's parent, as normal.

virtual void wxPropertyGridPage::OnShow ( ) `[virtual]`

Called every time page is about to be shown.

Useful, for instance, creating properties just-in-time.

virtual void wxPropertyGridPage::RefreshProperty (wxPGProperty * *p*) `[virtual]`

Refreshes given property on page.

void wxPropertyGridPage::SetSplitterPosition (int *splitterPos*, int *col* = 0)

Sets splitter position on page.

Remarks

Splitter position cannot exceed grid size, and therefore setting it during form creation may fail as initial grid size is often smaller than desired splitter position, especially when sizers are being used.

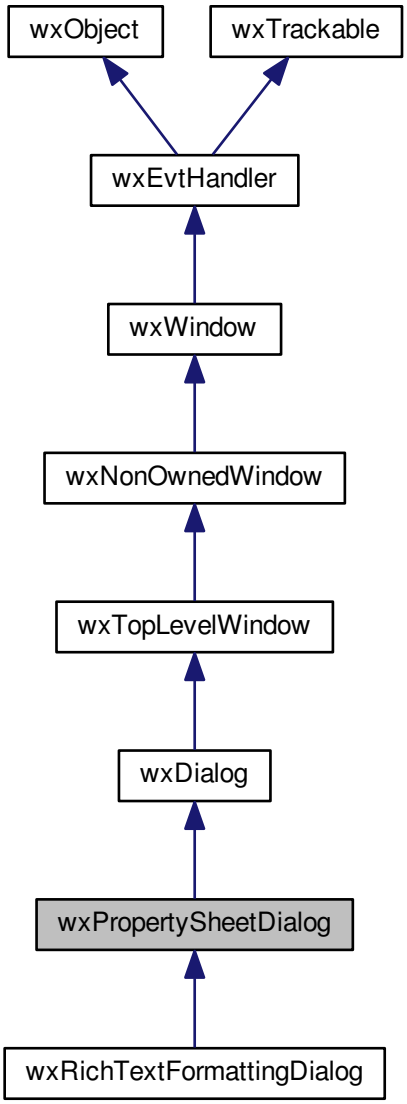
21.567.5 Friends And Related Function Documentation

friend class wxPropertyGridManager `[friend]`

21.568 wxPropertySheetDialog Class Reference

`#include <wx/propdlg.h>`

Inheritance diagram for wxPropertySheetDialog:



21.568.1 Detailed Description

This class represents a property sheet dialog: a tabbed dialog for showing settings.

It is optimized to show flat tabs on PocketPC devices, and can be customized to use different controllers instead of the default notebook style.

To use this class, call Create() from your own Create function. Then call CreateButtons(), and create pages, adding them to the book control. Finally call LayoutDialog().

For example:

```
bool MyPropertySheetDialog::Create(...)
{
    if (!wxPropertySheetDialog::Create(...))
        return false;

    CreateButtons(wxOK|wxCANCEL|wxHELP);

    // Add page
    wxPanel* panel = new wxPanel(GetBookCtrl(), ...);
    GetBookCtrl()->AddPage(panel, "General");

    LayoutDialog();
    return true;
}
```

If necessary, override CreateBookCtrl() and AddBookCtrl() to create and add a different kind of book control. You will then need to use two-step construction for the dialog or change the style of the book control by calling SetSheetStyle() before calling Create().

The Dialogs Sample shows this class being used with notebook and toolbook controllers (for Windows-style and Mac-style settings dialogs).

To make pages of the dialog scroll when the display is too small to fit the whole dialog, you can switch layout adaptation on globally with wxDialog::EnableLayoutAdaptation() or per dialog with wxDialog::SetLayoutAdaptationMode().

For more about layout adaptation, see Automatic Scrolled Dialogs.

Library: wxAdvanced

Category: Managed Windows

Public Member Functions

- wxPropertySheetDialog (wxWindow *parent, wxWindowID id, const wxString &title, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, long style=wxDEFAULT_DIALOG_STYLE, const wxString &name=wxDialogNameStr)

  Constructor.
- virtual void AddBookCtrl (wxSizer *sizer)

  Override this if you wish to add the book control in a way different from the standard way (for example, using different spacing).
- bool Create (wxWindow *parent, wxWindowID id, const wxString &title, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, long style=wxDEFAULT_DIALOG_STYLE, const wxString &name=wxDialogNameStr)

  Call this from your own Create function, before adding buttons and pages.
- virtual wxBookCtrlBase * CreateBookCtrl ()

  Override this if you wish to create a different kind of book control; by default, the value passed to SetSheetStyle() is used to determine the control.
- virtual void CreateButtons (int flags=wxOK|wxCANCEL)

Call this to create the buttons for the dialog.

- wxBookCtrlBase * GetBookCtrl () const

  Returns the book control that will contain your settings pages.
- wxSizer * GetInnerSizer () const

  Returns the inner sizer that contains the book control and button sizer.
- long GetSheetStyle () const

  Returns the sheet style.
- virtual void LayoutDialog (int centreFlags=wxBOTH)

  Call this to lay out the dialog.
- void SetBookCtrl (wxBookCtrlBase *bookCtrl)

  Sets the book control used for the dialog.
- void SetSheetStyle (long style)

  You can customize the look and feel of the dialog by setting the sheet style.

Additional Inherited Members

21.568.2 Constructor & Destructor Documentation

wxPropertySheetDialog::wxPropertySheetDialog (wxWindow * *parent*, wxWindowID *id*, const wxString & *title*, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, long *style* = wxDEFAULT_DIALOG_STYLE, const wxString & *name* = `wxDialogNameStr`)

Constructor.

21.568.3 Member Function Documentation

virtual void wxPropertySheetDialog::AddBookCtrl (wxSizer * *sizer*) `[virtual]`

Override this if you wish to add the book control in a way different from the standard way (for example, using different spacing).

bool wxPropertySheetDialog::Create (wxWindow * *parent*, wxWindowID *id*, const wxString & *title*, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, long *style* = wxDEFAULT_DIALOG_STYLE, const wxString & *name* = `wxDialogNameStr`)

Call this from your own Create function, before adding buttons and pages.

virtual wxBookCtrlBase* wxPropertySheetDialog::CreateBookCtrl ( ) `[virtual]`

Override this if you wish to create a different kind of book control; by default, the value passed to SetSheetStyle() is used to determine the control.

The default behaviour is to create a notebook except on Smartphone, where a choicebook is used.

virtual void wxPropertySheetDialog::CreateButtons (int *flags* = wxOK|wxCANCEL) `[virtual]`

Call this to create the buttons for the dialog.

This calls wxDialog::CreateButtonSizer(), and the flags are the same.

Note

On PocketPC, no buttons are created.

wxBookCtrlBase* wxPropertySheetDialog::GetBookCtrl ( ) const

Returns the book control that will contain your settings pages.

wxSizer* wxPropertySheetDialog::GetInnerSizer ( ) const

Returns the inner sizer that contains the book control and button sizer.

long wxPropertySheetDialog::GetSheetStyle ( ) const

Returns the sheet style.

See SetSheetStyle() for allowed values.

virtual void wxPropertySheetDialog::LayoutDialog (int *centreFlags* = wxBOTH) [virtual]

Call this to lay out the dialog.

Note

On PocketPC, this does nothing, since the dialog will be shown full-screen, and the layout will be done when the dialog receives a size event.

void wxPropertySheetDialog::SetBookCtrl (wxBookCtrlBase * *bookCtrl*)

Sets the book control used for the dialog.

You will normally not need to use this.

void wxPropertySheetDialog::SetSheetStyle (long *style*)

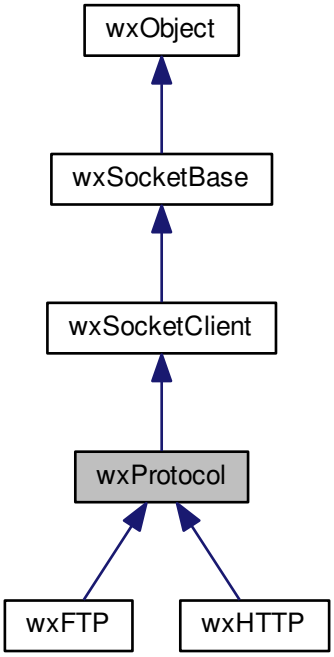
You can customize the look and feel of the dialog by setting the sheet style.

It is a bit list of the wxPropertySheetDialogFlags values.

21.569 wxProtocol Class Reference

```
#include <wx/protocol/protocol.h>
```

Inheritance diagram for wxProtocol:



21.569.1 Detailed Description

Represents a protocol for use with wxURL.

Note that you may want to change the default time-out for HTTP/FTP connections and network operations (using SetDefaultTimeout()) since the default time-out value is quite long (60 seconds).

Library: wxNet

Category: Networking

See also

wxSocketBase, wxURL

Public Member Functions

- virtual bool Abort ()=0

  Abort the current stream.
- virtual wxString GetContentType () const

  Returns the type of the content of the last opened stream.
- virtual wxProtocolError GetError () const

  Returns the last occurred error.

- virtual wxInputStream * GetInputStream (const wxString &path)=0

  Creates a new input stream on the specified path.
- bool Reconnect ()

  Tries to reestablish a previous opened connection (close and renegotiate connection).
- virtual void SetPassword (const wxString &user)

  Sets the authentication password.
- virtual void SetUser (const wxString &user)

  Sets the authentication user.
- void SetDefaultTimeout (wxUint32 Value)

  Sets a new default timeout for the network operations.

Logging support.

Each wxProtocol object may have the associated logger (by default there is none) which is used to log network requests and responses.

See also

wxProtocolLog

- void SetLog (wxProtocolLog *log)

  Set the logger, deleting the old one and taking ownership of this one.
- wxProtocolLog * GetLog () const

  Return the current logger, may be NULL.
- wxProtocolLog * DetachLog ()

  Detach the existing logger without deleting it.
- void LogRequest (const wxString &str)

  Call wxProtocolLog::LogRequest() if we have a valid logger or do nothing otherwise.
- void LogResponse (const wxString &str)

  Call wxProtocolLog::LogResponse() if we have a valid logger or do nothing otherwise.

Additional Inherited Members

21.569.2 Member Function Documentation

virtual bool wxProtocol::Abort ( ) [pure virtual]

Abort the current stream.

Warning

It is advised to destroy the input stream instead of aborting the stream this way.

Returns

Returns true, if successful, else false.

Implemented in wxFTP.

wxProtocolLog* wxProtocol::DetachLog ( )

Detach the existing logger without deleting it.

The caller is responsible for deleting the returned pointer if it's non-NULL.

virtual **wxString** wxProtocol::GetContentType ( ) const [virtual]

Returns the type of the content of the last opened stream.

It is a mime-type. May be an empty string if the content-type is unknown.

virtual **wxProtocolError** wxProtocol::GetError ( ) const [virtual]

Returns the last occurred error.

See also

wxProtocolError

virtual **wxInputStream*** wxProtocol::GetInputStream (const **wxString** & *path*) [pure virtual]

Creates a new input stream on the specified path.

You can use all but seek() functionality of wxStream. Seek() isn't available on all streams. For example, HTTP or FTP streams don't deal with it. Other functions like StreamSize() and Tell() aren't available for the moment for this sort of stream. You will be notified when the EOF is reached by an error.

Returns

Returns the initialized stream. You will have to delete it yourself once you don't use it anymore. The destructor closes the network connection.

See also

wxInputStream

Implemented in wxFTP, and wxHTTP.

wxProtocolLog* wxProtocol::GetLog ( ) const [inline]

Return the current logger, may be NULL.

void wxProtocol::LogRequest (const **wxString** & *str*)

Call wxProtocolLog::LogRequest() if we have a valid logger or do nothing otherwise.

void wxProtocol::LogResponse (const **wxString** & *str*)

Call wxProtocolLog::LogResponse() if we have a valid logger or do nothing otherwise.

bool wxProtocol::Reconnect ( )

Tries to reestablish a previous opened connection (close and renegotiate connection).

Returns

true, if the connection is established, else false.

void wxProtocol::SetDefaultTimeout (wxUint32 *Value*)

Sets a new default timeout for the network operations.

The default timeout is 60 seconds.

See also

wxSocketBase::SetTimeout

void wxProtocol::SetLog (wxProtocolLog * *log*)

Set the logger, deleting the old one and taking ownership of this one.

Parameters

log	New logger allocated on the heap or NULL.

virtual void wxProtocol::SetPassword (const wxString & *user*) `[virtual]`

Sets the authentication password.

Reimplemented in wxFTP.

virtual void wxProtocol::SetUser (const wxString & *user*) `[virtual]`

Sets the authentication user.

Reimplemented in wxFTP.

21.570 wxProtocolLog Class Reference

```
#include <wx/protocol/log.h>
```

21.570.1 Detailed Description

Class allowing to log network operations performed by wxProtocol.

Library: wxNet

Category: Networking

See also

wxProtocol

Public Member Functions

- wxProtocolLog (const wxString &traceMask)

  Create object doing the logging using wxLogTrace() with the specified trace mask.
- virtual void LogRequest (const wxString &str)

  Called by wxProtocol-derived objects to log strings sent to the server.

- virtual void LogResponse (const wxString &str)

  Called by wxProtocol-derived objects to log strings received from the server.

Protected Member Functions

- virtual void DoLogString (const wxString &str)

  Log the given string.

21.570.2 Constructor & Destructor Documentation

wxProtocolLog::wxProtocolLog (const wxString & *traceMask*)

Create object doing the logging using wxLogTrace() with the specified trace mask.

If you override DoLogString() in your class the *traceMask* may be left empty but it must have a valid value if you rely on the default DoLogString() implementation.

21.570.3 Member Function Documentation

virtual void wxProtocolLog::DoLogString (const wxString & *str*) `[protected],[virtual]`

Log the given string.

This function is called from LogRequest() and LogResponse() and by default uses wxLogTrace() with the trace mask specified in the constructor but can be overridden to do something different by the derived classes.

virtual void wxProtocolLog::LogRequest (const wxString & *str*) `[virtual]`

Called by wxProtocol-derived objects to log strings sent to the server.

Default implementation prepends a client-to-server marker to *str* and calls DoLogString().

virtual void wxProtocolLog::LogResponse (const wxString & *str*) `[virtual]`

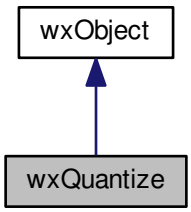
Called by wxProtocol-derived objects to log strings received from the server.

Default implementation prepends a server-to-client marker to *str* and calls DoLogString().

21.571 wxQuantize Class Reference

```
#include <wx/quantize.h>
```

Inheritance diagram for wxQuantize:



21.571.1 Detailed Description

Performs quantization, or colour reduction, on a wxImage.

Functions in this class are static and so a wxQuantize object need not be created.

Library: wxCore

Category: Miscellaneous

Public Member Functions

- wxQuantize ()

  Constructor.

Static Public Member Functions

- static void DoQuantize (unsigned int w, unsigned int h, unsigned char **in_rows, unsigned char **out_rows, unsigned char *palette, int desiredNoColours)

  Converts input bitmap(s) into 8bit representation with custom palette.

- static bool Quantize (const wxImage &src, wxImage &dest, wxPalette **pPalette, int desiredNoColours=236, unsigned char **eightBitData=0, int flags=wxQUANTIZE_INCLUDE_WINDOWS_COLOURS|wxQUANTIZE_FILL_DESTINATION_IMAGE|wxQUANTIZE_RETURN_8BIT_DATA)

  Reduce the colours in the source image and put the result into the destination image.

- static bool Quantize (const wxImage &src, wxImage &dest, int desiredNoColours=236, unsigned char **eightBitData=0, int flags=wxQUANTIZE_INCLUDE_WINDOWS_COLOURS|wxQUANTIZE_FILL_DESTINATION_IMAGE|wxQUANTIZE_RETURN_8BIT_DATA)

  This version sets a palette in the destination image so you don't have to manage it yourself.

Additional Inherited Members

21.571.2 Constructor & Destructor Documentation

wxQuantize::wxQuantize ( )

Constructor.

You do not need to construct a wxQuantize object since its functions are static.

21.571.3 Member Function Documentation

static void wxQuantize::DoQuantize (unsigned int *w,* unsigned int *h,* unsigned char ** *in_rows,* unsigned char ** *out_rows,* unsigned char * *palette,* int *desiredNoColours*) `[static]`

Converts input bitmap(s) into 8bit representation with custom palette.

in_rows and *out_rows* are arrays [0..h-1] of pointer to rows (*in_rows* contains *w* * 3 bytes per row, *out_rows w* bytes per row). Fills *out_rows* with indexes into palette (which is also stored into *palette* variable).

static bool wxQuantize::Quantize (const wxImage & *src,* wxImage & *dest,* wxPalette ** *pPalette,* int *desiredNoColours* = `236`, unsigned char ** *eightBitData* = `0`, int *flags* = `wxQUANTIZE_INCLUDE_WINDOWS_COLOURS|wxQUANTIZE_FILL_DESTINATION_IMAGE|wxQUANTIZE_RETURN_8BIT_DATA`) `[static]`

Reduce the colours in the source image and put the result into the destination image.

Both images may be the same, to overwrite the source image.

Specify an optional palette pointer to receive the resulting palette. This palette may be passed to ConvertImageToBitmap, for example.

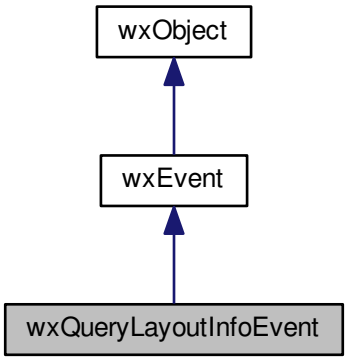
static bool wxQuantize::Quantize (const wxImage & *src,* wxImage & *dest,* int *desiredNoColours* = `236`, unsigned char ** *eightBitData* = `0`, int *flags* = `wxQUANTIZE_INCLUDE_WINDOWS_COLOURS|wxQUANTIZE_FILL_DESTINATION_IMAGE|wxQUANTIZE_RETURN_8BIT_DATA`) `[static]`

This version sets a palette in the destination image so you don't have to manage it yourself.

21.572 wxQueryLayoutInfoEvent Class Reference

`#include <wx/laywin.h>`

Inheritance diagram for wxQueryLayoutInfoEvent:



21.572.1 Detailed Description

This event is sent when wxLayoutAlgorithm wishes to get the size, orientation and alignment of a window.

More precisely, the event is sent by the OnCalculateLayout handler which is itself invoked by wxLayoutAlgorithm.

Events using this class

The following event handler macros redirect the events to member function handlers '**func**' with prototypes like: void handlerFuncName(wxQueryLayoutInfoEvent& event)

Event macros:

- EVT_QUERY_LAYOUT_INFO(func): Process a `wxEVT_QUERY_LAYOUT_INFO` event, to get size, orientation and alignment from a window.

Library: wxAdvanced

Category: Events

See also

wxCalculateLayoutEvent, wxSashLayoutWindow, wxLayoutAlgorithm.

Public Member Functions

- wxQueryLayoutInfoEvent (wxWindowID id=0)

  Constructor.
- wxLayoutAlignment GetAlignment () const

  Specifies the alignment of the window (which side of the remaining parent client area the window sticks to).
- int GetFlags () const

  Returns the flags associated with this event.

- wxLayoutOrientation GetOrientation () const

  Returns the orientation that the event handler specified to the event object.
- int GetRequestedLength () const

  Returns the requested length of the window in the direction of the window orientation.
- wxSize GetSize () const

  Returns the size that the event handler specified to the event object as being the requested size of the window.
- void SetAlignment (wxLayoutAlignment alignment)

  Call this to specify the alignment of the window (which side of the remaining parent client area the window sticks to).
- void SetFlags (int flags)

  Sets the flags associated with this event.
- void SetOrientation (wxLayoutOrientation orientation)

  Call this to specify the orientation of the window.
- void SetRequestedLength (int length)

  Sets the requested length of the window in the direction of the window orientation.
- void SetSize (const wxSize &size)

  Call this to let the calling code know what the size of the window is.

Additional Inherited Members

21.572.2 Constructor & Destructor Documentation

wxQueryLayoutInfoEvent::wxQueryLayoutInfoEvent (wxWindowID *id* = 0)

Constructor.

21.572.3 Member Function Documentation

wxLayoutAlignment wxQueryLayoutInfoEvent::GetAlignment ( ) const

Specifies the alignment of the window (which side of the remaining parent client area the window sticks to).

One of wxLAYOUT_TOP, wxLAYOUT_LEFT, wxLAYOUT_RIGHT, wxLAYOUT_BOTTOM.

int wxQueryLayoutInfoEvent::GetFlags ( ) const

Returns the flags associated with this event.

Not currently used.

wxLayoutOrientation wxQueryLayoutInfoEvent::GetOrientation ( ) const

Returns the orientation that the event handler specified to the event object.

May be one of wxLAYOUT_HORIZONTAL, wxLAYOUT_VERTICAL.

int wxQueryLayoutInfoEvent::GetRequestedLength ( ) const

Returns the requested length of the window in the direction of the window orientation.

This information is not yet used.

wxSize wxQueryLayoutInfoEvent::GetSize ( ) const

Returns the size that the event handler specified to the event object as being the requested size of the window.

void wxQueryLayoutInfoEvent::SetAlignment (wxLayoutAlignment *alignment*)

Call this to specify the alignment of the window (which side of the remaining parent client area the window sticks to).

May be one of wxLAYOUT_TOP, wxLAYOUT_LEFT, wxLAYOUT_RIGHT, wxLAYOUT_BOTTOM.

void wxQueryLayoutInfoEvent::SetFlags (int *flags*)

Sets the flags associated with this event.

Not currently used.

void wxQueryLayoutInfoEvent::SetOrientation (wxLayoutOrientation *orientation*)

Call this to specify the orientation of the window.

May be one of wxLAYOUT_HORIZONTAL, wxLAYOUT_VERTICAL.

void wxQueryLayoutInfoEvent::SetRequestedLength (int *length*)

Sets the requested length of the window in the direction of the window orientation.

This information is not yet used.

void wxQueryLayoutInfoEvent::SetSize (const wxSize & *size*)

Call this to let the calling code know what the size of the window is.

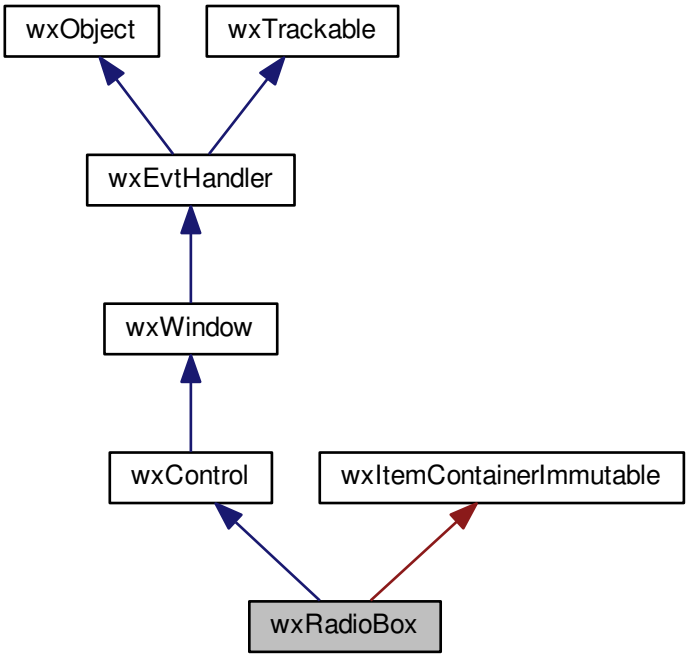
void wxQueryNewPaletteEvent::SetPaletteRealized (bool *realized*)

21.574 wxRadioBox Class Reference

```
#include <wx/radiobox.h>
```

Inheritance diagram for wxRadioBox:



21.574.1 Detailed Description

A radio box item is used to select one of number of mutually exclusive choices.

It is displayed as a vertical column or horizontal row of labelled buttons.

Styles

This class supports the following styles:

- wxRA_SPECIFY_ROWS: The major dimension parameter refers to the maximum number of rows.
- wxRA_SPECIFY_COLS: The major dimension parameter refers to the maximum number of columns.

Events emitted by this class

The following event handler macros redirect the events to member function handlers '**func**' with prototypes like: void handlerFuncName(wxCommandEvent& event)

Event macros for events emitted by this class:

- EVT_RADIOBOX(id, func): Process a `wxEVT_RADIOBOX` event, when a radiobutton is clicked.

Library: wxCore

Category: Controls

See also

Events and Event Handling, wxRadioButton, wxCheckBox

Public Member Functions

- wxRadioBox ()

  Default constructor.
- wxRadioBox (wxWindow *parent, wxWindowID id, const wxString &label, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, int n=0, const wxString choices[]=NULL, int majorDimension=0, long style=wxRA_SPECIFY_COLS, const wxValidator &validator=wxDefaultValidator, const wxString &name=wxRadioBoxNameStr)

  Constructor, creating and showing a radiobox.
- wxRadioBox (wxWindow *parent, wxWindowID id, const wxString &label, const wxPoint &pos, const wxSize &size, const wxArrayString &choices, int majorDimension=0, long style=wxRA_SPECIFY_COLS, const wxValidator &validator=wxDefaultValidator, const wxString &name=wxRadioBoxNameStr)

  Constructor, creating and showing a radiobox.
- virtual ~wxRadioBox ()

  Destructor, destroying the radiobox item.
- bool Create (wxWindow *parent, wxWindowID id, const wxString &label, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, int n=0, const wxString choices[]=NULL, int majorDimension=0, long style=wxRA_SPECIFY_COLS, const wxValidator &validator=wxDefaultValidator, const wxString &name=wxRadioBoxNameStr)

  Creates the radiobox for two-step construction.
- bool Create (wxWindow *parent, wxWindowID id, const wxString &label, const wxPoint &pos, const wxSize &size, const wxArrayString &choices, int majorDimension=0, long style=wxRA_SPECIFY_COLS, const wxValidator &validator=wxDefaultValidator, const wxString &name=wxRadioBoxNameStr)

  Creates the radiobox for two-step construction.
- virtual bool Enable (unsigned int n, bool enable=true)

  Enables or disables an individual button in the radiobox.
- virtual int FindString (const wxString &string, bool bCase=false) const

  Finds a button matching the given string, returning the position if found, or `wxNOT_FOUND` if not found.
- unsigned int GetColumnCount () const

  Returns the number of columns in the radiobox.
- virtual int GetItemFromPoint (const wxPoint &pt) const

  Returns a radio box item under the point, a zero-based item index, or `wxNOT_FOUND` if no item is under the point.
- wxString GetItemHelpText (unsigned int item) const

  Returns the helptext associated with the specified item if any or `wxEmptyString`.
- wxToolTip * GetItemToolTip (unsigned int item) const

  Returns the tooltip associated with the specified item if any or NULL.
- unsigned int GetRowCount () const

  Returns the number of rows in the radiobox.
- virtual bool IsItemEnabled (unsigned int n) const

  Returns true if the item is enabled or false if it was disabled using Enable(n, false).
- virtual bool IsItemShown (unsigned int n) const

  Returns true if the item is currently shown or false if it was hidden using Show(n, false).
- void SetItemHelpText (unsigned int item, const wxString &helptext)

  Sets the helptext for an item.
- void SetItemToolTip (unsigned int item, const wxString &text)

  Sets the tooltip text for the specified item in the radio group.
- virtual void SetSelection (int n)

Sets the selection to the given item.

- virtual bool Show (unsigned int item, bool show=true)

  Shows or hides individual buttons.

- virtual unsigned int GetCount () const

  Returns the number of items in the control.

- virtual wxString GetString (unsigned int n) const

  Returns the label of the item with the given index.

- virtual void SetString (unsigned int n, const wxString &string)

  Sets the label for the given item.

- virtual int GetSelection () const

  Returns the index of the selected item or `wxNOT_FOUND` *if no item is selected.*

Additional Inherited Members

21.574.2 Constructor & Destructor Documentation

wxRadioBox::wxRadioBox ( )

Default constructor.

See also

Create(), wxValidator

wxRadioBox::wxRadioBox (wxWindow * *parent*, wxWindowID *id*, const wxString & *label*, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, int *n* = `0`, const wxString *choices[]* = `NULL`, int *majorDimension* = `0`, long *style* = wxRA_SPECIFY_COLS, const wxValidator & *validator* = wxDefaultValidator, const wxString & *name* = `wxRadioBoxNameStr`)

Constructor, creating and showing a radiobox.

Parameters

parent	Parent window. Must not be NULL.
id	Window identifier. The value `wxID_ANY` indicates a default value.
label	Label for the static box surrounding the radio buttons.
pos	Window position. If wxDefaultPosition is specified then a default position is chosen.
size	Window size. If wxDefaultSize is specified then a default size is chosen.
n	Number of choices with which to initialize the radiobox.
choices	An array of choices with which to initialize the radiobox.
majorDimension	Specifies the maximum number of rows (if style contains `wxRA_SPECIFY_ROWS`) or columns (if style contains `wxRA_SPECIFY_COLS`) for a two-dimensional radiobox. The default value of 0 means to use the number of items, i.e. *n*.
style	Window style. See wxRadioBox.
validator	Window validator.
name	Window name.

wxPerl Note: Not supported by wxPerl.

Create(), wxValidator

wxRadioBox::wxRadioBox (wxWindow ∗ ***parent*****, wxWindowID** ***id*****,** const **wxString** & ***label*****,** const **wxPoint** & ***pos*****,** const **wxSize** & ***size*****,** const **wxArrayString** & ***choices*****,** int ***majorDimension*** **=** `0`**,** long ***style*** **= wxRA_SPECIFY_COLS,** const **wxValidator** & ***validator*** **= wxDefaultValidator,** const **wxString** & ***name*** **=** `wxRadioBoxNameStr` **)**

Constructor, creating and showing a radiobox.

Parameters

parent	Parent window. Must not be NULL.
id	Window identifier. The value `wxID_ANY` indicates a default value.
label	Label for the static box surrounding the radio buttons.
pos	Window position. If wxDefaultPosition is specified then a default position is chosen.
size	Window size. If wxDefaultSize is specified then a default size is chosen.
choices	An array of choices with which to initialize the radiobox.
majorDimension	Specifies the maximum number of rows (if style contains `wxRA_SPECIFY_ROWS`) or columns (if style contains `wxRA_SPECIFY_COLS`) for a two-dimensional radiobox. The default value of 0 means to use the number of items, i.e. number of elements in *choices*.
style	Window style. See wxRadioBox.
validator	Window validator.
name	Window name.

wxPerl Note: Use an array reference for the *choices* parameter.

See also

Create(), wxValidator

virtual wxRadioBox::~wxRadioBox ( ) [virtual]

Destructor, destroying the radiobox item.

21.574.3 Member Function Documentation

bool wxRadioBox::Create (wxWindow * *parent*, wxWindowID *id*, const wxString & *label*, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, int *n* = 0, const wxString *choices[]* = NULL, int *majorDimension* = 0, long *style* = wxRA_SPECIFY_COLS, const wxValidator & *validator* = wxDefaultValidator, const wxString & *name* = wxRadioBoxNameStr)

Creates the radiobox for two-step construction.

See wxRadioBox() for further details.

bool wxRadioBox::Create (wxWindow * *parent*, wxWindowID *id*, const wxString & *label*, const wxPoint & *pos*, const wxSize & *size*, const wxArrayString & *choices*, int *majorDimension* = 0, long *style* = wxRA_SPECIFY_COLS, const wxValidator & *validator* = wxDefaultValidator, const wxString & *name* = wxRadioBoxNameStr)

Creates the radiobox for two-step construction.

See wxRadioBox() for further details.

virtual bool wxRadioBox::Enable (unsigned int *n*, bool *enable* = true) [virtual]

Enables or disables an individual button in the radiobox.

Parameters

enable	true to enable, false to disable.
n	The zero-based button to enable or disable.

See also

wxWindow::Enable()

virtual int wxRadioBox::FindString (const wxString & *string,* bool *bCase* = `false`) const `[virtual]`

Finds a button matching the given string, returning the position if found, or `wxNOT_FOUND` if not found.

Parameters

string	The string to find.
bCase	Should the search be case-sensitive?

Reimplemented from wxItemContainerImmutable.

unsigned int wxRadioBox::GetColumnCount ( ) const

Returns the number of columns in the radiobox.

virtual unsigned int wxRadioBox::GetCount ( ) const `[virtual]`

Returns the number of items in the control.

See also

IsEmpty()

Implements wxItemContainerImmutable.

virtual int wxRadioBox::GetItemFromPoint (const wxPoint & *pt*) const `[virtual]`

Returns a radio box item under the point, a zero-based item index, or `wxNOT_FOUND` if no item is under the point.

Parameters

pt	Point in client coordinates.

wxString wxRadioBox::GetItemHelpText (unsigned int *item*) const

Returns the helptext associated with the specified *item* if any or `wxEmptyString`.

Parameters

item	The zero-based item index.

See also

SetItemHelpText()

wxToolTip* wxRadioBox::GetItemToolTip (unsigned int *item*) const

Returns the tooltip associated with the specified *item* if any or NULL.

See also

SetItemToolTip(), wxWindow::GetToolTip()

unsigned int wxRadioBox::GetRowCount ( ) const

Returns the number of rows in the radiobox.

virtual int wxRadioBox::GetSelection ( ) const `[virtual]`

Returns the index of the selected item or `wxNOT_FOUND` if no item is selected.

Returns

The position of the current selection.

Remarks

This method can be used with single selection list boxes only, you should use wxListBox::GetSelections() for the list boxes with wxLB_MULTIPLE style.

See also

SetSelection(), GetStringSelection()

Implements wxItemContainerImmutable.

virtual wxString wxRadioBox::GetString (unsigned int *n*) const `[virtual]`

Returns the label of the item with the given index.

Parameters

n	The zero-based index.

Returns

The label of the item or an empty string if the position was invalid.

Implements wxItemContainerImmutable.

virtual bool wxRadioBox::IsItemEnabled (unsigned int *n*) const `[virtual]`

Returns true if the item is enabled or false if it was disabled using Enable(n, false).

This function is currently only implemented in wxMSW, wxGTK, wxQT and wxUniversal and always returns true in the other ports.

Parameters

n	The zero-based button position.

virtual bool wxRadioBox::IsItemShown (unsigned int *n*) const `[virtual]`

Returns true if the item is currently shown or false if it was hidden using Show(n, false).

Note that this function returns true for an item which hadn't been hidden even if the entire radiobox is not currently shown.

This function is currently only implemented in wxMSW, wxGTK, wxQT and wxUniversal and always returns true in the other ports.

Parameters

n	The zero-based button position.

void wxRadioBox::SetItemHelpText (unsigned int *item*, const wxString & *helptext*)

Sets the helptext for an item.

Empty string erases any existing helptext.

Parameters

item	The zero-based item index.
helptext	The help text to set for the item.

See also

GetItemHelpText()

void wxRadioBox::SetItemToolTip (unsigned int *item*, const wxString & *text*)

Sets the tooltip text for the specified item in the radio group.

This function is currently only implemented in wxMSW and wxGTK2 and does nothing in the other ports.

Parameters

item	Index of the item the tooltip will be shown for.
text	Tooltip text for the item, the tooltip is removed if empty.

See also

GetItemToolTip(), wxWindow::SetToolTip()

virtual void wxRadioBox::SetSelection (int *n*) [virtual]

Sets the selection to the given item.

Notice that a radio box always has selection, so *n* must be valid here and passing `wxNOT_FOUND` is not allowed.

Implements wxItemContainerImmutable.

virtual void wxRadioBox::SetString (unsigned int *n*, const wxString & *string*) [virtual]

Sets the label for the given item.

Parameters

n	The zero-based item index.
string	The label to set.

Implements wxItemContainerImmutable.

virtual bool wxRadioBox::Show (unsigned int *item*, bool *show* = `true`) [virtual]

Shows or hides individual buttons.

Parameters

show	true to show, false to hide.
item	The zero-based position of the button to show or hide.

Returns

true if the item has been shown or hidden or false if nothing was done because it already was in the requested state.

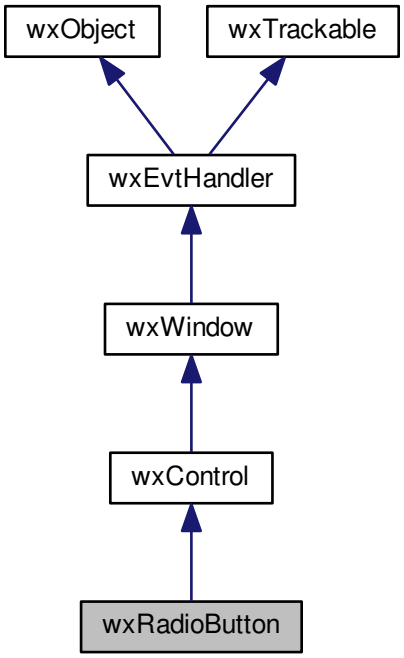
wxWindow::Show()

21.575 wxRadioButton Class Reference

`#include <wx/radiobut.h>`

Inheritance diagram for wxRadioButton:



21.575.1 Detailed Description

A radio button item is a button which usually denotes one of several mutually exclusive options.

It has a text label next to a (usually) round button.

You can create a group of mutually-exclusive radio buttons by specifying `wxRB_GROUP` for the first in the group. The group ends when another radio button group is created, or there are no more radio buttons.

Styles

This class supports the following styles:

- wxRB_GROUP: Marks the beginning of a new group of radio buttons.
- wxRB_SINGLE: In some circumstances, radio buttons that are not consecutive siblings trigger a hang bug in Windows (only). If this happens, add this style to mark the button as not belonging to a group, and implement the mutually-exclusive group behaviour yourself.

Events emitted by this class

The following event handler macros redirect the events to member function handlers '**func**' with prototypes like: void handlerFuncName(wxCommandEvent& event)

Event macros for events emitted by this class:

- EVT_RADIOBUTTON(id, func): Process a `wxEVT_RADIOBUTTON` event, when the radiobutton is clicked.

Library: wxCore

Category: Controls

Events and Event Handling, wxRadioBox, wxCheckBox

Public Member Functions

- wxRadioButton ()

  Default constructor.
- wxRadioButton (wxWindow *parent, wxWindowID id, const wxString &label, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, long style=0, const wxValidator &validator=wxDefaultValidator, const wxString &name=wxRadioButtonNameStr)

  Constructor, creating and showing a radio button.
- virtual ~wxRadioButton ()

  Destructor, destroying the radio button item.
- bool Create (wxWindow *parent, wxWindowID id, const wxString &label, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, long style=0, const wxValidator &validator=wxDefaultValidator, const wxString &name=wxRadioButtonNameStr)

  Creates the choice for two-step construction.
- virtual bool GetValue () const

  Returns true if the radio button is checked, false otherwise.
- virtual void SetValue (bool value)

  Sets the radio button to checked or unchecked status.

Additional Inherited Members

21.575.2 Constructor & Destructor Documentation

wxRadioButton::wxRadioButton ( )

Default constructor.

See also

Create(), wxValidator

wxRadioButton::wxRadioButton (wxWindow * *parent*, wxWindowID *id*, const wxString & *label*, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, long *style* = 0, const wxValidator & *validator* = wxDefaultValidator, const wxString & *name* = wxRadioButtonNameStr)

Constructor, creating and showing a radio button.

Parameters

parent	Parent window. Must not be NULL.
id	Window identifier. The value wxID_ANY indicates a default value.
label	Label for the radio button.
pos	Window position. If wxDefaultPosition is specified then a default position is chosen.
size	Window size. If wxDefaultSize is specified then a default size is chosen.
style	Window style. See wxRadioButton.
validator	Window validator.
name	Window name.

See also

Create(), wxValidator

virtual wxRadioButton::~wxRadioButton ( ) [virtual]

Destructor, destroying the radio button item.

21.575.3 Member Function Documentation

bool wxRadioButton::Create (wxWindow * *parent*, wxWindowID *id*, const wxString & *label*, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, long *style* = 0, const wxValidator & *validator* = wxDefaultValidator, const wxString & *name* = wxRadioButtonNameStr)

Creates the choice for two-step construction.

See wxRadioButton() for further details.

virtual bool wxRadioButton::GetValue ( ) const [virtual]

Returns true if the radio button is checked, false otherwise.

virtual void wxRadioButton::SetValue (bool *value*) [virtual]

Sets the radio button to checked or unchecked status.

This does not cause a wxEVT_RADIOBUTTON event to get emitted.

If the radio button belongs to a radio group exactly one button in the group may be checked and so this method can be only called with *value* set to true. To uncheck a radio button in a group you must check another button in the same group.

Parameters

value	true to check, false to uncheck.

21.576 wxRealPoint Class Reference

`#include <wx/gdicmn.h>`

21.576.1 Detailed Description

A wxRealPoint is a useful data structure for graphics operations.

It contains floating point *x* and *y* members. See wxPoint for an integer version.

Note that the coordinates stored inside a wxRealPoint object may be negative and that wxRealPoint functions do not perform any check against negative values.

Library: wxCore

Category: Data Structures

See also

wxPoint

Public Member Functions

- wxRealPoint ()

  Initializes to zero the x and y members.
- wxRealPoint (double x, double y)

  Initializes the point with the given coordinates.
- wxRealPoint (const wxPoint &pt)

  Converts the given wxPoint (with integer coordinates) to a wxRealPoint.

Miscellaneous operators

Note that these operators are documented as class members (to make them easier to find) but, as their prototype shows, they are implemented as global operators; note that this is transparent to the user but it helps to understand why the following functions are documented to take the wxPoint they operate on as an explicit argument.

- wxRealPoint & operator= (const wxRealPoint &pt)
- bool operator== (const wxRealPoint &p1, const wxRealPoint &p2)
- bool operator!= (const wxRealPoint &p1, const wxRealPoint &p2)
- wxRealPoint operator+ (const wxRealPoint &p1, const wxRealPoint &p2)
- wxRealPoint operator- (const wxRealPoint &p1, const wxRealPoint &p2)
- wxRealPoint & operator+= (const wxRealPoint &pt)
- wxRealPoint & operator-= (const wxRealPoint &pt)
- wxRealPoint operator+ (const wxRealPoint &pt, const wxSize &sz)
- wxRealPoint operator- (const wxRealPoint &pt, const wxSize &sz)
- wxRealPoint operator+ (const wxSize &sz, const wxRealPoint &pt)
- wxRealPoint operator- (const wxSize &sz, const wxRealPoint &pt)
- wxRealPoint & operator+= (const wxSize &sz)
- wxRealPoint & operator-= (const wxSize &sz)
- wxSize operator/ (const wxRealPoint &sz, int factor)

- wxSize operator∗ (const wxRealPoint &sz, int factor)
- wxSize operator∗ (int factor, const wxSize &sz)
- wxSize & operator/= (int factor)
- wxSize & operator∗= (int factor)

Public Attributes

- double x

  X coordinate of this point.
- double y

  Y coordinate of this point.

21.576.2 Constructor & Destructor Documentation

wxRealPoint::wxRealPoint ( )

Initializes to zero the x and y members.

wxRealPoint::wxRealPoint (double *x*, double *y*)

Initializes the point with the given coordinates.

wxRealPoint::wxRealPoint (const wxPoint & *pt*)

Converts the given wxPoint (with integer coordinates) to a wxRealPoint.

wxRealPoint& wxRealPoint::operator= (const wxRealPoint & *pt*)

bool wxRealPoint::operator== (const wxRealPoint & *p1*, const wxRealPoint & *p2*)

21.576.4 Member Data Documentation

double wxRealPoint::x

X coordinate of this point.

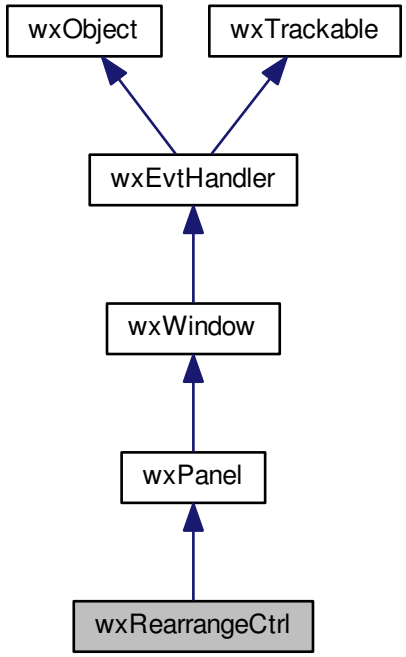
double wxRealPoint::y

Y coordinate of this point.

21.577 wxRearrangeCtrl Class Reference

`#include <wx/rearrangectrl.h>`

Inheritance diagram for wxRearrangeCtrl:



21.577.1 Detailed Description

A composite control containing a wxRearrangeList and the buttons allowing to move the items in it.

This control is in fact a panel containing the wxRearrangeList control and the "Up" and "Down" buttons to move the currently selected item up or down. It is used as the main part of a wxRearrangeDialog.

Since

2.9.0

Library: wxCore

Category: Controls

Public Member Functions

- wxRearrangeCtrl ()

  Default constructor.
- wxRearrangeCtrl (wxWindow *parent, wxWindowID id, const wxPoint &pos, const wxSize &size, const wxArrayInt &order, const wxArrayString &items, long style=0, const wxValidator &validator=wxDefaultValidator, const wxString &name=wxRearrangeListNameStr)

  Constructor really creating the control.
- bool Create (wxWindow *parent, wxWindowID id, const wxPoint &pos, const wxSize &size, const wxArrayInt &order, const wxArrayString &items, long style=0, const wxValidator &validator=wxDefaultValidator, const wxString &name=wxRearrangeListNameStr)

  Effectively creates the window for an object created using the default constructor.
- wxRearrangeList * GetList () const

  Return the listbox which is the main part of this control.

Additional Inherited Members

21.577.2 Constructor & Destructor Documentation

wxRearrangeCtrl::wxRearrangeCtrl ( )

Default constructor.

Create() must be called later to effectively create the control.

wxRearrangeCtrl::wxRearrangeCtrl (wxWindow * *parent*, wxWindowID *id*, const wxPoint & *pos*, const wxSize & *size*, const wxArrayInt & *order*, const wxArrayString & *items*, long *style* = `0`, const wxValidator & *validator* = wxDefaultValidator, const wxString & *name* = `wxRearrangeListNameStr`)

Constructor really creating the control.

Please see Create() for the parameters description.

21.577.3 Member Function Documentation

bool wxRearrangeCtrl::Create (wxWindow * *parent*, wxWindowID *id*, const wxPoint & *pos*, const wxSize & *size*, const wxArrayInt & *order*, const wxArrayString & *items*, long *style* = `0`, const wxValidator & *validator* = wxDefaultValidator, const wxString & *name* = `wxRearrangeListNameStr`)

Effectively creates the window for an object created using the default constructor.

The parameters of this method are the same as for wxRearrangeList::Create().

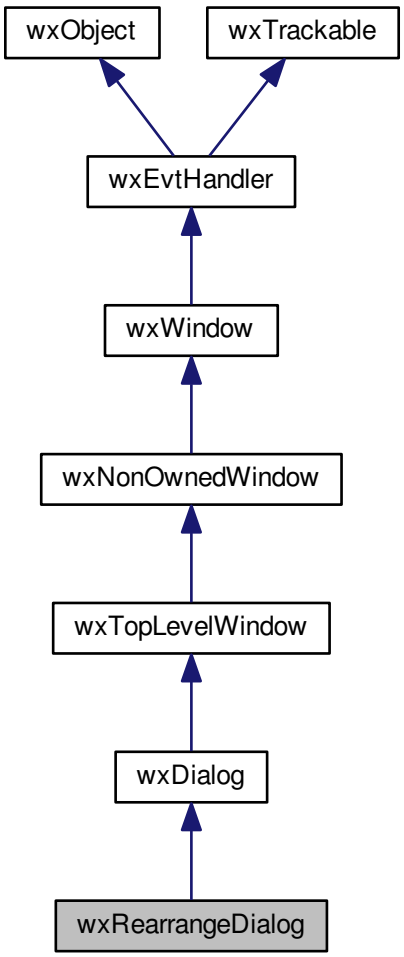
wxRearrangeList* wxRearrangeCtrl::GetList ( ) const

Return the listbox which is the main part of this control.

21.578 wxRearrangeDialog Class Reference

`#include <wx/rearrangectrl.h>`

Inheritance diagram for wxRearrangeDialog:



21.578.1 Detailed Description

A dialog allowing the user to rearrange the specified items.

This dialog can be used to allow the user to modify the order of the items and to enable or disable them individually. For example:

```
wxArrayString items;
items.push_back("meat");
items.push_back("fish");
items.push_back("fruits");
items.push_back("beer");
wxArrayInt order;
order.push_back(3);
order.push_back(0);
order.push_back(1);
order.push_back(2);

wxRearrangeDialog dlg(NULL,
                      "You can also uncheck the items you don't like "
                      "at all.",
                      "Sort the items in order of preference",
                      order, items);
if ( dlg.ShowModal() == wxID_OK ) {
    order = dlg.GetOrder();
    for ( size_t n = 0; n < order.size(); n++ ) {
        if ( order[n] >= 0 ) {
            wxLogMessage("Your most preferred item is \"%s\"",
                         items[order[n]]);
            break;
        }
    }
}
```

Since

2.9.0

Library: wxCore

Category: Common Dialogs

Public Member Functions

- wxRearrangeDialog ()

  Default constructor.

- wxRearrangeDialog (wxWindow *parent, const wxString &message, const wxString &title, const wxArrayInt &order, const wxArrayString &items, const wxPoint &pos=wxDefaultPosition, const wxString &name=wxRearrangeDialogNameStr)

  Constructor creating the dialog.

- bool Create (wxWindow *parent, const wxString &message, const wxString &title, const wxArrayInt &order, const wxArrayString &items, const wxPoint &pos=wxDefaultPosition, const wxString &name=wxRearrangeDialogNameStr)

  Effectively creates the dialog for an object created using the default constructor.

- void AddExtraControls (wxWindow *win)

  Customize the dialog by adding extra controls to it.

- wxRearrangeList * GetList () const

  Return the list control used by the dialog.

- wxArrayInt GetOrder () const

  Return the array describing the order of items after it was modified by the user.

Additional Inherited Members

21.578.2 Constructor & Destructor Documentation

wxRearrangeDialog::wxRearrangeDialog ( )

Default constructor.

Create() must be called later to effectively create the control.

wxRearrangeDialog::wxRearrangeDialog (wxWindow * *parent*, const wxString & *message*, const wxString & *title*, const wxArrayInt & *order*, const wxArrayString & *items*, const wxPoint & *pos* = wxDefaultPosition, const wxString & *name* = `wxRearrangeDialogNameStr`)

Constructor creating the dialog.

Please see Create() for the parameters description.

21.578.3 Member Function Documentation

void wxRearrangeDialog::AddExtraControls (wxWindow * *win*)

Customize the dialog by adding extra controls to it.

This function adds the given *win* to the dialog, putting it just below the part occupied by wxRearrangeCtrl. It must be called after creating the dialog and you will typically need to process the events generated by the extra controls for them to do something useful.

For example:

```
class MyRearrangeDialog : public wxRearrangeDialog
{
public:
    MyRearrangeDialog(wxWindow *parent, ...)
        : wxRearrangeDialog(parent, ...)
    {
        wxPanel *panel = new wxPanel(this);
        wxSizer *sizer = new wxBoxSizer(wxHORIZONTAL);
        sizer->Add(new wxStaticText(panel, wxID_ANY,
                                    "Column width in pixels:"));
        sizer->Add(new wxTextCtrl(panel, wxID_ANY, ""));
        panel->SetSizer(sizer);
        AddExtraControls(panel);
    }

    ... code to update the text control with the currently selected
        item width and to react to its changes omitted ...
};
```

See also the complete example of a custom rearrange dialog in the dialogs sample.

Parameters

win	The window containing the extra controls. It must have this dialog as its parent.

bool wxRearrangeDialog::Create (wxWindow * *parent*, const wxString & *message*, const wxString & *title*, const wxArrayInt & *order*, const wxArrayString & *items*, const wxPoint & *pos* = wxDefaultPosition, const wxString & *name* = `wxRearrangeDialogNameStr`)

Effectively creates the dialog for an object created using the default constructor.

Parameters

parent	The dialog parent, possibly NULL.
message	The message shown inside the dialog itself, above the items list.
title	The title of the dialog.
order	The initial order of the items in the convention used by wxRearrangeList.
items	The items to show in the dialog.
pos	Optional dialog position.
name	Optional dialog name.

Returns

true if the dialog was successfully created or false if creation failed.

wxRearrangeList* wxRearrangeDialog::GetList ( ) const

Return the list control used by the dialog.

See also

wxRearrangeCtrl::GetList()

wxArrayInt wxRearrangeDialog::GetOrder ( ) const

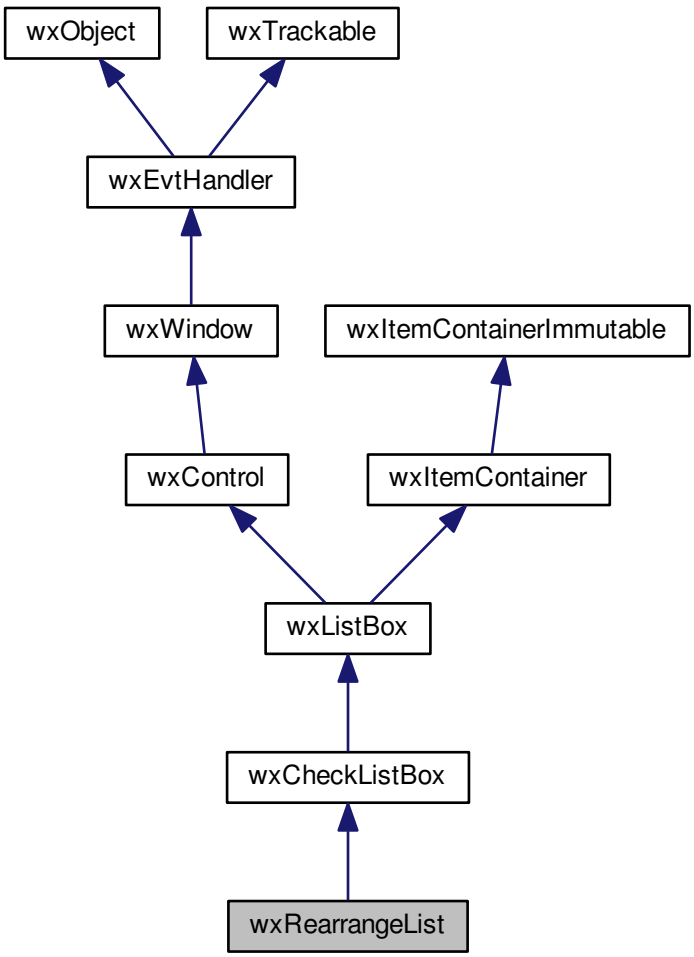
Return the array describing the order of items after it was modified by the user.

Please notice that the array will contain negative items if any items were unchecked. See wxRearrangeList for more information about the convention used for this array.

21.579 wxRearrangeList Class Reference

```
#include <wx/rearrangectrl.h>
```

Inheritance diagram for wxRearrangeList:



21.579.1 Detailed Description

A listbox-like control allowing the user to rearrange the items and to enable or disable them.

This class allows to change the order of the items shown in it as well as to check or uncheck them individually. The data structure used to allow this is the order array which contains the items indices indexed by their position with an added twist that the unchecked items are represented by the bitwise complement of the corresponding index (for any architecture using two's complement for negative numbers representation (i.e. just about any at all) this means that a checked item N is represented by -N-1 in unchecked state). In practice this means that you must apply the C bitwise complement operator when constructing the order array, e.g.

```
wxArrayInt order;
order.push_back(0); // checked item #0
order.push_back(~1); // unchecked item #1
```

So, for example, the array order [1 -3 0] used in conjunction with the items array ["first", "second", "third"] means that the items order is "second", "third", "first" and the "third" item is unchecked while the other two are checked.

This convention is used both for the order argument of the control ctor or Create() and for the array returned from GetCurrentOrder().

Usually this control will be used together with other controls allowing to move the items around in it interactively. The simplest possible solution is to use wxRearrangeCtrl which combines it with two standard buttons to move the current item up or down.

Since

2.9.0

Library: wxCore

Category: Controls

Public Member Functions

- wxRearrangeList ()

  Default constructor.

- wxRearrangeList (wxWindow *parent, wxWindowID id, const wxPoint &pos, const wxSize &size, const wxArrayInt &order, const wxArrayString &items, long style=0, const wxValidator &validator=wxDefaultValidator, const wxString &name=wxRearrangeListNameStr)

  Constructor really creating the control.

- bool Create (wxWindow *parent, wxWindowID id, const wxPoint &pos, const wxSize &size, const wxArrayInt &order, const wxArrayString &items, long style=0, const wxValidator &validator=wxDefaultValidator, const wxString &name=wxRearrangeListNameStr)

  Effectively creates the window for an object created using the default constructor.

- const wxArrayInt & GetCurrentOrder () const

  Return the current order of the items.

- bool CanMoveCurrentUp () const

  Return true if the currently selected item can be moved up.

- bool CanMoveCurrentDown () const

  Return true if the currently selected item can be moved down.

- bool MoveCurrentUp ()

  Move the currently selected item one position above.

- bool MoveCurrentDown ()

  Move the currently selected item one position below.

Additional Inherited Members

21.579.2 Constructor & Destructor Documentation

wxRearrangeList::wxRearrangeList ( )

Default constructor.

Create() must be called later to effectively create the control.

wxRearrangeList::wxRearrangeList (wxWindow * *parent*, wxWindowID *id*, const wxPoint & *pos*, const wxSize & *size*, const wxArrayInt & *order*, const wxArrayString & *items*, long *style* = 0, const wxValidator & *validator* = wxDefaultValidator, const wxString & *name* = wxRearrangeListNameStr)

Constructor really creating the control.

Please see Create() for the parameters description.

21.579.3 Member Function Documentation

bool wxRearrangeList::CanMoveCurrentDown ( ) const

Return true if the currently selected item can be moved down.

See also

CanMoveCurrentUp()

bool wxRearrangeList::CanMoveCurrentUp ( ) const

Return true if the currently selected item can be moved up.

This function is useful for EVT_UPDATE_UI handler for the standard "Up" button often used together with this control and wxRearrangeCtrl uses it in this way.

Returns

true if the currently selected item can be moved up in the listbox, false if there is no selection or the current item is the first one.

See also

CanMoveCurrentDown()

bool wxRearrangeList::Create (wxWindow * *parent*, wxWindowID *id*, const wxPoint & *pos*, const wxSize & *size*, const wxArrayInt & *order*, const wxArrayString & *items*, long *style* = 0, const wxValidator & *validator* = wxDefaultValidator, const wxString & *name* = wxRearrangeListNameStr)

Effectively creates the window for an object created using the default constructor.

This function is very similar to wxCheckListBox::Create() except that it has an additional parameter specifying the initial order of the items. Please see the class documentation for the explanation of the conventions used by the *order* argument.

Parameters

parent	The parent window, must be non-NULL.
id	The window identifier.
pos	The initial window position.
size	The initial window size.
order	Array specifying the initial order of the items in *items* array.
items	The items to display in the list.

style	The control style, there are no special styles for this class but the base class styles can be used here.
validator	Optional window validator.
name	Optional window name.

const wxArrayInt& wxRearrangeList::GetCurrentOrder ( ) const

Return the current order of the items.

The order may be different from the one passed to the constructor if MoveCurrentUp() or MoveCurrentDown() were called.

bool wxRearrangeList::MoveCurrentDown ( )

Move the currently selected item one position below.

See also

MoveCurrentUp()

bool wxRearrangeList::MoveCurrentUp ( )

Move the currently selected item one position above.

This method is useful to implement the standard "Up" button behaviour and wxRearrangeCtrl uses it for this.

Returns

true if the item was moved or false if this couldn't be done.

See also

MoveCurrentDown()

21.580 wxRect Class Reference

```
#include <wx/gdicmn.h>
```

21.580.1 Detailed Description

A class for manipulating rectangles.

Note that the x, y coordinates and the width and height stored inside a wxRect object may be negative and that wxRect functions do not perform any check against negative values.

Library: wxCore

Category: Data Structures

See also

wxPoint, wxSize

Public Member Functions

- wxRect ()

  Default constructor.
- wxRect (int x, int y, int width, int height)

  Creates a wxRect object from x, y, width and height values.
- wxRect (const wxPoint &topLeft, const wxPoint &bottomRight)

  Creates a wxRect object from top-left and bottom-right points.
- wxRect (const wxPoint &pos, const wxSize &size)

  Creates a wxRect object from position pos and size values.
- wxRect (const wxSize &size)

  Creates a wxRect object from size values at the origin.
- bool Contains (int x, int y) const

  Returns true if the given point is inside the rectangle (or on its boundary) and false otherwise.
- bool Contains (const wxPoint &pt) const

  Returns true if the given point is inside the rectangle (or on its boundary) and false otherwise.
- bool Contains (const wxRect &rect) const

  Returns true if the given rectangle is completely inside this rectangle (or touches its boundary) and false otherwise.
- int GetBottom () const

  Gets the bottom point of the rectangle.
- wxPoint GetBottomLeft () const

  Gets the position of the bottom left corner.
- wxPoint GetBottomRight () const

  Gets the position of the bottom right corner.
- int GetHeight () const

  Gets the height member.
- int GetLeft () const

  Gets the left point of the rectangle (the same as GetX()).
- wxPoint GetPosition () const

  Gets the position.
- int GetRight () const

  Gets the right point of the rectangle.
- wxSize GetSize () const

  Gets the size.
- int GetTop () const

  Gets the top point of the rectangle (the same as GetY()).
- wxPoint GetTopLeft () const

  Gets the position of the top left corner of the rectangle, same as GetPosition().
- wxPoint GetTopRight () const

  Gets the position of the top right corner.
- int GetWidth () const

  Gets the width member.
- int GetX () const

  Gets the x member.
- int GetY () const

  Gets the y member.
- wxRect & Intersect (const wxRect &rect)

  Modifies this rectangle to contain the overlapping portion of this rectangle and the one passed in as parameter.
- wxRect Intersect (const wxRect &rect) const

  Returns the overlapping portion of this rectangle and the one passed in as parameter.
- bool Intersects (const wxRect &rect) const

Returns true if this rectangle has a non-empty intersection with the rectangle rect and false otherwise.

- bool IsEmpty () const

  Returns true if this rectangle has a width or height less than or equal to 0 and false otherwise.
- void SetHeight (int height)

  Sets the height.
- void SetPosition (const wxPoint &pos)

  Sets the position.
- void SetSize (const wxSize &s)

  Sets the size.
- void SetWidth (int width)

  Sets the width.
- void SetX (int x)

  Sets the x position.
- void SetY (int y)

  Sets the y position.
- void SetLeft (int left)

  Set the left side of the rectangle.
- void SetRight (int right)

  Set the right side of the rectangle.
- void SetTop (int top)

  Set the top edge of the rectangle.
- void SetBottom (int bottom)

  Set the bottom edge of the rectangle.
- void SetTopLeft (const wxPoint &p)

  Set the top-left point of the rectangle.
- void SetBottomRight (const wxPoint &p)

  Set the bottom-right point of the rectangle.
- void SetTopRight (const wxPoint &p)

  Set the top-right point of the rectangle.
- void SetBottomLeft (const wxPoint &p)

  Set the bottom-left point of the rectangle.
- bool operator!= (const wxRect &r1, const wxRect &r2)

  Inequality operator.
- wxRect & operator= (const wxRect &rect)

  Assignment operator.
- bool operator== (const wxRect &r1, const wxRect &r2)

  Equality operator.

- wxRect CentreIn (const wxRect &r, int dir=wxBOTH) const

  Returns the rectangle having the same size as this one but centered relatively to the given rectangle r.
- wxRect CenterIn (const wxRect &r, int dir=wxBOTH) const

  Returns the rectangle having the same size as this one but centered relatively to the given rectangle r.

- wxRect & Deflate (wxCoord dx, wxCoord dy)

  Decrease the rectangle size.
- wxRect & Deflate (const wxSize &diff)

  Decrease the rectangle size.
- wxRect & Deflate (wxCoord diff)

  Decrease the rectangle size.
- wxRect Deflate (wxCoord dx, wxCoord dy) const

  Decrease the rectangle size.

- wxRect & Inflate (wxCoord dx, wxCoord dy)

  Increases the size of the rectangle.
- wxRect & Inflate (const wxSize &diff)

  Increases the size of the rectangle.
- wxRect & Inflate (wxCoord diff)

  Increases the size of the rectangle.
- wxRect Inflate (wxCoord dx, wxCoord dy) const

  Increases the size of the rectangle.

- void Offset (wxCoord dx, wxCoord dy)

  Moves the rectangle by the specified offset.
- void Offset (const wxPoint &pt)

  Moves the rectangle by the specified offset.

- wxRect Union (const wxRect &rect) const

  Modifies the rectangle to contain the bounding box of this rectangle and the one passed in as parameter.
- wxRect & Union (const wxRect &rect)

  Modifies the rectangle to contain the bounding box of this rectangle and the one passed in as parameter.

- wxRect operator+ (const wxRect &r1, const wxRect &r2)

  Like Union(), but doesn't treat empty rectangles specially.
- wxRect & operator+= (const wxRect &r)

  Like Union(), but doesn't treat empty rectangles specially.

- wxRect operator∗ (const wxRect &r1, const wxRect &r2)

  Returns the intersection of two rectangles (which may be empty).
- wxRect & operator∗= (const wxRect &r)

  Returns the intersection of two rectangles (which may be empty).

Public Attributes

- int height

  Height member.
- int width

  Width member.
- int x

  x coordinate of the top-level corner of the rectangle.
- int y

  y coordinate of the top-level corner of the rectangle.

21.580.2 Constructor & Destructor Documentation

wxRect::wxRect ( )

Default constructor.

Initializes to zero the internal *x*, *y*, *width* and *height* members.

wxRect::wxRect (int *x*, int *y*, int *width*, int *height*)

Creates a wxRect object from *x*, *y*, *width* and *height* values.

wxRect::wxRect (const wxPoint & *topLeft,* const wxPoint & *bottomRight*)

Creates a wxRect object from top-left and bottom-right points.

wxRect::wxRect (const wxPoint & *pos,* const wxSize & *size*)

Creates a wxRect object from position *pos* and *size* values.

wxRect::wxRect (const wxSize & *size*)

Creates a wxRect object from *size* values at the origin.

21.580.3 Member Function Documentation

wxRect wxRect::CenterIn (const wxRect & *r,* int *dir* = wxBOTH) const

Returns the rectangle having the same size as this one but centered relatively to the given rectangle *r*.

By default, rectangle is centred in both directions but if *dir* includes only `wxVERTICAL` or only `wxHORIZONTAL`, then it is only centered in this direction while the other component of its position remains unchanged.

wxRect wxRect::CentreIn (const wxRect & *r,* int *dir* = wxBOTH) const

Returns the rectangle having the same size as this one but centered relatively to the given rectangle *r*.

By default, rectangle is centred in both directions but if *dir* includes only `wxVERTICAL` or only `wxHORIZONTAL`, then it is only centered in this direction while the other component of its position remains unchanged.

bool wxRect::Contains (int *x,* int *y*) const

Returns true if the given point is inside the rectangle (or on its boundary) and false otherwise.

bool wxRect::Contains (const wxPoint & *pt*) const

Returns true if the given point is inside the rectangle (or on its boundary) and false otherwise.

bool wxRect::Contains (const wxRect & *rect*) const

Returns true if the given rectangle is completely inside this rectangle (or touches its boundary) and false otherwise.

wxRect& wxRect::Deflate (wxCoord *dx,* wxCoord *dy*)

Decrease the rectangle size.

This method is the opposite from Inflate(): Deflate(a, b) is equivalent to Inflate(-a, -b). Please refer to Inflate() for full description.

wxRect& wxRect::Deflate (const wxSize & *diff*)

Decrease the rectangle size.

This method is the opposite from Inflate(): Deflate(a, b) is equivalent to Inflate(-a, -b). Please refer to Inflate() for full description.

wxRect& wxRect::Deflate (wxCoord *diff*)

Decrease the rectangle size.

This method is the opposite from Inflate(): Deflate(a, b) is equivalent to Inflate(-a, -b). Please refer to Inflate() for full description.

wxRect wxRect::Deflate (wxCoord *dx*, wxCoord *dy*) const

Decrease the rectangle size.

This method is the opposite from Inflate(): Deflate(a, b) is equivalent to Inflate(-a, -b). Please refer to Inflate() for full description.

int wxRect::GetBottom ( ) const

Gets the bottom point of the rectangle.

wxPoint wxRect::GetBottomLeft ( ) const

Gets the position of the bottom left corner.

wxPoint wxRect::GetBottomRight ( ) const

Gets the position of the bottom right corner.

int wxRect::GetHeight ( ) const

Gets the height member.

int wxRect::GetLeft ( ) const

Gets the left point of the rectangle (the same as GetX()).

wxPoint wxRect::GetPosition ( ) const

Gets the position.

int wxRect::GetRight ( ) const

Gets the right point of the rectangle.

wxSize wxRect::GetSize ( ) const

Gets the size.

See also

SetSize()

int wxRect::GetTop ( ) const

Gets the top point of the rectangle (the same as GetY()).

wxPoint wxRect::GetTopLeft ( ) const

Gets the position of the top left corner of the rectangle, same as GetPosition().

wxPoint wxRect::GetTopRight ( ) const

Gets the position of the top right corner.

int wxRect::GetWidth ( ) const

Gets the width member.

int wxRect::GetX ( ) const

Gets the x member.

int wxRect::GetY ( ) const

Gets the y member.

wxRect& wxRect::Inflate (wxCoord *dx*, wxCoord *dy*)

Increases the size of the rectangle.

The left border is moved farther left and the right border is moved farther right by *dx*. The upper border is moved farther up and the bottom border is moved farther down by *dy*. (Note that the width and height of the rectangle thus change by 2∗dx and 2∗dy, respectively.) If one or both of *dx* and *dy* are negative, the opposite happens: the rectangle size decreases in the respective direction.

Inflating and deflating behaves "naturally". Defined more precisely, that means:

1. "Real" inflates (that is, *dx* and/or *dy* = 0) are not constrained. Thus inflating a rectangle can cause its upper left corner to move into the negative numbers. (2.5.4 and older forced the top left coordinate to not fall below (0, 0), which implied a forced move of the rectangle.)

2. Deflates are clamped to not reduce the width or height of the rectangle below zero. In such cases, the top-left corner is nonetheless handled properly. For example, a rectangle at (10, 10) with size (20, 40) that is inflated by (-15, -15) will become located at (20, 25) at size (0, 10). Finally, observe that the width and height are treated independently. In the above example, the width is reduced by 20, whereas the height is reduced by the full 30 (rather than also stopping at 20, when the width reached zero).

See also

Deflate()

wxRect& wxRect::Inflate (const wxSize & *diff*)

Increases the size of the rectangle.

The left border is moved farther left and the right border is moved farther right by *dx*. The upper border is moved farther up and the bottom border is moved farther down by *dy*. (Note that the width and height of the rectangle thus change by 2∗dx and 2∗dy, respectively.) If one or both of *dx* and *dy* are negative, the opposite happens: the rectangle size decreases in the respective direction.

Inflating and deflating behaves "naturally". Defined more precisely, that means:

1. "Real" inflates (that is, *dx* and/or *dy* = 0) are not constrained. Thus inflating a rectangle can cause its upper left corner to move into the negative numbers. (2.5.4 and older forced the top left coordinate to not fall below (0, 0), which implied a forced move of the rectangle.)
2. Deflates are clamped to not reduce the width or height of the rectangle below zero. In such cases, the top-left corner is nonetheless handled properly. For example, a rectangle at (10, 10) with size (20, 40) that is inflated by (-15, -15) will become located at (20, 25) at size (0, 10). Finally, observe that the width and height are treated independently. In the above example, the width is reduced by 20, whereas the height is reduced by the full 30 (rather than also stopping at 20, when the width reached zero).

Deflate()

wxRect& wxRect::Intersect (const wxRect & *rect*)

Modifies this rectangle to contain the overlapping portion of this rectangle and the one passed in as parameter.

Returns

This rectangle, modified.

wxRect wxRect::Intersect (const wxRect & *rect*) const

Returns the overlapping portion of this rectangle and the one passed in as parameter.

bool wxRect::Intersects (const wxRect & *rect*) const

Returns true if this rectangle has a non-empty intersection with the rectangle *rect* and false otherwise.

bool wxRect::IsEmpty ( ) const

Returns true if this rectangle has a width or height less than or equal to 0 and false otherwise.

void wxRect::Offset (wxCoord *dx,* wxCoord *dy*)

Moves the rectangle by the specified offset.

If *dx* is positive, the rectangle is moved to the right, if *dy* is positive, it is moved to the bottom, otherwise it is moved to the left or top respectively.

void wxRect::Offset (const wxPoint & *pt*)

Moves the rectangle by the specified offset.

If *dx* is positive, the rectangle is moved to the right, if *dy* is positive, it is moved to the bottom, otherwise it is moved to the left or top respectively.

bool wxRect::operator!= (const wxRect & *r1,* const wxRect & *r2*)

Inequality operator.

wxRect wxRect::operator∗ (const wxRect & *r1*, const wxRect & *r2*)

Returns the intersection of two rectangles (which may be empty).

wxRect& wxRect::operator∗= (const wxRect & *r*)

Returns the intersection of two rectangles (which may be empty).

wxRect wxRect::operator+ (const wxRect & *r1*, const wxRect & *r2*)

Like Union(), but doesn't treat empty rectangles specially.

wxRect& wxRect::operator+= (const wxRect & *r*)

Like Union(), but doesn't treat empty rectangles specially.

wxRect& wxRect::operator= (const wxRect & *rect*)

Assignment operator.

bool wxRect::operator== (const wxRect & *r1*, const wxRect & *r2*)

Equality operator.

void wxRect::SetBottom (int *bottom*)

Set the bottom edge of the rectangle.

Notice that this doesn't affect GetTop() return value but changes the rectangle height to set its bottom side to the given position.

void wxRect::SetBottomLeft (const wxPoint & *p*)

Set the bottom-left point of the rectangle.

void wxRect::SetBottomRight (const wxPoint & *p*)

Set the bottom-right point of the rectangle.

void wxRect::SetHeight (int *height*)

Sets the height.

void wxRect::SetLeft (int *left*)

Set the left side of the rectangle.

Notice that because the rectangle stores its left side and width, calling SetLeft() changes the right side position too – but does preserve the width.

void wxRect::SetPosition (const wxPoint & *pos*)

Sets the position.

void wxRect::SetRight (int *right*)

Set the right side of the rectangle.

Notice that this doesn't affect GetLeft() return value but changes the rectangle width to set its right side to the given position.

void wxRect::SetSize (const wxSize & *s*)

Sets the size.

See also

GetSize()

void wxRect::SetTop (int *top*)

Set the top edge of the rectangle.

Notice that because the rectangle stores its top side and height, calling SetTop() changes the bottom side position too – but does preserve the height.

void wxRect::SetTopLeft (const wxPoint & *p*)

Set the top-left point of the rectangle.

void wxRect::SetTopRight (const wxPoint & *p*)

Set the top-right point of the rectangle.

void wxRect::SetWidth (int *width*)

Sets the width.

void wxRect::SetX (int *x*)

Sets the x position.

void wxRect::SetY (int *y*)

Sets the y position.

wxRect wxRect::Union (const wxRect & *rect*) const

Modifies the rectangle to contain the bounding box of this rectangle and the one passed in as parameter.

wxRect& wxRect::Union (const wxRect & *rect*)

Modifies the rectangle to contain the bounding box of this rectangle and the one passed in as parameter.

21.580.4 Member Data Documentation

int wxRect::height

Height member.

int wxRect::width

Width member.

int wxRect::x

x coordinate of the top-level corner of the rectangle.

int wxRect::y

y coordinate of the top-level corner of the rectangle.

21.583 wxRecursionGuard Class Reference

#include <wx/recguard.h>

21.583.1 Detailed Description

wxRecursionGuard is a very simple class which can be used to prevent reentrancy problems in a function.

It is not thread-safe and so should be used only in single-threaded programs or in combination with some thread synchronization mechanisms.

wxRecursionGuard is always used together with the wxRecursionGuardFlag like in this example:

```
void Foo()
{
    static wxRecursionGuardFlag s_flag;
    wxRecursionGuard guard(s_flag);
    if ( guard.IsInside() )
    {
        // don't allow reentrancy
        return;
    }

    ...
}
```

As you can see, wxRecursionGuard simply tests the flag value and sets it to true if it hadn't been already set. IsInside() allows testing the old flag value. The advantage of using this class compared to directly manipulating the flag is that the flag is always reset in the wxRecursionGuard destructor and so you don't risk to forget to do it even if the function returns in an unexpected way (for example because an exception has been thrown).

Library: wxBase

Category: Miscellaneous

Public Member Functions

- wxRecursionGuard (wxRecursionGuardFlag &flag)

  A wxRecursionGuard object must always be initialized with a `static` wxRecursionGuardFlag.
- ~wxRecursionGuard ()

  The destructor resets the flag value so that the function can be entered again the next time.
- bool IsInside () const

  Returns true if we're already inside the code block "protected" by this wxRecursionGuard (i.e.

21.583.2 Constructor & Destructor Documentation

wxRecursionGuard::wxRecursionGuard (wxRecursionGuardFlag & *flag*)

A wxRecursionGuard object must always be initialized with a `static` wxRecursionGuardFlag.

The constructor saves the value of the flag to be able to return the correct value from IsInside().

wxRecursionGuard::~wxRecursionGuard ( )

The destructor resets the flag value so that the function can be entered again the next time.

Note

This is not virtual, so this class is not meant to be derived from (besides, there is absolutely no reason to do it anyhow).

21.583.3 Member Function Documentation

bool wxRecursionGuard::IsInside ( ) const

Returns true if we're already inside the code block "protected" by this wxRecursionGuard (i.e.

between this line and the end of current scope). Usually the function using wxRecursionGuard takes some specific actions in such case (may be simply returning) to prevent reentrant calls to itself.

If this method returns false, it is safe to continue.

21.584 wxRecursionGuardFlag Class Reference

`#include <wx/recguard.h>`

21.584.1 Detailed Description

This is a completely opaque class which exists only to be used with wxRecursionGuard, please see the example in that class' documentation.

Remarks

wxRecursionGuardFlag object must be declared `static` or the recursion would never be detected.

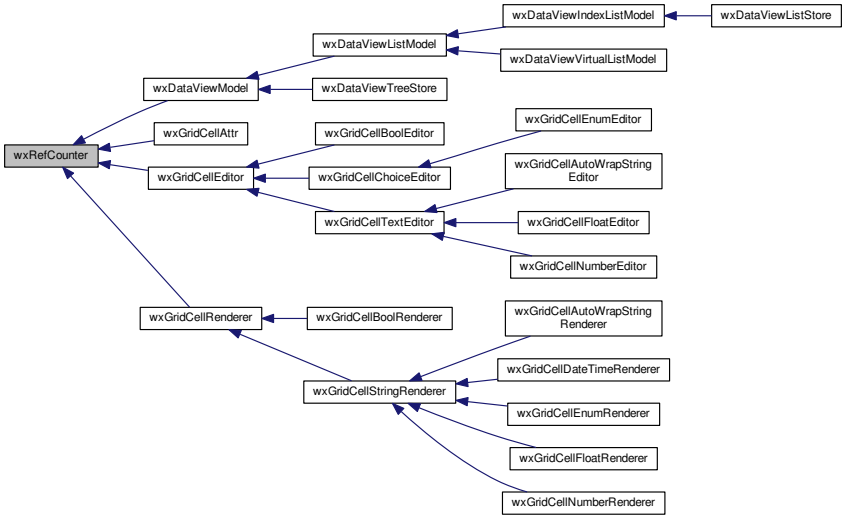
Library: wxBase

Category: Miscellaneous

21.585 wxRefCounter Class Reference

`#include <wx/object.h>`

Inheritance diagram for wxRefCounter:



21.585.1 Detailed Description

This class is used to manage reference-counting providing a simple interface and a counter.

wxRefCounter can be easily used together with wxObjectDataPtr<T> to ensure that no calls to wxRefCounter::↩ DecRef() are missed - thus avoiding memory leaks.

wxObjectRefData is a typedef to wxRefCounter and is used as the built-in reference counted storage for wxObject-derived classes.

Library: wxBase

Category: Runtime Type Information (RTTI)

See also

wxObject, wxObjectRefData, wxObjectDataPtr<T>, Reference Counting

Public Member Functions

- wxRefCounter ()

  Default constructor.

- void DecRef ()

  Decrements the reference count associated with this shared data and, if it reaches zero, destroys this instance of wxRefCounter releasing its memory.

- int GetRefCount () const

  Returns the reference count associated with this shared data.

- void IncRef ()

  Increments the reference count associated with this shared data.

Protected Member Functions

- virtual ~wxRefCounter ()

  Destructor.

21.585.2 Constructor & Destructor Documentation

virtual wxRefCounter::~wxRefCounter ( ) [protected], [virtual]

Destructor.

It's declared `protected` so that wxRefCounter instances will never be destroyed directly but only as result of a DecRef() call.

wxRefCounter::wxRefCounter ( )

Default constructor.

Initialises the internal reference count to 1.

21.585.3 Member Function Documentation

void wxRefCounter::DecRef ( )

Decrements the reference count associated with this shared data and, if it reaches zero, destroys this instance of wxRefCounter releasing its memory.

Please note that after calling this function, the caller should absolutely avoid to use the pointer to this instance since it may not be valid anymore.

int wxRefCounter::GetRefCount ( ) const

Returns the reference count associated with this shared data.

When this goes to zero during a DecRef() call, the object will auto-free itself.

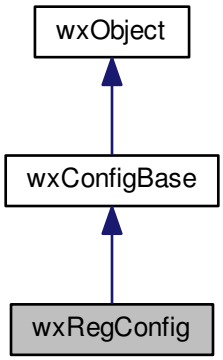
void wxRefCounter::IncRef ( )

Increments the reference count associated with this shared data.

21.586 wxRegConfig Class Reference

`#include <wx/msw/regconf.h>`

Inheritance diagram for wxRegConfig:



21.586.1 Detailed Description

wxRegConfig implements the wxConfigBase interface for storing and retrieving configuration information using Windows registry.

This class is used by default for wxConfig on Windows platforms; see wxFileConfig for an alternative you may want to use (also on Windows).

Library: wxBase

Category: Application and System configuration

See also

wxConfigBase

Public Member Functions

- wxRegConfig (const wxString &appName=wxEmptyString, const wxString &vendorName=wxEmptyString, const wxString &localFilename=wxEmptyString, const wxString &globalFilename=wxEmptyString, long style=wxCONFIG_USE_GLOBAL_FILE)

  The wxRegConfig constructor.

Additional Inherited Members

21.586.2 Constructor & Destructor Documentation

wxRegConfig::wxRegConfig (const wxString & *appName* = wxEmptyString, const wxString & *vendorName* = wxEmptyString, const wxString & *localFilename* = wxEmptyString, const wxString & *globalFilename* = wxEmptyString, long *style* = wxCONFIG_USE_GLOBAL_FILE)

The wxRegConfig constructor.

For more info see the docs for the wxConfigBase::wxConfigBase() constructor.

Note that wxRegConfig's *style* argument defaults to `wxCONFIG_USE_GLOBAL_FILE`, i.e. to the use of the `HKLM` key (also known as "HKEY_LOCAL_MACHINE").

21.587 wxRegEx Class Reference

`#include <wx/regex.h>`

21.587.1 Detailed Description

wxRegEx represents a regular expression.

This class provides support for regular expressions matching and also replacement.

It is built on top of either the system library (if it has support for POSIX regular expressions - which is the case of the most modern Unices) or uses the built in Henry Spencer's library. Henry Spencer would appreciate being given credit in the documentation of software which uses his library, but that is not a requirement.

Regular expressions, as defined by POSIX, come in two flavours: *extended* and *basic*. The builtin library also adds a third flavour of expression advanced, which is not available when using the system library.

Unicode is fully supported only when using the builtin library. When using the system library in Unicode mode, the expressions and data are translated to the default 8-bit encoding before being passed to the library.

On platforms where a system library is available, the default is to use the builtin library for Unicode builds, and the system library otherwise. It is possible to use the other if preferred by selecting it when building the wxWidgets.

Library: wxBase

Category: Data Structures

Examples:

A bad example of processing some text containing email addresses (the example is bad because the real email addresses can have more complicated form than `user@host.net`):

```
wxString text;
...
wxRegEx reEmail = "([^@]+)@([[:alnum:].-_].)+([[:alnum:]]+)";
if ( reEmail.Matches(text) )
{
    wxString text = reEmail.GetMatch(email);
    wxString username = reEmail.GetMatch(email, 1);
    if ( reEmail.GetMatch(email, 3) == "com" ) // .com TLD?
    {
        ...
    }
}

// or we could do this to hide the email address
size_t count = reEmail.ReplaceAll(text, "HIDDEN@\\2\\3");
printf("text now contains %u hidden addresses", count);
```

Public Member Functions

- wxRegEx ()

  Default constructor: use Compile() later.
- wxRegEx (const wxString &expr, int flags=wxRE_DEFAULT)

  Create and compile the regular expression, use IsValid() to test for compilation errors.
- ~wxRegEx ()

Destructor.

- bool Compile (const wxString &pattern, int flags=wxRE_DEFAULT)

  Compile the string into regular expression, return true if ok or false if string has a syntax error.
- bool GetMatch (size_t *start, size_t *len, size_t index=0) const

  Get the start index and the length of the match of the expression (if index is 0) or a bracketed subexpression (index different from 0).
- wxString GetMatch (const wxString &text, size_t index=0) const

  Returns the part of string corresponding to the match where index is interpreted as above.
- size_t GetMatchCount () const

  Returns the size of the array of matches, i.e. the number of bracketed subexpressions plus one for the expression itself, or 0 on error.
- bool IsValid () const

  Return true if this is a valid compiled regular expression, false otherwise.
- bool Matches (const wxString &text, int flags=0) const

  Matches the precompiled regular expression against the string text, returns true if matches and false otherwise.
- int Replace (wxString *text, const wxString &replacement, size_t maxMatches=0) const

  Replaces the current regular expression in the string pointed to by text, with the text in replacement and return number of matches replaced (maybe 0 if none found) or -1 on error.
- int ReplaceAll (wxString *text, const wxString &replacement) const

  Replace all occurrences: this is actually a synonym for Replace().
- int ReplaceFirst (wxString *text, const wxString &replacement) const

  Replace the first occurrence.

- bool Matches (const wxChar *text, int flags=0) const

  Matches the precompiled regular expression against the string text, returns true if matches and false otherwise.
- bool Matches (const wxChar *text, int flags, size_t len) const

  Matches the precompiled regular expression against the string text, returns true if matches and false otherwise.

21.587.2 Constructor & Destructor Documentation

wxRegEx::wxRegEx ( )

Default constructor: use Compile() later.

wxRegEx::wxRegEx (const wxString & *expr,* int *flags* = wxRE_DEFAULT)

Create and compile the regular expression, use IsValid() to test for compilation errors.

As for the flags, please see wxRE_FLAGS.

wxRegEx::~wxRegEx ( )

Destructor.

It's not virtual, don't derive from this class.

21.587.3 Member Function Documentation

bool wxRegEx::Compile (const wxString & *pattern,* int *flags* = wxRE_DEFAULT)

Compile the string into regular expression, return true if ok or false if string has a syntax error.

As for the flags, please see wxRE_FLAGS.

bool wxRegEx::GetMatch (size_t * *start*, size_t * *len*, size_t *index* = 0) const

Get the start index and the length of the match of the expression (if *index* is 0) or a bracketed subexpression (*index* different from 0).

May only be called after successful call to Matches() and only if `wxRE_NOSUB` was **not** used in Compile().

Returns false if no match or if an error occurred.

wxString wxRegEx::GetMatch (const wxString & *text*, size_t *index* = 0) const

Returns the part of string corresponding to the match where index is interpreted as above.

Empty string is returned if match failed.

May only be called after successful call to Matches() and only if `wxRE_NOSUB` was **not** used in Compile().

size_t wxRegEx::GetMatchCount ( ) const

Returns the size of the array of matches, i.e. the number of bracketed subexpressions plus one for the expression itself, or 0 on error.

May only be called after successful call to Compile(). and only if `wxRE_NOSUB` was **not** used.

bool wxRegEx::IsValid ( ) const

Return true if this is a valid compiled regular expression, false otherwise.

bool wxRegEx::Matches (const wxChar * *text*, int *flags* = 0) const

Matches the precompiled regular expression against the string *text*, returns true if matches and false otherwise.

Flags may be combination of `wxRE_NOTBOL` and `wxRE_NOTEOL`, see wxRE_NOT_FLAGS.

Some regex libraries assume that the text given is null terminated, while others require the length be given as a separate parameter. Therefore for maximum portability assume that *text* cannot contain embedded nulls.

When the **Matches(const wxChar *text, int flags = 0)** form is used, a wxStrlen() will be done internally if the regex library requires the length. When using Matches() in a loop the **Matches(text, flags, len)** form can be used instead, making it possible to avoid a wxStrlen() inside the loop.

May only be called after successful call to Compile().

bool wxRegEx::Matches (const wxChar * *text*, int *flags*, size_t *len*) const

Matches the precompiled regular expression against the string *text*, returns true if matches and false otherwise.

Flags may be combination of `wxRE_NOTBOL` and `wxRE_NOTEOL`, see wxRE_NOT_FLAGS.

Some regex libraries assume that the text given is null terminated, while others require the length be given as a separate parameter. Therefore for maximum portability assume that *text* cannot contain embedded nulls.

When the **Matches(const wxChar *text, int flags = 0)** form is used, a wxStrlen() will be done internally if the regex library requires the length. When using Matches() in a loop the **Matches(text, flags, len)** form can be used instead, making it possible to avoid a wxStrlen() inside the loop.

May only be called after successful call to Compile().

bool wxRegEx::Matches (const wxString & *text*, int *flags* = 0) const

Matches the precompiled regular expression against the string *text*, returns true if matches and false otherwise.

Flags may be combination of `wxRE_NOTBOL` and `wxRE_NOTEOL`, see wxRE_NOT_FLAGS.

May only be called after successful call to Compile().

int wxRegEx::Replace (wxString * *text*, const wxString & *replacement*, size_t *maxMatches* = `0`) const

Replaces the current regular expression in the string pointed to by *text*, with the text in *replacement* and return number of matches replaced (maybe 0 if none found) or -1 on error.

The replacement text may contain back references `\number` which will be replaced with the value of the corresponding subexpression in the pattern match. `\0` corresponds to the entire match and `&` is a synonym for it. Backslash may be used to quote itself or `&` character.

maxMatches may be used to limit the number of replacements made, setting it to 1, for example, will only replace first occurrence (if any) of the pattern in the text while default value of 0 means replace all.

int wxRegEx::ReplaceAll (wxString * *text*, const wxString & *replacement*) const

Replace all occurrences: this is actually a synonym for Replace().

See also

ReplaceFirst()

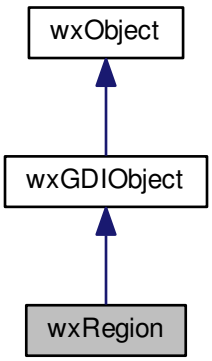
int wxRegEx::ReplaceFirst (wxString * *text*, const wxString & *replacement*) const

Replace the first occurrence.

21.588 wxRegion Class Reference

`#include <wx/region.h>`

Inheritance diagram for wxRegion:



21.588.1 Detailed Description

A wxRegion represents a simple or complex region on a device context or window.

This class uses reference counting and copy-on-write internally so that assignments between two instances of this class are very cheap. You can therefore use actual objects instead of pointers without efficiency problems. If an instance of this class is changed it will create its own data internally so that other instances, which previously shared the data using the reference counting, are not affected.

Predefined objects/pointers:

- wxNullRegion

Library: wxCore

Category: Data Structures, Graphics Device Interface (GDI)

See also

wxRegionIterator

Public Member Functions

- wxRegion ()

  Default constructor.
- wxRegion (wxCoord x, wxCoord y, wxCoord width, wxCoord height)

  Constructs a rectangular region with the given position and size.
- wxRegion (const wxPoint &topLeft, const wxPoint &bottomRight)

  Constructs a rectangular region from the top left point and the bottom right point.
- wxRegion (const wxRect &rect)

  Constructs a rectangular region a wxRect object.
- wxRegion (const wxRegion &region)

  Copy constructor, uses Reference Counting.
- wxRegion (size_t n, const wxPoint *points, wxPolygonFillMode fillStyle=wxODDEVEN_RULE)

  Constructs a region corresponding to the polygon made of n points in the provided array.
- wxRegion (const wxBitmap &bmp)

  Constructs a region using a bitmap.
- wxRegion (const wxBitmap &bmp, const wxColour &transColour, int tolerance=0)

  Constructs a region using the non-transparent pixels of a bitmap.
- virtual ~wxRegion ()

  Destructor.
- virtual void Clear ()

  Clears the current region.
- wxRegionContain Contains (wxCoord x, wxCoord y) const

  Returns a value indicating whether the given point is contained within the region.
- wxRegionContain Contains (const wxPoint &pt) const

  Returns a value indicating whether the given point is contained within the region.
- wxRegionContain Contains (wxCoord x, wxCoord y, wxCoord width, wxCoord height) const

  Returns a value indicating whether the given rectangle is contained within the region.
- wxRegionContain Contains (const wxRect &rect) const

  Returns a value indicating whether the given rectangle is contained within the region.
- wxBitmap ConvertToBitmap () const

Convert the region to a black and white bitmap with the white pixels being inside the region.

- bool Intersect (wxCoord x, wxCoord y, wxCoord width, wxCoord height)

  Finds the intersection of this region and another, rectangular region, specified using position and size.
- bool Intersect (const wxRect &rect)

  Finds the intersection of this region and another, rectangular region.
- bool Intersect (const wxRegion &region)

  Finds the intersection of this region and another region.
- virtual bool IsEmpty () const

  Returns true if the region is empty, false otherwise.
- bool IsEqual (const wxRegion &region) const

  Returns true if the region is equal to, i.e. covers the same area as, another one.
- bool Subtract (const wxRect &rect)

  Subtracts a rectangular region from this region.
- bool Subtract (const wxRegion &region)

  Subtracts a region from this region.
- bool Union (wxCoord x, wxCoord y, wxCoord width, wxCoord height)

  Finds the union of this region and another, rectangular region, specified using position and size.
- bool Union (const wxRect &rect)

  Finds the union of this region and another, rectangular region.
- bool Union (const wxRegion &region)

  Finds the union of this region and another region.
- bool Union (const wxBitmap &bmp)

  Finds the union of this region and the non-transparent pixels of a bitmap.
- bool Union (const wxBitmap &bmp, const wxColour &transColour, int tolerance=0)

  Finds the union of this region and the non-transparent pixels of a bitmap.
- bool Xor (wxCoord x, wxCoord y, wxCoord width, wxCoord height)

  Finds the Xor of this region and another, rectangular region, specified using position and size.
- bool Xor (const wxRect &rect)

  Finds the Xor of this region and another, rectangular region.
- bool Xor (const wxRegion &region)

  Finds the Xor of this region and another region.
- wxRegion & operator= (const wxRegion &region)

  Assignment operator, using Reference Counting.

- void GetBox (wxCoord &x, wxCoord &y, wxCoord &width, wxCoord &height) const

  Returns the outer bounds of the region.
- wxRect GetBox () const

  Returns the outer bounds of the region.

- bool Offset (wxCoord x, wxCoord y)

  Moves the region by the specified offsets in horizontal and vertical directions.
- bool Offset (const wxPoint &pt)

  Moves the region by the specified offsets in horizontal and vertical directions.

Additional Inherited Members

21.588.2 Constructor & Destructor Documentation

wxRegion::wxRegion ( )

Default constructor.

This constructor creates an invalid, or null, object, i.e. calling IsOk() on it returns false and IsEmpty() returns true.

wxRegion::wxRegion (wxCoord *x*, wxCoord *y*, wxCoord *width*, wxCoord *height*)

Constructs a rectangular region with the given position and size.

wxRegion::wxRegion (const wxPoint & *topLeft*, const wxPoint & *bottomRight*)

Constructs a rectangular region from the top left point and the bottom right point.

wxRegion::wxRegion (const wxRect & *rect*)

Constructs a rectangular region a wxRect object.

wxRegion::wxRegion (const wxRegion & *region*)

Copy constructor, uses Reference Counting.

wxRegion::wxRegion (size_t *n*, const wxPoint * *points*, wxPolygonFillMode *fillStyle* = wxODDEVEN_RULE)

Constructs a region corresponding to the polygon made of *n* points in the provided array.

fillStyle parameter may have values `wxWINDING_RULE` or `wxODDEVEN_RULE`.

wxRegion::wxRegion (const wxBitmap & *bmp*)

Constructs a region using a bitmap.

See Union() for more details.

wxRegion::wxRegion (const wxBitmap & *bmp*, const wxColour & *transColour*, int *tolerance* = 0)

Constructs a region using the non-transparent pixels of a bitmap.

See Union() for more details.

virtual wxRegion::~wxRegion ( ) [virtual]

Destructor.

See reference-counted object destruction for more info.

21.588.3 Member Function Documentation

virtual void wxRegion::Clear ( ) [virtual]

Clears the current region.

The object becomes invalid, or null, after being cleared.

wxRegionContain wxRegion::Contains (wxCoord *x*, wxCoord *y*) const

Returns a value indicating whether the given point is contained within the region.

This method always returns `wxOutRegion` for an invalid region but may, nevertheless, be safely called in this case.

Returns

The return value is one of `wxOutRegion` and `wxInRegion`.

wxRegionContain wxRegion::Contains (const wxPoint & *pt*) const

Returns a value indicating whether the given point is contained within the region.

This method always returns `wxOutRegion` for an invalid region but may, nevertheless, be safely called in this case.

Returns

The return value is one of `wxOutRegion` and `wxInRegion`.

wxRegionContain wxRegion::Contains (wxCoord *x,* wxCoord *y,* wxCoord *width,* wxCoord *height*) const

Returns a value indicating whether the given rectangle is contained within the region.

This method always returns `wxOutRegion` for an invalid region but may, nevertheless, be safely called in this case.

Returns

One of wxOutRegion, wxPartRegion or wxInRegion.

Note

On Windows, only wxOutRegion and wxInRegion are returned; a value wxInRegion then indicates that all or some part of the region is contained in this region.

wxRegionContain wxRegion::Contains (const wxRect & *rect*) const

Returns a value indicating whether the given rectangle is contained within the region.

This method always returns `wxOutRegion` for an invalid region but may, nevertheless, be safely called in this case.

Returns

One of wxOutRegion, wxPartRegion or wxInRegion.

Note

On Windows, only wxOutRegion and wxInRegion are returned; a value wxInRegion then indicates that all or some part of the region is contained in this region.

wxBitmap wxRegion::ConvertToBitmap ( ) const

Convert the region to a black and white bitmap with the white pixels being inside the region.

This method can't be used for invalid region.

void wxRegion::GetBox (wxCoord & *x,* wxCoord & *y,* wxCoord & *width,* wxCoord & *height*) const

Returns the outer bounds of the region.

This method returns 0-sized bounding box for invalid regions.

wxRect wxRegion::GetBox ( ) const

Returns the outer bounds of the region.

This method returns 0-sized bounding box for invalid regions.

bool wxRegion::Intersect (wxCoord *x,* wxCoord *y,* wxCoord *width,* wxCoord *height*)

Finds the intersection of this region and another, rectangular region, specified using position and size.

This method always fails, i.e. returns false, if this region is invalid but may nevertheless be safely used even in this case.

Returns

true if successful, false otherwise.

Remarks

Creates the intersection of the two regions, that is, the parts which are in both regions. The result is stored in this region.

bool wxRegion::Intersect (const wxRect & *rect*)

Finds the intersection of this region and another, rectangular region.

This method always fails, i.e. returns false, if this region is invalid but may nevertheless be safely used even in this case.

Returns

true if successful, false otherwise.

Remarks

Creates the intersection of the two regions, that is, the parts which are in both regions. The result is stored in this region.

bool wxRegion::Intersect (const wxRegion & *region*)

Finds the intersection of this region and another region.

This method always fails, i.e. returns false, if this region is invalid but may nevertheless be safely used even in this case.

Returns

true if successful, false otherwise.

Remarks

Creates the intersection of the two regions, that is, the parts which are in both regions. The result is stored in this region.

virtual bool wxRegion::IsEmpty ( ) const `[virtual]`

Returns true if the region is empty, false otherwise.

Always returns true if the region is invalid.

bool wxRegion::IsEqual (const wxRegion & *region*) const

Returns true if the region is equal to, i.e. covers the same area as, another one.

If both this region and *region* are both invalid, they are considered to be equal.

bool wxRegion::Offset (wxCoord *x*, wxCoord *y*)

Moves the region by the specified offsets in horizontal and vertical directions.

This method can't be called if the region is invalid as it doesn't make sense to offset it then. Attempts to do it will result in assert failure.

Returns

true if successful, false otherwise (the region is unchanged then).

bool wxRegion::Offset (const wxPoint & *pt*)

Moves the region by the specified offsets in horizontal and vertical directions.

This method can't be called if the region is invalid as it doesn't make sense to offset it then. Attempts to do it will result in assert failure.

Returns

true if successful, false otherwise (the region is unchanged then).

wxRegion& wxRegion::operator= (const wxRegion & *region*)

Assignment operator, using Reference Counting.

bool wxRegion::Subtract (const wxRect & *rect*)

Subtracts a rectangular region from this region.

This method always fails, i.e. returns false, if this region is invalid but may nevertheless be safely used even in this case.

Returns

true if successful, false otherwise.

Remarks

This operation combines the parts of 'this' region that are not part of the second region. The result is stored in this region.

bool wxRegion::Subtract (const wxRegion & *region*)

Subtracts a region from this region.

This method always fails, i.e. returns false, if this region is invalid but may nevertheless be safely used even in this case.

Returns

true if successful, false otherwise.

Remarks

This operation combines the parts of 'this' region that are not part of the second region. The result is stored in this region.

bool wxRegion::Union (wxCoord *x,* wxCoord *y,* wxCoord *width,* wxCoord *height*)

Finds the union of this region and another, rectangular region, specified using position and size.

This method can be used even if this region is invalid and has the natural behaviour in this case, i.e. makes this region equal to the given rectangle.

Returns

true if successful, false otherwise.

Remarks

This operation creates a region that combines all of this region and the second region. The result is stored in this region.

bool wxRegion::Union (const wxRect & *rect*)

Finds the union of this region and another, rectangular region.

This method can be used even if this region is invalid and has the natural behaviour in this case, i.e. makes this region equal to the given rectangle.

Returns

true if successful, false otherwise.

Remarks

This operation creates a region that combines all of this region and the second region. The result is stored in this region.

bool wxRegion::Union (const wxRegion & *region*)

Finds the union of this region and another region.

This method can be used even if this region is invalid and has the natural behaviour in this case, i.e. makes this region equal to the given *region*.

Returns

true if successful, false otherwise.

Remarks

This operation creates a region that combines all of this region and the second region. The result is stored in this region.

bool wxRegion::Union (const wxBitmap & *bmp*)

Finds the union of this region and the non-transparent pixels of a bitmap.

The bitmap's mask is used to determine transparency. If the bitmap doesn't have a mask, the bitmap's full dimensions are used.

Returns

true if successful, false otherwise.

Remarks

This operation creates a region that combines all of this region and the second region. The result is stored in this region.

bool wxRegion::Union (const wxBitmap & *bmp,* const wxColour & *transColour,* int *tolerance* = 0)

Finds the union of this region and the non-transparent pixels of a bitmap.

Colour to be treated as transparent is specified in the *transColour* argument, along with an optional colour tolerance value.

Returns

true if successful, false otherwise.

Remarks

This operation creates a region that combines all of this region and the second region. The result is stored in this region.

bool wxRegion::Xor (wxCoord *x,* wxCoord *y,* wxCoord *width,* wxCoord *height*)

Finds the Xor of this region and another, rectangular region, specified using position and size.

This method can be used even if this region is invalid and has the natural behaviour in this case, i.e. makes this region equal to the given rectangle.

Returns

true if successful, false otherwise.

Remarks

This operation creates a region that combines all of this region and the second region, except for any overlapping areas. The result is stored in this region.

bool wxRegion::Xor (const wxRect & *rect*)

Finds the Xor of this region and another, rectangular region.

This method can be used even if this region is invalid and has the natural behaviour in this case, i.e. makes this region equal to the given rectangle.

Returns

true if successful, false otherwise.

Remarks

This operation creates a region that combines all of this region and the second region, except for any overlapping areas. The result is stored in this region.

bool wxRegion::Xor (const wxRegion & *region*)

Finds the Xor of this region and another region.

This method can be used even if this region is invalid and has the natural behaviour in this case, i.e. makes this region equal to the given *region*.

Returns

true if successful, false otherwise.

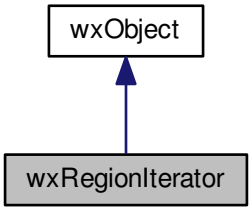
Remarks

This operation creates a region that combines all of this region and the second region, except for any overlapping areas. The result is stored in this region.

21.589 wxRegionIterator Class Reference

`#include <wx/region.h>`

Inheritance diagram for wxRegionIterator:



21.589.1 Detailed Description

This class is used to iterate through the rectangles in a region, typically when examining the damaged regions of a window within an OnPaint call.

To use it, construct an iterator object on the stack and loop through the regions, testing the object and incrementing the iterator at the end of the loop.

See wxPaintEvent for an example of use.

Library: wxCore

Category: Graphics Device Interface (GDI)

Predefined objects/pointers: wxNullRegion

See also

wxPaintEvent

Public Member Functions

- wxRegionIterator ()
  Default constructor.
- wxRegionIterator (const wxRegion &region)
  Creates an iterator object given a region.
- wxCoord GetH () const
  An alias for GetHeight().
- wxCoord GetHeight () const
  Returns the height value for the current region.
- wxRect GetRect () const
  Returns the current rectangle.
- wxCoord GetW () const
  An alias for GetWidth().
- wxCoord GetWidth () const
  Returns the width value for the current region.
- wxCoord GetX () const
  Returns the x value for the current region.
- wxCoord GetY () const
  Returns the y value for the current region.
- bool HaveRects () const
  Returns true if there are still some rectangles; otherwise returns false.
- void Reset ()
  Resets the iterator to the beginning of the rectangles.
- void Reset (const wxRegion &region)
  Resets the iterator to the given region.
- wxRegionIterator & operator++ ()
  Increment operator.
- operator bool () const
  Returns true if there are still some rectangles; otherwise returns false.

Additional Inherited Members

21.589.2 Constructor & Destructor Documentation

wxRegionIterator::wxRegionIterator ( )

Default constructor.

wxRegionIterator::wxRegionIterator (const wxRegion & *region*)

Creates an iterator object given a region.

21.589.3 Member Function Documentation

wxCoord wxRegionIterator::GetH ( ) const

An alias for GetHeight().

wxCoord wxRegionIterator::GetHeight ( ) const

Returns the height value for the current region.

wxRect wxRegionIterator::GetRect ( ) const

Returns the current rectangle.

wxCoord wxRegionIterator::GetW ( ) const

An alias for GetWidth().

wxCoord wxRegionIterator::GetWidth ( ) const

Returns the width value for the current region.

wxCoord wxRegionIterator::GetX ( ) const

Returns the x value for the current region.

wxCoord wxRegionIterator::GetY ( ) const

Returns the y value for the current region.

bool wxRegionIterator::HaveRects ( ) const

Returns true if there are still some rectangles; otherwise returns false.

wxRegionIterator::operator bool ( ) const

Returns true if there are still some rectangles; otherwise returns false.

You can use this to test the iterator object as if it were of type `bool`.

wxRegionIterator& wxRegionIterator::operator++ ( )

Increment operator.

Increments the iterator to the next region.

void wxRegionIterator::Reset ( )

Resets the iterator to the beginning of the rectangles.

void wxRegionIterator::Reset (const wxRegion & *region*)

Resets the iterator to the given region.

21.590 wxRegKey Class Reference

`#include <wx/msw/registry.h>`

21.590.1 Detailed Description

wxRegKey is a class representing the Windows registry (it is only available under Windows).

One can create, query and delete registry keys using this class.

The Windows registry is easy to understand. There are five registry keys, namely:

- `HKEY_CLASSES_ROOT` (HKCR)
- `HKEY_CURRENT_USER` (HKCU)
- `HKEY_LOCAL_MACHINE` (HKLM)
- `HKEY_CURRENT_CONFIG` (HKCC)
- `HKEY_USERS` (HKU)

After creating a key, it can hold a value. The values can be:

- String Value
- Binary Value
- DWORD Value
- Multi String Value
- Expandable String Value

Availability: only available for the wxMSW port.

Example:

```
// This assume that the key already exists, use HasSubKey() to check
// for the key existence if necessary.
wxRegKey key(wxRegKey::HKLM, "Software\\MyKey");

// Create a new value "MyValue" and set it to 12.
key.SetValue("MyValue", 12);

// Read the value back.
long value;
key.QueryValue("MyValue", &value);
wxMessageBox(wxString::Format("%d", value), "Registry Value",
      wxOK);

// Get the number of subkeys and enumerate them.
size_t subkeys;
key.GetKeyInfo(&subkeys, NULL, NULL, NULL);

wxString key_name;
key.GetFirstKey(key_name, 1);
for(int i = 0; i < subkeys; i++)
{
    wxMessageBox(key_name, "Subkey Name", wxOK);
    key.GetNextKey(key_name, 1);
}
```

Library: wxBase

Category: Application and System configuration

Public Types

- enum AccessMode {
  Read,
  Write }

  Access modes for wxRegKey.
- enum StdKey {
  HKCR,
  HKCU,
  HKLM,
  HKUSR,
  HKPD,
  HKCC,
  HKDD,
  HKMAX }

  The standard registry key enumerator.
- enum ValueType {
  Type_None,
  Type_String,
  Type_Expand_String,
  Type_Binary,
  Type_Dword,
  Type_Dword_little_endian,
  Type_Dword_big_endian,
  Type_Link,
  Type_Multi_String,
  Type_Resource_list,
  Type_Full_resource_descriptor,
  Type_Resource_requirements_list }

  The value type enumerator.
- enum WOW64ViewMode {
  WOW64ViewMode_Default,
  WOW64ViewMode_32,
  WOW64ViewMode_64 }

  Used to determine how the registry will be viewed, either as 32-bit or 64-bit.

Public Member Functions

- wxRegKey (WOW64ViewMode viewMode=WOW64ViewMode_Default)

  Default constructor, initializes to `HKEY_CLASSES_ROOT`.
- wxRegKey (const wxString &strKey, WOW64ViewMode viewMode=WOW64ViewMode_Default)

  The constructor to set the full name of the key.
- wxRegKey (StdKey keyParent, const wxString &strKey, WOW64ViewMode viewMode=WOW64ViewMode_Default)

  The constructor to set the full name of the key using one of the standard keys, that is, HKCR, HKCU, HKLM, HKUSR, HKPD, HKCC or HKDD.
- wxRegKey (const wxRegKey &keyParent, const wxString &strKey)

  The constructor to set the full name of the key under a previously created parent.
- void Close ()

Closes the key.

- bool Copy (const wxString &szNewName)

  Copy the entire contents of the key recursively to another location using the name.
- bool Copy (wxRegKey &keyDst)

  Copy the entire contents of the key recursively to another location using the key.
- bool CopyValue (const wxString &szValue, wxRegKey &keyDst, const wxString &szNewName=wxEmptyString)

  Copy the value to another key, possibly changing its name.
- bool Create (bool bOkIfExists=true)

  Creates the key.
- void DeleteKey (const wxString &szKey)

  Deletes the subkey with all its subkeys and values recursively.
- void DeleteSelf ()

  Deletes this key and all its subkeys and values recursively.
- void DeleteValue (const wxString &szKey)

  Deletes the named value or use an empty string argument to remove the default value of the key.
- bool Exists () const

  Returns true if the key exists.
- bool Export (const wxString &filename) const

  Write the contents of this key and all its subkeys to the given file.
- bool Export (wxOutputStream &ostr) const

  Write the contents of this key and all its subkeys to the opened stream.
- bool GetFirstKey (wxString &strKeyName, long &lIndex)

  Gets the first key.
- bool GetFirstValue (wxString &strValueName, long &lIndex)

  Gets the first value of this key.
- bool GetKeyInfo (size_t *pnSubKeys, size_t *pnMaxKeyLen, size_t *pnValues, size_t *pnMaxValueLen) const

  Gets information about the key.
- wxString GetName (bool bShortPrefix=true) const

  Gets the name of the registry key.
- WOW64ViewMode GetView () const

  Retrieves the registry view used by this key.
- bool GetNextKey (wxString &strKeyName, long &lIndex) const

  Gets the next key.
- bool GetNextValue (wxString &strValueName, long &lIndex) const

  Gets the next key value for this key.
- ValueType GetValueType (const wxString &szValue) const

  Gets the value type.
- bool HasSubKey (const wxString &szKey) const

  Returns true if given subkey exists.
- bool HasSubkeys () const

  Returns true if any subkeys exist.
- bool HasValue (const wxString &szValue) const

  Returns true if the value exists.
- bool HasValues () const

  Returns true if any values exist.
- bool IsEmpty () const

  Returns true if this key is empty, nothing under this key.
- bool IsNumericValue (const wxString &szValue) const

  Returns true if the value contains a number.

- bool IsOpened () const

  Returns true if the key is opened.
- bool Open (AccessMode mode=Write)

  Explicitly opens the key.
- wxRegKey & operator= (const wxString &strValue)

  Assignment operator to set the default value of the key.
- wxString QueryDefaultValue () const

  Return the default value of the key.
- bool QueryRawValue (const wxString &szValue, wxString &strValue) const

  Retrieves the raw string value.
- bool QueryValue (const wxString &szValue, wxString &strValue, bool raw) const

  Retrieves the raw or expanded string value.
- bool QueryValue (const wxString &szValue, long *plValue) const

  Retrieves the numeric value.
- bool QueryValue (const wxString &szValue, wxMemoryBuffer &buf) const

  Retrieves the binary structure.
- bool Rename (const wxString &szNewName)

  Renames the key.
- bool RenameValue (const wxString &szValueOld, const wxString &szValueNew)

  Renames a value.
- void ReserveMemoryForName (size_t bytes)

  Preallocate some memory for the name.
- void SetHkey (WXHKEY hKey)

  Set or change the HKEY handle.
- void SetName (const wxString &strKey)

  Set the full key name.
- void SetName (StdKey keyParent, const wxString &strKey)

  Set the name relative to the parent key.
- void SetName (const wxRegKey &keyParent, const wxString &strKey)

  Set the name relative to the parent key.
- bool SetValue (const wxString &szValue, long lValue)

  Sets the given szValue which must be numeric.
- bool SetValue (const wxString &szValue, const wxString &strValue)

  Sets the given szValue which must be string.
- bool SetValue (const wxString &szValue, const wxMemoryBuffer &buf)

  Sets the given szValue which must be binary.

21.590.2 Member Enumeration Documentation

enum wxRegKey::AccessMode

Access modes for wxRegKey.

Enumerator

Read Read-only.

Write Read and Write.

enum wxRegKey::StdKey

The standard registry key enumerator.

Enumerator

HKCR HKEY_CLASSES_ROOT.

HKCU HKEY_CURRENT_USER.

HKLM HKEY_LOCAL_MACHINE.

HKUSR HKEY_USERS.

HKPD HKEY_PERFORMANCE_DATA (Windows NT and 2K only)

HKCC HKEY_CURRENT_CONFIG.

HKDD HKEY_DYN_DATA (Windows 95 and 98 only)

HKMAX

enum wxRegKey::ValueType

The value type enumerator.

Enumerator

Type_None No value type.

Type_String Unicode null-terminated string.

Type_Expand_String Unicode null-terminated string (with environment variable references)

Type_Binary Free form binary.

Type_Dword 32-bit number

Type_Dword_little_endian 32-bit number (same as Type_Dword)

Type_Dword_big_endian 32-bit number

Type_Link Symbolic Link (Unicode)

Type_Multi_String Multiple Unicode strings.

Type_Resource_list Resource list in the resource map.

Type_Full_resource_descriptor Resource list in the hardware description.

Type_Resource_requirements_list

enum wxRegKey::WOW64ViewMode

Used to determine how the registry will be viewed, either as 32-bit or 64-bit.

Since

2.9.2

Enumerator

WOW64ViewMode_Default Uses 32-bit registry for 32-bit applications and 64-bit registry for 64-bit ones.

WOW64ViewMode_32 Can be used in 64-bit apps to access the 32-bit registry, has no effect (i.e. treated as default) in 32-bit apps.

WOW64ViewMode_64 Can be used in 32-bit apps to access the 64-bit registry, has no effect (i.e. treated as default) in 64-bit apps.

21.590.3 Constructor & Destructor Documentation

wxRegKey::wxRegKey (WOW64ViewMode *viewMode* = WOW64ViewMode_Default)

Default constructor, initializes to `HKEY_CLASSES_ROOT`.

The *viewMode* parameter is new since wxWidgets 2.9.2.

wxRegKey::wxRegKey (const wxString & *strKey,* WOW64ViewMode *viewMode* = WOW64ViewMode_Default)

The constructor to set the full name of the key.

The *viewMode* parameter is new since wxWidgets 2.9.2.

wxRegKey::wxRegKey (StdKey *keyParent,* const wxString & *strKey,* WOW64ViewMode *viewMode* = WOW64ViewMode_Default)

The constructor to set the full name of the key using one of the standard keys, that is, HKCR, HKCU, HKLM, HKUSR, HKPD, HKCC or HKDD.

The *viewMode* parameter is new since wxWidgets 2.9.2.

wxRegKey::wxRegKey (const wxRegKey & *keyParent,* const wxString & *strKey*)

The constructor to set the full name of the key under a previously created parent.

The registry view is inherited from the parent.

21.590.4 Member Function Documentation

void wxRegKey::Close ( )

Closes the key.

bool wxRegKey::Copy (const wxString & *szNewName*)

Copy the entire contents of the key recursively to another location using the name.

Returns true if successful.

bool wxRegKey::Copy (wxRegKey & *keyDst*)

Copy the entire contents of the key recursively to another location using the key.

Returns true if successful.

bool wxRegKey::CopyValue (const wxString & *szValue,* wxRegKey & *keyDst,* const wxString & *szNewName* = wxEmptyString)

Copy the value to another key, possibly changing its name.

By default it will remain the same. Returns true if successful.

bool wxRegKey::Create (bool *bOkIfExists* = `true`)

Creates the key.

Will fail if the key already exists and *bOkIfExists* is false. Returns true if successful.

void wxRegKey::DeleteKey (const wxString & *szKey*)

Deletes the subkey with all its subkeys and values recursively.

void wxRegKey::DeleteSelf ( )

Deletes this key and all its subkeys and values recursively.

void wxRegKey::DeleteValue (const wxString & *szKey*)

Deletes the named value or use an empty string argument to remove the default value of the key.

bool wxRegKey::Exists ( ) const

Returns true if the key exists.

bool wxRegKey::Export (const wxString & *filename*) const

Write the contents of this key and all its subkeys to the given file.

(The file will not be overwritten; it's an error if it already exists.) Note that we export the key in REGEDIT4 format, not RegSaveKey() binary format nor the newer REGEDIT5. Returns true if successful.

bool wxRegKey::Export (wxOutputStream & *ostr*) const

Write the contents of this key and all its subkeys to the opened stream.

Returns true if successful.

bool wxRegKey::GetFirstKey (wxString & *strKeyName,* long & *lIndex*)

Gets the first key.

Returns true if successful.

bool wxRegKey::GetFirstValue (wxString & *strValueName,* long & *lIndex*)

Gets the first value of this key.

Returns true if successful.

bool wxRegKey::GetKeyInfo (size_t * *pnSubKeys,* size_t * *pnMaxKeyLen,* size_t * *pnValues,* size_t * *pnMaxValueLen*) const

Gets information about the key.

Returns true if successful.

Parameters

pnSubKeys	The number of subkeys.
pnMaxKeyLen	The maximum length of the subkey name.
pnValues	The number of values.
pnMaxValueLen	The maximum length of a value.

wxString wxRegKey::GetName (bool *bShortPrefix* = `true`) const

Gets the name of the registry key.

bool wxRegKey::GetNextKey (wxString & *strKeyName,* long & *lIndex*) const

Gets the next key.

Returns true if successful.

bool wxRegKey::GetNextValue (wxString & *strValueName,* long & *lIndex*) const

Gets the next key value for this key.

Returns true if successful.

ValueType wxRegKey::GetValueType (const wxString & *szValue*) const

Gets the value type.

WOW64ViewMode wxRegKey::GetView ( ) const `[inline]`

Retrieves the registry view used by this key.

Since

2.9.2

Returns

The registry view given at the object's construction.

bool wxRegKey::HasSubKey (const wxString & *szKey*) const

Returns true if given subkey exists.

bool wxRegKey::HasSubkeys ( ) const

Returns true if any subkeys exist.

bool wxRegKey::HasValue (const wxString & *szValue*) const

Returns true if the value exists.

bool wxRegKey::HasValues ( ) const

Returns true if any values exist.

bool wxRegKey::IsEmpty ( ) const

Returns true if this key is empty, nothing under this key.

bool wxRegKey::IsNumericValue (const wxString & *szValue*) const

Returns true if the value contains a number.

bool wxRegKey::IsOpened ( ) const

Returns true if the key is opened.

bool wxRegKey::Open (AccessMode *mode* = Write)

Explicitly opens the key.

This method also allows the key to be opened in read-only mode by passing wxRegKey::Read instead of default wxRegKey::Write parameter. Returns true if successful.

wxRegKey& wxRegKey::operator= (const wxString & *strValue*)

Assignment operator to set the default value of the key.

wxString wxRegKey::QueryDefaultValue ( ) const

Return the default value of the key.

bool wxRegKey::QueryRawValue (const wxString & *szValue,* wxString & *strValue*) const

Retrieves the raw string value.

Returns true if successful. An empty *szValue* queries the default/unnamed key value.

bool wxRegKey::QueryValue (const wxString & *szValue,* wxString & *strValue,* bool *raw*) const

Retrieves the raw or expanded string value.

Returns true if successful. An empty *szValue* queries the default/unnamed key value.

bool wxRegKey::QueryValue (const wxString & *szValue,* long * *plValue*) const

Retrieves the numeric value.

Returns true if successful. An empty *szValue* queries the default/unnamed key value.

bool wxRegKey::QueryValue (const wxString & *szValue,* wxMemoryBuffer & *buf*) const

Retrieves the binary structure.

Returns true if successful. An empty *szValue* queries the default/unnamed key value.

bool wxRegKey::Rename (const wxString & *szNewName*)

Renames the key.

Returns true if successful.

bool wxRegKey::RenameValue (const wxString & *szValueOld,* const wxString & *szValueNew*)

Renames a value.

Returns true if successful.

void wxRegKey::ReserveMemoryForName (size_t *bytes*)

Preallocate some memory for the name.

For wxRegConfig usage only.

void wxRegKey::SetHkey (WXHKEY *hKey*)

Set or change the HKEY handle.

void wxRegKey::SetName (const wxString & *strKey*)

Set the full key name.

The name is absolute. It should start with HKEY_xxx.

void wxRegKey::SetName (StdKey *keyParent,* const wxString & *strKey*)

Set the name relative to the parent key.

void wxRegKey::SetName (const wxRegKey & *keyParent,* const wxString & *strKey*)

Set the name relative to the parent key.

bool wxRegKey::SetValue (const wxString & *szValue,* long *lValue*)

Sets the given *szValue* which must be numeric.

If the value doesn't exist, it is created. Returns true if successful. An empty *szValue* sets the default/unnamed key value.

bool wxRegKey::SetValue (const wxString & *szValue,* const wxString & *strValue*)

Sets the given *szValue* which must be string.

If the value doesn't exist, it is created. Returns true if successful. An empty *szValue* sets the default/unnamed key value.

bool wxRegKey::SetValue (const wxString & *szValue,* const wxMemoryBuffer & *buf*)

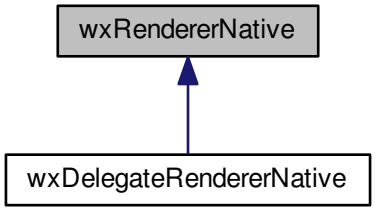
Sets the given *szValue* which must be binary.

If the value doesn't exist, it is created. Returns true if successful. An empty *szValue* sets the default/unnamed key value.

21.591 wxRendererNative Class Reference

`#include <wx/renderer.h>`

Inheritance diagram for wxRendererNative:



21.591.1 Detailed Description

First, a brief introduction to wxRendererNative and why it is needed.

Usually wxWidgets uses the underlying low level GUI system to draw all the controls - this is what we mean when we say that it is a "native" framework. However not all controls exist under all (or even any) platforms and in this case wxWidgets provides a default, generic, implementation of them written in wxWidgets itself.

These controls don't have the native appearance if only the standard line drawing and other graphics primitives are used, because the native appearance is different under different platforms while the lines are always drawn in the same way.

This is why we have renderers: wxRendererNative is a class which virtualizes the drawing, i.e. it abstracts the drawing operations and allows you to draw say, a button, without caring about exactly how this is done. Of course, as we can draw the button differently in different renderers, this also allows us to emulate the native look and feel.

So the renderers work by exposing a large set of high-level drawing functions which are used by the generic controls. There is always a default global renderer but it may be changed or extended by the user, see Render Sample.

All drawing functions take some standard parameters:

- *win* - The window being drawn. It is normally not used and when it is it should only be used as a generic wxWindow (in order to get its low level handle, for example), but you should not assume that it is of some given type as the same renderer function may be reused for drawing different kinds of control.
- *dc* - The wxDC to draw on. Only this device context should be used for drawing. It is not necessary to restore pens and brushes for it on function exit but, on the other hand, you shouldn't assume that it is in any specific state on function entry: the rendering functions should always prepare it.
- *rect* - The bounding rectangle for the element to be drawn.
- *flags* - The optional flags (none by default) which can be a combination of the wxCONTROL_FLAGS.

Note that each drawing function restores the wxDC attributes if it changes them, so it is safe to assume that the same pen, brush and colours that were active before the call to this function are still in effect after it.

Library: wxCore

Category: Graphics Device Interface (GDI)

Public Member Functions

- virtual ~wxRendererNative ()

  Virtual destructor as for any base class.
- virtual void DrawCheckBox (wxWindow *win, wxDC &dc, const wxRect &rect, int flags=0)=0

  Draw a check box.
- virtual void DrawComboBoxDropButton (wxWindow *win, wxDC &dc, const wxRect &rect, int flags=0)=0

  Draw a button like the one used by wxComboBox to show a drop down window.
- virtual void DrawDropArrow (wxWindow *win, wxDC &dc, const wxRect &rect, int flags=0)=0

  Draw a drop down arrow that is suitable for use outside a combo box.
- virtual void DrawFocusRect (wxWindow *win, wxDC &dc, const wxRect &rect, int flags=0)=0

  Draw a focus rectangle using the specified rectangle.
- virtual void DrawGauge (wxWindow *win, wxDC &dc, const wxRect &rect, int value, int max, int flags=0)=0

  Draw a progress bar in the specified rectangle.
- virtual int DrawHeaderButton (wxWindow *win, wxDC &dc, const wxRect &rect, int flags=0, wxHeaderSort↩IconType sortArrow=wxHDR_SORT_ICON_NONE, wxHeaderButtonParams *params=NULL)=0

  Draw the header control button (used, for example, by wxListCtrl).
- virtual int DrawHeaderButtonContents (wxWindow *win, wxDC &dc, const wxRect &rect, int flags=0, wx↩HeaderSortIconType sortArrow=wxHDR_SORT_ICON_NONE, wxHeaderButtonParams *params=NULL)=0

  Draw the contents of a header control button (label, sort arrows, etc.).
- virtual void DrawItemSelectionRect (wxWindow *win, wxDC &dc, const wxRect &rect, int flags=0)=0

  Draw a selection rectangle underneath the text as used e.g.
- virtual void DrawPushButton (wxWindow *win, wxDC &dc, const wxRect &rect, int flags=0)=0

  Draw a blank push button that looks very similar to wxButton.
- virtual void DrawSplitterBorder (wxWindow *win, wxDC &dc, const wxRect &rect, int flags=0)=0

  Draw the border for sash window: this border must be such that the sash drawn by DrawSplitterSash() blends into it well.
- virtual void DrawSplitterSash (wxWindow *win, wxDC &dc, const wxSize &size, wxCoord position, wx↩Orientation orient, int flags=0)=0

  Draw a sash.
- virtual void DrawTreeItemButton (wxWindow *win, wxDC &dc, const wxRect &rect, int flags=0)=0

  Draw the expanded/collapsed icon for a tree control item.
- virtual void DrawChoice (wxWindow *win, wxDC &dc, const wxRect &rect, int flags=0)=0

  Draw a native wxChoice.
- virtual void DrawComboBox (wxWindow *win, wxDC &dc, const wxRect &rect, int flags=0)=0

  Draw a native wxComboBox.
- virtual void DrawTextCtrl (wxWindow *win, wxDC &dc, const wxRect &rect, int flags=0)=0

  Draw a native wxTextCtrl frame.
- virtual void DrawRadioBitmap (wxWindow *win, wxDC &dc, const wxRect &rect, int flags=0)=0

  Draw a native wxRadioButton bitmap.
- virtual void DrawTitleBarBitmap (wxWindow *win, wxDC &dc, const wxRect &rect, wxTitleBarButton button, int flags=0)=0

  Draw a title bar button in the given state.

- virtual wxSize GetCheckBoxSize (wxWindow *win)=0

  Returns the size of a check box.
- virtual int GetHeaderButtonHeight (wxWindow *win)=0

  Returns the height of a header button, either a fixed platform height if available, or a generic height based on the win window's font.
- virtual int GetHeaderButtonMargin (wxWindow *win)=0

  Returns the horizontal margin on the left and right sides of header button's label.
- virtual wxSplitterRenderParams GetSplitterParams (const wxWindow *win)=0

  Get the splitter parameters, see wxSplitterRenderParams.
- virtual wxRendererVersion GetVersion () const =0

  This function is used for version checking: Load() refuses to load any shared libraries implementing an older or incompatible version.

Static Public Member Functions

- static wxRendererNative & Get ()

  Return the currently used renderer.
- static wxRendererNative & GetDefault ()

  Return the default (native) implementation for this platform – this is also the one used by default but this may be changed by calling Set() in which case the return value of this method may be different from the return value of Get().
- static wxRendererNative & GetGeneric ()

  Return the generic implementation of the renderer.
- static wxRendererNative * Load (const wxString &name)

  Load the renderer from the specified DLL, the returned pointer must be deleted by caller if not NULL when it is not used any more.
- static wxRendererNative * Set (wxRendererNative *renderer)

  Set the renderer to use, passing NULL reverts to using the default renderer (the global renderer must always exist).

21.591.2 Constructor & Destructor Documentation

virtual wxRendererNative::~wxRendererNative ( ) `[virtual]`

Virtual destructor as for any base class.

21.591.3 Member Function Documentation

virtual void wxRendererNative::DrawCheckBox (wxWindow * *win,* wxDC & *dc,* const wxRect & *rect,* int *flags* = `0`) `[pure virtual]`

Draw a check box.

flags may have the `wxCONTROL_CHECKED`, `wxCONTROL_CURRENT` or `wxCONTROL_UNDETERMINED` bit set, see wxCONTROL_FLAGS.

Implemented in wxDelegateRendererNative.

virtual void wxRendererNative::DrawChoice (wxWindow * *win,* wxDC & *dc,* const wxRect & *rect,* int *flags* = `0`) `[pure virtual]`

Draw a native wxChoice.

virtual void wxRendererNative::DrawComboBox (wxWindow * *win*, wxDC & *dc*, const wxRect & *rect*, int *flags* = 0) [pure virtual]

Draw a native wxComboBox.

virtual void wxRendererNative::DrawComboBoxDropButton (wxWindow * *win*, wxDC & *dc*, const wxRect & *rect*, int *flags* = 0) [pure virtual]

Draw a button like the one used by wxComboBox to show a drop down window.

The usual appearance is a downwards pointing arrow.

flags may have the wxCONTROL_PRESSED or wxCONTROL_CURRENT bit set, see wxCONTROL_FLAGS.

Implemented in wxDelegateRendererNative.

virtual void wxRendererNative::DrawDropArrow (wxWindow * *win*, wxDC & *dc*, const wxRect & *rect*, int *flags* = 0) [pure virtual]

Draw a drop down arrow that is suitable for use outside a combo box.

Arrow will have transparent background.

rect is not entirely filled by the arrow. Instead, you should use bounding rectangle of a drop down button which arrow matches the size you need.

flags may have the wxCONTROL_PRESSED or wxCONTROL_CURRENT bit set, see wxCONTROL_FLAGS.

Implemented in wxDelegateRendererNative.

virtual void wxRendererNative::DrawFocusRect (wxWindow * *win*, wxDC & *dc*, const wxRect & *rect*, int *flags* = 0) [pure virtual]

Draw a focus rectangle using the specified rectangle.

wxListCtrl.

The only supported flags is wxCONTROL_SELECTED for items which are selected. see wxCONTROL_FLAGS.

Implemented in wxDelegateRendererNative.

virtual void wxRendererNative::DrawGauge (wxWindow * *win*, wxDC & *dc*, const wxRect & *rect*, int *value*, int *max*, int *flags* = 0) [pure virtual]

Draw a progress bar in the specified rectangle.

The *value* and *max* arguments determine the part of the progress bar that is drawn as being filled in, *max* must be strictly positive and *value* must be between 0 and *max*.

Since

3.1.0

virtual int wxRendererNative::DrawHeaderButton (wxWindow * *win*, wxDC & *dc*, const wxRect & *rect*, int *flags* = 0, wxHeaderSortIconType *sortArrow* = wxHDR_SORT_ICON_NONE, wxHeaderButtonParams * *params* = NULL) [pure virtual]

Draw the header control button (used, for example, by wxListCtrl).

Depending on platforms the *flags* parameter may support the wxCONTROL_SELECTED wxCONTROL_DISABLED and wxCONTROL_CURRENT bits, see wxCONTROL_FLAGS.

Returns

The optimal width to contain the unabbreviated label text or bitmap, the sort arrow if present, and internal margins.

Implemented in wxDelegateRendererNative.

virtual int wxRendererNative::DrawHeaderButtonContents (wxWindow * *win*, wxDC & *dc*, const wxRect & *rect*, int *flags* = 0, wxHeaderSortIconType *sortArrow* = wxHDR_SORT_ICON_NONE, wxHeaderButtonParams * *params* = NULL) [pure virtual]

Draw the contents of a header control button (label, sort arrows, etc.).

This function is normally only called by DrawHeaderButton().

Depending on platforms the *flags* parameter may support the `wxCONTROL_SELECTED` `wxCONTROL_DISABLED` and `wxCONTROL_CURRENT` bits, see wxCONTROL_FLAGS.

Returns

The optimal width to contain the unabbreviated label text or bitmap, the sort arrow if present, and internal margins.

Implemented in wxDelegateRendererNative.

virtual void wxRendererNative::DrawItemSelectionRect (wxWindow * *win*, wxDC & *dc*, const wxRect & *rect*, int *flags* = 0) [pure virtual]

Draw a selection rectangle underneath the text as used e.g.

in a wxListCtrl.

The supported *flags* are `wxCONTROL_SELECTED` for items which are selected (e.g. often a blue rectangle) and `wxCONTROL_CURRENT` for the item that has the focus (often a dotted line around the item's text). `wxCONTROL_FOCUSED` may be used to indicate if the control has the focus (otherwise the selection rectangle is e.g. often grey and not blue). This may be ignored by the renderer or deduced by the code directly from the *win*.

Implemented in wxDelegateRendererNative.

virtual void wxRendererNative::DrawPushButton (wxWindow * *win*, wxDC & *dc*, const wxRect & *rect*, int *flags* = 0) [pure virtual]

Draw a blank push button that looks very similar to wxButton.

flags may have the `wxCONTROL_PRESSED`, `wxCONTROL_CURRENT` or `wxCONTROL_ISDEFAULT` bit set, see wxCONTROL_FLAGS.

Implemented in wxDelegateRendererNative.

virtual void wxRendererNative::DrawRadioBitmap (wxWindow * *win*, wxDC & *dc*, const wxRect & *rect*, int *flags* = 0) [pure virtual]

Draw a native wxRadioButton bitmap.

virtual void wxRendererNative::DrawSplitterBorder (wxWindow * *win*, wxDC & *dc*, const wxRect & *rect*, int *flags* = 0) [pure virtual]

Draw the border for sash window: this border must be such that the sash drawn by DrawSplitterSash() blends into it well.

Implemented in wxDelegateRendererNative.

virtual void wxRendererNative::DrawSplitterSash (wxWindow * *win,* wxDC & *dc,* const wxSize & *size,* wxCoord *position,* wxOrientation *orient,* int *flags* = 0) [pure virtual]

Draw a sash.

The *orient* parameter defines whether the sash should be vertical or horizontal and how the *position* should be interpreted.

Implemented in wxDelegateRendererNative.

virtual void wxRendererNative::DrawTextCtrl (wxWindow * *win,* wxDC & *dc,* const wxRect & *rect,* int *flags* = 0) [pure virtual]

Draw a native wxTextCtrl frame.

virtual void wxRendererNative::DrawTitleBarBitmap (wxWindow * *win,* wxDC & *dc,* const wxRect & *rect,* wxTitleBarButton *button,* int *flags* = 0) [pure virtual]

Draw a title bar button in the given state.

This function is currently only available under MSW and OS X (and only for wxTITLEBAR_BUTTON_CLOSE under the latter), its best replacement for the other platforms is to use wxArtProvider to retrieve the bitmaps for `wxART_HELP` and `wxART_CLOSE` (but not any other title bar buttons and not for any state but normal, i.e. not pressed and not current one).

The presence of this function is indicated by `wxHAS_DRAW_TITLE_BAR_BITMAP` symbol being defined.

Also notice that PNG handler must be enabled using wxImage::AddHandler() to use this function under OS X currently as the bitmaps are embedded in the library itself in PNG format.

Since

2.9.1

virtual void wxRendererNative::DrawTreeItemButton (wxWindow * *win,* wxDC & *dc,* const wxRect & *rect,* int *flags* = 0) [pure virtual]

Draw the expanded/collapsed icon for a tree control item.

To draw an expanded button the *flags* parameter must contain `wxCONTROL_EXPANDED` bit, see wxCONTROL_FLAGS.

Implemented in wxDelegateRendererNative.

static wxRendererNative& wxRendererNative::Get ( ) [static]

Return the currently used renderer.

virtual wxSize wxRendererNative::GetCheckBoxSize (wxWindow * *win*) [pure virtual]

Returns the size of a check box.

The *win* parameter is not used currently and can be NULL.

Implemented in wxDelegateRendererNative.

static wxRendererNative& wxRendererNative::GetDefault ( ) [static]

Return the default (native) implementation for this platform – this is also the one used by default but this may be changed by calling Set() in which case the return value of this method may be different from the return value of Get().

static wxRendererNative& wxRendererNative::GetGeneric ( ) [static]

Return the generic implementation of the renderer.

Under some platforms, this is the default renderer implementation, others have platform-specific default renderer which can be retrieved by calling GetDefault().

virtual int wxRendererNative::GetHeaderButtonHeight (wxWindow * *win*) [pure virtual]

Returns the height of a header button, either a fixed platform height if available, or a generic height based on the *win* window's font.

Implemented in wxDelegateRendererNative.

virtual int wxRendererNative::GetHeaderButtonMargin (wxWindow * *win*) [pure virtual]

Returns the horizontal margin on the left and right sides of header button's label.

Since

2.9.2

Implemented in wxDelegateRendererNative.

virtual wxSplitterRenderParams wxRendererNative::GetSplitterParams (const wxWindow * *win*) [pure virtual]

Get the splitter parameters, see wxSplitterRenderParams.

The *win* parameter should be a wxSplitterWindow.

Implemented in wxDelegateRendererNative.

virtual wxRendererVersion wxRendererNative::GetVersion ( ) const [pure virtual]

This function is used for version checking: Load() refuses to load any shared libraries implementing an older or incompatible version.

Remarks

The implementation of this method is always the same in all renderers (simply construct wxRendererVersion using the `wxRendererVersion::Current_XXX` values), but it has to be in the derived, not base, class, to detect mismatches between the renderers versions and so you have to implement it anew in all renderers.

Implemented in wxDelegateRendererNative.

static wxRendererNative* wxRendererNative::Load (const wxString & *name*) [static]

Load the renderer from the specified DLL, the returned pointer must be deleted by caller if not NULL when it is not used any more.

The *name* should be just the base name of the renderer and not the full name of the DLL file which is constructed differently (using wxDynamicLibrary::CanonicalizePluginName()) on different systems.

static wxRendererNative* wxRendererNative::Set (wxRendererNative * *renderer*) `[static]`

Set the renderer to use, passing NULL reverts to using the default renderer (the global renderer must always exist).

Return the previous renderer used with Set() or NULL if none.

21.592 wxRendererVersion Struct Reference

`#include <wx/renderer.h>`

21.592.1 Detailed Description

This simple struct represents the wxRendererNative interface version and is only used as the return value of wxRendererNative::GetVersion().

The version has two components: the version itself and the age. If the main program and the renderer have different versions they are never compatible with each other because the version is only changed when an existing virtual function is modified or removed. The age, on the other hand, is incremented each time a new virtual method is added and so, at least for the compilers using a common C++ object model, the calling program is compatible with any renderer which has the age greater or equal to its age. This verification is done by IsCompatible() method.

Library: wxCore

Category: Graphics Device Interface (GDI)

Public Member Functions

- wxRendererVersion (int version_, int age_)

Static Public Member Functions

- static bool IsCompatible (const wxRendererVersion &ver)

  Checks if the main program is compatible with the renderer having the version ver, returns true if it is and false otherwise.

Public Attributes

- const int age

  The age component.
- const int version

  The version component.

21.592.2 Constructor & Destructor Documentation

wxRendererVersion::wxRendererVersion (int *version_*, int *age_*)

21.592.3 Member Function Documentation

static bool wxRendererVersion::IsCompatible (const wxRendererVersion & *ver*) `[static]`

Checks if the main program is compatible with the renderer having the version *ver*, returns true if it is and false otherwise.

This method is used by wxRendererNative::Load() to determine whether a renderer can be used.

21.592.4 Member Data Documentation

const int wxRendererVersion::age

The age component.

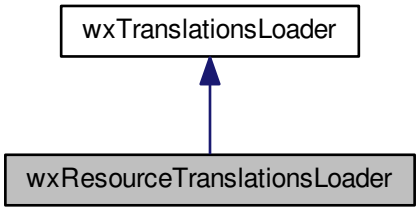
const int wxRendererVersion::version

The version component.

21.593 wxResourceTranslationsLoader Class Reference

`#include <wx/translation.h>`

Inheritance diagram for wxResourceTranslationsLoader:



21.593.1 Detailed Description

This loader makes it possible to load translations from Windows resources.

If you wish to store translation MO files in resources, you have to enable this loader before calling wxTranslations::AddCatalog() or wxLocale::AddCatalog():

```
wxTranslations::Get()->SetLoader(new
      wxResourceTranslationsLoader);
```

Translations are stored in resources as compiled MO files, with type set to "MOFILE" (unless you override GetResourceType()) and name consisting of the domain, followed by underscore, followed by language identification. For example, the relevant part of .rc file would look like this:

```
myapp_de      MOFILE   "catalogs/de/myapp.mo"
myapp_fr      MOFILE   "catalogs/fr/myapp.mo"
myapp_en_GB   MOFILE   "catalogs/en_GB/myapp.mo"
```

This class is only available on Windows.

Since

2.9.1

Protected Member Functions

- virtual wxString GetResourceType () const

  Returns resource type to use for translations.
- virtual WXHINSTANCE GetModule () const

  Returns handle of the module to load resources from.

Additional Inherited Members

21.593.2 Member Function Documentation

virtual WXHINSTANCE wxResourceTranslationsLoader::GetModule ( ) const `[protected], [virtual]`

Returns handle of the module to load resources from.

By default, the main executable is used.

virtual wxString wxResourceTranslationsLoader::GetResourceType ( ) const `[protected], [virtual]`

Returns resource type to use for translations.

Default type is "MOFILE".

21.594 wxRibbonArtProvider Class Reference

```
#include <wx/ribbon/art.h>
```

21.594.1 Detailed Description

wxRibbonArtProvider is responsible for drawing all the components of the ribbon interface.

This allows a ribbon bar to have a pluggable look-and-feel, while retaining the same underlying behaviour. As a single art provider is used for all ribbon components, a ribbon bar usually has a consistent (though unique) appearance.

By default, a wxRibbonBar uses an instance of this class called `wxRibbonDefaultArtProvider`, which resolves to `wxRibbonAUIArtProvider`, `wxRibbonMSWArtProvider`, or `wxRibbonOSXArtProvider` - whichever is most appropriate to the current platform. These art providers are all slightly configurable with regard to colours and fonts, but for larger modifications, you can derive from one of these classes, or write a completely new art provider class. Call wxRibbonBar::SetArtProvider to change the art provider being used.

Library: wxRibbon

Category: Ribbon User Interface

wxRibbonBar

Public Member Functions

- wxRibbonArtProvider ()

  Constructor.
- virtual ~wxRibbonArtProvider ()

  Destructor.
- virtual wxRibbonArtProvider * Clone () const =0

  Create a new art provider which is a clone of this one.
- virtual void SetFlags (long flags)=0

  Set the style flags.
- virtual long GetFlags () const =0

  Get the previously set style flags.
- virtual int GetMetric (int id) const =0

  Get the value of a certain integer setting.
- virtual void SetMetric (int id, int new_val)=0

  Set the value of a certain integer setting to the value new_val.
- virtual void SetFont (int id, const wxFont &font)=0

  Set the value of a certain font setting to the value font.
- virtual wxFont GetFont (int id) const =0

  Get the value of a certain font setting.
- virtual wxColour GetColour (int id) const =0

  Get the value of a certain colour setting.
- virtual void SetColour (int id, const wxColor &colour)=0

  Set the value of a certain colour setting to the value colour.
- wxColour GetColor (int id) const
- void SetColor (int id, const wxColour &color)
- virtual void GetColourScheme (wxColour *primary, wxColour *secondary, wxColour *tertiary) const =0

  Get the current colour scheme.
- virtual void SetColourScheme (const wxColour &primary, const wxColour &secondary, const wxColour &tertiary)=0

  Set all applicable colour settings from a few base colours.
- virtual void DrawTabCtrlBackground (wxDC &dc, wxWindow *wnd, const wxRect &rect)=0

  Draw the background of the tab region of a ribbon bar.
- virtual void DrawTab (wxDC &dc, wxWindow *wnd, const wxRibbonPageTabInfo &tab)=0

  Draw a single tab in the tab region of a ribbon bar.
- virtual void DrawTabSeparator (wxDC &dc, wxWindow *wnd, const wxRect &rect, double visibility)=0

  Draw a separator between two tabs in a ribbon bar.
- virtual void DrawPageBackground (wxDC &dc, wxWindow *wnd, const wxRect &rect)=0

  Draw the background of a ribbon page.
- virtual void DrawScrollButton (wxDC &dc, wxWindow *wnd, const wxRect &rect, long style)=0

  Draw a ribbon-style scroll button.
- virtual void DrawPanelBackground (wxDC &dc, wxRibbonPanel *wnd, const wxRect &rect)=0

  Draw the background and chrome for a ribbon panel.
- virtual void DrawGalleryBackground (wxDC &dc, wxRibbonGallery *wnd, const wxRect &rect)=0

  Draw the background and chrome for a wxRibbonGallery control.
- virtual void DrawGalleryItemBackground (wxDC &dc, wxRibbonGallery *wnd, const wxRect &rect, wxRibbonGalleryItem *item)=0

  Draw the background of a single item in a wxRibbonGallery control.

- virtual void DrawMinimisedPanel (wxDC &dc, wxRibbonPanel *wnd, const wxRect &rect, wxBitmap &bitmap)=0

  Draw a minimised ribbon panel.
- virtual void DrawButtonBarBackground (wxDC &dc, wxWindow *wnd, const wxRect &rect)=0

  Draw the background for a wxRibbonButtonBar control.
- virtual void DrawButtonBarButton (wxDC &dc, wxWindow *wnd, const wxRect &rect, wxRibbonButtonBarButtonKind kind, long state, const wxString &label, const wxBitmap &bitmap_large, const wxBitmap &bitmap_small)=0

  Draw a single button for a wxRibbonButtonBar control.
- virtual void DrawToolBarBackground (wxDC &dc, wxWindow *wnd, const wxRect &rect)=0

  Draw the background for a wxRibbonToolBar control.
- virtual void DrawToolGroupBackground (wxDC &dc, wxWindow *wnd, const wxRect &rect)=0

  Draw the background for a group of tools on a wxRibbonToolBar control.
- virtual void DrawTool (wxDC &dc, wxWindow *wnd, const wxRect &rect, const wxBitmap &bitmap, wxRibbonButtonKind kind, long state)=0

  Draw a single tool (for a wxRibbonToolBar control).
- virtual void DrawToggleButton (wxDC &dc, wxRibbonBar *wnd, const wxRect &rect, wxRibbonDisplayMode mode)=0

  Draw toggle button on wxRibbonBar.
- virtual void DrawHelpButton (wxDC &dc, wxRibbonBar *wnd, const wxRect &rect)=0

  Draw help button on wxRibbonBar.
- virtual void GetBarTabWidth (wxDC &dc, wxWindow *wnd, const wxString &label, const wxBitmap &bitmap, int *ideal, int *small_begin_need_separator, int *small_must_have_separator, int *minimum)=0

  Calculate the ideal and minimum width (in pixels) of a tab in a ribbon bar.
- virtual int GetTabCtrlHeight (wxDC &dc, wxWindow *wnd, const wxRibbonPageTabInfoArray &pages)=0

  Calculate the height (in pixels) of the tab region of a ribbon bar.
- virtual wxSize GetScrollButtonMinimumSize (wxDC &dc, wxWindow *wnd, long style)=0

  Calculate the minimum size (in pixels) of a scroll button.
- virtual wxSize GetPanelSize (wxDC &dc, const wxRibbonPanel *wnd, wxSize client_size, wxPoint *client_offset)=0

  Calculate the size of a panel for a given client size.
- virtual wxSize GetPanelClientSize (wxDC &dc, const wxRibbonPanel *wnd, wxSize size, wxPoint *client_offset)=0

  Calculate the client size of a panel for a given overall size.
- virtual wxRect GetPanelExtButtonArea (wxDC &dc, const wxRibbonPanel *wnd, wxRect rect)=0

  Calculate the position and size of the panel extension button.
- virtual wxSize GetGallerySize (wxDC &dc, const wxRibbonGallery *wnd, wxSize client_size)=0

  Calculate the size of a wxRibbonGallery control for a given client size.
- virtual wxSize GetGalleryClientSize (wxDC &dc, const wxRibbonGallery *wnd, wxSize size, wxPoint *client_offset, wxRect *scroll_up_button, wxRect *scroll_down_button, wxRect *extension_button)=0

  Calculate the client size of a wxRibbonGallery control for a given size.
- virtual wxRect GetPageBackgroundRedrawArea (wxDC &dc, const wxRibbonPage *wnd, wxSize page_old_size, wxSize page_new_size)=0

  Calculate the portion of a page background which needs to be redrawn when a page is resized.
- virtual bool GetButtonBarButtonSize (wxDC &dc, wxWindow *wnd, wxRibbonButtonBarButtonKind kind, wxRibbonButtonBarButtonState size, const wxString &label, wxSize bitmap_size_large, wxSize bitmap_size_small, wxSize *button_size, wxRect *normal_region, wxRect *dropdown_region)=0

  Calculate the size of a button within a wxRibbonButtonBar.
- virtual wxSize GetMinimisedPanelMinimumSize (wxDC &dc, const wxRibbonPanel *wnd, wxSize *desired_bitmap_size, wxDirection *expanded_panel_direction)=0

  Calculate the size of a minimised ribbon panel.
- virtual wxSize GetToolSize (wxDC &dc, wxWindow *wnd, wxSize bitmap_size, wxRibbonButtonKind kind, bool is_first, bool is_last, wxRect *dropdown_region)=0

Calculate the size of a tool within a wxRibbonToolBar.

- virtual wxRect GetBarToggleButtonArea (const wxRect &rect)=0

  Calculate the position and size of the ribbon's toggle button.

- virtual wxRect GetRibbonHelpButtonArea (const wxRect &rect)=0

  Calculate the position and size of the ribbon's help button.

21.594.2 Constructor & Destructor Documentation

wxRibbonArtProvider::wxRibbonArtProvider ( )

Constructor.

virtual wxRibbonArtProvider::~wxRibbonArtProvider ( ) [virtual]

Destructor.

21.594.3 Member Function Documentation

virtual wxRibbonArtProvider* wxRibbonArtProvider::Clone ( ) const [pure virtual]

Create a new art provider which is a clone of this one.

virtual void wxRibbonArtProvider::DrawButtonBarBackground (wxDC & *dc*, wxWindow * *wnd*, const wxRect & *rect*) [pure virtual]

Draw the background for a wxRibbonButtonBar control.

Parameters

dc	The device context to draw onto.
wnd	The window which is being drawn onto (which will typically be the button bar itself, though this is not guaranteed).
rect	The rectangle within which to draw.

virtual void wxRibbonArtProvider::DrawButtonBarButton (wxDC & *dc*, wxWindow * *wnd*, const wxRect & *rect*, wxRibbonButtonBarButtonKind *kind*, long *state*, const wxString & *label*, const wxBitmap & *bitmap_large*, const wxBitmap & *bitmap_small*) [pure virtual]

Draw a single button for a wxRibbonButtonBar control.

Parameters

dc	The device context to draw onto.
wnd	The window which is being drawn onto.
rect	The rectangle within which to draw. The size of this rectangle will be a size previously returned by GetButtonBarButtonSize(), and the rectangle will be entirely within a rectangle on the same device context previously painted with DrawButtonBarBackground().
kind	The kind of button to draw (normal, dropdown or hybrid).
state	Combination of a size flag and state flags from the wxRibbonButtonBarButtonState enumeration.

label	The label of the button.
bitmap_large	The large bitmap of the button (or the large disabled bitmap when wxRIBBON_BUTTONBAR_BUTTON_DISABLED is set in *state*).
bitmap_small	The small bitmap of the button (or the small disabled bitmap when wxRIBBON_BUTTONBAR_BUTTON_DISABLED is set in *state*).

virtual void wxRibbonArtProvider::DrawGalleryBackground (wxDC & *dc*, wxRibbonGallery * *wnd*, const wxRect & *rect*) [pure virtual]

Draw the background and chrome for a wxRibbonGallery control.

This should draw the border, background, scroll buttons, extension button, and any other UI elements which are not attached to a specific gallery item.

Parameters

dc	The device context to draw onto.
wnd	The window which is being drawn onto, which is always the gallery whose background and chrome is being drawn. Attributes used during drawing like the gallery hover state and individual button states can be queried from this parameter by wxRibbonGallery::IsHovered(), wxRibbonGallery::GetExtensionButtonState(), wxRibbonGallery::GetUpButtonState(), and wxRibbonGallery::GetDownButtonState().
rect	The rectangle within which to draw. This rectangle is the entire area of the gallery control, not just the client rectangle.

virtual void wxRibbonArtProvider::DrawGalleryItemBackground (wxDC & *dc*, wxRibbonGallery * *wnd*, const wxRect & *rect*, wxRibbonGalleryItem * *item*) [pure virtual]

Draw the background of a single item in a wxRibbonGallery control.

This is painted on top of a gallery background, and behind the items bitmap. Unlike DrawButtonBarButton() and DrawTool(), it is not expected to draw the item bitmap - that is done by the gallery control itself.

Parameters

dc	The device context to draw onto.
wnd	The window which is being drawn onto, which is always the gallery which contains the item being drawn.
rect	The rectangle within which to draw. The size of this rectangle will be the size of the item's bitmap, expanded by gallery item padding values (wxRIBBON_ART_GALLERY_BITMAP_PADDING_LEFT_SIZE, wxRIBBON_ART_GALLERY_BITMAP_PADDING_RIGHT_SIZE, wxRIBBON_ART_GALLERY_BITMAP_PADDING_TOP_SIZE, and wxRIBBON_ART_GALLERY_BITMAP_PADDING_BOTTOM_SIZE). The drawing rectangle will be entirely within a rectangle on the same device context previously painted with DrawGalleryBackground().
item	The item whose background is being painted. Typically the background will vary if the item is hovered, active, or selected; wxRibbonGallery::GetSelection(), wxRibbonGallery::GetActiveItem(), and wxRibbonGallery::GetHoveredItem() can be called to test if the given item is in one of these states.

virtual void wxRibbonArtProvider::DrawHelpButton (wxDC & *dc*, wxRibbonBar * *wnd*, const wxRect & *rect*) [pure virtual]

Draw help button on wxRibbonBar.

This should draw a help button at top right corner of ribbon bar.

Parameters

dc	The device context to draw onto.
wnd	The window which is being drawn onto, which is always the panel whose background and chrome is being drawn. The panel label and other panel attributes can be obtained by querying this.
rect	The rectangle within which to draw.

Since

2.9.5

virtual void wxRibbonArtProvider::DrawMinimisedPanel (wxDC & *dc*, wxRibbonPanel * *wnd*, const wxRect & *rect*, wxBitmap & *bitmap*) [pure virtual]

Draw a minimised ribbon panel.

Parameters

dc	The device context to draw onto.
wnd	The window which is being drawn onto, which is always the panel which is minimised. The panel label can be obtained from this window. The minimised icon obtained from querying the window may not be the size requested by GetMinimisedPanelMinimumSize() - the *bitmap* argument contains the icon in the requested size.
rect	The rectangle within which to draw. The size of the rectangle will be at least the size returned by GetMinimisedPanelMinimumSize().
bitmap	A copy of the panel's minimised bitmap rescaled to the size returned by GetMinimisedPanelMinimumSize().

virtual void wxRibbonArtProvider::DrawPageBackground (wxDC & *dc*, wxWindow * *wnd*, const wxRect & *rect*) [pure virtual]

Draw the background of a ribbon page.

Parameters

dc	The device context to draw onto.
wnd	The window which is being drawn onto (which is commonly the wxRibbonPage whose background is being drawn, but doesn't have to be).
rect	The rectangle within which to draw.

See also

GetPageBackgroundRedrawArea

virtual void wxRibbonArtProvider::DrawPanelBackground (wxDC & *dc*, wxRibbonPanel * *wnd*, const wxRect & *rect*) [pure virtual]

Draw the background and chrome for a ribbon panel.

This should draw the border, background, label, and any other items of a panel which are outside the client area of a panel.

Note that when a panel is minimised, this function is not called - only DrawMinimisedPanel() is called, so a background should be explicitly painted by that if required.

Parameters

dc	The device context to draw onto.
wnd	The window which is being drawn onto, which is always the panel whose background and chrome is being drawn. The panel label and other panel attributes can be obtained by querying this.
rect	The rectangle within which to draw.

virtual void wxRibbonArtProvider::DrawScrollButton (wxDC & *dc*, wxWindow * *wnd*, const wxRect & *rect*, long *style*) [pure virtual]

Draw a ribbon-style scroll button.

Parameters

dc	The device context to draw onto.
wnd	The window which is being drawn onto.
rect	The rectangle within which to draw. The size of this rectangle will be at least the size returned by GetScrollButtonMinimumSize() for a scroll button with the same style. For tab scroll buttons, this rectangle will be entirely within a rectangle on the same device context previously painted with DrawTabCtrlBackground(), but this is not guaranteed for other types of button (for example, page scroll buttons will not be painted on an area previously painted with DrawPageBackground()).
style	A combination of flags from wxRibbonScrollButtonStyle, including a direction, a for flag, and one or more states.

virtual void wxRibbonArtProvider::DrawTab (wxDC & *dc*, wxWindow * *wnd*, const wxRibbonPageTabInfo & *tab*) [pure virtual]

Draw a single tab in the tab region of a ribbon bar.

Parameters

dc	The device context to draw onto.
wnd	The window which is being drawn onto (not the wxRibbonPage associated with the tab being drawn).
tab	The rectangle within which to draw, and also the tab label, icon, and state (active and/or hovered). The drawing rectangle will be entirely within a rectangle on the same device context previously painted with DrawTabCtrlBackground(). The rectangle's width will be at least the minimum value returned by GetBarTabWidth(), and height will be the value returned by GetTabCtrlHeight().

virtual void wxRibbonArtProvider::DrawTabCtrlBackground (wxDC & *dc*, wxWindow * *wnd*, const wxRect & *rect*) [pure virtual]

Draw the background of the tab region of a ribbon bar.

Parameters

dc	The device context to draw onto.
wnd	The window which is being drawn onto.
rect	The rectangle within which to draw.

virtual void wxRibbonArtProvider::DrawTabSeparator (wxDC & *dc,* wxWindow * *wnd,* const wxRect & *rect,* double *visibility*) `[pure virtual]`

Draw a separator between two tabs in a ribbon bar.

Parameters

dc	The device context to draw onto.
wnd	The window which is being drawn onto.
rect	The rectangle within which to draw, which will be entirely within a rectangle on the same device context previously painted with DrawTabCtrlBackground().
visibility	The opacity with which to draw the separator. Values are in the range [0, 1], with 0 being totally transparent, and 1 being totally opaque.

virtual void wxRibbonArtProvider::DrawToggleButton (wxDC & *dc,* wxRibbonBar * *wnd,* const wxRect & *rect,* wxRibbonDisplayMode *mode*) [pure virtual]

Draw toggle button on wxRibbonBar.

This should draw a small toggle button at top right corner of ribbon bar.

Parameters

dc	The device context to draw onto.
wnd	The window which is being drawn onto, which is always the panel whose background and chrome is being drawn. The panel label and other panel attributes can be obtained by querying this.
rect	The rectangle within which to draw.
mode	The wxRibbonDisplayMode which should be applied to display button

Since

2.9.5

virtual void wxRibbonArtProvider::DrawTool (wxDC & *dc,* wxWindow * *wnd,* const wxRect & *rect,* const wxBitmap & *bitmap,* wxRibbonButtonKind *kind,* long *state*) [pure virtual]

Draw a single tool (for a wxRibbonToolBar control).

Parameters

dc	The device context to draw onto.
wnd	The window which is being drawn onto. In most cases this will be a wxRibbonToolBar, but it doesn't have to be.
rect	The rectangle within which to draw. The size of this rectangle will at least the size returned by GetToolSize(), and the height of it will be equal for all tools within the same group. The rectangle will be entirely within a rectangle on the same device context previously painted with DrawToolGroupBackground().
bitmap	The bitmap to use as the tool's foreground. If the tool is a hybrid or dropdown tool, then the foreground should also contain a standard dropdown button.
kind	The kind of tool to draw (normal, dropdown, or hybrid).
state	A combination of wxRibbonToolBarToolState flags giving the state of the tool and it's relative position within a tool group.

virtual void wxRibbonArtProvider::DrawToolBarBackground (wxDC & *dc,* wxWindow * *wnd,* const wxRect & *rect*) [pure virtual]

Draw the background for a wxRibbonToolBar control.

Parameters

dc	The device context to draw onto.
wnd	The which is being drawn onto. In most cases this will be a wxRibbonToolBar, but it doesn't have to be.
rect	The rectangle within which to draw. Some of this rectangle will later be drawn over using DrawToolGroupBackground() and DrawTool(), but not all of it will (unless there is only a single group of tools).

virtual void wxRibbonArtProvider::DrawToolGroupBackground (wxDC & *dc,* wxWindow * *wnd,* const wxRect & *rect*) [pure virtual]

Draw the background for a group of tools on a wxRibbonToolBar control.

Parameters

dc	The device context to draw onto.
wnd	The window which is being drawn onto. In most cases this will be a wxRibbonToolBar, but it doesn't have to be.
rect	The rectangle within which to draw. This rectangle is a union of the individual tools' rectangles. As there are no gaps between tools, this rectangle will be painted over exactly once by calls to DrawTool(). The group background could therefore be painted by DrawTool(), though it can be conceptually easier and more efficient to draw it all at once here. The rectangle will be entirely within a rectangle on the same device context previously painted with DrawToolBarBackground().

virtual void wxRibbonArtProvider::GetBarTabWidth (wxDC & *dc,* wxWindow * *wnd,* const wxString & *label,* const wxBitmap & *bitmap,* int * *ideal,* int * *small_begin_need_separator,* int * *small_must_have_separator,* int * *minimum*) [pure virtual]

Calculate the ideal and minimum width (in pixels) of a tab in a ribbon bar.

Parameters

	dc	A device context to use when one is required for size calculations.
	wnd	The window onto which the tab will eventually be drawn.
	label	The tab's label (or wxEmptyString if it has none).
	bitmap	The tab's icon (or wxNullBitmap if it has none).
out	*ideal*	The ideal width (in pixels) of the tab.
out	*small_begin_need_separator*	A size less than the *ideal* size, at which a tab separator should begin to be drawn (i.e. drawn, but still fairly transparent).
out	*small_must_have_separator*	A size less than the *small_begin_need_separator* size, at which a tab separator must be drawn (i.e. drawn at full opacity).
out	*minimum*	A size less than the *small_must_have_separator* size, and greater than or equal to zero, which is the minimum pixel width for the tab.

virtual wxRect wxRibbonArtProvider::GetBarToggleButtonArea (const wxRect & *rect*) [pure virtual]

Calculate the position and size of the ribbon's toggle button.

Parameters

rect	The ribbon bar rectangle from which calculate toggle button rectangle.

Since

2.9.5

virtual bool wxRibbonArtProvider::GetButtonBarButtonSize (wxDC & *dc*, wxWindow * *wnd*, wxRibbonButtonBarButtonKind *kind*, wxRibbonButtonBarButtonState *size*, const wxString & *label*, wxSize *bitmap_size_large*, wxSize *bitmap_size_small*, wxSize * *button_size*, wxRect * *normal_region*, wxRect * *dropdown_region*) [pure virtual]

Calculate the size of a button within a wxRibbonButtonBar.

Parameters

	dc	A device context to use when one is required for size calculations.
	wnd	The window onto which the button will eventually be drawn (which is normally a wxRibbonButtonBar, though this is not guaranteed).
	kind	The kind of button.
	size	The size-class to calculate the size for. Buttons on a button bar can have three distinct sizes: wxRIBBON_BUTTONBAR_BUTTON_SMALL, wxRIBBON_BUTTONBAR_BUTTON_MEDIUM, and wxRIBBON_BUTTONBAR_BUTTON_LARGE. If the requested size-class is not applicable, then false should be returned.
	label	The label of the button.
	bitmap_size_large	The size of all "large" bitmaps on the button bar.
	bitmap_size_small	The size of all "small" bitmaps on the button bar.
out	*button_size*	The size, in pixels, of the button.
out	*normal_region*	The region of the button which constitutes the normal button.
out	*dropdown_region*	The region of the button which constitutes the dropdown button.

Returns

true if a size exists for the button, false otherwise.

wxColour wxRibbonArtProvider::GetColor (int *id*) const

See also

wxRibbonArtProvider::GetColour()

virtual wxColour wxRibbonArtProvider::GetColour (int *id*) const [pure virtual]

Get the value of a certain colour setting.

id can be one of the colour values of wxRibbonArtSetting.

virtual void wxRibbonArtProvider::GetColourScheme (wxColour * *primary*, wxColour * *secondary*, wxColour * *tertiary*) const [pure virtual]

Get the current colour scheme.

Returns three colours such that if SetColourScheme() were called with them, the colour scheme would be restored to what it was when SetColourScheme() was last called. In practice, this usually means that the returned values are the three colours given in the last call to SetColourScheme(), however if SetColourScheme() performs an idempotent operation upon the colours it is given (like clamping a component of the colour), then the returned values may not be

the three colours given in the last call to SetColourScheme(). If SetColourScheme() has not been called, then the returned values should result in a colour scheme similar to, if not identical to, the default colours of the art provider. Note that if SetColour() is called, then GetColourScheme() does not try and return a colour scheme similar to colours being used - it's return values are dependent upon the last values given to SetColourScheme(), as described above.

Parameters

out	*primary*	Pointer to a location to store the primary colour, or NULL.
out	*secondary*	Pointer to a location to store the secondary colour, or NULL.
out	*tertiary*	Pointer to a location to store the tertiary colour, or NULL.

virtual long wxRibbonArtProvider::GetFlags ( ) const `[pure virtual]`

Get the previously set style flags.

virtual wxFont wxRibbonArtProvider::GetFont (int *id*) const `[pure virtual]`

Get the value of a certain font setting.

id can be one of the font values of wxRibbonArtSetting.

virtual wxSize wxRibbonArtProvider::GetGalleryClientSize (wxDC & *dc*, const wxRibbonGallery * *wnd*, wxSize *size*, wxPoint * *client_offset*, wxRect * *scroll_up_button*, wxRect * *scroll_down_button*, wxRect * *extension_button*) `[pure virtual]`

Calculate the client size of a wxRibbonGallery control for a given size.

This should act as the inverse to GetGallerySize(), and decrement the given size by enough to fir the gallery border, buttons, and other chrome.

Parameters

	dc	A device context to use if one is required for size calculations.
	wnd	The gallery in question.
	size	The overall size to calculate the client size for.
out	*client_offset*	The position within the given size at which the returned client size begins.
out	*scroll_up_button*	The rectangle within the given size which the scroll up button occupies.
out	*scroll_down_button*	The rectangle within the given size which the scroll down button occupies.
out	*extension_button*	The rectangle within the given size which the extension button occupies.

virtual wxSize wxRibbonArtProvider::GetGallerySize (wxDC & *dc*, const wxRibbonGallery * *wnd*, wxSize *client_size*) `[pure virtual]`

Calculate the size of a wxRibbonGallery control for a given client size.

This should increment the given size by enough to fit the gallery border, buttons, and any other chrome.

Parameters

dc	A device context to use if one is required for size calculations.
wnd	The gallery in question.
client_size	The client size.

See also

GetGalleryClientSize()

virtual int wxRibbonArtProvider::GetMetric (int *id*) const [pure virtual]

Get the value of a certain integer setting.

id can be one of the size values of wxRibbonArtSetting.

virtual wxSize wxRibbonArtProvider::GetMinimisedPanelMinimumSize (wxDC & *dc*, const wxRibbonPanel * *wnd*, wxSize * *desired_bitmap_size*, wxDirection * *expanded_panel_direction*) [pure virtual]

Calculate the size of a minimised ribbon panel.

Parameters

	dc	A device context to use when one is required for size calculations.
	wnd	The ribbon panel in question. Attributes like the panel label can be queried from this.
out	*desired_bitmap_size*	Optional parameter which is filled with the size of the bitmap suitable for a minimised ribbon panel.
out	*expanded_panel_direction*	Optional parameter which is filled with the direction of the minimised panel (wxEAST or wxSOUTH depending on the style).

virtual wxRect wxRibbonArtProvider::GetPageBackgroundRedrawArea (wxDC & *dc*, const wxRibbonPage * *wnd*, wxSize *page_old_size*, wxSize *page_new_size*) [pure virtual]

Calculate the portion of a page background which needs to be redrawn when a page is resized.

To optimise the drawing of page backgrounds, as small an area as possible should be returned. Of course, if the way in which a background is drawn means that the entire background needs to be repainted on resize, then the entire new size should be returned.

Parameters

dc	A device context to use when one is required for size calculations.
wnd	The page which is being resized.
page_old_size	The size of the page prior to the resize (which has already been painted).
page_new_size	The size of the page after the resize.

virtual wxSize wxRibbonArtProvider::GetPanelClientSize (wxDC & *dc*, const wxRibbonPanel * *wnd*, wxSize *size*, wxPoint * *client_offset*) [pure virtual]

Calculate the client size of a panel for a given overall size.

This should act as the inverse to GetPanelSize(), and decrement the given size by enough to fit the panel label and other chrome.

Parameters

	dc	A device context to use if one is required for size calculations.
	wnd	The ribbon panel in question.
	size	The overall size to calculate client size for.
out	*client_offset*	The offset where the returned client size begins within the given *size* (may be NULL).

See also

GetPanelSize()

virtual wxRect wxRibbonArtProvider::GetPanelExtButtonArea (wxDC & *dc,* const wxRibbonPanel * *wnd,* wxRect *rect*)
`[pure virtual]`

Calculate the position and size of the panel extension button.

Parameters

dc	A device context to use if one is required for size calculations.
wnd	The ribbon panel in question.
rect	The panel rectangle from which calculate extension button rectangle.

Since

2.9.4

virtual wxSize wxRibbonArtProvider::GetPanelSize (wxDC & *dc*, const wxRibbonPanel * *wnd*, wxSize *client_size*, wxPoint * *client_offset*) [pure virtual]

Calculate the size of a panel for a given client size.

This should increment the given size by enough to fit the panel label and other chrome.

Parameters

	dc	A device context to use if one is required for size calculations.
	wnd	The ribbon panel in question.
	client_size	The client size.
out	*client_offset*	The offset where the client rectangle begins within the panel (may be NULL).

See also

GetPanelClientSize()

virtual wxRect wxRibbonArtProvider::GetRibbonHelpButtonArea (const wxRect & *rect*) [pure virtual]

Calculate the position and size of the ribbon's help button.

Parameters

rect	The ribbon bar rectangle from which calculate help button rectangle.

Since

2.9.5

virtual wxSize wxRibbonArtProvider::GetScrollButtonMinimumSize (wxDC & *dc*, wxWindow * *wnd*, long *style*) [pure virtual]

Calculate the minimum size (in pixels) of a scroll button.

Parameters

dc	A device context to use when one is required for size calculations.
wnd	The window onto which the scroll button will eventually be drawn.
style	A combination of flags from wxRibbonScrollButtonStyle, including a direction, and a for flag (state flags may be given too, but should be ignored, as a button should retain a constant size, regardless of its state).

virtual int wxRibbonArtProvider::GetTabCtrlHeight (wxDC & *dc*, wxWindow * *wnd*, const wxRibbonPageTabInfoArray & *pages*) [pure virtual]

Calculate the height (in pixels) of the tab region of a ribbon bar.

Note that as the tab region can contain scroll buttons, the height should be greater than or equal to the minimum height for a tab scroll button.

Parameters

dc	A device context to use when one is required for size calculations.
wnd	The window onto which the tabs will eventually be drawn.
pages	The tabs which will acquire the returned height.

virtual wxSize wxRibbonArtProvider::GetToolSize (wxDC & *dc*, wxWindow * *wnd*, wxSize *bitmap_size*, wxRibbonButtonKind *kind*, bool *is_first*, bool *is_last*, wxRect * *dropdown_region*) [pure virtual]

Calculate the size of a tool within a wxRibbonToolBar.

Parameters

	dc	A device context to use when one is required for size calculations.
	wnd	The window onto which the tool will eventually be drawn.
	bitmap_size	The size of the tool's foreground bitmap.
	kind	The kind of tool (normal, dropdown, or hybrid).
	is_first	true if the tool is the first within its group. false otherwise.
	is_last	true if the tool is the last within its group. false otherwise.
out	*dropdown_region*	For dropdown and hybrid tools, the region within the returned size which counts as the dropdown part.

void wxRibbonArtProvider::SetColor (int *id*, const wxColour & *color*)

See also

wxRibbonArtProvider::SetColour()

virtual void wxRibbonArtProvider::SetColour (int *id*, const wxColor & *colour*) [pure virtual]

Set the value of a certain colour setting to the value *colour*.

id can be one of the colour values of wxRibbonArtSetting, though not all colour settings will have an effect on every art provider.

See also

SetColourScheme()

virtual void wxRibbonArtProvider::SetColourScheme (const wxColour & *primary*, const wxColour & *secondary*, const wxColour & *tertiary*) [pure virtual]

Set all applicable colour settings from a few base colours.

Uses any or all of the three given colours to create a colour scheme, and then sets all colour settings which are relevant to the art provider using that scheme. Note that some art providers may not use the tertiary colour for anything, and some may not use the secondary colour either.

See also

SetColour()
GetColourScheme()

virtual void wxRibbonArtProvider::SetFlags (long *flags*) `[pure virtual]`

Set the style flags.

Normally called automatically by wxRibbonBar::SetArtProvider with the ribbon bar's style flags, so that the art provider has the same flags as the bar which it is serving.

virtual void wxRibbonArtProvider::SetFont (int *id*, const wxFont & *font*) `[pure virtual]`

Set the value of a certain font setting to the value *font*.

id can be one of the font values of wxRibbonArtSetting.

virtual void wxRibbonArtProvider::SetMetric (int *id*, int *new_val*) `[pure virtual]`

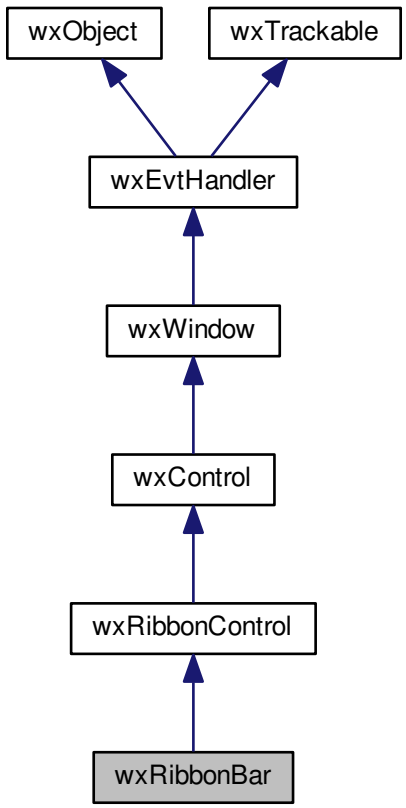
Set the value of a certain integer setting to the value *new_val*.

id can be one of the size values of wxRibbonArtSetting.

21.595 wxRibbonBar Class Reference

`#include <wx/ribbon/bar.h>`

Inheritance diagram for wxRibbonBar:



21.595.1 Detailed Description

Top-level control in a ribbon user interface.

Serves as a tabbed container for wxRibbonPage - a ribbon user interface typically has a ribbon bar, which contains one or more wxRibbonPages, which in turn each contain one or more wxRibbonPanels, which in turn contain controls.

While a wxRibbonBar has tabs similar to a wxNotebook, it does not follow the same API for adding pages. Containers like wxNotebook can contain any type of window as a page, hence the normal procedure is to create the sub-window and then call wxBookCtrlBase::AddPage(). As wxRibbonBar can only have wxRibbonPage as children (and a wxRibbonPage can only have a wxRibbonBar as parent), when a page is created, it is automatically added to the bar - there is no AddPage equivalent to call.

After all pages have been created, and all controls and panels placed on those pages, Realize() must be called.

wxRibbonPage
wxRibbonPanel

Styles

This class supports the following styles:

- wxRIBBON_BAR_DEFAULT_STYLE: Defined as wxRIBBON_BAR_FLOW_HORIZONTAL | wxRIBBON_BAR_SHOW_PAGE_LABELS | wxRIBBON_BAR_SHOW_PANEL_EXT_BUTTONS | wxRIBBON_BAR_SHOW_TOGGLE_BUTTON | wxRIBBON_BAR_SHOW_HELP_BUTTON.
- wxRIBBON_BAR_FOLDBAR_STYLE: Defined as wxRIBBON_BAR_FLOW_VERTICAL | wxRIBBON_BAR_SHOW_PAGE_ICONS | wxRIBBON_BAR_SHOW_PANEL_EXT_BUTTONS | wxRIBBON_BAR_SHOW_PANEL_MINIMISE_BUTTONS
- wxRIBBON_BAR_SHOW_PAGE_LABELS: Causes labels to be shown on the tabs in the ribbon bar.
- wxRIBBON_BAR_SHOW_PAGE_ICONS: Causes icons to be shown on the tabs in the ribbon bar.
- wxRIBBON_BAR_FLOW_HORIZONTAL: Causes panels within pages to stack horizontally.
- wxRIBBON_BAR_FLOW_VERTICAL: Causes panels within pages to stack vertically.
- wxRIBBON_BAR_SHOW_PANEL_EXT_BUTTONS: Causes extension buttons to be shown on panels (where the panel has such a button).
- wxRIBBON_BAR_SHOW_PANEL_MINIMISE_BUTTONS: Causes minimise buttons to be shown on panels (where the panel has such a button).
- wxRIBBON_BAR_SHOW_TOGGLE_BUTTON: Causes a toggle button to appear on the ribbon bar at top-right corner. This style is new since wxWidgets 2.9.5.
- wxRIBBON_BAR_SHOW_HELP_BUTTON: Causes a help button to appear on the ribbon bar at the top-right corner. This style is new since wxWidgets 2.9.5.

Events emitted by this class

The following event handler macros redirect the events to member function handlers '**func**' with prototypes like: void handlerFuncName(wxRibbonBarEvent& event)

Event macros for events emitted by this class:

- EVT_RIBBONBAR_PAGE_CHANGED(id, func): Triggered after the transition from one page being active to a different page being active.

- EVT_RIBBONBAR_PAGE_CHANGING(id, func): Triggered prior to the transition from one page being active to a different page being active, and can veto the change.
- EVT_RIBBONBAR_TAB_MIDDLE_DOWN(id, func): Triggered when the middle mouse button is pressed on a tab.
- EVT_RIBBONBAR_TAB_MIDDLE_UP(id, func): Triggered when the middle mouse button is released on a tab.
- EVT_RIBBONBAR_TAB_RIGHT_DOWN(id, func): Triggered when the right mouse button is pressed on a tab.
- EVT_RIBBONBAR_TAB_RIGHT_UP(id, func): Triggered when the right mouse button is released on a tab.
- EVT_RIBBONBAR_TAB_LEFT_DCLICK(id, func): Triggered when the left mouse button is double clicked on a tab.
- EVT_RIBBONBAR_TOGGLED(id, func): Triggered when the button triggering the ribbon bar is clicked. This event is new since wxWidgets 2.9.5.
- EVT_RIBBONBAR_HELP_CLICK(id, func): Triggered when the help button is clicked. This even is new since wxWidgets 2.9.5.

Library: wxRibbon

Category: Ribbon User Interface

Public Member Functions

- wxRibbonBar ()

  Default constructor.
- wxRibbonBar (wxWindow *parent, wxWindowID id=wxID_ANY, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, long style=wxRIBBON_BAR_DEFAULT_STYLE)

  Construct a ribbon bar with the given parameters.
- bool Create (wxWindow *parent, wxWindowID id=wxID_ANY, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, long style=wxRIBBON_BAR_DEFAULT_STYLE)

  Create a ribbon bar in two-step ribbon bar construction.
- virtual ~wxRibbonBar ()

  Destructor.
- void SetTabCtrlMargins (int left, int right)

  Set the margin widths (in pixels) on the left and right sides of the tab bar region of the ribbon bar.
- void SetArtProvider (wxRibbonArtProvider *art)

  Set the art provider to be used be the ribbon bar.
- bool SetActivePage (size_t page)

  Set the active page by index, without triggering any events.
- bool SetActivePage (wxRibbonPage *page)

  Set the active page, without triggering any events.
- int GetActivePage () const

  Get the index of the active page.
- wxRibbonPage * GetPage (int n)

  Get a page by index.
- size_t GetPageCount () const

  Get the number of pages in this bar.
- bool DismissExpandedPanel ()

Dismiss the expanded panel of the currently active page.

- int GetPageNumber (wxRibbonPage *page) const

  Returns the number for a given ribbon bar page.
- void DeletePage (size_t n)

  Delete a single page from this ribbon bar.
- void ClearPages ()

  Delete all pages from the ribbon bar.
- bool IsPageShown (size_t page) const

  Indicates whether the tab for the given page is shown to the user or not.
- void ShowPage (size_t page, bool show_tab=true)

  Show or hide the tab for a given page.
- void HidePage (size_t page)

  Hides the tab for a given page.
- bool IsPageHighlighted (size_t page) const

  Indicates whether a tab is currently highlighted.
- void AddPageHighlight (size_t page, bool highlight=true)

  Highlight the specified tab.
- void RemovePageHighlight (size_t page)

  Changes a tab to not be highlighted.
- void ShowPanels (wxRibbonDisplayMode mode)

  Shows or hide the panel area of the ribbon bar according to the given display mode.
- void ShowPanels (bool show=true)

  Shows or hides the panel area of the ribbon bar.
- void HidePanels ()

  Hides the panel area of the ribbon bar.
- bool ArePanelsShown () const

  Indicates whether the panel area of the ribbon bar is shown.
- wxRibbonDisplayMode GetDisplayMode () const

  Returns the current display mode of the panel area.
- virtual bool Realize ()

  Perform initial layout and size calculations of the bar and its children.

Additional Inherited Members

21.595.2 Constructor & Destructor Documentation

wxRibbonBar::wxRibbonBar ( )

Default constructor.

With this constructor, Create() should be called in order to create the ribbon bar.

wxRibbonBar::wxRibbonBar (wxWindow * *parent*, wxWindowID *id* = wxID_ANY, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, long *style* = `wxRIBBON_BAR_DEFAULT_STYLE`)

Construct a ribbon bar with the given parameters.

virtual wxRibbonBar::~wxRibbonBar ( ) `[virtual]`

Destructor.

21.595.3 Member Function Documentation

void wxRibbonBar::AddPageHighlight (size_t *page*, bool *highlight* = `true`)

Highlight the specified tab.

Highlighted tabs have a colour between that of the active tab and a tab over which the mouse is hovering. This can be used to make a tab (usually temporarily) more noticeable to the user.

Since

2.9.5

bool wxRibbonBar::ArePanelsShown ( ) const

Indicates whether the panel area of the ribbon bar is shown.

See also

ShowPanels()

Since

2.9.2

void wxRibbonBar::ClearPages ( )

Delete all pages from the ribbon bar.

Since

2.9.4

bool wxRibbonBar::Create (wxWindow * *parent*, wxWindowID *id* = wxID_ANY, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, long *style* = `wxRIBBON_BAR_DEFAULT_STYLE`)

Create a ribbon bar in two-step ribbon bar construction.

Should only be called when the default constructor is used, and arguments have the same meaning as in the full constructor.

void wxRibbonBar::DeletePage (size_t *n*)

Delete a single page from this ribbon bar.

The user must call wxRibbonBar::Realize() after one (or more) calls to this function.

Since

2.9.4

bool wxRibbonBar::DismissExpandedPanel ( )

Dismiss the expanded panel of the currently active page.

Calls and returns the value from wxRibbonPage::DismissExpandedPanel() for the currently active page, or false if there is no active page.

int wxRibbonBar::GetActivePage ( ) const

Get the index of the active page.

In the rare case of no page being active, -1 is returned.

wxRibbonDisplayMode wxRibbonBar::GetDisplayMode ( ) const

Returns the current display mode of the panel area.

See also

ShowPanels()

Since

3.1.0

wxRibbonPage* wxRibbonBar::GetPage (int *n*)

Get a page by index.

NULL will be returned if the given index is out of range.

size_t wxRibbonBar::GetPageCount ( ) const

Get the number of pages in this bar.

Since

2.9.4

int wxRibbonBar::GetPageNumber (wxRibbonPage * *page*) const

Returns the number for a given ribbon bar page.

The number can be used in other ribbon bar calls.

Since

2.9.5

void wxRibbonBar::HidePage (size_t *page*)

Hides the tab for a given page.

Equivalent to `ShowPage(page, false)`.

Since

2.9.5

void wxRibbonBar::HidePanels ( )

Hides the panel area of the ribbon bar.

This method behaves like ShowPanels() with false argument.

Since

2.9.2

bool wxRibbonBar::IsPageHighlighted (size_t *page*) const

Indicates whether a tab is currently highlighted.

See also

AddPageHighlight()

Since

2.9.5

bool wxRibbonBar::IsPageShown (size_t *page*) const

Indicates whether the tab for the given page is shown to the user or not.

By default all page tabs are shown.

Since

2.9.5

virtual bool wxRibbonBar::Realize ( ) [virtual]

Perform initial layout and size calculations of the bar and its children.

This must be called after all of the bar's children have been created (and their children created, etc.) - if it is not, then windows may not be laid out or sized correctly.

Also calls wxRibbonPage::Realize() on each child page.

Reimplemented from wxRibbonControl.

void wxRibbonBar::RemovePageHighlight (size_t *page*)

Changes a tab to not be highlighted.

See also

AddPageHighlight()

Since

2.9.5

bool wxRibbonBar::SetActivePage (size_t *page*)

Set the active page by index, without triggering any events.

Parameters

page	The zero-based index of the page to activate.

Returns

true if the specified page is now active, false if it could not be activated (for example because the page index is invalid).

bool wxRibbonBar::SetActivePage (wxRibbonPage * *page*)

Set the active page, without triggering any events.

Parameters

page	The page to activate.

Returns

true if the specified page is now active, false if it could not be activated (for example because the given page is not a child of the ribbon bar).

void wxRibbonBar::SetArtProvider (wxRibbonArtProvider * *art*) [virtual]

Set the art provider to be used be the ribbon bar.

Also sets the art provider on all current wxRibbonPage children, and any wxRibbonPage children added in the future.

Note that unlike most other ribbon controls, the ribbon bar creates a default art provider when initialised, so an explicit call to SetArtProvider() is not required if the default art provider is sufficient. Also, unlike other ribbon controls, the ribbon bar takes ownership of the given pointer, and will delete it when the art provider is changed or the bar is destroyed. If this behaviour is not desired, then clone the art provider before setting it.

Reimplemented from wxRibbonControl.

void wxRibbonBar::SetTabCtrlMargins (int *left*, int *right*)

Set the margin widths (in pixels) on the left and right sides of the tab bar region of the ribbon bar.

These margins will be painted with the tab background, but tabs and scroll buttons will never be painted in the margins.

The left margin could be used for rendering something equivalent to the "Office Button", though this is not currently implemented. The right margin could be used for rendering a help button, and/or MDI buttons, but again, this is not currently implemented.

void wxRibbonBar::ShowPage (size_t *page*, bool *show_tab* = true)

Show or hide the tab for a given page.

After showing or hiding a tab, you need to call wxRibbonBar::Realize(). If you hide the tab for the currently active page (GetActivePage) then you should call SetActivePage to activate a different page.

Since

2.9.5

void wxRibbonBar::ShowPanels (wxRibbonDisplayMode *mode*)

Shows or hide the panel area of the ribbon bar according to the given display mode.

Since

3.1.0

void wxRibbonBar::ShowPanels (bool *show* = `true`)

Shows or hides the panel area of the ribbon bar.

If the panel area is hidden, then only the tab of the ribbon bar will be shown. This is useful for giving the user more screen space to work with when he/she doesn't need to see the ribbon's options.

If the panel is currently shown, this method pins it, use the other overload of this method to specify the exact panel display mode to avoid it.

Since

2.9.2

Sets the page relating to this event.

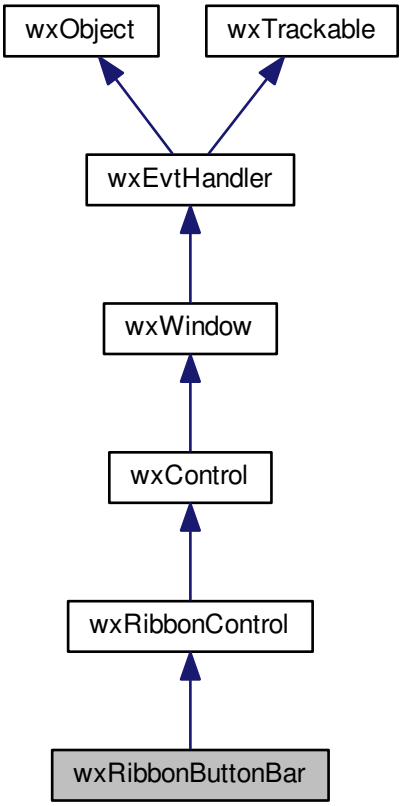
21.597 wxRibbonButtonBar Class Reference

```
#include <wx/ribbon/buttonbar.h>
```

Inheritance diagram for wxRibbonButtonBar:



21.597.1 Detailed Description

A ribbon button bar is similar to a traditional toolbar.

It contains one or more buttons (button bar buttons, not wxButtons), each of which has a label and an icon. It differs from a wxRibbonToolBar in several ways:

- Individual buttons can grow and contract.
- Buttons have labels as well as bitmaps.
- Bitmaps are typically larger (at least 32x32 pixels) on a button bar compared to a tool bar (which typically has 16x15).
- There is no grouping of buttons on a button bar
- A button bar typically has a border around each individual button, whereas a tool bar typically has a border around each group of buttons.

Events emitted by this class

The following event handler macros redirect the events to member function handlers '**func**' with prototypes like: void handlerFuncName(wxRibbonButtonBarEvent& event)

Event macros for events emitted by this class:

- EVT_RIBBONBUTTONBAR_CLICKED(id, func): Triggered when the normal (non-dropdown) region of a button on the button bar is clicked.
- EVT_RIBBONBUTTONBAR_DROPDOWN_CLICKED(id, func): Triggered when the dropdown region of a button on the button bar is clicked. wxRibbonButtonBarEvent::PopupMenu() should be called by the event handler if it wants to display a popup menu (which is what most dropdown buttons should be doing).

Library: wxRibbon

Category: Ribbon User Interface

Public Member Functions

- wxRibbonButtonBar ()

  Default constructor.
- wxRibbonButtonBar (wxWindow *parent, wxWindowID id=wxID_ANY, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, long style=0)

  Construct a ribbon button bar with the given parameters.
- virtual ~wxRibbonButtonBar ()

  Destructor.
- bool Create (wxWindow *parent, wxWindowID id=wxID_ANY, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, long style=0)

  Create a button bar in two-step button bar construction.
- virtual wxRibbonButtonBarButtonBase * AddButton (int button_id, const wxString &label, const wxBitmap &bitmap, const wxString &help_string, wxRibbonButtonKind kind=wxRIBBON_BUTTON_NORMAL)

  Add a button to the button bar (simple version).
- virtual wxRibbonButtonBarButtonBase * AddDropdownButton (int button_id, const wxString &label, const wxBitmap &bitmap, const wxString &help_string=wxEmptyString)

  Add a dropdown button to the button bar (simple version).
- virtual wxRibbonButtonBarButtonBase * AddHybridButton (int button_id, const wxString &label, const wxBitmap &bitmap, const wxString &help_string=wxEmptyString)

  Add a hybrid button to the button bar (simple version).
- virtual wxRibbonButtonBarButtonBase * AddToggleButton (int button_id, const wxString &label, const wxBitmap &bitmap, const wxString &help_string=wxEmptyString)

  Add a toggle button to the button bar (simple version).
- virtual wxRibbonButtonBarButtonBase * AddButton (int button_id, const wxString &label, const wxBitmap &bitmap, const wxBitmap &bitmap_small=wxNullBitmap, const wxBitmap &bitmap_disabled=wxNullBitmap, const wxBitmap &bitmap_small_disabled=wxNullBitmap, wxRibbonButtonKind kind=wxRIBBON_BUTTON_NORMAL, const wxString &help_string=wxEmptyString)

  Add a button to the button bar.
- virtual wxRibbonButtonBarButtonBase * InsertButton (size_t pos, int button_id, const wxString &label, const wxBitmap &bitmap, const wxString &help_string, wxRibbonButtonKind kind=wxRIBBON_BUTTON_NORMAL)

  Inserts a button to the button bar (simple version) at the given position.

- virtual wxRibbonButtonBarButtonBase * InsertDropdownButton (size_t pos, int button_id, const wxString &label, const wxBitmap &bitmap, const wxString &help_string=wxEmptyString)

  Inserts a dropdown button to the button bar (simple version) at the given position.
- virtual wxRibbonButtonBarButtonBase * InsertHybridButton (size_t pos, int button_id, const wxString &label, const wxBitmap &bitmap, const wxString &help_string=wxEmptyString)

  Inserts a hybrid button to the button bar (simple version) at the given position.
- virtual wxRibbonButtonBarButtonBase * InsertToggleButton (size_t pos, int button_id, const wxString &label, const wxBitmap &bitmap, const wxString &help_string=wxEmptyString)

  Inserts a toggle button to the button bar (simple version) at the given position.
- virtual wxRibbonButtonBarButtonBase * InsertButton (size_t pos, int button_id, const wxString &label, const wxBitmap &bitmap, const wxBitmap &bitmap_small=wxNullBitmap, const wxBitmap &bitmap_disabled=wxNullBitmap, const wxBitmap &bitmap_small_disabled=wxNullBitmap, wxRibbonButtonKind kind=wxRIBBON_BUTTON_NORMAL, const wxString &help_string=wxEmptyString)

  Insert a button to the button bar at the given position.
- virtual size_t GetButtonCount () const

  Returns the number of buttons in this button bar.
- void SetItemClientObject (wxRibbonButtonBarButtonBase *item, wxClientData *data)

  Set the client object associated with a button.
- wxClientData * GetItemClientObject (const wxRibbonButtonBarButtonBase *item) const

  Get the client object associated with a button.
- void SetItemClientData (wxRibbonButtonBarButtonBase *item, void *data)

  Set the client data associated with a button.
- void * GetItemClientData (const wxRibbonButtonBarButtonBase *item) const

  Get the client data associated with a button.
- virtual wxRibbonButtonBarButtonBase * GetItem (size_t n) const

  Returns the N-th button of the bar.
- virtual wxRibbonButtonBarButtonBase * GetItemById (int id) const

  Returns the first button having a given id or NULL if none matches.
- virtual int GetItemId (wxRibbonButtonBarButtonBase *) const

  Returns the id of a button.
- virtual bool Realize ()

  Calculate button layouts and positions.
- virtual void ClearButtons ()

  Delete all buttons from the button bar.
- virtual bool DeleteButton (int button_id)

  Delete a single button from the button bar.
- virtual void EnableButton (int button_id, bool enable=true)

  Enable or disable a single button on the bar.
- virtual void ToggleButton (int button_id, bool checked)

  Set a toggle button to the checked or unchecked state.
- virtual wxRibbonButtonBarButtonBase * GetActiveItem () const

  Returns the active item of the button bar or NULL if there is none.
- virtual wxRibbonButtonBarButtonBase * GetHoveredItem () const

  Returns the hovered item of the button bar or NULL if there is none.

- void SetShowToolTipsForDisabled (bool show)

  Indicates whether tooltips are shown for disabled buttons.
- bool GetShowToolTipsForDisabled () const

  Sets whether tooltips should be shown for disabled buttons or not.

Additional Inherited Members

21.597.2 Constructor & Destructor Documentation

wxRibbonButtonBar::wxRibbonButtonBar ( )

Default constructor.

With this constructor, Create() should be called in order to create the button bar.

wxRibbonButtonBar::wxRibbonButtonBar (wxWindow * *parent*, wxWindowID *id* = wxID_ANY, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, long *style* = 0)

Construct a ribbon button bar with the given parameters.

Parameters

parent	Parent window for the button bar (typically a wxRibbonPanel).
id	An identifier for the button bar. `wxID_ANY` is taken to mean a default.
pos	Initial position of the button bar.
size	Initial size of the button bar.
style	Button bar style, currently unused.

virtual wxRibbonButtonBar::~wxRibbonButtonBar ( ) `[virtual]`

Destructor.

21.597.3 Member Function Documentation

virtual wxRibbonButtonBarButtonBase* wxRibbonButtonBar::AddButton (int *button_id*, const wxString & *label*, const wxBitmap & *bitmap*, const wxString & *help_string*, wxRibbonButtonKind *kind* = wxRIBBON_BUTTON_NORMAL) `[virtual]`

Add a button to the button bar (simple version).

virtual wxRibbonButtonBarButtonBase* wxRibbonButtonBar::AddButton (int *button_id*, const wxString & *label*, const wxBitmap & *bitmap*, const wxBitmap & *bitmap_small* = wxNullBitmap, const wxBitmap & *bitmap_disabled* = wxNullBitmap, const wxBitmap & *bitmap_small_disabled* = wxNullBitmap, wxRibbonButtonKind *kind* = wxRIBBON_BUTTON_NORMAL, const wxString & *help_string* = wxEmptyString) `[virtual]`

Add a button to the button bar.

Parameters

button_id	ID of the new button (used for event callbacks).

label	Label of the new button.
bitmap	Large bitmap of the new button. Must be the same size as all other large bitmaps used on the button bar.
bitmap_small	Small bitmap of the new button. If left as null, then a small bitmap will be automatically generated. Must be the same size as all other small bitmaps used on the button bar.
bitmap_disabled	Large bitmap of the new button when it is disabled. If left as null, then a bitmap will be automatically generated from *bitmap*.
bitmap_small_disabled	Small bitmap of the new button when it is disabled. If left as null, then a bitmap will be automatically generated from *bitmap_small*.
kind	The kind of button to add.
help_string	The UI help string to associate with the new button.

Returns

An opaque pointer which can be used only with other button bar methods.

See also

AddDropdownButton()
AddHybridButton()
AddToggleButton()

virtual wxRibbonButtonBarButtonBase* wxRibbonButtonBar::AddDropdownButton (int *button_id,* const wxString & *label,* const wxBitmap & *bitmap,* const wxString & *help_string* = wxEmptyString) [virtual]

Add a dropdown button to the button bar (simple version).

See also

AddButton()

virtual wxRibbonButtonBarButtonBase* wxRibbonButtonBar::AddHybridButton (int *button_id,* const wxString & *label,* const wxBitmap & *bitmap,* const wxString & *help_string* = wxEmptyString) [virtual]

Add a hybrid button to the button bar (simple version).

See also

AddButton()

virtual wxRibbonButtonBarButtonBase* wxRibbonButtonBar::AddToggleButton (int *button_id,* const wxString & *label,* const wxBitmap & *bitmap,* const wxString & *help_string* = wxEmptyString) [virtual]

Add a toggle button to the button bar (simple version).

See also

AddButton()

virtual void wxRibbonButtonBar::ClearButtons ( ) [virtual]

Delete all buttons from the button bar.

See also

DeleteButton()

bool wxRibbonButtonBar::Create (wxWindow * *parent*, wxWindowID *id* = wxID_ANY, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, long *style* = 0)

Create a button bar in two-step button bar construction.

Should only be called when the default constructor is used, and arguments have the same meaning as in the full constructor.

virtual bool wxRibbonButtonBar::DeleteButton (int *button_id*) [virtual]

Delete a single button from the button bar.

The corresponding button is deleted by this function, so any pointers to it previously obtained by GetItem() or GetItemById() become invalid.

See also

ClearButtons()

virtual void wxRibbonButtonBar::EnableButton (int *button_id*, bool *enable* = true) [virtual]

Enable or disable a single button on the bar.

Parameters

button_id	ID of the button to enable or disable.
enable	true to enable the button, false to disable it.

virtual wxRibbonButtonBarButtonBase* wxRibbonButtonBar::GetActiveItem ( ) const [virtual]

Returns the active item of the button bar or NULL if there is none.

The active button is the one being clicked.

Since

2.9.5

virtual size_t wxRibbonButtonBar::GetButtonCount ( ) const [virtual]

Returns the number of buttons in this button bar.

Since

2.9.4

virtual wxRibbonButtonBarButtonBase* wxRibbonButtonBar::GetHoveredItem ( ) const [virtual]

Returns the hovered item of the button bar or NULL if there is none.

The hovered button is the one the mouse is over.

Since

2.9.5

virtual wxRibbonButtonBarButtonBase* wxRibbonButtonBar::GetItem (size_t *n*) const [virtual]

Returns the N-th button of the bar.

See also

GetButtonCount()

Since

2.9.5

virtual wxRibbonButtonBarButtonBase* wxRibbonButtonBar::GetItemById (int *id*) const [virtual]

Returns the first button having a given id or NULL if none matches.

Since

2.9.5

void* wxRibbonButtonBar::GetItemClientData (const wxRibbonButtonBarButtonBase * *item*) const

Get the client data associated with a button.

Since

2.9.5

wxClientData* wxRibbonButtonBar::GetItemClientObject (const wxRibbonButtonBarButtonBase * *item*) const

Get the client object associated with a button.

Since

2.9.5

virtual int wxRibbonButtonBar::GetItemId (wxRibbonButtonBarButtonBase *) const [virtual]

Returns the id of a button.

Since

2.9.5

bool wxRibbonButtonBar::GetShowToolTipsForDisabled ( ) const

Sets whether tooltips should be shown for disabled buttons or not.

You may wish to show it to explain why a button is disabled or what it normally does when enabled.

Since

2.9.5

virtual wxRibbonButtonBarButtonBase* wxRibbonButtonBar::InsertButton (size_t *pos*, int *button_id*, const wxString & *label*, const wxBitmap & *bitmap*, const wxString & *help_string*, wxRibbonButtonKind *kind* = wxRIBBON_BUTTON_NORMAL) [virtual]

Inserts a button to the button bar (simple version) at the given position.

See also

AddButton()

Since

2.9.4

virtual wxRibbonButtonBarButtonBase* wxRibbonButtonBar::InsertButton (size_t *pos*, int *button_id*, const wxString & *label*, const wxBitmap & *bitmap*, const wxBitmap & *bitmap_small* = wxNullBitmap, const wxBitmap & *bitmap_disabled* = wxNullBitmap, const wxBitmap & *bitmap_small_disabled* = wxNullBitmap, wxRibbonButtonKind *kind* = wxRIBBON_BUTTON_NORMAL, const wxString & *help_string* = wxEmptyString) [virtual]

Insert a button to the button bar at the given position.

Parameters

pos	Position of the new button in the button bar.
button_id	ID of the new button (used for event callbacks).
label	Label of the new button.
bitmap	Large bitmap of the new button. Must be the same size as all other large bitmaps used on the button bar.
bitmap_small	Small bitmap of the new button. If left as null, then a small bitmap will be automatically generated. Must be the same size as all other small bitmaps used on the button bar.
bitmap_disabled	Large bitmap of the new button when it is disabled. If left as null, then a bitmap will be automatically generated from *bitmap*.
bitmap_small_disabled	Small bitmap of the new button when it is disabled. If left as null, then a bitmap will be automatically generated from *bitmap_small*.
kind	The kind of button to add.
help_string	The UI help string to associate with the new button.

Returns

An opaque pointer which can be used only with other button bar methods.

See also

InsertDropdownButton()
InsertHybridButton()

AddHybridButton()
AddButton()

Since

2.9.4

virtual wxRibbonButtonBarButtonBase* wxRibbonButtonBar::InsertToggleButton (size_t *pos,* int *button_id,* const wxString & *label,* const wxBitmap & *bitmap,* const wxString & *help_string* = wxEmptyString) [virtual]

Inserts a toggle button to the button bar (simple version) at the given position.

See also

InsertButton()
AddToggleButton()
AddButton()

Since

2.9.4

virtual bool wxRibbonButtonBar::Realize ( ) [virtual]

Calculate button layouts and positions.

Must be called after buttons are added to the button bar, as otherwise the newly added buttons will not be displayed. In normal situations, it will be called automatically when wxRibbonBar::Realize() is called.

Reimplemented from wxRibbonControl.

void wxRibbonButtonBar::SetItemClientData (wxRibbonButtonBarButtonBase * *item,* void * *data*)

Set the client data associated with a button.

Please, note that you cannot use both client object and client data.

Since

2.9.5

void wxRibbonButtonBar::SetItemClientObject (wxRibbonButtonBarButtonBase * *item,* wxClientData * *data*)

Set the client object associated with a button.

The button bar owns the given object and takes care of its deletion. Please, note that you cannot use both client object and client data.

Since

2.9.5

void wxRibbonButtonBar::SetShowToolTipsForDisabled (bool *show*)

Indicates whether tooltips are shown for disabled buttons.

By default they are not shown.

Since

2.9.5

virtual void wxRibbonButtonBar::ToggleButton (int *button_id,* bool *checked*) `[virtual]`

Set a toggle button to the checked or unchecked state.

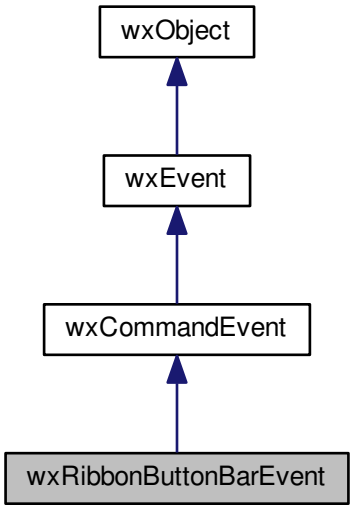
Parameters

button_id	ID of the toggle button to manipulate.
checked	true to set the button to the toggled/pressed/checked state, false to set it to the untoggled/unpressed/unchecked state.

21.598 wxRibbonButtonBarEvent Class Reference

`#include <wx/ribbon/buttonbar.h>`

Inheritance diagram for wxRibbonButtonBarEvent:



21.598.1 Detailed Description

Event used to indicate various actions relating to a button on a wxRibbonButtonBar.

For toggle buttons, IsChecked() can be used to test the state of the button.

See wxRibbonButtonBar for available event types.

Display a popup menu as a result of this (dropdown clicked) event.

void wxRibbonButtonBarEvent::SetBar (wxRibbonButtonBar * *bar*)

Sets the button bar relating to this event.

void wxRibbonButtonBarEvent::SetButton (wxRibbonButtonBarButtonBase * *bar*)

Sets the button relating to this event.

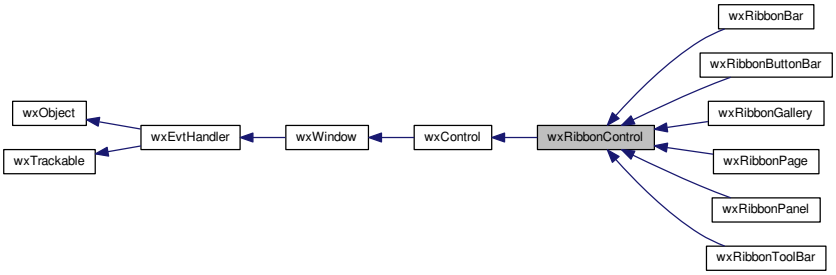
Since

2.9.5

21.599 wxRibbonControl Class Reference

`#include <wx/ribbon/control.h>`

Inheritance diagram for wxRibbonControl:



21.599.1 Detailed Description

wxRibbonControl serves as a base class for all controls which share the ribbon characteristics of having a ribbon art provider, and (optionally) non-continuous resizing.

Despite what the name may imply, it is not the top-level control for creating a ribbon interface - that is wxRibbonBar.

Ribbon controls often have a region which is "transparent", and shows the contents of the ribbon page or panel behind it. If implementing a new ribbon control, then it may be useful to realise that this effect is done by the art provider when painting the background of the control, and hence in the paint handler for the new control, you should call a draw background method on the art provider (wxRibbonArtProvider::DrawButtonBarBackground() and wxRibbonArtProvider::DrawToolBarBackground() typically just redraw what is behind the rectangle being painted) if you want transparent regions.

Library: wxRibbon

Category: Ribbon User Interface

Public Member Functions

- wxRibbonControl ()

  Constructor.
- wxRibbonControl (wxWindow *parent, wxWindowID id, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, long style=0, const wxValidator &validator=wxDefaultValidator, const wxString &name=wxControlNameStr)

  Constructor.
- virtual void SetArtProvider (wxRibbonArtProvider *art)

  Set the art provider to be used.
- wxRibbonArtProvider * GetArtProvider () const

  Get the art provider to be used.
- virtual bool IsSizingContinuous () const
- wxSize GetNextSmallerSize (wxOrientation direction) const

  If sizing is not continuous, then return a suitable size for the control which is smaller than the current size.
- wxSize GetNextSmallerSize (wxOrientation direction, wxSize relative_to) const

  If sizing is not continuous, then return a suitable size for the control which is smaller than the given size.
- wxSize GetNextLargerSize (wxOrientation direction) const

  If sizing is not continuous, then return a suitable size for the control which is larger than the current size.

- wxSize GetNextLargerSize (wxOrientation direction, wxSize relative_to) const

  If sizing is not continuous, then return a suitable size for the control which is larger than the given size.
- virtual bool Realize ()

  Perform initial size and layout calculations after children have been added, and/or realize children.
- bool Realise ()

  Alias for Realize().
- virtual wxRibbonBar * GetAncestorRibbonBar () const

  Get the first ancestor which is a wxRibbonBar (or derived) or NULL if not having such parent.
- virtual wxSize GetBestSizeForParentSize (const wxSize &parentSize) const

  Finds the best width and height given the parent's width and height.

Protected Member Functions

- virtual wxSize DoGetNextSmallerSize (wxOrientation direction, wxSize relative_to) const

  Implementation of GetNextSmallerSize().
- virtual wxSize DoGetNextLargerSize (wxOrientation direction, wxSize relative_to) const

  Implementation of GetNextLargerSize().

Additional Inherited Members

21.599.2 Constructor & Destructor Documentation

wxRibbonControl::wxRibbonControl ( )

Constructor.

wxRibbonControl::wxRibbonControl (wxWindow * *parent*, wxWindowID *id*, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, long *style* = `0`, const wxValidator & *validator* = wxDefaultValidator, const wxString & *name* = `wxControlNameStr`)

Constructor.

If *parent* is a wxRibbonControl with a non-NULL art provider, then the art provider of new control is set to that of *parent*.

21.599.3 Member Function Documentation

virtual wxSize wxRibbonControl::DoGetNextLargerSize (wxOrientation *direction*, wxSize *relative_to*) const `[protected], [virtual]`

Implementation of GetNextLargerSize().

Controls which have non-continuous sizing must override this virtual function rather than GetNextLargerSize().

virtual wxSize wxRibbonControl::DoGetNextSmallerSize (wxOrientation *direction*, wxSize *relative_to*) const `[protected], [virtual]`

Implementation of GetNextSmallerSize().

Controls which have non-continuous sizing must override this virtual function rather than GetNextSmallerSize().

virtual wxRibbonBar* wxRibbonControl::GetAncestorRibbonBar ( ) const `[virtual]`

Get the first ancestor which is a wxRibbonBar (or derived) or NULL if not having such parent.

Since

2.9.4

wxRibbonArtProvider* wxRibbonControl::GetArtProvider ( ) const

Get the art provider to be used.

Note that until an art provider has been set in some way, this function may return NULL.

virtual wxSize wxRibbonControl::GetBestSizeForParentSize (const wxSize & *parentSize*) const `[virtual]`

Finds the best width and height given the parent's width and height.

Used to implement the wxRIBBON_PANEL_FLEXIBLE panel style.

wxSize wxRibbonControl::GetNextLargerSize (wxOrientation *direction*) const

If sizing is not continuous, then return a suitable size for the control which is larger than the current size.

Parameters

direction	The direction(s) in which the size should increase.

Returns

The current size if there is no larger size, otherwise a suitable size which is larger in the given direction(s), and the same as the current size in the other direction (if any).

See also

IsSizingContinuous()

wxSize wxRibbonControl::GetNextLargerSize (wxOrientation *direction*, wxSize *relative_to*) const

If sizing is not continuous, then return a suitable size for the control which is larger than the given size.

Parameters

direction	The direction(s) in which the size should increase.
relative_to	The size for which a larger size should be found.

Returns

relative_to if there is no larger size, otherwise a suitable size which is larger in the given direction(s), and the same as *relative_to* in the other direction (if any).

See also

IsSizingContinuous()
DoGetNextLargerSize()

wxSize wxRibbonControl::GetNextSmallerSize (wxOrientation *direction*) const

If sizing is not continuous, then return a suitable size for the control which is smaller than the current size.

Parameters

direction	The direction(s) in which the size should reduce.

Returns

The current size if there is no smaller size, otherwise a suitable size which is smaller in the given direction(s), and the same as the current size in the other direction (if any).

See also

IsSizingContinuous()

wxSize wxRibbonControl::GetNextSmallerSize (wxOrientation *direction,* wxSize *relative_to*) const

If sizing is not continuous, then return a suitable size for the control which is smaller than the given size.

Parameters

direction	The direction(s) in which the size should reduce.
relative_to	The size for which a smaller size should be found.

Returns

relative_to if there is no smaller size, otherwise a suitable size which is smaller in the given direction(s), and the same as *relative_to* in the other direction (if any).

See also

IsSizingContinuous()
DoGetNextSmallerSize()

virtual bool wxRibbonControl::IsSizingContinuous ( ) const [virtual]

Returns

true if this window can take any size (greater than its minimum size), false if it can only take certain sizes.

See also

GetNextSmallerSize()
GetNextLargerSize()

bool wxRibbonControl::Realise ( )

Alias for Realize().

virtual bool wxRibbonControl::Realize ( ) [virtual]

Perform initial size and layout calculations after children have been added, and/or realize children.

Reimplemented in wxRibbonButtonBar, wxRibbonBar, wxRibbonToolBar, wxRibbonPanel, and wxRibbonPage.

virtual void wxRibbonControl::SetArtProvider (**wxRibbonArtProvider** * *art*) [virtual]

Set the art provider to be used.

In many cases, setting the art provider will also set the art provider on all child windows which extend wxRibbonControl.

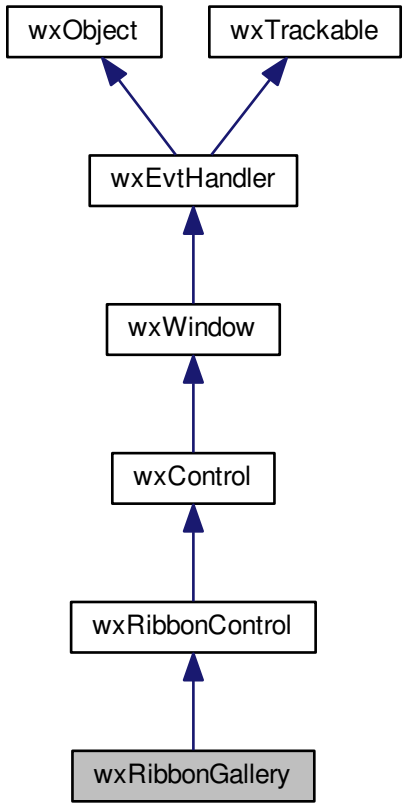
In most cases, controls will not take ownership of the given pointer, with the notable exception being wxRibbonBar::SetArtProvider().

Reimplemented in wxRibbonPanel, wxRibbonBar, and wxRibbonPage.

21.600 wxRibbonGallery Class Reference

`#include <wx/ribbon/gallery.h>`

Inheritance diagram for wxRibbonGallery:



21.600.1 Detailed Description

A ribbon gallery is like a wxListBox, but for bitmaps rather than strings.

It displays a collection of bitmaps arranged in a grid and allows the user to choose one. As there are typically more bitmaps in a gallery than can be displayed in the space used for a ribbon, a gallery always has scroll buttons to allow

the user to navigate through the entire gallery. It also has an "extension" button, the behaviour of which is outside the scope of the gallery control itself, though it typically displays some kind of dialog related to the gallery.

Events emitted by this class

The following event handler macros redirect the events to member function handlers '**func**' with prototypes like: void handlerFuncName(wxRibbonGalleryEvent& event)

Event macros for events emitted by this class:

- EVT_RIBBONGALLERY_SELECTED(id, func): Triggered when the user selects an item from the gallery. Note that the ID is that of the gallery, not of the item.
- EVT_RIBBONGALLERY_CLICKED(id, func): Similar to EVT_RIBBONGALLERY_SELECTED but triggered every time a gallery item is clicked, even if it is already selected. Note that the ID of the event is that of the gallery, not of the item, just as above. This event is available since wxWidgets 2.9.2.
- EVT_RIBBONGALLERY_HOVER_CHANGED(id, func): Triggered when the item being hovered over by the user changes. The item in the event will be the new item being hovered, or NULL if there is no longer an item being hovered. Note that the ID is that of the gallery, not of the item.

Events emitted by this class

The following event handler macros redirect the events to member function handlers '**func**' with prototypes like: void handlerFuncName(wxCommandEvent& event)

Event macros for events emitted by this class:

- EVT_BUTTON(id, func): Triggered when the "extension" button of the gallery is pressed.

Category: Ribbon User Interface

Public Member Functions

- wxRibbonGallery ()

  Default constructor.
- wxRibbonGallery (wxWindow *parent, wxWindowID id=wxID_ANY, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, long style=0)

  Construct a ribbon gallery with the given parameters.
- virtual ~wxRibbonGallery ()

  Destructor.
- bool Create (wxWindow *parent, wxWindowID id=wxID_ANY, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, long style=0)

  Create a gallery in two-step gallery construction.
- void Clear ()

  Remove all items from the gallery.
- bool IsEmpty () const

  Query if the gallery has no items in it.
- unsigned int GetCount () const

  Get the number of items in the gallery.
- wxRibbonGalleryItem * GetItem (unsigned int n)

Get an item by index.

- wxRibbonGalleryItem * Append (const wxBitmap &bitmap, int id)

  Add an item to the gallery (with no client data).
- wxRibbonGalleryItem * Append (const wxBitmap &bitmap, int id, void *clientData)

  Add an item to the gallery (with simple client data).
- wxRibbonGalleryItem * Append (const wxBitmap &bitmap, int id, wxClientData *clientData)

  Add an item to the gallery (with complex client data)
- void SetItemClientObject (wxRibbonGalleryItem *item, wxClientData *data)

  Set the client object associated with a gallery item.
- wxClientData * GetItemClientObject (const wxRibbonGalleryItem *item) const

  Get the client object associated with a gallery item.
- void SetItemClientData (wxRibbonGalleryItem *item, void *data)

  Set the client data associated with a gallery item.
- void * GetItemClientData (const wxRibbonGalleryItem *item) const

  Get the client data associated with a gallery item.
- void SetSelection (wxRibbonGalleryItem *item)

  Set the selection to the given item, or removes the selection if item == NULL.
- wxRibbonGalleryItem * GetSelection () const

  Get the currently selected item, or NULL if there is none.
- wxRibbonGalleryItem * GetHoveredItem () const

  Get the currently hovered item, or NULL if there is none.
- wxRibbonGalleryItem * GetActiveItem () const

  Get the currently active item, or NULL if there is none.
- wxRibbonGalleryButtonState GetUpButtonState () const

  Get the state of the scroll up button.
- wxRibbonGalleryButtonState GetDownButtonState () const

  Get the state of the scroll down button.
- wxRibbonGalleryButtonState GetExtensionButtonState () const

  Get the state of the "extension" button.
- bool IsHovered () const

  Query is the mouse is currently hovered over the gallery.
- virtual bool ScrollLines (int lines)

  Scroll the gallery contents by some amount.
- bool ScrollPixels (int pixels)

  Scroll the gallery contents by some fine-grained amount.
- void EnsureVisible (const wxRibbonGalleryItem *item)

  Scroll the gallery to ensure that the given item is visible.

Additional Inherited Members

21.600.2 Constructor & Destructor Documentation

wxRibbonGallery::wxRibbonGallery ( )

Default constructor.

With this constructor, Create() should be called in order to create the gallery.

wxRibbonGallery::wxRibbonGallery (wxWindow * *parent*, wxWindowID *id* = wxID_ANY, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, long *style* = 0)

Construct a ribbon gallery with the given parameters.

Parameters

parent	Parent window for the gallery (typically a wxRibbonPanel).
id	An identifier for the gallery. `wxID_ANY` is taken to mean a default.
pos	Initial position of the gallery.
size	Initial size of the gallery.
style	Gallery style, currently unused.

virtual wxRibbonGallery::~wxRibbonGallery ( ) [virtual]

Destructor.

21.600.3 Member Function Documentation

wxRibbonGalleryItem* wxRibbonGallery::Append (const wxBitmap & *bitmap*, int *id*)

Add an item to the gallery (with no client data).

Parameters

bitmap	The bitmap to display for the item. Note that all items must have equally sized bitmaps.
id	ID number to associate with the item. Not currently used for anything important.

wxRibbonGalleryItem* wxRibbonGallery::Append (const wxBitmap & *bitmap*, int *id*, void * *clientData*)

Add an item to the gallery (with simple client data).

Parameters

bitmap	The bitmap to display for the item. Note that all items must have equally sized bitmaps.
id	ID number to associate with the item. Not currently used for anything important.
clientData	An opaque pointer to associate with the item.

wxRibbonGalleryItem* wxRibbonGallery::Append (const wxBitmap & *bitmap*, int *id*, wxClientData * *clientData*)

Add an item to the gallery (with complex client data)

Parameters

bitmap	The bitmap to display for the item. Note that all items must have equally sized bitmaps.
id	ID number to associate with the item. Not currently used for anything important.
clientData	An object which contains data to associate with the item. The item takes ownership of this pointer, and will delete it when the item client data is changed to something else, or when the item is destroyed.

void wxRibbonGallery::Clear ( )

Remove all items from the gallery.

bool wxRibbonGallery::Create (wxWindow * *parent*, wxWindowID *id* = wxID_ANY, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, long *style* = 0)

Create a gallery in two-step gallery construction.

Should only be called when the default constructor is used, and arguments have the same meaning as in the full constructor.

void wxRibbonGallery::EnsureVisible (const wxRibbonGalleryItem * *item*)

Scroll the gallery to ensure that the given item is visible.

wxRibbonGalleryItem* wxRibbonGallery::GetActiveItem ( ) const

Get the currently active item, or NULL if there is none.

The active item is the item being pressed by the user, and will thus become the selected item if the user releases the mouse button.

unsigned int wxRibbonGallery::GetCount ( ) const

Get the number of items in the gallery.

wxRibbonGalleryButtonState wxRibbonGallery::GetDownButtonState ( ) const

Get the state of the scroll down button.

wxRibbonGalleryButtonState wxRibbonGallery::GetExtensionButtonState ( ) const

Get the state of the "extension" button.

wxRibbonGalleryItem* wxRibbonGallery::GetHoveredItem ( ) const

Get the currently hovered item, or NULL if there is none.

The hovered item is the item underneath the mouse cursor.

wxRibbonGalleryItem* wxRibbonGallery::GetItem (unsigned int *n*)

Get an item by index.

void* wxRibbonGallery::GetItemClientData (const wxRibbonGalleryItem * *item*) const

Get the client data associated with a gallery item.

wxClientData* wxRibbonGallery::GetItemClientObject (const wxRibbonGalleryItem * *item*) const

Get the client object associated with a gallery item.

wxRibbonGalleryItem* wxRibbonGallery::GetSelection ( ) const

Get the currently selected item, or NULL if there is none.

The selected item is set by SetSelection(), or by the user clicking on an item.

wxRibbonGalleryButtonState wxRibbonGallery::GetUpButtonState ( ) const

Get the state of the scroll up button.

bool wxRibbonGallery::IsEmpty ( ) const

Query if the gallery has no items in it.

bool wxRibbonGallery::IsHovered ( ) const

Query is the mouse is currently hovered over the gallery.

Returns

true if the cursor is within the bounds of the gallery (not just hovering over an item), false otherwise.

virtual bool wxRibbonGallery::ScrollLines (int *lines*) [virtual]

Scroll the gallery contents by some amount.

Parameters

lines	Positive values scroll toward the end of the gallery, while negative values scroll toward the start.

Returns

true if the gallery scrolled at least one pixel in the given direction, false if it did not scroll.

Reimplemented from wxWindow.

bool wxRibbonGallery::ScrollPixels (int *pixels*)

Scroll the gallery contents by some fine-grained amount.

Parameters

pixels	Positive values scroll toward the end of the gallery, while negative values scroll toward the start.

Returns

true if the gallery scrolled at least one pixel in the given direction, false if it did not scroll.

void wxRibbonGallery::SetItemClientData (wxRibbonGalleryItem * *item,* void * *data*)

Set the client data associated with a gallery item.

void wxRibbonGallery::SetItemClientObject (wxRibbonGalleryItem * *item,* wxClientData * *data*)

Set the client object associated with a gallery item.

void wxRibbonGallery::SetSelection (wxRibbonGalleryItem * *item*)

Set the selection to the given item, or removes the selection if *item* == NULL.

Note that this not cause any events to be emitted.

21.601 wxRibbonGalleryEvent Class Reference

`#include <wx/ribbon/gallery.h>`

wxRibbonGalleryEvent::wxRibbonGalleryEvent (wxEventType *command_type* = wxEVT_NULL, int *win_id* = 0, wxRibbonGallery * *gallery* = NULL, wxRibbonGalleryItem * *item* = NULL)

Constructor.

21.601.3 Member Function Documentation

wxRibbonGallery* wxRibbonGalleryEvent::GetGallery ( )

Returns the gallery which the event relates to.

wxRibbonGalleryItem* wxRibbonGalleryEvent::GetGalleryItem ( )

Returns the gallery item which the event relates to, or NULL if it does not relate to an item.

void wxRibbonGalleryEvent::SetGallery (wxRibbonGallery * *gallery*)

Sets the gallery relating to this event.

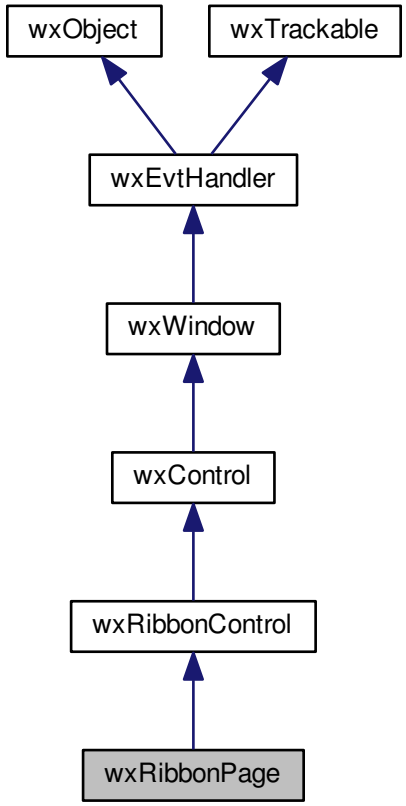
void wxRibbonGalleryEvent::SetGalleryItem (wxRibbonGalleryItem * *item*)

Sets the gallery item relating to this event.

21.602 wxRibbonPage Class Reference

```
#include <wx/ribbon/page.h>
```

Inheritance diagram for wxRibbonPage:



21.602.1 Detailed Description

Container for related ribbon panels, and a tab within a ribbon bar.

See also

wxRibbonBar
wxRibbonPanel

Library: wxRibbon

Category: Ribbon User Interface

Public Member Functions

- wxRibbonPage ()

  Default constructor.
- wxRibbonPage (wxRibbonBar *parent, wxWindowID id=wxID_ANY, const wxString &label=wxEmptyString, const wxBitmap &icon=wxNullBitmap, long style=0)

Constructs a ribbon page, which must be a child of a ribbon bar.

- virtual ~wxRibbonPage ()

  Destructor.

- bool Create (wxRibbonBar *parent, wxWindowID id=wxID_ANY, const wxString &label=wxEmptyString, const wxBitmap &icon=wxNullBitmap, long style=0)

  Create a ribbon page in two-step ribbon page construction.

- void SetArtProvider (wxRibbonArtProvider *art)

  Set the art provider to be used.

- wxBitmap & GetIcon ()

  Get the icon used for the page in the ribbon bar tab area (only displayed if the ribbon bar is actually showing icons).

- void SetSizeWithScrollButtonAdjustment (int x, int y, int width, int height)

  Set the size of the page and the external scroll buttons (if any).

- void AdjustRectToIncludeScrollButtons (wxRect *rect) const

  Expand a rectangle of the page to include external scroll buttons (if any).

- bool DismissExpandedPanel ()

  Dismiss the current externally expanded panel, if there is one.

- virtual bool Realize ()

  Perform a full re-layout of all panels on the page.

- virtual bool ScrollLines (int lines)

  Scroll the page by some amount up / down / left / right.

- bool ScrollPixels (int pixels)

  Scroll the page by a set number of pixels up / down / left / right.

- bool ScrollSections (int sections)

  Scroll the page by an entire child section.

- wxOrientation GetMajorAxis () const

  Get the direction in which ribbon panels are stacked within the page.

Additional Inherited Members

21.602.2 Constructor & Destructor Documentation

wxRibbonPage::wxRibbonPage ( )

Default constructor.

With this constructor, Create() should be called in order to create the ribbon page.

wxRibbonPage::wxRibbonPage (wxRibbonBar * *parent*, wxWindowID *id* = wxID_ANY, const wxString & *label* = wxEmptyString, const wxBitmap & *icon* = wxNullBitmap, long *style* = 0)

Constructs a ribbon page, which must be a child of a ribbon bar.

Parameters

parent	Pointer to a parent wxRibbonBar (unlike most controls, a wxRibbonPage can only have wxRibbonBar as a parent).
id	Window identifier.
label	Label to be used in the wxRibbonBar's tab list for this page (if the ribbon bar is set to display labels).

icon	Icon to be used in the wxRibbonBar's tab list for this page (if the ribbon bar is set to display icons).
style	Currently unused, should be zero.

virtual wxRibbonPage::~wxRibbonPage ( ) [virtual]

Destructor.

21.602.3 Member Function Documentation

void wxRibbonPage::AdjustRectToIncludeScrollButtons (wxRect * *rect*) const

Expand a rectangle of the page to include external scroll buttons (if any).

When no scroll buttons are shown, has no effect.

Parameters

in,out	*rect*	The rectangle to adjust. The width and height will not be reduced, and the x and y will not be increased.

bool wxRibbonPage::Create (wxRibbonBar * *parent*, wxWindowID *id* = wxID_ANY, const wxString & *label* = wxEmptyString, const wxBitmap & *icon* = wxNullBitmap, long *style* = 0)

Create a ribbon page in two-step ribbon page construction.

Should only be called when the default constructor is used, and arguments have the same meaning as in the full constructor.

bool wxRibbonPage::DismissExpandedPanel ( )

Dismiss the current externally expanded panel, if there is one.

When a ribbon panel automatically minimises, it can be externally expanded into a floating window. When the user clicks a button in such a panel, the panel should generally re-minimise. Event handlers for buttons on ribbon panels should call this method to achieve this behaviour.

Returns

true if a panel was minimised, false otherwise.

wxBitmap& wxRibbonPage::GetIcon ( )

Get the icon used for the page in the ribbon bar tab area (only displayed if the ribbon bar is actually showing icons).

wxOrientation wxRibbonPage::GetMajorAxis ( ) const

Get the direction in which ribbon panels are stacked within the page.

This is controlled by the style of the containing wxRibbonBar, meaning that all pages within a bar will have the same major axis. As well as being the direction in which panels are stacked, it is also the axis in which scrolling will occur (when required).

Returns

wxHORIZONTAL or wxVERTICAL (never wxBOTH).

virtual bool wxRibbonPage::Realize ( ) [virtual]

Perform a full re-layout of all panels on the page.

Should be called after panels are added to the page, or the sizing behaviour of a panel on the page changes (i.e. due to children being added to it). Usually called automatically when wxRibbonBar::Realize() is called.

Will invoke wxRibbonPanel::Realize() for all child panels.

Reimplemented from wxRibbonControl.

virtual bool wxRibbonPage::ScrollLines (int *lines*) [virtual]

Scroll the page by some amount up / down / left / right.

When the page's children are too big to fit in the onscreen area given to the page, scroll buttons will appear, and the page can be programmatically scrolled. Positive values of *lines* will scroll right or down, while negative values will scroll up or left (depending on the direction in which panels are stacked). A line is equivalent to a constant number of pixels.

Returns

true if the page scrolled at least one pixel in the given direction, false if it did not scroll.

See also

GetMajorAxis()
ScrollPixels()
ScrollSections()

Reimplemented from wxWindow.

bool wxRibbonPage::ScrollPixels (int *pixels*)

Scroll the page by a set number of pixels up / down / left / right.

When the page's children are too big to fit in the onscreen area given to the page, scroll buttons will appear, and the page can be programmatically scrolled. Positive values of *lines* will scroll right or down, while negative values will scroll up or left (depending on the direction in which panels are stacked).

Returns

true if the page scrolled at least one pixel in the given direction, false if it did not scroll.

See also

GetMajorAxis()
ScrollLines()
ScrollSections()

bool wxRibbonPage::ScrollSections (int *sections*)

Scroll the page by an entire child section.

The *sections* parameter value should be 1 or -1. This will scroll enough to uncover a partially visible child section or totally uncover the next child section that may not be visible at all.

Returns

true if the page scrolled at least one pixel in the given direction, false if it did not scroll.

See also

ScrollPixels()
ScrollSections()

Since

2.9.5

void wxRibbonPage::SetArtProvider (wxRibbonArtProvider * *art*) [virtual]

Set the art provider to be used.

Normally called automatically by wxRibbonBar when the page is created, or the art provider changed on the bar.

The new art provider will be propagated to the children of the page.

Reimplemented from wxRibbonControl.

void wxRibbonPage::SetSizeWithScrollButtonAdjustment (int *x*, int *y*, int *width*, int *height*)

Set the size of the page and the external scroll buttons (if any).

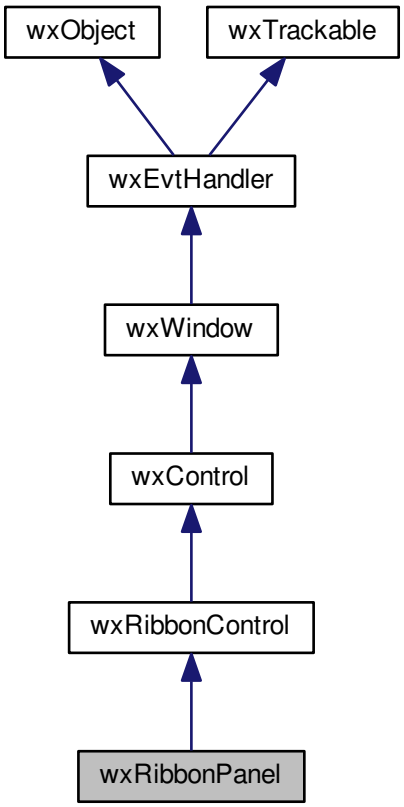
When a page is too small to display all of its children, scroll buttons will appear (and if the page is sized up enough, they will disappear again). Slightly counter-intuitively, these buttons are created as siblings of the page rather than children of the page (to achieve correct cropping and paint ordering of the children and the buttons). When there are no scroll buttons, this function behaves the same as SetSize(), however when there are scroll buttons, it positions them at the edges of the given area, and then calls SetSize() with the remaining area.

This is provided as a separate function to SetSize() rather than within the implementation of SetSize(), as interacting algorithms may not expect SetSize() to also set the size of siblings.

21.603 wxRibbonPanel Class Reference

`#include <wx/ribbon/panel.h>`

Inheritance diagram for wxRibbonPanel:



21.603.1 Detailed Description

Serves as a container for a group of (ribbon) controls.

A wxRibbonPage will typically have panels for children, with the controls for that page placed on the panels.

A panel adds a border and label to a group of controls, and can be minimised (either automatically to conserve space, or manually by the user).

Non ribbon controls can be placed on a panel using wxSizers to manage layout. Panel size is governed by the sizer's minimum calculated size and the parent wxRibbonPage's dimensions. For functional and aesthetic reasons it is recommended that ribbon and non ribbon controls are not mixed in one panel.

See also

wxRibbonPage

Styles

This class supports the following styles:

- wxRIBBON_PANEL_DEFAULT_STYLE: Defined as no other flags set.

- wxRIBBON_PANEL_NO_AUTO_MINIMISE: Prevents the panel from automatically minimising to conserve screen space.
- wxRIBBON_PANEL_EXT_BUTTON: Causes an extension button to be shown in the panel's chrome (if the bar in which it is contained has wxRIBBON_BAR_SHOW_PANEL_EXT_BUTTONS set). The behaviour of this button is application controlled, but typically will show an extended drop-down menu relating to the panel.
- wxRIBBON_PANEL_MINIMISE_BUTTON: Causes a (de)minimise button to be shown in the panel's chrome (if the bar in which it is contained has the wxRIBBON_BAR_SHOW_PANEL_MINIMISE_BUTTONS style set). This flag is typically combined with wxRIBBON_PANEL_NO_AUTO_MINIMISE to make a panel which the user always has manual control over when it minimises.
- wxRIBBON_PANEL_STRETCH: Stretches a single panel to fit the parent page.
- wxRIBBON_PANEL_FLEXIBLE: Allows the panel to size in both directions; currently only useful when a single wxRibbonToolBar is the child of the panel, particularly in vertical orientation where the number of rows is dependent on the amount of horizontal space available. Set the minimum and maximum toolbar rows to take full advantage of this wrapping behaviour.

Events emitted by this class

The following event handler macros redirect the events to member function handlers '**func**' with prototypes like: void handlerFuncName(wxRibbonPanelEvent& event)

Event macros for events emitted by this class:

- EVT_RIBBONPANEL_EXTBUTTON_ACTIVATED(id, func): Triggered when the user activate the panel extension button.

Library: wxRibbon

Category: Ribbon User Interface

Public Member Functions

- wxRibbonPanel ()

  Default constructor.
- wxRibbonPanel (wxWindow *parent, wxWindowID id=wxID_ANY, const wxString &label=wxEmptyString, const wxBitmap &minimised_icon=wxNullBitmap, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, long style=wxRIBBON_PANEL_DEFAULT_STYLE)

  Constructs a ribbon panel.
- bool Create (wxWindow *parent, wxWindowID id=wxID_ANY, const wxString &label=wxEmptyString, const wxBitmap &icon=wxNullBitmap, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, long style=wxRIBBON_PANEL_DEFAULT_STYLE)

  Create a ribbon panel in two-step ribbon panel construction.
- virtual ~wxRibbonPanel ()

  Destructor.
- wxBitmap & GetMinimisedIcon ()

  Get the bitmap to be used in place of the panel children when it is minimised.
- const wxBitmap & GetMinimisedIcon () const
- virtual bool HasExtButton () const

  Test if the panel has an extension button.
- bool IsMinimised () const

  Query if the panel is currently minimised.

- bool IsMinimised (wxSize at_size) const

  Query if the panel would be minimised at a given size.
- bool IsHovered () const

  Query is the mouse is currently hovered over the panel.
- bool IsExtButtonHovered () const

  Query if the mouse is currently hovered over the extension button.
- bool CanAutoMinimise () const

  Query if the panel can automatically minimise itself at small sizes.
- bool ShowExpanded ()

  Show the panel externally expanded.
- bool HideExpanded ()

  Hide the panel's external expansion.
- void SetArtProvider (wxRibbonArtProvider *art)

  Set the art provider to be used.
- bool Realize ()

  Realize all children of the panel.
- wxRibbonPanel * GetExpandedDummy ()

  Get the dummy panel of an expanded panel.
- wxRibbonPanel * GetExpandedPanel ()

  Get the expanded panel of a dummy panel.

Additional Inherited Members

21.603.2 Constructor & Destructor Documentation

wxRibbonPanel::wxRibbonPanel ( )

Default constructor.

With this constructor, Create() should be called in order to create the ribbon panel.

wxRibbonPanel::wxRibbonPanel (wxWindow * *parent*, wxWindowID *id* = wxID_ANY, const wxString & *label* = wxEmptyString, const wxBitmap & *minimised_icon* = wxNullBitmap, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, long *style* = `wxRIBBON_PANEL_DEFAULT_STYLE`)

Constructs a ribbon panel.

Parameters

parent	Pointer to a parent window, which is typically a wxRibbonPage, though it can be any window.
id	Window identifier.
label	Label to be used in the wxRibbonPanel's chrome.
minimised_icon	Icon to be used in place of the panel's children when the panel is minimised.
pos	The initial position of the panel. Not relevant when the parent is a ribbon page, as the position and size of the panel will be dictated by the page.
size	The initial size of the panel. Not relevant when the parent is a ribbon page, as the position and size of the panel will be dictated by the page.
style	Style flags for the panel.

virtual wxRibbonPanel::~wxRibbonPanel ( ) `[virtual]`

Destructor.

21.603.3 Member Function Documentation

bool wxRibbonPanel::CanAutoMinimise ( ) const

Query if the panel can automatically minimise itself at small sizes.

bool wxRibbonPanel::Create (wxWindow * *parent*, wxWindowID *id* = wxID_ANY, const wxString & *label* = wxEmptyString, const wxBitmap & *icon* = wxNullBitmap, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, long *style* = `wxRIBBON_PANEL_DEFAULT_STYLE`)

Create a ribbon panel in two-step ribbon panel construction.

Should only be called when the default constructor is used, and arguments have the same meaning as in the full constructor.

wxRibbonPanel* wxRibbonPanel::GetExpandedDummy ( )

Get the dummy panel of an expanded panel.

Note that this should be called on an expanded panel to get the dummy associated with it - it will return NULL when called on the dummy itself.

See also

ShowExpanded()
GetExpandedPanel()

wxRibbonPanel* wxRibbonPanel::GetExpandedPanel ( )

Get the expanded panel of a dummy panel.

Note that this should be called on a dummy panel to get the expanded panel associated with it - it will return NULL when called on the expanded panel itself.

See also

ShowExpanded()
GetExpandedDummy()

wxBitmap& wxRibbonPanel::GetMinimisedIcon ( )

Get the bitmap to be used in place of the panel children when it is minimised.

const wxBitmap& wxRibbonPanel::GetMinimisedIcon ( ) const

virtual bool wxRibbonPanel::HasExtButton ( ) const `[virtual]`

Test if the panel has an extension button.

Such button is shown in the top right corner of the panel if `wxRIBBON_PANEL_EXT_BUTTON` style is used for it.

Since

2.9.4

Returns

true if the panel and its wxRibbonBar allow it in their styles.

bool wxRibbonPanel::HideExpanded ( )

Hide the panel's external expansion.

Returns

true if the panel was un-expanded, false if it was not (normally due to it not being expanded in the first place).

See also

HideExpanded()
GetExpandedPanel()

bool wxRibbonPanel::IsExtButtonHovered ( ) const

Query if the mouse is currently hovered over the extension button.

Extension button is only shown for panels with `wxRIBBON_PANEL_EXT_BUTTON` style.

Since

2.9.4

bool wxRibbonPanel::IsHovered ( ) const

Query is the mouse is currently hovered over the panel.

Returns

true if the cursor is within the bounds of the panel (i.e. hovered over the panel or one of its children), false otherwise.

bool wxRibbonPanel::IsMinimised ( ) const

Query if the panel is currently minimised.

bool wxRibbonPanel::IsMinimised (wxSize *at_size*) const

Query if the panel would be minimised at a given size.

bool wxRibbonPanel::Realize ( ) [virtual]

Realize all children of the panel.

Reimplemented from wxRibbonControl.

void wxRibbonPanel::SetArtProvider (wxRibbonArtProvider * *art*) [virtual]

Set the art provider to be used.

Normally called automatically by wxRibbonPage when the panel is created, or the art provider changed on the page.

The new art provider will be propagated to the children of the panel.

Reimplemented from wxRibbonControl.

bool wxRibbonPanel::ShowExpanded ( )

Show the panel externally expanded.

When a panel is minimised, it can be shown full-size in a pop-out window, which is referred to as being (externally) expanded. Note that when a panel is expanded, there exist two panels - the original panel (which is referred to as the dummy panel) and the expanded panel. The original is termed a dummy as it sits in the ribbon bar doing nothing, while the expanded panel holds the panel children.

Returns

true if the panel was expanded, false if it was not (possibly due to it not being minimised, or already being expanded).

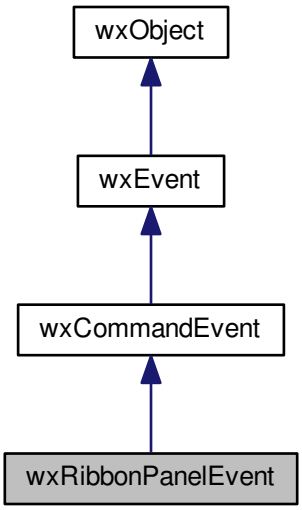
See also

HideExpanded()
GetExpandedPanel()

21.604 wxRibbonPanelEvent Class Reference

`#include <wx/ribbon/panel.h>`

Inheritance diagram for wxRibbonPanelEvent:



21.604.1 Detailed Description

Event used to indicate various actions relating to a wxRibbonPanel.

See wxRibbonPanel for available event types.

21.604.2 Constructor & Destructor Documentation

wxRibbonPanelEvent::wxRibbonPanelEvent (wxEventType *command_type* = wxEVT_NULL, int *win_id* = 0, wxRibbonPanel * *panel* = NULL)

Constructor.

Returns the panel relating to this event.

21.604.3 Member Function Documentation

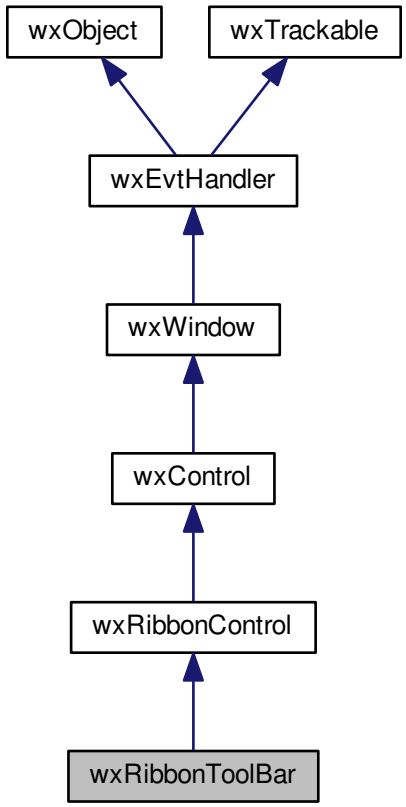
void wxRibbonPanelEvent::SetPanel (wxRibbonPanel * *page*)

Sets the page relating to this event.

21.605 wxRibbonToolBar Class Reference

```
#include <wx/ribbon/toolbar.h>
```

Inheritance diagram for wxRibbonToolBar:



21.605.1 Detailed Description

A ribbon tool bar is similar to a traditional toolbar which has no labels.

It contains one or more tool groups, each of which contains one or more tools. Each tool is represented by a (generally small, i.e. 16x15) bitmap.

Events emitted by this class

The following event handler macros redirect the events to member function handlers '**func**' with prototypes like: void handlerFuncName(wxRibbonToolBarEvent& event)

Event macros for events emitted by this class:

- EVT_RIBBONTOOLBAR_CLICKED(id, func): Triggered when the normal (non-dropdown) region of a tool on the tool bar is clicked.
- EVT_RIBBONTOOLBAR_DROPDOWN_CLICKED(id, func): Triggered when the dropdown region of a tool on the tool bar is clicked. wxRibbonToolBarEvent::PopupMenu() should be called by the event handler if it wants to display a popup menu (which is what most dropdown tools should be doing).

Library: wxRibbon

Category: Ribbon User Interface

Public Member Functions

- wxRibbonToolBar ()

  Default constructor.
- wxRibbonToolBar (wxWindow *parent, wxWindowID id=wxID_ANY, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, long style=0)

  Construct a ribbon tool bar with the given parameters.
- virtual ~wxRibbonToolBar ()

  Destructor.
- bool Create (wxWindow *parent, wxWindowID id=wxID_ANY, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, long style=0)

  Create a tool bar in two-step tool bar construction.
- virtual wxRibbonToolBarToolBase * AddTool (int tool_id, const wxBitmap &bitmap, const wxString &help_string, wxRibbonButtonKind kind=wxRIBBON_BUTTON_NORMAL)

  Add a tool to the tool bar (simple version).
- virtual wxRibbonToolBarToolBase * AddDropdownTool (int tool_id, const wxBitmap &bitmap, const wxString &help_string=wxEmptyString)

  Add a dropdown tool to the tool bar (simple version).
- virtual wxRibbonToolBarToolBase * AddHybridTool (int tool_id, const wxBitmap &bitmap, const wxString &help_string=wxEmptyString)

  Add a hybrid tool to the tool bar (simple version).
- virtual wxRibbonToolBarToolBase * AddToggleTool (int tool_id, const wxBitmap &bitmap, const wxString &help_string)

  Add a toggle tool to the tool bar (simple version).
- virtual wxRibbonToolBarToolBase * AddTool (int tool_id, const wxBitmap &bitmap, const wxBitmap &bitmap_disabled=wxNullBitmap, const wxString &help_string=wxEmptyString, wxRibbonButtonKind kind=wxRIBBON_BUTTON_NORMAL, wxObject *client_data=NULL)

  Add a tool to the tool bar.
- virtual wxRibbonToolBarToolBase * AddSeparator ()

  Add a separator to the tool bar.
- virtual wxRibbonToolBarToolBase * InsertTool (size_t pos, int tool_id, const wxBitmap &bitmap, const wxString &help_string, wxRibbonButtonKind kind=wxRIBBON_BUTTON_NORMAL)

  Insert a tool to the tool bar (simple version) as the specified position.
- virtual wxRibbonToolBarToolBase * InsertDropdownTool (size_t pos, int tool_id, const wxBitmap &bitmap, const wxString &help_string=wxEmptyString)

  Insert a dropdown tool to the tool bar (simple version) as the specified position.
- virtual wxRibbonToolBarToolBase * InsertHybridTool (size_t pos, int tool_id, const wxBitmap &bitmap, const wxString &help_string=wxEmptyString)

  Insert a hybrid tool to the tool bar (simple version) as the specified position.
- virtual wxRibbonToolBarToolBase * InsertToggleTool (size_t pos, int tool_id, const wxBitmap &bitmap, const wxString &help_string=wxEmptyString)

  Insert a toggle tool to the tool bar (simple version) as the specified position.
- virtual wxRibbonToolBarToolBase * InsertTool (size_t pos, int tool_id, const wxBitmap &bitmap, const wxBitmap &bitmap_disabled=wxNullBitmap, const wxString &help_string=wxEmptyString, wxRibbonButtonKind kind=wxRIBBON_BUTTON_NORMAL, wxObject *client_data=NULL)

  Insert a tool to the tool bar at the specified position.
- virtual wxRibbonToolBarToolBase * InsertSeparator (size_t pos)

Insert a separator to the tool bar at the specified position.

- virtual void ClearTools ()

  Deletes all the tools in the toolbar.
- virtual bool DeleteTool (int tool_id)

  Removes the specified tool from the toolbar and deletes it.
- virtual bool DeleteToolByPos (size_t pos)

  This function behaves like DeleteTool() but it deletes the tool at the specified position and not the one with the given id.
- virtual wxRibbonToolBarToolBase * FindById (int tool_id) const

  Returns a pointer to the tool opaque structure by id or NULL if no corresponding tool is found.
- wxRibbonToolBarToolBase * GetToolByPos (size_t pos) const virtual size_t GetToolCount() const

  Return the opaque pointer corresponding to the given tool.
- virtual int GetToolId (const wxRibbonToolBarToolBase *tool) const

  Return the id assciated to the tool opaque structure.
- virtual wxObject * GetToolClientData (int tool_id) const

  Get any client data associated with the tool.
- virtual bool GetToolEnabled (int tool_id) const

  Called to determine whether a tool is enabled (responds to user input).
- virtual wxString GetToolHelpString (int tool_id) const

  Returns the help string for the given tool.
- virtual wxRibbonButtonKind GetToolKind (int tool_id) const

  Return the kind of the given tool.
- virtual int GetToolPos (int tool_id) const

  Returns the tool position in the toolbar, or `wxNOT_FOUND` if the tool is not found.
- virtual bool GetToolState (int tool_id) const

  Gets the on/off state of a toggle tool.
- virtual bool Realize ()

  Calculate tool layouts and positions.
- virtual void SetRows (int nMin, int nMax=-1)

  Set the number of rows to distribute tool groups over.
- virtual void SetToolClientData (int tool_id, wxObject *clientData)

  Sets the client data associated with the tool.
- virtual void SetToolDisabledBitmap (int tool_id, const wxBitmap &bitmap)

  Sets the bitmap to be used by the tool with the given ID when the tool is in a disabled state.
- virtual void SetToolHelpString (int tool_id, const wxString &helpString)

  Sets the help string shown in tooltip for the given tool.
- virtual void SetToolNormalBitmap (int tool_id, const wxBitmap &bitmap)

  Sets the bitmap to be used by the tool with the given ID.
- virtual void EnableTool (int tool_id, bool enable=true)

  Enable or disable a single tool on the bar.
- virtual void ToggleTool (int tool_id, bool checked)

  Set a toggle tool to the checked or unchecked state.

Additional Inherited Members

21.605.2 Constructor & Destructor Documentation

wxRibbonToolBar::wxRibbonToolBar ( )

Default constructor.

With this constructor, Create() should be called in order to create the tool bar.

wxRibbonToolBar::wxRibbonToolBar (wxWindow * *parent*, wxWindowID *id* = wxID_ANY, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, long *style* = 0)

Construct a ribbon tool bar with the given parameters.

Parameters

parent	Parent window for the tool bar (typically a wxRibbonPanel).
id	An identifier for the toolbar. `wxID_ANY` is taken to mean a default.
pos	Initial position of the tool bar.
size	Initial size of the tool bar.
style	Tool bar style, currently unused.

virtual wxRibbonToolBar::~wxRibbonToolBar ( ) [virtual]

Destructor.

21.605.3 Member Function Documentation

virtual wxRibbonToolBarToolBase* wxRibbonToolBar::AddDropdownTool (int *tool_id,* const wxBitmap & *bitmap,* const wxString & *help_string* = wxEmptyString) [virtual]

Add a dropdown tool to the tool bar (simple version).

See also

AddTool()

virtual wxRibbonToolBarToolBase* wxRibbonToolBar::AddHybridTool (int *tool_id,* const wxBitmap & *bitmap,* const wxString & *help_string* = wxEmptyString) [virtual]

Add a hybrid tool to the tool bar (simple version).

See also

AddTool()

virtual wxRibbonToolBarToolBase* wxRibbonToolBar::AddSeparator ( ) [virtual]

Add a separator to the tool bar.

Separators are used to separate tools into groups. As such, a separator is not explicitly drawn, but is visually seen as the gap between tool groups.

virtual wxRibbonToolBarToolBase* wxRibbonToolBar::AddToggleTool (int *tool_id,* const wxBitmap & *bitmap,* const wxString & *help_string*) [virtual]

Add a toggle tool to the tool bar (simple version).

Since

2.9.4

See also

AddTool()

virtual wxRibbonToolBarToolBase* wxRibbonToolBar::AddTool (int *tool_id*, const wxBitmap & *bitmap*, const wxString & *help_string*, wxRibbonButtonKind *kind* = wxRIBBON_BUTTON_NORMAL) [virtual]

Add a tool to the tool bar (simple version).

virtual wxRibbonToolBarToolBase* wxRibbonToolBar::AddTool (int *tool_id*, const wxBitmap & *bitmap*, const wxBitmap & *bitmap_disabled* = wxNullBitmap, const wxString & *help_string* = wxEmptyString, wxRibbonButtonKind *kind* = wxRIBBON_BUTTON_NORMAL, wxObject * *client_data* = NULL) [virtual]

Add a tool to the tool bar.

Parameters

tool_id	ID of the new tool (used for event callbacks).
bitmap	Bitmap to use as the foreground for the new tool. Does not have to be the same size as other tool bitmaps, but should be similar as otherwise it will look visually odd.
bitmap_disabled	Bitmap to use when the tool is disabled. If left as wxNullBitmap, then a bitmap will be automatically generated from *bitmap*.
help_string	The UI help string to associate with the new tool.
kind	The kind of tool to add.
client_data	Client data to associate with the new tool.

Returns

An opaque pointer which can be used only with other tool bar methods.

See also

AddDropdownTool(), AddHybridTool(), AddSeparator(), InsertTool()

virtual void wxRibbonToolBar::ClearTools ( ) [virtual]

Deletes all the tools in the toolbar.

Since

2.9.4

bool wxRibbonToolBar::Create (wxWindow * *parent*, wxWindowID *id* = wxID_ANY, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, long *style* = 0)

Create a tool bar in two-step tool bar construction.

Should only be called when the default constructor is used, and arguments have the same meaning as in the full constructor.

virtual bool wxRibbonToolBar::DeleteTool (int *tool_id*) [virtual]

Removes the specified tool from the toolbar and deletes it.

Parameters

tool_id	ID of the tool to delete.

Returns

true if the tool was deleted, false otherwise.

Since

2.9.4

See also

DeleteToolByPos()

virtual bool wxRibbonToolBar::DeleteToolByPos (size_t *pos*) [virtual]

This function behaves like DeleteTool() but it deletes the tool at the specified position and not the one with the given id.

Useful to delete separators.

Since

2.9.4

virtual void wxRibbonToolBar::EnableTool (int *tool_id*, bool *enable* = true) [virtual]

Enable or disable a single tool on the bar.

Parameters

tool_id	ID of the tool to enable or disable.
enable	true to enable the tool, false to disable it.

Since

2.9.4

virtual wxRibbonToolBarToolBase* wxRibbonToolBar::FindById (int *tool_id*) const [virtual]

Returns a pointer to the tool opaque structure by *id* or NULL if no corresponding tool is found.

Since

2.9.4

wxRibbonToolBarToolBase* wxRibbonToolBar::GetToolByPos (size_t *pos*) const

Return the opaque pointer corresponding to the given tool.

Returns

an opaque pointer, NULL if is a separator or not found.

Since

2.9.4 Returns the number of tools in the toolbar.
2.9.4

virtual wxObject* wxRibbonToolBar::GetToolClientData (int *tool_id*) const `[virtual]`

Get any client data associated with the tool.

Parameters

tool_id	ID of the tool in question, as passed to AddTool().

Returns

Client data, or NULL if there is none.

Since

2.9.4

virtual bool wxRibbonToolBar::GetToolEnabled (int *tool_id*) const `[virtual]`

Called to determine whether a tool is enabled (responds to user input).

Parameters

tool_id	ID of the tool in question, as passed to AddTool().

Returns

true if the tool is enabled, false otherwise.

Since

2.9.4

See also

EnableTool()

virtual wxString wxRibbonToolBar::GetToolHelpString (int *tool_id*) const `[virtual]`

Returns the help string for the given tool.

Parameters

tool_id	ID of the tool in question, as passed to AddTool().

Since

2.9.4

virtual int wxRibbonToolBar::GetToolId (const wxRibbonToolBarToolBase * *tool*) const `[virtual]`

Return the id assciated to the tool opaque structure.

The structure pointer must not be NULL.

Since

2.9.4

virtual wxRibbonButtonKind wxRibbonToolBar::GetToolKind (int *tool_id*) const `[virtual]`

Return the kind of the given tool.

Parameters

tool_id	ID of the tool in question, as passed to AddTool().

Since

2.9.4

virtual int wxRibbonToolBar::GetToolPos (int *tool_id*) const `[virtual]`

Returns the tool position in the toolbar, or `wxNOT_FOUND` if the tool is not found.

Parameters

tool_id	ID of the tool in question, as passed to AddTool().

Since

2.9.4

virtual bool wxRibbonToolBar::GetToolState (int *tool_id*) const `[virtual]`

Gets the on/off state of a toggle tool.

Parameters

tool_id	ID of the tool in question, as passed to AddTool().

Returns

true if the tool is toggled on, false otherwise.

See also

ToggleTool()

Since

2.9.4

virtual wxRibbonToolBarToolBase* wxRibbonToolBar::InsertDropdownTool (size_t *pos*, int *tool_id*, const wxBitmap & *bitmap*, const wxString & *help_string* = wxEmptyString) `[virtual]`

Insert a dropdown tool to the tool bar (simple version) as the specified position.

Since

2.9.4

See also

AddDropdownTool(), InsertTool()

virtual wxRibbonToolBarToolBase* wxRibbonToolBar::InsertHybridTool (size_t *pos*, int *tool_id*, const wxBitmap & *bitmap*, const wxString & *help_string* = wxEmptyString) [virtual]

Insert a hybrid tool to the tool bar (simple version) as the specified position.

Since

2.9.4

See also

AddHybridTool(), InsertTool()

virtual wxRibbonToolBarToolBase* wxRibbonToolBar::InsertSeparator (size_t *pos*) [virtual]

Insert a separator to the tool bar at the specified position.

Since

2.9.4

See also

AddSeparator(), InsertTool()

virtual wxRibbonToolBarToolBase* wxRibbonToolBar::InsertToggleTool (size_t *pos*, int *tool_id*, const wxBitmap & *bitmap*, const wxString & *help_string* = wxEmptyString) [virtual]

Insert a toggle tool to the tool bar (simple version) as the specified position.

Since

2.9.4

See also

AddToggleTool(), InsertTool()

virtual wxRibbonToolBarToolBase* wxRibbonToolBar::InsertTool (size_t *pos*, int *tool_id*, const wxBitmap & *bitmap*, const wxString & *help_string*, wxRibbonButtonKind *kind* = wxRIBBON_BUTTON_NORMAL) [virtual]

Insert a tool to the tool bar (simple version) as the specified position.

Since

2.9.4

See also

InsertTool()

virtual wxRibbonToolBarToolBase* wxRibbonToolBar::InsertTool (size_t *pos*, int *tool_id*, const wxBitmap & *bitmap*, const wxBitmap & *bitmap_disabled* = wxNullBitmap, const wxString & *help_string* = wxEmptyString, wxRibbonButtonKind *kind* = wxRIBBON_BUTTON_NORMAL, wxObject * *client_data* = NULL) [virtual]

Insert a tool to the tool bar at the specified position.

Parameters

pos	Position of the new tool (number of tools and separators from the beginning of the toolbar).
tool_id	ID of the new tool (used for event callbacks).
bitmap	Bitmap to use as the foreground for the new tool. Does not have to be the same size as other tool bitmaps, but should be similar as otherwise it will look visually odd.
bitmap_disabled	Bitmap to use when the tool is disabled. If left as wxNullBitmap, then a bitmap will be automatically generated from *bitmap*.
help_string	The UI help string to associate with the new tool.
kind	The kind of tool to add.
client_data	Client data to associate with the new tool.

Returns

An opaque pointer which can be used only with other tool bar methods.

Since

2.9.4

See also

InsertDropdownTool(), InsertHybridTool(), InsertSeparator()

virtual bool wxRibbonToolBar::Realize ( ) [virtual]

Calculate tool layouts and positions.

Must be called after tools are added to the tool bar, as otherwise the newly added tools will not be displayed.

Reimplemented from wxRibbonControl.

virtual void wxRibbonToolBar::SetRows (int *nMin*, int *nMax* = -1) [virtual]

Set the number of rows to distribute tool groups over.

Tool groups can be distributed over a variable number of rows. The way in which groups are assigned to rows is not specified, and the order of groups may change, but they will be distributed in such a way as to minimise the overall size of the tool bar.

Parameters

nMin	The minimum number of rows to use.
nMax	The maximum number of rows to use (defaults to nMin).

virtual void wxRibbonToolBar::SetToolClientData (int *tool_id*, wxObject * *clientData*) [virtual]

Sets the client data associated with the tool.

Parameters

tool_id	ID of the tool in question, as passed to AddTool().
clientData	The client data to use.

Since

2.9.4

virtual void wxRibbonToolBar::SetToolDisabledBitmap (int *tool_id,* const wxBitmap & *bitmap*) `[virtual]`

Sets the bitmap to be used by the tool with the given ID when the tool is in a disabled state.

Parameters

tool_id	ID of the tool in question, as passed to AddTool().
bitmap	Bitmap to use for disabled tools.

Since

2.9.4

virtual void wxRibbonToolBar::SetToolHelpString (int *tool_id,* const wxString & *helpString*) [virtual]

Sets the help string shown in tooltip for the given tool.

Parameters

tool_id	ID of the tool in question, as passed to AddTool().
helpString	A string for the help.

See also

GetToolHelpString()

Since

2.9.4

virtual void wxRibbonToolBar::SetToolNormalBitmap (int *tool_id,* const wxBitmap & *bitmap*) [virtual]

Sets the bitmap to be used by the tool with the given ID.

Parameters

tool_id	ID of the tool in question, as passed to AddTool().
bitmap	Bitmap to use for normals tools.

Since

2.9.4

virtual void wxRibbonToolBar::ToggleTool (int *tool_id,* bool *checked*) [virtual]

Set a toggle tool to the checked or unchecked state.

Parameters

tool_id	ID of the toggle tool to manipulate.
checked	true to set the tool to the toggled/pressed/checked state, false to set it to the untoggled/unpressed/unchecked state.

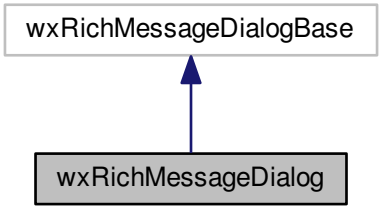
Since

2.9.4

21.606 wxRichMessageDialog Class Reference

`#include <wx/richmsgdlg.h>`

Inheritance diagram for wxRichMessageDialog:



21.606.1 Detailed Description

Extension of wxMessageDialog with additional functionality.

This class adds the possibility of using a checkbox (that is especially useful for implementing the "Don't ask me again" kind of dialogs) and an extra explanatory text which is initially collapsed and not shown to the user but can be expanded to show more information.

Notice that currently the native dialog is used only under MSW when using Vista or later Windows version. Elsewhere, or for older versions of Windows, a generic implementation which is less familiar to the users is used. Because of this it's recommended to use this class only if you do need its extra functionality and use wxMessageDialog which does have native implementation under all platforms otherwise. However if you do need to put e.g. a checkbox in a dialog, you should definitely consider using this class instead of using your own custom dialog because it will have much better appearance at least under recent Windows versions.

To use this class, you need to create the dialog object and call ShowCheckBox() and/or ShowDetailedText() to configure its contents. Other than that, it is used in exactly the same way as wxMessageDialog and supports all the styles supported by it. In particular, ShowModal() return value is the same as for wxMessageDialog. The only difference is that you need to use IsCheckBoxChecked() to examine the checkbox value if you had called ShowCheckBox().

Here is a simple example:

```
void MyFrame::ShowDialog()
{
    if ( ... shouldn't show this dialog again ... )
        return;

    wxRichMessageDialog dlg(this, "Welcome to my wonderful program!");
    dlg.ShowCheckBox("Don't show welcome dialog again");
    dlg.ShowModal(); // return value ignored as we have "Ok" only anyhow

    if ( dlg.IsCheckBoxChecked() )
        ... make sure we won't show it again the next time ...
}
```

Since

2.9.2

Library: wxCore

Category: Common Dialogs

wxMessageDialog Overview

Public Member Functions

- wxRichMessageDialog (wxWindow *parent, const wxString &message, const wxString &caption=wxMessageBoxCaptionStr, long style=wxOK|wxCENTRE)

  Constructor specifying the rich message dialog properties.
- void ShowCheckBox (const wxString &checkBoxText, bool checked=false)

  Shows a checkbox with a given label or hides it.
- wxString GetCheckBoxText () const

  Retrieves the label for the checkbox.
- void ShowDetailedText (const wxString &detailedText)

  Shows or hides a detailed text and an expander that is used to show or hide the detailed text.
- wxString GetDetailedText () const

  Retrieves the detailed text.
- bool IsCheckBoxChecked () const

  Retrieves the state of the checkbox.
- virtual int ShowModal ()

  Shows the dialog, returning one of wxID_OK, wxID_CANCEL, wxID_YES, wxID_NO.

21.606.2 Constructor & Destructor Documentation

wxRichMessageDialog::wxRichMessageDialog (wxWindow * *parent*, const wxString & *message*, const wxString & *caption* = wxMessageBoxCaptionStr, long *style* = wxOK|wxCENTRE)

Constructor specifying the rich message dialog properties.

Works just like the constructor for wxMessageDialog.

21.606.3 Member Function Documentation

wxString wxRichMessageDialog::GetCheckBoxText ( ) const

Retrieves the label for the checkbox.

Returns

The label for the checkbox, will be the empty string if no checkbox is used.

wxString wxRichMessageDialog::GetDetailedText ( ) const

Retrieves the detailed text.

Returns

The detailed text or empty if detailed text is not used.

bool wxRichMessageDialog::IsCheckBoxChecked ( ) const

Retrieves the state of the checkbox.

If this method is called before showing the dialog, the initial value of the checkbox, as set by ShowCheckBox() is used. If it is called after calling wxDialog::ShowModal(), the value set by the user is returned.

Returns

true if the checkbox is checked or false if not.

void wxRichMessageDialog::ShowCheckBox (const wxString & *checkBoxText,* bool *checked* = `false`)

Shows a checkbox with a given label or hides it.

Parameters

checkBoxText	If the parameter is non-empty a checkbox will be shown with that label, otherwise it will be hidden.
checked	The initial state of the checkbox.

void wxRichMessageDialog::ShowDetailedText (const wxString & *detailedText*)

Shows or hides a detailed text and an expander that is used to show or hide the detailed text.

Parameters

detailedText	The detailed text that can be expanded when the dialog is shown, if empty no detailed text will be used.

virtual int wxRichMessageDialog::ShowModal ( ) [virtual]

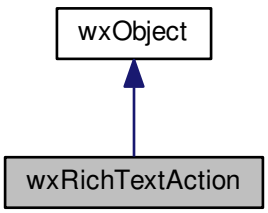
Shows the dialog, returning one of wxID_OK, wxID_CANCEL, wxID_YES, wxID_NO.

IsCheckBoxChecked() can be called afterwards to retrieve the value of the check box if one was used.

21.607 wxRichTextAction Class Reference

`#include <wx/richtext/richtextbuffer.h>`

Inheritance diagram for wxRichTextAction:



21.607.1 Detailed Description

Implements a part of a command.

Library: wxRichText

Category: Rich Text

See also

wxRichTextCommand

Public Member Functions

- wxRichTextAction (wxRichTextCommand *cmd, const wxString &name, wxRichTextCommandId id, wxRichTextBuffer *buffer, wxRichTextParagraphLayoutBox *container, wxRichTextCtrl *ctrl, bool ignoreFirstTime=false)

  Constructor.
- virtual ~wxRichTextAction ()
- bool Do ()

  Performs the action.
- bool Undo ()

  Undoes the action.
- void UpdateAppearance (long caretPosition, bool sendUpdateEvent=false, const wxRect &oldFloatRect=wxRect(), wxArrayInt *optimizationLineCharPositions=NULL, wxArrayInt *optimizationLineYPositions=NULL, bool isDoCmd=true)

  Updates the control appearance, optimizing if possible given information from the call to Layout.
- void ApplyParagraphs (const wxRichTextParagraphLayoutBox &fragment)

  Replaces the buffer paragraphs with the given fragment.
- wxRichTextParagraphLayoutBox & GetNewParagraphs ()

  Returns the new fragments.
- wxRichTextParagraphLayoutBox & GetOldParagraphs ()

  Returns the old fragments.
- wxRichTextAttr & GetAttributes ()

  Returns the attributes, for single-object commands.
- wxRichTextObject * GetObject () const

  Returns the object to replace the one at the position defined by the container address and the action's range start position.
- void StoreObject (wxRichTextObject *obj)

  Stores the object to replace the one at the position defined by the container address without making an address for it.
- void SetObject (wxRichTextObject *obj)

  Sets the object to replace the one at the position defined by the container address and the action's range start position.
- void MakeObject (wxRichTextObject *obj)

  Makes an address from the given object.
- void SetOldAndNewObjects (wxRichTextObject *oldObj, wxRichTextObject *newObj)

  Sets the existing and new objects, for use with wxRICHTEXT_CHANGE_OBJECT.
- void CalculateRefreshOptimizations (wxArrayInt &optimizationLineCharPositions, wxArrayInt &optimizationLineYPositions, wxRect &oldFloatRect)

  Calculate arrays for refresh optimization.
- void SetPosition (long pos)

  Sets the position used for e.g.

- long GetPosition () const

  Returns the position used for e.g.
- void SetRange (const wxRichTextRange &range)

  Sets the range for e.g.
- const wxRichTextRange & GetRange () const

  Returns the range for e.g.
- wxRichTextObjectAddress & GetContainerAddress ()

  Returns the address (nested position) of the container within the buffer being manipulated.
- const wxRichTextObjectAddress & GetContainerAddress () const

  Returns the address (nested position) of the container within the buffer being manipulated.
- void SetContainerAddress (const wxRichTextObjectAddress &address)

  Sets the address (nested position) of the container within the buffer being manipulated.
- void SetContainerAddress (wxRichTextParagraphLayoutBox *container, wxRichTextObject *obj)

  Sets the address (nested position) of the container within the buffer being manipulated.
- wxRichTextParagraphLayoutBox * GetContainer () const

  Returns the container that this action refers to, using the container address and top-level buffer.
- const wxString & GetName () const

  Returns the action name.
- void SetIgnoreFirstTime (bool b)

  Instructs the first Do() command should be skipped as it's already been applied.
- bool GetIgnoreFirstTime () const

  Returns true if the first Do() command should be skipped as it's already been applied.

Protected Attributes

- wxString m_name
- wxRichTextBuffer * m_buffer
- wxRichTextObjectAddress m_containerAddress
- wxRichTextCtrl * m_ctrl
- wxRichTextParagraphLayoutBox m_newParagraphs
- wxRichTextParagraphLayoutBox m_oldParagraphs
- wxRichTextObject * m_object
- wxRichTextAttr m_attributes
- wxRichTextObjectAddress m_objectAddress
- wxRichTextRange m_range
- long m_position
- bool m_ignoreThis
- wxRichTextCommandId m_cmdId

Additional Inherited Members

21.607.2 Constructor & Destructor Documentation

wxRichTextAction::wxRichTextAction (wxRichTextCommand * *cmd*, const wxString & *name*, wxRichTextCommandId *id*, wxRichTextBuffer * *buffer*, wxRichTextParagraphLayoutBox * *container*, wxRichTextCtrl * *ctrl*, bool *ignoreFirstTime* = `false`)

Constructor.

buffer is the top-level buffer, while *container* is the object within which the action is taking place. In the simplest case, they are the same.

virtual wxRichTextAction::~wxRichTextAction ( ) [virtual]

21.607.3 Member Function Documentation

void wxRichTextAction::ApplyParagraphs (const wxRichTextParagraphLayoutBox & *fragment*)

Replaces the buffer paragraphs with the given fragment.

void wxRichTextAction::CalculateRefreshOptimizations (wxArrayInt & *optimizationLineCharPositions,* wxArrayInt & *optimizationLineYPositions,* wxRect & *oldFloatRect*)

Calculate arrays for refresh optimization.

bool wxRichTextAction::Do ( )

Performs the action.

wxRichTextAttr& wxRichTextAction::GetAttributes ( ) [inline]

Returns the attributes, for single-object commands.

wxRichTextParagraphLayoutBox* wxRichTextAction::GetContainer ( ) const

Returns the container that this action refers to, using the container address and top-level buffer.

wxRichTextObjectAddress& wxRichTextAction::GetContainerAddress ( ) [inline]

Returns the address (nested position) of the container within the buffer being manipulated.

const wxRichTextObjectAddress& wxRichTextAction::GetContainerAddress ( ) const [inline]

Returns the address (nested position) of the container within the buffer being manipulated.

bool wxRichTextAction::GetIgnoreFirstTime ( ) const

Returns true if the first Do() command should be skipped as it's already been applied.

const wxString& wxRichTextAction::GetName ( ) const [inline]

Returns the action name.

wxRichTextParagraphLayoutBox& wxRichTextAction::GetNewParagraphs ( ) [inline]

Returns the new fragments.

wxRichTextObject* wxRichTextAction::GetObject ( ) const [inline]

Returns the object to replace the one at the position defined by the container address and the action's range start position.

wxRichTextParagraphLayoutBox& wxRichTextAction::GetOldParagraphs ( ) [inline]

Returns the old fragments.

long wxRichTextAction::GetPosition ( ) const [inline]

Returns the position used for e.g.

insertion.

const wxRichTextRange& wxRichTextAction::GetRange ( ) const [inline]

Returns the range for e.g.

deletion.

void wxRichTextAction::MakeObject (wxRichTextObject * *obj*) [inline]

Makes an address from the given object.

void wxRichTextAction::SetContainerAddress (const wxRichTextObjectAddress & *address*) [inline]

Sets the address (nested position) of the container within the buffer being manipulated.

void wxRichTextAction::SetContainerAddress (wxRichTextParagraphLayoutBox * *container,* wxRichTextObject * *obj*) [inline]

Sets the address (nested position) of the container within the buffer being manipulated.

void wxRichTextAction::SetIgnoreFirstTime (bool *b*)

Instructs the first Do() command should be skipped as it's already been applied.

void wxRichTextAction::SetObject (wxRichTextObject * *obj*) [inline]

Sets the object to replace the one at the position defined by the container address and the action's range start position.

void wxRichTextAction::SetOldAndNewObjects (wxRichTextObject * *oldObj,* wxRichTextObject * *newObj*)

Sets the existing and new objects, for use with wxRICHTEXT_CHANGE_OBJECT.

void wxRichTextAction::SetPosition (long *pos*) [inline]

Sets the position used for e.g.

insertion.

void wxRichTextAction::SetRange (const wxRichTextRange & *range*) [inline]

Sets the range for e.g.

deletion.

void wxRichTextAction::StoreObject (wxRichTextObject * *obj*) [inline]

Stores the object to replace the one at the position defined by the container address without making an address for it.

See also

SetObject(), MakeObject()).

bool wxRichTextAction::Undo ( )

Undoes the action.

void wxRichTextAction::UpdateAppearance (long *caretPosition*, bool *sendUpdateEvent* = false, const wxRect & *oldFloatRect* = wxRect(), wxArrayInt * *optimizationLineCharPositions* = NULL, wxArrayInt * *optimizationLineYPositions* = NULL, bool *isDoCmd* = true)

Updates the control appearance, optimizing if possible given information from the call to Layout.

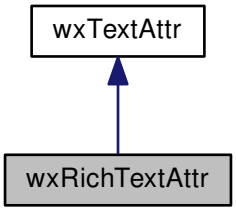
21.608 wxRichTextAttr Class Reference

#include <wx/richtext/richtextbuffer.h>

Inheritance diagram for wxRichTextAttr:



21.608.1 Detailed Description

A class representing enhanced attributes for rich text objects.

This adds a wxTextBoxAttr member to the basic wxTextAttr class.

Library: wxRichText

Category: Rich Text

See also

wxTextAttr, wxTextBoxAttr, wxRichTextCtrl

Public Member Functions

- wxRichTextAttr (const wxTextAttr &attr)
  Constructor taking a wxTextAttr.
- wxRichTextAttr (const wxRichTextAttr &attr)
  Copy constructor.
- wxRichTextAttr ()
  Default constructor.
- void Copy (const wxRichTextAttr &attr)
  Copy function.
- void operator= (const wxRichTextAttr &attr)
  Assignment operator.
- void operator= (const wxTextAttr &attr)
  Assignment operator.
- bool operator== (const wxRichTextAttr &attr) const
  Equality test.
- bool EqPartial (const wxRichTextAttr &attr, bool weakTest=true) const
  Partial equality test.
- bool Apply (const wxRichTextAttr &style, const wxRichTextAttr *compareWith=NULL)
  Merges the given attributes.
- void CollectCommonAttributes (const wxRichTextAttr &attr, wxRichTextAttr &clashingAttr, wxRichTextAttr &absentAttr)

Collects the attributes that are common to a range of content, building up a note of which attributes are absent in some objects and which clash in some objects.

- bool RemoveStyle (const wxRichTextAttr &attr)

  Removes the specified attributes from this object.
- wxTextBoxAttr & GetTextBoxAttr ()

  Returns the text box attributes.
- const wxTextBoxAttr & GetTextBoxAttr () const
- void SetTextBoxAttr (const wxTextBoxAttr &attr)

  Set the text box attributes.
- bool IsDefault () const

  Returns true if no attributes are set.

Public Attributes

- wxTextBoxAttr m_textBoxAttr

Additional Inherited Members

21.608.2 Constructor & Destructor Documentation

wxRichTextAttr::wxRichTextAttr (const wxTextAttr & *attr*) `[inline]`

Constructor taking a wxTextAttr.

wxRichTextAttr::wxRichTextAttr (const wxRichTextAttr & *attr*) `[inline]`

Copy constructor.

wxRichTextAttr::wxRichTextAttr ( ) `[inline]`

Default constructor.

21.608.3 Member Function Documentation

bool wxRichTextAttr::Apply (const wxRichTextAttr & *style,* const wxRichTextAttr * *compareWith* = `NULL`)

Merges the given attributes.

If *compareWith* is non-NULL, then it will be used to mask out those attributes that are the same in style and *compareWith*, for situations where we don't want to explicitly set inherited attributes.

void wxRichTextAttr::CollectCommonAttributes (const wxRichTextAttr & *attr,* wxRichTextAttr & *clashingAttr,* wxRichTextAttr & *absentAttr*)

Collects the attributes that are common to a range of content, building up a note of which attributes are absent in some objects and which clash in some objects.

void wxRichTextAttr::Copy (const wxRichTextAttr & *attr*)

Copy function.

bool wxRichTextAttr::EqPartial (const wxRichTextAttr & *attr,* bool *weakTest* = `true`) const

Partial equality test.

If *weakTest* is true, attributes of this object do not have to be present if those attributes of *attr* are present. If *weakTest* is false, the function will fail if an attribute is present in *attr* but not in this object.

wxTextBoxAttr& wxRichTextAttr::GetTextBoxAttr ( ) `[inline]`

Returns the text box attributes.

const wxTextBoxAttr& wxRichTextAttr::GetTextBoxAttr ( ) const `[inline]`

bool wxRichTextAttr::IsDefault ( ) const `[inline]`

Returns true if no attributes are set.

void wxRichTextAttr::operator= (const wxRichTextAttr & *attr*) `[inline]`

Assignment operator.

void wxRichTextAttr::operator= (const wxTextAttr & *attr*) `[inline]`

Assignment operator.

bool wxRichTextAttr::operator== (const wxRichTextAttr & *attr*) const

Equality test.

bool wxRichTextAttr::RemoveStyle (const wxRichTextAttr & *attr*)

Removes the specified attributes from this object.

void wxRichTextAttr::SetTextBoxAttr (const wxTextBoxAttr & *attr*) `[inline]`

Set the text box attributes.

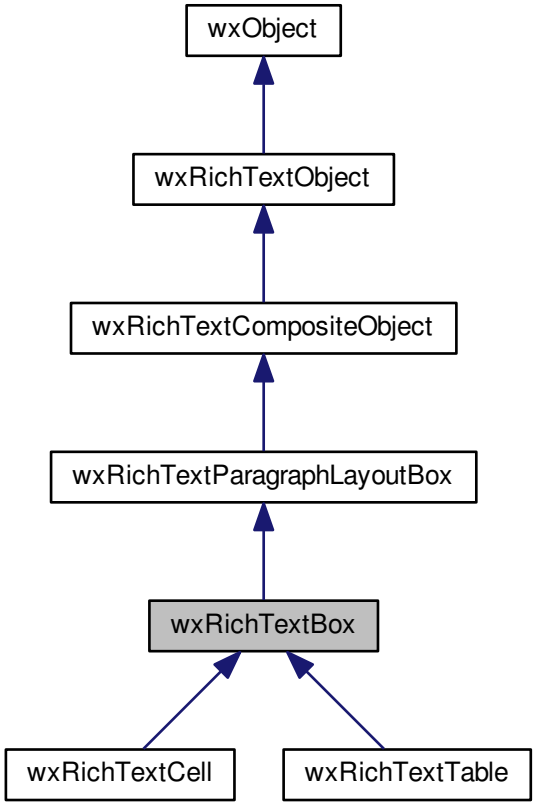
21.608.4 Member Data Documentation

wxTextBoxAttr wxRichTextAttr::m_textBoxAttr

21.609 wxRichTextBox Class Reference

`#include <wx/richtext/richtextbuffer.h>`

Inheritance diagram for wxRichTextBox:



21.609.1 Detailed Description

This class implements a floating or inline text box, containing paragraphs.

Library: wxRichText

Category: Rich Text

See also

wxRichTextParagraphLayoutBox, wxRichTextObject, wxRichTextBuffer, wxRichTextCtrl

Public Member Functions

- wxRichTextBox (wxRichTextObject *parent=NULL)

  Default constructor; optionally pass the parent object.
- wxRichTextBox (const wxRichTextBox &obj)

  Copy constructor.

- virtual bool Draw (wxDC &dc, wxRichTextDrawingContext &context, const wxRichTextRange &range, const wxRichTextSelection &selection, const wxRect &rect, int descent, int style)

  Draw the item, within the given range.
- virtual wxString GetXMLNodeName () const

  Returns the XML node name of this object.
- virtual bool CanEditProperties () const

  Returns true if we can edit the object's properties via a GUI.
- virtual bool EditProperties (wxWindow *parent, wxRichTextBuffer *buffer)

  Edits the object's properties via a GUI.
- virtual wxString GetPropertiesMenuLabel () const

  Returns the label to be used for the properties context menu item.
- virtual wxRichTextObject * Clone () const

  Clones the object.
- void Copy (const wxRichTextBox &obj)

Additional Inherited Members

21.609.2 Constructor & Destructor Documentation

wxRichTextBox::wxRichTextBox (wxRichTextObject * *parent* = NULL)

Default constructor; optionally pass the parent object.

wxRichTextBox::wxRichTextBox (const wxRichTextBox & *obj*) [inline]

Copy constructor.

21.609.3 Member Function Documentation

virtual bool wxRichTextBox::CanEditProperties ( ) const [inline], [virtual]

Returns true if we can edit the object's properties via a GUI.

Reimplemented from wxRichTextObject.

Reimplemented in wxRichTextTable, and wxRichTextCell.

virtual wxRichTextObject* wxRichTextBox::Clone ( ) const [inline], [virtual]

Clones the object.

Reimplemented from wxRichTextParagraphLayoutBox.

Reimplemented in wxRichTextTable, and wxRichTextCell.

void wxRichTextBox::Copy (const wxRichTextBox & *obj*)

virtual bool wxRichTextBox::Draw (wxDC & *dc*, wxRichTextDrawingContext & *context*, const wxRichTextRange & *range*, const wxRichTextSelection & *selection*, const wxRect & *rect*, int *descent*, int *style*) [virtual]

Draw the item, within the given range.

Some objects may ignore the range (for example paragraphs) while others must obey it (lines, to implement wrapping)

Reimplemented from wxRichTextParagraphLayoutBox.

Reimplemented in wxRichTextTable, and wxRichTextCell.

virtual bool wxRichTextBox::EditProperties (wxWindow * *parent,* wxRichTextBuffer * *buffer*) [virtual]

Edits the object's properties via a GUI.

Reimplemented from wxRichTextObject.

Reimplemented in wxRichTextTable, and wxRichTextCell.

virtual wxString wxRichTextBox::GetPropertiesMenuLabel ( ) const [inline], [virtual]

Returns the label to be used for the properties context menu item.

Reimplemented from wxRichTextObject.

Reimplemented in wxRichTextTable, and wxRichTextCell.

virtual wxString wxRichTextBox::GetXMLNodeName ( ) const [inline], [virtual]

Returns the XML node name of this object.

This must be overridden for wxXmlNode-base XML export to work.

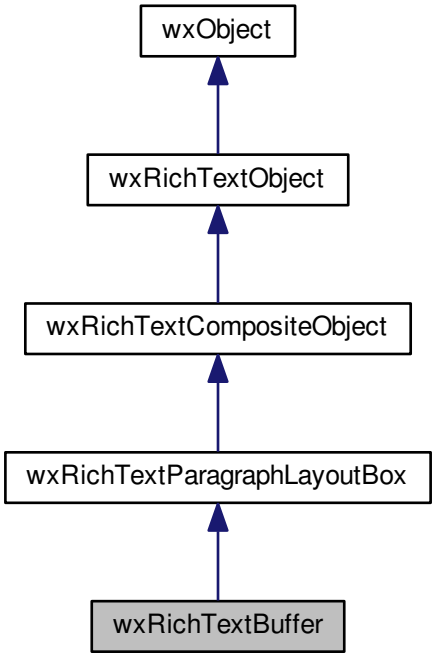
Reimplemented from wxRichTextParagraphLayoutBox.

Reimplemented in wxRichTextTable, and wxRichTextCell.

21.610 wxRichTextBuffer Class Reference

```
#include <wx/richtext/richtextbuffer.h>
```

Inheritance diagram for wxRichTextBuffer:



21.610.1 Detailed Description

This is a kind of paragraph layout box, used to represent the whole buffer.

Library: wxRichText

Category: Rich Text

See also

wxRichTextParagraphLayoutBox, wxRichTextCtrl

Public Member Functions

- wxRichTextBuffer ()

  Default constructor.
- wxRichTextBuffer (const wxRichTextBuffer &obj)

  Copy constructor.
- virtual ~wxRichTextBuffer ()
- wxCommandProcessor * GetCommandProcessor () const

  Returns the command processor.
- void SetStyleSheet (wxRichTextStyleSheet *styleSheet)

  Sets style sheet, if any.

- virtual wxRichTextStyleSheet * GetStyleSheet () const

  Returns the style sheet.
- bool SetStyleSheetAndNotify (wxRichTextStyleSheet *sheet)

  Sets the style sheet and sends a notification of the change.
- bool PushStyleSheet (wxRichTextStyleSheet *styleSheet)

  Pushes the style sheet to the top of the style sheet stack.
- wxRichTextStyleSheet * PopStyleSheet ()

  Pops the style sheet from the top of the style sheet stack.
- wxRichTextFontTable & GetFontTable ()

  Returns the table storing fonts, for quick access and font reuse.
- const wxRichTextFontTable & GetFontTable () const

  Returns the table storing fonts, for quick access and font reuse.
- void SetFontTable (const wxRichTextFontTable &table)

  Sets table storing fonts, for quick access and font reuse.
- void SetFontScale (double fontScale)

  Sets the scale factor for displaying fonts, for example for more comfortable editing.
- double GetFontScale () const

  Returns the scale factor for displaying fonts, for example for more comfortable editing.
- void SetDimensionScale (double dimScale)

  Sets the scale factor for displaying certain dimensions such as indentation and inter-paragraph spacing.
- double GetDimensionScale () const

  Returns the scale factor for displaying certain dimensions such as indentation and inter-paragraph spacing.
- void Init ()

  Initialisation.
- virtual void ResetAndClearCommands ()

  Clears the buffer, adds an empty paragraph, and clears the command processor.
- void SetHandlerFlags (int flags)

  Sets the handler flags, controlling loading and saving.
- int GetHandlerFlags () const

  Gets the handler flags, controlling loading and saving.
- virtual wxRichTextRange AddParagraph (const wxString &text, wxRichTextAttr *paraStyle=NULL)

  Convenience function to add a paragraph of text.
- virtual bool BeginBatchUndo (const wxString &cmdName)

  Begin collapsing undo/redo commands.
- virtual bool EndBatchUndo ()

  End collapsing undo/redo commands.
- virtual bool BatchingUndo () const

  Returns true if we are collapsing commands.
- virtual bool SubmitAction (wxRichTextAction *action)

  Submit the action immediately, or delay according to whether collapsing is on.
- virtual wxRichTextCommand * GetBatchedCommand () const

  Returns the collapsed command.
- virtual bool BeginSuppressUndo ()

  Begin suppressing undo/redo commands.
- virtual bool EndSuppressUndo ()

  End suppressing undo/redo commands.
- virtual bool SuppressingUndo () const

  Are we suppressing undo??
- virtual bool CopyToClipboard (const wxRichTextRange &range)

  Copy the range to the clipboard.
- virtual bool PasteFromClipboard (long position)

Paste the clipboard content to the buffer.

- virtual bool CanPasteFromClipboard () const

  Returns true if we can paste from the clipboard.

- virtual bool BeginStyle (const wxRichTextAttr &style)

  Begin using a style.

- virtual bool EndStyle ()

  End the style.

- virtual bool EndAllStyles ()

  End all styles.

- virtual void ClearStyleStack ()

  Clears the style stack.

- virtual size_t GetStyleStackSize () const

  Returns the size of the style stack, for example to check correct nesting.

- bool BeginBold ()

  Begins using bold.

- bool EndBold ()

  Ends using bold.

- bool BeginItalic ()

  Begins using italic.

- bool EndItalic ()

  Ends using italic.

- bool BeginUnderline ()

  Begins using underline.

- bool EndUnderline ()

  Ends using underline.

- bool BeginFontSize (int pointSize)

  Begins using point size.

- bool EndFontSize ()

  Ends using point size.

- bool BeginFont (const wxFont &font)

  Begins using this font.

- bool EndFont ()

  Ends using a font.

- bool BeginTextColour (const wxColour &colour)

  Begins using this colour.

- bool EndTextColour ()

  Ends using a colour.

- bool BeginAlignment (wxTextAttrAlignment alignment)

  Begins using alignment.

- bool EndAlignment ()

  Ends alignment.

- bool BeginLeftIndent (int leftIndent, int leftSubIndent=0)

  Begins using leftIndent for the left indent, and optionally leftSubIndent for the sub-indent.

- bool EndLeftIndent ()

  Ends left indent.

- bool BeginRightIndent (int rightIndent)

  Begins a right indent, specified in tenths of a millimetre.

- bool EndRightIndent ()

  Ends right indent.

- bool BeginParagraphSpacing (int before, int after)

  Begins paragraph spacing; pass the before-paragraph and after-paragraph spacing in tenths of a millimetre.

- bool EndParagraphSpacing ()

  Ends paragraph spacing.
- bool BeginLineSpacing (int lineSpacing)

  Begins line spacing using the specified value.
- bool EndLineSpacing ()

  Ends line spacing.
- bool BeginNumberedBullet (int bulletNumber, int leftIndent, int leftSubIndent, int bulletStyle=wxTEXT_ATTR_BULLET_STYLE_ARABIC|wxTEXT_ATTR_BULLET_STYLE_PERIOD)

  Begins numbered bullet.
- bool EndNumberedBullet ()

  Ends numbered bullet.
- bool BeginSymbolBullet (const wxString &symbol, int leftIndent, int leftSubIndent, int bulletStyle=wxTEXT_ATTR_BULLET_STYLE_SYMBOL)

  Begins applying a symbol bullet, using a character from the current font.
- bool EndSymbolBullet ()

  Ends symbol bullet.
- bool BeginStandardBullet (const wxString &bulletName, int leftIndent, int leftSubIndent, int bulletStyle=wxTEXT_ATTR_BULLET_STYLE_STANDARD)

  Begins applying a standard bullet, using one of the standard bullet names (currently `standard/circle` *or* `standard/square`*.*
- bool EndStandardBullet ()

  Ends standard bullet.
- bool BeginCharacterStyle (const wxString &characterStyle)

  Begins named character style.
- bool EndCharacterStyle ()

  Ends named character style.
- bool BeginParagraphStyle (const wxString &paragraphStyle)

  Begins named paragraph style.
- bool EndParagraphStyle ()

  Ends named character style.
- bool BeginListStyle (const wxString &listStyle, int level=1, int number=1)

  Begins named list style.
- bool EndListStyle ()

  Ends named character style.
- bool BeginURL (const wxString &url, const wxString &characterStyle=wxEmptyString)

  Begins applying wxTEXT_ATTR_URL to the content.
- bool EndURL ()

  Ends URL.
- bool AddEventHandler (wxEvtHandler *handler)

  Adds an event handler.
- bool RemoveEventHandler (wxEvtHandler *handler, bool deleteHandler=false)

  Removes an event handler from the buffer's list of handlers, deleting the object if deleteHandler is true.
- void ClearEventHandlers ()

  Clear event handlers.
- bool SendEvent (wxEvent &event, bool sendToAll=true)

  Send event to event handlers.
- virtual int HitTest (wxDC &dc, wxRichTextDrawingContext &context, const wxPoint &pt, long &textPosition, wxRichTextObject **obj, wxRichTextObject **contextObj, int flags=0)

  Hit-testing: returns a flag indicating hit test details, plus information about position.
- void Copy (const wxRichTextBuffer &obj)

  Copies the buffer.

- void operator= (const wxRichTextBuffer &obj)

  Assignment operator.
- virtual wxRichTextObject * Clone () const

  Clones the buffer.
- bool InsertParagraphsWithUndo (long pos, const wxRichTextParagraphLayoutBox &paragraphs, wxRich↩ TextCtrl *ctrl, int flags=0)

  Submits a command to insert paragraphs.
- bool InsertTextWithUndo (long pos, const wxString &text, wxRichTextCtrl *ctrl, int flags=0)

  Submits a command to insert the given text.
- bool InsertNewlineWithUndo (long pos, wxRichTextCtrl *ctrl, int flags=0)

  Submits a command to insert a newline.
- bool InsertImageWithUndo (long pos, const wxRichTextImageBlock &imageBlock, wxRichTextCtrl *ctrl, int flags=0, const wxRichTextAttr &textAttr=wxRichTextAttr())

  Submits a command to insert the given image.
- wxRichTextObject * InsertObjectWithUndo (long pos, wxRichTextObject *object, wxRichTextCtrl *ctrl, int flags)

  Submits a command to insert an object.
- bool DeleteRangeWithUndo (const wxRichTextRange &range, wxRichTextCtrl *ctrl)

  Submits a command to delete this range.
- void Modify (bool modify=true)

  Mark modified.
- bool IsModified () const

  Returns true if the buffer was modified.
- double GetScale () const

  Returns the scale factor for calculating dimensions.
- void SetScale (double scale)

  Sets the scale factor for calculating dimensions.

- virtual bool LoadFile (const wxString &filename, wxRichTextFileType type=wxRICHTEXT_TYPE_ANY)

  Loads content from a stream or file.
- virtual bool LoadFile (wxInputStream &stream, wxRichTextFileType type=wxRICHTEXT_TYPE_ANY)

  Loads content from a stream or file.

- virtual bool SaveFile (const wxString &filename, wxRichTextFileType type=wxRICHTEXT_TYPE_ANY)

  Saves content to a stream or file.
- virtual bool SaveFile (wxOutputStream &stream, wxRichTextFileType type=wxRICHTEXT_TYPE_ANY)

  Saves content to a stream or file.

- virtual void Dump ()

  Dumps contents of buffer for debugging purposes.
- virtual void Dump (wxTextOutputStream &stream)

  Dumps contents of buffer for debugging purposes.

Static Public Member Functions

- static wxList & GetHandlers ()

  Returns the file handlers.
- static void AddHandler (wxRichTextFileHandler *handler)

  Adds a file handler to the end.
- static void InsertHandler (wxRichTextFileHandler *handler)

  Inserts a file handler at the front.

- static bool RemoveHandler (const wxString &name)

  Removes a file handler.
- static wxRichTextFileHandler * FindHandler (const wxString &name)

  Finds a file handler by name.
- static wxRichTextFileHandler * FindHandler (const wxString &extension, wxRichTextFileType imageType)

  Finds a file handler by extension and type.
- static wxRichTextFileHandler * FindHandlerFilenameOrType (const wxString &filename, wxRichTextFileType imageType)

  Finds a handler by filename or, if supplied, type.
- static wxRichTextFileHandler * FindHandler (wxRichTextFileType imageType)

  Finds a handler by type.
- static wxString GetExtWildcard (bool combine=false, bool save=false, wxArrayInt *types=NULL)

  Gets a wildcard incorporating all visible handlers.
- static void CleanUpHandlers ()

  Clean up file handlers.
- static void InitStandardHandlers ()

  Initialise the standard file handlers.
- static wxList & GetDrawingHandlers ()

  Returns the drawing handlers.
- static void AddDrawingHandler (wxRichTextDrawingHandler *handler)

  Adds a drawing handler to the end.
- static void InsertDrawingHandler (wxRichTextDrawingHandler *handler)

  Inserts a drawing handler at the front.
- static bool RemoveDrawingHandler (const wxString &name)

  Removes a drawing handler.
- static wxRichTextDrawingHandler * FindDrawingHandler (const wxString &name)

  Finds a drawing handler by name.
- static void CleanUpDrawingHandlers ()

  Clean up drawing handlers.
- static wxRichTextFieldTypeHashMap & GetFieldTypes ()

  Returns the field types.
- static void AddFieldType (wxRichTextFieldType *fieldType)

  Adds a field type.
- static bool RemoveFieldType (const wxString &name)

  Removes a field type by name.
- static wxRichTextFieldType * FindFieldType (const wxString &name)

  Finds a field type by name.
- static void CleanUpFieldTypes ()

  Cleans up field types.
- static wxRichTextRenderer * GetRenderer ()

  Returns the renderer object.
- static void SetRenderer (wxRichTextRenderer *renderer)

  Sets renderer as the object to be used to render certain aspects of the content, such as bullets.
- static int GetBulletRightMargin ()

  Returns the minimum margin between bullet and paragraph in 10ths of a mm.
- static void SetBulletRightMargin (int margin)

  Sets the minimum margin between bullet and paragraph in 10ths of a mm.
- static float GetBulletProportion ()

  Returns the factor to multiply by character height to get a reasonable bullet size.
- static void SetBulletProportion (float prop)

  Sets the factor to multiply by character height to get a reasonable bullet size.

- static bool GetFloatingLayoutMode ()

  Returns the floating layout mode.
- static void SetFloatingLayoutMode (bool mode)

  Sets the floating layout mode.

Protected Attributes

- wxCommandProcessor * m_commandProcessor

  Command processor.
- wxRichTextFontTable m_fontTable

  Table storing fonts.
- bool m_modified

  Has been modified?
- int m_batchedCommandDepth

  Collapsed command stack.
- wxString m_batchedCommandsName

  Name for collapsed command.
- wxRichTextCommand * m_batchedCommand

  Current collapsed command accumulating actions.
- int m_suppressUndo

  Whether to suppress undo.
- wxRichTextStyleSheet * m_styleSheet

  Style sheet, if any.
- wxList m_eventHandlers

  List of event handlers that will be notified of events.
- wxList m_attributeStack

  Stack of attributes for convenience functions.
- int m_handlerFlags

  Flags to be passed to handlers.
- double m_scale

  Scaling factor in use: needed to calculate correct dimensions when printing.

Static Protected Attributes

- static wxList sm_handlers

  File handlers.
- static wxList sm_drawingHandlers

  Drawing handlers.
- static wxRichTextFieldTypeHashMap sm_fieldTypes

  Field types.
- static wxRichTextRenderer * sm_renderer

  Renderer.
- static int sm_bulletRightMargin

  Minimum margin between bullet and paragraph in 10ths of a mm.
- static float sm_bulletProportion

  Factor to multiply by character height to get a reasonable bullet size.

Additional Inherited Members

21.610.2 Constructor & Destructor Documentation

wxRichTextBuffer::wxRichTextBuffer ( ) [inline]

Default constructor.

wxRichTextBuffer::wxRichTextBuffer (const wxRichTextBuffer & *obj*) [inline]

Copy constructor.

virtual wxRichTextBuffer::~wxRichTextBuffer ( ) [virtual]

21.610.3 Member Function Documentation

static void wxRichTextBuffer::AddDrawingHandler (wxRichTextDrawingHandler * *handler*) [static]

Adds a drawing handler to the end.

bool wxRichTextBuffer::AddEventHandler (wxEvtHandler * *handler*)

Adds an event handler.

A buffer associated with a control has the control as the only event handler, but the application is free to add more if further notification is required. All handlers are notified of an event originating from the buffer, such as the replacement of a style sheet during loading.

The buffer never deletes any of the event handlers, unless RemoveEventHandler() is called with true as the second argument.

static void wxRichTextBuffer::AddFieldType (wxRichTextFieldType * *fieldType*) [static]

Adds a field type.

See also

RemoveFieldType(), FindFieldType(), wxRichTextField, wxRichTextFieldType, wxRichTextFieldTypeStandard

static void wxRichTextBuffer::AddHandler (wxRichTextFileHandler * *handler*) [static]

Adds a file handler to the end.

virtual wxRichTextRange wxRichTextBuffer::AddParagraph (const wxString & *text*, wxRichTextAttr * *paraStyle* = NULL) [inline], [virtual]

Convenience function to add a paragraph of text.

Reimplemented from wxRichTextParagraphLayoutBox.

virtual bool wxRichTextBuffer::BatchingUndo ( ) const [inline], [virtual]

Returns true if we are collapsing commands.

bool wxRichTextBuffer::BeginAlignment (wxTextAttrAlignment *alignment*)

Begins using alignment.

virtual bool wxRichTextBuffer::BeginBatchUndo (const wxString & *cmdName*) [virtual]

Begin collapsing undo/redo commands.

Note that this may not work properly if combining commands that delete or insert content, changing ranges for subsequent actions.

cmdName should be the name of the combined command that will appear next to Undo and Redo in the edit menu.

bool wxRichTextBuffer::BeginBold ( )

Begins using bold.

bool wxRichTextBuffer::BeginCharacterStyle (const wxString & *characterStyle*)

Begins named character style.

bool wxRichTextBuffer::BeginFont (const wxFont & *font*)

Begins using this font.

bool wxRichTextBuffer::BeginFontSize (int *pointSize*)

Begins using point size.

bool wxRichTextBuffer::BeginItalic ( )

Begins using italic.

bool wxRichTextBuffer::BeginLeftIndent (int *leftIndent,* int *leftSubIndent* = 0)

Begins using *leftIndent* for the left indent, and optionally *leftSubIndent* for the sub-indent.

Both are expressed in tenths of a millimetre.

The sub-indent is an offset from the left of the paragraph, and is used for all but the first line in a paragraph. A positive value will cause the first line to appear to the left of the subsequent lines, and a negative value will cause the first line to be indented relative to the subsequent lines.

bool wxRichTextBuffer::BeginLineSpacing (int *lineSpacing*)

Begins line spacing using the specified value.

spacing is a multiple, where 10 means single-spacing, 15 means 1.5 spacing, and 20 means double spacing.

The wxTextAttrLineSpacing enumeration values are defined for convenience.

bool wxRichTextBuffer::BeginListStyle (const wxString & *listStyle,* int *level* = 1, int *number* = 1)

Begins named list style.

Optionally, you can also pass a level and a number.

bool wxRichTextBuffer::BeginNumberedBullet (int *bulletNumber,* int *leftIndent,* int *leftSubIndent,* int *bulletStyle* = wxTEXT_ATTR_BULLET_STYLE_ARABIC|wxTEXT_ATTR_BULLET_STYLE_PERIOD)

Begins numbered bullet.

This call will be needed for each item in the list, and the application should take care of incrementing the numbering.

bulletNumber is a number, usually starting with 1. *leftIndent* and *leftSubIndent* are values in tenths of a millimetre. *bulletStyle* is a bitlist of the following values:

wxRichTextBuffer uses indentation to render a bulleted item. The left indent is the distance between the margin and the bullet. The content of the paragraph, including the first line, starts at leftMargin + leftSubIndent. So the distance between the left edge of the bullet and the left of the actual paragraph is leftSubIndent.

bool wxRichTextBuffer::BeginParagraphSpacing (int *before,* int *after*)

Begins paragraph spacing; pass the before-paragraph and after-paragraph spacing in tenths of a millimetre.

bool wxRichTextBuffer::BeginParagraphStyle (const wxString & *paragraphStyle*)

Begins named paragraph style.

bool wxRichTextBuffer::BeginRightIndent (int *rightIndent*)

Begins a right indent, specified in tenths of a millimetre.

bool wxRichTextBuffer::BeginStandardBullet (const wxString & *bulletName,* int *leftIndent,* int *leftSubIndent,* int *bulletStyle* = wxTEXT_ATTR_BULLET_STYLE_STANDARD)

Begins applying a standard bullet, using one of the standard bullet names (currently `standard/circle` or `standard/square`.

See BeginNumberedBullet() for an explanation of how indentation is used to render the bulleted paragraph.

virtual bool wxRichTextBuffer::BeginStyle (const wxRichTextAttr & *style*) [virtual]

Begin using a style.

virtual bool wxRichTextBuffer::BeginSuppressUndo ( ) [virtual]

Begin suppressing undo/redo commands.

The way undo is suppressed may be implemented differently by each command. If not dealt with by a command implementation, then it will be implemented automatically by not storing the command in the undo history when the action is submitted to the command processor.

bool wxRichTextBuffer::BeginSymbolBullet (const wxString & *symbol,* int *leftIndent,* int *leftSubIndent,* int *bulletStyle* = wxTEXT_ATTR_BULLET_STYLE_SYMBOL)

Begins applying a symbol bullet, using a character from the current font.

See BeginNumberedBullet() for an explanation of how indentation is used to render the bulleted paragraph.

bool wxRichTextBuffer::BeginTextColour (const wxColour & *colour*)

Begins using this colour.

bool wxRichTextBuffer::BeginUnderline ( )

Begins using underline.

bool wxRichTextBuffer::BeginURL (const wxString & *url,* const wxString & *characterStyle* = wxEmptyString)

Begins applying wxTEXT_ATTR_URL to the content.

Pass a URL and optionally, a character style to apply, since it is common to mark a URL with a familiar style such as blue text with underlining.

virtual bool wxRichTextBuffer::CanPasteFromClipboard ( ) const `[virtual]`

Returns true if we can paste from the clipboard.

static void wxRichTextBuffer::CleanUpDrawingHandlers ( ) `[static]`

Clean up drawing handlers.

static void wxRichTextBuffer::CleanUpFieldTypes ( ) `[static]`

Cleans up field types.

static void wxRichTextBuffer::CleanUpHandlers ( ) `[static]`

Clean up file handlers.

void wxRichTextBuffer::ClearEventHandlers ( )

Clear event handlers.

virtual void wxRichTextBuffer::ClearStyleStack ( ) `[virtual]`

Clears the style stack.

virtual wxRichTextObject* wxRichTextBuffer::Clone ( ) const `[inline], [virtual]`

Clones the buffer.

Reimplemented from wxRichTextParagraphLayoutBox.

void wxRichTextBuffer::Copy (const wxRichTextBuffer & *obj*)

Copies the buffer.

virtual bool wxRichTextBuffer::CopyToClipboard (const wxRichTextRange & *range*) [virtual]

Copy the range to the clipboard.

bool wxRichTextBuffer::DeleteRangeWithUndo (const wxRichTextRange & *range,* wxRichTextCtrl * *ctrl*)

Submits a command to delete this range.

virtual void wxRichTextBuffer::Dump ( ) [virtual]

Dumps contents of buffer for debugging purposes.

virtual void wxRichTextBuffer::Dump (wxTextOutputStream & *stream*) [inline], [virtual]

Dumps contents of buffer for debugging purposes.

Reimplemented from wxRichTextCompositeObject.

bool wxRichTextBuffer::EndAlignment ( ) [inline]

Ends alignment.

virtual bool wxRichTextBuffer::EndAllStyles ( ) [virtual]

End all styles.

virtual bool wxRichTextBuffer::EndBatchUndo ( ) [virtual]

End collapsing undo/redo commands.

bool wxRichTextBuffer::EndBold ( ) [inline]

Ends using bold.

bool wxRichTextBuffer::EndCharacterStyle ( ) [inline]

Ends named character style.

bool wxRichTextBuffer::EndFont ( ) [inline]

Ends using a font.

bool wxRichTextBuffer::EndFontSize ( ) [inline]

Ends using point size.

bool wxRichTextBuffer::EndItalic ( ) [inline]

Ends using italic.

bool wxRichTextBuffer::EndLeftIndent ( ) [inline]

Ends left indent.

bool wxRichTextBuffer::EndLineSpacing ( ) [inline]

Ends line spacing.

bool wxRichTextBuffer::EndListStyle ( ) [inline]

Ends named character style.

bool wxRichTextBuffer::EndNumberedBullet ( ) [inline]

Ends numbered bullet.

bool wxRichTextBuffer::EndParagraphSpacing ( ) [inline]

Ends paragraph spacing.

bool wxRichTextBuffer::EndParagraphStyle ( ) [inline]

Ends named character style.

bool wxRichTextBuffer::EndRightIndent ( ) [inline]

Ends right indent.

bool wxRichTextBuffer::EndStandardBullet ( ) [inline]

Ends standard bullet.

virtual bool wxRichTextBuffer::EndStyle ( ) [virtual]

End the style.

virtual bool wxRichTextBuffer::EndSuppressUndo ( ) [virtual]

End suppressing undo/redo commands.

bool wxRichTextBuffer::EndSymbolBullet ( ) [inline]

Ends symbol bullet.

bool wxRichTextBuffer::EndTextColour ( ) [inline]

Ends using a colour.

bool wxRichTextBuffer::EndUnderline ( ) [inline]

Ends using underline.

bool wxRichTextBuffer::EndURL ( ) [inline]

Ends URL.

static wxRichTextDrawingHandler* wxRichTextBuffer::FindDrawingHandler (const wxString & *name*) [static]

Finds a drawing handler by name.

static wxRichTextFieldType* wxRichTextBuffer::FindFieldType (const wxString & *name*) [static]

Finds a field type by name.

See also

RemoveFieldType(), AddFieldType(), wxRichTextField, wxRichTextFieldType, wxRichTextFieldTypeStandard

static wxRichTextFileHandler* wxRichTextBuffer::FindHandler (const wxString & *name*) [static]

Finds a file handler by name.

static wxRichTextFileHandler* wxRichTextBuffer::FindHandler (const wxString & *extension,* wxRichTextFileType *imageType*) [static]

Finds a file handler by extension and type.

static wxRichTextFileHandler* wxRichTextBuffer::FindHandler (wxRichTextFileType *imageType*) [static]

Finds a handler by type.

static wxRichTextFileHandler* wxRichTextBuffer::FindHandlerFilenameOrType (const wxString & *filename,* wxRichTextFileType *imageType*) [static]

Finds a handler by filename or, if supplied, type.

virtual wxRichTextCommand* wxRichTextBuffer::GetBatchedCommand ( ) const [inline], [virtual]

Returns the collapsed command.

static float wxRichTextBuffer::GetBulletProportion ( ) [inline], [static]

Returns the factor to multiply by character height to get a reasonable bullet size.

static int wxRichTextBuffer::GetBulletRightMargin ( ) [inline], [static]

Returns the minimum margin between bullet and paragraph in 10ths of a mm.

wxCommandProcessor* wxRichTextBuffer::GetCommandProcessor ( ) const [inline]

Returns the command processor.

A text buffer always creates its own command processor when it is initialized.

double wxRichTextBuffer::GetDimensionScale ( ) const [inline]

Returns the scale factor for displaying certain dimensions such as indentation and inter-paragraph spacing.

static wxList& wxRichTextBuffer::GetDrawingHandlers ( ) [inline], [static]

Returns the drawing handlers.

static wxString wxRichTextBuffer::GetExtWildcard (bool *combine* = false, bool *save* = false, wxArrayInt * *types* = NULL) [static]

Gets a wildcard incorporating all visible handlers.

If *types* is present, it will be filled with the file type corresponding to each filter. This can be used to determine the type to pass to LoadFile given a selected filter.

static wxRichTextFieldTypeHashMap& wxRichTextBuffer::GetFieldTypes ( ) [inline], [static]

Returns the field types.

static bool wxRichTextBuffer::GetFloatingLayoutMode ( ) [static]

Returns the floating layout mode.

The default is true, where objects are laid out according to their floating status.

double wxRichTextBuffer::GetFontScale ( ) const [inline]

Returns the scale factor for displaying fonts, for example for more comfortable editing.

wxRichTextFontTable& wxRichTextBuffer::GetFontTable ( ) [inline]

Returns the table storing fonts, for quick access and font reuse.

const wxRichTextFontTable& wxRichTextBuffer::GetFontTable ( ) const [inline]

Returns the table storing fonts, for quick access and font reuse.

int wxRichTextBuffer::GetHandlerFlags ( ) const [inline]

Gets the handler flags, controlling loading and saving.

static wxList& wxRichTextBuffer::GetHandlers ( ) [inline], [static]

Returns the file handlers.

static wxRichTextRenderer* wxRichTextBuffer::GetRenderer ( ) [inline], [static]

Returns the renderer object.

double wxRichTextBuffer::GetScale ( ) const [inline]

Returns the scale factor for calculating dimensions.

virtual wxRichTextStyleSheet* wxRichTextBuffer::GetStyleSheet ( ) const [inline], [virtual]

Returns the style sheet.

Reimplemented from wxRichTextParagraphLayoutBox.

virtual size_t wxRichTextBuffer::GetStyleStackSize ( ) const [inline], [virtual]

Returns the size of the style stack, for example to check correct nesting.

virtual int wxRichTextBuffer::HitTest (wxDC & *dc,* wxRichTextDrawingContext & *context,* const wxPoint & *pt,* long & *textPosition,* wxRichTextObject ** *obj,* wxRichTextObject ** *contextObj,* int *flags* = 0) [virtual]

Hit-testing: returns a flag indicating hit test details, plus information about position.

contextObj is returned to specify what object position is relevant to, since otherwise there's an ambiguity. @ obj might not be a child of *contextObj*, since we may be referring to the container itself if we have no hit on a child - for example if we click outside an object.

The function puts the position in *textPosition* if one is found. *pt* is in logical units (a zero y position is at the beginning of the buffer).

Returns

One of the wxRichTextHitTestFlags values.

Reimplemented from wxRichTextParagraphLayoutBox.

void wxRichTextBuffer::Init ( )

Initialisation.

static void wxRichTextBuffer::InitStandardHandlers ( ) [static]

Initialise the standard file handlers.

Currently, only the plain text loading/saving handler is initialised by default.

static void wxRichTextBuffer::InsertDrawingHandler (wxRichTextDrawingHandler * *handler*) [static]

Inserts a drawing handler at the front.

static void wxRichTextBuffer::InsertHandler (wxRichTextFileHandler * *handler*) [static]

Inserts a file handler at the front.

bool wxRichTextBuffer::InsertImageWithUndo (long *pos,* const wxRichTextImageBlock & *imageBlock,* wxRichTextCtrl * *ctrl,* int *flags* = 0, const wxRichTextAttr & *textAttr* = wxRichTextAttr())

Submits a command to insert the given image.

bool wxRichTextBuffer::InsertNewlineWithUndo (long *pos,* wxRichTextCtrl * *ctrl,* int *flags* = 0)

Submits a command to insert a newline.

wxRichTextObject* wxRichTextBuffer::InsertObjectWithUndo (long *pos,* wxRichTextObject * *object,* wxRichTextCtrl * *ctrl,* int *flags*)

Submits a command to insert an object.

bool wxRichTextBuffer::InsertParagraphsWithUndo (long *pos,* const wxRichTextParagraphLayoutBox & *paragraphs,* wxRichTextCtrl * *ctrl,* int *flags* = 0)

Submits a command to insert paragraphs.

bool wxRichTextBuffer::InsertTextWithUndo (long *pos,* const wxString & *text,* wxRichTextCtrl * *ctrl,* int *flags* = 0)

Submits a command to insert the given text.

bool wxRichTextBuffer::IsModified ( ) const [inline]

Returns true if the buffer was modified.

virtual bool wxRichTextBuffer::LoadFile (const wxString & *filename,* wxRichTextFileType *type* = wxRICHTEXT_TYPE_ANY) [virtual]

Loads content from a stream or file.

Not all handlers will implement file loading.

virtual bool wxRichTextBuffer::LoadFile (wxInputStream & *stream,* wxRichTextFileType *type* = wxRICHTEXT_TYPE_ANY) [virtual]

Loads content from a stream or file.

Not all handlers will implement file loading.

void wxRichTextBuffer::Modify (bool *modify* = true) [inline]

Mark modified.

void wxRichTextBuffer::operator= (const wxRichTextBuffer & *obj*) [inline]

Assignment operator.

virtual bool wxRichTextBuffer::PasteFromClipboard (long *position*) `[virtual]`

Paste the clipboard content to the buffer.

wxRichTextStyleSheet* wxRichTextBuffer::PopStyleSheet ( )

Pops the style sheet from the top of the style sheet stack.

bool wxRichTextBuffer::PushStyleSheet (wxRichTextStyleSheet * *styleSheet*)

Pushes the style sheet to the top of the style sheet stack.

static bool wxRichTextBuffer::RemoveDrawingHandler (const wxString & *name*) `[static]`

Removes a drawing handler.

bool wxRichTextBuffer::RemoveEventHandler (wxEvtHandler * *handler,* bool *deleteHandler* = `false`)

Removes an event handler from the buffer's list of handlers, deleting the object if *deleteHandler* is true.

static bool wxRichTextBuffer::RemoveFieldType (const wxString & *name*) `[static]`

Removes a field type by name.

See also

AddFieldType(), FindFieldType(), wxRichTextField, wxRichTextFieldType, wxRichTextFieldTypeStandard

static bool wxRichTextBuffer::RemoveHandler (const wxString & *name*) `[static]`

Removes a file handler.

virtual void wxRichTextBuffer::ResetAndClearCommands ( ) `[virtual]`

Clears the buffer, adds an empty paragraph, and clears the command processor.

virtual bool wxRichTextBuffer::SaveFile (const wxString & *filename,* wxRichTextFileType *type* = wxRICHTEXT_TYPE_ANY) `[virtual]`

Saves content to a stream or file.

Not all handlers will implement file saving.

virtual bool wxRichTextBuffer::SaveFile (wxOutputStream & *stream,* wxRichTextFileType *type* = wxRICHTEXT_TYPE_ANY) `[virtual]`

Saves content to a stream or file.

Not all handlers will implement file saving.

bool wxRichTextBuffer::SendEvent (wxEvent & *event*, bool *sendToAll* = `true`)

Send event to event handlers.

If sendToAll is true, will send to all event handlers, otherwise will stop at the first successful one.

static void wxRichTextBuffer::SetBulletProportion (float *prop*) `[inline], [static]`

Sets the factor to multiply by character height to get a reasonable bullet size.

static void wxRichTextBuffer::SetBulletRightMargin (int *margin*) `[inline], [static]`

Sets the minimum margin between bullet and paragraph in 10ths of a mm.

void wxRichTextBuffer::SetDimensionScale (double *dimScale*)

Sets the scale factor for displaying certain dimensions such as indentation and inter-paragraph spacing.

This can be useful when editing in a small control where you still want legible text, but a minimum of wasted white space.

static void wxRichTextBuffer::SetFloatingLayoutMode (bool *mode*) `[static]`

Sets the floating layout mode.

Pass false to speed up editing by not performing floating layout. This setting affects all buffers.

void wxRichTextBuffer::SetFontScale (double *fontScale*)

Sets the scale factor for displaying fonts, for example for more comfortable editing.

void wxRichTextBuffer::SetFontTable (const wxRichTextFontTable & *table*) `[inline]`

Sets table storing fonts, for quick access and font reuse.

void wxRichTextBuffer::SetHandlerFlags (int *flags*) `[inline]`

Sets the handler flags, controlling loading and saving.

static void wxRichTextBuffer::SetRenderer (wxRichTextRenderer * *renderer*) `[static]`

Sets *renderer* as the object to be used to render certain aspects of the content, such as bullets.

You can override default rendering by deriving a new class from wxRichTextRenderer or wxRichTextStdRenderer, overriding one or more virtual functions, and setting an instance of the class using this function.

void wxRichTextBuffer::SetScale (double *scale*) `[inline]`

Sets the scale factor for calculating dimensions.

void wxRichTextBuffer::SetStyleSheet (wxRichTextStyleSheet * *styleSheet*) [inline]

Sets style sheet, if any.

This will allow the application to use named character and paragraph styles found in the style sheet.

Neither the buffer nor the control owns the style sheet so must be deleted by the application.

bool wxRichTextBuffer::SetStyleSheetAndNotify (wxRichTextStyleSheet * *sheet*)

Sets the style sheet and sends a notification of the change.

virtual bool wxRichTextBuffer::SubmitAction (wxRichTextAction * *action*) [virtual]

Submit the action immediately, or delay according to whether collapsing is on.

virtual bool wxRichTextBuffer::SuppressingUndo ( ) const [inline], [virtual]

Are we suppressing undo??

21.610.4 Member Data Documentation

wxList wxRichTextBuffer::m_attributeStack [protected]

Stack of attributes for convenience functions.

wxRichTextCommand* wxRichTextBuffer::m_batchedCommand [protected]

Current collapsed command accumulating actions.

int wxRichTextBuffer::m_batchedCommandDepth [protected]

Collapsed command stack.

wxString wxRichTextBuffer::m_batchedCommandsName [protected]

Name for collapsed command.

wxCommandProcessor* wxRichTextBuffer::m_commandProcessor [protected]

Command processor.

wxList wxRichTextBuffer::m_eventHandlers [protected]

List of event handlers that will be notified of events.

wxRichTextFontTable wxRichTextBuffer::m_fontTable [protected]

Table storing fonts.

int wxRichTextBuffer::m_handlerFlags [protected]

Flags to be passed to handlers.

bool wxRichTextBuffer::m_modified [protected]

Has been modified?

double wxRichTextBuffer::m_scale [protected]

Scaling factor in use: needed to calculate correct dimensions when printing.

wxRichTextStyleSheet* **wxRichTextBuffer::m_styleSheet** [protected]

Style sheet, if any.

int wxRichTextBuffer::m_suppressUndo [protected]

Whether to suppress undo.

float wxRichTextBuffer::sm_bulletProportion [static], [protected]

Factor to multiply by character height to get a reasonable bullet size.

int wxRichTextBuffer::sm_bulletRightMargin [static], [protected]

Minimum margin between bullet and paragraph in 10ths of a mm.

wxList wxRichTextBuffer::sm_drawingHandlers [static], [protected]

Drawing handlers.

wxRichTextFieldTypeHashMap wxRichTextBuffer::sm_fieldTypes [static], [protected]

Field types.

wxList wxRichTextBuffer::sm_handlers [static], [protected]

File handlers.

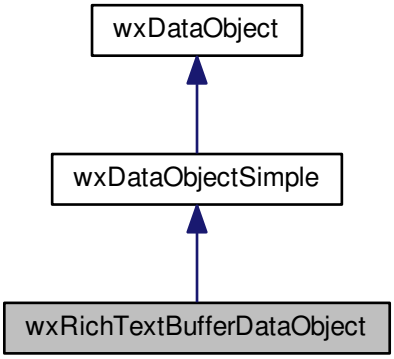
wxRichTextRenderer* **wxRichTextBuffer::sm_renderer** [static], [protected]

Renderer.

21.611 wxRichTextBufferDataObject Class Reference

`#include <wx/richtext/richtextbuffer.h>`

Inheritance diagram for wxRichTextBufferDataObject:



21.611.1 Detailed Description

Implements a rich text data object for clipboard transfer.

Library: wxRichText

Category: Rich Text

See also

wxDataObjectSimple, wxRichTextBuffer, wxRichTextCtrl

Public Member Functions

- wxRichTextBufferDataObject (wxRichTextBuffer *richTextBuffer=NULL)

  The constructor doesn't copy the pointer, so it shouldn't go away while this object is alive.
- virtual ~wxRichTextBufferDataObject ()
- wxRichTextBuffer * GetRichTextBuffer ()

  After a call to this function, the buffer is owned by the caller and it is responsible for deleting it.
- virtual wxDataFormat GetPreferredFormat (Direction dir) const

  Returns the preferred format for either rendering the data (if dir is `Get`, its default value) or for setting it.
- virtual size_t GetDataSize () const

  Gets the size of our data.
- virtual bool GetDataHere (void *pBuf) const

  Copy the data to the buffer, return true on success.
- virtual bool SetData (size_t len, const void *buf)

  Copy the data from the buffer, return true on success.
- virtual size_t GetDataSize (const wxDataFormat &) const

  Returns the data size of the given format format.
- virtual bool GetDataHere (const wxDataFormat &, void *buf) const

  The method will write the data of the format format to the buffer buf.

- virtual bool SetData (const wxDataFormat &, size_t len, const void *buf)

  Set the data in the format format of the length len provided in the buffer buf.

Static Public Member Functions

- static const wxChar * GetRichTextBufferFormatId ()

  Returns the id for the new data format.

Private Attributes

- wxDataFormat m_formatRichTextBuffer
- wxRichTextBuffer * m_richTextBuffer

Static Private Attributes

- static const wxChar * ms_richTextBufferFormatId

Additional Inherited Members

21.611.2 Constructor & Destructor Documentation

wxRichTextBufferDataObject::wxRichTextBufferDataObject (wxRichTextBuffer * *richTextBuffer* = NULL)

The constructor doesn't copy the pointer, so it shouldn't go away while this object is alive.

virtual wxRichTextBufferDataObject::~wxRichTextBufferDataObject ( ) [virtual]

21.611.3 Member Function Documentation

virtual bool wxRichTextBufferDataObject::GetDataHere (void * *buf*) const [virtual]

Copy the data to the buffer, return true on success.

Must be implemented in the derived class if the object supports rendering its data.

Reimplemented from wxDataObjectSimple.

virtual bool wxRichTextBufferDataObject::GetDataHere (const wxDataFormat & *format*, void * *buf*) const [inline], [virtual]

The method will write the data of the format *format* to the buffer *buf*.

In other words, copy the data from this object in the given format to the supplied buffer. Returns true on success, false on failure.

Implements wxDataObject.

virtual size_t wxRichTextBufferDataObject::GetDataSize ( ) const [virtual]

Gets the size of our data.

Must be implemented in the derived class if the object supports rendering its data.

Reimplemented from wxDataObjectSimple.

virtual size_t wxRichTextBufferDataObject::GetDataSize (const wxDataFormat & *format*) const `[inline], [virtual]`

Returns the data size of the given format *format*.

Implements wxDataObject.

virtual wxDataFormat wxRichTextBufferDataObject::GetPreferredFormat (Direction *dir*) const `[virtual]`

Returns the preferred format for either rendering the data (if *dir* is `Get`, its default value) or for setting it.

Usually this will be the native format of the wxDataObject.

Implements wxDataObject.

wxRichTextBuffer* wxRichTextBufferDataObject::GetRichTextBuffer ( )

After a call to this function, the buffer is owned by the caller and it is responsible for deleting it.

static const wxChar* wxRichTextBufferDataObject::GetRichTextBufferFormatId ( ) `[inline], [static]`

Returns the id for the new data format.

virtual bool wxRichTextBufferDataObject::SetData (size_t *len*, const void * *buf*) `[virtual]`

Copy the data from the buffer, return true on success.

Must be implemented in the derived class if the object supports setting its data.

Reimplemented from wxDataObjectSimple.

virtual bool wxRichTextBufferDataObject::SetData (const wxDataFormat & *format*, size_t *len*, const void * *buf*) `[inline], [virtual]`

Set the data in the format *format* of the length *len* provided in the buffer *buf*.

In other words, copy length bytes of data from the buffer to this data object.

Parameters

format	The format for which to set the data.
len	The size of data in bytes.
buf	Non-NULL pointer to the data.

Returns

true on success, false on failure.

Reimplemented from wxDataObject.

21.611.4 Member Data Documentation

wxDataFormat wxRichTextBufferDataObject::m_formatRichTextBuffer `[private]`

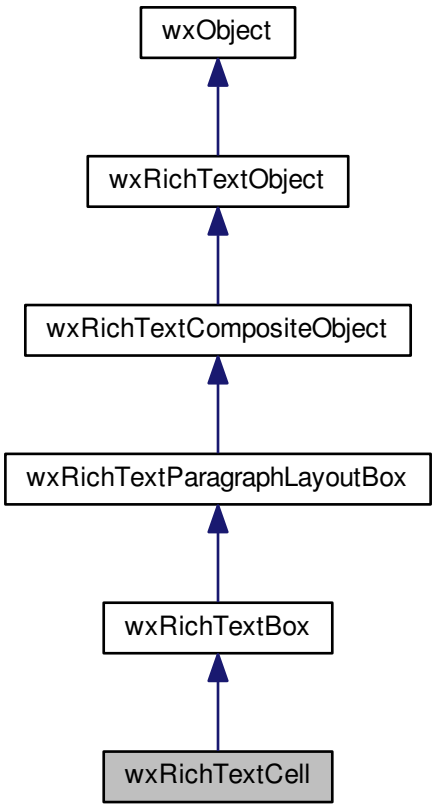
wxRichTextBuffer* wxRichTextBufferDataObject::m_richTextBuffer `[private]`

const wxChar* wxRichTextBufferDataObject::ms_richTextBufferFormatId [static],[private]

21.612 wxRichTextCell Class Reference

#include <wx/richtext/richtextbuffer.h>

Inheritance diagram for wxRichTextCell:



21.612.1 Detailed Description

wxRichTextCell is the cell in a table, in which the user can type.

As well as text, it can also contain objects e.g. an image, or even another wxRichTextTable.

A cell's appearance can be changed via its associated wxRichTextAttr; for example its size altered or its background colour set. It also has the properties of column- and row-span. By default these are 1, meaning that the cell only spans itself, but can be increased using the SetColSpan() and SetRowSpan() methods. Attempts to set too large a span are silently truncated to the table edge.

Public Member Functions

- wxRichTextCell (wxRichTextObject *parent=NULL)

  Default constructor; optionally pass the parent object.

- wxRichTextCell (const wxRichTextCell &obj)

  Copy constructor.
- virtual bool Draw (wxDC &dc, wxRichTextDrawingContext &context, const wxRichTextRange &range, const wxRichTextSelection &selection, const wxRect &rect, int descent, int style)

  Draw the item, within the given range.
- virtual int HitTest (wxDC &dc, wxRichTextDrawingContext &context, const wxPoint &pt, long &textPosition, wxRichTextObject **obj, wxRichTextObject **contextObj, int flags=0)

  Hit-testing: returns a flag indicating hit test details, plus information about position.
- virtual wxString GetXMLNodeName () const

  Returns the XML node name of this object.
- virtual bool CanEditProperties () const

  Returns true if we can edit the object's properties via a GUI.
- virtual bool EditProperties (wxWindow *parent, wxRichTextBuffer *buffer)

  Edits the object's properties via a GUI.
- virtual wxString GetPropertiesMenuLabel () const

  Returns the label to be used for the properties context menu item.
- int GetColSpan () const

  Returns the number of columns spanned by the cell.
- void SetColSpan (long span)

  Set the number of columns spanned by the cell.
- int GetRowSpan () const

  Returns the number of rows spanned by the cell.
- void SetRowSpan (long span)

  Set the number of rows spanned by the cell.
- virtual wxRichTextObject * Clone () const

  Clones the object.
- void Copy (const wxRichTextCell &obj)

Additional Inherited Members

21.612.2 Constructor & Destructor Documentation

wxRichTextCell::wxRichTextCell (wxRichTextObject * *parent* = NULL)

Default constructor; optionally pass the parent object.

wxRichTextCell::wxRichTextCell (const wxRichTextCell & *obj*) `[inline]`

Copy constructor.

21.612.3 Member Function Documentation

virtual bool wxRichTextCell::CanEditProperties ( ) const `[inline], [virtual]`

Returns true if we can edit the object's properties via a GUI.

Reimplemented from wxRichTextBox.

virtual wxRichTextObject* wxRichTextCell::Clone ( ) const `[inline], [virtual]`

Clones the object.

Reimplemented from wxRichTextBox.

void wxRichTextCell::Copy (const wxRichTextCell & *obj*)

virtual bool wxRichTextCell::Draw (wxDC & *dc,* wxRichTextDrawingContext & *context,* const wxRichTextRange & *range,* const wxRichTextSelection & *selection,* const wxRect & *rect,* int *descent,* int *style*) [virtual]

Draw the item, within the given range.

Some objects may ignore the range (for example paragraphs) while others must obey it (lines, to implement wrapping)

Reimplemented from wxRichTextBox.

virtual bool wxRichTextCell::EditProperties (wxWindow * *parent,* wxRichTextBuffer * *buffer*) [virtual]

Edits the object's properties via a GUI.

Reimplemented from wxRichTextBox.

int wxRichTextCell::GetColSpan ( ) const

Returns the number of columns spanned by the cell.

By default a cell doesn't span extra columns, so this function returns 1.

Since

2.9.5

See also

SetColSpan(), GetRowSpan()

virtual wxString wxRichTextCell::GetPropertiesMenuLabel ( ) const [inline], [virtual]

Returns the label to be used for the properties context menu item.

Reimplemented from wxRichTextBox.

int wxRichTextCell::GetRowSpan ( ) const

Returns the number of rows spanned by the cell.

By default a cell doesn't span extra rows, so this function returns 1.

Since

2.9.5

See also

SetRowSpan(), GetColSpan()

virtual wxString wxRichTextCell::GetXMLNodeName ( ) const [inline], [virtual]

Returns the XML node name of this object.

This must be overridden for wxXmlNode-base XML export to work.

Reimplemented from wxRichTextBox.

virtual int wxRichTextCell::HitTest (wxDC & *dc,* wxRichTextDrawingContext & *context,* const wxPoint & *pt,* long & *textPosition,* wxRichTextObject ** *obj,* wxRichTextObject ** *contextObj,* int *flags* = 0) [virtual]

Hit-testing: returns a flag indicating hit test details, plus information about position.

contextObj is returned to specify what object position is relevant to, since otherwise there's an ambiguity. @ obj might not be a child of *contextObj*, since we may be referring to the container itself if we have no hit on a child - for example if we click outside an object.

The function puts the position in *textPosition* if one is found. *pt* is in logical units (a zero y position is at the beginning of the buffer).

Returns

One of the wxRichTextHitTestFlags values.

Reimplemented from wxRichTextParagraphLayoutBox.

void wxRichTextCell::SetColSpan (long *span*)

Set the number of columns spanned by the cell.

By default colspan is 1 i.e. a cell doesn't span extra columns. Pass a value >1 to change this. Attempting to set a colspan <1 will assert and be ignored.

Since

2.9.5

See also

GetColSpan(), SetRowSpan()

void wxRichTextCell::SetRowSpan (long *span*)

Set the number of rows spanned by the cell.

By default colspan is 1 i.e. a cell doesn't span extra rows. Pass a value >1 to change this. Attempting to set a rowspan <1 will assert and be ignored.

Since

2.9.5

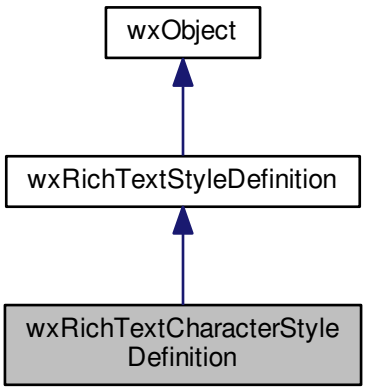
See also

GetRowSpan(), SetColSpan()

21.613 wxRichTextCharacterStyleDefinition Class Reference

```
#include <wx/richtext/richtextstyles.h>
```

Inheritance diagram for wxRichTextCharacterStyleDefinition:



21.613.1 Detailed Description

This class represents a character style definition, usually added to a wxRichTextStyleSheet.

Library: wxRichText

Category: Rich Text

Public Member Functions

- wxRichTextCharacterStyleDefinition (const wxString &name=wxEmptyString)

  Constructor.
- virtual ~wxRichTextCharacterStyleDefinition ()

  Destructor.

Additional Inherited Members

21.613.2 Constructor & Destructor Documentation

wxRichTextCharacterStyleDefinition::wxRichTextCharacterStyleDefinition (const wxString & *name* = wxEmptyString)

Constructor.

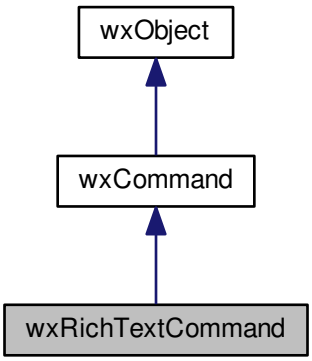
virtual wxRichTextCharacterStyleDefinition::~wxRichTextCharacterStyleDefinition ( ) [virtual]

Destructor.

21.614 wxRichTextCommand Class Reference

`#include <wx/richtext/richtextbuffer.h>`

Inheritance diagram for wxRichTextCommand:



21.614.1 Detailed Description

Implements a command on the undo/redo stack.

A wxRichTextCommand object contains one or more wxRichTextAction objects, allowing aggregation of a number of operations into one command.

Library: wxRichText

Category: Rich Text

See also

wxRichTextAction

Public Member Functions

- wxRichTextCommand (const wxString &name, wxRichTextCommandId id, wxRichTextBuffer *buffer, wxRichTextParagraphLayoutBox *container, wxRichTextCtrl *ctrl, bool ignoreFirstTime=false)

  Constructor for one action.
- wxRichTextCommand (const wxString &name)

  Constructor for multiple actions.
- virtual ~wxRichTextCommand ()
- bool Do ()

  Performs the command.
- bool Undo ()

  Undoes the command.
- void AddAction (wxRichTextAction *action)

Adds an action to the action list.

- void ClearActions ()

  Clears the action list.

- wxList & GetActions ()

  Returns the action list.

Protected Attributes

- wxList m_actions

Additional Inherited Members

21.614.2 Constructor & Destructor Documentation

wxRichTextCommand::wxRichTextCommand (const wxString & *name,* wxRichTextCommandId *id,* wxRichTextBuffer * *buffer,* wxRichTextParagraphLayoutBox * *container,* wxRichTextCtrl * *ctrl,* bool *ignoreFirstTime* = `false`)

Constructor for one action.

wxRichTextCommand::wxRichTextCommand (const wxString & *name*)

Constructor for multiple actions.

virtual wxRichTextCommand::~wxRichTextCommand ( ) `[virtual]`

21.614.3 Member Function Documentation

void wxRichTextCommand::AddAction (wxRichTextAction * *action*)

Adds an action to the action list.

void wxRichTextCommand::ClearActions ( )

Clears the action list.

bool wxRichTextCommand::Do ( ) `[virtual]`

Performs the command.

Implements wxCommand.

wxList& wxRichTextCommand::GetActions ( ) `[inline]`

Returns the action list.

bool wxRichTextCommand::Undo ( ) `[virtual]`

Undoes the command.

Implements wxCommand.

Public Member Functions

- wxRichTextCompositeObject (wxRichTextObject *parent=NULL)
- virtual ~wxRichTextCompositeObject ()
- virtual int HitTest (wxDC &dc, wxRichTextDrawingContext &context, const wxPoint &pt, long &textPosition, wxRichTextObject **obj, wxRichTextObject **contextObj, int flags=0)

Hit-testing: returns a flag indicating hit test details, plus information about position.

- virtual bool FindPosition (wxDC &dc, wxRichTextDrawingContext &context, long index, wxPoint &pt, int *height, bool forceLineStart)

  Finds the absolute position and row height for the given character position.

- virtual void CalculateRange (long start, long &end)

  Calculates the range of the object.

- virtual bool DeleteRange (const wxRichTextRange &range)

  Deletes the given range.

- virtual wxString GetTextForRange (const wxRichTextRange &range) const

  Returns any text in this object for the given range.

- virtual bool GetRangeSize (const wxRichTextRange &range, wxSize &size, int &descent, wxDC &dc, wxRichTextDrawingContext &context, int flags, const wxPoint &position=wxPoint(0, 0), const wxSize &parentSize=wxDefaultSize, wxArrayInt *partialExtents=NULL) const

  Returns the object size for the given range.

- virtual void Dump (wxTextOutputStream &stream)

  Dump object data to the given output stream for debugging.

- virtual void Invalidate (const wxRichTextRange &invalidRange=wxRICHTEXT_ALL)

  Invalidates the object at the given range.

- wxRichTextObjectList & GetChildren ()

  Returns the children.

- const wxRichTextObjectList & GetChildren () const

  Returns the children.

- size_t GetChildCount () const

  Returns the number of children.

- wxRichTextObject * GetChild (size_t n) const

  Returns the nth child.

- virtual bool IsComposite () const

  Returns true if this object is composite.

- virtual bool IsAtomic () const

  Returns true if no user editing can be done inside the object.

- virtual bool IsEmpty () const

  Returns true if the buffer is empty.

- virtual wxRichTextObject * GetChildAtPosition (long pos) const

  Returns the child object at the given character position.

- void Copy (const wxRichTextCompositeObject &obj)
- void operator= (const wxRichTextCompositeObject &obj)
- size_t AppendChild (wxRichTextObject *child)

  Appends a child, returning the position.

- bool InsertChild (wxRichTextObject *child, wxRichTextObject *inFrontOf)

  Inserts the child in front of the given object, or at the beginning.

- bool RemoveChild (wxRichTextObject *child, bool deleteChild=false)

  Removes and optionally deletes the specified child.

- bool DeleteChildren ()

  Deletes all the children.

- bool Defragment (wxRichTextDrawingContext &context, const wxRichTextRange &range=wxRICHTEXT_ALL)

  Recursively merges all pieces that can be merged.

- virtual void Move (const wxPoint &pt)

  Moves the object recursively, by adding the offset from old to new.

Protected Attributes

- wxRichTextObjectList m_children

Additional Inherited Members

21.615.2 Constructor & Destructor Documentation

wxRichTextCompositeObject::wxRichTextCompositeObject (wxRichTextObject * *parent* = NULL)

virtual wxRichTextCompositeObject::~wxRichTextCompositeObject ( ) [virtual]

21.615.3 Member Function Documentation

size_t wxRichTextCompositeObject::AppendChild (wxRichTextObject * *child*)

Appends a child, returning the position.

virtual void wxRichTextCompositeObject::CalculateRange (long *start*, long & *end*) [virtual]

Calculates the range of the object.

By default, guess that the object is 1 unit long.

Reimplemented from wxRichTextObject.

Reimplemented in wxRichTextTable, wxRichTextParagraph, and wxRichTextField.

void wxRichTextCompositeObject::Copy (const wxRichTextCompositeObject & *obj*)

bool wxRichTextCompositeObject::Defragment (wxRichTextDrawingContext & *context*, const wxRichTextRange & *range* = wxRICHTEXT_ALL)

Recursively merges all pieces that can be merged.

bool wxRichTextCompositeObject::DeleteChildren ( )

Deletes all the children.

virtual bool wxRichTextCompositeObject::DeleteRange (const wxRichTextRange & *range*) [virtual]

Deletes the given range.

Reimplemented from wxRichTextObject.

Reimplemented in wxRichTextTable, and wxRichTextParagraphLayoutBox.

virtual void wxRichTextCompositeObject::Dump (wxTextOutputStream & *stream*) [virtual]

Dump object data to the given output stream for debugging.

Reimplemented from wxRichTextObject.

Reimplemented in wxRichTextBuffer.

virtual bool wxRichTextCompositeObject::FindPosition (wxDC & *dc,* wxRichTextDrawingContext & *context,* long *index,* wxPoint & *pt,* int * *height,* bool *forceLineStart*) [virtual]

Finds the absolute position and row height for the given character position.

Reimplemented from wxRichTextObject.

Reimplemented in wxRichTextTable, and wxRichTextParagraph.

wxRichTextObject* wxRichTextCompositeObject::GetChild (size_t *n*) const

Returns the nth child.

virtual wxRichTextObject* wxRichTextCompositeObject::GetChildAtPosition (long *pos*) const [virtual]

Returns the child object at the given character position.

size_t wxRichTextCompositeObject::GetChildCount ( ) const

Returns the number of children.

wxRichTextObjectList& wxRichTextCompositeObject::GetChildren ( )

Returns the children.

const wxRichTextObjectList& wxRichTextCompositeObject::GetChildren ( ) const

Returns the children.

virtual bool wxRichTextCompositeObject::GetRangeSize (const wxRichTextRange & *range,* wxSize & *size,* int & *descent,* wxDC & *dc,* wxRichTextDrawingContext & *context,* int *flags,* const wxPoint & *position* = wxPoint(0, 0), const wxSize & *parentSize* = wxDefaultSize, wxArrayInt * *partialExtents* = NULL) const [virtual]

Returns the object size for the given range.

Returns false if the range is invalid for this object.

Implements wxRichTextObject.

Reimplemented in wxRichTextTable, wxRichTextParagraph, wxRichTextField, and wxRichTextParagraphLayoutBox.

virtual wxString wxRichTextCompositeObject::GetTextForRange (const wxRichTextRange & *range*) const [virtual]

Returns any text in this object for the given range.

Reimplemented from wxRichTextObject.

Reimplemented in wxRichTextTable, and wxRichTextParagraphLayoutBox.

virtual int wxRichTextCompositeObject::HitTest (wxDC & *dc,* wxRichTextDrawingContext & *context,* const wxPoint & *pt,* long & *textPosition,* wxRichTextObject ** *obj,* wxRichTextObject ** *contextObj,* int *flags* = 0) [virtual]

Hit-testing: returns a flag indicating hit test details, plus information about position.

contextObj is returned to specify what object position is relevant to, since otherwise there's an ambiguity. @ obj might not be a child of *contextObj*, since we may be referring to the container itself if we have no hit on a child - for example if we click outside an object.

The function puts the position in *textPosition* if one is found. *pt* is in logical units (a zero y position is at the beginning of the buffer).

Returns

One of the wxRichTextHitTestFlags values.

Reimplemented from wxRichTextObject.

Reimplemented in wxRichTextTable, wxRichTextCell, wxRichTextBuffer, wxRichTextParagraph, and wxRichTextParagraphLayoutBox.

bool wxRichTextCompositeObject::InsertChild (wxRichTextObject * *child,* wxRichTextObject * *inFrontOf*)

Inserts the child in front of the given object, or at the beginning.

virtual void wxRichTextCompositeObject::Invalidate (const wxRichTextRange & *invalidRange* = wxRICHTEXT_ALL) [virtual]

Invalidates the object at the given range.

With no argument, invalidates the whole object.

Reimplemented from wxRichTextObject.

Reimplemented in wxRichTextParagraphLayoutBox.

virtual bool wxRichTextCompositeObject::IsAtomic ( ) const [virtual]

Returns true if no user editing can be done inside the object.

This returns true for simple objects, false for most composite objects, but true for fields, which if composite, should not be user-edited.

Reimplemented from wxRichTextObject.

Reimplemented in wxRichTextField.

virtual bool wxRichTextCompositeObject::IsComposite ( ) const [virtual]

Returns true if this object is composite.

Reimplemented from wxRichTextObject.

virtual bool wxRichTextCompositeObject::IsEmpty ( ) const [virtual]

Returns true if the buffer is empty.

Reimplemented from wxRichTextObject.

Reimplemented in wxRichTextField.

virtual void wxRichTextCompositeObject::Move (const wxPoint & *pt*) [virtual]

Moves the object recursively, by adding the offset from old to new.

Reimplemented from wxRichTextObject.

void wxRichTextCompositeObject::operator= (const wxRichTextCompositeObject & *obj*)

bool wxRichTextCompositeObject::RemoveChild (wxRichTextObject * *child*, bool *deleteChild* = `false`)

Removes and optionally deletes the specified child.

21.616 wxRichTextContextMenuPropertiesInfo Class Reference

`#include <wx/richtext/richtextctrl.h>`

21.616.1 Detailed Description

wxRichTextContextMenuPropertiesInfo keeps track of objects that appear in the context menu, whose properties are available to be edited.

Public Member Functions

- wxRichTextContextMenuPropertiesInfo ()

  Constructor.
- void Init ()

  Initialisation.
- bool AddItem (const wxString &label, wxRichTextObject *obj)

  Adds an item.
- int AddMenuItems (wxMenu *menu, int startCmd=wxID_RICHTEXT_PROPERTIES1) const

  Returns the number of menu items that were added.
- int AddItems (wxRichTextCtrl *ctrl, wxRichTextObject *container, wxRichTextObject *obj)

  Adds appropriate menu items for the current container and clicked on object (and container's parent, if appropriate).
- void Clear ()

  Clears the items.
- wxString GetLabel (int n) const

  Returns the nth label.
- wxRichTextObject * GetObject (int n) const

  Returns the nth object.
- wxRichTextObjectPtrArray & GetObjects ()

  Returns the array of objects.
- const wxRichTextObjectPtrArray & GetObjects () const

  Returns the array of objects.
- wxArrayString & GetLabels ()

  Returns the array of labels.
- const wxArrayString & GetLabels () const

  Returns the array of labels.
- int GetCount () const

  Returns the number of items.

Public Attributes

- wxRichTextObjectPtrArray m_objects
- wxArrayString m_labels

21.616.2 Constructor & Destructor Documentation

wxRichTextContextMenuPropertiesInfo::wxRichTextContextMenuPropertiesInfo ( )

Constructor.

21.616.3 Member Function Documentation

bool wxRichTextContextMenuPropertiesInfo::AddItem (const wxString & *label*, wxRichTextObject * *obj*)

Adds an item.

int wxRichTextContextMenuPropertiesInfo::AddItems (wxRichTextCtrl * *ctrl*, wxRichTextObject * *container*, wxRichTextObject * *obj*)

Adds appropriate menu items for the current container and clicked on object (and container's parent, if appropriate).

int wxRichTextContextMenuPropertiesInfo::AddMenuItems (wxMenu * *menu*, int *startCmd* = wxID_RICHTEXT_PROPERTIES1) const

Returns the number of menu items that were added.

void wxRichTextContextMenuPropertiesInfo::Clear ( )

Clears the items.

int wxRichTextContextMenuPropertiesInfo::GetCount ( ) const

Returns the number of items.

wxString wxRichTextContextMenuPropertiesInfo::GetLabel (int *n*) const

Returns the nth label.

wxArrayString& wxRichTextContextMenuPropertiesInfo::GetLabels ( )

Returns the array of labels.

const wxArrayString& wxRichTextContextMenuPropertiesInfo::GetLabels ( ) const

Returns the array of labels.

wxRichTextObject* wxRichTextContextMenuPropertiesInfo::GetObject (int *n*) const

Returns the nth object.

wxRichTextObjectPtrArray& wxRichTextContextMenuPropertiesInfo::GetObjects ( )

Returns the array of objects.

const wxRichTextObjectPtrArray& wxRichTextContextMenuPropertiesInfo::GetObjects ( ) const

Returns the array of objects.

void wxRichTextContextMenuPropertiesInfo::Init ( )

Initialisation.

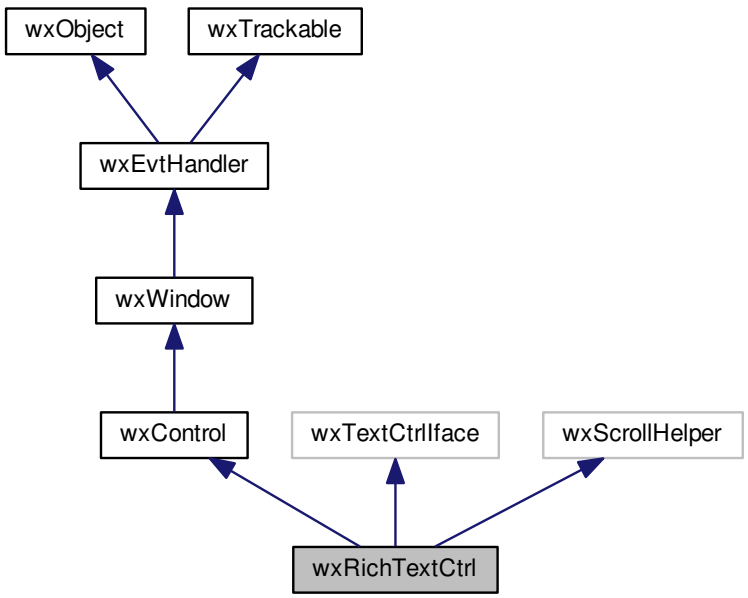
wxRichTextObjectPtrArray wxRichTextContextMenuPropertiesInfo::m_objects

21.617 wxRichTextCtrl Class Reference

`#include <wx/richtext/richtextctrl.h>`

Inheritance diagram for wxRichTextCtrl:



21.617.1 Detailed Description

wxRichTextCtrl provides a generic, ground-up implementation of a text control capable of showing multiple styles and images.

wxRichTextCtrl sends notification events: see wxRichTextEvent.

It also sends the standard wxTextCtrl events `wxEVT_TEXT_ENTER` and `wxEVT_TEXT`, and wxTextUrlEvent when URL content is clicked.

For more information, see the wxRichTextCtrl Overview.

Styles

This class supports the following styles:

- wxRE_CENTRE_CARET: The control will try to keep the caret line centred vertically while editing. wxRE_↩ CENTER_CARET is a synonym for this style.
- wxRE_MULTILINE: The control will be multiline (mandatory).
- wxRE_READONLY: The control will not be editable.

Library: wxRichText

Category: Rich Text

Public Member Functions

- wxRichTextCtrl ()

  Default constructor.
- wxRichTextCtrl (wxWindow *parent, wxWindowID id=-1, const wxString &value=wxEmptyString, const wx↩ Point &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, long style=wxRE_MULTILINE, const wx↩ Validator &validator=wxDefaultValidator, const wxString &name=wxTextCtrlNameStr)

  Constructor, creating and showing a rich text control.
- virtual ~wxRichTextCtrl ()

  Destructor.
- bool Create (wxWindow *parent, wxWindowID id=-1, const wxString &value=wxEmptyString, const wx↩ Point &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, long style=wxRE_MULTILINE, const wx↩ Validator &validator=wxDefaultValidator, const wxString &name=wxTextCtrlNameStr)

  Creates the underlying window.
- void Init ()

  Initialises the members of the control.
- virtual wxString GetRange (long from, long to) const

  Gets the text for the given range.
- virtual int GetLineLength (long lineNo) const

  Returns the length of the specified line in characters.
- virtual wxString GetLineText (long lineNo) const

  Returns the text for the given line.
- virtual int GetNumberOfLines () const

  Returns the number of lines in the buffer.
- virtual bool IsModified () const

  Returns true if the buffer has been modified.
- virtual bool IsEditable () const

  Returns true if the control is editable.
- bool IsSingleLine () const

  Returns true if the control is single-line.

- bool IsMultiLine () const

  Returns true if the control is multiline.
- virtual wxString GetStringSelection () const

  Returns the text within the current selection range, if any.
- wxString GetFilename () const

  Gets the current filename associated with the control.
- void SetFilename (const wxString &filename)

  Sets the current filename.
- void SetDelayedLayoutThreshold (long threshold)

  Sets the size of the buffer beyond which layout is delayed during resizing.
- long GetDelayedLayoutThreshold () const

  Gets the size of the buffer beyond which layout is delayed during resizing.
- bool GetFullLayoutRequired () const
- void SetFullLayoutRequired (bool b)
- wxLongLong GetFullLayoutTime () const
- void SetFullLayoutTime (wxLongLong t)
- long GetFullLayoutSavedPosition () const
- void SetFullLayoutSavedPosition (long p)
- void ForceDelayedLayout ()
- void SetTextCursor (const wxCursor &cursor)

  Sets the text (normal) cursor.
- wxCursor GetTextCursor () const

  Returns the text (normal) cursor.
- void SetURLCursor (const wxCursor &cursor)

  Sets the cursor to be used over URLs.
- wxCursor GetURLCursor () const

  Returns the cursor to be used over URLs.
- bool GetCaretAtLineStart () const

  Returns true if we are showing the caret position at the start of a line instead of at the end of the previous one.
- void SetCaretAtLineStart (bool atStart)

  Sets a flag to remember that we are showing the caret position at the start of a line instead of at the end of the previous one.
- bool GetDragging () const

  Returns true if we are extending a selection.
- void SetDragging (bool dragging)

  Sets a flag to remember if we are extending a selection.
- bool GetPreDrag () const

  Are we trying to start Drag'n'Drop?
- void SetPreDrag (bool pd)

  Set if we're trying to start Drag'n'Drop.
- const wxPoint GetDragStartPoint () const

  Get the possible Drag'n'Drop start point.
- void SetDragStartPoint (wxPoint sp)

  Set the possible Drag'n'Drop start point.
- const wxDateTime GetDragStartTime () const

  Get the possible Drag'n'Drop start time.
- void SetDragStartTime (wxDateTime st)

  Set the possible Drag'n'Drop start time.
- wxMenu * GetContextMenu () const

  Returns the current context menu.
- void SetContextMenu (wxMenu *menu)

Sets the current context menu.

- long GetSelectionAnchor () const

  Returns an anchor so we know how to extend the selection.
- void SetSelectionAnchor (long anchor)

  Sets an anchor so we know how to extend the selection.
- wxRichTextObject * GetSelectionAnchorObject () const

  Returns the anchor object if selecting multiple containers.
- void SetSelectionAnchorObject (wxRichTextObject *anchor)

  Sets the anchor object if selecting multiple containers.
- wxRichTextParagraphLayoutBox * GetFocusObject () const

  Returns the wxRichTextObject object that currently has the editing focus.
- void StoreFocusObject (wxRichTextParagraphLayoutBox *obj)

  Setter for m_focusObject.
- bool SetFocusObject (wxRichTextParagraphLayoutBox *obj, bool setCaretPosition=true)

  Sets the wxRichTextObject object that currently has the editing focus.
- void Invalidate ()

  Invalidates the whole buffer to trigger painting later.
- virtual void Clear ()

  Clears the buffer content, leaving a single empty paragraph.
- virtual void Replace (long from, long to, const wxString &value)

  Replaces the content in the specified range with the string specified by value.
- virtual void Remove (long from, long to)

  Removes the content in the specified range.
- bool LoadFile (const wxString &file, int type=wxRICHTEXT_TYPE_ANY)

  Loads content into the control's buffer using the given type.
- virtual bool DoLoadFile (const wxString &file, int fileType)

  Helper function for LoadFile().
- bool SaveFile (const wxString &file=wxEmptyString, int type=wxRICHTEXT_TYPE_ANY)

  Saves the buffer content using the given type.
- virtual bool DoSaveFile (const wxString &file=wxEmptyString, int fileType=wxRICHTEXT_TYPE_ANY)

  Helper function for SaveFile().
- void SetHandlerFlags (int flags)

  Sets flags that change the behaviour of loading or saving.
- int GetHandlerFlags () const

  Returns flags that change the behaviour of loading or saving.
- virtual void MarkDirty ()

  Marks the buffer as modified.
- virtual void DiscardEdits ()

  Sets the buffer's modified status to false, and clears the buffer's command history.
- void SetModified (bool modified)
- virtual void SetMaxLength (unsigned long len)

  Sets the maximum number of characters that may be entered in a single line text control.
- virtual void WriteText (const wxString &text)

  Writes text at the current position.
- virtual void AppendText (const wxString &text)

  Sets the insertion point to the end of the buffer and writes the text.
- virtual void SetStyle (wxRichTextObject *obj, const wxRichTextAttr &textAttr, int flags=wxRICHTEXT_SET↩ STYLE_WITH_UNDO)

  Sets the attributes for a single object.
- virtual bool SetStyleEx (const wxRichTextRange &range, const wxRichTextAttr &style, int flags=wxRICHTE↩ XT_SETSTYLE_WITH_UNDO)

Sets the attributes for the given range, passing flags to determine how the attributes are set.

- virtual const wxRichTextAttr & GetDefaultStyleEx () const

  Returns the current default style, which can be used to change how subsequently inserted text is displayed.

- virtual bool ClearListStyle (const wxRichTextRange &range, int flags=wxRICHTEXT_SETSTYLE_WITH_UNDO)

  Clears the list style from the given range, clearing list-related attributes and applying any named paragraph style associated with each paragraph.

- virtual bool SetProperties (const wxRichTextRange &range, const wxRichTextProperties &properties, int flags=wxRICHTEXT_SETPROPERTIES_WITH_UNDO)

  Sets the properties for the given range, passing flags to determine how the attributes are set.

- virtual bool Delete (const wxRichTextRange &range)

  Deletes the content within the given range.

- virtual long XYToPosition (long x, long y) const

  Translates from column and line number to position.

- virtual bool PositionToXY (long pos, long *x, long *y) const

  Converts a text position to zero-based column and line numbers.

- virtual void ShowPosition (long pos)

  Scrolls the buffer so that the given position is in view.

- virtual void Copy ()

  Copies the selected content (if any) to the clipboard.

- virtual void Cut ()

  Copies the selected content (if any) to the clipboard and deletes the selection.

- virtual void Paste ()

  Pastes content from the clipboard to the buffer.

- virtual void DeleteSelection ()

  Deletes the content in the selection, if any.

- virtual bool CanCopy () const

  Returns true if selected content can be copied to the clipboard.

- virtual bool CanCut () const

  Returns true if selected content can be copied to the clipboard and deleted.

- virtual bool CanPaste () const

  Returns true if the clipboard content can be pasted to the buffer.

- virtual bool CanDeleteSelection () const

  Returns true if selected content can be deleted.

- virtual void Undo ()

  Undoes the command at the top of the command history, if there is one.

- virtual void Redo ()

  Redoes the current command.

- virtual bool CanUndo () const

  Returns true if there is a command in the command history that can be undone.

- virtual bool CanRedo () const

  Returns true if there is a command in the command history that can be redone.

- virtual void SetInsertionPoint (long pos)

  Sets the insertion point and causes the current editing style to be taken from the new position (unlike wxRichTextCtrl::SetCaretPosition).

- virtual void SetInsertionPointEnd ()

  Sets the insertion point to the end of the text control.

- virtual long GetInsertionPoint () const

  Returns the current insertion point.

- virtual wxTextPos GetLastPosition () const

  Returns the last position in the buffer.

- virtual void SelectAll ()

  Selects all the text in the buffer.
- virtual void SetEditable (bool editable)

  Makes the control editable, or not.
- virtual bool HasSelection () const

  Returns true if there is a selection and the object containing the selection was the same as the current focus object.
- virtual bool HasUnfocusedSelection () const

  Returns true if there was a selection, whether or not the current focus object is the same as the selection's container object.
- virtual bool WriteImage (const wxString &filename, wxBitmapType bitmapType, const wxRichTextAttr &textAttr=wxRichTextAttr())

  Loads an image from a file and writes it at the current insertion point.
- virtual bool WriteImage (const wxRichTextImageBlock &imageBlock, const wxRichTextAttr &textAttr=wxRichTextAttr())

  Writes an image block at the current insertion point.
- virtual wxRichTextBox * WriteTextBox (const wxRichTextAttr &textAttr=wxRichTextAttr())

  Write a text box at the current insertion point, returning the text box.
- virtual wxRichTextField * WriteField (const wxString &fieldType, const wxRichTextProperties &properties, const wxRichTextAttr &textAttr=wxRichTextAttr())

  Writes a field at the current insertion point.
- virtual wxRichTextTable * WriteTable (int rows, int cols, const wxRichTextAttr &tableAttr=wxRichTextAttr(), const wxRichTextAttr &cellAttr=wxRichTextAttr())

  Write a table at the current insertion point, returning the table.
- virtual bool Newline ()

  Inserts a new paragraph at the current insertion point.
- virtual bool LineBreak ()

  Inserts a line break at the current insertion point.
- virtual void SetBasicStyle (const wxRichTextAttr &style)

  Sets the basic (overall) style.
- virtual const wxRichTextAttr & GetBasicStyle () const

  Gets the basic (overall) style.
- virtual bool BeginStyle (const wxRichTextAttr &style)

  Begins applying a style.
- virtual bool EndStyle ()

  Ends the current style.
- virtual bool EndAllStyles ()

  Ends application of all styles in the current style stack.
- bool BeginBold ()

  Begins using bold.
- bool EndBold ()

  Ends using bold.
- bool BeginItalic ()

  Begins using italic.
- bool EndItalic ()

  Ends using italic.
- bool BeginUnderline ()

  Begins using underlining.
- bool EndUnderline ()

  End applying underlining.
- bool BeginFontSize (int pointSize)

  Begins using the given point size.

- bool EndFontSize ()

  Ends using a point size.
- bool BeginFont (const wxFont &font)

  Begins using this font.
- bool EndFont ()

  Ends using a font.
- bool BeginTextColour (const wxColour &colour)

  Begins using this colour.
- bool EndTextColour ()

  Ends applying a text colour.
- bool BeginAlignment (wxTextAttrAlignment alignment)

  Begins using alignment.
- bool EndAlignment ()

  Ends alignment.
- bool BeginLeftIndent (int leftIndent, int leftSubIndent=0)

  Begins applying a left indent and subindent in tenths of a millimetre.
- bool EndLeftIndent ()

  Ends left indent.
- bool BeginRightIndent (int rightIndent)

  Begins a right indent, specified in tenths of a millimetre.
- bool EndRightIndent ()

  Ends right indent.
- bool BeginParagraphSpacing (int before, int after)

  Begins paragraph spacing; pass the before-paragraph and after-paragraph spacing in tenths of a millimetre.
- bool EndParagraphSpacing ()

  Ends paragraph spacing.
- bool BeginLineSpacing (int lineSpacing)

  Begins appling line spacing.
- bool EndLineSpacing ()

  Ends line spacing.
- bool BeginNumberedBullet (int bulletNumber, int leftIndent, int leftSubIndent, int bulletStyle=wxTEXT_ATTR_BULLET_STYLE_ARABIC|wxTEXT_ATTR_BULLET_STYLE_PERIOD)

  Begins a numbered bullet.
- bool EndNumberedBullet ()

  Ends application of a numbered bullet.
- bool BeginSymbolBullet (const wxString &symbol, int leftIndent, int leftSubIndent, int bulletStyle=wxTEXT_ATTR_BULLET_STYLE_SYMBOL)

  Begins applying a symbol bullet, using a character from the current font.
- bool EndSymbolBullet ()

  Ends applying a symbol bullet.
- bool BeginStandardBullet (const wxString &bulletName, int leftIndent, int leftSubIndent, int bulletStyle=wxTEXT_ATTR_BULLET_STYLE_STANDARD)

  Begins applying a symbol bullet.
- bool EndStandardBullet ()

  Begins applying a standard bullet.
- bool BeginCharacterStyle (const wxString &characterStyle)

  Begins using the named character style.
- bool EndCharacterStyle ()

  Ends application of a named character style.
- bool BeginParagraphStyle (const wxString &paragraphStyle)

  Begins applying the named paragraph style.

- bool EndParagraphStyle ()

  Ends application of a named paragraph style.
- bool BeginListStyle (const wxString &listStyle, int level=1, int number=1)

  Begins using a specified list style.
- bool EndListStyle ()

  Ends using a specified list style.
- bool BeginURL (const wxString &url, const wxString &characterStyle=wxEmptyString)

  Begins applying wxTEXT_ATTR_URL to the content.
- bool EndURL ()

  Ends applying a URL.
- bool SetDefaultStyleToCursorStyle ()

  Sets the default style to the style under the cursor.
- virtual void SelectNone ()

  Cancels any selection.
- virtual bool SelectWord (long position)

  Selects the word at the given character position.
- wxRichTextRange GetSelectionRange () const

  Returns the selection range in character positions.
- void SetSelectionRange (const wxRichTextRange &range)

  Sets the selection to the given range.
- wxRichTextRange GetInternalSelectionRange () const

  Returns the selection range in character positions.
- void SetInternalSelectionRange (const wxRichTextRange &range)

  Sets the selection range in character positions.
- virtual wxRichTextRange AddParagraph (const wxString &text)

  Adds a new paragraph of text to the end of the buffer.
- virtual wxRichTextRange AddImage (const wxImage &image)

  Adds an image to the control's buffer.
- virtual bool LayoutContent (bool onlyVisibleRect=false)

  Lays out the buffer, which must be done before certain operations, such as setting the caret position.
- virtual void DoLayoutBuffer (wxRichTextBuffer &buffer, wxDC &dc, wxRichTextDrawingContext &context, const wxRect &rect, const wxRect &parentRect, int flags)

  Implements layout.
- virtual bool MoveCaret (long pos, bool showAtLineStart=false, wxRichTextParagraphLayoutBox *container=NULL)

  Move the caret to the given character position.
- virtual bool MoveRight (int noPositions=1, int flags=0)

  Moves right.
- virtual bool MoveLeft (int noPositions=1, int flags=0)

  Moves left.
- virtual bool MoveUp (int noLines=1, int flags=0)

  Moves to the start of the paragraph.
- virtual bool MoveDown (int noLines=1, int flags=0)

  Moves the caret down.
- virtual bool MoveToLineEnd (int flags=0)

  Moves to the end of the line.
- virtual bool MoveToLineStart (int flags=0)

  Moves to the start of the line.
- virtual bool MoveToParagraphEnd (int flags=0)

  Moves to the end of the paragraph.
- virtual bool MoveToParagraphStart (int flags=0)

Moves to the start of the paragraph.

- virtual bool MoveHome (int flags=0)

  Moves to the start of the buffer.
- virtual bool MoveEnd (int flags=0)

  Moves to the end of the buffer.
- virtual bool PageUp (int noPages=1, int flags=0)

  Moves one or more pages up.
- virtual bool PageDown (int noPages=1, int flags=0)

  Moves one or more pages down.
- virtual bool WordLeft (int noPages=1, int flags=0)

  Moves a number of words to the left.
- virtual bool WordRight (int noPages=1, int flags=0)

  Move a nuber of words to the right.
- virtual bool BeginBatchUndo (const wxString &cmdName)

  Starts batching undo history for commands.
- virtual bool EndBatchUndo ()

  Ends batching undo command history.
- virtual bool BatchingUndo () const

  Returns true if undo commands are being batched.
- virtual bool BeginSuppressUndo ()

  Starts suppressing undo history for commands.
- virtual bool EndSuppressUndo ()

  Ends suppressing undo command history.
- virtual bool SuppressingUndo () const

  Returns true if undo history suppression is on.
- virtual bool HasCharacterAttributes (const wxRichTextRange &range, const wxRichTextAttr &style) const

  Test if this whole range has character attributes of the specified kind.
- virtual bool HasParagraphAttributes (const wxRichTextRange &range, const wxRichTextAttr &style) const

  Test if this whole range has paragraph attributes of the specified kind.
- virtual bool IsSelectionBold ()

  Returns true if all of the selection, or the content at the caret position, is bold.
- virtual bool IsSelectionItalics ()

  Returns true if all of the selection, or the content at the caret position, is italic.
- virtual bool IsSelectionUnderlined ()

  Returns true if all of the selection, or the content at the caret position, is underlined.
- virtual bool DoesSelectionHaveTextEffectFlag (int flag)

  Returns true if all of the selection, or the content at the current caret position, has the supplied wxTextAttrEffects flag(s).
- virtual bool IsSelectionAligned (wxTextAttrAlignment alignment)

  Returns true if all of the selection is aligned according to the specified flag.
- virtual bool ApplyBoldToSelection ()

  Apples bold to the selection or the default style (undoable).
- virtual bool ApplyItalicToSelection ()

  Applies italic to the selection or the default style (undoable).
- virtual bool ApplyUnderlineToSelection ()

  Applies underline to the selection or the default style (undoable).
- virtual bool ApplyTextEffectToSelection (int flags)

  Applies one or more wxTextAttrEffects flags to the selection (undoable).
- virtual bool ApplyAlignmentToSelection (wxTextAttrAlignment alignment)

  Applies the given alignment to the selection or the default style (undoable).
- virtual bool ApplyStyle (wxRichTextStyleDefinition *def)

Applies the style sheet to the buffer, matching paragraph styles in the sheet against named styles in the buffer.

- void SetStyleSheet (wxRichTextStyleSheet *styleSheet)

  Sets the style sheet associated with the control.
- wxRichTextStyleSheet * GetStyleSheet () const

  Returns the style sheet associated with the control, if any.
- bool PushStyleSheet (wxRichTextStyleSheet *styleSheet)

  Push the style sheet to top of stack.
- wxRichTextStyleSheet * PopStyleSheet ()

  Pops the style sheet from top of stack.
- bool ApplyStyleSheet (wxRichTextStyleSheet *styleSheet=NULL)

  Applies the style sheet to the buffer, for example if the styles have changed.
- virtual bool ShowContextMenu (wxMenu *menu, const wxPoint &pt, bool addPropertyCommands)

  Shows the given context menu, optionally adding appropriate property-editing commands for the current position in the object hierarchy.
- virtual int PrepareContextMenu (wxMenu *menu, const wxPoint &pt, bool addPropertyCommands)

  Prepares the context menu, optionally adding appropriate property-editing commands.
- virtual bool CanEditProperties (wxRichTextObject *obj) const

  Returns true if we can edit the object's properties via a GUI.
- virtual bool EditProperties (wxRichTextObject *obj, wxWindow *parent)

  Edits the object's properties via a GUI.
- virtual wxString GetPropertiesMenuLabel (wxRichTextObject *obj)

  Gets the object's properties menu label.
- virtual void PrepareContent (wxRichTextParagraphLayoutBox &container)

  Prepares the content just before insertion (or after buffer reset).
- virtual bool CanDeleteRange (wxRichTextParagraphLayoutBox &container, const wxRichTextRange &range) const

  Can we delete this range? Sends an event to the control.
- virtual bool CanInsertContent (wxRichTextParagraphLayoutBox &container, long pos) const

  Can we insert content at this position? Sends an event to the control.
- virtual void EnableVerticalScrollbar (bool enable)

  Enable or disable the vertical scrollbar.
- virtual bool GetVerticalScrollbarEnabled () const

  Returns true if the vertical scrollbar is enabled.
- void SetFontScale (double fontScale, bool refresh=false)

  Sets the scale factor for displaying fonts, for example for more comfortable editing.
- double GetFontScale () const

  Returns the scale factor for displaying fonts, for example for more comfortable editing.
- void SetDimensionScale (double dimScale, bool refresh=false)

  Sets the scale factor for displaying certain dimensions such as indentation and inter-paragraph spacing.
- double GetDimensionScale () const

  Returns the scale factor for displaying certain dimensions such as indentation and inter-paragraph spacing.
- void SetScale (double scale, bool refresh=false)

  Sets an overall scale factor for displaying and editing the content.
- double GetScale () const

  Returns an overall scale factor for displaying and editing the content.
- wxPoint GetUnscaledPoint (const wxPoint &pt) const

  Returns an unscaled point.
- wxPoint GetScaledPoint (const wxPoint &pt) const

  Returns a scaled point.
- wxSize GetUnscaledSize (const wxSize &sz) const

  Returns an unscaled size.

- wxSize GetScaledSize (const wxSize &sz) const

  Returns a scaled size.
- wxRect GetUnscaledRect (const wxRect &rect) const

  Returns an unscaled rectangle.
- wxRect GetScaledRect (const wxRect &rect) const

  Returns a scaled rectangle.
- bool GetVirtualAttributesEnabled () const

  Returns true if this control can use virtual attributes and virtual text.
- void EnableVirtualAttributes (bool b)

  Pass true to let the control use virtual attributes.
- void Command (wxCommandEvent &event)

  Sends the event to the control.
- void OnDropFiles (wxDropFilesEvent &event)

  Loads the first dropped file.
- void OnCaptureLost (wxMouseCaptureLostEvent &event)
- void OnSysColourChanged (wxSysColourChangedEvent &event)
- void OnCut (wxCommandEvent &event)

  Standard handler for the wxID_CUT command.
- void OnCopy (wxCommandEvent &event)

  Standard handler for the wxID_COPY command.
- void OnPaste (wxCommandEvent &event)

  Standard handler for the wxID_PASTE command.
- void OnUndo (wxCommandEvent &event)

  Standard handler for the wxID_UNDO command.
- void OnRedo (wxCommandEvent &event)

  Standard handler for the wxID_REDO command.
- void OnSelectAll (wxCommandEvent &event)

  Standard handler for the wxID_SELECTALL command.
- void OnProperties (wxCommandEvent &event)

  Standard handler for property commands.
- void OnClear (wxCommandEvent &event)

  Standard handler for the wxID_CLEAR command.
- void OnUpdateCut (wxUpdateUIEvent &event)

  Standard update handler for the wxID_CUT command.
- void OnUpdateCopy (wxUpdateUIEvent &event)

  Standard update handler for the wxID_COPY command.
- void OnUpdatePaste (wxUpdateUIEvent &event)

  Standard update handler for the wxID_PASTE command.
- void OnUpdateUndo (wxUpdateUIEvent &event)

  Standard update handler for the wxID_UNDO command.
- void OnUpdateRedo (wxUpdateUIEvent &event)

  Standard update handler for the wxID_REDO command.
- void OnUpdateSelectAll (wxUpdateUIEvent &event)

  Standard update handler for the wxID_SELECTALL command.
- void OnUpdateProperties (wxUpdateUIEvent &event)

  Standard update handler for property commands.
- void OnUpdateClear (wxUpdateUIEvent &event)

  Standard update handler for the wxID_CLEAR command.
- void OnContextMenu (wxContextMenuEvent &event)

  Shows a standard context menu with undo, redo, cut, copy, paste, clear, and select all commands.
- void OnPaint (wxPaintEvent &event)

- void OnEraseBackground (wxEraseEvent &event)
- void OnLeftClick (wxMouseEvent &event)
- void OnLeftUp (wxMouseEvent &event)
- void OnMoveMouse (wxMouseEvent &event)
- void OnLeftDClick (wxMouseEvent &event)
- void OnMiddleClick (wxMouseEvent &event)
- void OnRightClick (wxMouseEvent &event)
- void OnChar (wxKeyEvent &event)
- void OnSize (wxSizeEvent &event)
- void OnSetFocus (wxFocusEvent &event)
- void OnKillFocus (wxFocusEvent &event)
- void OnIdle (wxIdleEvent &event)
- void OnScroll (wxScrollWinEvent &event)
- virtual bool SetFont (const wxFont &font)

  Sets the font, and also the basic and default attributes (see wxRichTextCtrl::SetDefaultStyle).
- virtual void SetupScrollbars (bool atTop=false)

  A helper function setting up scrollbars, for example after a resize.
- virtual bool KeyboardNavigate (int keyCode, int flags)

  Helper function implementing keyboard navigation.
- virtual void PaintBackground (wxDC &dc)

  Paints the background.
- virtual void PaintAboveContent (wxDC &WXUNUSED(dc))

  Other user defined painting after everything else (i.e. all text) is painted.
- virtual void DoWriteText (const wxString &value, int flags=0)
- virtual bool ShouldInheritColours () const

  Return true from here to allow the colours of this window to be changed by InheritAttributes().
- virtual void PositionCaret (wxRichTextParagraphLayoutBox *container=NULL)

  Internal function to position the visible caret according to the current caret position.
- virtual bool ExtendSelection (long oldPosition, long newPosition, int flags)

  Helper function for extending the selection, returning true if the selection was changed.
- virtual bool ExtendCellSelection (wxRichTextTable *table, int noRowSteps, int noColSteps)

  Extends a table selection in the given direction.
- virtual bool StartCellSelection (wxRichTextTable *table, wxRichTextParagraphLayoutBox *newCell)

  Starts selecting table cells.
- virtual bool ScrollIntoView (long position, int keyCode)

  Scrolls position into view.
- bool RefreshForSelectionChange (const wxRichTextSelection &oldSelection, const wxRichTextSelection &newSelection)

  Refreshes the area affected by a selection change.
- void SetCaretPosition (long position, bool showAtLineStart=false)

  Sets the caret position.
- long GetCaretPosition () const

  Returns the current caret position.
- long GetAdjustedCaretPosition (long caretPos) const

  The adjusted caret position is the character position adjusted to take into account whether we're at the start of a paragraph, in which case style information should be taken from the next position, not current one.
- void MoveCaretForward (long oldPosition)

  Move the caret one visual step forward: this may mean setting a flag and keeping the same position if we're going from the end of one line to the start of the next, which may be the exact same caret position.
- void MoveCaretBack (long oldPosition)

  Move the caret one visual step forward: this may mean setting a flag and keeping the same position if we're going from the end of one line to the start of the next, which may be the exact same caret position.

- bool GetCaretPositionForIndex (long position, wxRect &rect, wxRichTextParagraphLayoutBox *container=NULL)

  Returns the caret height and position for the given character position.
- wxRichTextLine * GetVisibleLineForCaretPosition (long caretPosition) const

  Internal helper function returning the line for the visible caret position.
- wxCommandProcessor * GetCommandProcessor () const

  Gets the command processor associated with the control's buffer.
- bool DeleteSelectedContent (long *newPos=NULL)

  Deletes content if there is a selection, e.g.
- wxPoint GetPhysicalPoint (const wxPoint &ptLogical) const

  Transforms logical (unscrolled) position to physical window position.
- wxPoint GetLogicalPoint (const wxPoint &ptPhysical) const

  Transforms physical window position to logical (unscrolled) position.
- virtual long FindNextWordPosition (int direction=1) const

  Helper function for finding the caret position for the next word.
- bool IsPositionVisible (long pos) const

  Returns true if the given position is visible on the screen.
- long GetFirstVisiblePosition () const

  Returns the first visible position in the current view.
- void EnableImages (bool b)

  Enable or disable images.
- bool GetImagesEnabled () const

  Returns true if images are enabled.
- void EnableDelayedImageLoading (bool b)

  Enable or disable delayed image loading.
- bool GetDelayedImageLoading () const

  Returns true if delayed image loading is enabled.
- bool GetDelayedImageProcessingRequired () const

  Gets the flag indicating that delayed image processing is required.
- void SetDelayedImageProcessingRequired (bool b)

  Sets the flag indicating that delayed image processing is required.
- wxLongLong GetDelayedImageProcessingTime () const

  Returns the last time delayed image processing was performed.
- void SetDelayedImageProcessingTime (wxLongLong t)

  Sets the last time delayed image processing was performed.
- long GetCaretPositionForDefaultStyle () const

  Returns the caret position since the default formatting was changed.
- void SetCaretPositionForDefaultStyle (long pos)

  Set the caret position for the default style that the user is selecting.
- bool IsDefaultStyleShowing () const

  Returns true if the user has recently set the default style without moving the caret, and therefore the UI needs to reflect the default style and not the style at the caret.
- void SetAndShowDefaultStyle (const wxRichTextAttr &attr)

  Sets attr as the default style and tells the control that the UI should reflect this attribute until the user moves the caret.
- wxPoint GetFirstVisiblePoint () const

  Returns the first visible point in the window.
- virtual wxString GetValue () const

  Returns the content of the entire control as a string.
- virtual void SetValue (const wxString &value)

  Replaces existing content with the given text.
- virtual bool ProcessBackKey (wxKeyEvent &event, int flags)

Processes the back key.

- virtual wxRichTextRange FindRangeForList (long pos, bool &isNumberedList)

  Given a character position at which there is a list style, find the range encompassing the same list style by looking backwards and forwards.
- bool SetCaretPositionAfterClick (wxRichTextParagraphLayoutBox *container, long position, int hitTestFlags, bool extendSelection=false)

  Sets up the caret for the given position and container, after a mouse click.
- long FindCaretPositionForCharacterPosition (long position, int hitTestFlags, wxRichTextParagraphLayoutBox *container, bool &caretLineStart)

  Find the caret position for the combination of hit-test flags and character position.
- virtual bool ProcessMouseMovement (wxRichTextParagraphLayoutBox *container, wxRichTextObject *obj, long position, const wxPoint &pos)

  Processes mouse movement in order to change the cursor.
- virtual wxString DoGetValue () const
- bool ProcessDelayedImageLoading (bool refresh)

  Do delayed image loading and garbage-collect other images.
- bool ProcessDelayedImageLoading (const wxRect &screenRect, wxRichTextParagraphLayoutBox *box, int &loadCount)
- void RequestDelayedImageProcessing ()

  Request delayed image processing.
- void OnTimer (wxTimerEvent &event)

  Respond to timer events.

- virtual void GetSelection (long *from, long *to) const

  Returns the range of the current selection.
- const wxRichTextSelection & GetSelection () const

  Returns the range of the current selection.
- wxRichTextSelection & GetSelection ()

  Returns the range of the current selection.

- wxRichTextContextMenuPropertiesInfo & GetContextMenuPropertiesInfo ()

  Returns an object that stores information about context menu property item(s), in order to communicate between the context menu event handler and the code that responds to it.
- const wxRichTextContextMenuPropertiesInfo & GetContextMenuPropertiesInfo () const

  Returns an object that stores information about context menu property item(s), in order to communicate between the context menu event handler and the code that responds to it.

- virtual bool GetStyle (long position, wxTextAttr &style)

  Gets the attributes at the given position.
- virtual bool GetStyle (long position, wxRichTextAttr &style)

  Gets the attributes at the given position.
- virtual bool GetStyle (long position, wxRichTextAttr &style, wxRichTextParagraphLayoutBox *container)

  Gets the attributes at the given position.

- virtual bool SetStyle (long start, long end, const wxTextAttr &style)

  Sets the attributes for the given range.
- virtual bool SetStyle (long start, long end, const wxRichTextAttr &style)

  Sets the attributes for the given range.
- virtual bool SetStyle (const wxRichTextRange &range, const wxTextAttr &style)

  Sets the attributes for the given range.
- virtual bool SetStyle (const wxRichTextRange &range, const wxRichTextAttr &style)

Sets the attributes for the given range.

- virtual bool GetStyleForRange (const wxRichTextRange &range, wxTextAttr &style)

  Gets the attributes common to the specified range.
- virtual bool GetStyleForRange (const wxRichTextRange &range, wxRichTextAttr &style)

  Gets the attributes common to the specified range.
- virtual bool GetStyleForRange (const wxRichTextRange &range, wxRichTextAttr &style, wxRichTextParagraphLayoutBox *container)

  Gets the attributes common to the specified range.

- virtual bool GetUncombinedStyle (long position, wxRichTextAttr &style)

  Gets the attributes at the given position.
- virtual bool GetUncombinedStyle (long position, wxRichTextAttr &style, wxRichTextParagraphLayoutBox *container)

  Gets the attributes at the given position.

- virtual bool SetDefaultStyle (const wxTextAttr &style)

  Sets the current default style, which can be used to change how subsequently inserted text is displayed.
- virtual bool SetDefaultStyle (const wxRichTextAttr &style)

  Sets the current default style, which can be used to change how subsequently inserted text is displayed.

- virtual bool SetListStyle (const wxRichTextRange &range, wxRichTextListStyleDefinition *def, int flags=wxRICHTEXT_SETSTYLE_WITH_UNDO, int startFrom=1, int specifiedLevel=-1)

  Sets the list attributes for the given range, passing flags to determine how the attributes are set.
- virtual bool SetListStyle (const wxRichTextRange &range, const wxString &defName, int flags=wxRICHTEXT_SETSTYLE_WITH_UNDO, int startFrom=1, int specifiedLevel=-1)

  Sets the list attributes for the given range, passing flags to determine how the attributes are set.

- virtual bool NumberList (const wxRichTextRange &range, wxRichTextListStyleDefinition *def=NULL, int flags=wxRICHTEXT_SETSTYLE_WITH_UNDO, int startFrom=1, int specifiedLevel=-1)

  Numbers the paragraphs in the given range.
- virtual bool NumberList (const wxRichTextRange &range, const wxString &defName, int flags=wxRICHTEXT_SETSTYLE_WITH_UNDO, int startFrom=1, int specifiedLevel=-1)

  Numbers the paragraphs in the given range.

- virtual bool PromoteList (int promoteBy, const wxRichTextRange &range, wxRichTextListStyleDefinition *def=NULL, int flags=wxRICHTEXT_SETSTYLE_WITH_UNDO, int specifiedLevel=-1)

  Promotes or demotes the paragraphs in the given range.
- virtual bool PromoteList (int promoteBy, const wxRichTextRange &range, const wxString &defName, int flags=wxRICHTEXT_SETSTYLE_WITH_UNDO, int specifiedLevel=-1)

  Promotes or demotes the paragraphs in the given range.

- virtual wxTextCtrlHitTestResult HitTest (const wxPoint &pt, long *pos) const

  Finds the character at the given position in pixels.
- virtual wxTextCtrlHitTestResult HitTest (const wxPoint &pt, wxTextCoord *col, wxTextCoord *row) const

  Finds the character at the given position in pixels.
- wxRichTextParagraphLayoutBox * FindContainerAtPoint (const wxPoint pt, long &position, int &hit, wxRichTextObject *hitObj, int flags=0)

  Finds the container at the given point, which is assumed to be in client coordinates.

- virtual void SetSelection (long from, long to)

  Sets the selection to the given range.

- void SetSelection (const wxRichTextSelection &sel)

  Sets the selection to the given range.

- virtual bool WriteImage (const wxImage &image, wxBitmapType bitmapType=wxBITMAP_TYPE_PNG, const wxRichTextAttr &textAttr=wxRichTextAttr())

  Write a bitmap or image at the current insertion point.
- virtual bool WriteImage (const wxBitmap &bitmap, wxBitmapType bitmapType=wxBITMAP_TYPE_PNG, const wxRichTextAttr &textAttr=wxRichTextAttr())

  Write a bitmap or image at the current insertion point.

- wxRichTextBuffer & GetBuffer ()

  Returns the buffer associated with the control.
- const wxRichTextBuffer & GetBuffer () const

  Returns the buffer associated with the control.

Static Public Member Functions

- static const wxArrayString & GetAvailableFontNames ()

  Font names take a long time to retrieve, so cache them (on demand).
- static void ClearAvailableFontNames ()

  Clears the cache of available font names.

Protected Member Functions

- virtual wxWindow * GetEditableWindow ()
- virtual bool DoSetMargins (const wxPoint &pt)
- virtual wxPoint DoGetMargins () const
- virtual wxSize DoGetBestSize () const

  Currently this simply returns `wxSize(10, 10)`.
- virtual void DoSetValue (const wxString &value, int flags=0)
- virtual void DoThaw ()

Protected Attributes

- wxRichTextBuffer m_buffer

  Text buffer.
- wxMenu * m_contextMenu
- long m_caretPosition

  Caret position (1 less than the character position, so -1 is the first caret position).
- long m_caretPositionForDefaultStyle

  Caret position when the default formatting has been changed.
- wxRichTextSelection m_selection

  Selection range in character positions. -2, -2 means no selection.
- wxRichTextCtrlSelectionState m_selectionState
- long m_selectionAnchor

  Anchor so we know how to extend the selection It's a caret position since it's between two characters.
- wxRichTextObject * m_selectionAnchorObject

  Anchor object if selecting multiple container objects, such as grid cells.
- bool m_editable

  Are we editable?
- bool m_caretAtLineStart

Are we showing the caret position at the start of a line instead of at the end of the previous one?

- bool m_dragging

  Are we dragging a selection?
- bool m_fullLayoutRequired

  Do we need full layout in idle?
- wxLongLong m_fullLayoutTime
- long m_fullLayoutSavedPosition
- long m_delayedLayoutThreshold

  Threshold for doing delayed layout.
- wxCursor m_textCursor

  Cursors.
- wxCursor m_urlCursor
- wxRichTextContextMenuPropertiesInfo m_contextMenuPropertiesInfo
- wxRichTextParagraphLayoutBox * m_focusObject

  The object that currently has the editing focus.
- double m_scale

  An overall scale factor.
- wxSize m_lastWindowSize

  Variables for scrollbar hysteresis detection.
- int m_setupScrollbarsCount
- int m_setupScrollbarsCountInOnSize
- bool m_enableImages

  Whether images are enabled for this control.
- bool m_enableDelayedImageLoading

  Whether delayed image loading is enabled for this control.
- bool m_delayedImageProcessingRequired
- wxLongLong m_delayedImageProcessingTime
- wxTimer m_delayedImageProcessingTimer

Static Protected Attributes

- static wxArrayString sm_availableFontNames

21.617.2 Constructor & Destructor Documentation

wxRichTextCtrl::wxRichTextCtrl ( )

Default constructor.

wxRichTextCtrl::wxRichTextCtrl (wxWindow * *parent*, wxWindowID *id* = -1, const wxString & *value* = wxEmptyString, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, long *style* = wxRE_MULTILINE, const wxValidator & *validator* = wxDefaultValidator, const wxString & *name* = wxTextCtrlNameStr)

Constructor, creating and showing a rich text control.

Parameters

parent	Parent window. Must not be NULL.
id	Window identifier. The value wxID_ANY indicates a default value.

value	Default string.
pos	Window position.
size	Window size.
style	Window style.
validator	Window validator.
name	Window name.

See also

Create(), wxValidator

virtual wxRichTextCtrl::~wxRichTextCtrl ( ) [virtual]

Destructor.

21.617.3 Member Function Documentation

virtual wxRichTextRange wxRichTextCtrl::AddImage (const wxImage & *image*) [virtual]

Adds an image to the control's buffer.

virtual wxRichTextRange wxRichTextCtrl::AddParagraph (const wxString & *text*) [virtual]

Adds a new paragraph of text to the end of the buffer.

virtual void wxRichTextCtrl::AppendText (const wxString & *text*) [virtual]

Sets the insertion point to the end of the buffer and writes the text.

virtual bool wxRichTextCtrl::ApplyAlignmentToSelection (wxTextAttrAlignment *alignment*) [virtual]

Applies the given alignment to the selection or the default style (undoable).

For alignment values, see wxTextAttr.

virtual bool wxRichTextCtrl::ApplyBoldToSelection ( ) [virtual]

Apples bold to the selection or the default style (undoable).

virtual bool wxRichTextCtrl::ApplyItalicToSelection ( ) [virtual]

Applies italic to the selection or the default style (undoable).

virtual bool wxRichTextCtrl::ApplyStyle (wxRichTextStyleDefinition * *def*) [virtual]

Applies the style sheet to the buffer, matching paragraph styles in the sheet against named styles in the buffer.

This might be useful if the styles have changed. If *sheet* is NULL, the sheet set with SetStyleSheet() is used. Currently this applies paragraph styles only.

bool wxRichTextCtrl::ApplyStyleSheet (wxRichTextStyleSheet * *styleSheet* = NULL)

Applies the style sheet to the buffer, for example if the styles have changed.

virtual bool wxRichTextCtrl::ApplyTextEffectToSelection (int *flags*) [virtual]

Applies one or more wxTextAttrEffects flags to the selection (undoable).

If there is no selection, it is applied to the default style.

virtual bool wxRichTextCtrl::ApplyUnderlineToSelection ( ) [virtual]

Applies underline to the selection or the default style (undoable).

virtual bool wxRichTextCtrl::BatchingUndo ( ) const [virtual]

Returns true if undo commands are being batched.

bool wxRichTextCtrl::BeginAlignment (wxTextAttrAlignment *alignment*)

Begins using alignment.

For alignment values, see wxTextAttr.

virtual bool wxRichTextCtrl::BeginBatchUndo (const wxString & *cmdName*) [virtual]

Starts batching undo history for commands.

bool wxRichTextCtrl::BeginBold ( )

Begins using bold.

bool wxRichTextCtrl::BeginCharacterStyle (const wxString & *characterStyle*)

Begins using the named character style.

bool wxRichTextCtrl::BeginFont (const wxFont & *font*)

Begins using this font.

bool wxRichTextCtrl::BeginFontSize (int *pointSize*)

Begins using the given point size.

bool wxRichTextCtrl::BeginItalic ( )

Begins using italic.

bool wxRichTextCtrl::BeginLeftIndent (int *leftIndent,* int *leftSubIndent* = 0)

Begins applying a left indent and subindent in tenths of a millimetre.

The subindent is an offset from the left edge of the paragraph, and is used for all but the first line in a paragraph. A positive value will cause the first line to appear to the left of the subsequent lines, and a negative value will cause the first line to be indented to the right of the subsequent lines.

wxRichTextBuffer uses indentation to render a bulleted item. The content of the paragraph, including the first line, starts at the *leftIndent* plus the *leftSubIndent*.

Parameters

leftIndent	The distance between the margin and the bullet.
leftSubIndent	The distance between the left edge of the bullet and the left edge of the actual paragraph.

bool wxRichTextCtrl::BeginLineSpacing (int *lineSpacing*)

Begins appling line spacing.

spacing is a multiple, where 10 means single-spacing, 15 means 1.5 spacing, and 20 means double spacing.

The wxTextAttrLineSpacing constants are defined for convenience.

bool wxRichTextCtrl::BeginListStyle (const wxString & *listStyle,* int *level* = 1, int *number* = 1)

Begins using a specified list style.

Optionally, you can also pass a level and a number.

bool wxRichTextCtrl::BeginNumberedBullet (int *bulletNumber,* int *leftIndent,* int *leftSubIndent,* int *bulletStyle* = wxTEXT_ATTR_BULLET_STYLE_ARABIC|wxTEXT_ATTR_BULLET_STYLE_PERIOD)

Begins a numbered bullet.

This call will be needed for each item in the list, and the application should take care of incrementing the numbering.

bulletNumber is a number, usually starting with 1. *leftIndent* and *leftSubIndent* are values in tenths of a millimetre. *bulletStyle* is a bitlist of the wxTextAttrBulletStyle values.

wxRichTextBuffer uses indentation to render a bulleted item. The left indent is the distance between the margin and the bullet. The content of the paragraph, including the first line, starts at leftMargin + leftSubIndent. So the distance between the left edge of the bullet and the left of the actual paragraph is leftSubIndent.

bool wxRichTextCtrl::BeginParagraphSpacing (int *before,* int *after*)

Begins paragraph spacing; pass the before-paragraph and after-paragraph spacing in tenths of a millimetre.

bool wxRichTextCtrl::BeginParagraphStyle (const wxString & *paragraphStyle*)

Begins applying the named paragraph style.

bool wxRichTextCtrl::BeginRightIndent (int *rightIndent*)

Begins a right indent, specified in tenths of a millimetre.

bool wxRichTextCtrl::BeginStandardBullet (const wxString & *bulletName,* int *leftIndent,* int *leftSubIndent,* int *bulletStyle =* wxTEXT_ATTR_BULLET_STYLE_STANDARD)

Begins applying a symbol bullet.

virtual bool wxRichTextCtrl::BeginStyle (const wxRichTextAttr & *style*) `[virtual]`

Begins applying a style.

virtual bool wxRichTextCtrl::BeginSuppressUndo ( ) `[virtual]`

Starts suppressing undo history for commands.

bool wxRichTextCtrl::BeginSymbolBullet (const wxString & *symbol,* int *leftIndent,* int *leftSubIndent,* int *bulletStyle =* wxTEXT_ATTR_BULLET_STYLE_SYMBOL)

Begins applying a symbol bullet, using a character from the current font.

See BeginNumberedBullet() for an explanation of how indentation is used to render the bulleted paragraph.

bool wxRichTextCtrl::BeginTextColour (const wxColour & *colour*)

Begins using this colour.

bool wxRichTextCtrl::BeginUnderline ( )

Begins using underlining.

bool wxRichTextCtrl::BeginURL (const wxString & *url,* const wxString & *characterStyle =* wxEmptyString)

Begins applying wxTEXT_ATTR_URL to the content.

Pass a URL and optionally, a character style to apply, since it is common to mark a URL with a familiar style such as blue text with underlining.

virtual bool wxRichTextCtrl::CanCopy ( ) const `[virtual]`

Returns true if selected content can be copied to the clipboard.

virtual bool wxRichTextCtrl::CanCut ( ) const `[virtual]`

Returns true if selected content can be copied to the clipboard and deleted.

virtual bool wxRichTextCtrl::CanDeleteRange (wxRichTextParagraphLayoutBox & *container,* const wxRichTextRange & *range*) const `[virtual]`

Can we delete this range? Sends an event to the control.

virtual bool wxRichTextCtrl::CanDeleteSelection ( ) const `[virtual]`

Returns true if selected content can be deleted.

virtual bool wxRichTextCtrl::CanEditProperties (wxRichTextObject * *obj*) const [virtual]

Returns true if we can edit the object's properties via a GUI.

virtual bool wxRichTextCtrl::CanInsertContent (wxRichTextParagraphLayoutBox & *container,* long *pos*) const [virtual]

Can we insert content at this position? Sends an event to the control.

virtual bool wxRichTextCtrl::CanPaste ( ) const [virtual]

Returns true if the clipboard content can be pasted to the buffer.

virtual bool wxRichTextCtrl::CanRedo ( ) const [virtual]

Returns true if there is a command in the command history that can be redone.

virtual bool wxRichTextCtrl::CanUndo ( ) const [virtual]

Returns true if there is a command in the command history that can be undone.

virtual void wxRichTextCtrl::Clear ( ) [virtual]

Clears the buffer content, leaving a single empty paragraph.

Cannot be undone.

static void wxRichTextCtrl::ClearAvailableFontNames ( ) [static]

Clears the cache of available font names.

virtual bool wxRichTextCtrl::ClearListStyle (const wxRichTextRange & *range,* int *flags* = wxRICHTEXT_SETSTYLE_WITH_UNDO) [virtual]

Clears the list style from the given range, clearing list-related attributes and applying any named paragraph style associated with each paragraph.

flags is a bit list of the following:

- wxRICHTEXT_SETSTYLE_WITH_UNDO: specifies that this command will be undoable.

See also

SetListStyle(), PromoteList(), NumberList().

void wxRichTextCtrl::Command (wxCommandEvent & *event*) [virtual]

Sends the event to the control.

Reimplemented from wxControl.

virtual void wxRichTextCtrl::Copy ( ) [virtual]

Copies the selected content (if any) to the clipboard.

bool wxRichTextCtrl::Create (wxWindow * *parent*, wxWindowID *id* = -1, const wxString & *value* = wxEmptyString, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, long *style* = wxRE_MULTILINE, const wxValidator & *validator* = wxDefaultValidator, const wxString & *name* = wxTextCtrlNameStr)

Creates the underlying window.

virtual void wxRichTextCtrl::Cut ( ) [virtual]

Copies the selected content (if any) to the clipboard and deletes the selection.

This is undoable.

virtual bool wxRichTextCtrl::Delete (const wxRichTextRange & *range*) [virtual]

Deletes the content within the given range.

bool wxRichTextCtrl::DeleteSelectedContent (long * *newPos* = NULL)

Deletes content if there is a selection, e.g.

when pressing a key. Returns the new caret position in *newPos*, or leaves it if there was no action. This is undoable.

wxPerl Note: In wxPerl this method takes no arguments and returns a 2-element list (ok, newPos).

virtual void wxRichTextCtrl::DeleteSelection ( ) [virtual]

Deletes the content in the selection, if any.

This is undoable.

virtual void wxRichTextCtrl::DiscardEdits ( ) [virtual]

Sets the buffer's modified status to false, and clears the buffer's command history.

virtual bool wxRichTextCtrl::DoesSelectionHaveTextEffectFlag (int *flag*) [virtual]

Returns true if all of the selection, or the content at the current caret position, has the supplied wxTextAttrEffects flag(s).

virtual wxSize wxRichTextCtrl::DoGetBestSize ( ) const [protected], [virtual]

Currently this simply returns `wxSize(10, 10)`.

Reimplemented from wxWindow.

virtual wxPoint wxRichTextCtrl::DoGetMargins ( ) const [protected], [virtual]

virtual wxString wxRichTextCtrl::DoGetValue ( ) const [virtual]

virtual void wxRichTextCtrl::DoLayoutBuffer (**wxRichTextBuffer** & *buffer,* **wxDC** & *dc,* **wxRichTextDrawingContext** & *context,* const **wxRect** & *rect,* const **wxRect** & *parentRect,* int *flags*) [virtual]

Implements layout.

An application may override this to perform operations before or after layout.

virtual bool wxRichTextCtrl::DoLoadFile (const **wxString** & *file,* int *fileType*) [virtual]

Helper function for LoadFile().

Loads content into the control's buffer using the given type.

If the specified type is wxRICHTEXT_TYPE_ANY, the type is deduced from the filename extension.

This function looks for a suitable wxRichTextFileHandler object.

virtual bool wxRichTextCtrl::DoSaveFile (const **wxString** & *file* = **wxEmptyString,** int *fileType* = **wxRICHTEXT_TYPE_ANY**) [virtual]

Helper function for SaveFile().

Saves the buffer content using the given type.

If the specified type is wxRICHTEXT_TYPE_ANY, the type is deduced from the filename extension.

This function looks for a suitable wxRichTextFileHandler object.

virtual bool wxRichTextCtrl::DoSetMargins (const **wxPoint** & *pt*) [protected], [virtual]

virtual void wxRichTextCtrl::DoSetValue (const **wxString** & *value,* int *flags* = 0) [protected], [virtual]

virtual void wxRichTextCtrl::DoThaw ( ) [protected], [virtual]

virtual void wxRichTextCtrl::DoWriteText (const **wxString** & *value,* int *flags* = 0) [virtual]

virtual bool wxRichTextCtrl::EditProperties (**wxRichTextObject** * *obj,* **wxWindow** * *parent*) [virtual]

Edits the object's properties via a GUI.

void wxRichTextCtrl::EnableDelayedImageLoading (bool *b*) [inline]

Enable or disable delayed image loading.

void wxRichTextCtrl::EnableImages (bool *b*)

Enable or disable images.

virtual void wxRichTextCtrl::EnableVerticalScrollbar (bool *enable*) [virtual]

Enable or disable the vertical scrollbar.

void wxRichTextCtrl::EnableVirtualAttributes (bool *b*)

Pass true to let the control use virtual attributes.

The default is false.

bool wxRichTextCtrl::EndAlignment ( )

Ends alignment.

virtual bool wxRichTextCtrl::EndAllStyles ( ) [virtual]

Ends application of all styles in the current style stack.

virtual bool wxRichTextCtrl::EndBatchUndo ( ) [virtual]

Ends batching undo command history.

bool wxRichTextCtrl::EndBold ( )

Ends using bold.

bool wxRichTextCtrl::EndCharacterStyle ( )

Ends application of a named character style.

bool wxRichTextCtrl::EndFont ( )

Ends using a font.

bool wxRichTextCtrl::EndFontSize ( )

Ends using a point size.

bool wxRichTextCtrl::EndItalic ( )

Ends using italic.

bool wxRichTextCtrl::EndLeftIndent ( )

Ends left indent.

bool wxRichTextCtrl::EndLineSpacing ( )

Ends line spacing.

bool wxRichTextCtrl::EndListStyle ( )

Ends using a specified list style.

bool wxRichTextCtrl::EndNumberedBullet ( )

Ends application of a numbered bullet.

bool wxRichTextCtrl::EndParagraphSpacing ( )

Ends paragraph spacing.

bool wxRichTextCtrl::EndParagraphStyle ( )

Ends application of a named paragraph style.

bool wxRichTextCtrl::EndRightIndent ( )

Ends right indent.

bool wxRichTextCtrl::EndStandardBullet ( )

Begins applying a standard bullet.

virtual bool wxRichTextCtrl::EndStyle ( ) `[virtual]`

Ends the current style.

virtual bool wxRichTextCtrl::EndSuppressUndo ( ) `[virtual]`

Ends suppressing undo command history.

bool wxRichTextCtrl::EndSymbolBullet ( )

Ends applying a symbol bullet.

bool wxRichTextCtrl::EndTextColour ( )

Ends applying a text colour.

bool wxRichTextCtrl::EndUnderline ( )

End applying underlining.

bool wxRichTextCtrl::EndURL ( )

Ends applying a URL.

virtual bool wxRichTextCtrl::ExtendCellSelection (wxRichTextTable * *table,* int *noRowSteps,* int *noColSteps*) `[virtual]`

Extends a table selection in the given direction.

virtual bool wxRichTextCtrl::ExtendSelection (long *oldPosition,* long *newPosition,* int *flags*) `[virtual]`

Helper function for extending the selection, returning true if the selection was changed.

Selections are in caret positions.

long wxRichTextCtrl::FindCaretPositionForCharacterPosition (long *position,* int *hitTestFlags,* wxRichTextParagraphLayoutBox * *container,* bool & *caretLineStart*)

Find the caret position for the combination of hit-test flags and character position.

Returns the caret position and also an indication of where to place the caret (caretLineStart) since this is ambiguous (same position used for end of line and start of next).

wxRichTextParagraphLayoutBox* wxRichTextCtrl::FindContainerAtPoint (const wxPoint *pt,* long & *position,* int & *hit,* wxRichTextObject * *hitObj,* int *flags* = 0)

Finds the container at the given point, which is assumed to be in client coordinates.

virtual long wxRichTextCtrl::FindNextWordPosition (int *direction* = 1) const [virtual]

Helper function for finding the caret position for the next word.

Direction is 1 (forward) or -1 (backwards).

virtual wxRichTextRange wxRichTextCtrl::FindRangeForList (long *pos,* bool & *isNumberedList*) [virtual]

Given a character position at which there is a list style, find the range encompassing the same list style by looking backwards and forwards.

void wxRichTextCtrl::ForceDelayedLayout ( )

long wxRichTextCtrl::GetAdjustedCaretPosition (long *caretPos*) const

The adjusted caret position is the character position adjusted to take into account whether we're at the start of a paragraph, in which case style information should be taken from the next position, not current one.

static const wxArrayString& wxRichTextCtrl::GetAvailableFontNames ( ) [static]

Font names take a long time to retrieve, so cache them (on demand).

virtual const wxRichTextAttr& wxRichTextCtrl::GetBasicStyle ( ) const [virtual]

Gets the basic (overall) style.

This is the style of the whole buffer before further styles are applied, unlike the default style, which only affects the style currently being applied (for example, setting the default style to bold will cause subsequently inserted text to be bold).

wxRichTextBuffer& wxRichTextCtrl::GetBuffer ( )

Returns the buffer associated with the control.

const wxRichTextBuffer& wxRichTextCtrl::GetBuffer ( ) const

Returns the buffer associated with the control.

bool wxRichTextCtrl::GetCaretAtLineStart ( ) const

Returns true if we are showing the caret position at the start of a line instead of at the end of the previous one.

long wxRichTextCtrl::GetCaretPosition ( ) const

Returns the current caret position.

long wxRichTextCtrl::GetCaretPositionForDefaultStyle ( ) const

Returns the caret position since the default formatting was changed.

As soon as this position changes, we no longer reflect the default style in the UI. A value of -2 means that we should only reflect the style of the content under the caret.

bool wxRichTextCtrl::GetCaretPositionForIndex (long *position,* wxRect & *rect,* wxRichTextParagraphLayoutBox * *container* = NULL)

Returns the caret height and position for the given character position.

If container is null, the current focus object will be used.

wxPerl Note: In wxPerl this method is implemented as GetCaretPositionForIndex(*position*) returning a 2-element list (ok, rect).

wxCommandProcessor* wxRichTextCtrl::GetCommandProcessor ( ) const

Gets the command processor associated with the control's buffer.

wxMenu* wxRichTextCtrl::GetContextMenu ( ) const

Returns the current context menu.

wxRichTextContextMenuPropertiesInfo& wxRichTextCtrl::GetContextMenuPropertiesInfo ( )

Returns an object that stores information about context menu property item(s), in order to communicate between the context menu event handler and the code that responds to it.

The wxRichTextContextMenuPropertiesInfo stores one item for each object that could respond to a property-editing event. If objects are nested, several might be editable.

const wxRichTextContextMenuPropertiesInfo& wxRichTextCtrl::GetContextMenuPropertiesInfo ( ) const

Returns an object that stores information about context menu property item(s), in order to communicate between the context menu event handler and the code that responds to it.

The wxRichTextContextMenuPropertiesInfo stores one item for each object that could respond to a property-editing event. If objects are nested, several might be editable.

virtual const wxRichTextAttr& wxRichTextCtrl::GetDefaultStyleEx ( ) const `[virtual]`

Returns the current default style, which can be used to change how subsequently inserted text is displayed.

bool wxRichTextCtrl::GetDelayedImageLoading ( ) const `[inline]`

Returns true if delayed image loading is enabled.

bool wxRichTextCtrl::GetDelayedImageProcessingRequired ( ) const `[inline]`

Gets the flag indicating that delayed image processing is required.

wxLongLong wxRichTextCtrl::GetDelayedImageProcessingTime ( ) const `[inline]`

Returns the last time delayed image processing was performed.

long wxRichTextCtrl::GetDelayedLayoutThreshold ( ) const

Gets the size of the buffer beyond which layout is delayed during resizing.
This optimizes sizing for large buffers. The default is 20000.

double wxRichTextCtrl::GetDimensionScale ( ) const `[inline]`

Returns the scale factor for displaying certain dimensions such as indentation and inter-paragraph spacing.

bool wxRichTextCtrl::GetDragging ( ) const

Returns true if we are extending a selection.

const wxPoint wxRichTextCtrl::GetDragStartPoint ( ) const

Get the possible Drag'n'Drop start point.

const wxDateTime wxRichTextCtrl::GetDragStartTime ( ) const

Get the possible Drag'n'Drop start time.

virtual wxWindow* wxRichTextCtrl::GetEditableWindow ( ) `[protected], [virtual]`

wxString wxRichTextCtrl::GetFilename ( ) const

Gets the current filename associated with the control.

wxPoint wxRichTextCtrl::GetFirstVisiblePoint ( ) const

Returns the first visible point in the window.

long wxRichTextCtrl::GetFirstVisiblePosition ( ) const

Returns the first visible position in the current view.

wxRichTextParagraphLayoutBox* wxRichTextCtrl::GetFocusObject ( ) const

Returns the wxRichTextObject object that currently has the editing focus.

If there are no composite objects, this will be the top-level buffer.

double wxRichTextCtrl::GetFontScale ( ) const `[inline]`

Returns the scale factor for displaying fonts, for example for more comfortable editing.

bool wxRichTextCtrl::GetFullLayoutRequired ( ) const

long wxRichTextCtrl::GetFullLayoutSavedPosition ( ) const

wxLongLong wxRichTextCtrl::GetFullLayoutTime ( ) const

int wxRichTextCtrl::GetHandlerFlags ( ) const

Returns flags that change the behaviour of loading or saving.

See the documentation for each handler class to see what flags are relevant for each handler.

bool wxRichTextCtrl::GetImagesEnabled ( ) const

Returns true if images are enabled.

virtual long wxRichTextCtrl::GetInsertionPoint ( ) const `[virtual]`

Returns the current insertion point.

wxRichTextRange wxRichTextCtrl::GetInternalSelectionRange ( ) const

Returns the selection range in character positions.

-2, -2 means no selection -1, -1 means select everything. The range is in internal format, i.e. a single character selection is denoted by (n, n)

virtual wxTextPos wxRichTextCtrl::GetLastPosition ( ) const `[virtual]`

Returns the last position in the buffer.

virtual int wxRichTextCtrl::GetLineLength (long *lineNo*) const `[virtual]`

Returns the length of the specified line in characters.

virtual wxString wxRichTextCtrl::GetLineText (long *lineNo*) const `[virtual]`

Returns the text for the given line.

wxPoint wxRichTextCtrl::GetLogicalPoint (const wxPoint & *ptPhysical*) const

Transforms physical window position to logical (unscrolled) position.

virtual int wxRichTextCtrl::GetNumberOfLines ( ) const [virtual]

Returns the number of lines in the buffer.

wxPoint wxRichTextCtrl::GetPhysicalPoint (const wxPoint & *ptLogical*) const

Transforms logical (unscrolled) position to physical window position.

bool wxRichTextCtrl::GetPreDrag ( ) const

Are we trying to start Drag'n'Drop?

virtual wxString wxRichTextCtrl::GetPropertiesMenuLabel (wxRichTextObject * *obj*) [virtual]

Gets the object's properties menu label.

virtual wxString wxRichTextCtrl::GetRange (long *from,* long *to*) const [virtual]

Gets the text for the given range.

The end point of range is specified as the last character position of the span of text, plus one.

double wxRichTextCtrl::GetScale ( ) const

Returns an overall scale factor for displaying and editing the content.

wxPoint wxRichTextCtrl::GetScaledPoint (const wxPoint & *pt*) const

Returns a scaled point.

wxRect wxRichTextCtrl::GetScaledRect (const wxRect & *rect*) const

Returns a scaled rectangle.

wxSize wxRichTextCtrl::GetScaledSize (const wxSize & *sz*) const

Returns a scaled size.

virtual void wxRichTextCtrl::GetSelection (long * *from,* long * *to*) const [virtual]

Returns the range of the current selection.

The end point of range is specified as the last character position of the span of text, plus one. If the return values *from* and *to* are the same, there is no selection.

const wxRichTextSelection& wxRichTextCtrl::GetSelection ( ) const

Returns the range of the current selection.

The end point of range is specified as the last character position of the span of text, plus one. If the return values *from* and *to* are the same, there is no selection.

wxRichTextSelection& wxRichTextCtrl::GetSelection ( )

Returns the range of the current selection.

The end point of range is specified as the last character position of the span of text, plus one. If the return values *from* and *to* are the same, there is no selection.

long wxRichTextCtrl::GetSelectionAnchor ( ) const

Returns an anchor so we know how to extend the selection.

It's a caret position since it's between two characters.

wxRichTextObject* wxRichTextCtrl::GetSelectionAnchorObject ( ) const

Returns the anchor object if selecting multiple containers.

wxRichTextRange wxRichTextCtrl::GetSelectionRange ( ) const

Returns the selection range in character positions.

-1, -1 means no selection.

The range is in API convention, i.e. a single character selection is denoted by (n, n+1)

virtual wxString wxRichTextCtrl::GetStringSelection ( ) const `[virtual]`

Returns the text within the current selection range, if any.

virtual bool wxRichTextCtrl::GetStyle (long *position,* wxTextAttr & *style*) `[virtual]`

Gets the attributes at the given position.

This function gets the combined style - that is, the style you see on the screen as a result of combining base style, paragraph style and character style attributes.

To get the character or paragraph style alone, use GetUncombinedStyle().

wxPerl Note: In wxPerl this method is implemented as GetStyle(*position*) returning a 2-element list (ok, attr).

virtual bool wxRichTextCtrl::GetStyle (long *position,* wxRichTextAttr & *style*) `[virtual]`

Gets the attributes at the given position.

This function gets the combined style - that is, the style you see on the screen as a result of combining base style, paragraph style and character style attributes.

To get the character or paragraph style alone, use GetUncombinedStyle().

wxPerl Note: In wxPerl this method is implemented as GetStyle(*position*) returning a 2-element list (ok, attr).

virtual bool wxRichTextCtrl::GetStyle (long *position,* wxRichTextAttr & *style,* wxRichTextParagraphLayoutBox * *container*) `[virtual]`

Gets the attributes at the given position.

This function gets the combined style - that is, the style you see on the screen as a result of combining base style, paragraph style and character style attributes.

To get the character or paragraph style alone, use GetUncombinedStyle().

wxPerl Note: In wxPerl this method is implemented as GetStyle(*position*) returning a 2-element list (ok, attr).

virtual bool wxRichTextCtrl::GetStyleForRange (const wxRichTextRange & *range,* wxTextAttr & *style*) `[virtual]`

Gets the attributes common to the specified range.

Attributes that differ in value within the range will not be included in *style* flags.

wxPerl Note: In wxPerl this method is implemented as GetStyleForRange(*position*) returning a 2-element list (ok, attr).

virtual bool wxRichTextCtrl::GetStyleForRange (const wxRichTextRange & *range,* wxRichTextAttr & *style*) `[virtual]`

Gets the attributes common to the specified range.

Attributes that differ in value within the range will not be included in *style* flags.

wxPerl Note: In wxPerl this method is implemented as GetStyleForRange(*position*) returning a 2-element list (ok, attr).

virtual bool wxRichTextCtrl::GetStyleForRange (const wxRichTextRange & *range,* wxRichTextAttr & *style,* wxRichTextParagraphLayoutBox * *container*) `[virtual]`

Gets the attributes common to the specified range.

Attributes that differ in value within the range will not be included in *style* flags.

wxPerl Note: In wxPerl this method is implemented as GetStyleForRange(*position*) returning a 2-element list (ok, attr).

wxRichTextStyleSheet* wxRichTextCtrl::GetStyleSheet ( ) const

Returns the style sheet associated with the control, if any.

A style sheet allows named character and paragraph styles to be applied.

wxCursor wxRichTextCtrl::GetTextCursor ( ) const

Returns the text (normal) cursor.

virtual bool wxRichTextCtrl::GetUncombinedStyle (long *position,* wxRichTextAttr & *style*) `[virtual]`

Gets the attributes at the given position.

This function gets the *uncombined* style - that is, the attributes associated with the paragraph or character content, and not necessarily the combined attributes you see on the screen. To get the combined attributes, use GetStyle().

If you specify (any) paragraph attribute in *style's* flags, this function will fetch the paragraph attributes. Otherwise, it will return the character attributes.

wxPerl Note: In wxPerl this method is implemented as GetUncombinedStyle(*position*) returning a 2-element list (ok, attr).

virtual bool wxRichTextCtrl::GetUncombinedStyle (long *position,* wxRichTextAttr & *style,* wxRichTextParagraphLayoutBox * *container*) [virtual]

Gets the attributes at the given position.

This function gets the *uncombined* style - that is, the attributes associated with the paragraph or character content, and not necessarily the combined attributes you see on the screen. To get the combined attributes, use GetStyle().

If you specify (any) paragraph attribute in *style's* flags, this function will fetch the paragraph attributes. Otherwise, it will return the character attributes.

wxPerl Note: In wxPerl this method is implemented as GetUncombinedStyle(*position*) returning a 2-element list (ok, attr).

wxPoint wxRichTextCtrl::GetUnscaledPoint (const wxPoint & *pt*) const

Returns an unscaled point.

wxRect wxRichTextCtrl::GetUnscaledRect (const wxRect & *rect*) const

Returns an unscaled rectangle.

wxSize wxRichTextCtrl::GetUnscaledSize (const wxSize & *sz*) const

Returns an unscaled size.

wxCursor wxRichTextCtrl::GetURLCursor ( ) const

Returns the cursor to be used over URLs.

virtual wxString wxRichTextCtrl::GetValue ( ) const [virtual]

Returns the content of the entire control as a string.

virtual bool wxRichTextCtrl::GetVerticalScrollbarEnabled ( ) const [virtual]

Returns true if the vertical scrollbar is enabled.

bool wxRichTextCtrl::GetVirtualAttributesEnabled ( ) const

Returns true if this control can use virtual attributes and virtual text.

The default is false.

wxRichTextLine* wxRichTextCtrl::GetVisibleLineForCaretPosition (long *caretPosition*) const

Internal helper function returning the line for the visible caret position.

If the caret is shown at the very end of the line, it means the next character is actually on the following line. So this function gets the line we're expecting to find if this is the case.

virtual bool wxRichTextCtrl::HasCharacterAttributes (const wxRichTextRange & *range,* const wxRichTextAttr & *style*) const [virtual]

Test if this whole range has character attributes of the specified kind.

If any of the attributes are different within the range, the test fails.

You can use this to implement, for example, bold button updating. *style* must have flags indicating which attributes are of interest.

virtual bool wxRichTextCtrl::HasParagraphAttributes (const wxRichTextRange & *range,* const wxRichTextAttr & *style*) const [virtual]

Test if this whole range has paragraph attributes of the specified kind.

If any of the attributes are different within the range, the test fails. You can use this to implement, for example, centering button updating. *style* must have flags indicating which attributes are of interest.

virtual bool wxRichTextCtrl::HasSelection ( ) const [virtual]

Returns true if there is a selection and the object containing the selection was the same as the current focus object.

virtual bool wxRichTextCtrl::HasUnfocusedSelection ( ) const [virtual]

Returns true if there was a selection, whether or not the current focus object is the same as the selection's container object.

virtual wxTextCtrlHitTestResult wxRichTextCtrl::HitTest (const wxPoint & *pt,* long * *pos*) const [virtual]

Finds the character at the given position in pixels.

pt is in device coords (not adjusted for the client area origin nor for scrolling).

virtual wxTextCtrlHitTestResult wxRichTextCtrl::HitTest (const wxPoint & *pt,* wxTextCoord * *col,* wxTextCoord * *row*) const [virtual]

Finds the character at the given position in pixels.

pt is in device coords (not adjusted for the client area origin nor for scrolling).

void wxRichTextCtrl::Init ( )

Initialises the members of the control.

void wxRichTextCtrl::Invalidate ( )

Invalidates the whole buffer to trigger painting later.

bool wxRichTextCtrl::IsDefaultStyleShowing ( ) const

Returns true if the user has recently set the default style without moving the caret, and therefore the UI needs to reflect the default style and not the style at the caret.

Below is an example of code that uses this function to determine whether the UI should show that the current style is bold.

See also

SetAndShowDefaultStyle().

virtual bool wxRichTextCtrl::IsEditable ( ) const `[virtual]`

Returns true if the control is editable.

virtual bool wxRichTextCtrl::IsModified ( ) const `[virtual]`

Returns true if the buffer has been modified.

bool wxRichTextCtrl::IsMultiLine ( ) const

Returns true if the control is multiline.

bool wxRichTextCtrl::IsPositionVisible (long *pos*) const

Returns true if the given position is visible on the screen.

virtual bool wxRichTextCtrl::IsSelectionAligned (wxTextAttrAlignment *alignment*) `[virtual]`

Returns true if all of the selection is aligned according to the specified flag.

virtual bool wxRichTextCtrl::IsSelectionBold ( ) `[virtual]`

Returns true if all of the selection, or the content at the caret position, is bold.

virtual bool wxRichTextCtrl::IsSelectionItalics ( ) `[virtual]`

Returns true if all of the selection, or the content at the caret position, is italic.

virtual bool wxRichTextCtrl::IsSelectionUnderlined ( ) `[virtual]`

Returns true if all of the selection, or the content at the caret position, is underlined.

bool wxRichTextCtrl::IsSingleLine ( ) const

Returns true if the control is single-line.

Currently wxRichTextCtrl does not support single-line editing.

virtual bool wxRichTextCtrl::KeyboardNavigate (int *keyCode,* int *flags*) `[virtual]`

Helper function implementing keyboard navigation.

virtual bool wxRichTextCtrl::LayoutContent (bool *onlyVisibleRect* = `false`) `[virtual]`

Lays out the buffer, which must be done before certain operations, such as setting the caret position.

This function should not normally be required by the application.

virtual bool wxRichTextCtrl::LineBreak ( ) [virtual]

Inserts a line break at the current insertion point.

A line break forces wrapping within a paragraph, and can be introduced by using this function, by appending the wxChar value **wxRichTextLineBreakChar** to text content, or by typing Shift-Return.

bool wxRichTextCtrl::LoadFile (const wxString & *file*, int *type* = wxRICHTEXT_TYPE_ANY)

Loads content into the control's buffer using the given type.

If the specified type is wxRICHTEXT_TYPE_ANY, the type is deduced from the filename extension.

This function looks for a suitable wxRichTextFileHandler object.

virtual void wxRichTextCtrl::MarkDirty ( ) [virtual]

Marks the buffer as modified.

virtual bool wxRichTextCtrl::MoveCaret (long *pos*, bool *showAtLineStart* = false, wxRichTextParagraphLayoutBox * *container* = NULL) [virtual]

Move the caret to the given character position.

Please note that this does not update the current editing style from the new position; to do that, call wxRichTextCtrl::SetInsertionPoint instead.

void wxRichTextCtrl::MoveCaretBack (long *oldPosition*)

Move the caret one visual step forward: this may mean setting a flag and keeping the same position if we're going from the end of one line to the start of the next, which may be the exact same caret position.

void wxRichTextCtrl::MoveCaretForward (long *oldPosition*)

Move the caret one visual step forward: this may mean setting a flag and keeping the same position if we're going from the end of one line to the start of the next, which may be the exact same caret position.

virtual bool wxRichTextCtrl::MoveDown (int *noLines* = 1, int *flags* = 0) [virtual]

Moves the caret down.

virtual bool wxRichTextCtrl::MoveEnd (int *flags* = 0) [virtual]

Moves to the end of the buffer.

virtual bool wxRichTextCtrl::MoveHome (int *flags* = 0) [virtual]

Moves to the start of the buffer.

virtual bool wxRichTextCtrl::MoveLeft (int *noPositions* = 1, int *flags* = 0) [virtual]

Moves left.

virtual bool wxRichTextCtrl::MoveRight (int *noPositions* = 1, int *flags* = 0) [virtual]

Moves right.

virtual bool wxRichTextCtrl::MoveToLineEnd (int *flags* = 0) [virtual]

Moves to the end of the line.

virtual bool wxRichTextCtrl::MoveToLineStart (int *flags* = 0) [virtual]

Moves to the start of the line.

virtual bool wxRichTextCtrl::MoveToParagraphEnd (int *flags* = 0) [virtual]

Moves to the end of the paragraph.

virtual bool wxRichTextCtrl::MoveToParagraphStart (int *flags* = 0) [virtual]

Moves to the start of the paragraph.

virtual bool wxRichTextCtrl::MoveUp (int *noLines* = 1, int *flags* = 0) [virtual]

Moves to the start of the paragraph.

virtual bool wxRichTextCtrl::Newline ( ) [virtual]

Inserts a new paragraph at the current insertion point.

See also

LineBreak().

virtual bool wxRichTextCtrl::NumberList (const wxRichTextRange & *range*, wxRichTextListStyleDefinition * *def* = NULL, int *flags* = wxRICHTEXT_SETSTYLE_WITH_UNDO, int *startFrom* = 1, int *specifiedLevel* = -1) [virtual]

Numbers the paragraphs in the given range.

Pass flags to determine how the attributes are set.

Either the style definition or the name of the style definition (in the current sheet) can be passed.

flags is a bit list of the following:

- wxRICHTEXT_SETSTYLE_WITH_UNDO: specifies that this command will be undoable.
- wxRICHTEXT_SETSTYLE_RENUMBER: specifies that numbering should start from *startFrom*, otherwise existing attributes are used.
- wxRICHTEXT_SETSTYLE_SPECIFY_LEVEL: specifies that *listLevel* should be used as the level for all paragraphs, otherwise the current indentation will be used.

See also

SetListStyle(), PromoteList(), ClearListStyle().

virtual bool wxRichTextCtrl::NumberList (const wxRichTextRange & *range*, const wxString & *defName*, int *flags* = wxRICHTEXT_SETSTYLE_WITH_UNDO, int *startFrom* = 1, int *specifiedLevel* = -1) [virtual]

Numbers the paragraphs in the given range.

Pass flags to determine how the attributes are set.

Either the style definition or the name of the style definition (in the current sheet) can be passed.

flags is a bit list of the following:

- wxRICHTEXT_SETSTYLE_WITH_UNDO: specifies that this command will be undoable.
- wxRICHTEXT_SETSTYLE_RENUMBER: specifies that numbering should start from *startFrom*, otherwise existing attributes are used.
- wxRICHTEXT_SETSTYLE_SPECIFY_LEVEL: specifies that *listLevel* should be used as the level for all paragraphs, otherwise the current indentation will be used.

See also

SetListStyle(), PromoteList(), ClearListStyle().

void wxRichTextCtrl::OnCaptureLost (wxMouseCaptureLostEvent & *event*)

void wxRichTextCtrl::OnChar (wxKeyEvent & *event*)

void wxRichTextCtrl::OnClear (wxCommandEvent & *event*)

Standard handler for the wxID_CLEAR command.

void wxRichTextCtrl::OnContextMenu (wxContextMenuEvent & *event*)

Shows a standard context menu with undo, redo, cut, copy, paste, clear, and select all commands.

void wxRichTextCtrl::OnCopy (wxCommandEvent & *event*)

Standard handler for the wxID_COPY command.

void wxRichTextCtrl::OnCut (wxCommandEvent & *event*)

Standard handler for the wxID_CUT command.

void wxRichTextCtrl::OnDropFiles (wxDropFilesEvent & *event*)

Loads the first dropped file.

void wxRichTextCtrl::OnEraseBackground (wxEraseEvent & *event*)

void wxRichTextCtrl::OnIdle (wxIdleEvent & *event*)

void wxRichTextCtrl::OnKillFocus (wxFocusEvent & *event*)

void wxRichTextCtrl::OnLeftClick (wxMouseEvent & *event*)

void wxRichTextCtrl::OnLeftDClick (wxMouseEvent & *event*)

void wxRichTextCtrl::OnLeftUp (wxMouseEvent & *event*)

void wxRichTextCtrl::OnMiddleClick (wxMouseEvent & *event*)

void wxRichTextCtrl::OnMoveMouse (wxMouseEvent & *event*)

void wxRichTextCtrl::OnPaint (wxPaintEvent & *event*)

void wxRichTextCtrl::OnPaste (wxCommandEvent & *event*)

Standard handler for the wxID_PASTE command.

void wxRichTextCtrl::OnProperties (wxCommandEvent & *event*)

Standard handler for property commands.

void wxRichTextCtrl::OnRedo (wxCommandEvent & *event*)

Standard handler for the wxID_REDO command.

void wxRichTextCtrl::OnRightClick (wxMouseEvent & *event*)

void wxRichTextCtrl::OnScroll (wxScrollWinEvent & *event*)

void wxRichTextCtrl::OnSelectAll (wxCommandEvent & *event*)

Standard handler for the wxID_SELECTALL command.

void wxRichTextCtrl::OnSetFocus (wxFocusEvent & *event*)

void wxRichTextCtrl::OnSize (wxSizeEvent & *event*)

void wxRichTextCtrl::OnSysColourChanged (wxSysColourChangedEvent & *event*)

void wxRichTextCtrl::OnTimer (wxTimerEvent & *event*)

Respond to timer events.

void wxRichTextCtrl::OnUndo (wxCommandEvent & *event*)

Standard handler for the wxID_UNDO command.

void wxRichTextCtrl::OnUpdateClear (wxUpdateUIEvent & *event*)

Standard update handler for the wxID_CLEAR command.

void wxRichTextCtrl::OnUpdateCopy (wxUpdateUIEvent & *event*)

Standard update handler for the wxID_COPY command.

void wxRichTextCtrl::OnUpdateCut (wxUpdateUIEvent & *event*)

Standard update handler for the wxID_CUT command.

void wxRichTextCtrl::OnUpdatePaste (wxUpdateUIEvent & *event*)

Standard update handler for the wxID_PASTE command.

void wxRichTextCtrl::OnUpdateProperties (wxUpdateUIEvent & *event*)

Standard update handler for property commands.

void wxRichTextCtrl::OnUpdateRedo (wxUpdateUIEvent & *event*)

Standard update handler for the wxID_REDO command.

void wxRichTextCtrl::OnUpdateSelectAll (wxUpdateUIEvent & *event*)

Standard update handler for the wxID_SELECTALL command.

void wxRichTextCtrl::OnUpdateUndo (wxUpdateUIEvent & *event*)

Standard update handler for the wxID_UNDO command.

virtual bool wxRichTextCtrl::PageDown (int *noPages* = 1, int *flags* = 0) [virtual]

Moves one or more pages down.

virtual bool wxRichTextCtrl::PageUp (int *noPages* = 1, int *flags* = 0) [virtual]

Moves one or more pages up.

virtual void wxRichTextCtrl::PaintAboveContent (wxDC & *WXUNUSEDdc*) [inline], [virtual]

Other user defined painting after everything else (i.e. all text) is painted.

Since

2.9.1

virtual void wxRichTextCtrl::PaintBackground (wxDC & *dc*) [virtual]

Paints the background.

virtual void wxRichTextCtrl::Paste ( ) [virtual]

Pastes content from the clipboard to the buffer.

wxRichTextStyleSheet* wxRichTextCtrl::PopStyleSheet ( )

Pops the style sheet from top of stack.

virtual void wxRichTextCtrl::PositionCaret (wxRichTextParagraphLayoutBox * *container* = NULL) [virtual]

Internal function to position the visible caret according to the current caret position.

virtual bool wxRichTextCtrl::PositionToXY (long *pos*, long * *x*, long * *y*) const [virtual]

Converts a text position to zero-based column and line numbers.

virtual void wxRichTextCtrl::PrepareContent (wxRichTextParagraphLayoutBox & *container*) [virtual]

Prepares the content just before insertion (or after buffer reset).

Called by the same function in wxRichTextBuffer. Currently is only called if undo mode is on.

virtual int wxRichTextCtrl::PrepareContextMenu (wxMenu * *menu*, const wxPoint & *pt*, bool *addPropertyCommands*) [virtual]

Prepares the context menu, optionally adding appropriate property-editing commands.

Returns the number of property commands added.

virtual bool wxRichTextCtrl::ProcessBackKey (wxKeyEvent & *event*, int *flags*) [virtual]

Processes the back key.

bool wxRichTextCtrl::ProcessDelayedImageLoading (bool *refresh*)

Do delayed image loading and garbage-collect other images.

bool wxRichTextCtrl::ProcessDelayedImageLoading (const wxRect & *screenRect*, wxRichTextParagraphLayoutBox * *box*, int & *loadCount*)

virtual bool wxRichTextCtrl::ProcessMouseMovement (wxRichTextParagraphLayoutBox * *container*, wxRichTextObject * *obj*, long *position*, const wxPoint & *pos*) [virtual]

Processes mouse movement in order to change the cursor.

virtual bool wxRichTextCtrl::PromoteList (int *promoteBy*, const wxRichTextRange & *range*, wxRichTextList↩ StyleDefinition * *def* = NULL, int *flags* = wxRICHTEXT_SETSTYLE_WITH_UNDO, int *specifiedLevel* = -1) [virtual]

Promotes or demotes the paragraphs in the given range.

A positive *promoteBy* produces a smaller indent, and a negative number produces a larger indent. Pass flags to determine how the attributes are set. Either the style definition or the name of the style definition (in the current sheet) can be passed.

flags is a bit list of the following:

- wxRICHTEXT_SETSTYLE_WITH_UNDO: specifies that this command will be undoable.

- wxRICHTEXT_SETSTYLE_RENUMBER: specifies that numbering should start from *startFrom*, otherwise existing attributes are used.
- wxRICHTEXT_SETSTYLE_SPECIFY_LEVEL: specifies that *listLevel* should be used as the level for all paragraphs, otherwise the current indentation will be used.

See also

SetListStyle(),
SetListStyle(), ClearListStyle().

virtual bool wxRichTextCtrl::PromoteList (int *promoteBy,* const wxRichTextRange & *range,* const wxString & *defName,* int *flags* = wxRICHTEXT_SETSTYLE_WITH_UNDO, int *specifiedLevel* = −1) [virtual]

Promotes or demotes the paragraphs in the given range.

A positive *promoteBy* produces a smaller indent, and a negative number produces a larger indent. Pass flags to determine how the attributes are set. Either the style definition or the name of the style definition (in the current sheet) can be passed.

flags is a bit list of the following:

- wxRICHTEXT_SETSTYLE_WITH_UNDO: specifies that this command will be undoable.
- wxRICHTEXT_SETSTYLE_RENUMBER: specifies that numbering should start from *startFrom*, otherwise existing attributes are used.
- wxRICHTEXT_SETSTYLE_SPECIFY_LEVEL: specifies that *listLevel* should be used as the level for all paragraphs, otherwise the current indentation will be used.

See also

SetListStyle(),
SetListStyle(), ClearListStyle().

bool wxRichTextCtrl::PushStyleSheet (wxRichTextStyleSheet * *styleSheet*)

Push the style sheet to top of stack.

virtual void wxRichTextCtrl::Redo ( ) [virtual]

Redoes the current command.

bool wxRichTextCtrl::RefreshForSelectionChange (const wxRichTextSelection & *oldSelection,* const wxRichTextSelection & *newSelection*)

Refreshes the area affected by a selection change.

virtual void wxRichTextCtrl::Remove (long *from,* long *to*) [virtual]

Removes the content in the specified range.

virtual void wxRichTextCtrl::Replace (long *from,* long *to,* const wxString & *value*) [virtual]

Replaces the content in the specified range with the string specified by *value*.

void wxRichTextCtrl::RequestDelayedImageProcessing ( )

Request delayed image processing.

bool wxRichTextCtrl::SaveFile (const wxString & *file* = wxEmptyString, int *type* = wxRICHTEXT_TYPE_ANY)

Saves the buffer content using the given type.

If the specified type is wxRICHTEXT_TYPE_ANY, the type is deduced from the filename extension.

This function looks for a suitable wxRichTextFileHandler object.

virtual bool wxRichTextCtrl::ScrollIntoView (long *position*, int *keyCode*) [virtual]

Scrolls *position* into view.

This function takes a caret position.

virtual void wxRichTextCtrl::SelectAll ( ) [virtual]

Selects all the text in the buffer.

virtual void wxRichTextCtrl::SelectNone ( ) [virtual]

Cancels any selection.

virtual bool wxRichTextCtrl::SelectWord (long *position*) [virtual]

Selects the word at the given character position.

void wxRichTextCtrl::SetAndShowDefaultStyle (const wxRichTextAttr & *attr*)

Sets *attr* as the default style and tells the control that the UI should reflect this attribute until the user moves the caret.

See also

IsDefaultStyleShowing().

virtual void wxRichTextCtrl::SetBasicStyle (const wxRichTextAttr & *style*) [virtual]

Sets the basic (overall) style.

This is the style of the whole buffer before further styles are applied, unlike the default style, which only affects the style currently being applied (for example, setting the default style to bold will cause subsequently inserted text to be bold).

void wxRichTextCtrl::SetCaretAtLineStart (bool *atStart*)

Sets a flag to remember that we are showing the caret position at the start of a line instead of at the end of the previous one.

void wxRichTextCtrl::SetCaretPosition (long *position,* bool *showAtLineStart* = `false`)

Sets the caret position.

The caret position is the character position just before the caret. A value of -1 means the caret is at the start of the buffer. Please note that this does not update the current editing style from the new position or cause the actual caret to be refreshed; to do that, call wxRichTextCtrl::SetInsertionPoint instead.

bool wxRichTextCtrl::SetCaretPositionAfterClick (wxRichTextParagraphLayoutBox * *container,* long *position,* int *hitTestFlags,* bool *extendSelection* = `false`)

Sets up the caret for the given position and container, after a mouse click.

void wxRichTextCtrl::SetCaretPositionForDefaultStyle (long *pos*)

Set the caret position for the default style that the user is selecting.

void wxRichTextCtrl::SetContextMenu (wxMenu * *menu*)

Sets the current context menu.

virtual bool wxRichTextCtrl::SetDefaultStyle (const wxTextAttr & *style*) `[virtual]`

Sets the current default style, which can be used to change how subsequently inserted text is displayed.

virtual bool wxRichTextCtrl::SetDefaultStyle (const wxRichTextAttr & *style*) `[virtual]`

Sets the current default style, which can be used to change how subsequently inserted text is displayed.

bool wxRichTextCtrl::SetDefaultStyleToCursorStyle ( )

Sets the default style to the style under the cursor.

void wxRichTextCtrl::SetDelayedImageProcessingRequired (bool *b*) `[inline]`

Sets the flag indicating that delayed image processing is required.

void wxRichTextCtrl::SetDelayedImageProcessingTime (wxLongLong *t*) `[inline]`

Sets the last time delayed image processing was performed.

void wxRichTextCtrl::SetDelayedLayoutThreshold (long *threshold*)

Sets the size of the buffer beyond which layout is delayed during resizing.

This optimizes sizing for large buffers. The default is 20000.

void wxRichTextCtrl::SetDimensionScale (double *dimScale,* bool *refresh* = `false`)

Sets the scale factor for displaying certain dimensions such as indentation and inter-paragraph spacing.

This can be useful when editing in a small control where you still want legible text, but a minimum of wasted white space.

void wxRichTextCtrl::SetDragging (bool *dragging*)

Sets a flag to remember if we are extending a selection.

void wxRichTextCtrl::SetDragStartPoint (wxPoint *sp*)

Set the possible Drag'n'Drop start point.

void wxRichTextCtrl::SetDragStartTime (wxDateTime *st*)

Set the possible Drag'n'Drop start time.

virtual void wxRichTextCtrl::SetEditable (bool *editable*) `[virtual]`

Makes the control editable, or not.

void wxRichTextCtrl::SetFilename (const wxString & *filename*)

Sets the current filename.

bool wxRichTextCtrl::SetFocusObject (wxRichTextParagraphLayoutBox * *obj*, bool *setCaretPosition* = `true`)

Sets the wxRichTextObject object that currently has the editing focus.

Parameters

obj	The wxRichTextObject to set focus on.
setCaretPosition	Optionally set the caret position.

virtual bool wxRichTextCtrl::SetFont (const wxFont & *font*) `[virtual]`

Sets the font, and also the basic and default attributes (see wxRichTextCtrl::SetDefaultStyle).

Reimplemented from wxWindow.

void wxRichTextCtrl::SetFontScale (double *fontScale*, bool *refresh* = `false`)

Sets the scale factor for displaying fonts, for example for more comfortable editing.

void wxRichTextCtrl::SetFullLayoutRequired (bool *b*)

void wxRichTextCtrl::SetFullLayoutSavedPosition (long *p*)

void wxRichTextCtrl::SetFullLayoutTime (wxLongLong *t*)

void wxRichTextCtrl::SetHandlerFlags (int *flags*)

Sets flags that change the behaviour of loading or saving.

See the documentation for each handler class to see what flags are relevant for each handler.

virtual void wxRichTextCtrl::SetInsertionPoint (long *pos*) `[virtual]`

Sets the insertion point and causes the current editing style to be taken from the new position (unlike wxRichTextCtrl::SetCaretPosition).

virtual void wxRichTextCtrl::SetInsertionPointEnd ( ) `[virtual]`

Sets the insertion point to the end of the text control.

void wxRichTextCtrl::SetInternalSelectionRange (const wxRichTextRange & *range*)

Sets the selection range in character positions.

-2, -2 means no selection -1, -1 means select everything. The range is in internal format, i.e. a single character selection is denoted by (n, n)

virtual bool wxRichTextCtrl::SetListStyle (const wxRichTextRange & *range*, wxRichTextListStyleDefinition * *def*, int *flags* = wxRICHTEXT_SETSTYLE_WITH_UNDO, int *startFrom* = 1, int *specifiedLevel* = -1) `[virtual]`

Sets the list attributes for the given range, passing flags to determine how the attributes are set.

Either the style definition or the name of the style definition (in the current sheet) can be passed. *flags* is a bit list of the following:

- wxRICHTEXT_SETSTYLE_WITH_UNDO: specifies that this command will be undoable.
- wxRICHTEXT_SETSTYLE_RENUMBER: specifies that numbering should start from *startFrom*, otherwise existing attributes are used.
- wxRICHTEXT_SETSTYLE_SPECIFY_LEVEL: specifies that *listLevel* should be used as the level for all paragraphs, otherwise the current indentation will be used.

See also

NumberList(), PromoteList(), ClearListStyle().

virtual bool wxRichTextCtrl::SetListStyle (const wxRichTextRange & *range*, const wxString & *defName*, int *flags* = wxRICHTEXT_SETSTYLE_WITH_UNDO, int *startFrom* = 1, int *specifiedLevel* = -1) `[virtual]`

Sets the list attributes for the given range, passing flags to determine how the attributes are set.

Either the style definition or the name of the style definition (in the current sheet) can be passed. *flags* is a bit list of the following:

- wxRICHTEXT_SETSTYLE_WITH_UNDO: specifies that this command will be undoable.
- wxRICHTEXT_SETSTYLE_RENUMBER: specifies that numbering should start from *startFrom*, otherwise existing attributes are used.
- wxRICHTEXT_SETSTYLE_SPECIFY_LEVEL: specifies that *listLevel* should be used as the level for all paragraphs, otherwise the current indentation will be used.

See also

NumberList(), PromoteList(), ClearListStyle().

virtual void wxRichTextCtrl::SetMaxLength (unsigned long *len*) `[virtual]`

Sets the maximum number of characters that may be entered in a single line text control.

For compatibility only; currently does nothing.

void wxRichTextCtrl::SetModified (bool *modified*)

void wxRichTextCtrl::SetPreDrag (bool *pd*)

Set if we're trying to start Drag'n'Drop.

virtual bool wxRichTextCtrl::SetProperties (const wxRichTextRange & *range,* const wxRichTextProperties & *properties,* int *flags* = wxRICHTEXT_SETPROPERTIES_WITH_UNDO) `[virtual]`

Sets the properties for the given range, passing flags to determine how the attributes are set.

You can merge properties or replace them.

The end point of range is specified as the last character position of the span of text, plus one. So, for example, to set the properties for a character at position 5, use the range (5,6).

flags may contain a bit list of the following values:

- wxRICHTEXT_SETSPROPERTIES_NONE: no flag.
- wxRICHTEXT_SETPROPERTIES_WITH_UNDO: specifies that this operation should be undoable.
- wxRICHTEXT_SETPROPERTIES_PARAGRAPHS_ONLY: specifies that the properties should only be applied to paragraphs, and not the content.
- wxRICHTEXT_SETPROPERTIES_CHARACTERS_ONLY: specifies that the properties should only be applied to characters, and not the paragraph.
- wxRICHTEXT_SETPROPERTIES_RESET: resets (clears) the existing properties before applying the new properties.
- wxRICHTEXT_SETPROPERTIES_REMOVE: removes the specified properties.

void wxRichTextCtrl::SetScale (double *scale,* bool *refresh* = `false`)

Sets an overall scale factor for displaying and editing the content.

virtual void wxRichTextCtrl::SetSelection (long *from,* long *to*) `[virtual]`

Sets the selection to the given range.

The end point of range is specified as the last character position of the span of text, plus one.

So, for example, to set the selection for a character at position 5, use the range (5,6).

void wxRichTextCtrl::SetSelection (const wxRichTextSelection & *sel*)

Sets the selection to the given range.

The end point of range is specified as the last character position of the span of text, plus one.

So, for example, to set the selection for a character at position 5, use the range (5,6).

void wxRichTextCtrl::SetSelectionAnchor (long *anchor*)

Sets an anchor so we know how to extend the selection.

It's a caret position since it's between two characters.

void wxRichTextCtrl::SetSelectionAnchorObject (wxRichTextObject * *anchor*)

Sets the anchor object if selecting multiple containers.

void wxRichTextCtrl::SetSelectionRange (const wxRichTextRange & *range*)

Sets the selection to the given range.

The end point of range is specified as the last character position of the span of text, plus one.

So, for example, to set the selection for a character at position 5, use the range (5,6).

virtual bool wxRichTextCtrl::SetStyle (long *start,* long *end,* const wxTextAttr & *style*) [virtual]

Sets the attributes for the given range.

The end point of range is specified as the last character position of the span of text, plus one.

So, for example, to set the style for a character at position 5, use the range (5,6).

virtual bool wxRichTextCtrl::SetStyle (long *start,* long *end,* const wxRichTextAttr & *style*) [virtual]

Sets the attributes for the given range.

The end point of range is specified as the last character position of the span of text, plus one.

So, for example, to set the style for a character at position 5, use the range (5,6).

virtual bool wxRichTextCtrl::SetStyle (const wxRichTextRange & *range,* const wxTextAttr & *style*) [virtual]

Sets the attributes for the given range.

The end point of range is specified as the last character position of the span of text, plus one.

So, for example, to set the style for a character at position 5, use the range (5,6).

virtual bool wxRichTextCtrl::SetStyle (const wxRichTextRange & *range,* const wxRichTextAttr & *style*) [virtual]

Sets the attributes for the given range.

The end point of range is specified as the last character position of the span of text, plus one.

So, for example, to set the style for a character at position 5, use the range (5,6).

virtual void wxRichTextCtrl::SetStyle (wxRichTextObject * *obj,* const wxRichTextAttr & *textAttr,* int *flags* = wxRICHTEXT_SETSTYLE_WITH_UNDO) [virtual]

Sets the attributes for a single object.

virtual bool wxRichTextCtrl::SetStyleEx (const wxRichTextRange & *range,* const wxRichTextAttr & *style,* int *flags =* wxRICHTEXT_SETSTYLE_WITH_UNDO) `[virtual]`

Sets the attributes for the given range, passing flags to determine how the attributes are set.

The end point of range is specified as the last character position of the span of text, plus one. So, for example, to set the style for a character at position 5, use the range (5,6).

flags may contain a bit list of the following values:

- wxRICHTEXT_SETSTYLE_NONE: no style flag.
- wxRICHTEXT_SETSTYLE_WITH_UNDO: specifies that this operation should be undoable.
- wxRICHTEXT_SETSTYLE_OPTIMIZE: specifies that the style should not be applied if the combined style at this point is already the style in question.
- wxRICHTEXT_SETSTYLE_PARAGRAPHS_ONLY: specifies that the style should only be applied to paragraphs, and not the content. This allows content styling to be preserved independently from that of e.g. a named paragraph style.
- wxRICHTEXT_SETSTYLE_CHARACTERS_ONLY: specifies that the style should only be applied to characters, and not the paragraph. This allows content styling to be preserved independently from that of e.g. a named paragraph style.
- wxRICHTEXT_SETSTYLE_RESET: resets (clears) the existing style before applying the new style.
- wxRICHTEXT_SETSTYLE_REMOVE: removes the specified style. Only the style flags are used in this operation.

void wxRichTextCtrl::SetStyleSheet (wxRichTextStyleSheet * *styleSheet*)

Sets the style sheet associated with the control.

A style sheet allows named character and paragraph styles to be applied.

void wxRichTextCtrl::SetTextCursor (const wxCursor & *cursor*)

Sets the text (normal) cursor.

virtual void wxRichTextCtrl::SetupScrollbars (bool *atTop =* `false`) `[virtual]`

A helper function setting up scrollbars, for example after a resize.

void wxRichTextCtrl::SetURLCursor (const wxCursor & *cursor*)

Sets the cursor to be used over URLs.

virtual void wxRichTextCtrl::SetValue (const wxString & *value*) `[virtual]`

Replaces existing content with the given text.

virtual bool wxRichTextCtrl::ShouldInheritColours ( ) const [virtual]

Return true from here to allow the colours of this window to be changed by InheritAttributes().

Returning false forbids inheriting them from the parent window.

The base class version returns false, but this method is overridden in wxControl where it returns true.

Reimplemented from wxWindow.

virtual bool wxRichTextCtrl::ShowContextMenu (wxMenu * *menu*, const wxPoint & *pt*, bool *addPropertyCommands*) [virtual]

Shows the given context menu, optionally adding appropriate property-editing commands for the current position in the object hierarchy.

virtual void wxRichTextCtrl::ShowPosition (long *pos*) [virtual]

Scrolls the buffer so that the given position is in view.

virtual bool wxRichTextCtrl::StartCellSelection (wxRichTextTable * *table*, wxRichTextParagraphLayoutBox * *newCell*) [virtual]

Starts selecting table cells.

void wxRichTextCtrl::StoreFocusObject (wxRichTextParagraphLayoutBox * *obj*)

Setter for m_focusObject.

virtual bool wxRichTextCtrl::SuppressingUndo ( ) const [virtual]

Returns true if undo history suppression is on.

virtual void wxRichTextCtrl::Undo ( ) [virtual]

Undoes the command at the top of the command history, if there is one.

virtual bool wxRichTextCtrl::WordLeft (int *noPages* = 1, int *flags* = 0) [virtual]

Moves a number of words to the left.

virtual bool wxRichTextCtrl::WordRight (int *noPages* = 1, int *flags* = 0) [virtual]

Move a nuber of words to the right.

virtual wxRichTextField* wxRichTextCtrl::WriteField (const wxString & *fieldType*, const wxRichTextProperties & *properties*, const wxRichTextAttr & *textAttr* = wxRichTextAttr()) [virtual]

Writes a field at the current insertion point.

Parameters

fieldType	The field type, matching an existing field type definition.
properties	Extra data for the field.
textAttr	Optional attributes.

See also

wxRichTextField, wxRichTextFieldType, wxRichTextFieldTypeStandard

virtual bool wxRichTextCtrl::WriteImage (const wxImage & *image*, wxBitmapType *bitmapType* = wxBITMAP_TYPE_PNG, const wxRichTextAttr & *textAttr* = wxRichTextAttr()) [virtual]

Write a bitmap or image at the current insertion point.

Supply an optional type to use for internal and file storage of the raw data.

virtual bool wxRichTextCtrl::WriteImage (const wxBitmap & *bitmap*, wxBitmapType *bitmapType* = wxBITMAP_TYPE_PNG, const wxRichTextAttr & *textAttr* = wxRichTextAttr()) [virtual]

Write a bitmap or image at the current insertion point.

Supply an optional type to use for internal and file storage of the raw data.

virtual bool wxRichTextCtrl::WriteImage (const wxString & *filename*, wxBitmapType *bitmapType*, const wxRichTextAttr & *textAttr* = wxRichTextAttr()) [virtual]

Loads an image from a file and writes it at the current insertion point.

virtual bool wxRichTextCtrl::WriteImage (const wxRichTextImageBlock & *imageBlock*, const wxRichTextAttr & *textAttr* = wxRichTextAttr()) [virtual]

Writes an image block at the current insertion point.

virtual wxRichTextTable* wxRichTextCtrl::WriteTable (int *rows*, int *cols*, const wxRichTextAttr & *tableAttr* = wxRichTextAttr(), const wxRichTextAttr & *cellAttr* = wxRichTextAttr()) [virtual]

Write a table at the current insertion point, returning the table.

You can then call SetFocusObject() to set the focus to the new object.

virtual void wxRichTextCtrl::WriteText (const wxString & *text*) [virtual]

Writes text at the current position.

virtual wxRichTextBox* wxRichTextCtrl::WriteTextBox (const wxRichTextAttr & *textAttr* = wxRichTextAttr()) [virtual]

Write a text box at the current insertion point, returning the text box.

You can then call SetFocusObject() to set the focus to the new object.

virtual long wxRichTextCtrl::XYToPosition (long *x*, long *y*) const [virtual]

Translates from column and line number to position.

21.617.4 Member Data Documentation

wxRichTextBuffer wxRichTextCtrl::m_buffer [protected]

Text buffer.

bool wxRichTextCtrl::m_caretAtLineStart [protected]

Are we showing the caret position at the start of a line instead of at the end of the previous one?

long wxRichTextCtrl::m_caretPosition [protected]

Caret position (1 less than the character position, so -1 is the first caret position).

long wxRichTextCtrl::m_caretPositionForDefaultStyle [protected]

Caret position when the default formatting has been changed.

As soon as this position changes, we no longer reflect the default style in the UI.

wxMenu* wxRichTextCtrl::m_contextMenu [protected]

wxRichTextContextMenuPropertiesInfo wxRichTextCtrl::m_contextMenuPropertiesInfo [protected]

bool wxRichTextCtrl::m_delayedImageProcessingRequired [protected]

wxLongLong wxRichTextCtrl::m_delayedImageProcessingTime [protected]

wxTimer wxRichTextCtrl::m_delayedImageProcessingTimer [protected]

long wxRichTextCtrl::m_delayedLayoutThreshold [protected]

Threshold for doing delayed layout.

bool wxRichTextCtrl::m_dragging [protected]

Are we dragging a selection?

bool wxRichTextCtrl::m_editable [protected]

Are we editable?

bool wxRichTextCtrl::m_enableDelayedImageLoading [protected]

Whether delayed image loading is enabled for this control.

bool wxRichTextCtrl::m_enableImages [protected]

Whether images are enabled for this control.

wxRichTextParagraphLayoutBox* **wxRichTextCtrl::m_focusObject** [protected]

The object that currently has the editing focus.

bool wxRichTextCtrl::m_fullLayoutRequired [protected]

Do we need full layout in idle?

long wxRichTextCtrl::m_fullLayoutSavedPosition [protected]

wxLongLong wxRichTextCtrl::m_fullLayoutTime [protected]

wxSize wxRichTextCtrl::m_lastWindowSize [protected]

Variables for scrollbar hysteresis detection.

double wxRichTextCtrl::m_scale [protected]

An overall scale factor.

wxRichTextSelection wxRichTextCtrl::m_selection [protected]

Selection range in character positions. -2, -2 means no selection.

long wxRichTextCtrl::m_selectionAnchor [protected]

Anchor so we know how to extend the selection It's a caret position since it's between two characters.

wxRichTextObject* **wxRichTextCtrl::m_selectionAnchorObject** [protected]

Anchor object if selecting multiple container objects, such as grid cells.

wxRichTextCtrlSelectionState wxRichTextCtrl::m_selectionState [protected]

int wxRichTextCtrl::m_setupScrollbarsCount [protected]

int wxRichTextCtrl::m_setupScrollbarsCountInOnSize [protected]

wxCursor wxRichTextCtrl::m_textCursor [protected]

Cursors.

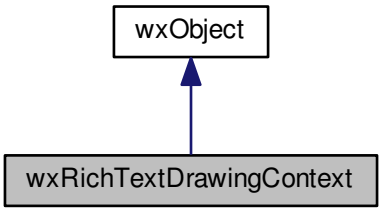
wxCursor wxRichTextCtrl::m_urlCursor [protected]

wxArrayString wxRichTextCtrl::sm_availableFontNames [static], [protected]

21.618 wxRichTextDrawingContext Class Reference

`#include <wx/richtext/richtextbuffer.h>`

Inheritance diagram for wxRichTextDrawingContext:



21.618.1 Detailed Description

A class for passing information to drawing and measuring functions.

Library: wxRichText

Category: Rich Text

See also

wxRichTextBuffer, wxRichTextCtrl

Public Member Functions

- wxRichTextDrawingContext (wxRichTextBuffer ∗buffer)

  Pass the buffer to the context so the context can retrieve information such as virtual attributes.
- void Init ()
- bool HasVirtualAttributes (wxRichTextObject ∗obj) const

  Does this object have virtual attributes? Virtual attributes can be provided for visual cues without affecting the actual styling.
- wxRichTextAttr GetVirtualAttributes (wxRichTextObject ∗obj) const

  Returns the virtual attributes for this object.
- bool ApplyVirtualAttributes (wxRichTextAttr &attr, wxRichTextObject ∗obj) const

  Applies any virtual attributes relevant to this object.
- int GetVirtualSubobjectAttributesCount (wxRichTextObject ∗obj) const

  Gets the count for mixed virtual attributes for individual positions within the object.
- int GetVirtualSubobjectAttributes (wxRichTextObject ∗obj, wxArrayInt &positions, wxRichTextAttrArray &attributes) const

  Gets the mixed virtual attributes for individual positions within the object.
- bool HasVirtualText (const wxRichTextPlainText ∗obj) const

  Do we have virtual text for this object? Virtual text allows an application to replace characters in an object for editing and display purposes, for example for highlighting special characters.
- bool GetVirtualText (const wxRichTextPlainText ∗obj, wxString &text) const

  Gets the virtual text for this object.
- void EnableVirtualAttributes (bool b)

Enables virtual attribute processing.

- bool GetVirtualAttributesEnabled () const

  Returns true if virtual attribute processing is enabled.

- void EnableImages (bool b)

  Enable or disable images.

- bool GetImagesEnabled () const

  Returns true if images are enabled.

- void SetLayingOut (bool b)

  Set laying out flag.

- bool GetLayingOut () const

  Returns true if laying out.

- void EnableDelayedImageLoading (bool b)

  Enable or disable delayed image loading.

- bool GetDelayedImageLoading () const

  Returns true if delayed image loading is enabled.

Public Attributes

- wxRichTextBuffer * m_buffer
- bool m_enableVirtualAttributes
- bool m_enableImages
- bool m_enableDelayedImageLoading
- bool m_layingOut

Additional Inherited Members

21.618.2 Constructor & Destructor Documentation

wxRichTextDrawingContext::wxRichTextDrawingContext (wxRichTextBuffer * *buffer*)

Pass the buffer to the context so the context can retrieve information such as virtual attributes.

21.618.3 Member Function Documentation

bool wxRichTextDrawingContext::ApplyVirtualAttributes (wxRichTextAttr & *attr,* wxRichTextObject * *obj*) const

Applies any virtual attributes relevant to this object.

void wxRichTextDrawingContext::EnableDelayedImageLoading (bool *b*) `[inline]`

Enable or disable delayed image loading.

void wxRichTextDrawingContext::EnableImages (bool *b*) `[inline]`

Enable or disable images.

void wxRichTextDrawingContext::EnableVirtualAttributes (bool *b*)

Enables virtual attribute processing.

bool wxRichTextDrawingContext::GetDelayedImageLoading ( ) const `[inline]`

Returns true if delayed image loading is enabled.

bool wxRichTextDrawingContext::GetImagesEnabled ( ) const `[inline]`

Returns true if images are enabled.

bool wxRichTextDrawingContext::GetLayingOut ( ) const `[inline]`

Returns true if laying out.

wxRichTextAttr wxRichTextDrawingContext::GetVirtualAttributes (wxRichTextObject * *obj*) const

Returns the virtual attributes for this object.

Virtual attributes can be provided for visual cues without affecting the actual styling.

bool wxRichTextDrawingContext::GetVirtualAttributesEnabled ( ) const

Returns true if virtual attribute processing is enabled.

int wxRichTextDrawingContext::GetVirtualSubobjectAttributes (wxRichTextObject * *obj*, wxArrayInt & *positions*, wxRichTextAttrArray & *attributes*) const

Gets the mixed virtual attributes for individual positions within the object.

For example, individual characters within a text object may require special highlighting. The function is passed the count returned by GetVirtualSubobjectAttributesCount.

int wxRichTextDrawingContext::GetVirtualSubobjectAttributesCount (wxRichTextObject * *obj*) const

Gets the count for mixed virtual attributes for individual positions within the object.

For example, individual characters within a text object may require special highlighting.

bool wxRichTextDrawingContext::GetVirtualText (const wxRichTextPlainText * *obj*, wxString & *text*) const

Gets the virtual text for this object.

bool wxRichTextDrawingContext::HasVirtualAttributes (wxRichTextObject * *obj*) const

Does this object have virtual attributes? Virtual attributes can be provided for visual cues without affecting the actual styling.

bool wxRichTextDrawingContext::HasVirtualText (const wxRichTextPlainText * *obj*) const

Do we have virtual text for this object? Virtual text allows an application to replace characters in an object for editing and display purposes, for example for highlighting special characters.

void wxRichTextDrawingContext::Init ( )

void wxRichTextDrawingContext::SetLayingOut (bool *b*) `[inline]`

Set laying out flag.

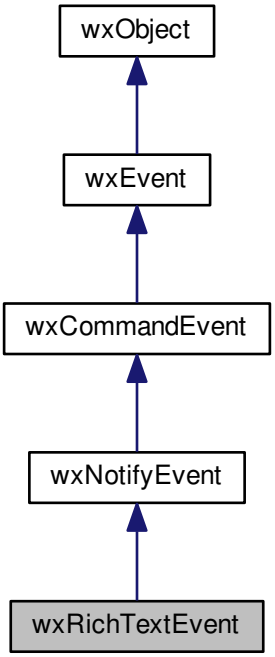
21.620 wxRichTextEvent Class Reference

```
#include <wx/richtext/richtextctrl.h>
```

Inheritance diagram for wxRichTextEvent:



21.620.1 Detailed Description

This is the event class for wxRichTextCtrl notifications.

Events using this class

The following event handler macros redirect the events to member function handlers '**func**' with prototypes like: void handlerFuncName(wxRichTextEvent& event)

Event macros:

- EVT_RICHTEXT_LEFT_CLICK(id, func): Process a `wxEVT_RICHTEXT_LEFT_CLICK` event, generated when the user releases the left mouse button over an object.
- EVT_RICHTEXT_RIGHT_CLICK(id, func): Process a `wxEVT_RICHTEXT_RIGHT_CLICK` event, generated when the user releases the right mouse button over an object.
- EVT_RICHTEXT_MIDDLE_CLICK(id, func): Process a `wxEVT_RICHTEXT_MIDDLE_CLICK` event, generated when the user releases the middle mouse button over an object.
- EVT_RICHTEXT_LEFT_DCLICK(id, func): Process a `wxEVT_RICHTEXT_LEFT_DCLICK` event, generated when the user double-clicks an object.
- EVT_RICHTEXT_RETURN(id, func): Process a `wxEVT_RICHTEXT_RETURN` event, generated when the user presses the return key. Valid event functions: GetFlags, GetPosition.
- EVT_RICHTEXT_CHARACTER(id, func): Process a `wxEVT_RICHTEXT_CHARACTER` event, generated when the user presses a character key. Valid event functions: GetFlags, GetPosition, GetCharacter.

- EVT_RICHTEXT_CONSUMING_CHARACTER(id, func): Process a wxEVT_RICHTEXT_CONSUMING_CHARACTER event, generated when the user presses a character key but before it is processed and inserted into the control. Call Veto to prevent normal processing. Valid event functions: GetFlags, GetPosition, GetCharacter, Veto.
- EVT_RICHTEXT_DELETE(id, func): Process a wxEVT_RICHTEXT_DELETE event, generated when the user presses the backspace or delete key. Valid event functions: GetFlags, GetPosition.
- EVT_RICHTEXT_RETURN(id, func): Process a wxEVT_RICHTEXT_RETURN event, generated when the user presses the return key. Valid event functions: GetFlags, GetPosition.
- EVT_RICHTEXT_STYLE_CHANGED(id, func): Process a wxEVT_RICHTEXT_STYLE_CHANGED event, generated when styling has been applied to the control. Valid event functions: GetPosition, GetRange.
- EVT_RICHTEXT_STYLESHEET_CHANGED(id, func): Process a wxEVT_RICHTEXT_STYLESHEET_CHANGING event, generated when the control's stylesheet has changed, for example the user added, edited or deleted a style. Valid event functions: GetRange, GetPosition.
- EVT_RICHTEXT_STYLESHEET_REPLACING(id, func): Process a wxEVT_RICHTEXT_STYLESHEET_REPLACING event, generated when the control's stylesheet is about to be replaced, for example when a file is loaded into the control. Valid event functions: Veto, GetOldStyleSheet, GetNewStyleSheet.
- EVT_RICHTEXT_STYLESHEET_REPLACED(id, func): Process a wxEVT_RICHTEXT_STYLESHEET_REPLACED event, generated when the control's stylesheet has been replaced, for example when a file is loaded into the control. Valid event functions: GetOldStyleSheet, GetNewStyleSheet.
- EVT_RICHTEXT_PROPERTIES_CHANGED(id, func): Process a wxEVT_RICHTEXT_PROPERTIES_CHANGED event, generated when properties have been applied to the control. Valid event functions: GetPosition, GetRange.
- EVT_RICHTEXT_CONTENT_INSERTED(id, func): Process a wxEVT_RICHTEXT_CONTENT_INSERTED event, generated when content has been inserted into the control. Valid event functions: GetPosition, GetRange.
- EVT_RICHTEXT_CONTENT_DELETED(id, func): Process a wxEVT_RICHTEXT_CONTENT_DELETED event, generated when content has been deleted from the control. Valid event functions: GetPosition, GetRange.
- EVT_RICHTEXT_BUFFER_RESET(id, func): Process a wxEVT_RICHTEXT_BUFFER_RESET event, generated when the buffer has been reset by deleting all content. You can use this to set a default style for the first new paragraph.
- EVT_RICHTEXT_SELECTION_CHANGED(id, func): Process a wxEVT_RICHTEXT_SELECTION_CHANGED event, generated when the selection range has changed.
- EVT_RICHTEXT_FOCUS_OBJECT_CHANGED(id, func): Process a wxEVT_RICHTEXT_FOCUS_OBJECT_CHANGED event, generated when the current focus object has changed.

Library: wxRichText

Category: Events, Rich Text

Public Member Functions

- wxRichTextEvent (wxEventType commandType=wxEVT_NULL, int winid=0)

  Constructor.
- wxRichTextEvent (const wxRichTextEvent &event)

  Copy constructor.
- long GetPosition () const

Returns the buffer position at which the event occurred.

- void SetPosition (long pos)

  Sets the buffer position variable.
- int GetFlags () const

  Returns flags indicating modifier keys pressed.
- void SetFlags (int flags)

  Sets flags indicating modifier keys pressed.
- wxRichTextStyleSheet * GetOldStyleSheet () const

  Returns the old style sheet.
- void SetOldStyleSheet (wxRichTextStyleSheet *sheet)

  Sets the old style sheet variable.
- wxRichTextStyleSheet * GetNewStyleSheet () const

  Returns the new style sheet.
- void SetNewStyleSheet (wxRichTextStyleSheet *sheet)

  Sets the new style sheet variable.
- const wxRichTextRange & GetRange () const

  Gets the range for the current operation.
- void SetRange (const wxRichTextRange &range)

  Sets the range variable.
- wxChar GetCharacter () const

  Returns the character pressed, within a `wxEVT_RICHTEXT_CHARACTER` event.
- void SetCharacter (wxChar ch)

  Sets the character variable.
- wxRichTextParagraphLayoutBox * GetContainer () const

  Returns the container for which the event is relevant.
- void SetContainer (wxRichTextParagraphLayoutBox *container)

  Sets the container for which the event is relevant.
- wxRichTextParagraphLayoutBox * GetOldContainer () const

  Returns the old container, for a focus change event.
- void SetOldContainer (wxRichTextParagraphLayoutBox *container)

  Sets the old container, for a focus change event.
- virtual wxEvent * Clone () const

  Returns a copy of the event.

Protected Attributes

- long m_position
- wxRichTextStyleSheet * m_oldStyleSheet
- wxRichTextStyleSheet * m_newStyleSheet
- wxRichTextRange m_range
- wxChar m_char
- wxRichTextParagraphLayoutBox * m_container
- wxRichTextParagraphLayoutBox * m_oldContainer

Additional Inherited Members

21.620.2 Constructor & Destructor Documentation

wxRichTextEvent::wxRichTextEvent (wxEventType *commandType* = wxEVT_NULL, int *winid* = 0)

Constructor.

Parameters

commandType	The type of the event.
winid	Window identifier. The value `wxID_ANY` indicates a default value.

wxRichTextEvent::wxRichTextEvent (const wxRichTextEvent & *event*)

Copy constructor.

21.620.3 Member Function Documentation

virtual wxEvent* wxRichTextEvent::Clone ( ) const [virtual]

Returns a copy of the event.

Any event that is posted to the wxWidgets event system for later action (via wxEvtHandler::AddPendingEvent, wxEvtHandler::QueueEvent or wxPostEvent()) must implement this method.

All wxWidgets events fully implement this method, but any derived events implemented by the user should also implement this method just in case they (or some event derived from them) are ever posted.

All wxWidgets events implement a copy constructor, so the easiest way of implementing the Clone function is to implement a copy constructor for a new event (call it MyEvent) and then define the Clone function like this:

```
wxEvent *Clone() const { return new MyEvent(*this); }
```

Implements wxEvent.

wxChar wxRichTextEvent::GetCharacter ( ) const

Returns the character pressed, within a `wxEVT_RICHTEXT_CHARACTER` event.

wxRichTextParagraphLayoutBox* wxRichTextEvent::GetContainer ( ) const

Returns the container for which the event is relevant.

int wxRichTextEvent::GetFlags ( ) const

Returns flags indicating modifier keys pressed.

Possible values are `wxRICHTEXT_CTRL_DOWN`, `wxRICHTEXT_SHIFT_DOWN`, and `wxRICHTEXT_ALT_DOWN`.

wxRichTextStyleSheet* wxRichTextEvent::GetNewStyleSheet ( ) const

Returns the new style sheet.

Can be used in a `wxEVT_RICHTEXT_STYLESHEET_CHANGING` or `wxEVT_RICHTEXT_STYLESHEET_CHANGED` event handler.

wxRichTextParagraphLayoutBox* wxRichTextEvent::GetOldContainer ( ) const

Returns the old container, for a focus change event.

wxRichTextStyleSheet* wxRichTextEvent::GetOldStyleSheet ( ) const

Returns the old style sheet.

Can be used in a `wxEVT_RICHTEXT_STYLESHEET_CHANGING` or `wxEVT_RICHTEXT_STYLESHEET_CHANGED` event handler.

long wxRichTextEvent::GetPosition ( ) const

Returns the buffer position at which the event occurred.

const wxRichTextRange& wxRichTextEvent::GetRange ( ) const

Gets the range for the current operation.

void wxRichTextEvent::SetCharacter (wxChar *ch*)

Sets the character variable.

void wxRichTextEvent::SetContainer (wxRichTextParagraphLayoutBox * *container*)

Sets the container for which the event is relevant.

void wxRichTextEvent::SetFlags (int *flags*)

Sets flags indicating modifier keys pressed.

Possible values are `wxRICHTEXT_CTRL_DOWN`, `wxRICHTEXT_SHIFT_DOWN`, and `wxRICHTEXT_ALT_DOWN`.

void wxRichTextEvent::SetNewStyleSheet (wxRichTextStyleSheet * *sheet*)

Sets the new style sheet variable.

void wxRichTextEvent::SetOldContainer (wxRichTextParagraphLayoutBox * *container*)

Sets the old container, for a focus change event.

void wxRichTextEvent::SetOldStyleSheet (wxRichTextStyleSheet * *sheet*)

Sets the old style sheet variable.

void wxRichTextEvent::SetPosition (long *pos*)

Sets the buffer position variable.

void wxRichTextEvent::SetRange (const wxRichTextRange & *range*)

Sets the range variable.

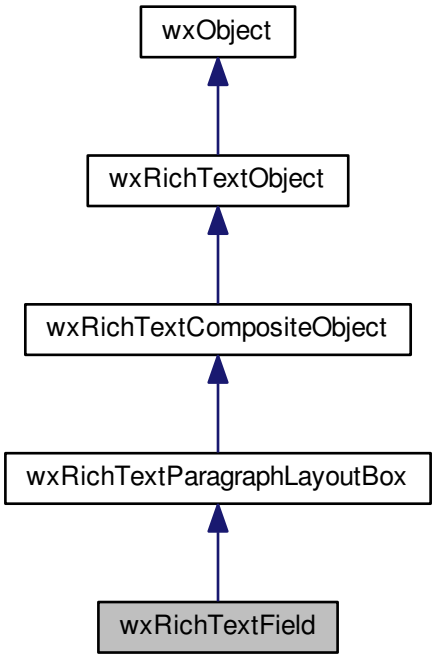
21.621 wxRichTextField Class Reference

`#include <wx/richtext/richtextbuffer.h>`

Inheritance diagram for wxRichTextField:



21.621.1 Detailed Description

This class implements the general concept of a field, an object that represents additional functionality such as a footnote, a bookmark, a page number, a table of contents, and so on.

Extra information (such as a bookmark name) can be stored in the object properties.

Drawing, layout, and property editing is delegated to classes derived from wxRichTextFieldType, such as instances of wxRichTextFieldTypeStandard; this makes the use of fields an efficient method of introducing extra functionality, since most of the information required to draw a field (such as a bitmap) is kept centrally in a single field type definition.

The FieldType property, accessed by SetFieldType/GetFieldType, is used to retrieve the field type definition. So be careful not to overwrite this property.

wxRichTextField is derived from wxRichTextParagraphLayoutBox, which means that it can contain its own read-only content, refreshed when the application calls the UpdateField function. Whether a field is treated as a composite or a single graphic is determined by the field type definition. If using wxRichTextFieldTypeStandard, passing the display type wxRICHTEXT_FIELD_STYLE_COMPOSITE to the field type definition causes the field to behave like a composite; the other display styles display a simple graphic. When implementing a composite field, you will still need to derive from wxRichTextFieldTypeStandard or wxRichTextFieldType, if only to implement UpdateField to refresh the field content appropriately. wxRichTextFieldTypeStandard is only one possible implementation, but covers common needs especially for simple, static fields using text or a bitmap.

Register field types on application initialisation with the static function wxRichTextBuffer::AddFieldType. They will be deleted automatically on application exit.

An application can write a field to a control with wxRichTextCtrl::WriteField, taking a field type, the properties for the field, and optional attributes.

Public Member Functions

- wxRichTextField (const wxString &fieldType=wxEmptyString, wxRichTextObject *parent=NULL)

  Default constructor; optionally pass the parent object.
- wxRichTextField (const wxRichTextField &obj)

  Copy constructor.
- virtual bool Draw (wxDC &dc, wxRichTextDrawingContext &context, const wxRichTextRange &range, const wxRichTextSelection &selection, const wxRect &rect, int descent, int style)

  Draw the item, within the given range.
- virtual bool Layout (wxDC &dc, wxRichTextDrawingContext &context, const wxRect &rect, const wxRect &parentRect, int style)

  Lay the item out at the specified position with the given size constraint.
- virtual bool GetRangeSize (const wxRichTextRange &range, wxSize &size, int &descent, wxDC &dc, wxRichTextDrawingContext &context, int flags, const wxPoint &position=wxPoint(0, 0), const wxSize &parentSize=wxDefaultSize, wxArrayInt *partialExtents=NULL) const

  Returns the object size for the given range.
- virtual wxString GetXMLNodeName () const

  Returns the XML node name of this object.
- virtual bool CanEditProperties () const

  Returns true if we can edit the object's properties via a GUI.
- virtual bool EditProperties (wxWindow *parent, wxRichTextBuffer *buffer)

  Edits the object's properties via a GUI.

- virtual wxString GetPropertiesMenuLabel () const

  Returns the label to be used for the properties context menu item.
- virtual bool AcceptsFocus () const

  Returns true if objects of this class can accept the focus, i.e. a call to SetFocusObject is possible.
- virtual void CalculateRange (long start, long &end)

  Calculates the range of the object.
- virtual bool IsAtomic () const

  If a field has children, we don't want the user to be able to edit it.
- virtual bool IsEmpty () const

  Returns true if the buffer is empty.
- virtual bool IsTopLevel () const

  Returns true if this object is top-level, i.e. contains its own paragraphs, such as a text box.
- void SetFieldType (const wxString &fieldType)
- wxString GetFieldType () const
- virtual bool UpdateField (wxRichTextBuffer *buffer)

  Update the field; delegated to the associated field type.
- virtual wxRichTextObject * Clone () const

  Clones the object.
- void Copy (const wxRichTextField &obj)

Additional Inherited Members

21.621.2 Constructor & Destructor Documentation

wxRichTextField::wxRichTextField (const wxString & *fieldType* = wxEmptyString, wxRichTextObject * *parent* = NULL)

Default constructor; optionally pass the parent object.

wxRichTextField::wxRichTextField (const wxRichTextField & *obj*) `[inline]`

Copy constructor.

21.621.3 Member Function Documentation

virtual bool wxRichTextField::AcceptsFocus ( ) const `[inline], [virtual]`

Returns true if objects of this class can accept the focus, i.e. a call to SetFocusObject is possible.

For example, containers supporting text, such as a text box object, can accept the focus, but a table can't (set the focus to individual cells instead).

Reimplemented from wxRichTextParagraphLayoutBox.

virtual void wxRichTextField::CalculateRange (long *start*, long & *end*) `[virtual]`

Calculates the range of the object.

By default, guess that the object is 1 unit long.

Reimplemented from wxRichTextCompositeObject.

virtual bool wxRichTextField::CanEditProperties ( ) const `[virtual]`

Returns true if we can edit the object's properties via a GUI.

Reimplemented from wxRichTextObject.

virtual wxRichTextObject* wxRichTextField::Clone ( ) const `[inline], [virtual]`

Clones the object.

Reimplemented from wxRichTextParagraphLayoutBox.

void wxRichTextField::Copy (const wxRichTextField & *obj*)

virtual bool wxRichTextField::Draw (wxDC & *dc*, wxRichTextDrawingContext & *context*, const wxRichTextRange & *range*, const wxRichTextSelection & *selection*, const wxRect & *rect*, int *descent*, int *style*) `[virtual]`

Draw the item, within the given range.

Some objects may ignore the range (for example paragraphs) while others must obey it (lines, to implement wrapping)

Reimplemented from wxRichTextParagraphLayoutBox.

virtual bool wxRichTextField::EditProperties (wxWindow * *parent*, wxRichTextBuffer * *buffer*) `[virtual]`

Edits the object's properties via a GUI.

Reimplemented from wxRichTextObject.

wxString wxRichTextField::GetFieldType ( ) const `[inline]`

virtual wxString wxRichTextField::GetPropertiesMenuLabel ( ) const `[virtual]`

Returns the label to be used for the properties context menu item.

Reimplemented from wxRichTextObject.

virtual bool wxRichTextField::GetRangeSize (const wxRichTextRange & *range*, wxSize & *size*, int & *descent*, wxDC & *dc*, wxRichTextDrawingContext & *context*, int *flags*, const wxPoint & *position* = wxPoint(0, 0), const wxSize & *parentSize* = wxDefaultSize, wxArrayInt * *partialExtents* = NULL) const `[virtual]`

Returns the object size for the given range.

Returns false if the range is invalid for this object.

Reimplemented from wxRichTextParagraphLayoutBox.

virtual wxString wxRichTextField::GetXMLNodeName ( ) const `[inline], [virtual]`

Returns the XML node name of this object.

This must be overridden for wxXmlNode-base XML export to work.

Reimplemented from wxRichTextParagraphLayoutBox.

virtual bool wxRichTextField::IsAtomic ( ) const `[inline], [virtual]`

If a field has children, we don't want the user to be able to edit it.

Reimplemented from wxRichTextCompositeObject.

virtual bool wxRichTextField::IsEmpty ( ) const `[inline], [virtual]`

Returns true if the buffer is empty.

Reimplemented from wxRichTextCompositeObject.

virtual bool wxRichTextField::IsTopLevel ( ) const `[virtual]`

Returns true if this object is top-level, i.e. contains its own paragraphs, such as a text box.

Reimplemented from wxRichTextParagraphLayoutBox.

virtual bool wxRichTextField::Layout (wxDC & *dc,* wxRichTextDrawingContext & *context,* const wxRect & *rect,* const wxRect & *parentRect,* int *style*) `[virtual]`

Lay the item out at the specified position with the given size constraint.

Layout must set the cached size. *rect* is the available space for the object, and *parentRect* is the container that is used to determine a relative size or position (for example if a text box must be 50% of the parent text box).

Reimplemented from wxRichTextParagraphLayoutBox.

void wxRichTextField::SetFieldType (const wxString & *fieldType*) `[inline]`

virtual bool wxRichTextField::UpdateField (wxRichTextBuffer * *buffer*) `[virtual]`

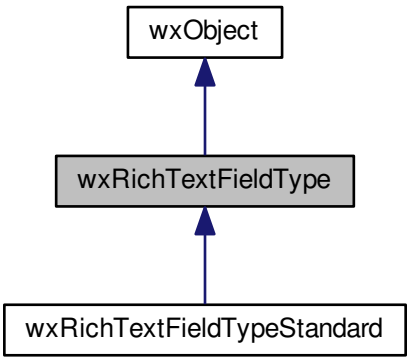
Update the field; delegated to the associated field type.

This would typically expand the field to its value, if this is a dynamically changing and/or composite field.

21.622 wxRichTextFieldType Class Reference

`#include <wx/richtext/richtextbuffer.h>`

Inheritance diagram for wxRichTextFieldType:



21.622.1 Detailed Description

The base class for custom field types.

Each type definition handles one field type. Override functions to provide drawing, layout, updating and property editing functionality for a field.

Register field types on application initialisation with the static function wxRichTextBuffer::AddFieldType. They will be deleted automatically on application exit.

virtual bool wxRichTextFieldType::Draw (wxRichTextField ∗ *obj,* wxDC & *dc,* wxRichTextDrawingContext & *context,* const wxRichTextRange & *range,* const wxRichTextSelection & *selection,* const wxRect & *rect,* int *descent,* int *style*) `[pure virtual]`

Draw the item, within the given range.

Some objects may ignore the range (for example paragraphs) while others must obey it (lines, to implement wrapping)

Implemented in wxRichTextFieldTypeStandard.

virtual bool wxRichTextFieldType::EditProperties (wxRichTextField * *obj*, wxWindow * *parent*, wxRichTextBuffer * *buffer*) [inline], [virtual]

Edits the object's properties via a GUI.

wxString wxRichTextFieldType::GetName ( ) const [inline]

Returns the field type name.

There should be a unique name per field type object.

virtual wxString wxRichTextFieldType::GetPropertiesMenuLabel (wxRichTextField * *obj*) const [inline], [virtual]

Returns the label to be used for the properties context menu item.

virtual bool wxRichTextFieldType::GetRangeSize (wxRichTextField * *obj*, const wxRichTextRange & *range*, wxSize & *size*, int & *descent*, wxDC & *dc*, wxRichTextDrawingContext & *context*, int *flags*, const wxPoint & *position* = wxPoint(0, 0), const wxSize & *parentSize* = wxDefaultSize, wxArrayInt * *partialExtents* = NULL) const [pure virtual]

Returns the object size for the given range.

Returns false if the range is invalid for this object.

Implemented in wxRichTextFieldTypeStandard.

virtual bool wxRichTextFieldType::IsTopLevel (wxRichTextField * *obj*) const [inline], [virtual]

Returns true if this object is top-level, i.e. contains its own paragraphs, such as a text box.

Reimplemented in wxRichTextFieldTypeStandard.

virtual bool wxRichTextFieldType::Layout (wxRichTextField * *obj*, wxDC & *dc*, wxRichTextDrawingContext & *context*, const wxRect & *rect*, const wxRect & *parentRect*, int *style*) [pure virtual]

Lay the item out at the specified position with the given size constraint.

Layout must set the cached size. *rect* is the available space for the object, and *parentRect* is the container that is used to determine a relative size or position (for example if a text box must be 50% of the parent text box).

Implemented in wxRichTextFieldTypeStandard.

void wxRichTextFieldType::SetName (const wxString & *name*) [inline]

Sets the field type name.

There should be a unique name per field type object.

virtual bool wxRichTextFieldType::UpdateField (wxRichTextBuffer * *buffer*, wxRichTextField * *obj*) [inline], [virtual]

Update the field.

This would typically expand the field to its value, if this is a dynamically changing and/or composite field.

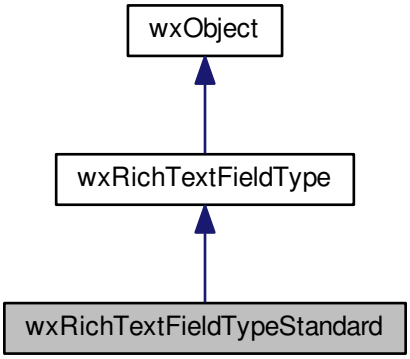
21.622.4 Member Data Documentation

wxString wxRichTextFieldType::m_name `[protected]`

21.623 wxRichTextFieldTypeStandard Class Reference

`#include <wx/richtext/richtextbuffer.h>`

Inheritance diagram for wxRichTextFieldTypeStandard:



21.623.1 Detailed Description

A field type that can handle fields with text or bitmap labels, with a small range of styles for implementing rectangular fields and fields that can be used for start and end tags.

The border, text and background colours can be customised; the default is white text on a black background.

The following display styles can be used.

Styles

This class supports the following styles:

- wxRICHTEXT_FIELD_STYLE_COMPOSITE: Creates a composite field; you will probably need to derive a new class to implement UpdateField.
- wxRICHTEXT_FIELD_STYLE_RECTANGLE: Shows a rounded rectangle background.
- wxRICHTEXT_FIELD_STYLE_NO_BORDER: Suppresses the background and border; mostly used with a bitmap label.
- wxRICHTEXT_FIELD_STYLE_START_TAG: Shows a start tag background, with the pointy end facing right.
- wxRICHTEXT_FIELD_STYLE_END_TAG: Shows an end tag background, with the pointy end facing left.

Library: wxRichText

  wxRICHTEXT_FIELD_STYLE_START_TAG = 0x08,
  wxRICHTEXT_FIELD_STYLE_END_TAG = 0x10 }

Public Member Functions

- wxRichTextFieldTypeStandard (const wxString &name, const wxString &label, int displayStyle=wxRICHTEXT_FIELD_STYLE_RECTANGLE)

  Constructor, creating a field type definition with a text label.
- wxRichTextFieldTypeStandard (const wxString &name, const wxBitmap &bitmap, int displayStyle=wxRICHTEXT_FIELD_STYLE_NO_BORDER)

  Constructor, creating a field type definition with a bitmap label.
- wxRichTextFieldTypeStandard ()

  The default constructor.
- wxRichTextFieldTypeStandard (const wxRichTextFieldTypeStandard &field)

  The copy constructor.
- void Init ()

  Initialises the object.
- void Copy (const wxRichTextFieldTypeStandard &field)

  Copies the object.
- void operator= (const wxRichTextFieldTypeStandard &field)

  The assignment operator.
- virtual bool Draw (wxRichTextField *obj, wxDC &dc, wxRichTextDrawingContext &context, const wxRichTextRange &range, const wxRichTextSelection &selection, const wxRect &rect, int descent, int style)

  Draw the item, within the given range.
- virtual bool Layout (wxRichTextField *obj, wxDC &dc, wxRichTextDrawingContext &context, const wxRect &rect, const wxRect &parentRect, int style)

  Lay the item out at the specified position with the given size constraint.
- virtual bool GetRangeSize (wxRichTextField *obj, const wxRichTextRange &range, wxSize &size, int &descent, wxDC &dc, wxRichTextDrawingContext &context, int flags, const wxPoint &position=wxPoint(0, 0), const wxSize &parentSize=wxDefaultSize, wxArrayInt *partialExtents=NULL) const

  Returns the object size for the given range.
- wxSize GetSize (wxRichTextField *obj, wxDC &dc, wxRichTextDrawingContext &context, int style) const

  Get the size of the field, given the label, font size, and so on.
- virtual bool IsTopLevel (wxRichTextField *obj) const

  Returns true if the display type is wxRICHTEXT_FIELD_STYLE_COMPOSITE, false otherwise.
- void SetLabel (const wxString &label)

  Sets the text label for fields of this type.
- const wxString & GetLabel () const

  Returns the text label for fields of this type.
- void SetBitmap (const wxBitmap &bitmap)

  Sets the bitmap label for fields of this type.

- const wxBitmap & GetBitmap () const

  Gets the bitmap label for fields of this type.
- int GetDisplayStyle () const

  Gets the display style for fields of this type.
- void SetDisplayStyle (int displayStyle)

  Sets the display style for fields of this type.
- const wxFont & GetFont () const

  Gets the font used for drawing the text label.
- void SetFont (const wxFont &font)

  Sets the font used for drawing the text label.
- const wxColour & GetTextColour () const

  Gets the colour used for drawing the text label.
- void SetTextColour (const wxColour &colour)

  Sets the colour used for drawing the text label.
- const wxColour & GetBorderColour () const

  Gets the colour used for drawing the field border.
- void SetBorderColour (const wxColour &colour)

  Sets the colour used for drawing the field border.
- const wxColour & GetBackgroundColour () const

  Gets the colour used for drawing the field background.
- void SetBackgroundColour (const wxColour &colour)

  Sets the colour used for drawing the field background.
- void SetVerticalPadding (int padding)

  Sets the vertical padding (the distance between the border and the text).
- int GetVerticalPadding () const

  Gets the vertical padding (the distance between the border and the text).
- void SetHorizontalPadding (int padding)

  Sets the horizontal padding (the distance between the border and the text).
- int GetHorizontalPadding () const

  Sets the horizontal padding (the distance between the border and the text).
- void SetHorizontalMargin (int margin)

  Sets the horizontal margin surrounding the field object.
- int GetHorizontalMargin () const

  Gets the horizontal margin surrounding the field object.
- void SetVerticalMargin (int margin)

  Sets the vertical margin surrounding the field object.
- int GetVerticalMargin () const

  Gets the vertical margin surrounding the field object.

21.623.3 Constructor & Destructor Documentation

wxRichTextFieldTypeStandard::wxRichTextFieldTypeStandard (const wxString & *name,* const wxString & *label,* int *displayStyle* = wxRICHTEXT_FIELD_STYLE_RECTANGLE)

Constructor, creating a field type definition with a text label.

Parameters

name	The name of the type definition. This must be unique, and is the type name used when adding a field to a control.
label	The text label to be shown on the field.
displayStyle	The display style: one of wxRICHTEXT_FIELD_STYLE_RECTANGLE, wxRICHTEXT_FIELD_STYLE_NO_BORDER, wxRICHTEXT_FIELD_STYLE_START_TAG, wxRICHTEXT_FIELD_STYLE_END_TAG.

wxRichTextFieldTypeStandard::wxRichTextFieldTypeStandard (const wxString & *name,* const wxBitmap & *bitmap,* int *displayStyle* = wxRICHTEXT_FIELD_STYLE_NO_BORDER)

Constructor, creating a field type definition with a bitmap label.

Parameters

name	The name of the type definition. This must be unique, and is the type name used when adding a field to a control.
bitmap	The bitmap label to be shown on the field.
displayStyle	The display style: one of wxRICHTEXT_FIELD_STYLE_RECTANGLE, wxRICHTEXT_FIELD_STYLE_NO_BORDER, wxRICHTEXT_FIELD_STYLE_START_TAG, wxRICHTEXT_FIELD_STYLE_END_TAG.

wxRichTextFieldTypeStandard::wxRichTextFieldTypeStandard ( ) [inline]

The default constructor.

wxRichTextFieldTypeStandard::wxRichTextFieldTypeStandard (const wxRichTextFieldTypeStandard & *field*) [inline]

The copy constructor.

21.623.4 Member Function Documentation

void wxRichTextFieldTypeStandard::Copy (const wxRichTextFieldTypeStandard & *field*)

Copies the object.

virtual bool wxRichTextFieldTypeStandard::Draw (wxRichTextField * *obj,* wxDC & *dc,* wxRichTextDrawingContext & *context,* const wxRichTextRange & *range,* const wxRichTextSelection & *selection,* const wxRect & *rect,* int *descent,* int *style*) [virtual]

Draw the item, within the given range.

Some objects may ignore the range (for example paragraphs) while others must obey it (lines, to implement wrapping)

Implements wxRichTextFieldType.

const wxColour& wxRichTextFieldTypeStandard::GetBackgroundColour ( ) const [inline]

Gets the colour used for drawing the field background.

const wxBitmap& wxRichTextFieldTypeStandard::GetBitmap ( ) const [inline]

Gets the bitmap label for fields of this type.

const wxColour& wxRichTextFieldTypeStandard::GetBorderColour ( ) const [inline]

Gets the colour used for drawing the field border.

int wxRichTextFieldTypeStandard::GetDisplayStyle ( ) const [inline]

Gets the display style for fields of this type.

const wxFont& wxRichTextFieldTypeStandard::GetFont ( ) const [inline]

Gets the font used for drawing the text label.

int wxRichTextFieldTypeStandard::GetHorizontalMargin ( ) const [inline]

Gets the horizontal margin surrounding the field object.

int wxRichTextFieldTypeStandard::GetHorizontalPadding ( ) const [inline]

Sets the horizontal padding (the distance between the border and the text).

const wxString& wxRichTextFieldTypeStandard::GetLabel ( ) const [inline]

Returns the text label for fields of this type.

virtual bool wxRichTextFieldTypeStandard::GetRangeSize (wxRichTextField * *obj*, const wxRichTextRange & *range*, wxSize & *size*, int & *descent*, wxDC & *dc*, wxRichTextDrawingContext & *context*, int *flags*, const wxPoint & *position* = wxPoint(0, 0), const wxSize & *parentSize* = wxDefaultSize, wxArrayInt * *partialExtents* = NULL) const [virtual]

Returns the object size for the given range.

Returns false if the range is invalid for this object.

Implements wxRichTextFieldType.

wxSize wxRichTextFieldTypeStandard::GetSize (wxRichTextField * *obj*, wxDC & *dc*, wxRichTextDrawingContext & *context*, int *style*) const

Get the size of the field, given the label, font size, and so on.

const wxColour& wxRichTextFieldTypeStandard::GetTextColour ( ) const [inline]

Gets the colour used for drawing the text label.

int wxRichTextFieldTypeStandard::GetVerticalMargin ( ) const [inline]

Gets the vertical margin surrounding the field object.

int wxRichTextFieldTypeStandard::GetVerticalPadding ( ) const [inline]

Gets the vertical padding (the distance between the border and the text).

void wxRichTextFieldTypeStandard::Init ( )

Initialises the object.

virtual bool wxRichTextFieldTypeStandard::IsTopLevel (wxRichTextField * *obj*) const [inline], [virtual]

Returns true if the display type is wxRICHTEXT_FIELD_STYLE_COMPOSITE, false otherwise.

Reimplemented from wxRichTextFieldType.

virtual bool wxRichTextFieldTypeStandard::Layout (wxRichTextField * *obj*, wxDC & *dc*, wxRichTextDrawingContext & *context*, const wxRect & *rect*, const wxRect & *parentRect*, int *style*) [virtual]

Lay the item out at the specified position with the given size constraint.

Layout must set the cached size. *rect* is the available space for the object, and *parentRect* is the container that is used to determine a relative size or position (for example if a text box must be 50% of the parent text box).

Implements wxRichTextFieldType.

void wxRichTextFieldTypeStandard::operator= (const wxRichTextFieldTypeStandard & *field*) [inline]

The assignment operator.

void wxRichTextFieldTypeStandard::SetBackgroundColour (const wxColour & *colour*) `[inline]`

Sets the colour used for drawing the field background.

void wxRichTextFieldTypeStandard::SetBitmap (const wxBitmap & *bitmap*) `[inline]`

Sets the bitmap label for fields of this type.

void wxRichTextFieldTypeStandard::SetBorderColour (const wxColour & *colour*) `[inline]`

Sets the colour used for drawing the field border.

void wxRichTextFieldTypeStandard::SetDisplayStyle (int *displayStyle*) `[inline]`

Sets the display style for fields of this type.

void wxRichTextFieldTypeStandard::SetFont (const wxFont & *font*) `[inline]`

Sets the font used for drawing the text label.

void wxRichTextFieldTypeStandard::SetHorizontalMargin (int *margin*) `[inline]`

Sets the horizontal margin surrounding the field object.

void wxRichTextFieldTypeStandard::SetHorizontalPadding (int *padding*) `[inline]`

Sets the horizontal padding (the distance between the border and the text).

void wxRichTextFieldTypeStandard::SetLabel (const wxString & *label*) `[inline]`

Sets the text label for fields of this type.

void wxRichTextFieldTypeStandard::SetTextColour (const wxColour & *colour*) `[inline]`

Sets the colour used for drawing the text label.

void wxRichTextFieldTypeStandard::SetVerticalMargin (int *margin*) `[inline]`

Sets the vertical margin surrounding the field object.

void wxRichTextFieldTypeStandard::SetVerticalPadding (int *padding*) `[inline]`

Sets the vertical padding (the distance between the border and the text).

wxRichTextBuffer, wxRichTextCtrl

Public Member Functions

- wxRichTextFileHandler (const wxString &name=wxEmptyString, const wxString &ext=wxEmptyString, int type=0)

Creates a file handler object.

- bool LoadFile (wxRichTextBuffer *buffer, wxInputStream &stream)

  Loads the buffer from a stream.
- bool SaveFile (wxRichTextBuffer *buffer, wxOutputStream &stream)

  Saves the buffer to a stream.
- virtual bool LoadFile (wxRichTextBuffer *buffer, const wxString &filename)

  Loads the buffer from a file.
- virtual bool SaveFile (wxRichTextBuffer *buffer, const wxString &filename)

  Saves the buffer to a file.
- virtual bool CanHandle (const wxString &filename) const

  Returns true if we handle this filename (if using files).
- virtual bool CanSave () const

  Returns true if we can save using this handler.
- virtual bool CanLoad () const

  Returns true if we can load using this handler.
- virtual bool IsVisible () const

  Returns true if this handler should be visible to the user.
- virtual void SetVisible (bool visible)

  Sets whether the handler should be visible to the user (via the application's load and save dialogs).
- void SetName (const wxString &name)

  Sets the name of the handler.
- wxString GetName () const

  Returns the name of the handler.
- void SetExtension (const wxString &ext)

  Sets the default extension to recognise.
- wxString GetExtension () const

  Returns the default extension to recognise.
- void SetType (int type)

  Sets the handler type.
- int GetType () const

  Returns the handler type.
- void SetFlags (int flags)

  Sets flags that change the behaviour of loading or saving.
- int GetFlags () const

  Returns flags controlling how loading and saving is done.
- void SetEncoding (const wxString &encoding)

  Sets the encoding to use when saving a file.
- const wxString & GetEncoding () const

  Returns the encoding to use when saving a file.

Protected Member Functions

- virtual bool DoLoadFile (wxRichTextBuffer *buffer, wxInputStream &stream)=0

  Override to load content from stream into buffer.
- virtual bool DoSaveFile (wxRichTextBuffer *buffer, wxOutputStream &stream)=0

  Override to save content to stream from buffer.

Protected Attributes

- wxString m_name
- wxString m_encoding
- wxString m_extension
- int m_type
- int m_flags
- bool m_visible

21.624.2 Constructor & Destructor Documentation

wxRichTextFileHandler::wxRichTextFileHandler (const wxString & *name* = wxEmptyString, const wxString & *ext* = wxEmptyString, int *type* = 0) `[inline]`

Creates a file handler object.

21.624.3 Member Function Documentation

virtual bool wxRichTextFileHandler::CanHandle (const wxString & *filename*) const `[virtual]`

Returns true if we handle this filename (if using files).

By default, checks the extension.

virtual bool wxRichTextFileHandler::CanLoad ( ) const `[inline]`, `[virtual]`

Returns true if we can load using this handler.

Reimplemented in wxRichTextPlainTextHandler, and wxRichTextXMLHandler.

virtual bool wxRichTextFileHandler::CanSave ( ) const `[inline]`, `[virtual]`

Returns true if we can save using this handler.

Reimplemented in wxRichTextPlainTextHandler, and wxRichTextXMLHandler.

virtual bool wxRichTextFileHandler::DoLoadFile (wxRichTextBuffer * *buffer*, wxInputStream & *stream*) `[protected]`, `[pure virtual]`

Override to load content from *stream* into *buffer*.

Implemented in wxRichTextPlainTextHandler, and wxRichTextXMLHandler.

virtual bool wxRichTextFileHandler::DoSaveFile (wxRichTextBuffer * *buffer*, wxOutputStream & *stream*) `[protected]`, `[pure virtual]`

Override to save content to *stream* from *buffer*.

Implemented in wxRichTextPlainTextHandler, wxRichTextHTMLHandler, and wxRichTextXMLHandler.

const wxString& wxRichTextFileHandler::GetEncoding ( ) const `[inline]`

Returns the encoding to use when saving a file.

If empty, a suitable encoding is chosen.

wxString wxRichTextFileHandler::GetExtension ( ) const [inline]

Returns the default extension to recognise.

int wxRichTextFileHandler::GetFlags ( ) const [inline]

Returns flags controlling how loading and saving is done.

wxString wxRichTextFileHandler::GetName ( ) const [inline]

Returns the name of the handler.

int wxRichTextFileHandler::GetType ( ) const [inline]

Returns the handler type.

virtual bool wxRichTextFileHandler::IsVisible ( ) const [inline], [virtual]

Returns true if this handler should be visible to the user.

bool wxRichTextFileHandler::LoadFile (wxRichTextBuffer * *buffer,* wxInputStream & *stream*) [inline]

Loads the buffer from a stream.

Not all handlers will implement file loading.

virtual bool wxRichTextFileHandler::LoadFile (wxRichTextBuffer * *buffer,* const wxString & *filename*) [virtual]

Loads the buffer from a file.

bool wxRichTextFileHandler::SaveFile (wxRichTextBuffer * *buffer,* wxOutputStream & *stream*) [inline]

Saves the buffer to a stream.

Not all handlers will implement file saving.

virtual bool wxRichTextFileHandler::SaveFile (wxRichTextBuffer * *buffer,* const wxString & *filename*) [virtual]

Saves the buffer to a file.

void wxRichTextFileHandler::SetEncoding (const wxString & *encoding*) [inline]

Sets the encoding to use when saving a file.

If empty, a suitable encoding is chosen.

void wxRichTextFileHandler::SetExtension (const wxString & *ext*) [inline]

Sets the default extension to recognise.

void wxRichTextFileHandler::SetFlags (int *flags*) [inline]

Sets flags that change the behaviour of loading or saving.

See the documentation for each handler class to see what flags are relevant for each handler.

You call this function directly if you are using a file handler explicitly (without going through the text control or buffer LoadFile/SaveFile API). Or, you can call the control or buffer's SetHandlerFlags function to set the flags that will be used for subsequent load and save operations.

void wxRichTextFileHandler::SetName (const wxString & *name*) [inline]

Sets the name of the handler.

void wxRichTextFileHandler::SetType (int *type*) [inline]

Sets the handler type.

virtual void wxRichTextFileHandler::SetVisible (bool *visible*) [inline], [virtual]

Sets whether the handler should be visible to the user (via the application's load and save dialogs).

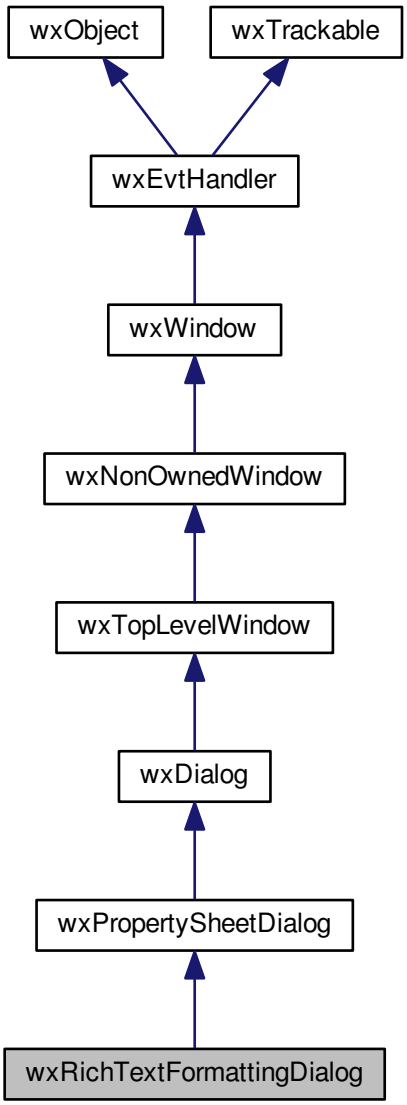
21.626 wxRichTextFormattingDialog Class Reference

`#include <wx/richtext/richtextformatdlg.h>`

Inheritance diagram for wxRichTextFormattingDialog:



21.626.1 Detailed Description

This dialog allows the user to edit a character and/or paragraph style.

In the constructor, specify the pages that will be created. Use wxRichTextFormattingDialog::GetStyle() to retrieve the common style for a given range, and then use wxRichTextFormattingDialog::ApplyStyle() to apply the user-selected formatting to a control.

For example:

```
wxRichTextRange range;
if (m_richTextCtrl-HasSelection())
    range = m_richTextCtrl-GetSelectionRange();
else
    range = wxRichTextRange(0, m_richTextCtrl-GetLastPosition()+1);

int pages = wxRICHTEXT_FORMAT_FONT|
      wxRICHTEXT_FORMAT_INDENTS_SPACING| \
            wxRICHTEXT_FORMAT_TABS|
      wxRICHTEXT_FORMAT_BULLETS;

wxRichTextFormattingDialog formatDlg(pages, this);
formatDlg.GetStyle(m_richTextCtrl, range);

if (formatDlg.ShowModal() == wxID_OK)
{
    formatDlg.ApplyStyle(m_richTextCtrl, range);
}
```

Library: wxRichText

Category: Rich Text

Public Types

- enum { Option_AllowPixelFontSize = 0x0001 }

Public Member Functions

- wxRichTextFormattingDialog ()

  Default ctor.
- wxRichTextFormattingDialog (long flags, wxWindow *parent, const wxString &title="Formatting", wxWindowID id=wxID_ANY, const wxPoint &pos=wxDefaultPosition, const wxSize &sz=wxDefaultSize, long style=wxDEFAULT_DIALOG_STYLE)

  Constructors.
- virtual ~wxRichTextFormattingDialog ()

  Destructor.
- virtual bool ApplyStyle (wxRichTextCtrl *ctrl, const wxRichTextRange &range, int flags=wxRICHTEXT_SETSTYLE_WITH_UNDO|wxRICHTEXT_SETSTYLE_OPTIMIZE)

  Apply attributes to the given range, only changing attributes that need to be changed.
- bool Create (long flags, wxWindow *parent, const wxString &title=wxGetTranslation("Formatting"), wxWindowID id=wxID_ANY, const wxPoint &pos=wxDefaultPosition, const wxSize &sz=wxDefaultSize, long style=wxDEFAULT_DIALOG_STYLE)

  Creation: see wxRichTextFormattingDialog() "the constructor" for details about the parameters.
- wxImageList * GetImageList () const

  Returns the image list associated with the dialog, used for example if showing the dialog as a toolbook.
- virtual bool GetStyle (wxRichTextCtrl *ctrl, const wxRichTextRange &range)

  Gets common attributes from the given range and calls SetAttributes().
- virtual wxRichTextStyleDefinition * GetStyleDefinition () const

  Gets the associated style definition, if any.
- virtual wxRichTextStyleSheet * GetStyleSheet () const

  Gets the associated style sheet, if any.

- void SetAttributes (const wxTextAttr &attr)

  Sets the attributes to be edited.
- void SetOptions (int options)

  Sets the dialog options, determining what the interface presents to the user.
- int GetOptions () const

  Gets the dialog options, determining what the interface presents to the user.
- bool HasOption (int option) const

  Returns true if the given option is present.
- void SetImageList (wxImageList *imageList)

  Sets the image list associated with the dialog's property sheet.
- virtual bool SetStyle (const wxTextAttr &style, bool update=true)

  Sets the attributes and optionally updates the display, if update is true.
- virtual bool SetStyleDefinition (const wxRichTextStyleDefinition &styleDef, wxRichTextStyleSheet *sheet, bool update=true)

  Sets the style definition and optionally update the display, if update is true.
- virtual bool UpdateDisplay ()

  Updates the display.

- const wxTextAttr & GetAttributes () const

  Gets the attributes being edited.
- wxTextAttr & GetAttributes ()

  Gets the attributes being edited.

Static Public Member Functions

- static wxRichTextFormattingDialog * GetDialog (wxWindow *win)

  Helper for pages to get the top-level dialog.
- static wxTextAttr * GetDialogAttributes (wxWindow *win)

  Helper for pages to get the attributes.
- static wxRichTextStyleDefinition * GetDialogStyleDefinition (wxWindow *win)

  Helper for pages to get the style.
- static wxRichTextFormattingDialogFactory * GetFormattingDialogFactory ()

  Returns the object to be used to customize the dialog and provide pages.
- static void SetFormattingDialogFactory (wxRichTextFormattingDialogFactory *factory)

  Sets the formatting factory object to be used for customization and page creation.
- static bool GetRestoreLastPage ()

  Returns true if the dialog will restore the last-selected page.
- static void SetRestoreLastPage (bool b)

  Pass true if the dialog should restore the last-selected page.
- static int GetLastPage ()

  Returns the page identifier of the last page selected (not the control id).
- static void SetLastPage (int lastPage)

  Sets the page identifier of the last page selected (not the control id).
- static void SetColourData (const wxColourData &colourData)

  Sets the custom colour data for use by the colour dialog.
- static wxColourData GetColourData ()

  Returns the custom colour data for use by the colour dialog.

virtual bool wxRichTextFormattingDialog::ApplyStyle (wxRichTextCtrl * *ctrl*, const wxRichTextRange & *range*, int *flags* = wxRICHTEXT_SETSTYLE_WITH_UNDO|wxRICHTEXT_SETSTYLE_OPTIMIZE) [virtual]

Apply attributes to the given range, only changing attributes that need to be changed.

bool wxRichTextFormattingDialog::Create (long *flags*, wxWindow * *parent*, const wxString & *title* = wxGetTranslation("Formatting"), wxWindowID *id* = wxID_ANY, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *sz* = wxDefaultSize, long *style* = wxDEFAULT_DIALOG_STYLE)

Creation: see wxRichTextFormattingDialog() "the constructor" for details about the parameters.

const wxTextAttr& wxRichTextFormattingDialog::GetAttributes ( ) const

Gets the attributes being edited.

wxTextAttr& wxRichTextFormattingDialog::GetAttributes ( )

Gets the attributes being edited.

static wxColourData wxRichTextFormattingDialog::GetColourData ( ) [static]

Returns the custom colour data for use by the colour dialog.

static wxRichTextFormattingDialog* wxRichTextFormattingDialog::GetDialog (wxWindow * *win*) [static]

Helper for pages to get the top-level dialog.

static wxTextAttr* wxRichTextFormattingDialog::GetDialogAttributes (wxWindow * *win*) [static]

Helper for pages to get the attributes.

static wxRichTextStyleDefinition* wxRichTextFormattingDialog::GetDialogStyleDefinition (wxWindow * *win*) [static]

Helper for pages to get the style.

static wxRichTextFormattingDialogFactory* wxRichTextFormattingDialog::GetFormattingDialogFactory ( ) [static]

Returns the object to be used to customize the dialog and provide pages.

wxImageList* wxRichTextFormattingDialog::GetImageList ( ) const

Returns the image list associated with the dialog, used for example if showing the dialog as a toolbook.

static int wxRichTextFormattingDialog::GetLastPage ( ) [static]

Returns the page identifier of the last page selected (not the control id).

int wxRichTextFormattingDialog::GetOptions ( ) const [inline]

Gets the dialog options, determining what the interface presents to the user.

Currently the only option is Option_AllowPixelFontSize.

static bool wxRichTextFormattingDialog::GetRestoreLastPage ( ) [static]

Returns true if the dialog will restore the last-selected page.

virtual bool wxRichTextFormattingDialog::GetStyle (wxRichTextCtrl * *ctrl*, const wxRichTextRange & *range*) [virtual]

Gets common attributes from the given range and calls SetAttributes().

Attributes that do not have common values in the given range will be omitted from the style's flags.

virtual wxRichTextStyleDefinition* wxRichTextFormattingDialog::GetStyleDefinition ( ) const [virtual]

Gets the associated style definition, if any.

virtual wxRichTextStyleSheet* wxRichTextFormattingDialog::GetStyleSheet ( ) const [virtual]

Gets the associated style sheet, if any.

bool wxRichTextFormattingDialog::HasOption (int *option*) const [inline]

Returns true if the given option is present.

void wxRichTextFormattingDialog::SetAttributes (const wxTextAttr & *attr*)

Sets the attributes to be edited.

static void wxRichTextFormattingDialog::SetColourData (const wxColourData & *colourData*) [static]

Sets the custom colour data for use by the colour dialog.

static void wxRichTextFormattingDialog::SetFormattingDialogFactory (wxRichTextFormattingDialogFactory * *factory*) [static]

Sets the formatting factory object to be used for customization and page creation.

It deletes the existing factory object.

void wxRichTextFormattingDialog::SetImageList (wxImageList * *imageList*)

Sets the image list associated with the dialog's property sheet.

static void wxRichTextFormattingDialog::SetLastPage (int *lastPage*) [static]

Sets the page identifier of the last page selected (not the control id).

void wxRichTextFormattingDialog::SetOptions (int *options*) [inline]

Sets the dialog options, determining what the interface presents to the user.

Currently the only option is Option_AllowPixelFontSize.

static void wxRichTextFormattingDialog::SetRestoreLastPage (bool *b*) [static]

Pass true if the dialog should restore the last-selected page.

virtual bool wxRichTextFormattingDialog::SetStyle (const wxTextAttr & *style,* bool *update* = true) [virtual]

Sets the attributes and optionally updates the display, if *update* is true.

virtual bool wxRichTextFormattingDialog::SetStyleDefinition (const wxRichTextStyleDefinition & *styleDef,* wxRichTextStyleSheet * *sheet,* bool *update* = `true`) [virtual]

Sets the style definition and optionally update the display, if *update* is true.

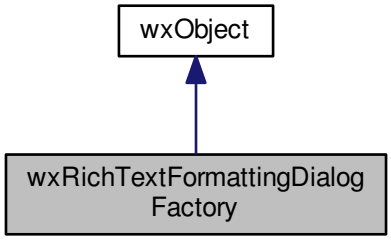
virtual bool wxRichTextFormattingDialog::UpdateDisplay ( ) [virtual]

Updates the display.

21.627 wxRichTextFormattingDialogFactory Class Reference

`#include <wx/richtext/richtextformatdlg.h>`

Inheritance diagram for wxRichTextFormattingDialogFactory:



21.627.1 Detailed Description

This class provides pages for wxRichTextFormattingDialog, and allows other customization of the dialog.

A default instance of this class is provided automatically. If you wish to change the behaviour of the formatting dialog (for example add or replace a page), you may derive from this class, override one or more functions, and call the static function wxRichTextFormattingDialog::SetFormattingDialogFactory.

Library: wxRichText

Category: Rich Text

Public Member Functions

- wxRichTextFormattingDialogFactory ()

  Constructor.
- virtual ~wxRichTextFormattingDialogFactory ()

  Destructor.
- virtual bool CreateButtons (wxRichTextFormattingDialog *dialog)

  Creates the main dialog buttons.
- virtual wxPanel * CreatePage (int page, wxString &title, wxRichTextFormattingDialog *dialog)

Creates a page, given a page identifier.

- virtual bool CreatePages (long pages, wxRichTextFormattingDialog *dialog)

  Creates all pages under the dialog's book control, also calling AddPage().
- virtual int GetPageId (int i) const

  Enumerate all available page identifiers.
- virtual int GetPageIdCount () const

  Gets the number of available page identifiers.
- virtual int GetPageImage (int id) const

  Gets the image index for the given page identifier.
- virtual bool SetSheetStyle (wxRichTextFormattingDialog *dialog)

  Set the property sheet style, called at the start of wxRichTextFormattingDialog::Create.
- virtual bool ShowHelp (int page, wxRichTextFormattingDialog *dialog)

  Invokes help for the dialog.

Additional Inherited Members

21.627.2 Constructor & Destructor Documentation

wxRichTextFormattingDialogFactory::wxRichTextFormattingDialogFactory ( )

Constructor.

virtual wxRichTextFormattingDialogFactory::~wxRichTextFormattingDialogFactory ( ) [virtual]

Destructor.

21.627.3 Member Function Documentation

virtual bool wxRichTextFormattingDialogFactory::CreateButtons (wxRichTextFormattingDialog * *dialog*) [virtual]

Creates the main dialog buttons.

virtual wxPanel* wxRichTextFormattingDialogFactory::CreatePage (int *page,* wxString & *title,* wxRichTextFormattingDialog * *dialog*) [virtual]

Creates a page, given a page identifier.

virtual bool wxRichTextFormattingDialogFactory::CreatePages (long *pages,* wxRichTextFormattingDialog * *dialog*) [virtual]

Creates all pages under the dialog's book control, also calling AddPage().

virtual int wxRichTextFormattingDialogFactory::GetPageId (int *i*) const [virtual]

Enumerate all available page identifiers.

virtual int wxRichTextFormattingDialogFactory::GetPageIdCount ( ) const [virtual]

Gets the number of available page identifiers.

virtual int wxRichTextFormattingDialogFactory::GetPageImage (int *id*) const `[virtual]`

Gets the image index for the given page identifier.

virtual bool wxRichTextFormattingDialogFactory::SetSheetStyle (wxRichTextFormattingDialog * *dialog*) `[virtual]`

Set the property sheet style, called at the start of wxRichTextFormattingDialog::Create.

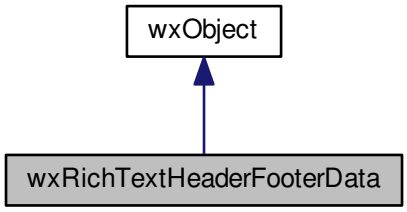
virtual bool wxRichTextFormattingDialogFactory::ShowHelp (int *page*, wxRichTextFormattingDialog * *dialog*) `[virtual]`

Invokes help for the dialog.

21.628 wxRichTextHeaderFooterData Class Reference

`#include <wx/richtext/richtextprint.h>`

Inheritance diagram for wxRichTextHeaderFooterData:



21.628.1 Detailed Description

This class represents header and footer data to be passed to the wxRichTextPrinting and wxRichTextPrintout classes.

Headers and footers can be specified independently for odd, even or both page sides. Different text can be specified for left, centre and right locations on the page, and the font and text colour can also be specified.

You can specify the following keywords in header and footer text, which will be substituted for the actual values during printing and preview.

- @DATE@: the current date.
- @PAGESCNT@: the total number of pages.
- @PAGENUM@: the current page number.
- @TIME@: the current time.
- @TITLE@: the title of the document, as passed to the wxRichTextPrinting or wxRichTextLayout constructor.

Library: wxRichText

Category: Rich Text

Public Member Functions

- void Clear ()

  Clears all text.
- void Copy (const wxRichTextHeaderFooterData &data)

  Copies the data.
- const wxFont & GetFont () const

  Returns the font specified for printing the header and footer.
- int GetFooterMargin () const

  Returns the margin between the text and the footer.
- wxString GetFooterText (wxRichTextOddEvenPage page=wxRICHTEXT_PAGE_EVEN, wxRichTextPageLocation location=wxRICHTEXT_PAGE_CENTRE) const

  Returns the footer text on odd or even pages, and at a given position on the page (left, centre or right).
- int GetHeaderMargin () const

  Returns the margin between the text and the header.
- wxString GetHeaderText (wxRichTextOddEvenPage page=wxRICHTEXT_PAGE_EVEN, wxRichTextPageLocation location=wxRICHTEXT_PAGE_CENTRE) const

  Returns the header text on odd or even pages, and at a given position on the page (left, centre or right).
- bool GetShowOnFirstPage () const

  Returns true if the header and footer will be shown on the first page.
- wxString GetText (int headerFooter, wxRichTextOddEvenPage page, wxRichTextPageLocation location) const

  Helper function for getting the header or footer text, odd or even pages, and at a given position on the page (left, centre or right).
- const wxColour & GetTextColour () const

  Returns the text colour for drawing the header and footer.
- void Init ()

  Initialises the object.
- void SetFont (const wxFont &font)

  Sets the font for drawing the header and footer.
- void SetFooterText (const wxString &text, wxRichTextOddEvenPage page=wxRICHTEXT_PAGE_ALL, wxRichTextPageLocation location=wxRICHTEXT_PAGE_CENTRE)

  Sets the footer text on odd or even pages, and at a given position on the page (left, centre or right).
- void SetHeaderText (const wxString &text, wxRichTextOddEvenPage page=wxRICHTEXT_PAGE_ALL, wxRichTextPageLocation location=wxRICHTEXT_PAGE_CENTRE)

  Sets the header text on odd or even pages, and at a given position on the page (left, centre or right).
- void SetMargins (int headerMargin, int footerMargin)

  Sets the margins between text and header or footer, in tenths of a millimeter.
- void SetShowOnFirstPage (bool showOnFirstPage)

  Pass true to show the header or footer on first page (the default).
- void SetText (const wxString &text, int headerFooter, wxRichTextOddEvenPage page, wxRichTextPageLocation location)

  Helper function for setting the header or footer text, odd or even pages, and at a given position on the page (left, centre or right).
- void SetTextColour (const wxColour &col)

  Sets the text colour for drawing the header and footer.
- void operator operator= (const wxRichTextHeaderFooterData &data)

Assignment operator.

- wxRichTextHeaderFooterData ()
  Constructors.
- wxRichTextHeaderFooterData (const wxRichTextHeaderFooterData &data)
  Constructors.

Additional Inherited Members

21.628.2 Constructor & Destructor Documentation

wxRichTextHeaderFooterData::wxRichTextHeaderFooterData ( )

Constructors.

wxRichTextHeaderFooterData::wxRichTextHeaderFooterData (const wxRichTextHeaderFooterData & *data*)

Constructors.

21.628.3 Member Function Documentation

void wxRichTextHeaderFooterData::Clear ( )

Clears all text.

void wxRichTextHeaderFooterData::Copy (const wxRichTextHeaderFooterData & *data*)

Copies the data.

const wxFont& wxRichTextHeaderFooterData::GetFont ( ) const

Returns the font specified for printing the header and footer.

int wxRichTextHeaderFooterData::GetFooterMargin ( ) const

Returns the margin between the text and the footer.

wxString wxRichTextHeaderFooterData::GetFooterText (wxRichTextOddEvenPage *page* = wxRICHTEXT_PAGE_EVEN, wxRichTextPageLocation *location* = wxRICHTEXT_PAGE_CENTRE) const

Returns the footer text on odd or even pages, and at a given position on the page (left, centre or right).

int wxRichTextHeaderFooterData::GetHeaderMargin ( ) const

Returns the margin between the text and the header.

wxString wxRichTextHeaderFooterData::GetHeaderText (wxRichTextOddEvenPage *page* = wxRICHTEXT_PAGE_EVEN, wxRichTextPageLocation *location* = wxRICHTEXT_PAGE_CENTRE) const

Returns the header text on odd or even pages, and at a given position on the page (left, centre or right).

bool wxRichTextHeaderFooterData::GetShowOnFirstPage ( ) const

Returns true if the header and footer will be shown on the first page.

wxString wxRichTextHeaderFooterData::GetText (int *headerFooter,* wxRichTextOddEvenPage *page,* wxRichTextPageLocation *location*) const

Helper function for getting the header or footer text, odd or even pages, and at a given position on the page (left, centre or right).

const wxColour& wxRichTextHeaderFooterData::GetTextColour ( ) const

Returns the text colour for drawing the header and footer.

void wxRichTextHeaderFooterData::Init ( )

Initialises the object.

void wxRichTextHeaderFooterData::operator operator= (const wxRichTextHeaderFooterData & *data*)

Assignment operator.

void wxRichTextHeaderFooterData::SetFont (const wxFont & *font*)

Sets the font for drawing the header and footer.

void wxRichTextHeaderFooterData::SetFooterText (const wxString & *text,* wxRichTextOddEvenPage *page* = wxRICHTEXT_PAGE_ALL, wxRichTextPageLocation *location* = wxRICHTEXT_PAGE_CENTRE)

Sets the footer text on odd or even pages, and at a given position on the page (left, centre or right).

void wxRichTextHeaderFooterData::SetHeaderText (const wxString & *text,* wxRichTextOddEvenPage *page* = wxRICHTEXT_PAGE_ALL, wxRichTextPageLocation *location* = wxRICHTEXT_PAGE_CENTRE)

Sets the header text on odd or even pages, and at a given position on the page (left, centre or right).

void wxRichTextHeaderFooterData::SetMargins (int *headerMargin,* int *footerMargin*)

Sets the margins between text and header or footer, in tenths of a millimeter.

void wxRichTextHeaderFooterData::SetShowOnFirstPage (bool *showOnFirstPage*)

Pass true to show the header or footer on first page (the default).

void wxRichTextHeaderFooterData::SetText (const wxString & *text,* int *headerFooter,* wxRichTextOddEvenPage *page,* wxRichTextPageLocation *location*)

Helper function for setting the header or footer text, odd or even pages, and at a given position on the page (left, centre or right).

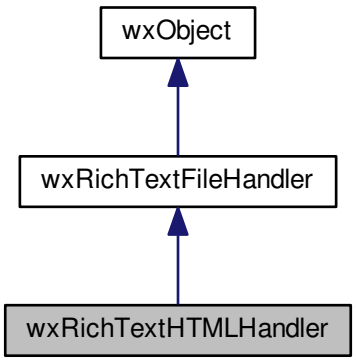
void wxRichTextHeaderFooterData::SetTextColour (const wxColour & *col*)

Sets the text colour for drawing the header and footer.

21.629 wxRichTextHTMLHandler Class Reference

`#include <wx/richtext/richtexthtml.h>`

Inheritance diagram for wxRichTextHTMLHandler:



21.629.1 Detailed Description

Handles HTML output (only) for wxRichTextCtrl content.

The most flexible way to use this class is to create a temporary object and call its functions directly, rather than use wxRichTextBuffer::SaveFile or wxRichTextCtrl::SaveFile.

Image handling requires a little extra work from the application, to choose an appropriate image format for the target HTML viewer and to clean up the temporary images later. If you are planning to load the HTML into a standard web browser, you can specify the handler flag wxRICHTEXT_HANDLER_SAVE_IMAGES_TO_BASE64 (the default) and no extra work is required: the images will be written with the HTML.

However, if you want wxHTML compatibility, you will need to use `wxRICHTEXT_HANDLER_SAVE_IMAGES_↩TO_MEMORY` or `wxRICHTEXT_HANDLER_SAVE_IMAGES_TO_FILES`.

In this case, you must either call wxRichTextHTMLHandler::DeleteTemporaryImages before the next load operation, or you must store the image locations and delete them yourself when appropriate.

You can call wxRichTextHTMLHandler::GetTemporaryImageLocations to get the array of temporary image names.

21.629.2 Handler flags

The following flags can be used with this handler, via the handler's SetFlags() function or the buffer or control's SetHandlerFlags() function:

- wxRICHTEXT_HANDLER_SAVE_IMAGES_TO_MEMORY Images are saved to the memory filesystem↩ : suitable for showing wxHTML windows.

- wxRICHTEXT_HANDLER_SAVE_IMAGES_TO_FILES Images are saved to temporary files: suitable for showing in wxHTML windows.
- wxRICHTEXT_HANDLER_SAVE_IMAGES_TO_BASE64 Images are written with the HTML files in Base 64 format: suitable for showing in web browsers.
- wxRICHTEXT_HANDLER_NO_HEADER_FOOTER Don't include header and footer tags (HTML, HEAD, BODY), so that the HTML can be used as part of a larger document.
- wxRICHTEXT_HANDLER_USE_CSS Use CSS where possible, otherwise use workarounds that will show in wxHtmlWindow.

Library: wxRichText

Category: Rich Text

Public Member Functions

- wxRichTextHTMLHandler (const wxString &name="HTML", const wxString &ext="html", int type=wxRICHTEXT_TYPE_HTML)

  Constructor.
- void ClearTemporaryImageLocations ()

  Clears the image locations generated by the last operation.
- bool DeleteTemporaryImages ()

  Deletes the in-memory or temporary files generated by the last operation.
- wxArrayInt GetFontSizeMapping () const

  Returns the mapping for converting point sizes to HTML font sizes.
- const wxString & GetTempDir () const

  Returns the directory used to store temporary image files.
- const wxArrayString & GetTemporaryImageLocations () const

  Returns the image locations for the last operation.
- void SetFontSizeMapping (const wxArrayInt &fontSizeMapping)

  Sets the mapping for converting point sizes to HTML font sizes.
- void SetTempDir (const wxString &tempDir)

  Sets the directory for storing temporary files.
- void SetTemporaryImageLocations (const wxArrayString &locations)

  Sets the list of image locations generated by the last operation.

Static Public Member Functions

- static bool DeleteTemporaryImages (int flags, const wxArrayString &imageLocations)

  Delete the in-memory or temporary files generated by the last operation.
- static void SetFileCounter (int counter)

  Reset the file counter, in case, for example, the same names are required each time.

Protected Member Functions

- virtual bool DoSaveFile (wxRichTextBuffer *buffer, wxOutputStream &stream)

  Saves the buffer content to the HTML stream.

Additional Inherited Members

21.629.3 Constructor & Destructor Documentation

wxRichTextHTMLHandler::wxRichTextHTMLHandler (const wxString & *name* = "HTML", const wxString & *ext* = "html", int *type* = wxRICHTEXT_TYPE_HTML)

Constructor.

21.629.4 Member Function Documentation

void wxRichTextHTMLHandler::ClearTemporaryImageLocations ( )

Clears the image locations generated by the last operation.

bool wxRichTextHTMLHandler::DeleteTemporaryImages ( )

Deletes the in-memory or temporary files generated by the last operation.

static bool wxRichTextHTMLHandler::DeleteTemporaryImages (int *flags*, const wxArrayString & *imageLocations*) [static]

Delete the in-memory or temporary files generated by the last operation.

This is a static function that can be used to delete the saved locations from an earlier operation, for example after the user has viewed the HTML file.

virtual bool wxRichTextHTMLHandler::DoSaveFile (wxRichTextBuffer * *buffer*, wxOutputStream & *stream*) [protected], [virtual]

Saves the buffer content to the HTML stream.

Implements wxRichTextFileHandler.

wxArrayInt wxRichTextHTMLHandler::GetFontSizeMapping ( ) const

Returns the mapping for converting point sizes to HTML font sizes.

const wxString& wxRichTextHTMLHandler::GetTempDir ( ) const

Returns the directory used to store temporary image files.

const wxArrayString& wxRichTextHTMLHandler::GetTemporaryImageLocations ( ) const

Returns the image locations for the last operation.

static void wxRichTextHTMLHandler::SetFileCounter (int *counter*) [static]

Reset the file counter, in case, for example, the same names are required each time.

void wxRichTextHTMLHandler::SetFontSizeMapping (const wxArrayInt & *fontSizeMapping*)

Sets the mapping for converting point sizes to HTML font sizes.

There should be 7 elements, one for each HTML font size, each element specifying the maximum point size for that HTML font size. For example:

```
wxArrayInt fontSizeMapping;
fontSizeMapping.Add(7);
fontSizeMapping.Add(9);
fontSizeMapping.Add(11);
fontSizeMapping.Add(12);
fontSizeMapping.Add(14);
fontSizeMapping.Add(22);
fontSizeMapping.Add(100);

htmlHandler.SetFontSizeMapping(fontSizeMapping);
```

void wxRichTextHTMLHandler::SetTempDir (const wxString & *tempDir*)

Sets the directory for storing temporary files.

If empty, the system temporary directory will be used.

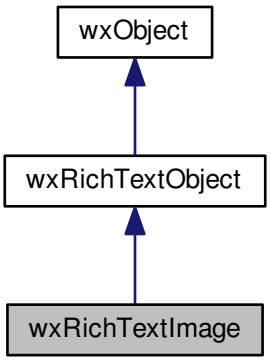
void wxRichTextHTMLHandler::SetTemporaryImageLocations (const wxArrayString & *locations*)

Sets the list of image locations generated by the last operation.

21.630 wxRichTextImage Class Reference

`#include <wx/richtext/richtextbuffer.h>`

Inheritance diagram for wxRichTextImage:



21.630.1 Detailed Description

This class implements a graphic object.

Library: wxRichText

Category: Rich Text

See also

wxRichTextBuffer, wxRichTextCtrl, wxRichTextImageBlock

Public Member Functions

- wxRichTextImage (wxRichTextObject *parent=NULL)

  Default constructor.
- wxRichTextImage (const wxImage &image, wxRichTextObject *parent=NULL, wxRichTextAttr *charStyle=NULL)

  Creates a wxRichTextImage from a wxImage.
- wxRichTextImage (const wxRichTextImageBlock &imageBlock, wxRichTextObject *parent=NULL, wxRichTextAttr *charStyle=NULL)

  Creates a wxRichTextImage from an image block.
- wxRichTextImage (const wxRichTextImage &obj)

  Copy constructor.
- virtual bool Draw (wxDC &dc, wxRichTextDrawingContext &context, const wxRichTextRange &range, const wxRichTextSelection &selection, const wxRect &rect, int descent, int style)

  Draw the item, within the given range.
- virtual bool Layout (wxDC &dc, wxRichTextDrawingContext &context, const wxRect &rect, const wxRect &parentRect, int style)

  Lay the item out at the specified position with the given size constraint.
- virtual bool GetRangeSize (const wxRichTextRange &range, wxSize &size, int &descent, wxDC &dc, wxRichTextDrawingContext &context, int flags, const wxPoint &position=wxPoint(0, 0), const wxSize &parentSize=wxDefaultSize, wxArrayInt *partialExtents=NULL) const

  Returns the object size for the given range.
- virtual wxTextAttrSize GetNaturalSize () const

  Returns the 'natural' size for this object - the image size.
- virtual bool IsEmpty () const

  Returns true if the object is empty.
- virtual bool CanEditProperties () const

  Returns true if we can edit the object's properties via a GUI.
- virtual bool EditProperties (wxWindow *parent, wxRichTextBuffer *buffer)

  Edits the object's properties via a GUI.
- virtual wxString GetPropertiesMenuLabel () const

  Returns the label to be used for the properties context menu item.
- virtual bool UsesParagraphAttributes () const

  Returns true if this object takes note of paragraph attributes (text and image objects don't).
- virtual bool ImportFromXML (wxRichTextBuffer *buffer, wxXmlNode *node, wxRichTextXMLHandler *handler, bool *recurse)

  Imports this object from XML.
- virtual bool IsFloatable () const

  Returns true if this class of object is floatable.
- virtual wxString GetXMLNodeName () const

  Returns the XML node name of this object.
- const wxBitmap & GetImageCache () const

  Returns the image cache (a scaled bitmap).

- void SetImageCache (const wxBitmap &bitmap)

  Sets the image cache.
- void ResetImageCache ()

  Resets the image cache.
- wxRichTextImageBlock & GetImageBlock ()

  Returns the image block containing the raw data.
- wxSize GetOriginalImageSize () const

  Gets the original image size.
- void SetOriginalImageSize (const wxSize &sz)

  Sets the original image size.
- void Copy (const wxRichTextImage &obj)

  Copies the image object.
- virtual wxRichTextObject * Clone () const

  Clones the image object.
- virtual bool LoadImageCache (wxDC &dc, wxRichTextDrawingContext &context, wxSize &retImageSize, bool resetCache=false, const wxSize &parentSize=wxDefaultSize)

  Creates a cached image at the required size.
- virtual bool LoadAndScaleImageCache (wxImage &image, const wxSize &sz, bool delayLoading, bool &changed)

  Do the loading and scaling.
- int GetImageState () const

  Gets the image state.
- void SetImageState (int state)

  Sets the image state.

Protected Attributes

- wxRichTextImageBlock m_imageBlock
- wxBitmap m_imageCache
- wxSize m_originalImageSize
- int m_imageState

Additional Inherited Members

21.630.2 Constructor & Destructor Documentation

wxRichTextImage::wxRichTextImage (wxRichTextObject * *parent* = `NULL`) `[inline]`

Default constructor.

wxRichTextImage::wxRichTextImage (const wxImage & *image*, wxRichTextObject * *parent* = `NULL`, wxRichTextAttr * *charStyle* = `NULL`)

Creates a wxRichTextImage from a wxImage.

wxRichTextImage::wxRichTextImage (const wxRichTextImageBlock & *imageBlock*, wxRichTextObject * *parent* = `NULL`, wxRichTextAttr * *charStyle* = `NULL`)

Creates a wxRichTextImage from an image block.

wxRichTextImage::wxRichTextImage (const wxRichTextImage & *obj*) `[inline]`

Copy constructor.

21.630.3 Member Function Documentation

virtual bool wxRichTextImage::CanEditProperties ( ) const `[inline], [virtual]`

Returns true if we can edit the object's properties via a GUI.

Reimplemented from wxRichTextObject.

virtual wxRichTextObject* wxRichTextImage::Clone ( ) const `[inline], [virtual]`

Clones the image object.

Reimplemented from wxRichTextObject.

void wxRichTextImage::Copy (const wxRichTextImage & *obj*)

Copies the image object.

virtual bool wxRichTextImage::Draw (wxDC & *dc*, wxRichTextDrawingContext & *context*, const wxRichTextRange & *range*, const wxRichTextSelection & *selection*, const wxRect & *rect*, int *descent*, int *style*) `[virtual]`

Draw the item, within the given range.

Some objects may ignore the range (for example paragraphs) while others must obey it (lines, to implement wrapping)

Implements wxRichTextObject.

virtual bool wxRichTextImage::EditProperties (wxWindow * *parent*, wxRichTextBuffer * *buffer*) `[virtual]`

Edits the object's properties via a GUI.

Reimplemented from wxRichTextObject.

wxRichTextImageBlock& wxRichTextImage::GetImageBlock ( ) `[inline]`

Returns the image block containing the raw data.

const wxBitmap& wxRichTextImage::GetImageCache ( ) const `[inline]`

Returns the image cache (a scaled bitmap).

int wxRichTextImage::GetImageState ( ) const `[inline]`

Gets the image state.

virtual wxTextAttrSize wxRichTextImage::GetNaturalSize ( ) const `[virtual]`

Returns the 'natural' size for this object - the image size.

Reimplemented from wxRichTextObject.

wxSize wxRichTextImage::GetOriginalImageSize ( ) const

Gets the original image size.

virtual wxString wxRichTextImage::GetPropertiesMenuLabel ( ) const `[inline], [virtual]`

Returns the label to be used for the properties context menu item.

Reimplemented from wxRichTextObject.

virtual bool wxRichTextImage::GetRangeSize (const wxRichTextRange & *range,* wxSize & *size,* int & *descent,* wxDC & *dc,* wxRichTextDrawingContext & *context,* int *flags,* const wxPoint & *position* = wxPoint(0, 0), const wxSize & *parentSize* = wxDefaultSize, wxArrayInt * *partialExtents* = NULL) const `[virtual]`

Returns the object size for the given range.

Returns false if the range is invalid for this object.

Implements wxRichTextObject.

virtual wxString wxRichTextImage::GetXMLNodeName ( ) const `[inline], [virtual]`

Returns the XML node name of this object.

This must be overridden for wxXmlNode-base XML export to work.

Reimplemented from wxRichTextObject.

virtual bool wxRichTextImage::ImportFromXML (wxRichTextBuffer * *buffer,* wxXmlNode * *node,* wxRichTextXMLHandler * *handler,* bool * *recurse*) `[virtual]`

Imports this object from XML.

Reimplemented from wxRichTextObject.

virtual bool wxRichTextImage::IsEmpty ( ) const `[inline], [virtual]`

Returns true if the object is empty.

Reimplemented from wxRichTextObject.

virtual bool wxRichTextImage::IsFloatable ( ) const `[inline], [virtual]`

Returns true if this class of object is floatable.

Reimplemented from wxRichTextObject.

virtual bool wxRichTextImage::Layout (wxDC & *dc,* wxRichTextDrawingContext & *context,* const wxRect & *rect,* const wxRect & *parentRect,* int *style*) `[virtual]`

Lay the item out at the specified position with the given size constraint.

Layout must set the cached size. *rect* is the available space for the object, and *parentRect* is the container that is used to determine a relative size or position (for example if a text box must be 50% of the parent text box).

Implements wxRichTextObject.

virtual bool wxRichTextImage::LoadAndScaleImageCache (wxImage & *image*, const wxSize & *sz*, bool *delayLoading*, bool & *changed*) [virtual]

Do the loading and scaling.

virtual bool wxRichTextImage::LoadImageCache (wxDC & *dc*, wxRichTextDrawingContext & *context*, wxSize & *retImageSize*, bool *resetCache* = false, const wxSize & *parentSize* = wxDefaultSize) [virtual]

Creates a cached image at the required size.

void wxRichTextImage::ResetImageCache ( ) [inline]

Resets the image cache.

void wxRichTextImage::SetImageCache (const wxBitmap & *bitmap*) [inline]

Sets the image cache.

void wxRichTextImage::SetImageState (int *state*) [inline]

Sets the image state.

void wxRichTextImage::SetOriginalImageSize (const wxSize & *sz*)

Sets the original image size.

virtual bool wxRichTextImage::UsesParagraphAttributes ( ) const [inline], [virtual]

Returns true if this object takes note of paragraph attributes (text and image objects don't).

Reimplemented from wxRichTextObject.

```

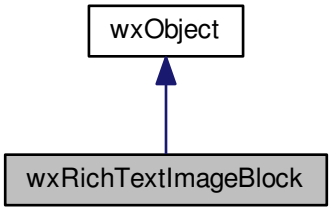
Inheritance diagram for wxRichTextImageBlock:



21.631.1 Detailed Description

This class stores information about an image, in binary in-memory form.

Library: wxRichText

Category: Rich Text

See also

wxRichTextBuffer, wxRichTextCtrl

Public Member Functions

- wxRichTextImageBlock ()

  Constructor.
- wxRichTextImageBlock (const wxRichTextImageBlock &block)

  Copy constructor.
- virtual ~wxRichTextImageBlock ()
- void Init ()

  Initialises the block.
- void Clear ()

  Clears the block.
- virtual bool MakeImageBlock (const wxString &filename, wxBitmapType imageType, wxImage &image, bool convertToJPEG=true)

  Load the original image into a memory block.
- virtual bool MakeImageBlock (wxImage &image, wxBitmapType imageType, int quality=80)

  Make an image block from the wxImage in the given format.
- virtual bool MakeImageBlockDefaultQuality (const wxImage &image, wxBitmapType imageType)

  Uses a const wxImage for efficiency, but can't set quality (only relevant for JPEG)
- virtual bool DoMakeImageBlock (const wxImage &image, wxBitmapType imageType)

  Makes the image block.
- bool Write (const wxString &filename)

  Writes the block to a file.
- bool WriteHex (wxOutputStream &stream)

Writes the data in hex to a stream.

- bool ReadHex (wxInputStream &stream, int length, wxBitmapType imageType)

  Reads the data in hex from a stream.
- void Copy (const wxRichTextImageBlock &block)

  Copy from block.
- bool Load (wxImage &image)
- void operator= (const wxRichTextImageBlock &block)

  Assignment operation.
- unsigned char * GetData () const

  Returns the raw data.
- size_t GetDataSize () const

  Returns the data size in bytes.
- wxBitmapType GetImageType () const

  Returns the image type.
- void SetData (unsigned char *image)
- void SetDataSize (size_t size)

  Sets the data size.
- void SetImageType (wxBitmapType imageType)

  Sets the image type.
- bool IsOk () const

  Returns true if the data is non-NULL.
- bool Ok () const
- wxString GetExtension () const

  Gets the extension for the block's type.

Static Public Member Functions

- static unsigned char * ReadBlock (wxInputStream &stream, size_t size)

  Implementation.
- static unsigned char * ReadBlock (const wxString &filename, size_t size)

  Allocates and reads from a file as a block of memory.
- static bool WriteBlock (wxOutputStream &stream, unsigned char *block, size_t size)

  Writes a memory block to stream.
- static bool WriteBlock (const wxString &filename, unsigned char *block, size_t size)

  Writes a memory block to a file.

Protected Attributes

- unsigned char * m_data
- size_t m_dataSize
- wxBitmapType m_imageType

Additional Inherited Members

21.631.2 Constructor & Destructor Documentation

wxRichTextImageBlock::wxRichTextImageBlock ( )

Constructor.

wxRichTextImageBlock::wxRichTextImageBlock (const wxRichTextImageBlock & *block*)

Copy constructor.

virtual wxRichTextImageBlock::~wxRichTextImageBlock ( ) [virtual]

21.631.3 Member Function Documentation

void wxRichTextImageBlock::Clear ( )

Clears the block.

void wxRichTextImageBlock::Copy (const wxRichTextImageBlock & *block*)

Copy from *block*.

virtual bool wxRichTextImageBlock::DoMakeImageBlock (const wxImage & *image,* wxBitmapType *imageType*) [virtual]

Makes the image block.

unsigned char* wxRichTextImageBlock::GetData ( ) const [inline]

Returns the raw data.

size_t wxRichTextImageBlock::GetDataSize ( ) const [inline]

Returns the data size in bytes.

wxString wxRichTextImageBlock::GetExtension ( ) const

Gets the extension for the block's type.

wxBitmapType wxRichTextImageBlock::GetImageType ( ) const [inline]

Returns the image type.

void wxRichTextImageBlock::Init ( )

Initialises the block.

bool wxRichTextImageBlock::IsOk ( ) const [inline]

Returns true if the data is non-NULL.

bool wxRichTextImageBlock::Load (wxImage & *image*)

virtual bool wxRichTextImageBlock::MakeImageBlock (const wxString & *filename,* wxBitmapType *imageType,* wxImage & *image,* bool *convertToJPEG* = `true`) `[virtual]`

Load the original image into a memory block.

If the image is not a JPEG, we must convert it into a JPEG to conserve space. If it's not a JPEG we can make use of *image*, already scaled, so we don't have to load the image a second time.

virtual bool wxRichTextImageBlock::MakeImageBlock (wxImage & *image,* wxBitmapType *imageType,* int *quality* = `80`) `[virtual]`

Make an image block from the wxImage in the given format.

virtual bool wxRichTextImageBlock::MakeImageBlockDefaultQuality (const wxImage & *image,* wxBitmapType *imageType*) `[virtual]`

Uses a const wxImage for efficiency, but can't set quality (only relevant for JPEG)

bool wxRichTextImageBlock::Ok ( ) const `[inline]`

void wxRichTextImageBlock::operator= (const wxRichTextImageBlock & *block*)

Assignment operation.

static unsigned char* wxRichTextImageBlock::ReadBlock (wxInputStream & *stream,* size_t *size*) `[static]`

Implementation.

Allocates and reads from a stream as a block of memory.

static unsigned char* wxRichTextImageBlock::ReadBlock (const wxString & *filename,* size_t *size*) `[static]`

Allocates and reads from a file as a block of memory.

bool wxRichTextImageBlock::ReadHex (wxInputStream & *stream,* int *length,* wxBitmapType *imageType*)

Reads the data in hex from a stream.

void wxRichTextImageBlock::SetData (unsigned char * *image*) `[inline]`

void wxRichTextImageBlock::SetDataSize (size_t *size*) `[inline]`

Sets the data size.

void wxRichTextImageBlock::SetImageType (wxBitmapType *imageType*) `[inline]`

Sets the image type.

bool wxRichTextImageBlock::Write (const wxString & *filename*)

Writes the block to a file.

static bool wxRichTextImageBlock::WriteBlock (wxOutputStream & *stream*, unsigned char * *block*, size_t *size*) `[static]`

Writes a memory block to stream.

static bool wxRichTextImageBlock::WriteBlock (const wxString & *filename*, unsigned char * *block*, size_t *size*) `[static]`

Writes a memory block to a file.

bool wxRichTextImageBlock::WriteHex (wxOutputStream & *stream*)

Writes the data in hex to a stream.

21.631.4 Member Data Documentation

unsigned char* wxRichTextImageBlock::m_data `[protected]`

size_t wxRichTextImageBlock::m_dataSize `[protected]`

wxBitmapType wxRichTextImageBlock::m_imageType `[protected]`

21.632 wxRichTextLine Class Reference

`#include <wx/richtext/richtextbuffer.h>`

21.632.1 Detailed Description

This object represents a line in a paragraph, and stores offsets from the start of the paragraph representing the start and end positions of the line.

Library: wxRichText

Category: Rich Text

See also

wxRichTextBuffer, wxRichTextCtrl

Public Member Functions

- wxRichTextLine (wxRichTextParagraph *parent)
- wxRichTextLine (const wxRichTextLine &obj)
- virtual ~wxRichTextLine ()
- void SetRange (const wxRichTextRange &range)

  Sets the range associated with this line.
- void SetRange (long from, long to)

  Sets the range associated with this line.
- wxRichTextParagraph * GetParent ()

  Returns the parent paragraph.

- const wxRichTextRange & GetRange () const

  Returns the range.
- wxRichTextRange & GetRange ()

  Returns the range.
- wxRichTextRange GetAbsoluteRange () const

  Returns the absolute range.
- virtual wxSize GetSize () const

  Returns the line size as calculated by Layout.
- virtual void SetSize (const wxSize &sz)

  Sets the line size as calculated by Layout.
- virtual wxPoint GetPosition () const

  Returns the object position relative to the parent.
- virtual void SetPosition (const wxPoint &pos)

  Sets the object position relative to the parent.
- virtual wxPoint GetAbsolutePosition () const

  Returns the absolute object position.
- virtual wxRect GetRect () const

  Returns the rectangle enclosing the line.
- void SetDescent (int descent)

  Sets the stored descent.
- int GetDescent () const

  Returns the stored descent.
- void Init (wxRichTextParagraph *parent)

  Initialises the object.
- void Copy (const wxRichTextLine &obj)

  Copies from obj.
- virtual wxRichTextLine * Clone () const

Protected Attributes

- wxRichTextRange m_range
- wxPoint m_pos
- wxSize m_size
- int m_descent
- wxRichTextParagraph * m_parent

virtual wxRichTextLine::~wxRichTextLine ( ) `[inline]`, `[virtual]`

21.632.3 Member Function Documentation

virtual wxRichTextLine* wxRichTextLine::Clone ( ) const `[inline]`, `[virtual]`

void wxRichTextLine::Copy (const wxRichTextLine & *obj*)

Copies from *obj*.

virtual wxPoint wxRichTextLine::GetAbsolutePosition ( ) const [virtual]

Returns the absolute object position.

wxRichTextRange wxRichTextLine::GetAbsoluteRange ( ) const

Returns the absolute range.

int wxRichTextLine::GetDescent ( ) const [inline]

Returns the stored descent.

wxRichTextParagraph* wxRichTextLine::GetParent ( ) [inline]

Returns the parent paragraph.

virtual wxPoint wxRichTextLine::GetPosition ( ) const [inline], [virtual]

Returns the object position relative to the parent.

const wxRichTextRange& wxRichTextLine::GetRange ( ) const [inline]

Returns the range.

wxRichTextRange& wxRichTextLine::GetRange ( ) [inline]

Returns the range.

virtual wxRect wxRichTextLine::GetRect ( ) const [inline], [virtual]

Returns the rectangle enclosing the line.

virtual wxSize wxRichTextLine::GetSize ( ) const [inline], [virtual]

Returns the line size as calculated by Layout.

void wxRichTextLine::Init (wxRichTextParagraph * *parent*)

Initialises the object.

void wxRichTextLine::SetDescent (int *descent*) [inline]

Sets the stored descent.

virtual void wxRichTextLine::SetPosition (const wxPoint & *pos*) [inline], [virtual]

Sets the object position relative to the parent.

void wxRichTextLine::SetRange (const wxRichTextRange & *range*) `[inline]`

Sets the range associated with this line.

void wxRichTextLine::SetRange (long *from,* long *to*) `[inline]`

Sets the range associated with this line.

virtual void wxRichTextLine::SetSize (const wxSize & *sz*) `[inline], [virtual]`

Sets the line size as calculated by Layout.

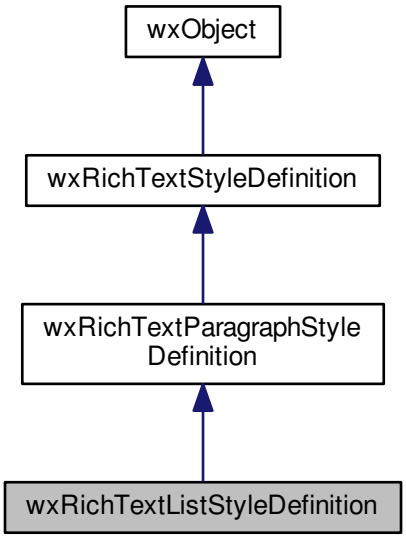
21.633 wxRichTextListStyleDefinition Class Reference

`#include <wx/richtext/richtextstyles.h>`

Inheritance diagram for wxRichTextListStyleDefinition:



21.633.1 Detailed Description

This class represents a list style definition, usually added to a wxRichTextStyleSheet.

The class inherits paragraph attributes from wxRichTextStyleParagraphDefinition, and adds 10 further attribute objects, one for each level of a list. When applying a list style to a paragraph, the list style's base and appropriate level attributes are merged with the paragraph's existing attributes.

You can apply a list style to one or more paragraphs using wxRichTextCtrl::SetListStyle. You can also use the functions wxRichTextCtrl::NumberList, wxRichTextCtrl::PromoteList and wxRichTextCtrl::ClearListStyle.

As usual, there are wxRichTextBuffer versions of these functions so that you can apply them directly to a buffer without requiring a control.

Library: wxRichText

Category: Rich Text

Public Member Functions

- wxRichTextListStyleDefinition (const wxString &name=wxEmptyString)

  Constructor.
- virtual ~wxRichTextListStyleDefinition ()

  Destructor.
- wxRichTextAttr CombineWithParagraphStyle (int indent, const wxRichTextAttr &paraStyle, wxRichTextStyleSheet *styleSheet=NULL)

  This function combines the given paragraph style with the list style's base attributes and level style matching the given indent, returning the combined attributes.
- int FindLevelForIndent (int indent) const

  This function finds the level (from 0 to 9) whose indentation attribute mostly closely matches indent (expressed in tenths of a millimetre).
- wxRichTextAttr GetCombinedStyle (int indent, wxRichTextStyleSheet *styleSheet=NULL)

  This function combines the list style's base attributes and the level style matching the given indent, returning the combined attributes.
- wxRichTextAttr GetCombinedStyleForLevel (int level, wxRichTextStyleSheet *styleSheet=NULL)

  This function combines the list style's base attributes and the style for the specified level, returning the combined attributes.
- const wxRichTextAttr * GetLevelAttributes (int level) const

  Returns the style for the given level.
- int GetLevelCount () const

  Returns the number of levels.
- bool IsNumbered (int level) const

  Returns true if the given level has numbered list attributes.
- void SetLevelAttributes (int level, const wxRichTextAttr &attr)

  Sets the style for the given level.

Additional Inherited Members

21.633.2 Constructor & Destructor Documentation

wxRichTextListStyleDefinition::wxRichTextListStyleDefinition (const wxString & *name* = wxEmptyString)

Constructor.

virtual wxRichTextListStyleDefinition::~wxRichTextListStyleDefinition ( ) [virtual]

Destructor.

21.633.3 Member Function Documentation

wxRichTextAttr wxRichTextListStyleDefinition::CombineWithParagraphStyle (int *indent,* const wxRichTextAttr & *paraStyle,* wxRichTextStyleSheet * *styleSheet* = NULL)

This function combines the given paragraph style with the list style's base attributes and level style matching the given indent, returning the combined attributes.

If *styleSheet* is specified, the base style for this definition will also be included in the result.

int wxRichTextListStyleDefinition::FindLevelForIndent (int *indent*) const

This function finds the level (from 0 to 9) whose indentation attribute mostly closely matches *indent* (expressed in tenths of a millimetre).

wxRichTextAttr wxRichTextListStyleDefinition::GetCombinedStyle (int *indent,* wxRichTextStyleSheet * *styleSheet* = NULL)

This function combines the list style's base attributes and the level style matching the given indent, returning the combined attributes.

If *styleSheet* is specified, the base style for this definition will also be included in the result.

wxRichTextAttr wxRichTextListStyleDefinition::GetCombinedStyleForLevel (int *level,* wxRichTextStyleSheet * *styleSheet* = NULL)

This function combines the list style's base attributes and the style for the specified level, returning the combined attributes.

If *styleSheet* is specified, the base style for this definition will also be included in the result.

const wxRichTextAttr* wxRichTextListStyleDefinition::GetLevelAttributes (int *level*) const

Returns the style for the given level.

level is a number between 0 and 9.

int wxRichTextListStyleDefinition::GetLevelCount ( ) const

Returns the number of levels.

This is hard-wired to 10. Returns the style for the given level. *level* is a number between 0 and 9.

bool wxRichTextListStyleDefinition::IsNumbered (int *level*) const

Returns true if the given level has numbered list attributes.

void wxRichTextListStyleDefinition::SetLevelAttributes (int *level,* const wxRichTextAttr & *attr*)

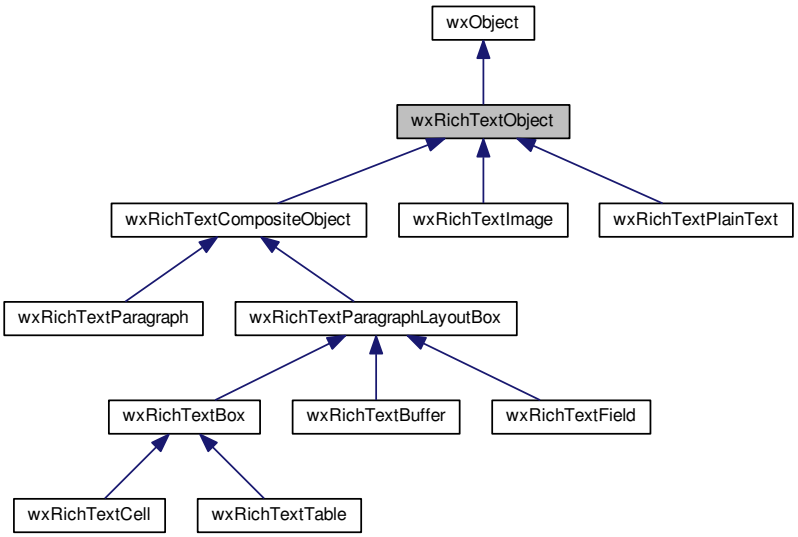
Sets the style for the given level.

level is a number between 0 and 9. The first and most flexible form uses a wxTextAttr object, while the second form is for convenient setting of the most commonly-used attributes.

21.634 wxRichTextObject Class Reference

`#include <wx/richtext/richtextbuffer.h>`

Inheritance diagram for wxRichTextObject:



21.634.1 Detailed Description

This is the base for drawable rich text objects.

Library: wxRichText

Category: Rich Text

See also

wxRichTextBuffer, wxRichTextCtrl

Public Member Functions

- wxRichTextObject (wxRichTextObject *parent=NULL)

  Constructor, taking an optional parent pointer.
- virtual ~wxRichTextObject ()
- virtual bool Draw (wxDC &dc, wxRichTextDrawingContext &context, const wxRichTextRange &range, const wxRichTextSelection &selection, const wxRect &rect, int descent, int style)=0

  Draw the item, within the given range.

- virtual bool Layout (wxDC &dc, wxRichTextDrawingContext &context, const wxRect &rect, const wxRect &parentRect, int style)=0

  Lay the item out at the specified position with the given size constraint.
- virtual int HitTest (wxDC &dc, wxRichTextDrawingContext &context, const wxPoint &pt, long &textPosition, wxRichTextObject **obj, wxRichTextObject **contextObj, int flags=0)

  Hit-testing: returns a flag indicating hit test details, plus information about position.
- virtual bool FindPosition (wxDC &dc, wxRichTextDrawingContext &context, long index, wxPoint &pt, int *height, bool forceLineStart)

  Finds the absolute position and row height for the given character position.
- virtual wxSize GetBestSize () const

  Returns the best size, i.e. the ideal starting size for this object irrespective of available space.
- virtual bool GetRangeSize (const wxRichTextRange &range, wxSize &size, int &descent, wxDC &dc, wxRichTextDrawingContext &context, int flags, const wxPoint &position=wxPoint(0, 0), const wxSize &parentSize=wxDefaultSize, wxArrayInt *partialExtents=NULL) const =0

  Returns the object size for the given range.
- virtual wxRichTextObject * DoSplit (long pos)

  Do a split from pos, returning an object containing the second part, and setting the first part in 'this'.
- virtual void CalculateRange (long start, long &end)

  Calculates the range of the object.
- virtual bool DeleteRange (const wxRichTextRange &range)

  Deletes the given range.
- virtual bool IsEmpty () const

  Returns true if the object is empty.
- virtual bool IsFloatable () const

  Returns true if this class of object is floatable.
- virtual bool IsFloating () const

  Returns true if this object is currently floating.
- virtual int GetFloatDirection () const

  Returns the floating direction.
- virtual wxString GetTextForRange (const wxRichTextRange &range) const

  Returns any text in this object for the given range.
- virtual bool CanMerge (wxRichTextObject *object, wxRichTextDrawingContext &context) const

  Returns true if this object can merge itself with the given one.
- virtual bool Merge (wxRichTextObject *object, wxRichTextDrawingContext &context)

  Returns true if this object merged itself with the given one.
- virtual bool CanSplit (wxRichTextDrawingContext &context) const

  Returns true if this object can potentially be split, by virtue of having different virtual attributes for individual sub-objects.
- virtual wxRichTextObject * Split (wxRichTextDrawingContext &context)

  Returns the final object in the split objects if this object was split due to differences between sub-object virtual attributes.
- virtual void Dump (wxTextOutputStream &stream)

  Dump object data to the given output stream for debugging.
- virtual bool CanEditProperties () const

  Returns true if we can edit the object's properties via a GUI.
- virtual bool EditProperties (wxWindow *parent, wxRichTextBuffer *buffer)

  Edits the object's properties via a GUI.
- virtual wxString GetPropertiesMenuLabel () const

  Returns the label to be used for the properties context menu item.
- virtual bool AcceptsFocus () const

  Returns true if objects of this class can accept the focus, i.e. a call to SetFocusObject is possible.

- virtual bool ImportFromXML (wxRichTextBuffer *buffer, wxXmlNode *node, wxRichTextXMLHandler *handler, bool *recurse)

  Imports this object from XML.
- virtual bool UsesParagraphAttributes () const

  Returns true if this object takes note of paragraph attributes (text and image objects don't).
- virtual wxString GetXMLNodeName () const

  Returns the XML node name of this object.
- virtual void Invalidate (const wxRichTextRange &invalidRange=wxRICHTEXT_ALL)

  Invalidates the object at the given range.
- virtual bool HandlesChildSelections () const

  Returns true if this object can handle the selections of its children, fOr example a table.
- virtual wxRichTextSelection GetSelection (long start, long end) const

  Returns a selection object specifying the selections between start and end character positions.
- virtual wxSize GetCachedSize () const

  Gets the cached object size as calculated by Layout.
- virtual void SetCachedSize (const wxSize &sz)

  Sets the cached object size as calculated by Layout.
- virtual wxSize GetMaxSize () const

  Gets the maximum object size as calculated by Layout.
- virtual void SetMaxSize (const wxSize &sz)

  Sets the maximum object size as calculated by Layout.
- virtual wxSize GetMinSize () const

  Gets the minimum object size as calculated by Layout.
- virtual void SetMinSize (const wxSize &sz)

  Sets the minimum object size as calculated by Layout.
- virtual wxTextAttrSize GetNaturalSize () const

  Gets the 'natural' size for an object.
- virtual wxPoint GetPosition () const

  Returns the object position in pixels.
- virtual void SetPosition (const wxPoint &pos)

  Sets the object position in pixels.
- virtual wxPoint GetAbsolutePosition () const

  Returns the absolute object position, by traversing up the child/parent hierarchy.
- virtual wxRect GetRect () const

  Returns the rectangle enclosing the object.
- void SetRange (const wxRichTextRange &range)

  Sets the object's range within its container.
- const wxRichTextRange & GetRange () const

  Returns the object's range.
- wxRichTextRange & GetRange ()

  Returns the object's range.
- void SetOwnRange (const wxRichTextRange &range)

  Set the object's own range, for a top-level object with its own position space.
- const wxRichTextRange & GetOwnRange () const

  Returns the object's own range (valid if top-level).
- wxRichTextRange & GetOwnRange ()

  Returns the object's own range (valid if top-level).
- wxRichTextRange GetOwnRangeIfTopLevel () const

  Returns the object's own range only if a top-level object.
- virtual bool IsComposite () const

  Returns true if this object is composite.

- virtual bool IsAtomic () const

  Returns true if no user editing can be done inside the object.
- virtual wxRichTextObject * GetParent () const

  Returns a pointer to the parent object.
- virtual void SetParent (wxRichTextObject *parent)

  Sets the pointer to the parent object.
- virtual wxRichTextParagraphLayoutBox * GetContainer () const

  Returns the top-level container of this object.
- virtual wxRichTextParagraphLayoutBox * GetParentContainer () const

  Returns the top-level container of this object.
- virtual void SetMargins (int margin)

  Set the margin around the object, in pixels.
- virtual void SetMargins (int leftMargin, int rightMargin, int topMargin, int bottomMargin)

  Set the margin around the object, in pixels.
- virtual int GetLeftMargin () const

  Returns the left margin of the object, in pixels.
- virtual int GetRightMargin () const

  Returns the right margin of the object, in pixels.
- virtual int GetTopMargin () const

  Returns the top margin of the object, in pixels.
- virtual int GetBottomMargin () const

  Returns the bottom margin of the object, in pixels.
- virtual wxRect GetAvailableContentArea (wxDC &dc, wxRichTextDrawingContext &context, const wxRect &outerRect) const

  Calculates the available content space in the given rectangle, given the margins, border and padding specified in the object's attributes.
- virtual bool LayoutToBestSize (wxDC &dc, wxRichTextDrawingContext &context, wxRichTextBuffer *buffer, const wxRichTextAttr &parentAttr, const wxRichTextAttr &attr, const wxRect &availableParentSpace, const wxRect &availableContainerSpace, int style)

  Lays out the object first with a given amount of space, and then if no width was specified in attr, lays out the object again using the minimum size.
- virtual bool AdjustAttributes (wxRichTextAttr &attr, wxRichTextDrawingContext &context)

  Adjusts the attributes for virtual attribute provision, collapsed borders, etc.
- void SetAttributes (const wxRichTextAttr &attr)

  Sets the object's attributes.
- const wxRichTextAttr & GetAttributes () const

  Returns the object's attributes.
- wxRichTextAttr & GetAttributes ()

  Returns the object's attributes.
- wxRichTextProperties & GetProperties ()

  Returns the object's properties.
- const wxRichTextProperties & GetProperties () const

  Returns the object's properties.
- void SetProperties (const wxRichTextProperties &props)

  Sets the object's properties.
- void SetDescent (int descent)

  Sets the stored descent value.
- int GetDescent () const

  Returns the stored descent value.
- wxRichTextBuffer * GetBuffer () const

Returns the containing buffer.

- void SetName (const wxString &name)

  Sets the identifying name for this object as a property using the "name" key.

- wxString GetName () const

  Returns the identifying name for this object from the properties, using the "name" key.

- virtual bool IsTopLevel () const

  Returns true if this object is top-level, i.e. contains its own paragraphs, such as a text box.

- bool IsShown () const

  Returns true if the object will be shown, false otherwise.

- virtual void Show (bool show)

  Call to show or hide this object.

- virtual wxRichTextObject * Clone () const

  Clones the object.

- void Copy (const wxRichTextObject &obj)

  Copies the object.

- void Reference ()

  Reference-counting allows us to use the same object in multiple lists (not yet used).

- void Dereference ()

  Reference-counting allows us to use the same object in multiple lists (not yet used).

- virtual void Move (const wxPoint &pt)

  Moves the object recursively, by adding the offset from old to new.

- int ConvertTenthsMMToPixels (wxDC &dc, int units) const

  Converts units in tenths of a millimetre to device units.

- int ConvertPixelsToTenthsMM (wxDC &dc, int pixels) const

  Convert units in pixels to tenths of a millimetre.

Static Public Member Functions

- static int ConvertTenthsMMToPixels (int ppi, int units, double scale=1.0)

  Converts units in tenths of a millimetre to device units.

- static int ConvertPixelsToTenthsMM (int ppi, int pixels, double scale=1.0)

  Convert units in pixels to tenths of a millimetre.

- static bool DrawBoxAttributes (wxDC &dc, wxRichTextBuffer *buffer, const wxRichTextAttr &attr, const wxRect &boxRect, int flags=0, wxRichTextObject *obj=NULL)

  Draws the borders and background for the given rectangle and attributes.

- static bool DrawBorder (wxDC &dc, wxRichTextBuffer *buffer, const wxRichTextAttr &attr, const wxTextAttr↩ Borders &borders, const wxRect &rect, int flags=0)

  Draws a border.

- static bool GetBoxRects (wxDC &dc, wxRichTextBuffer *buffer, const wxRichTextAttr &attr, wxRect &margin↩ Rect, wxRect &borderRect, wxRect &contentRect, wxRect &paddingRect, wxRect &outlineRect)

  Returns the various rectangles of the box model in pixels.

- static bool GetTotalMargin (wxDC &dc, wxRichTextBuffer *buffer, const wxRichTextAttr &attr, int &leftMargin, int &rightMargin, int &topMargin, int &bottomMargin)

  Returns the total margin for the object in pixels, taking into account margin, padding and border size.

- static wxRect AdjustAvailableSpace (wxDC &dc, wxRichTextBuffer *buffer, const wxRichTextAttr &parentAttr, const wxRichTextAttr &childAttr, const wxRect &availableParentSpace, const wxRect &availableContainer↩ Space)

  Returns the rectangle which the child has available to it given restrictions specified in the child attribute, e.g.

Protected Attributes

- wxSize m_size
- wxSize m_maxSize
- wxSize m_minSize
- wxPoint m_pos
- int m_descent
- int m_refCount
- bool m_show
- wxRichTextObject * m_parent
- wxRichTextRange m_range
- wxRichTextRange m_ownRange
- wxRichTextAttr m_attributes
- wxRichTextProperties m_properties

Additional Inherited Members

21.634.2 Constructor & Destructor Documentation

wxRichTextObject::wxRichTextObject (wxRichTextObject * *parent* = NULL)

Constructor, taking an optional parent pointer.

virtual wxRichTextObject::~wxRichTextObject ( ) [virtual]

21.634.3 Member Function Documentation

virtual bool wxRichTextObject::AcceptsFocus ( ) const [virtual]

Returns true if objects of this class can accept the focus, i.e. a call to SetFocusObject is possible.

For example, containers supporting text, such as a text box object, can accept the focus, but a table can't (set the focus to individual cells instead).

Reimplemented in wxRichTextTable, wxRichTextField, and wxRichTextParagraphLayoutBox.

virtual bool wxRichTextObject::AdjustAttributes (wxRichTextAttr & *attr,* wxRichTextDrawingContext & *context*) [virtual]

Adjusts the attributes for virtual attribute provision, collapsed borders, etc.

static wxRect wxRichTextObject::AdjustAvailableSpace (wxDC & *dc,* wxRichTextBuffer * *buffer,* const wxRichTextAttr & *parentAttr,* const wxRichTextAttr & *childAttr,* const wxRect & *availableParentSpace,* const wxRect & *availableContainerSpace*) [static]

Returns the rectangle which the child has available to it given restrictions specified in the child attribute, e.g.

50% width of the parent, 400 pixels, x position 20% of the parent, etc. availableContainerSpace might be a parent that the cell has to compute its width relative to. E.g. a cell that's 50% of its parent.

virtual void wxRichTextObject::CalculateRange (long *start,* long & *end*) [virtual]

Calculates the range of the object.

By default, guess that the object is 1 unit long.

Reimplemented in wxRichTextTable, wxRichTextPlainText, wxRichTextParagraph, wxRichTextField, and wxRichTextCompositeObject.

virtual bool wxRichTextObject::CanEditProperties ( ) const `[virtual]`

Returns true if we can edit the object's properties via a GUI.

Reimplemented in wxRichTextTable, wxRichTextCell, wxRichTextImage, wxRichTextField, and wxRichTextBox.

virtual bool wxRichTextObject::CanMerge (wxRichTextObject * *object,* wxRichTextDrawingContext & *context*) const `[virtual]`

Returns true if this object can merge itself with the given one.

Reimplemented in wxRichTextPlainText.

virtual bool wxRichTextObject::CanSplit (wxRichTextDrawingContext & *context*) const `[virtual]`

Returns true if this object can potentially be split, by virtue of having different virtual attributes for individual sub-objects.

Reimplemented in wxRichTextPlainText.

virtual wxRichTextObject* wxRichTextObject::Clone ( ) const `[virtual]`

Clones the object.

Reimplemented in wxRichTextTable, wxRichTextCell, wxRichTextBuffer, wxRichTextImage, wxRichTextPlainText, wxRichTextParagraph, wxRichTextField, wxRichTextBox, and wxRichTextParagraphLayoutBox.

int wxRichTextObject::ConvertPixelsToTenthsMM (wxDC & *dc,* int *pixels*) const

Convert units in pixels to tenths of a millimetre.

static int wxRichTextObject::ConvertPixelsToTenthsMM (int *ppi,* int *pixels,* double *scale* = `1.0`) `[static]`

Convert units in pixels to tenths of a millimetre.

int wxRichTextObject::ConvertTenthsMMToPixels (wxDC & *dc,* int *units*) const

Converts units in tenths of a millimetre to device units.

static int wxRichTextObject::ConvertTenthsMMToPixels (int *ppi,* int *units,* double *scale* = `1.0`) `[static]`

Converts units in tenths of a millimetre to device units.

void wxRichTextObject::Copy (const wxRichTextObject & *obj*)

Copies the object.

virtual bool wxRichTextObject::DeleteRange (const wxRichTextRange & *range*) [virtual]

Deletes the given range.

Reimplemented in wxRichTextTable, wxRichTextPlainText, wxRichTextParagraphLayoutBox, and wxRichTextCompositeObject.

void wxRichTextObject::Dereference ( )

Reference-counting allows us to use the same object in multiple lists (not yet used).

virtual wxRichTextObject* wxRichTextObject::DoSplit (long *pos*) [virtual]

Do a split from *pos*, returning an object containing the second part, and setting the first part in 'this'.

Reimplemented in wxRichTextPlainText.

virtual bool wxRichTextObject::Draw (wxDC & *dc,* wxRichTextDrawingContext & *context,* const wxRichTextRange & *range,* const wxRichTextSelection & *selection,* const wxRect & *rect,* int *descent,* int *style*) [pure virtual]

Draw the item, within the given range.

Some objects may ignore the range (for example paragraphs) while others must obey it (lines, to implement wrapping)

Implemented in wxRichTextTable, wxRichTextCell, wxRichTextImage, wxRichTextPlainText, wxRichTextParagraph, wxRichTextField, wxRichTextBox, and wxRichTextParagraphLayoutBox.

static bool wxRichTextObject::DrawBorder (wxDC & *dc,* wxRichTextBuffer * *buffer,* const wxRichTextAttr & *attr,* const wxTextAttrBorders & *borders,* const wxRect & *rect,* int *flags* = 0) [static]

Draws a border.

static bool wxRichTextObject::DrawBoxAttributes (wxDC & *dc,* wxRichTextBuffer * *buffer,* const wxRichTextAttr & *attr,* const wxRect & *boxRect,* int *flags* = 0, wxRichTextObject * *obj* = NULL) [static]

Draws the borders and background for the given rectangle and attributes.

boxRect is taken to be the outer margin box, not the box around the content.

virtual void wxRichTextObject::Dump (wxTextOutputStream & *stream*) [virtual]

Dump object data to the given output stream for debugging.

Reimplemented in wxRichTextBuffer, wxRichTextPlainText, and wxRichTextCompositeObject.

virtual bool wxRichTextObject::EditProperties (wxWindow * *parent,* wxRichTextBuffer * *buffer*) [virtual]

Edits the object's properties via a GUI.

Reimplemented in wxRichTextTable, wxRichTextCell, wxRichTextImage, wxRichTextField, and wxRichTextBox.

virtual bool wxRichTextObject::FindPosition (wxDC & *dc,* wxRichTextDrawingContext & *context,* long *index,* wxPoint & *pt,* int * *height,* bool *forceLineStart*) [virtual]

Finds the absolute position and row height for the given character position.

Reimplemented in wxRichTextTable, wxRichTextParagraph, and wxRichTextCompositeObject.

virtual wxPoint wxRichTextObject::GetAbsolutePosition ( ) const [virtual]

Returns the absolute object position, by traversing up the child/parent hierarchy.

TODO: may not be needed, if all object positions are in fact relative to the top of the coordinate space.

const wxRichTextAttr& wxRichTextObject::GetAttributes ( ) const

Returns the object's attributes.

wxRichTextAttr& wxRichTextObject::GetAttributes ( )

Returns the object's attributes.

virtual wxRect wxRichTextObject::GetAvailableContentArea (wxDC & *dc,* wxRichTextDrawingContext & *context,* const wxRect & *outerRect*) const [virtual]

Calculates the available content space in the given rectangle, given the margins, border and padding specified in the object's attributes.

virtual wxSize wxRichTextObject::GetBestSize ( ) const [virtual]

Returns the best size, i.e. the ideal starting size for this object irrespective of available space.

For a short text string, it will be the size that exactly encloses the text. For a longer string, it might use the parent width for example.

virtual int wxRichTextObject::GetBottomMargin ( ) const [virtual]

Returns the bottom margin of the object, in pixels.

static bool wxRichTextObject::GetBoxRects (wxDC & *dc,* wxRichTextBuffer * *buffer,* const wxRichTextAttr & *attr,* wxRect & *marginRect,* wxRect & *borderRect,* wxRect & *contentRect,* wxRect & *paddingRect,* wxRect & *outlineRect*) [static]

Returns the various rectangles of the box model in pixels.

You can either specify *contentRect* (inner) or *marginRect* (outer), and the other must be the default rectangle (no width or height). Note that the outline doesn't affect the position of the rectangle, it's drawn in whatever space is available.

wxRichTextBuffer* wxRichTextObject::GetBuffer ( ) const

Returns the containing buffer.

virtual wxSize wxRichTextObject::GetCachedSize ( ) const [virtual]

Gets the cached object size as calculated by Layout.

virtual wxRichTextParagraphLayoutBox* wxRichTextObject::GetContainer ( ) const [virtual]

Returns the top-level container of this object.

May return itself if it's a container; use GetParentContainer to return a different container.

int wxRichTextObject::GetDescent ( ) const

Returns the stored descent value.

virtual int wxRichTextObject::GetFloatDirection ( ) const [virtual]

Returns the floating direction.

virtual int wxRichTextObject::GetLeftMargin ( ) const [virtual]

Returns the left margin of the object, in pixels.

virtual wxSize wxRichTextObject::GetMaxSize ( ) const [virtual]

Gets the maximum object size as calculated by Layout.

This allows us to fit an object to its contents or allocate extra space if required.

virtual wxSize wxRichTextObject::GetMinSize ( ) const [virtual]

Gets the minimum object size as calculated by Layout.

This allows us to constrain an object to its absolute minimum size if necessary.

wxString wxRichTextObject::GetName ( ) const

Returns the identifying name for this object from the properties, using the "name" key.

virtual wxTextAttrSize wxRichTextObject::GetNaturalSize ( ) const [virtual]

Gets the 'natural' size for an object.

For an image, it would be the image size.

Reimplemented in wxRichTextImage.

const wxRichTextRange& wxRichTextObject::GetOwnRange ( ) const

Returns the object's own range (valid if top-level).

wxRichTextRange& wxRichTextObject::GetOwnRange ( )

Returns the object's own range (valid if top-level).

wxRichTextRange wxRichTextObject::GetOwnRangeIfTopLevel ( ) const

Returns the object's own range only if a top-level object.

virtual wxRichTextObject* wxRichTextObject::GetParent ( ) const [virtual]

Returns a pointer to the parent object.

virtual wxRichTextParagraphLayoutBox* wxRichTextObject::GetParentContainer ( ) const [virtual]

Returns the top-level container of this object.

Returns a different container than itself, unless there's no parent, in which case it will return NULL.

virtual wxPoint wxRichTextObject::GetPosition ( ) const [virtual]

Returns the object position in pixels.

wxRichTextProperties& wxRichTextObject::GetProperties ( )

Returns the object's properties.

const wxRichTextProperties& wxRichTextObject::GetProperties ( ) const

Returns the object's properties.

virtual wxString wxRichTextObject::GetPropertiesMenuLabel ( ) const [virtual]

Returns the label to be used for the properties context menu item.

Reimplemented in wxRichTextTable, wxRichTextCell, wxRichTextImage, wxRichTextField, and wxRichTextBox.

const wxRichTextRange& wxRichTextObject::GetRange ( ) const

Returns the object's range.

wxRichTextRange& wxRichTextObject::GetRange ( )

Returns the object's range.

virtual bool wxRichTextObject::GetRangeSize (const wxRichTextRange & *range,* wxSize & *size,* int & *descent,* wxDC & *dc,* wxRichTextDrawingContext & *context,* int *flags,* const wxPoint & *position* = wxPoint(0, 0), const wxSize & *parentSize* = wxDefaultSize, wxArrayInt * *partialExtents* = NULL) const [pure virtual]

Returns the object size for the given range.

Returns false if the range is invalid for this object.

Implemented in wxRichTextTable, wxRichTextImage, wxRichTextPlainText, wxRichTextParagraph, wxRichTextField, wxRichTextParagraphLayoutBox, and wxRichTextCompositeObject.

virtual wxRect wxRichTextObject::GetRect ( ) const [virtual]

Returns the rectangle enclosing the object.

virtual int wxRichTextObject::GetRightMargin ( ) const [virtual]

Returns the right margin of the object, in pixels.

virtual wxRichTextSelection wxRichTextObject::GetSelection (long *start*, long *end*) const [virtual]

Returns a selection object specifying the selections between start and end character positions.

For example, a table would deduce what cells (of range length 1) are selected when dragging across the table.

Reimplemented in wxRichTextTable.

virtual wxString wxRichTextObject::GetTextForRange (const wxRichTextRange & *range*) const [virtual]

Returns any text in this object for the given range.

Reimplemented in wxRichTextTable, wxRichTextPlainText, wxRichTextParagraphLayoutBox, and wxRichTextCompositeObject.

virtual int wxRichTextObject::GetTopMargin ( ) const [virtual]

Returns the top margin of the object, in pixels.

static bool wxRichTextObject::GetTotalMargin (wxDC & *dc*, wxRichTextBuffer * *buffer*, const wxRichTextAttr & *attr*, int & *leftMargin*, int & *rightMargin*, int & *topMargin*, int & *bottomMargin*) [static]

Returns the total margin for the object in pixels, taking into account margin, padding and border size.

virtual wxString wxRichTextObject::GetXMLNodeName ( ) const [virtual]

Returns the XML node name of this object.

This must be overridden for wxXmlNode-base XML export to work.

Reimplemented in wxRichTextTable, wxRichTextCell, wxRichTextImage, wxRichTextPlainText, wxRichTextParagraph, wxRichTextField, wxRichTextBox, and wxRichTextParagraphLayoutBox.

virtual bool wxRichTextObject::HandlesChildSelections ( ) const [virtual]

Returns true if this object can handle the selections of its children, fOr example a table.

Required for composite selection handling to work.

Reimplemented in wxRichTextTable.

virtual int wxRichTextObject::HitTest (wxDC & *dc*, wxRichTextDrawingContext & *context*, const wxPoint & *pt*, long & *textPosition*, wxRichTextObject ** *obj*, wxRichTextObject ** *contextObj*, int *flags* = 0) [virtual]

Hit-testing: returns a flag indicating hit test details, plus information about position.

contextObj is returned to specify what object position is relevant to, since otherwise there's an ambiguity. @ obj might not be a child of *contextObj*, since we may be referring to the container itself if we have no hit on a child - for example if we click outside an object.

The function puts the position in *textPosition* if one is found. *pt* is in logical units (a zero y position is at the beginning of the buffer).

Returns

One of the wxRichTextHitTestFlags values.

Reimplemented in wxRichTextTable, wxRichTextCell, wxRichTextBuffer, wxRichTextParagraph, wxRichTextParagraphLayoutBox, and wxRichTextCompositeObject.

virtual bool wxRichTextObject::ImportFromXML (wxRichTextBuffer * *buffer,* wxXmlNode * *node,* wxRichTextXMLHandler * *handler,* bool * *recurse*) [virtual]

Imports this object from XML.

Reimplemented in wxRichTextTable, wxRichTextImage, wxRichTextPlainText, and wxRichTextParagraphLayoutBox.

virtual void wxRichTextObject::Invalidate (const wxRichTextRange & *invalidRange* = wxRICHTEXT_ALL) [virtual]

Invalidates the object at the given range.

With no argument, invalidates the whole object.

Reimplemented in wxRichTextParagraphLayoutBox, and wxRichTextCompositeObject.

virtual bool wxRichTextObject::IsAtomic ( ) const [virtual]

Returns true if no user editing can be done inside the object.

This returns true for simple objects, false for most composite objects, but true for fields, which if composite, should not be user-edited.

Reimplemented in wxRichTextField, and wxRichTextCompositeObject.

virtual bool wxRichTextObject::IsComposite ( ) const [virtual]

Returns true if this object is composite.

Reimplemented in wxRichTextCompositeObject.

virtual bool wxRichTextObject::IsEmpty ( ) const [virtual]

Returns true if the object is empty.

Reimplemented in wxRichTextImage, wxRichTextPlainText, wxRichTextField, and wxRichTextCompositeObject.

virtual bool wxRichTextObject::IsFloatable ( ) const [virtual]

Returns true if this class of object is floatable.

Reimplemented in wxRichTextImage.

virtual bool wxRichTextObject::IsFloating ( ) const [virtual]

Returns true if this object is currently floating.

bool wxRichTextObject::IsShown ( ) const

Returns true if the object will be shown, false otherwise.

virtual bool wxRichTextObject::IsTopLevel ( ) const [virtual]

Returns true if this object is top-level, i.e. contains its own paragraphs, such as a text box.

Reimplemented in wxRichTextField, and wxRichTextParagraphLayoutBox.

virtual bool wxRichTextObject::Layout (wxDC & *dc,* wxRichTextDrawingContext & *context,* const wxRect & *rect,* const wxRect & *parentRect,* int *style*) [pure virtual]

Lay the item out at the specified position with the given size constraint.

Layout must set the cached size. *rect* is the available space for the object, and *parentRect* is the container that is used to determine a relative size or position (for example if a text box must be 50% of the parent text box).

Implemented in wxRichTextTable, wxRichTextImage, wxRichTextPlainText, wxRichTextParagraph, wxRichTextField, and wxRichTextParagraphLayoutBox.

virtual bool wxRichTextObject::LayoutToBestSize (wxDC & *dc,* wxRichTextDrawingContext & *context,* wxRichTextBuffer * *buffer,* const wxRichTextAttr & *parentAttr,* const wxRichTextAttr & *attr,* const wxRect & *availableParentSpace,* const wxRect & *availableContainerSpace,* int *style*) [virtual]

Lays out the object first with a given amount of space, and then if no width was specified in attr, lays out the object again using the minimum size.

availableParentSpace is the maximum space for the object, whereas *availableContainerSpace* is the container with which relative positions and sizes should be computed. For example, a text box whose space has already been constrained in a previous layout pass to *availableParentSpace*, but should have a width of 50% of *availableContainerSpace*. (If these two rects were the same, a 2nd pass could see the object getting too small.)

virtual bool wxRichTextObject::Merge (wxRichTextObject * *object,* wxRichTextDrawingContext & *context*) [virtual]

Returns true if this object merged itself with the given one.

The calling code will then delete the given object.

Reimplemented in wxRichTextPlainText.

virtual void wxRichTextObject::Move (const wxPoint & *pt*) [virtual]

Moves the object recursively, by adding the offset from old to new.

Reimplemented in wxRichTextCompositeObject.

void wxRichTextObject::Reference ( )

Reference-counting allows us to use the same object in multiple lists (not yet used).

void wxRichTextObject::SetAttributes (const wxRichTextAttr & *attr*)

Sets the object's attributes.

virtual void wxRichTextObject::SetCachedSize (const wxSize & *sz*) [virtual]

Sets the cached object size as calculated by Layout.

void wxRichTextObject::SetDescent (int *descent*)

Sets the stored descent value.

virtual void wxRichTextObject::SetMargins (int *margin*) [virtual]

Set the margin around the object, in pixels.

virtual void wxRichTextObject::SetMargins (int *leftMargin,* int *rightMargin,* int *topMargin,* int *bottomMargin*) [virtual]

Set the margin around the object, in pixels.

virtual void wxRichTextObject::SetMaxSize (const wxSize & *sz*) [virtual]

Sets the maximum object size as calculated by Layout.

This allows us to fit an object to its contents or allocate extra space if required.

virtual void wxRichTextObject::SetMinSize (const wxSize & *sz*) [virtual]

Sets the minimum object size as calculated by Layout.

This allows us to constrain an object to its absolute minimum size if necessary.

void wxRichTextObject::SetName (const wxString & *name*)

Sets the identifying name for this object as a property using the "name" key.

void wxRichTextObject::SetOwnRange (const wxRichTextRange & *range*)

Set the object's own range, for a top-level object with its own position space.

virtual void wxRichTextObject::SetParent (wxRichTextObject * *parent*) [virtual]

Sets the pointer to the parent object.

virtual void wxRichTextObject::SetPosition (const wxPoint & *pos*) [virtual]

Sets the object position in pixels.

void wxRichTextObject::SetProperties (const wxRichTextProperties & *props*)

Sets the object's properties.

void wxRichTextObject::SetRange (const wxRichTextRange & *range*)

Sets the object's range within its container.

virtual void wxRichTextObject::Show (bool *show*) `[virtual]`

Call to show or hide this object.

This function does not cause the content to be laid out or redrawn.

virtual wxRichTextObject* wxRichTextObject::Split (wxRichTextDrawingContext & *context*) `[virtual]`

Returns the final object in the split objects if this object was split due to differences between sub-object virtual attributes.

Returns itself if it was not split.

Reimplemented in wxRichTextPlainText.

virtual bool wxRichTextObject::UsesParagraphAttributes ( ) const `[virtual]`

Returns true if this object takes note of paragraph attributes (text and image objects don't).

Reimplemented in wxRichTextImage, and wxRichTextPlainText.

21.635 wxRichTextObjectAddress Class Reference

`#include <wx/richtext/richtextbuffer.h>`

21.635.1 Detailed Description

A class for specifying an object anywhere in an object hierarchy, without using a pointer, necessary since wxRTC commands may delete and recreate sub-objects so physical object addresses change.

An array of positions (one per hierarchy level) is used.

Library: wxRichText

Category: Rich Text

wxRichTextCommand

Public Member Functions

- wxRichTextObjectAddress (wxRichTextParagraphLayoutBox *topLevelContainer, wxRichTextObject *obj)
  Creates the address given a container and an object.
- wxRichTextObjectAddress ()
- wxRichTextObjectAddress (const wxRichTextObjectAddress &address)
- void Init ()
- void Copy (const wxRichTextObjectAddress &address)
  Copies the address.
- void operator= (const wxRichTextObjectAddress &address)
  Assignment operator.
- wxRichTextObject * GetObject (wxRichTextParagraphLayoutBox *topLevelContainer) const
  Returns the object specified by the address, given a top level container.
- bool Create (wxRichTextParagraphLayoutBox *topLevelContainer, wxRichTextObject *obj)
  Creates the address given a container and an object.
- wxArrayInt & GetAddress ()
  Returns the array of integers representing the object address.
- const wxArrayInt & GetAddress () const
  Returns the array of integers representing the object address.
- void SetAddress (const wxArrayInt &address)
  Sets the address from an array of integers.

Protected Attributes

- wxArrayInt m_address

21.635.2 Constructor & Destructor Documentation

wxRichTextObjectAddress::wxRichTextObjectAddress (wxRichTextParagraphLayoutBox * *topLevelContainer,* wxRichTextObject * *obj*) `[inline]`

Creates the address given a container and an object.

wxRichTextObjectAddress::wxRichTextObjectAddress ( ) `[inline]`

wxRichTextObjectAddress::wxRichTextObjectAddress (const wxRichTextObjectAddress & *address*) `[inline]`

21.635.3 Member Function Documentation

void wxRichTextObjectAddress::Copy (const wxRichTextObjectAddress & *address*) `[inline]`

Copies the address.

bool wxRichTextObjectAddress::Create (wxRichTextParagraphLayoutBox * *topLevelContainer,* wxRichTextObject * *obj*)

Creates the address given a container and an object.

wxArrayInt& wxRichTextObjectAddress::GetAddress ( ) [inline]

Returns the array of integers representing the object address.

const wxArrayInt& wxRichTextObjectAddress::GetAddress ( ) const [inline]

Returns the array of integers representing the object address.

wxRichTextObject* wxRichTextObjectAddress::GetObject (wxRichTextParagraphLayoutBox * *topLevelContainer*) const

Returns the object specified by the address, given a top level container.

void wxRichTextObjectAddress::Init ( ) [inline]

void wxRichTextObjectAddress::operator= (const wxRichTextObjectAddress & *address*) [inline]

Assignment operator.

void wxRichTextObjectAddress::SetAddress (const wxArrayInt & *address*) [inline]

Sets the address from an array of integers.

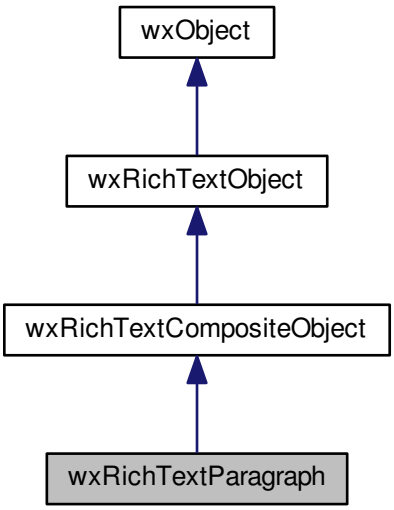
21.636 wxRichTextParagraph Class Reference

```
#include <wx/richtext/richtextbuffer.h>
```

Inheritance diagram for wxRichTextParagraph:



21.636.1 Detailed Description

This object represents a single paragraph containing various objects such as text content, images, and further paragraph layout objects.

Library: wxRichText

Category: Rich Text

See also

wxRichTextBuffer, wxRichTextCtrl

Public Member Functions

- wxRichTextParagraph (wxRichTextObject *parent=NULL, wxRichTextAttr *style=NULL)

  Constructor taking a parent and style.
- wxRichTextParagraph (const wxString &text, wxRichTextObject *parent=NULL, wxRichTextAttr *paraStyle=NULL, wxRichTextAttr *charStyle=NULL)

  Constructor taking a text string, a parent and paragraph and character attributes.
- virtual ~wxRichTextParagraph ()
- wxRichTextParagraph (const wxRichTextParagraph &obj)
- void Init ()
- virtual bool Draw (wxDC &dc, wxRichTextDrawingContext &context, const wxRichTextRange &range, const wxRichTextSelection &selection, const wxRect &rect, int descent, int style)

  Draw the item, within the given range.
- virtual bool Layout (wxDC &dc, wxRichTextDrawingContext &context, const wxRect &rect, const wxRect &parentRect, int style)

Lay the item out at the specified position with the given size constraint.

- virtual bool GetRangeSize (const wxRichTextRange &range, wxSize &size, int &descent, wxDC &dc, wxRichTextDrawingContext &context, int flags, const wxPoint &position=wxPoint(0, 0), const wxSize &parentSize=wxDefaultSize, wxArrayInt *partialExtents=NULL) const

  Returns the object size for the given range.
- virtual bool FindPosition (wxDC &dc, wxRichTextDrawingContext &context, long index, wxPoint &pt, int *height, bool forceLineStart)

  Finds the absolute position and row height for the given character position.
- virtual int HitTest (wxDC &dc, wxRichTextDrawingContext &context, const wxPoint &pt, long &textPosition, wxRichTextObject **obj, wxRichTextObject **contextObj, int flags=0)

  Hit-testing: returns a flag indicating hit test details, plus information about position.
- virtual void CalculateRange (long start, long &end)

  Calculates the range of the object.
- virtual wxString GetXMLNodeName () const

  Returns the XML node name of this object.
- wxRichTextLineList & GetLines ()

  Returns the cached lines.
- void Copy (const wxRichTextParagraph &obj)

  Copies the object.
- virtual wxRichTextObject * Clone () const

  Clones the object.
- void ClearLines ()

  Clears the cached lines.
- virtual void ApplyParagraphStyle (wxRichTextLine *line, const wxRichTextAttr &attr, const wxRect &rect, wxDC &dc)

  Applies paragraph styles such as centering to the wrapped lines.
- virtual bool InsertText (long pos, const wxString &text)

  Inserts text at the given position.
- virtual wxRichTextObject * SplitAt (long pos, wxRichTextObject **previousObject=NULL)

  Splits an object at this position if necessary, and returns the previous object, or NULL if inserting at the beginning.
- virtual void MoveToList (wxRichTextObject *obj, wxList &list)

  Moves content to a list from this point.
- virtual void MoveFromList (wxList &list)

  Adds content back from a list.
- bool GetContiguousPlainText (wxString &text, const wxRichTextRange &range, bool fromStart=true)

  Returns the plain text searching from the start or end of the range.
- bool FindWrapPosition (const wxRichTextRange &range, wxDC &dc, wxRichTextDrawingContext &context, int availableSpace, long &wrapPosition, wxArrayInt *partialExtents)

  Finds a suitable wrap position.
- wxRichTextObject * FindObjectAtPosition (long position)

  Finds the object at the given position.
- wxString GetBulletText ()

  Returns the bullet text for this paragraph.
- wxRichTextLine * AllocateLine (int pos)

  Allocates or reuses a line object.
- bool ClearUnusedLines (int lineCount)

  Clears remaining unused line objects, if any.
- wxRichTextAttr GetCombinedAttributes (const wxRichTextAttr &contentStyle, bool includingBoxAttr=false) const

  Returns combined attributes of the base style, paragraph style and character style.
- wxRichTextAttr GetCombinedAttributes (bool includingBoxAttr=false) const

  Returns the combined attributes of the base style and paragraph style.

- long GetFirstLineBreakPosition (long pos)

  Returns the first position from pos that has a line break character.

- void LayoutFloat (wxDC &dc, wxRichTextDrawingContext &context, const wxRect &rect, const wxRect &parentRect, int style, wxRichTextFloatCollector *floatCollector)

  Lays out the floating objects.

- int GetImpactedByFloatingObjects () const

  Whether the paragraph is impacted by floating objects from above.

- void SetImpactedByFloatingObjects (int i)

  Sets whether the paragraph is impacted by floating objects from above.

Static Public Member Functions

- static void InitDefaultTabs ()

  Creates a default tabstop array.

- static void ClearDefaultTabs ()

  Clears the default tabstop array.

- static const wxArrayInt & GetDefaultTabs ()

  Returns the default tabstop array.

21.636.2 Constructor & Destructor Documentation

wxRichTextParagraph::wxRichTextParagraph (wxRichTextObject * *parent* = NULL, wxRichTextAttr * *style* = NULL)

Constructor taking a parent and style.

wxRichTextParagraph::wxRichTextParagraph (const wxString & *text*, wxRichTextObject * *parent* = NULL, wxRichTextAttr * *paraStyle* = NULL, wxRichTextAttr * *charStyle* = NULL)

Constructor taking a text string, a parent and paragraph and character attributes.

virtual wxRichTextParagraph::~wxRichTextParagraph ( ) [virtual]

wxRichTextParagraph::wxRichTextParagraph (const wxRichTextParagraph & *obj*) [inline]

21.636.3 Member Function Documentation

wxRichTextLine* wxRichTextParagraph::AllocateLine (int *pos*)

Allocates or reuses a line object.

virtual void wxRichTextParagraph::ApplyParagraphStyle (wxRichTextLine * *line,* const wxRichTextAttr & *attr,* const wxRect & *rect,* wxDC & *dc*) [virtual]

Applies paragraph styles such as centering to the wrapped lines.

virtual void wxRichTextParagraph::CalculateRange (long *start,* long & *end*) [virtual]

Calculates the range of the object.

By default, guess that the object is 1 unit long.

Reimplemented from wxRichTextCompositeObject.

static void wxRichTextParagraph::ClearDefaultTabs ( ) [static]

Clears the default tabstop array.

void wxRichTextParagraph::ClearLines ( )

Clears the cached lines.

bool wxRichTextParagraph::ClearUnusedLines (int *lineCount*)

Clears remaining unused line objects, if any.

virtual wxRichTextObject* wxRichTextParagraph::Clone ( ) const [inline], [virtual]

Clones the object.

Reimplemented from wxRichTextObject.

void wxRichTextParagraph::Copy (const wxRichTextParagraph & *obj*)

Copies the object.

virtual bool wxRichTextParagraph::Draw (wxDC & *dc,* wxRichTextDrawingContext & *context,* const wxRichTextRange & *range,* const wxRichTextSelection & *selection,* const wxRect & *rect,* int *descent,* int *style*) [virtual]

Draw the item, within the given range.

Some objects may ignore the range (for example paragraphs) while others must obey it (lines, to implement wrapping)

Implements wxRichTextObject.

wxRichTextObject* **wxRichTextParagraph::FindObjectAtPosition** (**long** *position*)

Finds the object at the given position.

virtual bool wxRichTextParagraph::FindPosition (**wxDC** & *dc,* **wxRichTextDrawingContext** & *context,* **long** *index,* **wxPoint** & *pt,* **int** * *height,* **bool** *forceLineStart*) `[virtual]`

Finds the absolute position and row height for the given character position.

Reimplemented from wxRichTextCompositeObject.

bool wxRichTextParagraph::FindWrapPosition (**const wxRichTextRange** & *range,* **wxDC** & *dc,* **wxRichTextDrawingContext** & *context,* **int** *availableSpace,* **long** & *wrapPosition,* **wxArrayInt** * *partialExtents*)

Finds a suitable wrap position.

wrapPosition is the last position in the line to the left of the split.

wxString wxRichTextParagraph::GetBulletText ( )

Returns the bullet text for this paragraph.

wxRichTextAttr wxRichTextParagraph::GetCombinedAttributes (**const wxRichTextAttr** & *contentStyle,* **bool** *includingBoxAttr* = `false`) **const**

Returns combined attributes of the base style, paragraph style and character style.

We use this to dynamically retrieve the actual style.

wxRichTextAttr wxRichTextParagraph::GetCombinedAttributes (**bool** *includingBoxAttr* = `false`) **const**

Returns the combined attributes of the base style and paragraph style.

bool wxRichTextParagraph::GetContiguousPlainText (**wxString** & *text,* **const wxRichTextRange** & *range,* **bool** *fromStart* = `true`)

Returns the plain text searching from the start or end of the range.

The resulting string may be shorter than the range given.

static const wxArrayInt& wxRichTextParagraph::GetDefaultTabs ( ) `[inline],[static]`

Returns the default tabstop array.

long wxRichTextParagraph::GetFirstLineBreakPosition (**long** *pos*)

Returns the first position from pos that has a line break character.

int wxRichTextParagraph::GetImpactedByFloatingObjects ( ) **const** `[inline]`

Whether the paragraph is impacted by floating objects from above.

wxRichTextLineList& wxRichTextParagraph::GetLines ( ) [inline]

Returns the cached lines.

virtual bool wxRichTextParagraph::GetRangeSize (const wxRichTextRange & *range,* wxSize & *size,* int & *descent,* wxDC & *dc,* wxRichTextDrawingContext & *context,* int *flags,* const wxPoint & *position* = wxPoint(0, 0), const wxSize & *parentSize* = wxDefaultSize, wxArrayInt * *partialExtents* = NULL) const [virtual]

Returns the object size for the given range.

Returns false if the range is invalid for this object.

Reimplemented from wxRichTextCompositeObject.

virtual wxString wxRichTextParagraph::GetXMLNodeName ( ) const [inline], [virtual]

Returns the XML node name of this object.

This must be overridden for wxXmlNode-base XML export to work.

Reimplemented from wxRichTextObject.

virtual int wxRichTextParagraph::HitTest (wxDC & *dc,* wxRichTextDrawingContext & *context,* const wxPoint & *pt,* long & *textPosition,* wxRichTextObject ** *obj,* wxRichTextObject ** *contextObj,* int *flags* = 0) [virtual]

Hit-testing: returns a flag indicating hit test details, plus information about position.

contextObj is returned to specify what object position is relevant to, since otherwise there's an ambiguity. @ obj might not be a child of *contextObj*, since we may be referring to the container itself if we have no hit on a child - for example if we click outside an object.

The function puts the position in *textPosition* if one is found. *pt* is in logical units (a zero y position is at the beginning of the buffer).

Returns

One of the wxRichTextHitTestFlags values.

Reimplemented from wxRichTextCompositeObject.

void wxRichTextParagraph::Init ( )

static void wxRichTextParagraph::InitDefaultTabs ( ) [static]

Creates a default tabstop array.

virtual bool wxRichTextParagraph::InsertText (long *pos,* const wxString & *text*) [virtual]

Inserts text at the given position.

virtual bool wxRichTextParagraph::Layout (wxDC & *dc,* wxRichTextDrawingContext & *context,* const wxRect & *rect,* const wxRect & *parentRect,* int *style*) [virtual]

Lay the item out at the specified position with the given size constraint.

Layout must set the cached size. *rect* is the available space for the object, and *parentRect* is the container that is used to determine a relative size or position (for example if a text box must be 50% of the parent text box).

Implements wxRichTextObject.

void wxRichTextParagraph::LayoutFloat (wxDC & *dc,* wxRichTextDrawingContext & *context,* const wxRect & *rect,* const wxRect & *parentRect,* int *style,* wxRichTextFloatCollector * *floatCollector*)

Lays out the floating objects.

virtual void wxRichTextParagraph::MoveFromList (wxList & *list*) `[virtual]`

Adds content back from a list.

virtual void wxRichTextParagraph::MoveToList (wxRichTextObject * *obj,* wxList & *list*) `[virtual]`

Moves content to a list from this point.

void wxRichTextParagraph::SetImpactedByFloatingObjects (int *i*) `[inline]`

Sets whether the paragraph is impacted by floating objects from above.

virtual wxRichTextObject* wxRichTextParagraph::SplitAt (long *pos,* wxRichTextObject ** *previousObject* = NULL) `[virtual]`

Splits an object at this position if necessary, and returns the previous object, or NULL if inserting at the beginning.

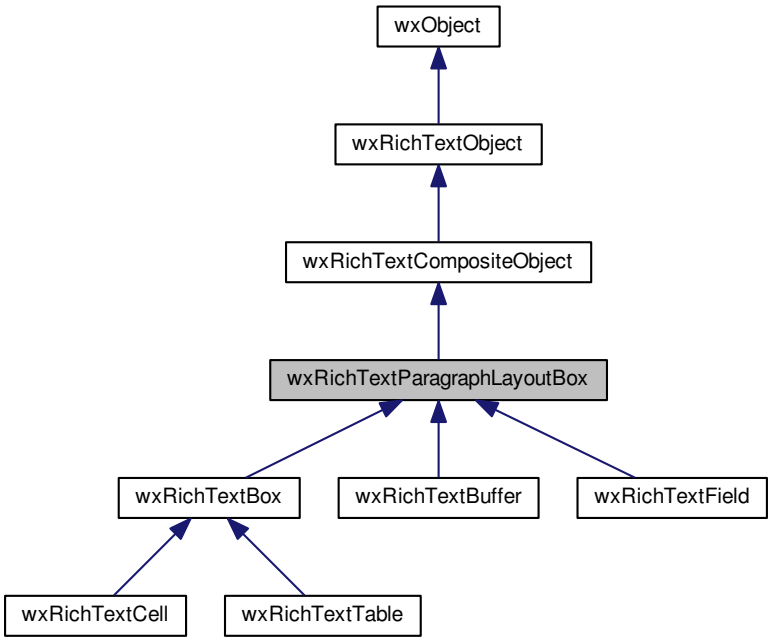
Inheritance diagram for wxRichTextParagraphLayoutBox:



21.637.1 Detailed Description

This class knows how to lay out paragraphs.

Library: wxRichText

Category: Rich Text

Public Member Functions

- wxRichTextParagraphLayoutBox (wxRichTextObject *parent=NULL)
- wxRichTextParagraphLayoutBox (const wxRichTextParagraphLayoutBox &obj)
- ~wxRichTextParagraphLayoutBox ()
- virtual int HitTest (wxDC &dc, wxRichTextDrawingContext &context, const wxPoint &pt, long &textPosition, wxRichTextObject **obj, wxRichTextObject **contextObj, int flags=0)

  Hit-testing: returns a flag indicating hit test details, plus information about position.
- virtual bool Draw (wxDC &dc, wxRichTextDrawingContext &context, const wxRichTextRange &range, const wxRichTextSelection &selection, const wxRect &rect, int descent, int style)

  Draw the item, within the given range.
- virtual bool Layout (wxDC &dc, wxRichTextDrawingContext &context, const wxRect &rect, const wxRect &parentRect, int style)

Lay the item out at the specified position with the given size constraint.

- virtual bool GetRangeSize (const wxRichTextRange &range, wxSize &size, int &descent, wxDC &dc, wxRichTextDrawingContext &context, int flags, const wxPoint &position=wxPoint(0, 0), const wxSize &parentSize=wxDefaultSize, wxArrayInt *partialExtents=NULL) const

  Returns the object size for the given range.

- virtual bool DeleteRange (const wxRichTextRange &range)

  Deletes the given range.

- virtual wxString GetTextForRange (const wxRichTextRange &range) const

  Returns any text in this object for the given range.

- virtual bool ImportFromXML (wxRichTextBuffer *buffer, wxXmlNode *node, wxRichTextXMLHandler *handler, bool *recurse)

  Imports this object from XML.

- virtual wxString GetXMLNodeName () const

  Returns the XML node name of this object.

- virtual bool AcceptsFocus () const

  Returns true if objects of this class can accept the focus, i.e. a call to SetFocusObject is possible.

- void SetRichTextCtrl (wxRichTextCtrl *ctrl)

  Associates a control with the buffer, for operations that for example require refreshing the window.

- wxRichTextCtrl * GetRichTextCtrl () const

  Returns the associated control.

- void SetPartialParagraph (bool partialPara)

  Sets a flag indicating whether the last paragraph is partial or complete.

- bool GetPartialParagraph () const

  Returns a flag indicating whether the last paragraph is partial or complete.

- virtual wxRichTextStyleSheet * GetStyleSheet () const

  Returns the style sheet associated with the overall buffer.

- virtual bool IsTopLevel () const

  Returns true if this object is top-level, i.e. contains its own paragraphs, such as a text box.

- bool InsertParagraphsWithUndo (wxRichTextBuffer *buffer, long pos, const wxRichTextParagraphLayoutBox &paragraphs, wxRichTextCtrl *ctrl, int flags=0)

  Submits a command to insert paragraphs.

- bool InsertTextWithUndo (wxRichTextBuffer *buffer, long pos, const wxString &text, wxRichTextCtrl *ctrl, int flags=0)

  Submits a command to insert the given text.

- bool InsertNewlineWithUndo (wxRichTextBuffer *buffer, long pos, wxRichTextCtrl *ctrl, int flags=0)

  Submits a command to insert the given text.

- bool InsertImageWithUndo (wxRichTextBuffer *buffer, long pos, const wxRichTextImageBlock &imageBlock, wxRichTextCtrl *ctrl, int flags, const wxRichTextAttr &textAttr)

  Submits a command to insert the given image.

- wxRichTextField * InsertFieldWithUndo (wxRichTextBuffer *buffer, long pos, const wxString &fieldType, const wxRichTextProperties &properties, wxRichTextCtrl *ctrl, int flags, const wxRichTextAttr &textAttr)

  Submits a command to insert the given field.

- wxRichTextAttr GetStyleForNewParagraph (wxRichTextBuffer *buffer, long pos, bool caretPosition=false, bool lookUpNewParaStyle=false) const

  Returns the style that is appropriate for a new paragraph at this position.

- wxRichTextObject * InsertObjectWithUndo (wxRichTextBuffer *buffer, long pos, wxRichTextObject *object, wxRichTextCtrl *ctrl, int flags=0)

  Inserts an object.

- bool DeleteRangeWithUndo (const wxRichTextRange &range, wxRichTextCtrl *ctrl, wxRichTextBuffer *buffer)

  Submits a command to delete this range.

- void DrawFloats (wxDC &dc, wxRichTextDrawingContext &context, const wxRichTextRange &range, const wxRichTextSelection &selection, const wxRect &rect, int descent, int style)

  Draws the floating objects in this buffer.
- void MoveAnchoredObjectToParagraph (wxRichTextParagraph *from, wxRichTextParagraph *to, wxRichTextObject *obj)

  Moves an anchored object to another paragraph.
- void Init ()

  Initializes the object.
- virtual void Clear ()

  Clears all the children.
- virtual void Reset ()

  Clears and initializes with one blank paragraph.
- virtual wxRichTextRange AddParagraph (const wxString &text, wxRichTextAttr *paraStyle=NULL)

  Convenience function to add a paragraph of text.
- virtual wxRichTextRange AddImage (const wxImage &image, wxRichTextAttr *paraStyle=NULL)

  Convenience function to add an image.
- virtual wxRichTextRange AddParagraphs (const wxString &text, wxRichTextAttr *paraStyle=NULL)

  Adds multiple paragraphs, based on newlines.
- virtual wxRichTextLine * GetLineAtPosition (long pos, bool caretPosition=false) const

  Returns the line at the given position.
- virtual wxRichTextLine * GetLineAtYPosition (int y) const

  Returns the line at the given y pixel position, or the last line.
- virtual wxRichTextParagraph * GetParagraphAtPosition (long pos, bool caretPosition=false) const

  Returns the paragraph at the given character or caret position.
- virtual wxSize GetLineSizeAtPosition (long pos, bool caretPosition=false) const

  Returns the line size at the given position.
- virtual long GetVisibleLineNumber (long pos, bool caretPosition=false, bool startOfLine=false) const

  Given a position, returns the number of the visible line (potentially many to a paragraph), starting from zero at the start of the buffer.
- virtual wxRichTextLine * GetLineForVisibleLineNumber (long lineNumber) const

  Given a line number, returns the corresponding wxRichTextLine object.
- virtual wxRichTextObject * GetLeafObjectAtPosition (long position) const

  Returns the leaf object in a paragraph at this position.
- virtual wxRichTextParagraph * GetParagraphAtLine (long paragraphNumber) const

  Returns the paragraph by number.
- virtual wxRichTextParagraph * GetParagraphForLine (wxRichTextLine *line) const

  Returns the paragraph for a given line.
- virtual int GetParagraphLength (long paragraphNumber) const

  Returns the length of the paragraph.
- virtual int GetParagraphCount () const

  Returns the number of paragraphs.
- virtual int GetLineCount () const

  Returns the number of visible lines.
- virtual wxString GetParagraphText (long paragraphNumber) const

  Returns the text of the paragraph.
- virtual long XYToPosition (long x, long y) const

  Converts zero-based line column and paragraph number to a position.
- virtual bool PositionToXY (long pos, long *x, long *y) const

  Converts a zero-based position to line column and paragraph number.
- virtual bool SetStyle (const wxRichTextRange &range, const wxRichTextAttr &style, int flags=wxRICHTEXT_SETSTYLE_WITH_UNDO)

Sets the attributes for the given range.

- virtual void SetStyle (wxRichTextObject *obj, const wxRichTextAttr &textAttr, int flags=wxRICHTEXT_SETSTYLE_WITH_UNDO)

  Sets the attributes for the given object only, for example the box attributes for a text box.
- virtual bool GetStyle (long position, wxRichTextAttr &style)

  Returns the combined text attributes for this position.
- virtual bool GetUncombinedStyle (long position, wxRichTextAttr &style)

  Returns the content (uncombined) attributes for this position.
- virtual bool DoGetStyle (long position, wxRichTextAttr &style, bool combineStyles=true)

  Implementation helper for GetStyle.
- virtual bool GetStyleForRange (const wxRichTextRange &range, wxRichTextAttr &style)

  This function gets a style representing the common, combined attributes in the given range.
- bool CollectStyle (wxRichTextAttr &currentStyle, const wxRichTextAttr &style, wxRichTextAttr &clashingAttr, wxRichTextAttr &absentAttr)

  Combines style with currentStyle for the purpose of summarising the attributes of a range of content.
- virtual bool ClearListStyle (const wxRichTextRange &range, int flags=wxRICHTEXT_SETSTYLE_WITH_UNDO)

  Clears the list style from the given range, clearing list-related attributes and applying any named paragraph style associated with each paragraph.
- virtual bool DoNumberList (const wxRichTextRange &range, const wxRichTextRange &promotionRange, int promoteBy, wxRichTextListStyleDefinition *def, int flags=wxRICHTEXT_SETSTYLE_WITH_UNDO, int startFrom=1, int specifiedLevel=-1)

  Helper for NumberList and PromoteList, that does renumbering and promotion simultaneously def can be NULL/empty to indicate that the existing list style should be used.
- virtual bool FindNextParagraphNumber (wxRichTextParagraph *previousParagraph, wxRichTextAttr &attr) const

  Fills in the attributes for numbering a paragraph after previousParagraph.
- virtual bool SetProperties (const wxRichTextRange &range, const wxRichTextProperties &properties, int flags=wxRICHTEXT_SETPROPERTIES_WITH_UNDO)

  Sets the properties for the given range, passing flags to determine how the attributes are set.
- virtual bool SetObjectPropertiesWithUndo (wxRichTextObject &obj, const wxRichTextProperties &properties, wxRichTextObject *objToSet=NULL)

  Sets with undo the properties for the given object.
- virtual bool HasCharacterAttributes (const wxRichTextRange &range, const wxRichTextAttr &style) const

  Test if this whole range has character attributes of the specified kind.
- virtual bool HasParagraphAttributes (const wxRichTextRange &range, const wxRichTextAttr &style) const

  Test if this whole range has paragraph attributes of the specified kind.
- virtual wxRichTextObject * Clone () const

  Clones the object.
- virtual void PrepareContent (wxRichTextParagraphLayoutBox &container)

  Prepares the content just before insertion (or after buffer reset).
- virtual bool InsertFragment (long position, wxRichTextParagraphLayoutBox &fragment)

  Insert fragment into this box at the given position.
- virtual bool CopyFragment (const wxRichTextRange &range, wxRichTextParagraphLayoutBox &fragment)

  Make a copy of the fragment corresponding to the given range, putting it in fragment.
- virtual bool ApplyStyleSheet (wxRichTextStyleSheet *styleSheet)

  Apply the style sheet to the buffer, for example if the styles have changed.
- void Copy (const wxRichTextParagraphLayoutBox &obj)
- void operator= (const wxRichTextParagraphLayoutBox &obj)
- virtual void UpdateRanges ()

  Calculate ranges.
- virtual wxString GetText () const

Get all the text.

- virtual bool SetDefaultStyle (const wxRichTextAttr &style)

  Sets the default style, affecting the style currently being applied (for example, setting the default style to bold will cause subsequently inserted text to be bold).
- virtual const wxRichTextAttr & GetDefaultStyle () const

  Returns the current default style, affecting the style currently being applied (for example, setting the default style to bold will cause subsequently inserted text to be bold).
- virtual void SetBasicStyle (const wxRichTextAttr &style)

  Sets the basic (overall) style.
- virtual const wxRichTextAttr & GetBasicStyle () const

  Returns the basic (overall) style.
- virtual void Invalidate (const wxRichTextRange &invalidRange=wxRICHTEXT_ALL)

  Invalidates the buffer.
- virtual void DoInvalidate (const wxRichTextRange &invalidRange)

  Do the (in)validation for this object only.
- virtual void InvalidateHierarchy (const wxRichTextRange &invalidRange=wxRICHTEXT_ALL)

  Do the (in)validation both up and down the hierarchy.
- virtual bool UpdateFloatingObjects (const wxRect &availableRect, wxRichTextObject *untilObj=NULL)

  Gather information about floating objects.
- wxRichTextRange GetInvalidRange (bool wholeParagraphs=false) const

  Get invalid range, rounding to entire paragraphs if argument is true.
- bool IsDirty () const

  Returns true if this object needs layout.
- wxRichTextFloatCollector * GetFloatCollector ()

  Returns the wxRichTextFloatCollector of this object.
- int GetFloatingObjectCount () const

  Returns the number of floating objects at this level.
- bool GetFloatingObjects (wxRichTextObjectList &objects) const

  Returns a list of floating objects.

- virtual bool SetListStyle (const wxRichTextRange &range, wxRichTextListStyleDefinition *def, int flags=wxRICHTEXT_SETSTYLE_WITH_UNDO, int startFrom=1, int specifiedLevel=-1)

  Sets the list attributes for the given range, passing flags to determine how the attributes are set.
- virtual bool SetListStyle (const wxRichTextRange &range, const wxString &defName, int flags=wxRICHTEXT_SETSTYLE_WITH_UNDO, int startFrom=1, int specifiedLevel=-1)

  Sets the list attributes for the given range, passing flags to determine how the attributes are set.

- virtual bool NumberList (const wxRichTextRange &range, wxRichTextListStyleDefinition *def=NULL, int flags=wxRICHTEXT_SETSTYLE_WITH_UNDO, int startFrom=1, int specifiedLevel=-1)

  Numbers the paragraphs in the given range.
- virtual bool NumberList (const wxRichTextRange &range, const wxString &defName, int flags=wxRICHTEXT_SETSTYLE_WITH_UNDO, int startFrom=1, int specifiedLevel=-1)

  Numbers the paragraphs in the given range.

- virtual bool PromoteList (int promoteBy, const wxRichTextRange &range, wxRichTextListStyleDefinition *def=NULL, int flags=wxRICHTEXT_SETSTYLE_WITH_UNDO, int specifiedLevel=-1)

  Promotes the list items within the given range.
- virtual bool PromoteList (int promoteBy, const wxRichTextRange &range, const wxString &defName, int flags=wxRICHTEXT_SETSTYLE_WITH_UNDO, int specifiedLevel=-1)

  Promotes the list items within the given range.

Protected Attributes

- wxRichTextCtrl * m_ctrl
- wxRichTextAttr m_defaultAttributes
- wxRichTextRange m_invalidRange
- bool m_partialParagraph
- wxRichTextFloatCollector * m_floatCollector

Additional Inherited Members

21.637.2 Constructor & Destructor Documentation

wxRichTextParagraphLayoutBox::wxRichTextParagraphLayoutBox (wxRichTextObject * *parent* = NULL)

wxRichTextParagraphLayoutBox::wxRichTextParagraphLayoutBox (const wxRichTextParagraphLayoutBox & *obj*) `[inline]`

wxRichTextParagraphLayoutBox::~wxRichTextParagraphLayoutBox ( )

21.637.3 Member Function Documentation

virtual bool wxRichTextParagraphLayoutBox::AcceptsFocus ( ) const `[inline], [virtual]`

Returns true if objects of this class can accept the focus, i.e. a call to SetFocusObject is possible.

For example, containers supporting text, such as a text box object, can accept the focus, but a table can't (set the focus to individual cells instead).

Reimplemented from wxRichTextObject.

Reimplemented in wxRichTextTable, and wxRichTextField.

virtual wxRichTextRange wxRichTextParagraphLayoutBox::AddImage (const wxImage & *image*, wxRichTextAttr * *paraStyle* = NULL) `[virtual]`

Convenience function to add an image.

virtual wxRichTextRange wxRichTextParagraphLayoutBox::AddParagraph (const wxString & *text*, wxRichTextAttr * *paraStyle* = NULL) `[virtual]`

Convenience function to add a paragraph of text.

Reimplemented in wxRichTextBuffer.

virtual wxRichTextRange wxRichTextParagraphLayoutBox::AddParagraphs (const wxString & *text*, wxRichTextAttr * *paraStyle* = NULL) `[virtual]`

Adds multiple paragraphs, based on newlines.

virtual bool wxRichTextParagraphLayoutBox::ApplyStyleSheet (wxRichTextStyleSheet * *styleSheet*) `[virtual]`

Apply the style sheet to the buffer, for example if the styles have changed.

virtual void wxRichTextParagraphLayoutBox::Clear ( ) [virtual]

Clears all the children.

virtual bool wxRichTextParagraphLayoutBox::ClearListStyle (const wxRichTextRange & *range,* int *flags =* wxRICHTEXT_SETSTYLE_WITH_UNDO) [virtual]

Clears the list style from the given range, clearing list-related attributes and applying any named paragraph style associated with each paragraph.

flags is a bit list of the following:

- wxRICHTEXT_SETSTYLE_WITH_UNDO: specifies that this command will be undoable.

See also

SetListStyle(), PromoteList(), NumberList()

virtual wxRichTextObject* wxRichTextParagraphLayoutBox::Clone ( ) const [inline], [virtual]

Clones the object.

Reimplemented from wxRichTextObject.

Reimplemented in wxRichTextTable, wxRichTextCell, wxRichTextBuffer, wxRichTextField, and wxRichTextBox.

bool wxRichTextParagraphLayoutBox::CollectStyle (wxRichTextAttr & *currentStyle,* const wxRichTextAttr & *style,* wxRichTextAttr & *clashingAttr,* wxRichTextAttr & *absentAttr*)

Combines *style* with *currentStyle* for the purpose of summarising the attributes of a range of content.

void wxRichTextParagraphLayoutBox::Copy (const wxRichTextParagraphLayoutBox & *obj*)

virtual bool wxRichTextParagraphLayoutBox::CopyFragment (const wxRichTextRange & *range,* wxRichTextParagraphLayoutBox & *fragment*) [virtual]

Make a copy of the fragment corresponding to the given range, putting it in *fragment*.

virtual bool wxRichTextParagraphLayoutBox::DeleteRange (const wxRichTextRange & *range*) [virtual]

Deletes the given range.

Reimplemented from wxRichTextCompositeObject.

Reimplemented in wxRichTextTable.

bool wxRichTextParagraphLayoutBox::DeleteRangeWithUndo (const wxRichTextRange & *range,* wxRichTextCtrl * *ctrl,* wxRichTextBuffer * *buffer*)

Submits a command to delete this range.

virtual bool wxRichTextParagraphLayoutBox::DoGetStyle (long *position*, wxRichTextAttr & *style*, bool *combineStyles* = true) [virtual]

Implementation helper for GetStyle.

If combineStyles is true, combine base, paragraph and context attributes.

virtual void wxRichTextParagraphLayoutBox::DoInvalidate (const wxRichTextRange & *invalidRange*) [virtual]

Do the (in)validation for this object only.

virtual bool wxRichTextParagraphLayoutBox::DoNumberList (const wxRichTextRange & *range*, const wxRichTextRange & *promotionRange*, int *promoteBy*, wxRichTextListStyleDefinition * *def*, int *flags* = wxRICHTEXT_SETSTYLE_WITH_UNDO, int *startFrom* = 1, int *specifiedLevel* = -1) [virtual]

Helper for NumberList and PromoteList, that does renumbering and promotion simultaneously *def* can be NUL↩ L/empty to indicate that the existing list style should be used.

virtual bool wxRichTextParagraphLayoutBox::Draw (wxDC & *dc*, wxRichTextDrawingContext & *context*, const wxRichTextRange & *range*, const wxRichTextSelection & *selection*, const wxRect & *rect*, int *descent*, int *style*) [virtual]

Draw the item, within the given range.

Some objects may ignore the range (for example paragraphs) while others must obey it (lines, to implement wrapping)

Implements wxRichTextObject.

Reimplemented in wxRichTextTable, wxRichTextCell, wxRichTextField, and wxRichTextBox.

void wxRichTextParagraphLayoutBox::DrawFloats (wxDC & *dc*, wxRichTextDrawingContext & *context*, const wxRichTextRange & *range*, const wxRichTextSelection & *selection*, const wxRect & *rect*, int *descent*, int *style*)

Draws the floating objects in this buffer.

virtual bool wxRichTextParagraphLayoutBox::FindNextParagraphNumber (wxRichTextParagraph * *previousParagraph*, wxRichTextAttr & *attr*) const [virtual]

Fills in the attributes for numbering a paragraph after previousParagraph.

virtual const wxRichTextAttr& wxRichTextParagraphLayoutBox::GetBasicStyle ( ) const [inline], [virtual]

Returns the basic (overall) style.

This is the style of the whole buffer before further styles are applied, unlike the default style, which only affects the style currently being applied (for example, setting the default style to bold will cause subsequently inserted text to be bold).

virtual const wxRichTextAttr& wxRichTextParagraphLayoutBox::GetDefaultStyle ( ) const [inline], [virtual]

Returns the current default style, affecting the style currently being applied (for example, setting the default style to bold will cause subsequently inserted text to be bold).

wxRichTextFloatCollector* wxRichTextParagraphLayoutBox::GetFloatCollector ( ) [inline]

Returns the wxRichTextFloatCollector of this object.

int wxRichTextParagraphLayoutBox::GetFloatingObjectCount ( ) const

Returns the number of floating objects at this level.

bool wxRichTextParagraphLayoutBox::GetFloatingObjects (wxRichTextObjectList & *objects*) const

Returns a list of floating objects.

wxRichTextRange wxRichTextParagraphLayoutBox::GetInvalidRange (bool *wholeParagraphs* = false) const

Get invalid range, rounding to entire paragraphs if argument is true.

virtual wxRichTextObject* wxRichTextParagraphLayoutBox::GetLeafObjectAtPosition (long *position*) const [virtual]

Returns the leaf object in a paragraph at this position.

virtual wxRichTextLine* wxRichTextParagraphLayoutBox::GetLineAtPosition (long *pos,* bool *caretPosition* = false) const [virtual]

Returns the line at the given position.

If *caretPosition* is true, the position is a caret position, which is normally a smaller number.

virtual wxRichTextLine* wxRichTextParagraphLayoutBox::GetLineAtYPosition (int *y*) const [virtual]

Returns the line at the given y pixel position, or the last line.

virtual int wxRichTextParagraphLayoutBox::GetLineCount ( ) const [virtual]

Returns the number of visible lines.

virtual wxRichTextLine* wxRichTextParagraphLayoutBox::GetLineForVisibleLineNumber (long *lineNumber*) const [virtual]

Given a line number, returns the corresponding wxRichTextLine object.

virtual wxSize wxRichTextParagraphLayoutBox::GetLineSizeAtPosition (long *pos,* bool *caretPosition* = false) const [virtual]

Returns the line size at the given position.

virtual wxRichTextParagraph* wxRichTextParagraphLayoutBox::GetParagraphAtLine (long *paragraphNumber*) const [virtual]

Returns the paragraph by number.

virtual wxRichTextParagraph* wxRichTextParagraphLayoutBox::GetParagraphAtPosition (long *pos,* bool *caretPosition* = false) const [virtual]

Returns the paragraph at the given character or caret position.

virtual int wxRichTextParagraphLayoutBox::GetParagraphCount ( ) const [inline], [virtual]

Returns the number of paragraphs.

virtual wxRichTextParagraph* wxRichTextParagraphLayoutBox::GetParagraphForLine (wxRichTextLine * *line*) const [virtual]

Returns the paragraph for a given line.

virtual int wxRichTextParagraphLayoutBox::GetParagraphLength (long *paragraphNumber*) const [virtual]

Returns the length of the paragraph.

virtual wxString wxRichTextParagraphLayoutBox::GetParagraphText (long *paragraphNumber*) const [virtual]

Returns the text of the paragraph.

bool wxRichTextParagraphLayoutBox::GetPartialParagraph ( ) const [inline]

Returns a flag indicating whether the last paragraph is partial or complete.

virtual bool wxRichTextParagraphLayoutBox::GetRangeSize (const wxRichTextRange & *range,* wxSize & *size,* int & *descent,* wxDC & *dc,* wxRichTextDrawingContext & *context,* int *flags,* const wxPoint & *position* = wxPoint (0, 0), const wxSize & *parentSize* = wxDefaultSize, wxArrayInt * *partialExtents* = NULL) const [virtual]

Returns the object size for the given range.

Returns false if the range is invalid for this object.

Reimplemented from wxRichTextCompositeObject.

Reimplemented in wxRichTextTable, and wxRichTextField.

wxRichTextCtrl* wxRichTextParagraphLayoutBox::GetRichTextCtrl ( ) const [inline]

Returns the associated control.

virtual bool wxRichTextParagraphLayoutBox::GetStyle (long *position,* wxRichTextAttr & *style*) [virtual]

Returns the combined text attributes for this position.

This function gets the *uncombined* style - that is, the attributes associated with the paragraph or character content, and not necessarily the combined attributes you see on the screen. To get the combined attributes, use GetStyle(). If you specify (any) paragraph attribute in *style's* flags, this function will fetch the paragraph attributes. Otherwise, it will return the character attributes.

wxRichTextAttr wxRichTextParagraphLayoutBox::GetStyleForNewParagraph (wxRichTextBuffer * *buffer,* long *pos,* bool *caretPosition* = false, bool *lookUpNewParaStyle* = false) const

Returns the style that is appropriate for a new paragraph at this position.

If the previous paragraph has a paragraph style name, looks up the next-paragraph style.

virtual bool wxRichTextParagraphLayoutBox::GetStyleForRange (const wxRichTextRange & *range,* wxRichTextAttr & *style*) [virtual]

This function gets a style representing the common, combined attributes in the given range.

Attributes which have different values within the specified range will not be included the style flags.

The function is used to get the attributes to display in the formatting dialog: the user can edit the attributes common to the selection, and optionally specify the values of further attributes to be applied uniformly.

To apply the edited attributes, you can use SetStyle() specifying the wxRICHTEXT_SETSTYLE_OPTIMIZE flag, which will only apply attributes that are different from the *combined* attributes within the range. So, the user edits the effective, displayed attributes for the range, but his choice won't be applied unnecessarily to content. As an example, say the style for a paragraph specifies bold, but the paragraph text doesn't specify a weight. The combined style is bold, and this is what the user will see on-screen and in the formatting dialog. The user now specifies red text, in addition to bold. When applying with SetStyle(), the content font weight attributes won't be changed to bold because this is already specified by the paragraph. However the text colour attributes *will* be changed to show red.

virtual wxRichTextStyleSheet* wxRichTextParagraphLayoutBox::GetStyleSheet ( ) const [virtual]

Returns the style sheet associated with the overall buffer.

Reimplemented in wxRichTextBuffer.

virtual wxString wxRichTextParagraphLayoutBox::GetText ( ) const [virtual]

Get all the text.

virtual wxString wxRichTextParagraphLayoutBox::GetTextForRange (const wxRichTextRange & *range*) const [virtual]

Returns any text in this object for the given range.

Reimplemented from wxRichTextCompositeObject.

Reimplemented in wxRichTextTable.

virtual bool wxRichTextParagraphLayoutBox::GetUncombinedStyle (long *position,* wxRichTextAttr & *style*) [virtual]

Returns the content (uncombined) attributes for this position.

virtual long wxRichTextParagraphLayoutBox::GetVisibleLineNumber (long *pos,* bool *caretPosition* = false, bool *startOfLine* = false) const [virtual]

Given a position, returns the number of the visible line (potentially many to a paragraph), starting from zero at the start of the buffer.

We also have to pass a bool (*startOfLine*) that indicates whether the caret is being shown at the end of the previous line or at the start of the next, since the caret can be shown at two visible positions for the same underlying position.

virtual wxString wxRichTextParagraphLayoutBox::GetXMLNodeName ( ) const `[inline], [virtual]`

Returns the XML node name of this object.

This must be overridden for wxXmlNode-base XML export to work.

Reimplemented from wxRichTextObject.

Reimplemented in wxRichTextTable, wxRichTextCell, wxRichTextField, and wxRichTextBox.

virtual bool wxRichTextParagraphLayoutBox::HasCharacterAttributes (const wxRichTextRange & *range,* const wxRichTextAttr & *style*) const `[virtual]`

Test if this whole range has character attributes of the specified kind.

If any of the attributes are different within the range, the test fails. You can use this to implement, for example, bold button updating. style must have flags indicating which attributes are of interest.

virtual bool wxRichTextParagraphLayoutBox::HasParagraphAttributes (const wxRichTextRange & *range,* const wxRichTextAttr & *style*) const `[virtual]`

Test if this whole range has paragraph attributes of the specified kind.

If any of the attributes are different within the range, the test fails. You can use this to implement, for example, centering button updating. style must have flags indicating which attributes are of interest.

virtual int wxRichTextParagraphLayoutBox::HitTest (wxDC & *dc,* wxRichTextDrawingContext & *context,* const wxPoint & *pt,* long & *textPosition,* wxRichTextObject ** *obj,* wxRichTextObject ** *contextObj,* int *flags* = 0) `[virtual]`

Hit-testing: returns a flag indicating hit test details, plus information about position.

contextObj is returned to specify what object position is relevant to, since otherwise there's an ambiguity. @ obj might not be a child of *contextObj*, since we may be referring to the container itself if we have no hit on a child - for example if we click outside an object.

The function puts the position in *textPosition* if one is found. *pt* is in logical units (a zero y position is at the beginning of the buffer).

Returns

One of the wxRichTextHitTestFlags values.

Reimplemented from wxRichTextCompositeObject.

Reimplemented in wxRichTextTable, wxRichTextCell, and wxRichTextBuffer.

virtual bool wxRichTextParagraphLayoutBox::ImportFromXML (wxRichTextBuffer * *buffer,* wxXmlNode * *node,* wxRichTextXMLHandler * *handler,* bool * *recurse*) `[virtual]`

Imports this object from XML.

Reimplemented from wxRichTextObject.

Reimplemented in wxRichTextTable.

void wxRichTextParagraphLayoutBox::Init ( )

Initializes the object.

wxRichTextField* wxRichTextParagraphLayoutBox::InsertFieldWithUndo (**wxRichTextBuffer** * *buffer,* long *pos,* const **wxString** & *fieldType,* const **wxRichTextProperties** & *properties,* **wxRichTextCtrl** * *ctrl,* int *flags,* const **wxRichTextAttr** & *textAttr*)

Submits a command to insert the given field.

Field data can be included in properties.

See also

wxRichTextField, wxRichTextFieldType, wxRichTextFieldTypeStandard

virtual bool wxRichTextParagraphLayoutBox::InsertFragment (long *position,* **wxRichTextParagraphLayoutBox** & *fragment*) [virtual]

Insert fragment into this box at the given position.

If partialParagraph is true, it is assumed that the last (or only) paragraph is just a piece of data with no paragraph marker.

bool wxRichTextParagraphLayoutBox::InsertImageWithUndo (**wxRichTextBuffer** * *buffer,* long *pos,* const **wxRichTextImageBlock** & *imageBlock,* **wxRichTextCtrl** * *ctrl,* int *flags,* const **wxRichTextAttr** & *textAttr*)

Submits a command to insert the given image.

bool wxRichTextParagraphLayoutBox::InsertNewlineWithUndo (**wxRichTextBuffer** * *buffer,* long *pos,* **wxRichTextCtrl** * *ctrl,* int *flags* = 0)

Submits a command to insert the given text.

wxRichTextObject* wxRichTextParagraphLayoutBox::InsertObjectWithUndo (**wxRichTextBuffer** * *buffer,* long *pos,* **wxRichTextObject** * *object,* **wxRichTextCtrl** * *ctrl,* int *flags* = 0)

Inserts an object.

bool wxRichTextParagraphLayoutBox::InsertParagraphsWithUndo (**wxRichTextBuffer** * *buffer,* long *pos,* const **wxRichTextParagraphLayoutBox** & *paragraphs,* **wxRichTextCtrl** * *ctrl,* int *flags* = 0)

Submits a command to insert paragraphs.

bool wxRichTextParagraphLayoutBox::InsertTextWithUndo (**wxRichTextBuffer** * *buffer,* long *pos,* const **wxString** & *text,* **wxRichTextCtrl** * *ctrl,* int *flags* = 0)

Submits a command to insert the given text.

virtual void wxRichTextParagraphLayoutBox::Invalidate (const **wxRichTextRange** & *invalidRange* = **wxRICHTEXT_ALL**) [virtual]

Invalidates the buffer.

With no argument, invalidates whole buffer.

Reimplemented from wxRichTextCompositeObject.

virtual void wxRichTextParagraphLayoutBox::InvalidateHierarchy (const wxRichTextRange & *invalidRange* = wxRICHTEXT_ALL) [virtual]

Do the (in)validation both up and down the hierarchy.

bool wxRichTextParagraphLayoutBox::IsDirty ( ) const [inline]

Returns true if this object needs layout.

virtual bool wxRichTextParagraphLayoutBox::IsTopLevel ( ) const [inline], [virtual]

Returns true if this object is top-level, i.e. contains its own paragraphs, such as a text box.

Reimplemented from wxRichTextObject.

Reimplemented in wxRichTextField.

virtual bool wxRichTextParagraphLayoutBox::Layout (wxDC & *dc*, wxRichTextDrawingContext & *context*, const wxRect & *rect*, const wxRect & *parentRect*, int *style*) [virtual]

Lay the item out at the specified position with the given size constraint.

Layout must set the cached size. *rect* is the available space for the object, and *parentRect* is the container that is used to determine a relative size or position (for example if a text box must be 50% of the parent text box).

Implements wxRichTextObject.

Reimplemented in wxRichTextTable, and wxRichTextField.

void wxRichTextParagraphLayoutBox::MoveAnchoredObjectToParagraph (wxRichTextParagraph * *from*, wxRichTextParagraph * *to*, wxRichTextObject * *obj*)

Moves an anchored object to another paragraph.

virtual bool wxRichTextParagraphLayoutBox::NumberList (const wxRichTextRange & *range*, wxRichTextListStyleDefinition * *def* = NULL, int *flags* = wxRICHTEXT_SETSTYLE_WITH_UNDO, int *startFrom* = 1, int *specifiedLevel* = -1) [virtual]

Numbers the paragraphs in the given range.

Pass flags to determine how the attributes are set. Either the style definition or the name of the style definition (in the current sheet) can be passed.

flags is a bit list of the following:

- wxRICHTEXT_SETSTYLE_WITH_UNDO: specifies that this command will be undoable.
- wxRICHTEXT_SETSTYLE_RENUMBER: specifies that numbering should start from *startFrom*, otherwise existing attributes are used.
- wxRICHTEXT_SETSTYLE_SPECIFY_LEVEL: specifies that *listLevel* should be used as the level for all paragraphs, otherwise the current indentation will be used.

def can be NULL to indicate that the existing list style should be used.

See also

SetListStyle(), PromoteList(), ClearListStyle()

virtual bool wxRichTextParagraphLayoutBox::NumberList (const wxRichTextRange & *range*, const wxString & *defName*, int *flags* = wxRICHTEXT_SETSTYLE_WITH_UNDO, int *startFrom* = 1, int *specifiedLevel* = -1) [virtual]

Numbers the paragraphs in the given range.

Pass flags to determine how the attributes are set. Either the style definition or the name of the style definition (in the current sheet) can be passed.

flags is a bit list of the following:

- wxRICHTEXT_SETSTYLE_WITH_UNDO: specifies that this command will be undoable.
- wxRICHTEXT_SETSTYLE_RENUMBER: specifies that numbering should start from *startFrom*, otherwise existing attributes are used.
- wxRICHTEXT_SETSTYLE_SPECIFY_LEVEL: specifies that *listLevel* should be used as the level for all paragraphs, otherwise the current indentation will be used.

def can be NULL to indicate that the existing list style should be used.

See also

SetListStyle(), PromoteList(), ClearListStyle()

void wxRichTextParagraphLayoutBox::operator= (const wxRichTextParagraphLayoutBox & *obj*) [inline]

virtual bool wxRichTextParagraphLayoutBox::PositionToXY (long *pos*, long * *x*, long * *y*) const [virtual]

Converts a zero-based position to line column and paragraph number.

virtual void wxRichTextParagraphLayoutBox::PrepareContent (wxRichTextParagraphLayoutBox & *container*) [virtual]

Prepares the content just before insertion (or after buffer reset).

Currently is only called if undo mode is on.

virtual bool wxRichTextParagraphLayoutBox::PromoteList (int *promoteBy*, const wxRichTextRange & *range*, wxRichTextListStyleDefinition * *def* = NULL, int *flags* = wxRICHTEXT_SETSTYLE_WITH_UNDO, int *specifiedLevel* = -1) [virtual]

Promotes the list items within the given range.

A positive *promoteBy* produces a smaller indent, and a negative number produces a larger indent. Pass flags to determine how the attributes are set. Either the style definition or the name of the style definition (in the current sheet) can be passed.

flags is a bit list of the following:

- wxRICHTEXT_SETSTYLE_WITH_UNDO: specifies that this command will be undoable.
- wxRICHTEXT_SETSTYLE_RENUMBER: specifies that numbering should start from *startFrom*, otherwise existing attributes are used.
- wxRICHTEXT_SETSTYLE_SPECIFY_LEVEL: specifies that *listLevel* should be used as the level for all paragraphs, otherwise the current indentation will be used.

See also

SetListStyle(), SetListStyle(), ClearListStyle()

virtual bool wxRichTextParagraphLayoutBox::PromoteList (int *promoteBy,* const wxRichTextRange & *range,* const wxString & *defName,* int *flags* = wxRICHTEXT_SETSTYLE_WITH_UNDO, int *specifiedLevel* = -1) [virtual]

Promotes the list items within the given range.

A positive *promoteBy* produces a smaller indent, and a negative number produces a larger indent. Pass flags to determine how the attributes are set. Either the style definition or the name of the style definition (in the current sheet) can be passed.

flags is a bit list of the following:

- wxRICHTEXT_SETSTYLE_WITH_UNDO: specifies that this command will be undoable.
- wxRICHTEXT_SETSTYLE_RENUMBER: specifies that numbering should start from *startFrom*, otherwise existing attributes are used.
- wxRICHTEXT_SETSTYLE_SPECIFY_LEVEL: specifies that *listLevel* should be used as the level for all paragraphs, otherwise the current indentation will be used.

See also

SetListStyle(), SetListStyle(), ClearListStyle()

virtual void wxRichTextParagraphLayoutBox::Reset ( ) [virtual]

Clears and initializes with one blank paragraph.

virtual void wxRichTextParagraphLayoutBox::SetBasicStyle (const wxRichTextAttr & *style*) [inline], [virtual]

Sets the basic (overall) style.

This is the style of the whole buffer before further styles are applied, unlike the default style, which only affects the style currently being applied (for example, setting the default style to bold will cause subsequently inserted text to be bold).

virtual bool wxRichTextParagraphLayoutBox::SetDefaultStyle (const wxRichTextAttr & *style*) [virtual]

Sets the default style, affecting the style currently being applied (for example, setting the default style to bold will cause subsequently inserted text to be bold).

This is not cumulative - setting the default style will replace the previous default style.

Setting it to a default attribute object makes new content take on the 'basic' style.

virtual bool wxRichTextParagraphLayoutBox::SetListStyle (const wxRichTextRange & *range,* wxRichTextListStyle↩ Definition * *def,* int *flags* = wxRICHTEXT_SETSTYLE_WITH_UNDO, int *startFrom* = 1, int *specifiedLevel* = -1) [virtual]

Sets the list attributes for the given range, passing flags to determine how the attributes are set.

Either the style definition or the name of the style definition (in the current sheet) can be passed.

flags is a bit list of the following:

- wxRICHTEXT_SETSTYLE_WITH_UNDO: specifies that this command will be undoable.
- wxRICHTEXT_SETSTYLE_RENUMBER: specifies that numbering should start from *startFrom*, otherwise existing attributes are used.

- wxRICHTEXT_SETSTYLE_SPECIFY_LEVEL: specifies that *listLevel* should be used as the level for all paragraphs, otherwise the current indentation will be used.

See also

NumberList(), PromoteList(), ClearListStyle().

virtual bool wxRichTextParagraphLayoutBox::SetListStyle (const wxRichTextRange & *range,* const wxString & *defName,* int *flags* = wxRICHTEXT_SETSTYLE_WITH_UNDO, int *startFrom* = 1, int *specifiedLevel* = -1) [virtual]

Sets the list attributes for the given range, passing flags to determine how the attributes are set.

Either the style definition or the name of the style definition (in the current sheet) can be passed.

flags is a bit list of the following:

- wxRICHTEXT_SETSTYLE_WITH_UNDO: specifies that this command will be undoable.
- wxRICHTEXT_SETSTYLE_RENUMBER: specifies that numbering should start from *startFrom*, otherwise existing attributes are used.
- wxRICHTEXT_SETSTYLE_SPECIFY_LEVEL: specifies that *listLevel* should be used as the level for all paragraphs, otherwise the current indentation will be used.

See also

NumberList(), PromoteList(), ClearListStyle().

virtual bool wxRichTextParagraphLayoutBox::SetObjectPropertiesWithUndo (wxRichTextObject & *obj,* const wxRichTextProperties & *properties,* wxRichTextObject * *objToSet* = NULL) [virtual]

Sets with undo the properties for the given object.

void wxRichTextParagraphLayoutBox::SetPartialParagraph (bool *partialPara*) [inline]

Sets a flag indicating whether the last paragraph is partial or complete.

virtual bool wxRichTextParagraphLayoutBox::SetProperties (const wxRichTextRange & *range,* const wxRichTextProperties & *properties,* int *flags* = wxRICHTEXT_SETPROPERTIES_WITH_UNDO) [virtual]

Sets the properties for the given range, passing flags to determine how the attributes are set.

You can merge properties or replace them.

The end point of range is specified as the last character position of the span of text, plus one. So, for example, to set the properties for a character at position 5, use the range (5,6).

flags may contain a bit list of the following values:

- wxRICHTEXT_SETPROPERTIES_NONE: no flag.
- wxRICHTEXT_SETPROPERTIES_WITH_UNDO: specifies that this operation should be undoable.
- wxRICHTEXT_SETPROPERTIES_PARAGRAPHS_ONLY: specifies that the properties should only be applied to paragraphs, and not the content.
- wxRICHTEXT_SETPROPERTIES_CHARACTERS_ONLY: specifies that the properties should only be applied to characters, and not the paragraph.

- wxRICHTEXT_SETPROPERTIES_RESET: resets (clears) the existing properties before applying the new properties.
- wxRICHTEXT_SETPROPERTIES_REMOVE: removes the specified properties.

void wxRichTextParagraphLayoutBox::SetRichTextCtrl (wxRichTextCtrl * *ctrl*) [inline]

Associates a control with the buffer, for operations that for example require refreshing the window.

virtual bool wxRichTextParagraphLayoutBox::SetStyle (const wxRichTextRange & *range,* const wxRichTextAttr & *style,* int *flags* = wxRICHTEXT_SETSTYLE_WITH_UNDO) [virtual]

Sets the attributes for the given range.

Pass flags to determine how the attributes are set.

The end point of range is specified as the last character position of the span of text. So, for example, to set the style for a character at position 5, use the range (5,5). This differs from the wxRichTextCtrl API, where you would specify (5,6).

flags may contain a bit list of the following values:

- wxRICHTEXT_SETSTYLE_NONE: no style flag.
- wxRICHTEXT_SETSTYLE_WITH_UNDO: specifies that this operation should be undoable.
- wxRICHTEXT_SETSTYLE_OPTIMIZE: specifies that the style should not be applied if the combined style at this point is already the style in question.
- wxRICHTEXT_SETSTYLE_PARAGRAPHS_ONLY: specifies that the style should only be applied to paragraphs, and not the content. This allows content styling to be preserved independently from that of e.g. a named paragraph style.
- wxRICHTEXT_SETSTYLE_CHARACTERS_ONLY: specifies that the style should only be applied to characters, and not the paragraph. This allows content styling to be preserved independently from that of e.g. a named paragraph style.
- wxRICHTEXT_SETSTYLE_RESET: resets (clears) the existing style before applying the new style.
- wxRICHTEXT_SETSTYLE_REMOVE: removes the specified style. Only the style flags are used in this operation.

virtual void wxRichTextParagraphLayoutBox::SetStyle (wxRichTextObject * *obj,* const wxRichTextAttr & *textAttr,* int *flags* = wxRICHTEXT_SETSTYLE_WITH_UNDO) [virtual]

Sets the attributes for the given object only, for example the box attributes for a text box.

virtual bool wxRichTextParagraphLayoutBox::UpdateFloatingObjects (const wxRect & *availableRect,* wxRichTextObject * *untilObj* = NULL) [virtual]

Gather information about floating objects.

If untilObj is non-NULL, will stop getting information if the current object is this, since we will collect the rest later.

virtual void wxRichTextParagraphLayoutBox::UpdateRanges ( ) [virtual]

Calculate ranges.

virtual long wxRichTextParagraphLayoutBox::XYToPosition (long *x*, long *y*) const `[virtual]`

Converts zero-based line column and paragraph number to a position.

21.637.4 Member Data Documentation

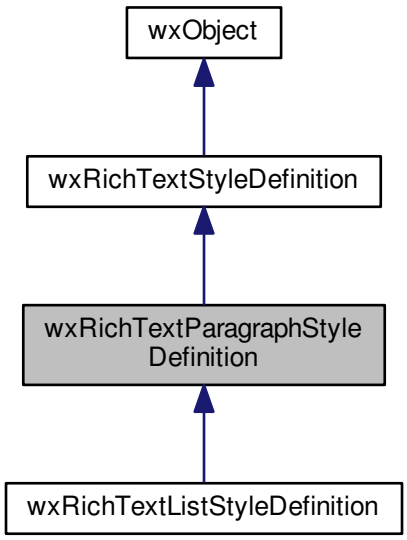
21.638 wxRichTextParagraphStyleDefinition Class Reference

`#include <wx/richtext/richtextstyles.h>`

Inheritance diagram for wxRichTextParagraphStyleDefinition:



21.638.1 Detailed Description

This class represents a paragraph style definition, usually added to a wxRichTextStyleSheet.

Library: wxRichText

Category: Rich Text

Public Member Functions

- wxRichTextParagraphStyleDefinition (const wxString &name=wxEmptyString)

  Constructor.

- virtual ~wxRichTextParagraphStyleDefinition ()

  Destructor.

- const wxString & GetNextStyle () const

  Returns the style that should normally follow this style.

- void SetNextStyle (const wxString &name)

  Sets the style that should normally follow this style.

Additional Inherited Members

21.638.2 Constructor & Destructor Documentation

wxRichTextParagraphStyleDefinition::wxRichTextParagraphStyleDefinition (const wxString & *name* = wxEmptyString)

Constructor.

virtual wxRichTextParagraphStyleDefinition::~wxRichTextParagraphStyleDefinition ( ) [virtual]

Destructor.

21.638.3 Member Function Documentation

const wxString& wxRichTextParagraphStyleDefinition::GetNextStyle ( ) const

Returns the style that should normally follow this style.

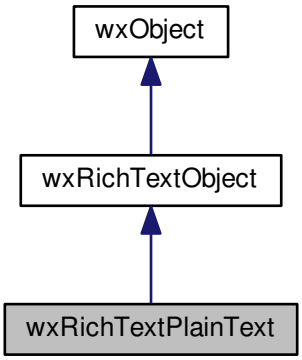
void wxRichTextParagraphStyleDefinition::SetNextStyle (const wxString & *name*)

Sets the style that should normally follow this style.

21.639 wxRichTextPlainText Class Reference

`#include <wx/richtext/richtextbuffer.h>`

Inheritance diagram for wxRichTextPlainText:



21.639.1 Detailed Description

This object represents a single piece of text.

Library: wxRichText

Category: Rich Text

wxRichTextBuffer, wxRichTextCtrl

Public Member Functions

- wxRichTextPlainText (const wxString &text=wxEmptyString, wxRichTextObject *parent=NULL, wxRichTextAttr *style=NULL)

  Constructor.
- wxRichTextPlainText (const wxRichTextPlainText &obj)

  Copy constructor.
- virtual bool Draw (wxDC &dc, wxRichTextDrawingContext &context, const wxRichTextRange &range, const wxRichTextSelection &selection, const wxRect &rect, int descent, int style)

  Draw the item, within the given range.
- virtual bool Layout (wxDC &dc, wxRichTextDrawingContext &context, const wxRect &rect, const wxRect &parentRect, int style)

  Lay the item out at the specified position with the given size constraint.
- virtual bool GetRangeSize (const wxRichTextRange &range, wxSize &size, int &descent, wxDC &dc, wxRichTextDrawingContext &context, int flags, const wxPoint &position=wxPoint(0, 0), const wxSize &parentSize=wxDefaultSize, wxArrayInt *partialExtents=NULL) const

  Returns the object size for the given range.
- virtual wxString GetTextForRange (const wxRichTextRange &range) const

  Returns any text in this object for the given range.

- virtual wxRichTextObject * DoSplit (long pos)

  Do a split from pos, returning an object containing the second part, and setting the first part in 'this'.
- virtual void CalculateRange (long start, long &end)

  Calculates the range of the object.
- virtual bool DeleteRange (const wxRichTextRange &range)

  Deletes the given range.
- virtual bool IsEmpty () const

  Returns true if the object is empty.
- virtual bool CanMerge (wxRichTextObject *object, wxRichTextDrawingContext &context) const

  Returns true if this object can merge itself with the given one.
- virtual bool Merge (wxRichTextObject *object, wxRichTextDrawingContext &context)

  Returns true if this object merged itself with the given one.
- virtual bool CanSplit (wxRichTextDrawingContext &context) const

  Returns true if this object can potentially be split, by virtue of having different virtual attributes for individual sub-objects.
- virtual wxRichTextObject * Split (wxRichTextDrawingContext &context)

  Returns the final object in the split objects if this object was split due to differences between sub-object virtual attributes.
- virtual void Dump (wxTextOutputStream &stream)

  Dump object data to the given output stream for debugging.
- long GetFirstLineBreakPosition (long pos)

  Get the first position from pos that has a line break character.
- virtual bool UsesParagraphAttributes () const

  Does this object take note of paragraph attributes? Text and image objects don't.
- virtual bool ImportFromXML (wxRichTextBuffer *buffer, wxXmlNode *node, wxRichTextXMLHandler *handler, bool *recurse)

  Imports this object from XML.
- virtual wxString GetXMLNodeName () const

  Returns the XML node name of this object.
- const wxString & GetText () const

  Returns the text.
- void SetText (const wxString &text)

  Sets the text.
- void Copy (const wxRichTextPlainText &obj)
- virtual wxRichTextObject * Clone () const

  Clones the object.

Protected Attributes

- wxString m_text

Private Member Functions

- bool DrawTabbedString (wxDC &dc, const wxRichTextAttr &attr, const wxRect &rect, wxString &str, wxCoord &x, wxCoord &y, bool selected)

Additional Inherited Members

21.639.2 Constructor & Destructor Documentation

wxRichTextPlainText::wxRichTextPlainText (const wxString & *text* = wxEmptyString, wxRichTextObject * *parent* = NULL, wxRichTextAttr * *style* = NULL)

Constructor.

wxRichTextPlainText::wxRichTextPlainText (const wxRichTextPlainText & *obj*) [inline]

Copy constructor.

21.639.3 Member Function Documentation

virtual void wxRichTextPlainText::CalculateRange (long *start*, long & *end*) [virtual]

Calculates the range of the object.

By default, guess that the object is 1 unit long.

Reimplemented from wxRichTextObject.

virtual bool wxRichTextPlainText::CanMerge (wxRichTextObject * *object*, wxRichTextDrawingContext & *context*) const [virtual]

Returns true if this object can merge itself with the given one.

Reimplemented from wxRichTextObject.

virtual bool wxRichTextPlainText::CanSplit (wxRichTextDrawingContext & *context*) const [virtual]

Returns true if this object can potentially be split, by virtue of having different virtual attributes for individual sub-objects.

Reimplemented from wxRichTextObject.

virtual wxRichTextObject* wxRichTextPlainText::Clone ( ) const [inline], [virtual]

Clones the object.

Reimplemented from wxRichTextObject.

void wxRichTextPlainText::Copy (const wxRichTextPlainText & *obj*)

virtual bool wxRichTextPlainText::DeleteRange (const wxRichTextRange & *range*) [virtual]

Deletes the given range.

Reimplemented from wxRichTextObject.

virtual wxRichTextObject* wxRichTextPlainText::DoSplit (long *pos*) [virtual]

Do a split from *pos*, returning an object containing the second part, and setting the first part in 'this'.

Reimplemented from wxRichTextObject.

virtual bool wxRichTextPlainText::Draw (wxDC & *dc,* wxRichTextDrawingContext & *context,* const wxRichTextRange & *range,* const wxRichTextSelection & *selection,* const wxRect & *rect,* int *descent,* int *style*) [virtual]

Draw the item, within the given range.

Some objects may ignore the range (for example paragraphs) while others must obey it (lines, to implement wrapping)

Implements wxRichTextObject.

bool wxRichTextPlainText::DrawTabbedString (wxDC & *dc,* const wxRichTextAttr & *attr,* const wxRect & *rect,* wxString & *str,* wxCoord & *x,* wxCoord & *y,* bool *selected*) [private]

virtual void wxRichTextPlainText::Dump (wxTextOutputStream & *stream*) [virtual]

Dump object data to the given output stream for debugging.

Reimplemented from wxRichTextObject.

long wxRichTextPlainText::GetFirstLineBreakPosition (long *pos*)

Get the first position from pos that has a line break character.

virtual bool wxRichTextPlainText::GetRangeSize (const wxRichTextRange & *range,* wxSize & *size,* int & *descent,* wxDC & *dc,* wxRichTextDrawingContext & *context,* int *flags,* const wxPoint & *position* = wxPoint(0, 0), const wxSize & *parentSize* = wxDefaultSize, wxArrayInt * *partialExtents* = NULL) const [virtual]

Returns the object size for the given range.

Returns false if the range is invalid for this object.

Implements wxRichTextObject.

const wxString& wxRichTextPlainText::GetText ( ) const [inline]

Returns the text.

virtual wxString wxRichTextPlainText::GetTextForRange (const wxRichTextRange & *range*) const [virtual]

Returns any text in this object for the given range.

Reimplemented from wxRichTextObject.

virtual wxString wxRichTextPlainText::GetXMLNodeName ( ) const [inline], [virtual]

Returns the XML node name of this object.

This must be overridden for wxXmlNode-base XML export to work.

Reimplemented from wxRichTextObject.

virtual bool wxRichTextPlainText::ImportFromXML (wxRichTextBuffer * *buffer,* wxXmlNode * *node,* wxRichTextXMLHandler * *handler,* bool * *recurse*) [virtual]

Imports this object from XML.

Reimplemented from wxRichTextObject.

virtual bool wxRichTextPlainText::IsEmpty ( ) const `[inline], [virtual]`

Returns true if the object is empty.

Reimplemented from wxRichTextObject.

virtual bool wxRichTextPlainText::Layout (wxDC & *dc,* wxRichTextDrawingContext & *context,* const wxRect & *rect,* const wxRect & *parentRect,* int *style*) `[virtual]`

Lay the item out at the specified position with the given size constraint.

Layout must set the cached size. *rect* is the available space for the object, and *parentRect* is the container that is used to determine a relative size or position (for example if a text box must be 50% of the parent text box).

Implements wxRichTextObject.

virtual bool wxRichTextPlainText::Merge (wxRichTextObject * *object,* wxRichTextDrawingContext & *context*) `[virtual]`

Returns true if this object merged itself with the given one.

The calling code will then delete the given object.

Reimplemented from wxRichTextObject.

void wxRichTextPlainText::SetText (const wxString & *text*) `[inline]`

Sets the text.

virtual wxRichTextObject* wxRichTextPlainText::Split (wxRichTextDrawingContext & *context*) `[virtual]`

Returns the final object in the split objects if this object was split due to differences between sub-object virtual attributes.

Returns itself if it was not split.

Reimplemented from wxRichTextObject.

virtual bool wxRichTextPlainText::UsesParagraphAttributes ( ) const `[inline], [virtual]`

Does this object take note of paragraph attributes? Text and image objects don't.

Reimplemented from wxRichTextObject.

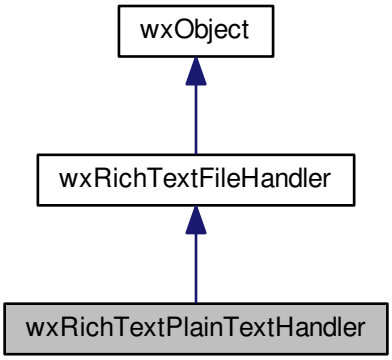
21.639.4 Member Data Documentation

wxString wxRichTextPlainText::m_text `[protected]`

21.640 wxRichTextPlainTextHandler Class Reference

`#include <wx/richtext/richtextbuffer.h>`

Inheritance diagram for wxRichTextPlainTextHandler:



21.640.1 Detailed Description

Implements saving a buffer to plain text.

Library: wxRichText

Category: Rich Text

See also

wxRichTextFileHandler, wxRichTextBuffer, wxRichTextCtrl

Public Member Functions

- wxRichTextPlainTextHandler (const wxString &name="Text", const wxString &ext="txt", wxRichTextFileType type=wxRICHTEXT_TYPE_TEXT)
- virtual bool CanSave () const

  Returns true if we can save using this handler.
- virtual bool CanLoad () const

  Returns true if we can load using this handler.

Protected Member Functions

- virtual bool DoLoadFile (wxRichTextBuffer *buffer, wxInputStream &stream)

  Override to load content from stream into buffer.
- virtual bool DoSaveFile (wxRichTextBuffer *buffer, wxOutputStream &stream)

  Override to save content to stream from buffer.

Additional Inherited Members

21.640.2 Constructor & Destructor Documentation

wxRichTextPlainTextHandler::wxRichTextPlainTextHandler (const wxString & *name* = "Text", const wxString & *ext* = "txt", wxRichTextFileType *type* = wxRICHTEXT_TYPE_TEXT) `[inline]`

21.640.3 Member Function Documentation

virtual bool wxRichTextPlainTextHandler::CanLoad ( ) const `[inline], [virtual]`

Returns true if we can load using this handler.

Reimplemented from wxRichTextFileHandler.

virtual bool wxRichTextPlainTextHandler::CanSave ( ) const `[inline], [virtual]`

Returns true if we can save using this handler.

Reimplemented from wxRichTextFileHandler.

virtual bool wxRichTextPlainTextHandler::DoLoadFile (wxRichTextBuffer * *buffer*, wxInputStream & *stream*) `[protected], [virtual]`

Override to load content from *stream* into *buffer*.

Implements wxRichTextFileHandler.

virtual bool wxRichTextPlainTextHandler::DoSaveFile (wxRichTextBuffer * *buffer*, wxOutputStream & *stream*) `[protected], [virtual]`

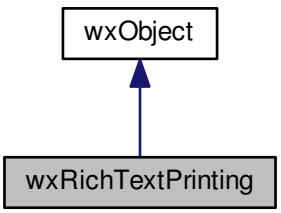
Override to save content to *stream* from *buffer*.

Implements wxRichTextFileHandler.

21.641 wxRichTextPrinting Class Reference

`#include <wx/richtext/richtextprint.h>`

Inheritance diagram for wxRichTextPrinting:



21.641.1 Detailed Description

This class provides a simple interface for performing wxRichTextBuffer printing and previewing.

It uses wxRichTextPrintout for layout and rendering.

Library: wxRichText

Category: Rich Text

Public Member Functions

- wxRichTextPrinting (const wxString &name="Printing", wxWindow *parentWindow=NULL)

  Constructor.
- wxString GetFooterText (wxRichTextOddEvenPage page=wxRICHTEXT_PAGE_EVEN, wxRichTextPageLocation location=wxRICHTEXT_PAGE_CENTRE) const

  A convenience function to get the footer text.
- const wxRichTextHeaderFooterData & GetHeaderFooterData () const

  Returns the internal wxRichTextHeaderFooterData object.
- wxString GetHeaderText (wxRichTextOddEvenPage page=wxRICHTEXT_PAGE_EVEN, wxRichTextPageLocation location=wxRICHTEXT_PAGE_CENTRE) const

  A convenience function to get the header text.
- wxPageSetupDialogData * GetPageSetupData ()

  Returns a pointer to the internal page setup data.
- wxWindow * GetParentWindow () const

  Returns the parent window to be used for the preview window and printing wait dialog.
- const wxRect & GetPreviewRect () const

  Returns the dimensions to be used for the preview window.
- wxPrintData * GetPrintData ()

  Returns a pointer to the internal print data.
- const wxString & GetTitle () const

  Returns the title of the preview window or printing wait caption.
- void PageSetup ()

  Shows the page setup dialog.
- bool PreviewBuffer (const wxRichTextBuffer &buffer)

  Shows a preview window for the given buffer.
- bool PreviewFile (const wxString &richTextFile)

  Shows a preview window for the given file.
- bool PrintBuffer (const wxRichTextBuffer &buffer, bool showPrintDialog=true)

  Prints the given buffer.
- bool PrintFile (const wxString &richTextFile, bool showPrintDialog=true)

  Prints the given file.
- void SetFooterText (const wxString &text, wxRichTextOddEvenPage page=wxRICHTEXT_PAGE_ALL, wxRichTextPageLocation location=wxRICHTEXT_PAGE_CENTRE)

  A convenience function to set the footer text.
- void SetHeaderFooterData (const wxRichTextHeaderFooterData &data)

  Sets the internal wxRichTextHeaderFooterData object.
- void SetHeaderFooterFont (const wxFont &font)

  Sets the wxRichTextHeaderFooterData font.
- void SetHeaderFooterTextColour (const wxColour &colour)

Sets the wxRichTextHeaderFooterData text colour.

- void SetHeaderText (const wxString &text, wxRichTextOddEvenPage page=wxRICHTEXT_PAGE_ALL, wxRichTextPageLocation location=wxRICHTEXT_PAGE_CENTRE)

  A convenience function to set the header text.

- void SetPageSetupData (const wxPageSetupDialogData &pageSetupData)

  Sets the page setup data.

- void SetParentWindow (wxWindow *parent)

  Sets the parent window to be used for the preview window and printing wait dialog.

- void SetPreviewRect (const wxRect &rect)

  Sets the dimensions to be used for the preview window.

- void SetPrintData (const wxPrintData &printData)

  Sets the print data.

- void SetShowOnFirstPage (bool show)

  Pass true to show the header and footer on the first page.

- void SetTitle (const wxString &title)

  Pass the title of the preview window or printing wait caption.

Additional Inherited Members

21.641.2 Constructor & Destructor Documentation

wxRichTextPrinting::wxRichTextPrinting (const wxString & *name* = "Printing", wxWindow * *parentWindow* = NULL)

Constructor.

Optionally pass a title to be used in the preview frame and printing wait dialog, and also a parent window for these windows.

21.641.3 Member Function Documentation

wxString wxRichTextPrinting::GetFooterText (wxRichTextOddEvenPage *page* = wxRICHTEXT_PAGE_EVEN, wxRichTextPageLocation *location* = wxRICHTEXT_PAGE_CENTRE) const

A convenience function to get the footer text.

See wxRichTextHeaderFooterData for details.

const wxRichTextHeaderFooterData& wxRichTextPrinting::GetHeaderFooterData ( ) const

Returns the internal wxRichTextHeaderFooterData object.

wxString wxRichTextPrinting::GetHeaderText (wxRichTextOddEvenPage *page* = wxRICHTEXT_PAGE_EVEN, wxRichTextPageLocation *location* = wxRICHTEXT_PAGE_CENTRE) const

A convenience function to get the header text.

See wxRichTextHeaderFooterData for details.

wxPageSetupDialogData* wxRichTextPrinting::GetPageSetupData ( )

Returns a pointer to the internal page setup data.

wxWindow* wxRichTextPrinting::GetParentWindow ( ) const

Returns the parent window to be used for the preview window and printing wait dialog.

const wxRect& wxRichTextPrinting::GetPreviewRect ( ) const

Returns the dimensions to be used for the preview window.

wxPrintData* wxRichTextPrinting::GetPrintData ( )

Returns a pointer to the internal print data.

const wxString& wxRichTextPrinting::GetTitle ( ) const

Returns the title of the preview window or printing wait caption.

void wxRichTextPrinting::PageSetup ( )

Shows the page setup dialog.

bool wxRichTextPrinting::PreviewBuffer (const wxRichTextBuffer & *buffer*)

Shows a preview window for the given buffer.

The function takes its own copy of *buffer*.

bool wxRichTextPrinting::PreviewFile (const wxString & *richTextFile*)

Shows a preview window for the given file.

richTextFile can be a text file or XML file, or other file depending on the available file handlers.

bool wxRichTextPrinting::PrintBuffer (const wxRichTextBuffer & *buffer*, bool *showPrintDialog* = `true`)

Prints the given buffer.

The function takes its own copy of *buffer*. *showPrintDialog* can be true to show the print dialog, or false to print quietly.

bool wxRichTextPrinting::PrintFile (const wxString & *richTextFile*, bool *showPrintDialog* = `true`)

Prints the given file.

richTextFile can be a text file or XML file, or other file depending on the available file handlers. *showPrintDialog* can be true to show the print dialog, or false to print quietly.

void wxRichTextPrinting::SetFooterText (const wxString & *text*, wxRichTextOddEvenPage *page* = wxRICHTEXT_PAGE_ALL, wxRichTextPageLocation *location* = wxRICHTEXT_PAGE_CENTRE)

A convenience function to set the footer text.

See wxRichTextHeaderFooterData for details.

void wxRichTextPrinting::SetHeaderFooterData (const wxRichTextHeaderFooterData & *data*)

Sets the internal wxRichTextHeaderFooterData object.

void wxRichTextPrinting::SetHeaderFooterFont (const wxFont & *font*)

Sets the wxRichTextHeaderFooterData font.

void wxRichTextPrinting::SetHeaderFooterTextColour (const wxColour & *colour*)

Sets the wxRichTextHeaderFooterData text colour.

void wxRichTextPrinting::SetHeaderText (const wxString & *text*, wxRichTextOddEvenPage *page* = wxRICHTEXT_PAGE_ALL, wxRichTextPageLocation *location* = wxRICHTEXT_PAGE_CENTRE)

A convenience function to set the header text.

See wxRichTextHeaderFooterData for details.

void wxRichTextPrinting::SetPageSetupData (const wxPageSetupDialogData & *pageSetupData*)

Sets the page setup data.

void wxRichTextPrinting::SetParentWindow (wxWindow * *parent*)

Sets the parent window to be used for the preview window and printing wait dialog.

void wxRichTextPrinting::SetPreviewRect (const wxRect & *rect*)

Sets the dimensions to be used for the preview window.

void wxRichTextPrinting::SetPrintData (const wxPrintData & *printData*)

Sets the print data.

void wxRichTextPrinting::SetShowOnFirstPage (bool *show*)

Pass true to show the header and footer on the first page.

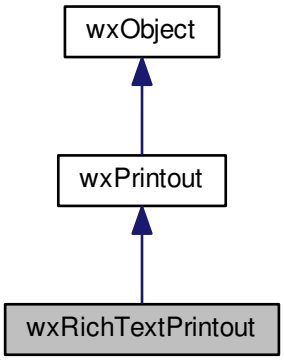
void wxRichTextPrinting::SetTitle (const wxString & *title*)

Pass the title of the preview window or printing wait caption.

21.642 wxRichTextPrintout Class Reference

```
#include <wx/richtext/richtextprint.h>
```

Inheritance diagram for wxRichTextPrintout:



21.642.1 Detailed Description

This class implements print layout for wxRichTextBuffer.

Instead of using it directly, you should normally use the wxRichTextPrinting class.

Library: wxRichText

Category: Rich Text

Public Member Functions

- wxRichTextPrintout (const wxString &title="Printout")

  Constructor.
- void CalculateScaling (wxDC *dc, wxRect &textRect, wxRect &headerRect, wxRect &footerRect)

  Calculates scaling and text, header and footer rectangles.
- const wxRichTextHeaderFooterData & GetHeaderFooterData () const

  Returns the header and footer data associated with the printout.
- virtual void GetPageInfo (int *minPage, int *maxPage, int *selPageFrom, int *selPageTo)

  Gets the page information.
- wxRichTextBuffer * GetRichTextBuffer () const

  Returns a pointer to the buffer being rendered.
- virtual bool HasPage (int page)

  Returns true if the given page exists in the printout.
- virtual void OnPreparePrinting ()

  Prepares for printing, laying out the buffer and calculating pagination.
- virtual bool OnPrintPage (int page)

  Does the actual printing for this page.
- void SetHeaderFooterData (const wxRichTextHeaderFooterData &data)

  Sets the header and footer data associated with the printout.

- void SetMargins (int top=254, int bottom=254, int left=254, int right=254)

  Sets margins in 10ths of millimetre.
- void SetRichTextBuffer (wxRichTextBuffer *buffer)

  Sets the buffer to print.

Additional Inherited Members

21.642.2 Constructor & Destructor Documentation

wxRichTextPrintout::wxRichTextPrintout (const wxString & *title* = "Printout")

Constructor.

21.642.3 Member Function Documentation

void wxRichTextPrintout::CalculateScaling (wxDC * *dc,* wxRect & *textRect,* wxRect & *headerRect,* wxRect & *footerRect*)

Calculates scaling and text, header and footer rectangles.

const wxRichTextHeaderFooterData& wxRichTextPrintout::GetHeaderFooterData ( ) const

Returns the header and footer data associated with the printout.

virtual void wxRichTextPrintout::GetPageInfo (int * *minPage,* int * *maxPage,* int * *selPageFrom,* int * *selPageTo*) [virtual]

Gets the page information.

Reimplemented from wxPrintout.

wxRichTextBuffer* wxRichTextPrintout::GetRichTextBuffer ( ) const

Returns a pointer to the buffer being rendered.

virtual bool wxRichTextPrintout::HasPage (int *page*) [virtual]

Returns true if the given page exists in the printout.

Reimplemented from wxPrintout.

virtual void wxRichTextPrintout::OnPreparePrinting ( ) [virtual]

Prepares for printing, laying out the buffer and calculating pagination.

Reimplemented from wxPrintout.

virtual bool wxRichTextPrintout::OnPrintPage (int *page*) [virtual]

Does the actual printing for this page.

Implements wxPrintout.

void wxRichTextPrintout::SetHeaderFooterData (const wxRichTextHeaderFooterData & *data*)

Sets the header and footer data associated with the printout.

void wxRichTextPrintout::SetMargins (int *top* = 254, int *bottom* = 254, int *left* = 254, int *right* = 254)

Sets margins in 10ths of millimetre.

Defaults to 1 inch for margins.

void wxRichTextPrintout::SetRichTextBuffer (wxRichTextBuffer * *buffer*)

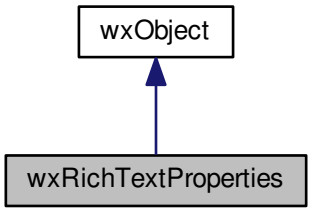
Sets the buffer to print.

wxRichTextPrintout does not manage this pointer; it should be managed by the calling code, such as wxRichText↩Printing.

21.643 wxRichTextProperties Class Reference

`#include <wx/richtext/richtextbuffer.h>`

Inheritance diagram for wxRichTextProperties:



21.643.1 Detailed Description

A simple property class using wxVariants.

This is used to give each rich text object the ability to store custom properties that can be used by the application.

Library: wxRichText

Category: Rich Text

wxRichTextBuffer, wxRichTextObject, wxRichTextCtrl

Public Member Functions

- wxRichTextProperties ()

  Default constructor.
- wxRichTextProperties (const wxRichTextProperties &props)

  Copy constructor.
- void operator= (const wxRichTextProperties &props)

  Assignment operator.
- bool operator== (const wxRichTextProperties &props) const

  Equality operator.
- void Copy (const wxRichTextProperties &props)

  Copies from props.
- const wxVariant & operator[] (size_t idx) const

  Returns the variant at the given index.
- wxVariant & operator[] (size_t idx)

  Returns the variant at the given index.
- void Clear ()

  Clears the properties.
- const wxRichTextVariantArray & GetProperties () const

  Returns the array of variants implementing the properties.
- wxRichTextVariantArray & GetProperties ()

  Returns the array of variants implementing the properties.
- void SetProperties (const wxRichTextVariantArray &props)

  Sets the array of variants.
- wxArrayString GetPropertyNames () const

  Returns all the property names.
- size_t GetCount () const

  Returns a count of the properties.
- bool HasProperty (const wxString &name) const

  Returns true if the given property is found.
- int Find (const wxString &name) const

  Finds the given property.
- bool Remove (const wxString &name)

  Removes the given property.
- const wxVariant & GetProperty (const wxString &name) const

  Gets the property variant by name.
- wxVariant * FindOrCreateProperty (const wxString &name)

  Finds or creates a property with the given name, returning a pointer to the variant.
- wxString GetPropertyString (const wxString &name) const

  Gets the value of the named property as a string.
- long GetPropertyLong (const wxString &name) const

  Gets the value of the named property as a long integer.
- bool GetPropertyBool (const wxString &name) const

  Gets the value of the named property as a boolean.
- double GetPropertyDouble (const wxString &name) const

  Gets the value of the named property as a double.
- void SetProperty (const wxVariant &variant)

  Sets the property by passing a variant which contains a name and value.
- void SetProperty (const wxString &name, const wxVariant &variant)

  Sets a property by name and variant.
- void SetProperty (const wxString &name, const wxString &value)

Sets a property by name and string value.

- void SetProperty (const wxString &name, const wxChar *value)

  Sets a property by name and wxChar value.*

- void SetProperty (const wxString &name, long value)

  Sets property by name and long integer value.

- void SetProperty (const wxString &name, double value)

  Sets property by name and double value.

- void SetProperty (const wxString &name, bool value)

  Sets property by name and boolean value.

- void RemoveProperties (const wxRichTextProperties &properties)

  Removes the given properties from these properties.

- void MergeProperties (const wxRichTextProperties &properties)

  Merges the given properties with these properties.

Protected Attributes

- wxRichTextVariantArray m_properties

Additional Inherited Members

21.643.2 Constructor & Destructor Documentation

wxRichTextProperties::wxRichTextProperties ( ) [inline]

Default constructor.

wxRichTextProperties::wxRichTextProperties (const wxRichTextProperties & *props*) [inline]

Copy constructor.

21.643.3 Member Function Documentation

void wxRichTextProperties::Clear ( ) [inline]

Clears the properties.

void wxRichTextProperties::Copy (const wxRichTextProperties & *props*) [inline]

Copies from *props*.

int wxRichTextProperties::Find (const wxString & *name*) const

Finds the given property.

wxVariant* wxRichTextProperties::FindOrCreateProperty (const wxString & *name*)

Finds or creates a property with the given name, returning a pointer to the variant.

size_t wxRichTextProperties::GetCount ( ) const `[inline]`

Returns a count of the properties.

const wxRichTextVariantArray& wxRichTextProperties::GetProperties ( ) const `[inline]`

Returns the array of variants implementing the properties.

wxRichTextVariantArray& wxRichTextProperties::GetProperties ( ) `[inline]`

Returns the array of variants implementing the properties.

const wxVariant& wxRichTextProperties::GetProperty (const wxString & *name*) const

Gets the property variant by name.

bool wxRichTextProperties::GetPropertyBool (const wxString & *name*) const

Gets the value of the named property as a boolean.

double wxRichTextProperties::GetPropertyDouble (const wxString & *name*) const

Gets the value of the named property as a double.

long wxRichTextProperties::GetPropertyLong (const wxString & *name*) const

Gets the value of the named property as a long integer.

wxArrayString wxRichTextProperties::GetPropertyNames ( ) const

Returns all the property names.

wxString wxRichTextProperties::GetPropertyString (const wxString & *name*) const

Gets the value of the named property as a string.

bool wxRichTextProperties::HasProperty (const wxString & *name*) const `[inline]`

Returns true if the given property is found.

void wxRichTextProperties::MergeProperties (const wxRichTextProperties & *properties*)

Merges the given properties with these properties.

void wxRichTextProperties::operator= (const wxRichTextProperties & *props*) `[inline]`

Assignment operator.

bool wxRichTextProperties::operator== (const wxRichTextProperties & *props*) const

Equality operator.

const wxVariant& wxRichTextProperties::operator[] (size_t *idx*) const `[inline]`

Returns the variant at the given index.

wxVariant& wxRichTextProperties::operator[] (size_t *idx*) `[inline]`

Returns the variant at the given index.

bool wxRichTextProperties::Remove (const wxString & *name*)

Removes the given property.

void wxRichTextProperties::RemoveProperties (const wxRichTextProperties & *properties*)

Removes the given properties from these properties.

void wxRichTextProperties::SetProperties (const wxRichTextVariantArray & *props*) `[inline]`

Sets the array of variants.

void wxRichTextProperties::SetProperty (const wxVariant & *variant*)

Sets the property by passing a variant which contains a name and value.

void wxRichTextProperties::SetProperty (const wxString & *name,* const wxVariant & *variant*)

Sets a property by name and variant.

void wxRichTextProperties::SetProperty (const wxString & *name,* const wxString & *value*)

Sets a property by name and string value.

void wxRichTextProperties::SetProperty (const wxString & *name,* const wxChar * *value*)

Sets a property by name and wxChar* value.

void wxRichTextProperties::SetProperty (const wxString & *name,* long *value*)

Sets property by name and long integer value.

void wxRichTextProperties::SetProperty (const wxString & *name,* double *value*)

Sets property by name and double value.

void wxRichTextProperties::SetProperty (const wxString & *name,* bool *value*)

Sets property by name and boolean value.

21.643.4 Member Data Documentation

wxRichTextVariantArray wxRichTextProperties::m_properties `[protected]`

21.644 wxRichTextRange Class Reference

`#include <wx/richtext/richtextbuffer.h>`

21.644.1 Detailed Description

This stores beginning and end positions for a range of data.

Library: wxRichText

Category: Rich Text

See also

wxRichTextBuffer, wxRichTextCtrl

Public Member Functions

- wxRichTextRange ()
  Default constructor.
- wxRichTextRange (long start, long end)
  Constructor taking start and end positions.
- wxRichTextRange (const wxRichTextRange &range)
  Copy constructor.
- ~wxRichTextRange ()
- void operator= (const wxRichTextRange &range)
  Assigns range to this range.
- bool operator== (const wxRichTextRange &range) const
  Equality operator.
- bool operator!= (const wxRichTextRange &range) const
  Inequality operator.
- wxRichTextRange operator- (const wxRichTextRange &range) const
  Subtracts a range from this range.
- wxRichTextRange operator+ (const wxRichTextRange &range) const
  Adds a range to this range.
- void SetRange (long start, long end)
  Sets the range start and end positions.
- void SetStart (long start)
  Sets the start position.
- long GetStart () const
  Returns the start position.

- void SetEnd (long end)

  Sets the end position.
- long GetEnd () const

  Gets the end position.
- bool IsOutside (const wxRichTextRange &range) const

  Returns true if this range is completely outside range.
- bool IsWithin (const wxRichTextRange &range) const

  Returns true if this range is completely within range.
- bool Contains (long pos) const

  Returns true if pos was within the range.
- bool LimitTo (const wxRichTextRange &range)

  Limit this range to be within range.
- long GetLength () const

  Gets the length of the range.
- void Swap ()

  Swaps the start and end.
- wxRichTextRange ToInternal () const

  Converts the API-standard range, whose end is one past the last character in the range, to the internal form, which uses the first and last character positions of the range.
- wxRichTextRange FromInternal () const

  Converts the internal range, which uses the first and last character positions of the range, to the API-standard range, whose end is one past the last character in the range.

Protected Attributes

- long m_start
- long m_end

21.644.2 Constructor & Destructor Documentation

wxRichTextRange::wxRichTextRange ( ) [inline]

Default constructor.

wxRichTextRange::wxRichTextRange (long *start,* long *end*) [inline]

Constructor taking start and end positions.

wxRichTextRange::wxRichTextRange (const wxRichTextRange & *range*) [inline]

Copy constructor.

wxRichTextRange::~wxRichTextRange ( ) [inline]

21.644.3 Member Function Documentation

bool wxRichTextRange::Contains (long *pos*) const [inline]

Returns true if *pos* was within the range.

Does not match if the range is empty.

wxRichTextRange wxRichTextRange::FromInternal ( ) const `[inline]`

Converts the internal range, which uses the first and last character positions of the range, to the API-standard range, whose end is one past the last character in the range.

In other words, one is added to the end position. (n, n+1) is the range of a single character.

long wxRichTextRange::GetEnd ( ) const `[inline]`

Gets the end position.

long wxRichTextRange::GetLength ( ) const `[inline]`

Gets the length of the range.

long wxRichTextRange::GetStart ( ) const `[inline]`

Returns the start position.

bool wxRichTextRange::IsOutside (const wxRichTextRange & *range*) const `[inline]`

Returns true if this range is completely outside *range*.

bool wxRichTextRange::IsWithin (const wxRichTextRange & *range*) const `[inline]`

Returns true if this range is completely within *range*.

bool wxRichTextRange::LimitTo (const wxRichTextRange & *range*)

Limit this range to be within *range*.

bool wxRichTextRange::operator!= (const wxRichTextRange & *range*) const `[inline]`

Inequality operator.

wxRichTextRange wxRichTextRange::operator+ (const wxRichTextRange & *range*) const `[inline]`

Adds a range to this range.

wxRichTextRange wxRichTextRange::operator- (const wxRichTextRange & *range*) const `[inline]`

Subtracts a range from this range.

void wxRichTextRange::operator= (const wxRichTextRange & *range*) `[inline]`

Assigns *range* to this range.

bool wxRichTextRange::operator== (const wxRichTextRange & *range*) const [inline]

Equality operator.

Returns true if *range* is the same as this range.

void wxRichTextRange::SetEnd (long *end*) [inline]

Sets the end position.

void wxRichTextRange::SetRange (long *start,* long *end*) [inline]

Sets the range start and end positions.

void wxRichTextRange::SetStart (long *start*) [inline]

Sets the start position.

void wxRichTextRange::Swap ( ) [inline]

Swaps the start and end.

wxRichTextRange wxRichTextRange::ToInternal ( ) const [inline]

Converts the API-standard range, whose end is one past the last character in the range, to the internal form, which uses the first and last character positions of the range.

In other words, one is subtracted from the end position. (n, n) is the range of a single character.

Public Member Functions

- wxRichTextRenderer ()

  Constructor.
- virtual ~wxRichTextRenderer ()
- virtual bool DrawStandardBullet (wxRichTextParagraph *paragraph, wxDC &dc, const wxRichTextAttr &attr, const wxRect &rect)=0

  Draws a standard bullet, as specified by the value of GetBulletName.
- virtual bool DrawTextBullet (wxRichTextParagraph *paragraph, wxDC &dc, const wxRichTextAttr &attr, const wxRect &rect, const wxString &text)=0

  Draws a bullet that can be described by text, such as numbered or symbol bullets.
- virtual bool DrawBitmapBullet (wxRichTextParagraph *paragraph, wxDC &dc, const wxRichTextAttr &attr, const wxRect &rect)=0

  Draws a bitmap bullet, where the bullet bitmap is specified by the value of GetBulletName.
- virtual bool EnumerateStandardBulletNames (wxArrayString &bulletNames)=0

  Enumerate the standard bullet names currently supported.

Additional Inherited Members

21.645.2 Constructor & Destructor Documentation

wxRichTextRenderer::wxRichTextRenderer ( ) [inline]

Constructor.

virtual wxRichTextRenderer::~wxRichTextRenderer ( ) [inline], [virtual]

21.645.3 Member Function Documentation

virtual bool wxRichTextRenderer::DrawBitmapBullet (wxRichTextParagraph * *paragraph,* wxDC & *dc,* const wxRichTextAttr & *attr,* const wxRect & *rect*) [pure virtual]

Draws a bitmap bullet, where the bullet bitmap is specified by the value of GetBulletName.

This function should be overridden.

Implemented in wxRichTextStdRenderer.

virtual bool wxRichTextRenderer::DrawStandardBullet (wxRichTextParagraph * *paragraph,* wxDC & *dc,* const wxRichTextAttr & *attr,* const wxRect & *rect*) [pure virtual]

Draws a standard bullet, as specified by the value of GetBulletName.

This function should be overridden.

Implemented in wxRichTextStdRenderer.

virtual bool wxRichTextRenderer::DrawTextBullet (wxRichTextParagraph * *paragraph,* wxDC & *dc,* const wxRichTextAttr & *attr,* const wxRect & *rect,* const wxString & *text*) [pure virtual]

Draws a bullet that can be described by text, such as numbered or symbol bullets.

This function should be overridden.

Implemented in wxRichTextStdRenderer.

virtual bool wxRichTextRenderer::EnumerateStandardBulletNames (wxArrayString & *bulletNames*) [pure virtual]

Enumerate the standard bullet names currently supported.

This function should be overridden.

Implemented in wxRichTextStdRenderer.

21.646 wxRichTextSelection Class Reference

`#include <wx/richtext/richtextbuffer.h>`

21.646.1 Detailed Description

Stores selection information.

The selection does not have to be contiguous, though currently non-contiguous selections are only supported for a range of table cells (a geometric block of cells can consist of a set of non-contiguous positions).

The selection consists of an array of ranges, and the container that is the context for the selection. It follows that a single selection object can only represent ranges with the same parent container.

Library: wxRichText

Category: Rich Text

wxRichTextBuffer, wxRichTextCtrl

Public Member Functions

- wxRichTextSelection (const wxRichTextSelection &sel)

  Copy constructor.
- wxRichTextSelection (const wxRichTextRange &range, wxRichTextParagraphLayoutBox *container)

  Creates a selection from a range and a container.
- wxRichTextSelection ()

  Default constructor.
- void Reset ()

  Resets the selection.
- void Set (const wxRichTextRange &range, wxRichTextParagraphLayoutBox *container)

  Sets the selection.
- void Add (const wxRichTextRange &range)

  Adds a range to the selection.
- void Set (const wxRichTextRangeArray &ranges, wxRichTextParagraphLayoutBox *container)

  Sets the selections from an array of ranges and a container object.
- void Copy (const wxRichTextSelection &sel)

  Copies from sel.
- void operator= (const wxRichTextSelection &sel)

  Assignment operator.
- bool operator== (const wxRichTextSelection &sel) const

  Equality operator.
- wxRichTextRange operator[] (size_t i) const

  Index operator.
- wxRichTextRangeArray & GetRanges ()

  Returns the selection ranges.
- const wxRichTextRangeArray & GetRanges () const

  Returns the selection ranges.
- void SetRanges (const wxRichTextRangeArray &ranges)

  Sets the selection ranges.
- size_t GetCount () const

  Returns the number of ranges in the selection.
- wxRichTextRange GetRange (size_t i) const

  Returns the range at the given index.
- wxRichTextRange GetRange () const

  Returns the first range if there is one, otherwise wxRICHTEXT_NO_SELECTION.
- void SetRange (const wxRichTextRange &range)

  Sets a single range.
- wxRichTextParagraphLayoutBox * GetContainer () const

Returns the container for which the selection is valid.

- void SetContainer (wxRichTextParagraphLayoutBox ∗container)

  Sets the container for which the selection is valid.

- bool IsValid () const

  Returns true if the selection is valid.

- wxRichTextRangeArray GetSelectionForObject (wxRichTextObject ∗obj) const

  Returns the selection appropriate to the specified object, if any; returns an empty array if none at the level of the object's container.

- bool WithinSelection (long pos, wxRichTextObject ∗obj) const

  Returns true if the given position is within the selection.

- bool WithinSelection (long pos) const

  Returns true if the given position is within the selection.

Static Public Member Functions

- static bool WithinSelection (long pos, const wxRichTextRangeArray &ranges)

  Returns true if the given position is within the selection range.

- static bool WithinSelection (const wxRichTextRange &range, const wxRichTextRangeArray &ranges)

  Returns true if the given range is within the selection range.

Public Attributes

- wxRichTextRangeArray m_ranges
- wxRichTextParagraphLayoutBox ∗ m_container

21.646.2 Constructor & Destructor Documentation

wxRichTextSelection::wxRichTextSelection (const wxRichTextSelection & *sel*) `[inline]`

Copy constructor.

wxRichTextSelection::wxRichTextSelection (const wxRichTextRange & *range,* wxRichTextParagraphLayoutBox ∗ *container*) `[inline]`

Creates a selection from a range and a container.

wxRichTextSelection::wxRichTextSelection ( ) `[inline]`

Default constructor.

21.646.3 Member Function Documentation

void wxRichTextSelection::Add (const wxRichTextRange & *range*) `[inline]`

Adds a range to the selection.

void wxRichTextSelection::Copy (const wxRichTextSelection & *sel*) `[inline]`

Copies from *sel*.

wxRichTextParagraphLayoutBox* wxRichTextSelection::GetContainer ( ) const [inline]

Returns the container for which the selection is valid.

size_t wxRichTextSelection::GetCount ( ) const [inline]

Returns the number of ranges in the selection.

wxRichTextRange wxRichTextSelection::GetRange (size_t *i*) const [inline]

Returns the range at the given index.

wxRichTextRange wxRichTextSelection::GetRange ( ) const [inline]

Returns the first range if there is one, otherwise wxRICHTEXT_NO_SELECTION.

wxRichTextRangeArray& wxRichTextSelection::GetRanges ( ) [inline]

Returns the selection ranges.

const wxRichTextRangeArray& wxRichTextSelection::GetRanges ( ) const [inline]

Returns the selection ranges.

wxRichTextRangeArray wxRichTextSelection::GetSelectionForObject (wxRichTextObject * *obj*) const

Returns the selection appropriate to the specified object, if any; returns an empty array if none at the level of the object's container.

bool wxRichTextSelection::IsValid ( ) const [inline]

Returns true if the selection is valid.

void wxRichTextSelection::operator= (const wxRichTextSelection & *sel*) [inline]

Assignment operator.

bool wxRichTextSelection::operator== (const wxRichTextSelection & *sel*) const

Equality operator.

wxRichTextRange wxRichTextSelection::operator[] (size_t *i*) const [inline]

Index operator.

void wxRichTextSelection::Reset ( ) [inline]

Resets the selection.

void wxRichTextSelection::Set (const wxRichTextRange & *range,* wxRichTextParagraphLayoutBox * *container*) [inline]

Sets the selection.

void wxRichTextSelection::Set (const wxRichTextRangeArray & *ranges,* wxRichTextParagraphLayoutBox * *container*) [inline]

Sets the selections from an array of ranges and a container object.

void wxRichTextSelection::SetContainer (wxRichTextParagraphLayoutBox * *container*) [inline]

Sets the container for which the selection is valid.

void wxRichTextSelection::SetRange (const wxRichTextRange & *range*) [inline]

Sets a single range.

void wxRichTextSelection::SetRanges (const wxRichTextRangeArray & *ranges*) [inline]

Sets the selection ranges.

bool wxRichTextSelection::WithinSelection (long *pos,* wxRichTextObject * *obj*) const

Returns true if the given position is within the selection.

bool wxRichTextSelection::WithinSelection (long *pos*) const [inline]

Returns true if the given position is within the selection.

static bool wxRichTextSelection::WithinSelection (long *pos,* const wxRichTextRangeArray & *ranges*) [static]

Returns true if the given position is within the selection range.

static bool wxRichTextSelection::WithinSelection (const wxRichTextRange & *range,* const wxRichTextRangeArray & *ranges*) [static]

Returns true if the given range is within the selection range.

Public Member Functions

- wxRichTextStdRenderer ()

  Constructor.

- virtual bool DrawStandardBullet (wxRichTextParagraph *paragraph, wxDC &dc, const wxRichTextAttr &attr, const wxRect &rect)

  Draws a standard bullet, as specified by the value of GetBulletName.

- virtual bool DrawTextBullet (wxRichTextParagraph *paragraph, wxDC &dc, const wxRichTextAttr &attr, const wxRect &rect, const wxString &text)

  Draws a bullet that can be described by text, such as numbered or symbol bullets.

- virtual bool DrawBitmapBullet (wxRichTextParagraph *paragraph, wxDC &dc, const wxRichTextAttr &attr, const wxRect &rect)

  Draws a bitmap bullet, where the bullet bitmap is specified by the value of GetBulletName.

- virtual bool EnumerateStandardBulletNames (wxArrayString &bulletNames)

  Enumerate the standard bullet names currently supported.

Additional Inherited Members

21.647.2 Constructor & Destructor Documentation

wxRichTextStdRenderer::wxRichTextStdRenderer ( ) [inline]

Constructor.

21.647.3 Member Function Documentation

virtual bool wxRichTextStdRenderer::DrawBitmapBullet (wxRichTextParagraph * *paragraph,* wxDC & *dc,* const wxRichTextAttr & *attr,* const wxRect & *rect*) [virtual]

Draws a bitmap bullet, where the bullet bitmap is specified by the value of GetBulletName.

This function should be overridden.

Implements wxRichTextRenderer.

virtual bool wxRichTextStdRenderer::DrawStandardBullet (wxRichTextParagraph * *paragraph,* wxDC & *dc,* const wxRichTextAttr & *attr,* const wxRect & *rect*) [virtual]

Draws a standard bullet, as specified by the value of GetBulletName.

This function should be overridden.

Implements wxRichTextRenderer.

virtual bool wxRichTextStdRenderer::DrawTextBullet (wxRichTextParagraph * *paragraph,* wxDC & *dc,* const wxRichTextAttr & *attr,* const wxRect & *rect,* const wxString & *text*) [virtual]

Draws a bullet that can be described by text, such as numbered or symbol bullets.

This function should be overridden.

Implements wxRichTextRenderer.

virtual bool wxRichTextStdRenderer::EnumerateStandardBulletNames (wxArrayString & *bulletNames*) [virtual]

Enumerate the standard bullet names currently supported.

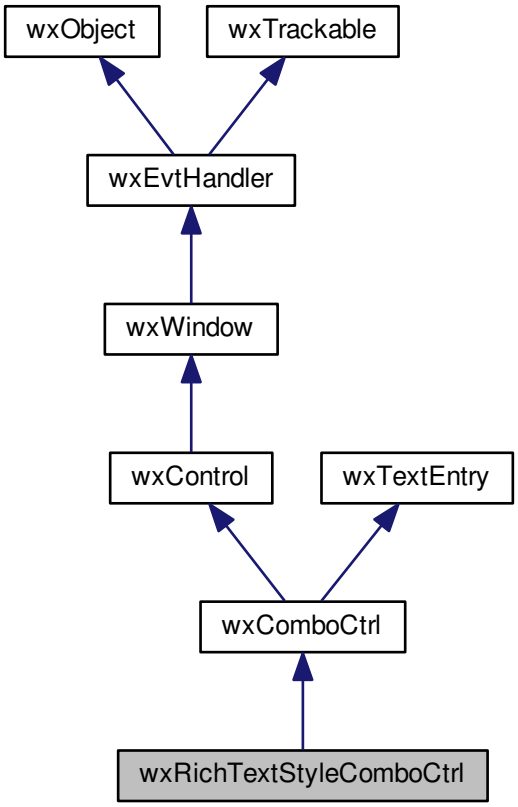
This function should be overridden.

Implements wxRichTextRenderer.

21.648 wxRichTextStyleComboCtrl Class Reference

`#include <wx/richtext/richtextstyles.h>`

Inheritance diagram for wxRichTextStyleComboCtrl:



21.648.1 Detailed Description

This is a combo control that can display the styles in a wxRichTextStyleSheet, and apply the selection to an associated wxRichTextCtrl.

See `samples/richtext` for an example of how to use it.

21.649.1 Detailed Description

This is a base class for paragraph and character styles.

Library: wxRichText

Category: Rich Text

Public Member Functions

- wxRichTextStyleDefinition (const wxString &name=wxEmptyString)
  Constructor.
- virtual ~wxRichTextStyleDefinition ()
  Destructor.
- const wxString & GetBaseStyle () const
  Returns the style on which this style is based.
- const wxString & GetDescription () const
  Returns the style's description.
- const wxString & GetName () const
  Returns the style name.
- virtual wxRichTextAttr GetStyleMergedWithBase (const wxRichTextStyleSheet *sheet) const
  Returns the style attributes combined with the attributes of the specified base style, if any.
- void SetBaseStyle (const wxString &name)

Sets the name of the style that this style is based on.

- void SetDescription (const wxString &descr)

  Sets the style description.
- void SetName (const wxString &name)

  Sets the name of the style.
- void SetStyle (const wxRichTextAttr &style)

  Sets the attributes for this style.
- wxRichTextProperties & GetProperties ()

  Returns the definition's properties.
- const wxRichTextProperties & GetProperties () const

  Returns the definition's properties.
- void SetProperties (const wxRichTextProperties &props)

  Sets the definition's properties.

- wxRichTextAttr GetStyle () const

  Returns the attributes associated with this style.
- const wxRichTextAttr GetStyle () const

  Returns the attributes associated with this style.

Additional Inherited Members

  wxRICHTEXT_STYLE_BOX }

  Which type of style definition is currently showing?

Public Member Functions

- wxRichTextStyleListBox (wxWindow *parent, wxWindowID id=wxID_ANY, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, long style=0)

  Constructor.
- virtual ~wxRichTextStyleListBox ()

  Destructor.
- void ApplyStyle (int i)

  Applies the ith style to the associated rich text control.
- int ConvertTenthsMMToPixels (wxDC &dc, int units) const

  Converts units in tenths of a millimetre to device units.
- wxString CreateHTML (wxRichTextStyleDefinition *def) const

  Creates a suitable HTML fragment for a definition.
- bool GetApplyOnSelection () const

  If the return value is true, clicking on a style name in the list will immediately apply the style to the associated rich text control.
- wxRichTextCtrl * GetRichTextCtrl () const

  Returns the wxRichTextCtrl associated with this listbox.
- wxRichTextStyleDefinition * GetStyle (size_t i) const

  Gets a style for a listbox index.
- wxRichTextStyleSheet * GetStyleSheet () const

  Returns the style sheet associated with this listbox.
- wxRichTextStyleListBox::wxRichTextStyleType GetStyleType () const

  Returns the type of style to show in the list box.
- void OnLeftDown (wxMouseEvent &event)

  Implements left click behaviour, applying the clicked style to the wxRichTextCtrl.
- void SetApplyOnSelection (bool applyOnSelection)

  If applyOnSelection is true, clicking on a style name in the list will immediately apply the style to the associated rich text control.
- void SetRichTextCtrl (wxRichTextCtrl *ctrl)

  Associates the listbox with a wxRichTextCtrl.
- void SetStyleSheet (wxRichTextStyleSheet *styleSheet)

  Associates the control with a style sheet.
- void SetStyleType (wxRichTextStyleListBox::wxRichTextStyleType styleType)

  Sets the style type to display.
- void UpdateStyles ()

  Updates the list from the associated style sheet.

Protected Member Functions

- virtual wxString OnGetItem (size_t n) const

  Returns the HTML for this item.

Implements left click behaviour, applying the clicked style to the wxRichTextCtrl.

void wxRichTextStyleListBox::SetApplyOnSelection (**bool** *applyOnSelection*)

If *applyOnSelection* is true, clicking on a style name in the list will immediately apply the style to the associated rich text control.

void wxRichTextStyleListBox::SetRichTextCtrl (**wxRichTextCtrl** * *ctrl*)

Associates the listbox with a wxRichTextCtrl.

void wxRichTextStyleListBox::SetStyleSheet (**wxRichTextStyleSheet** * *styleSheet*)

Associates the control with a style sheet.

void wxRichTextStyleListBox::SetStyleType (**wxRichTextStyleListBox::wxRichTextStyleType** *styleType*)

Sets the style type to display.

One of

- wxRichTextStyleListBox::wxRICHTEXT_STYLE_ALL,
- wxRichTextStyleListBox::wxRICHTEXT_STYLE_PARAGRAPH,
- wxRichTextStyleListBox::wxRICHTEXT_STYLE_CHARACTER
- wxRichTextStyleListBox::wxRICHTEXT_STYLE_LIST.

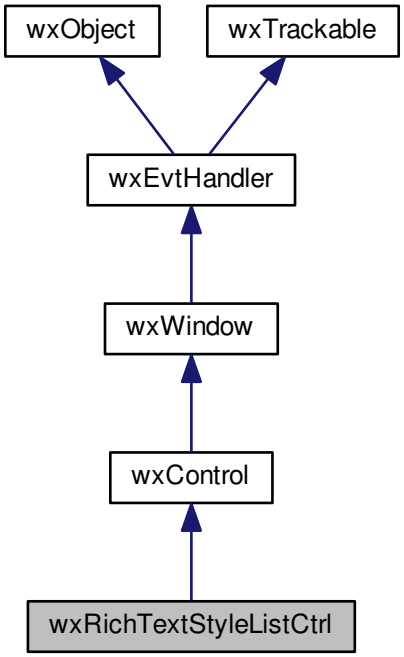
void wxRichTextStyleListBox::UpdateStyles ( )

Updates the list from the associated style sheet.

21.651 wxRichTextStyleListCtrl Class Reference

`#include <wx/richtext/richtextstyles.h>`

Inheritance diagram for wxRichTextStyleListCtrl:



21.651.1 Detailed Description

This class incorporates a wxRichTextStyleListBox and a choice control that allows the user to select the category of style to view.

It is demonstrated in the wxRichTextCtrl sample in `samples/richtext`.

To use wxRichTextStyleListCtrl, add the control to your window hierarchy and call wxRichTextStyleListCtrl::SetStyleType with one of wxRichTextStyleListBox::wxRICHTEXT_STYLE_ALL, wxRichTextStyleListBox::wxRICHTEXT_STYLE_PARAGRAPH, wxRichTextStyleListBox::wxRICHTEXT_STYLE_CHARACTER and wxRichTextStyleListBox::wxRICHTEXT_STYLE_LIST to set the current view.

Associate the control with a style sheet and rich text control with SetStyleSheet and SetRichTextCtrl, so that when a style is double-clicked, it is applied to the selection.

Styles

This class supports the following styles:

- wxRICHTEXTSTYLELIST_HIDE_TYPE_SELECTOR: This style hides the category selection control.

Library: wxRichText

Category: Rich Text

Public Member Functions

- bool Create (wxWindow *parent, wxWindowID id=wxID_ANY, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, long style=0)

  Creates the windows.

bool wxRichTextStyleListCtrl::Create (wxWindow * *parent*, wxWindowID *id* = wxID_ANY, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, long *style* = 0)

Creates the windows.

wxRichTextCtrl* wxRichTextStyleListCtrl::GetRichTextCtrl ( ) const

Returns the associated rich text control, if any.

wxChoice* wxRichTextStyleListCtrl::GetStyleChoice ( ) const

Returns the wxChoice control used for selecting the style category.

wxRichTextStyleListBox* wxRichTextStyleListCtrl::GetStyleListBox ( ) const

Returns the wxListBox control used to view the style list.

wxRichTextStyleSheet* wxRichTextStyleListCtrl::GetStyleSheet ( ) const

Returns the associated style sheet, if any.

wxRichTextStyleListBox::wxRichTextStyleType wxRichTextStyleListCtrl::GetStyleType ( ) const

Returns the type of style to show in the list box.

void wxRichTextStyleListCtrl::SetRichTextCtrl (wxRichTextCtrl * *ctrl*)

Associates the control with a wxRichTextCtrl.

void wxRichTextStyleListCtrl::SetStyleSheet (wxRichTextStyleSheet * *styleSheet*)

Associates the control with a style sheet.

void wxRichTextStyleListCtrl::SetStyleType (wxRichTextStyleListBox::wxRichTextStyleType *styleType*)

Sets the style type to display.

One of

- wxRichTextStyleListBox::wxRICHTEXT_STYLE_ALL,
- wxRichTextStyleListBox::wxRICHTEXT_STYLE_PARAGRAPH,
- wxRichTextStyleListBox::wxRICHTEXT_STYLE_CHARACTER
- wxRichTextStyleListBox::wxRICHTEXT_STYLE_LIST.

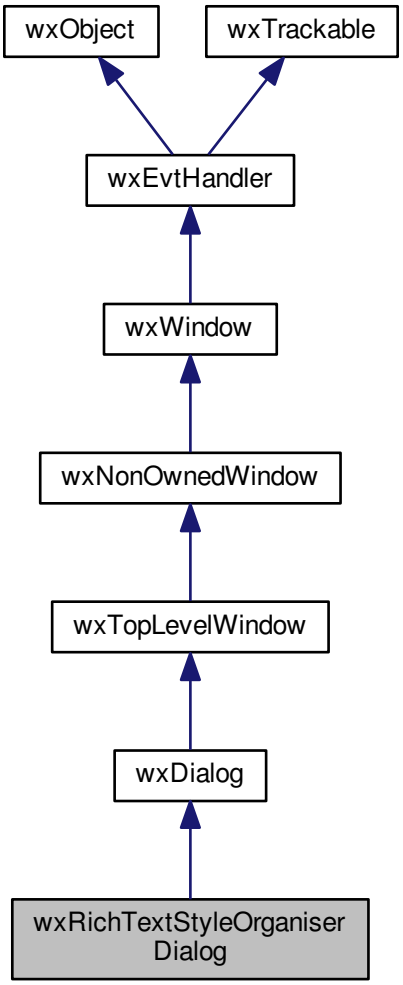
void wxRichTextStyleListCtrl::UpdateStyles ( )

Updates the style list box.

21.652 wxRichTextStyleOrganiserDialog Class Reference

`#include <wx/richtext/richtextstyledlg.h>`

Inheritance diagram for wxRichTextStyleOrganiserDialog:



21.652.1 Detailed Description

This class shows a style sheet and allows the user to edit, add and remove styles.

It can also be used as a style browser, for example if the application is not using a permanent wxRichTextStyleComboCtrl or wxRichTextStyleListCtrl to present styles.

Library: wxRichText

Category: Rich Text

Public Member Functions

- wxRichTextStyleOrganiserDialog ()

  Default ctor.
- wxRichTextStyleOrganiserDialog (int flags, wxRichTextStyleSheet *sheet, wxRichTextCtrl *ctrl, wxWindow *parent, wxWindowID id=wxID_ANY, const wxString &caption=_("Style Organiser"), const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, long style=wxDEFAULT_DIALOG_STYLE|wxRESIZE_BORDER|wxSYSTEM_MENU|wxCLOSE_BOX)

  Constructor.
- bool ApplyStyle (wxRichTextCtrl *ctrl=NULL)

  Applies the selected style to selection in the given control or the control passed to the constructor.
- bool Create (int flags, wxRichTextStyleSheet *sheet, wxRichTextCtrl *ctrl, wxWindow *parent, wxWindowID id=wxID_ANY, const wxString &caption=wxGetTranslation("Style Organiser"), const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxSize(400, 300), long style=wxDEFAULT_DIALOG_STYLE|wxRESIZE_BORDER|wxSYSTEM_MENU|wxCLOSE_BOX)

  Creates the dialog.
- bool GetRestartNumbering () const

  Returns true if the user has opted to restart numbering.
- wxRichTextCtrl * GetRichTextCtrl () const

  Returns the associated rich text control (if any).
- wxString GetSelectedStyle () const

  Returns selected style name.
- wxRichTextStyleDefinition * GetSelectedStyleDefinition () const

  Returns selected style definition.
- wxRichTextStyleSheet * GetStyleSheet () const

  Returns the associated style sheet.
- void SetFlags (int flags)

  Sets the flags used to control the interface presented to the user.
- void SetRestartNumbering (bool restartNumbering)

  Checks or unchecks the restart numbering checkbox.
- void SetRichTextCtrl (wxRichTextCtrl *ctrl)

  Sets the control to be associated with the dialog, for the purposes of applying a style to the selection.
- void SetStyleSheet (wxRichTextStyleSheet *sheet)

  Sets the associated style sheet.
- int GetFlags () const

  Returns the flags used to control the interface presented to the user.

Static Public Member Functions

- static void SetShowToolTips (bool show)

  Determines whether tooltips will be shown.

Additional Inherited Members

21.652.2 Constructor & Destructor Documentation

wxRichTextStyleOrganiserDialog::wxRichTextStyleOrganiserDialog ( )

Default ctor.

wxRichTextStyleOrganiserDialog::wxRichTextStyleOrganiserDialog (int *flags,* wxRichTextStyleSheet * *sheet,* wxRichTextCtrl * *ctrl,* wxWindow * *parent,* wxWindowID *id* = wxID_ANY, const wxString & *caption* = _("Style Organiser"), const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, long *style* = wxDEFAULT_DIALOG_STYLE|wxRESIZE_BORDER|wxSYSTEM_MENU|wxCLOSE_BOX)

Constructor.

To create a dialog, pass a bitlist of *flags* (see below), a style sheet, a text control to apply a selected style to (or NULL), followed by the usual window parameters.

To specify the operations available to the user, pass a combination of these values to *flags:*

- **wxRICHTEXT_ORGANISER_DELETE_STYLES:** Provides a button for deleting styles.
- **wxRICHTEXT_ORGANISER_CREATE_STYLES:** Provides buttons for creating styles.
- **wxRICHTEXT_ORGANISER_APPLY_STYLES:** Provides a button for applying the currently selected style to the selection.
- **wxRICHTEXT_ORGANISER_EDIT_STYLES:** Provides a button for editing styles.
- **wxRICHTEXT_ORGANISER_RENAME_STYLES:** Provides a button for renaming styles.
- **wxRICHTEXT_ORGANISER_OK_CANCEL:** Provides OK and Cancel buttons.
- **wxRICHTEXT_ORGANISER_RENUMBER:** Provides a checkbox for specifying that the selection should be renumbered.

The following flags determine what will be displayed in the style list:

- **wxRICHTEXT_ORGANISER_SHOW_CHARACTER:** Displays character styles only.
- **wxRICHTEXT_ORGANISER_SHOW_PARAGRAPH:** Displays paragraph styles only.
- **wxRICHTEXT_ORGANISER_SHOW_LIST:** Displays list styles only.
- **wxRICHTEXT_ORGANISER_SHOW_ALL:** Displays all styles.

The following symbols define commonly-used combinations of flags:

- **wxRICHTEXT_ORGANISER_ORGANISE:** Enable all style editing operations so the dialog behaves as a style organiser.
- **wxRICHTEXT_ORGANISER_BROWSE:** Show a list of all styles and their previews, but only allow application of a style or cancellation of the dialog. This makes the dialog behave as a style browser.
- **wxRICHTEXT_ORGANISER_BROWSE_NUMBERING:** Enables only list style browsing, plus a control to specify renumbering. This allows the dialog to be used for applying list styles to the selection.

21.652.3 Member Function Documentation

bool wxRichTextStyleOrganiserDialog::ApplyStyle (wxRichTextCtrl * *ctrl* = NULL)

Applies the selected style to selection in the given control or the control passed to the constructor.

bool wxRichTextStyleOrganiserDialog::Create (int *flags,* wxRichTextStyleSheet * *sheet,* wxRichTextCtrl * *ctrl,* wxWindow * *parent,* wxWindowID *id* = wxID_ANY, const wxString & *caption* = wxGetTranslation("Style Organiser"), const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxSize(400, 300), long *style* = wxDEFAULT_DIALOG_STYLE|wxRESIZE_BORDER|wxSYSTEM_MEN↩ U|wxCLOSE_BOX)

Creates the dialog.

See the ctor.

int wxRichTextStyleOrganiserDialog::GetFlags ( ) const

Returns the flags used to control the interface presented to the user.

bool wxRichTextStyleOrganiserDialog::GetRestartNumbering ( ) const

Returns true if the user has opted to restart numbering.

wxRichTextCtrl* wxRichTextStyleOrganiserDialog::GetRichTextCtrl ( ) const

Returns the associated rich text control (if any).

wxString wxRichTextStyleOrganiserDialog::GetSelectedStyle ( ) const

Returns selected style name.

wxRichTextStyleDefinition* wxRichTextStyleOrganiserDialog::GetSelectedStyleDefinition ( ) const

Returns selected style definition.

wxRichTextStyleSheet* wxRichTextStyleOrganiserDialog::GetStyleSheet ( ) const

Returns the associated style sheet.

void wxRichTextStyleOrganiserDialog::SetFlags (int *flags*)

Sets the flags used to control the interface presented to the user.

void wxRichTextStyleOrganiserDialog::SetRestartNumbering (bool *restartNumbering*)

Checks or unchecks the restart numbering checkbox.

void wxRichTextStyleOrganiserDialog::SetRichTextCtrl (wxRichTextCtrl * *ctrl*)

Sets the control to be associated with the dialog, for the purposes of applying a style to the selection.

static void wxRichTextStyleOrganiserDialog::SetShowToolTips (bool *show*) `[static]`

Determines whether tooltips will be shown.

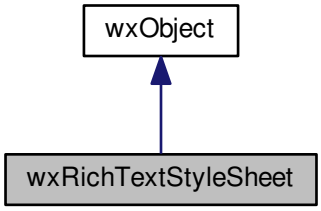
void wxRichTextStyleOrganiserDialog::SetStyleSheet (wxRichTextStyleSheet * *sheet*)

Sets the associated style sheet.

21.653 wxRichTextStyleSheet Class Reference

`#include <wx/richtext/richtextstyles.h>`

Inheritance diagram for wxRichTextStyleSheet:



21.653.1 Detailed Description

A style sheet contains named paragraph and character styles that make it easy for a user to apply combinations of attributes to a wxRichTextCtrl.

You can use a wxRichTextStyleListBox in your user interface to show available styles to the user, and allow application of styles to the control.

Library: wxRichText

Category: Rich Text

Public Member Functions

- wxRichTextStyleSheet ()

  Constructor.
- virtual ~wxRichTextStyleSheet ()

  Destructor.
- bool AddCharacterStyle (wxRichTextCharacterStyleDefinition *def)

  Adds a definition to the character style list.
- bool AddListStyle (wxRichTextListStyleDefinition *def)

  Adds a definition to the list style list.
- bool AddParagraphStyle (wxRichTextParagraphStyleDefinition *def)

  Adds a definition to the paragraph style list.
- bool AddStyle (wxRichTextStyleDefinition *def)

  Adds a definition to the appropriate style list.
- void DeleteStyles ()

  Deletes all styles.
- wxRichTextCharacterStyleDefinition * FindCharacterStyle (const wxString &name, bool recurse=true) const

  Finds a character definition by name.
- wxRichTextListStyleDefinition * FindListStyle (const wxString &name, bool recurse=true) const

  Finds a list definition by name.
- wxRichTextParagraphStyleDefinition * FindParagraphStyle (const wxString &name, bool recurse=true) const

  Finds a paragraph definition by name.
- wxRichTextStyleDefinition * FindStyle (const wxString &name) const

Finds a style definition by name.

- wxRichTextCharacterStyleDefinition * GetCharacterStyle (size_t n) const

  Returns the nth character style.

- size_t GetCharacterStyleCount () const

  Returns the number of character styles.

- const wxString & GetDescription () const

  Returns the style sheet's description.

- wxRichTextListStyleDefinition * GetListStyle (size_t n) const

  Returns the nth list style.

- size_t GetListStyleCount () const

  Returns the number of list styles.

- const wxString & GetName () const

  Returns the style sheet's name.

  Returns the nth paragraph style.

- size_t GetParagraphStyleCount () const

  Returns the number of paragraph styles.

- bool RemoveCharacterStyle (wxRichTextStyleDefinition *def, bool deleteStyle=false)

  Removes a character style.

- bool RemoveListStyle (wxRichTextStyleDefinition *def, bool deleteStyle=false)

  Removes a list style.

- bool RemoveParagraphStyle (wxRichTextStyleDefinition *def, bool deleteStyle=false)

  Removes a paragraph style.

- bool RemoveStyle (wxRichTextStyleDefinition *def, bool deleteStyle=false)

  Removes a style.

- void SetDescription (const wxString &descr)

  Sets the style sheet's description.

- void SetName (const wxString &name)

  Sets the style sheet's name.

- wxRichTextProperties & GetProperties ()

  Returns the sheet's properties.

- const wxRichTextProperties & GetProperties () const

  Returns the sheet's properties.

- void SetProperties (const wxRichTextProperties &props)

  Sets the sheet's properties.

Additional Inherited Members

21.653.2 Constructor & Destructor Documentation

wxRichTextStyleSheet::wxRichTextStyleSheet ( )

Constructor.

virtual wxRichTextStyleSheet::~wxRichTextStyleSheet ( ) [virtual]

Destructor.

21.653.3 Member Function Documentation

bool wxRichTextStyleSheet::AddCharacterStyle (wxRichTextCharacterStyleDefinition * *def*)

Adds a definition to the character style list.

bool wxRichTextStyleSheet::AddListStyle (wxRichTextListStyleDefinition * *def*)

Adds a definition to the list style list.

bool wxRichTextStyleSheet::AddParagraphStyle (wxRichTextParagraphStyleDefinition * *def*)

Adds a definition to the paragraph style list.

bool wxRichTextStyleSheet::AddStyle (wxRichTextStyleDefinition * *def*)

Adds a definition to the appropriate style list.

void wxRichTextStyleSheet::DeleteStyles ( )

Deletes all styles.

wxRichTextCharacterStyleDefinition* wxRichTextStyleSheet::FindCharacterStyle (const wxString & *name,* bool *recurse* = `true`) const

Finds a character definition by name.

wxRichTextListStyleDefinition* wxRichTextStyleSheet::FindListStyle (const wxString & *name,* bool *recurse* = `true`) const

Finds a list definition by name.

wxRichTextParagraphStyleDefinition* wxRichTextStyleSheet::FindParagraphStyle (const wxString & *name,* bool *recurse* = `true`) const

Finds a paragraph definition by name.

wxRichTextStyleDefinition* wxRichTextStyleSheet::FindStyle (const wxString & *name*) const

Finds a style definition by name.

wxRichTextCharacterStyleDefinition* wxRichTextStyleSheet::GetCharacterStyle (size_t *n*) const

Returns the *nth* character style.

size_t wxRichTextStyleSheet::GetCharacterStyleCount ( ) const

Returns the number of character styles.

const wxString& wxRichTextStyleSheet::GetDescription ( ) const

Returns the style sheet's description.

wxRichTextListStyleDefinition* wxRichTextStyleSheet::GetListStyle (size_t *n*) const

Returns the *nth* list style.

size_t wxRichTextStyleSheet::GetListStyleCount ( ) const

Returns the number of list styles.

const wxString& wxRichTextStyleSheet::GetName ( ) const

Returns the style sheet's name.

wxRichTextParagraphStyleDefinition* wxRichTextStyleSheet::GetParagraphStyle (size_t *n*) const

Returns the *nth* paragraph style.

size_t wxRichTextStyleSheet::GetParagraphStyleCount ( ) const

Returns the number of paragraph styles.

wxRichTextProperties& wxRichTextStyleSheet::GetProperties ( )

Returns the sheet's properties.

const wxRichTextProperties& wxRichTextStyleSheet::GetProperties ( ) const

Returns the sheet's properties.

bool wxRichTextStyleSheet::RemoveCharacterStyle (wxRichTextStyleDefinition * *def,* bool *deleteStyle* = `false`)

Removes a character style.

bool wxRichTextStyleSheet::RemoveListStyle (wxRichTextStyleDefinition * *def,* bool *deleteStyle* = `false`)

Removes a list style.

bool wxRichTextStyleSheet::RemoveParagraphStyle (wxRichTextStyleDefinition * *def,* bool *deleteStyle* = `false`)

Removes a paragraph style.

bool wxRichTextStyleSheet::RemoveStyle (wxRichTextStyleDefinition * *def,* bool *deleteStyle* = `false`)

Removes a style.

void wxRichTextStyleSheet::SetDescription (const wxString & *descr*)

Sets the style sheet's description.

void wxRichTextStyleSheet::SetName (const wxString & *name*)

Sets the style sheet's name.

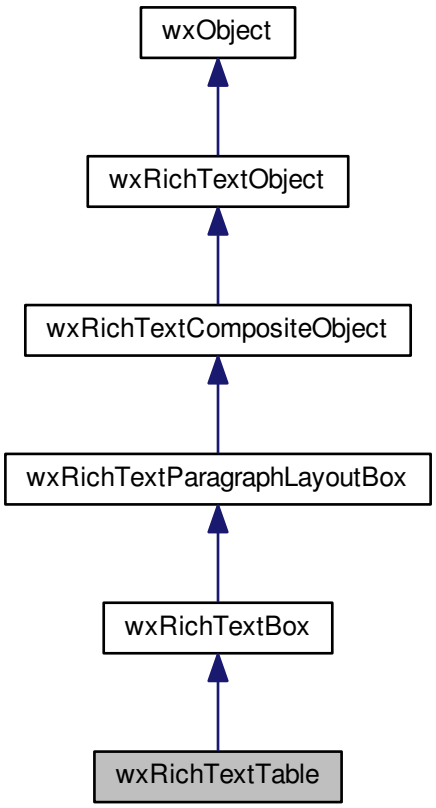
void wxRichTextStyleSheet::SetProperties (const wxRichTextProperties & *props*)

Sets the sheet's properties.

21.654 wxRichTextTable Class Reference

`#include <wx/richtext/richtextbuffer.h>`

Inheritance diagram for wxRichTextTable:



21.654.1 Detailed Description

wxRichTextTable represents a table with arbitrary columns and rows.

Public Member Functions

- wxRichTextTable (wxRichTextObject *parent=NULL)

  Default constructor; optionally pass the parent object.
- wxRichTextTable (const wxRichTextTable &obj)

  Copy constructor.
- virtual bool Draw (wxDC &dc, wxRichTextDrawingContext &context, const wxRichTextRange &range, const wxRichTextSelection &selection, const wxRect &rect, int descent, int style)

  Draw the item, within the given range.
- virtual int HitTest (wxDC &dc, wxRichTextDrawingContext &context, const wxPoint &pt, long &textPosition, wxRichTextObject **obj, wxRichTextObject **contextObj, int flags=0)

  Hit-testing: returns a flag indicating hit test details, plus information about position.
- virtual wxString GetXMLNodeName () const

  Returns the XML node name of this object.
- virtual bool Layout (wxDC &dc, wxRichTextDrawingContext &context, const wxRect &rect, const wxRect &parentRect, int style)

  Lay the item out at the specified position with the given size constraint.
- virtual bool GetRangeSize (const wxRichTextRange &range, wxSize &size, int &descent, wxDC &dc, wxRichTextDrawingContext &context, int flags, const wxPoint &position=wxPoint(0, 0), const wxSize &parentSize=wxDefaultSize, wxArrayInt *partialExtents=NULL) const

  Returns the object size for the given range.
- virtual bool DeleteRange (const wxRichTextRange &range)

  Deletes the given range.
- virtual wxString GetTextForRange (const wxRichTextRange &range) const

  Returns any text in this object for the given range.
- virtual bool ImportFromXML (wxRichTextBuffer *buffer, wxXmlNode *node, wxRichTextXMLHandler *handler, bool *recurse)

  Imports this object from XML.
- virtual bool FindPosition (wxDC &dc, wxRichTextDrawingContext &context, long index, wxPoint &pt, int *height, bool forceLineStart)

  Finds the absolute position and row height for the given character position.
- virtual void CalculateRange (long start, long &end)

  Calculates the range of the object.
- virtual bool HandlesChildSelections () const

  Returns true if this object can handle the selections of its children, fOr example a table.
- virtual wxRichTextSelection GetSelection (long start, long end) const

  Returns a selection object specifying the selections between start and end character positions.
- virtual bool CanEditProperties () const

  Returns true if we can edit the object's properties via a GUI.
- virtual bool EditProperties (wxWindow *parent, wxRichTextBuffer *buffer)

  Edits the object's properties via a GUI.
- virtual wxString GetPropertiesMenuLabel () const

  Returns the label to be used for the properties context menu item.
- virtual bool AcceptsFocus () const

  Returns true if objects of this class can accept the focus, i.e. a call to SetFocusObject is possible.
- const wxRichTextObjectPtrArrayArray & GetCells () const

  Returns the cells array.
- wxRichTextObjectPtrArrayArray & GetCells ()

  Returns the cells array.
- int GetRowCount () const

  Returns the row count.

- int GetColumnCount () const

  Returns the column count.
- virtual wxRichTextCell * GetCell (int row, int col) const

  Returns the cell at the given row/column position.
- virtual wxRichTextCell * GetCell (long pos) const

  Returns the cell at the given character position (in the range of the table).
- virtual bool GetCellRowColumnPosition (long pos, int &row, int &col) const

  Returns the row/column for a given character position.
- virtual wxPosition GetFocusedCell () const

  Returns the coordinates of the cell with keyboard focus, or (-1,-1) if none.
- virtual void ClearTable ()

  Clears the table.
- virtual bool CreateTable (int rows, int cols)

  Creates a table of the given dimensions.
- virtual bool SetCellStyle (const wxRichTextSelection &selection, const wxRichTextAttr &style, int flags=wxRICHTEXT_SETSTYLE_WITH_UNDO)

  Sets the attributes for the cells specified by the selection.
- virtual bool DeleteRows (int startRow, int noRows=1)

  Deletes rows from the given row position.
- virtual bool DeleteColumns (int startCol, int noCols=1)

  Deletes columns from the given column position.
- virtual bool AddRows (int startRow, int noRows=1, const wxRichTextAttr &attr=wxRichTextAttr())

  Adds rows from the given row position.
- virtual bool AddColumns (int startCol, int noCols=1, const wxRichTextAttr &attr=wxRichTextAttr())

  Adds columns from the given column position.
- virtual wxRichTextObject * Clone () const

  Clones the object.
- void Copy (const wxRichTextTable &obj)

Protected Attributes

- int m_rowCount
- int m_colCount
- wxRichTextObjectPtrArrayArray m_cells

Additional Inherited Members

21.654.2 Constructor & Destructor Documentation

wxRichTextTable::wxRichTextTable (wxRichTextObject * *parent* = NULL)

Default constructor; optionally pass the parent object.

wxRichTextTable::wxRichTextTable (const wxRichTextTable & *obj*) [inline]

Copy constructor.

21.654.3 Member Function Documentation

virtual bool wxRichTextTable::AcceptsFocus ( ) const `[inline], [virtual]`

Returns true if objects of this class can accept the focus, i.e. a call to SetFocusObject is possible.

For example, containers supporting text, such as a text box object, can accept the focus, but a table can't (set the focus to individual cells instead).

Reimplemented from wxRichTextParagraphLayoutBox.

virtual bool wxRichTextTable::AddColumns (int *startCol,* int *noCols* = `1`, const wxRichTextAttr & *attr* = wxRichTextAttr `()`) `[virtual]`

Adds columns from the given column position.

virtual bool wxRichTextTable::AddRows (int *startRow,* int *noRows* = `1`, const wxRichTextAttr & *attr* = wxRichTextAttr `()`) `[virtual]`

Adds rows from the given row position.

virtual void wxRichTextTable::CalculateRange (long *start,* long & *end*) `[virtual]`

Calculates the range of the object.

By default, guess that the object is 1 unit long.

Reimplemented from wxRichTextCompositeObject.

virtual bool wxRichTextTable::CanEditProperties ( ) const `[inline], [virtual]`

Returns true if we can edit the object's properties via a GUI.

Reimplemented from wxRichTextBox.

virtual void wxRichTextTable::ClearTable ( ) `[virtual]`

Clears the table.

virtual wxRichTextObject* wxRichTextTable::Clone ( ) const `[inline], [virtual]`

Clones the object.

Reimplemented from wxRichTextBox.

void wxRichTextTable::Copy (const wxRichTextTable & *obj*)

virtual bool wxRichTextTable::CreateTable (int *rows,* int *cols*) `[virtual]`

Creates a table of the given dimensions.

virtual bool wxRichTextTable::DeleteColumns (int *startCol,* int *noCols* = `1`) `[virtual]`

Deletes columns from the given column position.

virtual bool wxRichTextTable::DeleteRange (const wxRichTextRange & *range*) `[virtual]`

Deletes the given range.

Reimplemented from wxRichTextParagraphLayoutBox.

virtual bool wxRichTextTable::DeleteRows (int *startRow,* int *noRows* = 1) `[virtual]`

Deletes rows from the given row position.

virtual bool wxRichTextTable::Draw (wxDC & *dc,* wxRichTextDrawingContext & *context,* const wxRichTextRange & *range,* const wxRichTextSelection & *selection,* const wxRect & *rect,* int *descent,* int *style*) `[virtual]`

Draw the item, within the given range.

Some objects may ignore the range (for example paragraphs) while others must obey it (lines, to implement wrapping)

Reimplemented from wxRichTextBox.

virtual bool wxRichTextTable::EditProperties (wxWindow * *parent,* wxRichTextBuffer * *buffer*) `[virtual]`

Edits the object's properties via a GUI.

Reimplemented from wxRichTextBox.

virtual bool wxRichTextTable::FindPosition (wxDC & *dc,* wxRichTextDrawingContext & *context,* long *index,* wxPoint & *pt,* int * *height,* bool *forceLineStart*) `[virtual]`

Finds the absolute position and row height for the given character position.

Reimplemented from wxRichTextCompositeObject.

virtual wxRichTextCell* wxRichTextTable::GetCell (int *row,* int *col*) const `[virtual]`

Returns the cell at the given row/column position.

virtual wxRichTextCell* wxRichTextTable::GetCell (long *pos*) const `[virtual]`

Returns the cell at the given character position (in the range of the table).

virtual bool wxRichTextTable::GetCellRowColumnPosition (long *pos,* int & *row,* int & *col*) const `[virtual]`

Returns the row/column for a given character position.

const wxRichTextObjectPtrArrayArray& wxRichTextTable::GetCells ( ) const `[inline]`

Returns the cells array.

wxRichTextObjectPtrArrayArray& wxRichTextTable::GetCells ( ) `[inline]`

Returns the cells array.

int wxRichTextTable::GetColumnCount ( ) const `[inline]`

Returns the column count.

virtual wxPosition wxRichTextTable::GetFocusedCell ( ) const `[virtual]`

Returns the coordinates of the cell with keyboard focus, or (-1,-1) if none.

virtual wxString wxRichTextTable::GetPropertiesMenuLabel ( ) const `[inline], [virtual]`

Returns the label to be used for the properties context menu item.

Reimplemented from wxRichTextBox.

virtual bool wxRichTextTable::GetRangeSize (const wxRichTextRange & *range*, wxSize & *size*, int & *descent*, wxDC & *dc*, wxRichTextDrawingContext & *context*, int *flags*, const wxPoint & *position* = wxPoint(0, 0), const wxSize & *parentSize* = wxDefaultSize, wxArrayInt * *partialExtents* = NULL) const `[virtual]`

Returns the object size for the given range.

Returns false if the range is invalid for this object.

Reimplemented from wxRichTextParagraphLayoutBox.

int wxRichTextTable::GetRowCount ( ) const `[inline]`

Returns the row count.

virtual wxRichTextSelection wxRichTextTable::GetSelection (long *start*, long *end*) const `[virtual]`

Returns a selection object specifying the selections between start and end character positions.

For example, a table would deduce what cells (of range length 1) are selected when dragging across the table.

Reimplemented from wxRichTextObject.

virtual wxString wxRichTextTable::GetTextForRange (const wxRichTextRange & *range*) const `[virtual]`

Returns any text in this object for the given range.

Reimplemented from wxRichTextParagraphLayoutBox.

virtual wxString wxRichTextTable::GetXMLNodeName ( ) const `[inline], [virtual]`

Returns the XML node name of this object.

This must be overridden for wxXmlNode-base XML export to work.

Reimplemented from wxRichTextBox.

virtual bool wxRichTextTable::HandlesChildSelections ( ) const `[inline], [virtual]`

Returns true if this object can handle the selections of its children, fOr example a table.

Required for composite selection handling to work.

Reimplemented from wxRichTextObject.

virtual int wxRichTextTable::HitTest (wxDC & *dc,* wxRichTextDrawingContext & *context,* const wxPoint & *pt,* long & *textPosition,* wxRichTextObject ** *obj,* wxRichTextObject ** *contextObj,* int *flags* = 0) [virtual]

Hit-testing: returns a flag indicating hit test details, plus information about position.

contextObj is returned to specify what object position is relevant to, since otherwise there's an ambiguity. @ obj might not be a child of *contextObj*, since we may be referring to the container itself if we have no hit on a child - for example if we click outside an object.

The function puts the position in *textPosition* if one is found. *pt* is in logical units (a zero y position is at the beginning of the buffer).

Returns

One of the wxRichTextHitTestFlags values.

Reimplemented from wxRichTextParagraphLayoutBox.

virtual bool wxRichTextTable::ImportFromXML (wxRichTextBuffer * *buffer,* wxXmlNode * *node,* wxRichTextXMLHandler * *handler,* bool * *recurse*) [virtual]

Imports this object from XML.

Reimplemented from wxRichTextParagraphLayoutBox.

virtual bool wxRichTextTable::Layout (wxDC & *dc,* wxRichTextDrawingContext & *context,* const wxRect & *rect,* const wxRect & *parentRect,* int *style*) [virtual]

Lay the item out at the specified position with the given size constraint.

Layout must set the cached size. *rect* is the available space for the object, and *parentRect* is the container that is used to determine a relative size or position (for example if a text box must be 50% of the parent text box).

Reimplemented from wxRichTextParagraphLayoutBox.

virtual bool wxRichTextTable::SetCellStyle (const wxRichTextSelection & *selection,* const wxRichTextAttr & *style,* int *flags* = wxRICHTEXT_SETSTYLE_WITH_UNDO) [virtual]

Sets the attributes for the cells specified by the selection.

21.654.4 Member Data Documentation

21.655 wxRichTextTableBlock Class Reference

`#include <wx/richtext/richtextbuffer.h>`

21.655.1 Detailed Description

Stores the coordinates for a block of cells.

Public Member Functions

- wxRichTextTableBlock ()
- wxRichTextTableBlock (int colStart, int colEnd, int rowStart, int rowEnd)
- wxRichTextTableBlock (const wxRichTextTableBlock &block)
- void Init ()
- void Copy (const wxRichTextTableBlock &block)
- void operator= (const wxRichTextTableBlock &block)
- bool operator== (const wxRichTextTableBlock &block)
- bool ComputeBlockForSelection (wxRichTextTable *table, wxRichTextCtrl *ctrl, bool requireCell↩ Selection=true)

  Computes the block given a table (perhaps about to be edited) and a rich text control that may have a selection.
- bool IsWholeTable (wxRichTextTable *table) const

  Does this block represent the whole table?
- int & ColStart ()
- int ColStart () const
- int & ColEnd ()
- int ColEnd () const
- int & RowStart ()
- int RowStart () const
- int & RowEnd ()
- int RowEnd () const

Static Public Member Functions

- static wxRichTextCell * GetFocusedCell (wxRichTextCtrl *ctrl)

  Returns the cell focused in the table, if any.

Public Attributes

- int m_colStart
- int m_colEnd
- int m_rowStart
- int m_rowEnd

21.655.2 Constructor & Destructor Documentation

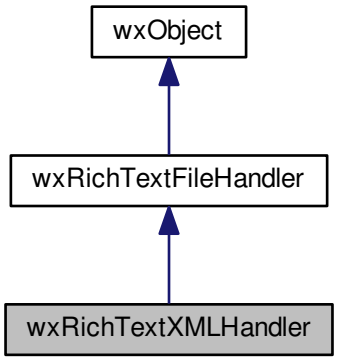
21.656 wxRichTextXMLHandler Class Reference

`#include <wx/richtext/richtextxml.h>`

Inheritance diagram for wxRichTextXMLHandler:



21.656.1 Detailed Description

A handler for loading and saving content in an XML format specific to wxRichTextBuffer.

You can either add the handler to the buffer and load and save through the buffer or control API, or you can create an instance of the handler on the stack and call its functions directly.

21.656.2 Handler flags

The following flags can be used with this handler, via the handler's SetFlags() function or the buffer or control's SetHandlerFlags() function:

- wxRICHTEXT_HANDLER_INCLUDE_STYLESHEET Include the style sheet in loading and saving operations.

Library: wxRichText

Category: Rich Text

Public Member Functions

- wxRichTextXMLHandler (const wxString &name="XML", const wxString &ext="xml", int type=wxRICHTEXT_TYPE_XML)

  Constructor.
- virtual bool CanLoad () const

  Returns true.
- virtual bool CanSave () const

  Returns true.
- bool ExportXML (wxOutputStream &stream, wxRichTextObject &obj, int level)

  Recursively exports an object to the stream.
- bool ImportXML (wxRichTextBuffer *buffer, wxRichTextObject *obj, wxXmlNode *node)

  Recursively imports an object.

Static Public Member Functions

- static void RegisterNodeName (const wxString &nodeName, const wxString &className)

  Call with XML node name, C++ class name so that wxRTC can read in the node.
- static void ClearNodeToClassMap ()

  Cleans up the mapping between node name and C++ class.

Protected Member Functions

- virtual bool DoLoadFile (wxRichTextBuffer *buffer, wxInputStream &stream)

  Loads buffer context from the given stream.
- virtual bool DoSaveFile (wxRichTextBuffer *buffer, wxOutputStream &stream)

  Saves buffer context to the given stream.

Additional Inherited Members

21.656.3 Constructor & Destructor Documentation

wxRichTextXMLHandler::wxRichTextXMLHandler (const wxString & *name* = "XML", const wxString & *ext* = "xml", int *type* = wxRICHTEXT_TYPE_XML)

Constructor.

21.656.4 Member Function Documentation

virtual bool wxRichTextXMLHandler::CanLoad ( ) const `[virtual]`

Returns true.

Reimplemented from wxRichTextFileHandler.

virtual bool wxRichTextXMLHandler::CanSave ( ) const `[virtual]`

Returns true.

Reimplemented from wxRichTextFileHandler.

static void wxRichTextXMLHandler::ClearNodeToClassMap ( ) `[inline], [static]`

Cleans up the mapping between node name and C++ class.

virtual bool wxRichTextXMLHandler::DoLoadFile (wxRichTextBuffer * *buffer*, wxInputStream & *stream*) `[protected], [virtual]`

Loads buffer context from the given stream.

Implements wxRichTextFileHandler.

virtual bool wxRichTextXMLHandler::DoSaveFile (wxRichTextBuffer * *buffer*, wxOutputStream & *stream*) `[protected], [virtual]`

Saves buffer context to the given stream.

Implements wxRichTextFileHandler.

bool wxRichTextXMLHandler::ExportXML (wxOutputStream & *stream,* wxRichTextObject & *obj,* int *level*)

Recursively exports an object to the stream.

bool wxRichTextXMLHandler::ImportXML (wxRichTextBuffer * *buffer,* wxRichTextObject * *obj,* wxXmlNode * *node*)

Recursively imports an object.

static void wxRichTextXMLHandler::RegisterNodeName (const wxString & *nodeName,* const wxString & *className*)
`[inline], [static]`

Call with XML node name, C++ class name so that wxRTC can read in the node.

If you add a custom object, call this.

21.657 wxRichToolTip Class Reference

`#include <wx/richtooltip.h>`

21.657.1 Detailed Description

Allows to show a tool tip with more customizations than wxToolTip.

Using this class is very simple, to give a standard warning for a password text control if the password was entered correctly you could simply do:

```
wxTextCtrl* password = new wxTextCtrl(..., wxTE_PASSWORD);
...
wxRichToolTip tip("Caps Lock is on",
                  "You might have made an error in your password\n"
                  "entry because Caps Lock is turned on.\n"
                  "\n"
                  "Press Caps Lock key to turn it off.");
tip.SetIcon(wxICON_WARNING);
tip.ShowFor(password);
```

Currently this class has generic implementation that can be used with any window and implements all the functionality but doesn't exactly match the appearance of the native tooltips (even though it makes some efforts to use the style most appropriate for the current platform) and a native MSW version which can be only used with text controls and doesn't provide as much in the way of customization. Because of this, it's inadvisable to customize the tooltips unnecessarily as doing this turns off auto-detection of the native style in the generic version and may prevent the native MSW version from being used at all.

Notice that this class is not derived from wxWindow and hence doesn't represent a window, even if its ShowFor() method does create one internally to show the tooltip.

The images below show some examples of rich tooltips on different platforms, with various customizations applied.

Library: wxAdvanced

Category: Miscellaneous Windows

Since

2.9.3

Public Member Functions

- wxRichToolTip (const wxString &title, const wxString &message)

  Constructor must specify the tooltip title and main message.
- void SetBackgroundColour (const wxColour &col, const wxColour &colEnd=wxColour())

  Set the background colour.
- void SetTimeout (unsigned millisecondsTimeout, unsigned millisecondsDelay=0)

  Set timeout after which the tooltip should disappear and optionally set a delay before the tooltip is shown, in milliseconds.
- void SetTipKind (wxTipKind tipKind)

  Choose the tip kind, possibly none.
- void SetTitleFont (const wxFont &font)

  Set the title text font.
- void ShowFor (wxWindow *win, const wxRect *rect=NULL)

  Show the tooltip for the given window and optionally specify where to show the tooltip.
- ~wxRichToolTip ()

  Destructor.

- void SetIcon (int icon=wxICON_INFORMATION)

  Set the small icon to show.
- void SetIcon (const wxIcon &icon)

  Set the small icon to show.

21.657.2 Constructor & Destructor Documentation

wxRichToolTip::wxRichToolTip (const wxString & *title,* const wxString & *message*)

Constructor must specify the tooltip title and main message.

The main message can contain embedded new lines. Both the title and message must be non-empty.

Additional attributes can be set later.

wxRichToolTip::~wxRichToolTip ( )

Destructor.

Notice that destroying this object does not hide the tooltip if it's currently shown, it will be hidden and destroyed when the user dismisses it or the timeout expires.

The destructor is non-virtual as this class is not supposed to be derived from.

21.657.3 Member Function Documentation

void wxRichToolTip::SetBackgroundColour (const wxColour & *col,* const wxColour & *colEnd* = wxColour ( ))

Set the background colour.

If two colours are specified, the background is drawn using a gradient from top to bottom, otherwise a single solid colour is used.

By default the colour or colours most appropriate for the current platform are used. If a colour is explicitly set, native MSW version won't be used as it doesn't support setting the colour.

void wxRichToolTip::SetIcon (int *icon* = wxICON_INFORMATION)

Set the small icon to show.

The icon can be either one of the standard information/warning/error ones, i.e. wxICON_INFORMATION, wxICO↩N_WARNING or wxICON_ERROR respectively (the question icon doesn't make sense for a tooltip so wxICON_↩QUESTION can't be used here) or a custom icon. The latter is unsupported by the native MSW implementation of this class so the use of a standard icon is preferred.

void wxRichToolTip::SetIcon (const wxIcon & *icon*)

Set the small icon to show.

The icon can be either one of the standard information/warning/error ones, i.e. wxICON_INFORMATION, wxICO↩N_WARNING or wxICON_ERROR respectively (the question icon doesn't make sense for a tooltip so wxICON_↩QUESTION can't be used here) or a custom icon. The latter is unsupported by the native MSW implementation of this class so the use of a standard icon is preferred.

void wxRichToolTip::SetTimeout (unsigned *millisecondsTimeout,* unsigned *millisecondsDelay* = 0)

Set timeout after which the tooltip should disappear and optionally set a delay before the tooltip is shown, in milliseconds.

By default the tooltip is shown immediately and hidden after a system-dependent interval of time elapses. This method can be used to change this or also disable hiding the tooltip automatically entirely by passing 0 in this parameter (but doing this will prevent the native MSW version from being used).

Notice that the tooltip will always be hidden if the user presses a key or clicks a mouse button.

Parameter *millisecondsDelay* is new since wxWidgets 2.9.5.

void wxRichToolTip::SetTipKind (wxTipKind *tipKind*)

Choose the tip kind, possibly none.

See wxTipKind documentation for the possible choices here.

By default the tip is positioned automatically, as if wxTipKind_Auto was used. Native MSW implementation doesn't support setting the tip kind explicitly and won't be used if this method is called with any value other than wxTip↩Kind_Auto.

Notice that using non automatic tooltip kind may result in the tooltip being positioned partially off screen and it's the callers responsibility to ensure that this doesn't happen in this case.

void wxRichToolTip::SetTitleFont (const wxFont & *font*)

Set the title text font.

By default it's emphasized using the font style or colour appropriate for the current platform. Calling this method prevents the native MSW implementation from being used as it doesn't support changing the font.

void wxRichToolTip::ShowFor (wxWindow * *win,* const wxRect * *rect* = NULL)

Show the tooltip for the given window and optionally specify where to show the tooltip.

By default the tooltip tip points to the (middle of the) specified window which must be non-NULL or, if *rect* is non-NULL, the middle of the specified wxRect.

The coordinates of the *rect* parameter are relative to the given window.

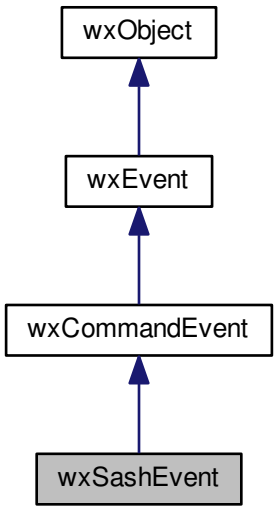
Currently the native MSW implementation is used only if *win* is a wxTextCtrl and *rect* is NULL. This limitation may be removed in the future.

Parameter *rect* is new since wxWidgets 2.9.5.

21.658 wxSashEvent Class Reference

`#include <wx/sashwin.h>`

Inheritance diagram for wxSashEvent:



21.658.1 Detailed Description

A sash event is sent when the sash of a wxSashWindow has been dragged by the user.

Remarks

When a sash belonging to a sash window is dragged by the user, and then released, this event is sent to the window, where it may be processed by an event table entry in a derived class, a plug-in event handler or an ancestor class. Note that the wxSashWindow doesn't change the window's size itself. It relies on the application's event handler to do that. This is because the application may have to handle other consequences of the resize, or it may wish to veto it altogether. The event handler should look at the drag rectangle: see wxSashEvent::GetDragRect to see what the new size of the window would be if the resize were to be applied. It should also call wxSashEvent::GetDragStatus to see whether the drag was OK or out of the current allowed range.

Events using this class

The following event handler macros redirect the events to member function handlers '**func**' with prototypes like: void handlerFuncName(wxSashEvent& event)

Event macros:

- EVT_SASH_DRAGGED(id, func): Process a `wxEVT_SASH_DRAGGED` event, when the user has finished dragging a sash.
- EVT_SASH_DRAGGED_RANGE(id1, id2, func): Process a `wxEVT_SASH_DRAGGED_RANGE` event, when the user has finished dragging a sash. The event handler is called when windows with ids in the given range have their sashes dragged.

Library: wxAdvanced

Category: Events

wxSashWindow, Events and Event Handling

Public Member Functions

- wxSashEvent (int id=0, wxSashEdgePosition edge=wxSASH_NONE)

  Constructor.
- wxRect GetDragRect () const

  Returns the rectangle representing the new size the window would be if the resize was applied.
- wxSashDragStatus GetDragStatus () const

  Returns the status of the sash: one of wxSASH_STATUS_OK, wxSASH_STATUS_OUT_OF_RANGE.
- wxSashEdgePosition GetEdge () const

  Returns the dragged edge.
- void SetEdge (wxSashEdgePosition edge)
- void SetDragRect (const wxRect &rect)
- void SetDragStatus (wxSashDragStatus status)

Additional Inherited Members

21.658.2 Constructor & Destructor Documentation

wxSashEvent::wxSashEvent (int *id* = 0, wxSashEdgePosition *edge* = wxSASH_NONE)

Constructor.

21.658.3 Member Function Documentation

wxRect wxSashEvent::GetDragRect ( ) const

Returns the rectangle representing the new size the window would be if the resize was applied.

It is up to the application to set the window size if required.

wxSashDragStatus wxSashEvent::GetDragStatus ( ) const

Returns the status of the sash: one of wxSASH_STATUS_OK, wxSASH_STATUS_OUT_OF_RANGE.

If the drag caused the notional bounding box of the window to flip over, for example, the drag will be out of rage.

wxSashEdgePosition wxSashEvent::GetEdge ( ) const

Returns the dragged edge.

The return value is one of wxSASH_TOP, wxSASH_RIGHT, wxSASH_BOTTOM, wxSASH_LEFT.

void wxSashEvent::SetDragRect (const wxRect & *rect*)

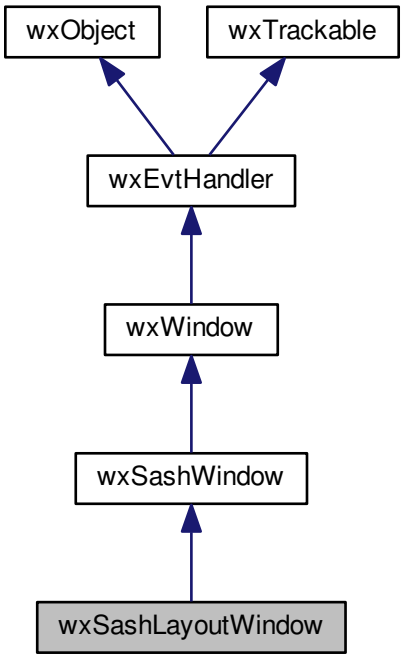
void wxSashEvent::SetDragStatus (wxSashDragStatus *status*)

void wxSashEvent::SetEdge (wxSashEdgePosition *edge*)

21.659 wxSashLayoutWindow Class Reference

`#include <wx/laywin.h>`

Inheritance diagram for wxSashLayoutWindow:



21.659.1 Detailed Description

wxSashLayoutWindow responds to OnCalculateLayout events generated by wxLayoutAlgorithm.

It allows the application to use simple accessors to specify how the window should be laid out, rather than having to respond to events.

The fact that the class derives from wxSashWindow allows sashes to be used if required, to allow the windows to be user-resizable.

The documentation for wxLayoutAlgorithm explains the purpose of this class in more detail.

For the window styles see wxSashWindow.

This class handles the EVT_QUERY_LAYOUT_INFO and EVT_CALCULATE_LAYOUT events for you. However, if you use sashes, see wxSashWindow for relevant event information. See also wxLayoutAlgorithm for information about the layout events.

Library: wxAdvanced

Category: Miscellaneous Windows

wxLayoutAlgorithm, wxSashWindow, Events and Event Handling

Public Member Functions

- wxSashLayoutWindow ()

  Default ctor.
- wxSashLayoutWindow (wxWindow *parent, wxWindowID id, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, long style=wxCLIP_CHILDREN|wxSW_3D, const wxString &name="layoutWindow")

  Constructs a sash layout window, which can be a child of a frame, dialog or any other non-control window.
- bool Create (wxWindow *parent, wxWindowID id=wxID_ANY, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, long style=wxCLIP_CHILDREN|wxSW_3D, const wxString &name="layoutWindow")

  Initializes a sash layout window, which can be a child of a frame, dialog or any other non-control window.
- wxLayoutAlignment GetAlignment () const

  Returns the alignment of the window: one of wxLAYOUT_TOP, wxLAYOUT_LEFT, wxLAYOUT_RIGHT, wxLAYOUT_BOTTOM.
- wxLayoutOrientation GetOrientation () const

  Returns the orientation of the window: one of wxLAYOUT_HORIZONTAL, wxLAYOUT_VERTICAL.
- void OnCalculateLayout (wxCalculateLayoutEvent &event)

  The default handler for the event that is generated by wxLayoutAlgorithm.
- void OnQueryLayoutInfo (wxQueryLayoutInfoEvent &event)

  The default handler for the event that is generated by OnCalculateLayout to get size, alignment and orientation information for the window.
- void SetAlignment (wxLayoutAlignment alignment)

  Sets the alignment of the window (which edge of the available parent client area the window is attached to).
- void SetDefaultSize (const wxSize &size)

  Sets the default dimensions of the window.
- void SetOrientation (wxLayoutOrientation orientation)

  Sets the orientation of the window (the direction the window will stretch in, to fill the available parent client area).

Additional Inherited Members

21.659.2 Constructor & Destructor Documentation

wxSashLayoutWindow::wxSashLayoutWindow ( )

Default ctor.

wxSashLayoutWindow::wxSashLayoutWindow (wxWindow * *parent*, wxWindowID *id*, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, long *style* = wxCLIP_CHILDREN|wxSW_3D, const wxString & *name* = "layoutWindow")

Constructs a sash layout window, which can be a child of a frame, dialog or any other non-control window.

Parameters

parent	Pointer to a parent window.
id	Window identifier. If -1, will automatically create an identifier.
pos	Window position. wxDefaultPosition is (-1, -1) which indicates that wxSashLayoutWindows should generate a default position for the window. If using the wxSashLayoutWindow class directly, supply an actual position.
size	Window size. wxDefaultSize is (-1, -1) which indicates that wxSashLayoutWindows should generate a default size for the window.
style	Window style. For window styles, please see wxSashLayoutWindow.
name	Window name.

21.659.3 Member Function Documentation

bool wxSashLayoutWindow::Create (wxWindow * *parent*, wxWindowID *id* = wxID_ANY, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, long *style* = wxCLIP_CHILDREN|wxSW_3D, const wxString & *name* = "layoutWindow")

Initializes a sash layout window, which can be a child of a frame, dialog or any other non-control window.

Parameters

parent	Pointer to a parent window.
id	Window identifier. If -1, will automatically create an identifier.
pos	Window position. wxDefaultPosition is (-1, -1) which indicates that wxSashLayoutWindows should generate a default position for the window. If using the wxSashLayoutWindow class directly, supply an actual position.
size	Window size. wxDefaultSize is (-1, -1) which indicates that wxSashLayoutWindows should generate a default size for the window.
style	Window style. For window styles, please see wxSashLayoutWindow.
name	Window name.

wxLayoutAlignment wxSashLayoutWindow::GetAlignment ( ) const

Returns the alignment of the window: one of wxLAYOUT_TOP, wxLAYOUT_LEFT, wxLAYOUT_RIGHT, wxLAYOUT_BOTTOM.

wxLayoutOrientation wxSashLayoutWindow::GetOrientation ( ) const

Returns the orientation of the window: one of wxLAYOUT_HORIZONTAL, wxLAYOUT_VERTICAL.

void wxSashLayoutWindow::OnCalculateLayout (wxCalculateLayoutEvent & *event*)

The default handler for the event that is generated by wxLayoutAlgorithm.

The implementation of this function calls wxCalculateLayoutEvent::SetRect to shrink the provided size according to how much space this window takes up. For further details, see wxLayoutAlgorithm and wxCalculateLayoutEvent.

void wxSashLayoutWindow::OnQueryLayoutInfo (wxQueryLayoutInfoEvent & *event*)

The default handler for the event that is generated by OnCalculateLayout to get size, alignment and orientation information for the window.

The implementation of this function uses member variables as set by accessors called by the application.

For further details, see wxLayoutAlgorithm and wxQueryLayoutInfoEvent.

void wxSashLayoutWindow::SetAlignment (wxLayoutAlignment *alignment*)

Sets the alignment of the window (which edge of the available parent client area the window is attached to).

alignment is one of wxLAYOUT_TOP, wxLAYOUT_LEFT, wxLAYOUT_RIGHT, wxLAYOUT_BOTTOM.

void wxSashLayoutWindow::SetDefaultSize (const wxSize & *size*)

Sets the default dimensions of the window.

The dimension other than the orientation will be fixed to this value, and the orientation dimension will be ignored and the window stretched to fit the available space.

void wxSashLayoutWindow::SetOrientation (wxLayoutOrientation *orientation*)

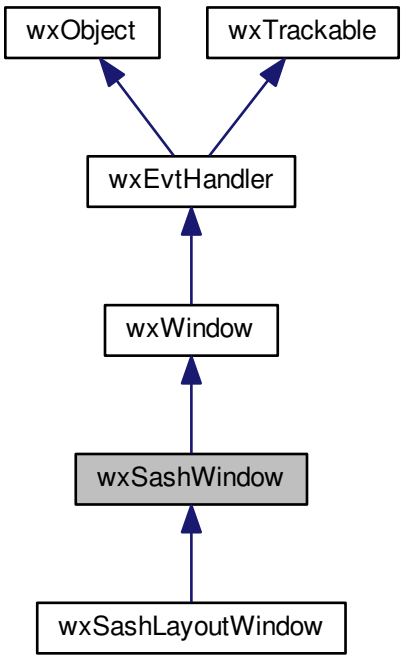
Sets the orientation of the window (the direction the window will stretch in, to fill the available parent client area).

orientation is one of wxLAYOUT_HORIZONTAL, wxLAYOUT_VERTICAL.

21.660 wxSashWindow Class Reference

`#include <wx/sashwin.h>`

Inheritance diagram for wxSashWindow:



21.660.1 Detailed Description

wxSashWindow allows any of its edges to have a sash which can be dragged to resize the window.

The actual content window will be created by the application as a child of wxSashWindow.

The window (or an ancestor) will be notified of a drag via a wxSashEvent notification.

Styles

This class supports the following styles:

- wxSW_3D: Draws a 3D effect sash and border.
- wxSW_3DSASH: Draws a 3D effect sash.
- wxSW_3DBORDER: Draws a 3D effect border.
- wxSW_BORDER: Draws a thin black border.

Events emitted by this class

The following event handler macros redirect the events to member function handlers '**func**' with prototypes like: void handlerFuncName(wxSashEvent& event)

Event macros for events emitted by this class:

- EVT_SASH_DRAGGED(id, func): Process a `wxEVT_SASH_DRAGGED` event, when the user has finished dragging a sash.
- EVT_SASH_DRAGGED_RANGE(id1, id2, func): Process a `wxEVT_SASH_DRAGGED_RANGE` event, when the user has finished dragging a sash. The event handler is called when windows with ids in the given range have their sashes dragged.

Public Member Functions

- wxSashWindow ()

  Default ctor.
- wxSashWindow (wxWindow *parent, wxWindowID id, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, long style=wxCLIP_CHILDREN|wxSW_3D, const wxString &name="sashWindow")

  Constructs a sash window, which can be a child of a frame, dialog or any other non-control window.
- virtual ~wxSashWindow ()

  Destructor.
- virtual int GetMaximumSizeX () const

  Gets the maximum window size in the x direction.
- virtual int GetMaximumSizeY () const

  Gets the maximum window size in the y direction.

- virtual int GetMinimumSizeX () const

  Gets the minimum window size in the x direction.
- virtual int GetMinimumSizeY () const

  Gets the minimum window size in the y direction.
- bool GetSashVisible (wxSashEdgePosition edge) const

  Returns true if a sash is visible on the given edge, false otherwise.
- virtual void SetMaximumSizeX (int min)

  Sets the maximum window size in the x direction.
- virtual void SetMaximumSizeY (int min)

  Sets the maximum window size in the y direction.
- virtual void SetMinimumSizeX (int min)

  Sets the minimum window size in the x direction.
- virtual void SetMinimumSizeY (int min)

  Sets the minimum window size in the y direction.
- void SetSashVisible (wxSashEdgePosition edge, bool visible)

  Call this function to make a sash visible or invisible on a particular edge.
- int GetEdgeMargin (wxSashEdgePosition edge) const

  Get border size.
- void SetDefaultBorderSize (int width)

  Sets the default sash border size.
- int GetDefaultBorderSize () const

  Gets the default sash border size.
- void SetExtraBorderSize (int width)

  Sets the additional border size between child and sash window.
- int GetExtraBorderSize () const

  Gets the addition border size between child and sash window.
- wxSashEdgePosition SashHitTest (int x, int y, int tolerance=2)

  Tests for x, y over sash.
- void SizeWindows ()

  Resizes subwindows.

Additional Inherited Members

21.660.2 Constructor & Destructor Documentation

wxSashWindow::wxSashWindow ( )

Default ctor.

wxSashWindow::wxSashWindow (wxWindow * *parent*, wxWindowID *id*, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, long *style* = wxCLIP_CHILDREN|wxSW_3D, const wxString & *name* = "sashWindow")

Constructs a sash window, which can be a child of a frame, dialog or any other non-control window.

Parameters

parent	Pointer to a parent window.

id	Window identifier. If -1, will automatically create an identifier.
pos	Window position. wxDefaultPosition is (-1, -1) which indicates that wxSashWindows should generate a default position for the window. If using the wxSashWindow class directly, supply an actual position.
size	Window size. wxDefaultSize is (-1, -1) which indicates that wxSashWindows should generate a default size for the window.
style	Window style. For window styles, please see wxSashWindow.
name	Window name.

virtual wxSashWindow::~wxSashWindow ( ) [virtual]

Destructor.

int wxSashWindow::GetDefaultBorderSize ( ) const

Gets the default sash border size.

int wxSashWindow::GetEdgeMargin (wxSashEdgePosition *edge*) const

Get border size.

int wxSashWindow::GetExtraBorderSize ( ) const

Gets the addition border size between child and sash window.

virtual int wxSashWindow::GetMaximumSizeX ( ) const [virtual]

Gets the maximum window size in the x direction.

virtual int wxSashWindow::GetMaximumSizeY ( ) const [virtual]

Gets the maximum window size in the y direction.

virtual int wxSashWindow::GetMinimumSizeX ( ) const [virtual]

Gets the minimum window size in the x direction.

virtual int wxSashWindow::GetMinimumSizeY ( ) const [virtual]

Gets the minimum window size in the y direction.

bool wxSashWindow::GetSashVisible (wxSashEdgePosition *edge*) const

Returns true if a sash is visible on the given edge, false otherwise.

Parameters

edge	Edge. One of wxSASH_TOP, wxSASH_RIGHT, wxSASH_BOTTOM, wxSASH_LEFT.

See also

SetSashVisible()

wxSashEdgePosition wxSashWindow::SashHitTest (int *x,* int *y,* int *tolerance* = 2)

Tests for x, y over sash.

void wxSashWindow::SetDefaultBorderSize (int *width*)

Sets the default sash border size.

void wxSashWindow::SetExtraBorderSize (int *width*)

Sets the additional border size between child and sash window.

virtual void wxSashWindow::SetMaximumSizeX (int *min*) [virtual]

Sets the maximum window size in the x direction.

virtual void wxSashWindow::SetMaximumSizeY (int *min*) [virtual]

Sets the maximum window size in the y direction.

virtual void wxSashWindow::SetMinimumSizeX (int *min*) [virtual]

Sets the minimum window size in the x direction.

virtual void wxSashWindow::SetMinimumSizeY (int *min*) [virtual]

Sets the minimum window size in the y direction.

void wxSashWindow::SetSashVisible (wxSashEdgePosition *edge,* bool *visible*)

Call this function to make a sash visible or invisible on a particular edge.

Parameters

edge	Edge to change. One of wxSASH_TOP, wxSASH_RIGHT, wxSASH_BOTTOM, wxSASH_↩ LEFT.
visible	true to make the sash visible, false to make it invisible.

GetSashVisible()

void wxSashWindow::SizeWindows ( )

Resizes subwindows.

21.661 wxScopedArray< T > Class Template Reference

`#include <wx/scopedarray.h>`

21.661.1 Detailed Description

template<class T>class wxScopedArray< T >

A scoped array template class.

This is a simple scoped smart pointer array implementation that is similar to the Boost smart pointers (see http://www.boost.org/) but rewritten to use macros instead.

This class is similar to boost scoped_array class: http://www.boost.org/doc/libs/1_37_0/libs/smart_ptr/scoped_array.htm

Notice that objects of this class intentionally cannot be copied.

Library: wxBase

Category: Smart Pointers

Example:

Below is an example of using a wxWidgets scoped smart pointer and pointer array.

```
class MyClass { ... };

// declare a smart pointer to a MyClass called wxMyClassPtr
wxDECLARE_SCOPED_PTR(MyClass, wxMyClassPtr)
// declare a smart pointer to an array of chars
wxDECLARE_SCOPED_ARRAY(char, wxCharArray)

...

// define the first pointer class, must be complete
wxDEFINE_SCOPED_PTR(MyClass, wxMyClassPtr)
// define the second pointer class
wxDEFINE_SCOPED_ARRAY(char, wxCharArray)

// create an object with a new pointer to MyClass
wxMyClassPtr theObj(new MyClass());
// reset the pointer (deletes the previous one)
theObj.reset(new MyClass());

// access the pointer
theObj->MyFunc();

// create an object with a new array of chars
wxCharArray theCharObj(new char[100]);

// access the array
theCharObj[0] = "!";
```

Declaring new smart pointer types:

```
wxDECLAR_SCOPED_ARRAY( TYPE,        // type of the values
                       CLASSNAME ); // name of the class
```

A smart pointer holds a pointer to an object (which must be complete when wxDEFINE_SCOPED_ARRAY() is called).

The memory used by the object is deleted when the smart pointer goes out of scope. The first argument of the macro is the pointer type, the second is the name of the new smart pointer class being created. Below we will use wxScopedArray to represent the scoped pointer array class, but the user may create the class with any legal name.

Library: wxBase

Category: Smart Pointers

See also

wxScopedPtr

Public Types

- typedef T element_type

  The type of the array elements.

Public Member Functions

- wxScopedArray (type *T=NULL)

  Creates the smart pointer with the given pointer or none if NULL.
- const T * get ()

  This operator gets the pointer stored in the smart pointer or returns NULL if there is none.
- const T & operator[] (long int i)

  This operator acts like the standard [] indexing operator for C++ arrays.
- reset (T *p=NULL)

  Deletes the currently held pointer and sets it to 'p' or to NULL if no arguments are specified.
- swap (wxScopedArray &ot)

  Swap the pointer inside the smart pointer with ot.
- wxScopedArray (T *array=NULL)

  Constructor takes ownership of the given array.
- wxScopedArray (size_t count)

  Constructor allocating a new array of the specified size.
- ~wxScopedArray ()

  Destructor destroy the array.
- operator unspecified_bool_type () const

  Conversion to a boolean expression (in a variant which is not convertible to anything but a boolean expression).
- void reset (T *array=NULL)

  Change the array pointer stored.
- T & operator[] (size_t n) const

  Return the n-th element of the array.
- T * get () const

  Return the array pointer.
- void swap (wxScopedArray &other)

  Swaps the contents of this array with another one.

21.661.2 Member Typedef Documentation

template<class T > typedef T wxScopedArray< T >::element_type

The type of the array elements.

21.661.3 Constructor & Destructor Documentation

template<class T > wxScopedArray< T >::wxScopedArray (type * *T* = NULL)

Creates the smart pointer with the given pointer or none if NULL.

On compilers that support it, this uses the explicit keyword.

template<class T > wxScopedArray< T >::wxScopedArray (T * *array* = NULL) [explicit]

Constructor takes ownership of the given array.

If *array* is NULL, reset() must presumably be called later.

Parameters

array	An array allocated using `new`[] or NULL.

template<class T > wxScopedArray< T >::wxScopedArray (size_t *count*) [explicit]

Constructor allocating a new array of the specified size.

Parameters

count	The number of elements to allocate.

Since

3.1.0

template<class T > wxScopedArray< T >::~wxScopedArray ( )

Destructor destroy the array.

21.661.4 Member Function Documentation

template<class T > const T* wxScopedArray< T >::get ( )

This operator gets the pointer stored in the smart pointer or returns NULL if there is none.

template<class T > T* wxScopedArray< T >::get ( ) const

Return the array pointer.

The returned pointer may be NULL. It must not be deleted by the caller, call `reset(NULL)` instead.

template<class T > wxScopedArray< T >::operator unspecified_bool_type ( ) const

Conversion to a boolean expression (in a variant which is not convertible to anything but a boolean expression).

If this class contains a valid array it will return true, if it contains a NULL pointer it will return false.

template<class T > const T& wxScopedArray< T >::operator[] (long int *i*)

This operator acts like the standard [] indexing operator for C++ arrays.

The function does not do bounds checking.

template<class T > T& wxScopedArray< T >::operator[] (size_t *n*) const

Return the n-th element of the array.

Must not be called if the array has no valid pointer.

template<class T > wxScopedArray< T >::reset (T * *p* = NULL)

Deletes the currently held pointer and sets it to 'p' or to NULL if no arguments are specified.

This function does check to make sure that the pointer you are assigning is not the same pointer that is already stored.

template<class T > void wxScopedArray< T >::reset (T * *array* = NULL)

Change the array pointer stored.

The previously stored array is deleted.

Parameters

array	An array allocated using new[] or NULL.

template<class T > wxScopedArray< T >::swap (wxScopedArray< T > & *ot*)

Swap the pointer inside the smart pointer with *ot*.

The pointer being swapped must be of the same type (hence the same class name).

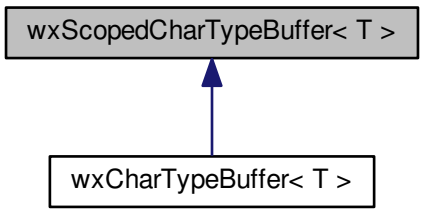
template<class T > void wxScopedArray< T >::swap (wxScopedArray< T > & *other*)

Swaps the contents of this array with another one.

21.662 wxScopedCharTypeBuffer< T > Class Template Reference

#include <wx/buffer.h>

Inheritance diagram for wxScopedCharTypeBuffer< T >:



21.662.1 Detailed Description

template<typename T>class wxScopedCharTypeBuffer< T >

wxScopedCharTypeBuffer<T> is a template class for storing characters.

Data are stored in reference-counted buffer. In other words, making a copy of wxScopedCharTypeBuffer<T> will *not* make another copy of the stored string data, it will still point to the same location in memory.

wxScopedCharTypeBuffer<T> supports two storage modes: owned and non-owned. "Owned" data buffer (created with CreateOwned() or wxCharTypeBuffer<T> derived class) owns the data and frees them when the last buffer pointing to them is destroyed.

"Non-owned" buffer (created with CreateNonOwned()), on the other hand, references data owned by somebody else – typical use is by wxString::mb_str() or wxString::wc_str(), which may return non-owned buffer pointing to wxString's internal store.

Because of this, the validity of data stored in wxScopedCharTypeBuffer<T> is limited by the lifetime of the "parent" object that created the buffer (e.g. the wxString on which mb_str() was called).

If you need to preserve the data for longer, assign it to wxCharTypeBuffer<T> instead of wxScopedCharTypeBuffer<T>. On the other hand, use wxScopedCharTypeBuffer<T> if the buffer is to be destroyed before the "parent" object – typical use would be creating it on the stack and destroying when it goes out of scope (hence the class' name).

Template Parameters

T	The type of the characters stored in this class.

Since

2.9.0

Library: None; this class implementation is entirely header-based.

Category: Data Structures

Public Types

- typedef T CharType

  Stored characters type.

Public Member Functions

- wxScopedCharTypeBuffer ()

  Default constructor, creates NULL buffer.
- wxScopedCharTypeBuffer (const wxScopedCharTypeBuffer &src)

  Copy constructor.
- wxScopedCharTypeBuffer & operator= (const wxScopedCharTypeBuffer &src)

  Assignment operator behaves in the same way as the copy constructor.
- ~wxScopedCharTypeBuffer ()

  Destructor.
- CharType * release () const

  Returns the internal pointer and resets the buffer.
- void reset ()

  Resets the buffer to NULL, freeing the data if necessary.
- CharType * data ()

  Returns pointer to the stored data.
- const CharType * data () const

  Returns const pointer to the stored data.
- size_t length () const

  Returns length of the string stored.
- operator const CharType * () const

  Implicit conversion to C string.
- CharType operator[] (size_t n) const

  Random access to the stored C string.

Static Public Member Functions

- static const wxScopedCharTypeBuffer CreateNonOwned (const CharType *str, size_t len=wxNO_LEN)

  Creates non-owned buffer from string data str.
- static const wxScopedCharTypeBuffer CreateOwned (CharType *str, size_t len=wxNO_LEN)

  Creates owned buffer from str and takes ownership of it.

21.662.2 Member Typedef Documentation

template<typename T> typedef T wxScopedCharTypeBuffer< T >::CharType

Stored characters type.

21.662.3 Constructor & Destructor Documentation

template<typename T> wxScopedCharTypeBuffer< T >::wxScopedCharTypeBuffer ( )

Default constructor, creates NULL buffer.

template<typename T> wxScopedCharTypeBuffer< T >::wxScopedCharTypeBuffer (const wxScopedCharTypeBuffer< T > & *src*)

Copy constructor.

Increases reference count on the data, does *not* make wxStrdup() copy of the data.

template<typename T> wxScopedCharTypeBuffer< T >::~wxScopedCharTypeBuffer ( )

Destructor.

Frees stored data if it is in "owned" mode and data's reference count reaches zero.

21.662.4 Member Function Documentation

template<typename T> static const wxScopedCharTypeBuffer wxScopedCharTypeBuffer< T >::CreateNonOwned (const CharType * *str*, size_t *len* = wxNO_LEN) [static]

Creates non-owned buffer from string data *str*.

The buffer's destructor will not destroy *str*. The returned buffer's data is valid only as long as *str* is valid.

Parameters

str	String data.
len	If specified, length of the string, otherwise the string is considered to be NUL-terminated.

template<typename T> static const wxScopedCharTypeBuffer wxScopedCharTypeBuffer< T >::CreateOwned (CharType * *str*, size_t *len* = wxNO_LEN) [static]

Creates owned buffer from *str* and takes ownership of it.

The buffer's destructor will free *str* when its reference count reaches zero (initial count is 1).

Parameters

str	String data.
len	If specified, length of the string, otherwise the string is considered to be NUL-terminated.

template<typename T> CharType* wxScopedCharTypeBuffer< T >::data ( )

Returns pointer to the stored data.

template<typename T> const CharType* wxScopedCharTypeBuffer< T >::data ( ) const

Returns const pointer to the stored data.

template<typename T> size_t wxScopedCharTypeBuffer< T >::length ( ) const

Returns length of the string stored.

template<typename T> wxScopedCharTypeBuffer< T >::operator const CharType * ( ) const

Implicit conversion to C string.

template<typename T> wxScopedCharTypeBuffer& wxScopedCharTypeBuffer< T >::operator= (const wxScopedCharTypeBuffer< T > & *src*)

Assignment operator behaves in the same way as the copy constructor.

template<typename T> CharType wxScopedCharTypeBuffer< T >::operator[] (size_t *n*) const

Random access to the stored C string.

template<typename T> CharType* wxScopedCharTypeBuffer< T >::release ( ) const

Returns the internal pointer and resets the buffer.

It's the caller responsibility to deallocate the returned pointer using `free()` function.

Notice that this method is dangerous because it can only be called on a non-shared owning buffer. Calling it on any other kind of buffer object will result in a crash after the pointer is freed, so avoid using it unless absolutely necessary and you are absolutely certain that the buffer is not shared.

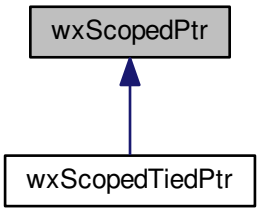
template<typename T> void wxScopedCharTypeBuffer< T >::reset ( )

Resets the buffer to NULL, freeing the data if necessary.

21.663 wxScopedPtr Class Reference

`#include <wx/scopedptr.h>`

Inheritance diagram for wxScopedPtr:



21.663.1 Detailed Description

This is a simple scoped smart pointer implementation that is similar to the Boost smart pointers (see http://www.boost.org) but rewritten to use macros instead.

Since wxWidgets 2.9.0 there is also a templated version of this class with the same name. See wxScopedPtr<T>.

A smart pointer holds a pointer to an object. The memory used by the object is deleted when the smart pointer goes out of scope. This class is different from the `std::auto_ptr<>` in so far as it doesn't provide copy constructor nor assignment operator. This limits what you can do with it but is much less surprising than the "destructive copy" behaviour of the standard class.

Example:

Below is an example of using a wxWidgets scoped smart pointer and pointer array.

```
class MyClass{ ... };

// declare a smart pointer to a MyClass called wxMyClassPtr
wxDECLARE_SCOPED_PTR(MyClass, wxMyClassPtr)
```

```
// declare a smart pointer to an array of chars
wxDECLARE_SCOPED_ARRAY(char, wxCharArray)

...

// define the first pointer class, must be complete
wxDEFINE_SCOPED_PTR(MyClass, wxMyClassPtr)
// define the second pointer class
wxDEFINE_SCOPED_ARRAY(char, wxCharArray)

// create an object with a new pointer to MyClass
wxMyClassPtr theObj(new MyClass());
// reset the pointer (deletes the previous one)
theObj.reset(new MyClass());

// access the pointer
theObj->MyFunc();

// create an object with a new array of chars
wxCharArray theCharObj(new char[100]);

// access the array
theCharObj[0] = "!";
```

21.663.2 Declaring new smart pointer types

To declare the smart pointer class `CLASSNAME` containing pointer to a (possibly incomplete) type `TYPE` you should use

```
wxDECLARE_SCOPED_PTR( TYPE,        // type of the values
                      CLASSNAME ); // name of the class
```

And later, when `TYPE` is fully defined, you must also use

```
wxDEFINE_SCOPED_PTR( TYPE, CLASSNAME );
```

to implement the scoped pointer class.

The first argument of these macro is the pointer type, the second is the name of the new smart pointer class being created. Below we will use wxScopedPtr to represent the scoped pointer class, but the user may create the class with any legal name.

Alternatively, if you don't have to separate the point of declaration and definition of this class and if you accept the standard naming convention, that is that the scoped pointer for the class `Foo` is called `FooPtr`, you can use a single macro which replaces two macros above:

```
wxDEFINE_SCOPED_PTR_TYPE( TYPE );
```

Once again, in this cass `CLASSNAME` will be `TYPEPtr`.

Library: wxBase

wxScopedArray

Public Member Functions

- wxScopedPtr (type *T=NULL)

  Creates the smart pointer with the given pointer or none if NULL.
- ~wxScopedPtr ()

Destructor frees the pointer help by this object if it is not NULL.

- T * get () const

  This operator gets the pointer stored in the smart pointer or returns NULL if there is none.

- T & operator* () const

  This operator works like the standard C++ pointer operator to return the object being pointed to by the pointer.

- T * operator-> () const

  Smart pointer member access.

- T * release ()

  Returns the currently hold pointer and resets the smart pointer object to NULL.

- reset (T *p=NULL)

  Deletes the currently held pointer and sets it to p or to NULL if no arguments are specified.

- swap (wxScopedPtr &other)

  Swap the pointer inside the smart pointer with other.

21.663.3 Constructor & Destructor Documentation

wxScopedPtr::wxScopedPtr (type * *T* = NULL) [explicit]

Creates the smart pointer with the given pointer or none if NULL.

On compilers that support it, this uses the explicit keyword.

wxScopedPtr::~wxScopedPtr ( )

Destructor frees the pointer help by this object if it is not NULL.

21.663.4 Member Function Documentation

T* wxScopedPtr::get ( ) const

This operator gets the pointer stored in the smart pointer or returns NULL if there is none.

T& wxScopedPtr::operator* ( ) const

This operator works like the standard C++ pointer operator to return the object being pointed to by the pointer.

If the internal pointer is NULL this method will cause an assert in debug mode.

T* wxScopedPtr::operator-> ( ) const

Smart pointer member access.

Returns pointer to its object.

If the internal pointer is NULL this method will cause an assert in debug mode.

T* wxScopedPtr::release ( )

Returns the currently hold pointer and resets the smart pointer object to NULL.

Remarks

After a call to this function the caller is responsible for deleting the pointer.

wxScopedPtr::reset (T * *p* = NULL)

Deletes the currently held pointer and sets it to *p* or to NULL if no arguments are specified.

Note

This function does check to make sure that the pointer you are assigning is not the same pointer that is already stored.

wxScopedPtr::swap (wxScopedPtr & *other*)

Swap the pointer inside the smart pointer with *other*.

The pointer being swapped must be of the same type (hence the same class name).

21.664 wxScopedPtr< T > Class Template Reference

`#include <wx/scopedptr.h>`

21.664.1 Detailed Description

template<typename T>class wxScopedPtr< T >

A scoped pointer template class.

It is the template version of the old-style scoped pointer macros.

Notice that objects of this class intentionally cannot be copied.

Library: wxBase

Category: Smart Pointers

See also

wxSharedPtr<T>, wxWeakRef<T>

Public Member Functions

- wxScopedPtr (T *ptr=NULL)

  Constructor takes ownership of the pointer.
- ~wxScopedPtr ()

  Destructor deletes the pointer.
- T * get () const

  Returns pointer to object or NULL.
- operator unspecified_bool_type () const

  Conversion to a boolean expression (in a variant which is not convertible to anything but a boolean expression).
- T & operator* () const

  Returns a reference to the object.
- T * operator-> () const

  Smart pointer member access.

- T * release ()

  Releases the current pointer and returns it.
- void reset (T *ptr=NULL)

  Reset pointer to the value of ptr.
- void swap (wxScopedPtr< T > &ot)

  Swaps pointers.

21.664.2 Constructor & Destructor Documentation

template<typename T > wxScopedPtr< T >::wxScopedPtr (T * *ptr* = NULL)

Constructor takes ownership of the pointer.

Parameters

ptr	Pointer allocated with `new` or NULL.

template<typename T > wxScopedPtr< T >::~wxScopedPtr ( )

Destructor deletes the pointer.

21.664.3 Member Function Documentation

template<typename T > T* wxScopedPtr< T >::get ( ) const

Returns pointer to object or NULL.

template<typename T > wxScopedPtr< T >::operator unspecified_bool_type ( ) const

Conversion to a boolean expression (in a variant which is not convertible to anything but a boolean expression).

If this class contains a valid pointer it will return true, if it contains a NULL pointer it will return false.

template<typename T > T& wxScopedPtr< T >::operator* ( ) const

Returns a reference to the object.

If the internal pointer is NULL this method will cause an assert in debug mode.

template<typename T > T* wxScopedPtr< T >::operator-> ( ) const

Smart pointer member access.

Returns pointer to object.

If the internal pointer is NULL this method will cause an assert in debug mode.

template<typename T > T* wxScopedPtr< T >::release ( )

Releases the current pointer and returns it.

Remarks

Afterwards the caller is responsible for deleting the data contained in the scoped pointer before.

template<typename T > void wxScopedPtr< T >::reset (T * *ptr* = NULL)

Reset pointer to the value of *ptr*.

The previous pointer will be deleted.

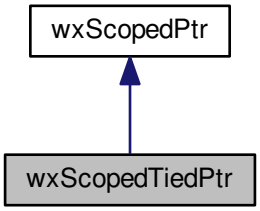
template<typename T > void wxScopedPtr< T >::swap (wxScopedPtr< T > & *ot*)

Swaps pointers.

21.665 wxScopedTiedPtr Class Reference

`#include <wx/scopedptr.h>`

Inheritance diagram for wxScopedTiedPtr:



21.665.1 Detailed Description

This is a variation on the topic of wxScopedPtr.

This class is also a smart pointer but in addition it "ties" the pointer value to another variable. In other words, during the life time of this class the value of that variable is set to be the same as the value of the pointer itself and it is reset to its old value when the object is destroyed. This class is especially useful when converting the existing code (which may already store the pointers value in some variable) to the smart pointers.

Library: wxBase

Category: Smart Pointers

Public Member Functions

- wxScopedTiedPtr (T **ppTie, T *ptr)

  Constructor creates a smart pointer initialized with ptr and stores ptr in the location specified by ppTie which must not be NULL.
- ~wxScopedTiedPtr ()

  Destructor frees the pointer help by this object and restores the value stored at the tied location (as specified in the wxScopedTiedPtr() constructor) to the old value.

21.665.2 Constructor & Destructor Documentation

wxScopedTiedPtr::wxScopedTiedPtr (T ∗∗ *ppTie*, T ∗ *ptr*)

Constructor creates a smart pointer initialized with *ptr* and stores *ptr* in the location specified by *ppTie* which must not be NULL.

wxScopedTiedPtr::∼wxScopedTiedPtr ( )

Destructor frees the pointer help by this object and restores the value stored at the tied location (as specified in the wxScopedTiedPtr() constructor) to the old value.

Warning

This location may now contain an uninitialized value if it hadn't been initialized previously, in particular don't count on it magically being NULL!

21.666 wxScopeGuard Class Reference

`#include <wx/scopeguard.h>`

21.666.1 Detailed Description

Scope guard is an object which allows executing an action on scope exit.

The objects of this class must be constructed using wxMakeGuard() function.

Library: None; this class implementation is entirely header-based.

Category: Miscellaneous

Public Member Functions

- void Dismiss ()

  Call this method to dismiss the execution of the action on scope exit.

21.666.2 Member Function Documentation

void wxScopeGuard::Dismiss ( )

Call this method to dismiss the execution of the action on scope exit.

A typical example:

```
Update1();

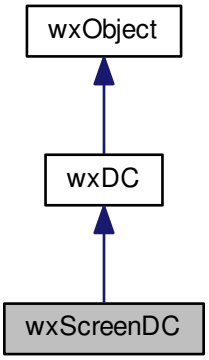
// ensure that changes done so far are rolled back if the next
// operation throws
wxScopeGuard guard = wxMakeGuard(RollBack);
Update2();

// it didn't throw so commit the changes, i.e. avoid rolling back
guard.Dismiss();
```

21.667 wxScreenDC Class Reference

`#include <wx/dcscreen.h>`

Inheritance diagram for wxScreenDC:



21.667.1 Detailed Description

A wxScreenDC can be used to paint on the screen.

This should normally be constructed as a temporary stack object; don't store a wxScreenDC object.

Library: wxCore

Category: Device Contexts

Public Member Functions

- wxScreenDC ()

  Constructor.

Static Public Member Functions

- static bool EndDrawingOnTop ()

  Use this in conjunction with StartDrawingOnTop().
- static bool StartDrawingOnTop (wxWindow *window)

  Use this in conjunction with EndDrawingOnTop() to ensure that drawing to the screen occurs on top of existing windows.
- static bool StartDrawingOnTop (wxRect *rect=NULL)

  Use this in conjunction with EndDrawingOnTop() to ensure that drawing to the screen occurs on top of existing windows.

Additional Inherited Members

21.667.2 Constructor & Destructor Documentation

wxScreenDC::wxScreenDC ( )

Constructor.

21.667.3 Member Function Documentation

static bool wxScreenDC::EndDrawingOnTop ( ) [static]

Use this in conjunction with StartDrawingOnTop().

This function destroys the temporary window created to implement on-top drawing (X only).

static bool wxScreenDC::StartDrawingOnTop (wxWindow * *window*) [static]

Use this in conjunction with EndDrawingOnTop() to ensure that drawing to the screen occurs on top of existing windows.

Without this, some window systems (such as X) only allow drawing to take place underneath other windows.

This version of StartDrawingOnTop() is used to specify that the area that will be drawn on coincides with the given window. It is recommended that an area of the screen is specified with StartDrawingOnTop(wxRect*) because with large regions, flickering effects are noticeable when destroying the temporary transparent window used to implement this feature.

You might use this function when implementing a drag feature, for example as in the wxSplitterWindow implementation.

Remarks

This function is probably obsolete since the X implementations allow drawing directly on the screen now. However, the fact that this function allows the screen to be refreshed afterwards, may be useful to some applications.

static bool wxScreenDC::StartDrawingOnTop (wxRect * *rect* = NULL) [static]

Use this in conjunction with EndDrawingOnTop() to ensure that drawing to the screen occurs on top of existing windows.

Without this, some window systems (such as X) only allow drawing to take place underneath other windows.

This version of StartDrawingOnTop() is used to specify an area of the screen which is to be drawn on. If NULL is passed, the whole screen is available. It is recommended that an area of the screen is specified with this function rather than with StartDrawingOnTop(wxWindow*), because with large regions, flickering effects are noticeable when destroying the temporary transparent window used to implement this feature.

You might use this function when implementing a drag feature, for example as in the wxSplitterWindow implementation.

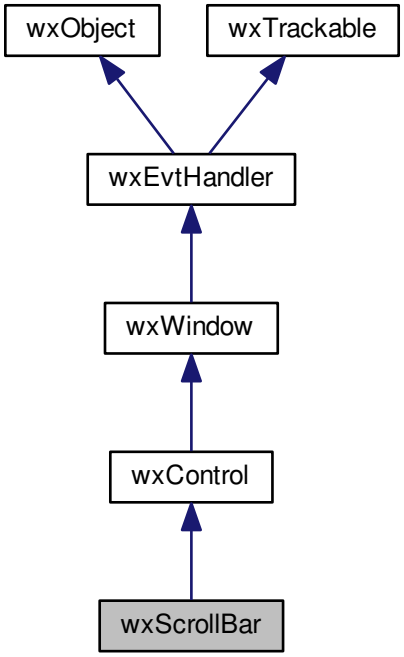
Remarks

This function is probably obsolete since the X implementations allow drawing directly on the screen now. However, the fact that this function allows the screen to be refreshed afterwards, may be useful to some applications.

21.668 wxScrollBar Class Reference

`#include <wx/scrolbar.h>`

Inheritance diagram for wxScrollBar:



21.668.1 Detailed Description

A wxScrollBar is a control that represents a horizontal or vertical scrollbar.

It is distinct from the two scrollbars that some windows provide automatically, but the two types of scrollbar share the way events are received.

Remarks

A scrollbar has the following main attributes: range, thumb size, page size, and position. The range is the total number of units associated with the view represented by the scrollbar. For a table with 15 columns, the range would be 15. The thumb size is the number of units that are currently visible. For the table example, the window might be sized so that only 5 columns are currently visible, in which case the application would set the thumb size to 5. When the thumb size becomes the same as or greater than the range, the scrollbar will be automatically hidden on most platforms. The page size is the number of units that the scrollbar should scroll by, when 'paging' through the data. This value is normally the same as the thumb size length, because it is natural to assume that the visible window size defines a page. The scrollbar position is the current thumb position. Most applications will find it convenient to provide a function called AdjustScrollbars() which can be called initially, from an OnSize event handler, and whenever the application data changes in size. It will adjust the view, object and page size according to the size of the window and the size of the data.

Styles

This class supports the following styles:

- wxSB_HORIZONTAL: Specifies a horizontal scrollbar.
- wxSB_VERTICAL: Specifies a vertical scrollbar.

Events emitted by this class

The following event handler macros redirect the events to member function handlers '**func**' with prototypes like: void handlerFuncName(wxScrollEvent& event)

Event macros for events emitted by this class: You can use EVT_COMMAND_SCROLL... macros with window IDs for when intercepting scroll events from controls, or EVT_SCROLL... macros without window IDs for intercepting scroll events from the receiving window – except for this, the macros behave exactly the same.

- EVT_SCROLL(func): Process all scroll events.
- EVT_SCROLL_TOP(func): Process `wxEVT_SCROLL_TOP` scroll to top or leftmost (minimum) position events.
- EVT_SCROLL_BOTTOM(func): Process `wxEVT_SCROLL_BOTTOM` scroll to bottom or rightmost (maximum) position events.
- EVT_SCROLL_LINEUP(func): Process `wxEVT_SCROLL_LINEUP` line up or left events.
- EVT_SCROLL_LINEDOWN(func): Process `wxEVT_SCROLL_LINEDOWN` line down or right events.
- EVT_SCROLL_PAGEUP(func): Process `wxEVT_SCROLL_PAGEUP` page up or left events.
- EVT_SCROLL_PAGEDOWN(func): Process `wxEVT_SCROLL_PAGEDOWN` page down or right events.
- EVT_SCROLL_THUMBTRACK(func): Process `wxEVT_SCROLL_THUMBTRACK` thumbtrack events (frequent events sent as the user drags the thumbtrack).
- EVT_SCROLL_THUMBRELEASE(func): Process `wxEVT_SCROLL_THUMBRELEASE` thumb release events.
- EVT_SCROLL_CHANGED(func): Process `wxEVT_SCROLL_CHANGED` end of scrolling events (MSW only).
- EVT_COMMAND_SCROLL(id, func): Process all scroll events.
- EVT_COMMAND_SCROLL_TOP(id, func): Process `wxEVT_SCROLL_TOP` scroll to top or leftmost (minimum) position events.
- EVT_COMMAND_SCROLL_BOTTOM(id, func): Process `wxEVT_SCROLL_BOTTOM` scroll to bottom or rightmost (maximum) position events.
- EVT_COMMAND_SCROLL_LINEUP(id, func): Process `wxEVT_SCROLL_LINEUP` line up or left events.
- EVT_COMMAND_SCROLL_LINEDOWN(id, func): Process `wxEVT_SCROLL_LINEDOWN` line down or right events.
- EVT_COMMAND_SCROLL_PAGEUP(id, func): Process `wxEVT_SCROLL_PAGEUP` page up or left events.
- EVT_COMMAND_SCROLL_PAGEDOWN(id, func): Process `wxEVT_SCROLL_PAGEDOWN` page down or right events.
- EVT_COMMAND_SCROLL_THUMBTRACK(id, func): Process `wxEVT_SCROLL_THUMBTRACK` thumbtrack events (frequent events sent as the user drags the thumbtrack).
- EVT_COMMAND_SCROLL_THUMBRELEASE(func): Process `wxEVT_SCROLL_THUMBRELEASE` thumb release events.
- EVT_COMMAND_SCROLL_CHANGED(func): Process `wxEVT_SCROLL_CHANGED` end of scrolling events (MSW only).

21.668.2 The difference between EVT_SCROLL_THUMBRELEASE and EVT_SCROLL_CHANGED

The EVT_SCROLL_THUMBRELEASE event is only emitted when actually dragging the thumb using the mouse and releasing it (This EVT_SCROLL_THUMBRELEASE event is also followed by an EVT_SCROLL_CHANGED event).

The EVT_SCROLL_CHANGED event also occurs when using the keyboard to change the thumb position, and when clicking next to the thumb (In all these cases the EVT_SCROLL_THUMBRELEASE event does not happen).

In short, the EVT_SCROLL_CHANGED event is triggered when scrolling/moving has finished independently of the way it had started. Please see the widgets sample ("Slider" page) to see the difference between EVT_SCROLL_↩ THUMBRELEASE and EVT_SCROLL_CHANGED in action.

Public Member Functions

- wxScrollBar ()

  Default constructor.

- wxScrollBar (wxWindow *parent, wxWindowID id, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, long style=wxSB_HORIZONTAL, const wxValidator &validator=wxDefaultValidator, const wxString &name=wxScrollBarNameStr)

  Constructor, creating and showing a scrollbar.

- virtual ~wxScrollBar ()

  Destructor, destroying the scrollbar.

- bool Create (wxWindow *parent, wxWindowID id, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, long style=wxSB_HORIZONTAL, const wxValidator &validator=wxDefaultValidator, const wxString &name=wxScrollBarNameStr)

  Scrollbar creation function called by the scrollbar constructor.

- virtual int GetPageSize () const

  Returns the page size of the scrollbar.

- virtual int GetRange () const

  Returns the length of the scrollbar.

- virtual int GetThumbPosition () const

  Returns the current position of the scrollbar thumb.

- virtual int GetThumbSize () const

  Returns the thumb or 'view' size.

- virtual void SetScrollbar (int position, int thumbSize, int range, int pageSize, bool refresh=true)

  Sets the scrollbar properties.

- virtual void SetThumbPosition (int viewStart)

  Sets the position of the scrollbar.

- bool IsVertical () const

  Returns true for scrollbars that have the vertical style set.

Additional Inherited Members

21.668.3 Constructor & Destructor Documentation

wxScrollBar::wxScrollBar ( )

Default constructor.

wxScrollBar::wxScrollBar (wxWindow * *parent*, wxWindowID *id*, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, long *style* = wxSB_HORIZONTAL, const wxValidator & *validator* = wxDefaultValidator, const wxString & *name* = `wxScrollBarNameStr`)

Constructor, creating and showing a scrollbar.

Parameters

parent	Parent window. Must be non-NULL.
id	Window identifier. The value wxID_ANY indicates a default value.
pos	Window position. If wxDefaultPosition is specified then a default position is chosen.
size	Window size. If wxDefaultSize is specified then a default size is chosen.
style	Window style. See wxScrollBar.
validator	Window validator.
name	Window name.

See also

Create(), wxValidator

virtual wxScrollBar::~wxScrollBar ( ) `[virtual]`

Destructor, destroying the scrollbar.

21.668.4 Member Function Documentation

bool wxScrollBar::Create (wxWindow * *parent*, wxWindowID *id*, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, long *style* = wxSB_HORIZONTAL, const wxValidator & *validator* = wxDefaultValidator, const wxString & *name* = `wxScrollBarNameStr`)

Scrollbar creation function called by the scrollbar constructor.

See wxScrollBar() for details.

virtual int wxScrollBar::GetPageSize ( ) const `[virtual]`

Returns the page size of the scrollbar.

This is the number of scroll units that will be scrolled when the user pages up or down. Often it is the same as the thumb size.

SetScrollbar()

virtual int wxScrollBar::GetRange ( ) const `[virtual]`

Returns the length of the scrollbar.

See also

SetScrollbar()

virtual int wxScrollBar::GetThumbPosition ( ) const `[virtual]`

Returns the current position of the scrollbar thumb.

See also

SetThumbPosition()

virtual int wxScrollBar::GetThumbSize ( ) const `[virtual]`

Returns the thumb or 'view' size.

See also

SetScrollbar()

bool wxScrollBar::IsVertical ( ) const

Returns true for scrollbars that have the vertical style set.

virtual void wxScrollBar::SetScrollbar (int *position,* int *thumbSize,* int *range,* int *pageSize,* bool *refresh* = `true`) `[virtual]`

Sets the scrollbar properties.

Parameters

position	The position of the scrollbar in scroll units.
thumbSize	The size of the thumb, or visible portion of the scrollbar, in scroll units.
range	The maximum position of the scrollbar.
pageSize	The size of the page size in scroll units. This is the number of units the scrollbar will scroll when it is paged up or down. Often it is the same as the thumb size.
refresh	true to redraw the scrollbar, false otherwise.

Remarks

Let's say you wish to display 50 lines of text, using the same font. The window is sized so that you can only see 16 lines at a time. You would use:

```
scrollbar->SetScrollbar(0, 16, 50, 15);
```

The page size is 1 less than the thumb size so that the last line of the previous page will be visible on the next page, to help orient the user. Note that with the window at this size, the thumb position can never go above 50 minus 16, or 34. You can determine how many lines are currently visible by dividing the current view size by the character height in pixels. When defining your own scrollbar behaviour, you will always need to recalculate the scrollbar settings when the window size changes. You could therefore put your scrollbar calculations and SetScrollbar() call into a function named AdjustScrollbars, which can be called initially and also from a wxSizeEvent event handler function.

Reimplemented from wxWindow.

virtual void wxScrollBar::SetThumbPosition (int *viewStart*) `[virtual]`

Sets the position of the scrollbar.

Parameters

viewStart	The position of the scrollbar thumb.

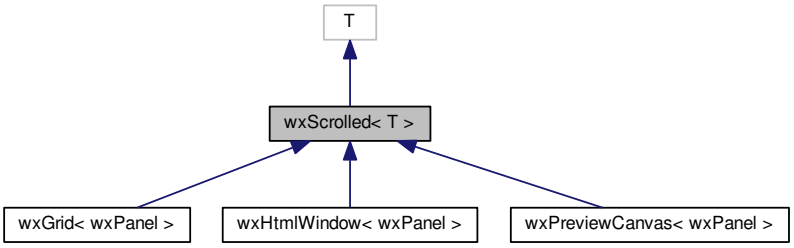
GetThumbPosition()

21.669 wxScrolled< T > Class Template Reference

`#include <wx/scrolwin.h>`

Inheritance diagram for wxScrolled< T >:



21.669.1 Detailed Description

template<class T>class wxScrolled< T >

The wxScrolled class manages scrolling for its client area, transforming the coordinates according to the scrollbar positions, and setting the scroll positions, thumb sizes and ranges according to the area in view.

There are two commonly used (but not the only possible!) specializations of this class:

- wxScrolledWindow, aka wxScrolled<wxPanel>, is equivalent to wxScrolledWindow from earlier versions. Derived from wxPanel, it shares wxPanel's behaviour with regard to TAB traversal and focus handling. Use this if the scrolled window will have child controls.
- wxScrolledCanvas, aka wxScrolled<wxWindow>, derives from wxWindow and so doesn't handle children specially. This is suitable e.g. for implementing scrollable controls such as tree or list controls.

Starting from version 2.4 of wxWidgets, there are several ways to use a wxScrolledWindow (and now wxScrolled). In particular, there are three ways to set the size of the scrolling area:

One way is to set the scrollbars directly using a call to SetScrollbars(). This is the way it used to be in any previous version of wxWidgets and it will be kept for backwards compatibility.

An additional method of manual control, which requires a little less computation of your own, is to set the total size of the scrolling area by calling either wxWindow::SetVirtualSize(), or wxWindow::FitInside(), and setting the scrolling increments for it by calling SetScrollRate(). Scrolling in some orientation is enabled by setting a non-zero increment for it.

The most automatic and newest way is to simply let sizers determine the scrolling area. This is now the default when you set an interior sizer into a wxScrolled with wxWindow::SetSizer(). The scrolling area will be set to the size requested by the sizer and the scrollbars will be assigned for each orientation according to the need for them and the scrolling increment set by SetScrollRate(). As above, scrolling is only enabled in orientations with a non-zero

increment. You can influence the minimum size of the scrolled area controlled by a sizer by calling wxWindow::↩ SetVirtualSizeHints(). (Calling SetScrollbars() has analogous effects in wxWidgets 2.4 – in later versions it may not continue to override the sizer.)

Note that if maximum size hints are still supported by wxWindow::SetVirtualSizeHints(), use them at your own dire risk. They may or may not have been removed for 2.4, but it really only makes sense to set minimum size hints here. We should probably replace wxWindow::SetVirtualSizeHints() with wxWindow::SetMinVirtualSize() or similar and remove it entirely in future.

Todo review docs for this class replacing SetVirtualSizeHints() with SetMinClientSize().

As with all windows, an application can draw onto a wxScrolled using a device context.

You have the option of handling the OnPaint handler or overriding the wxScrolled::OnDraw() function, which is passed a pre-scrolled device context (prepared by wxScrolled::DoPrepareDC()).

If you don't wish to calculate your own scrolling, you must call DoPrepareDC() when not drawing from within On↩ Draw(), to set the device origin for the device context according to the current scroll position.

A wxScrolled will normally scroll itself and therefore its child windows as well. It might however be desired to scroll a different window than itself: e.g. when designing a spreadsheet, you will normally only have to scroll the (usually white) cell area, whereas the (usually grey) label area will scroll very differently. For this special purpose, you can call SetTargetWindow() which means that pressing the scrollbars will scroll a different window.

Note that the underlying system knows nothing about scrolling coordinates, so that all system functions (mouse events, expose events, refresh calls etc) as well as the position of subwindows are relative to the "physical" origin of the scrolled window. If the user insert a child window at position (10,10) and scrolls the window down 100 pixels (moving the child window out of the visible area), the child window will report a position of (10,-90).

Styles

This class supports the following styles:

- wxHSCROLL: If this style is specified and wxVSCROLL isn't, the window will be scrollable only in horizontal direction (by default, i.e. if neither this style nor wxVSCROLL is specified, it scrolls in both directions).
- wxVSCROLL: If this style is specified and wxHSCROLL isn't, the window will be scrollable only in vertical direction (by default, i.e. if neither this style nor wxHSCROLL is specified, it scrolls in both directions).
- wxALWAYS_SHOW_SB: Since wxWidgets 2.9.5, specifying this style makes the window always show its scrollbars, even if they are not used. See ShowScrollbars().
- wxRETAINED: Uses a backing pixmap to speed refreshes. Motif only.

Events emitted by this class

The following event handler macros redirect the events to member function handlers '**func**' with prototypes like: void handlerFuncName(wxScrollWinEvent& event)

Event macros for events emitted by this class:

- EVT_SCROLLWIN(func): Process all scroll events.
- EVT_SCROLLWIN_TOP(func): Process `wxEVT_SCROLLWIN_TOP` scroll-to-top events.
- EVT_SCROLLWIN_BOTTOM(func): Process `wxEVT_SCROLLWIN_BOTTOM` scroll-to-bottom events.
- EVT_SCROLLWIN_LINEUP(func): Process `wxEVT_SCROLLWIN_LINEUP` line up events.
- EVT_SCROLLWIN_LINEDOWN(func): Process `wxEVT_SCROLLWIN_LINEDOWN` line down events.
- EVT_SCROLLWIN_PAGEUP(func): Process `wxEVT_SCROLLWIN_PAGEUP` page up events.

- EVT_SCROLLWIN_PAGEDOWN(func): Process `wxEVT_SCROLLWIN_PAGEDOWN` page down events.
- EVT_SCROLLWIN_THUMBTRACK(func): Process `wxEVT_SCROLLWIN_THUMBTRACK` thumbtrack events (frequent events sent as the user drags the thumbtrack).
- EVT_SCROLLWIN_THUMBRELEASE(func): Process `wxEVT_SCROLLWIN_THUMBRELEASE` thumb release events.

Note

Don't confuse wxScrollWinEvents generated by this class with wxScrollEvent objects generated by wxScrollBar and wxSlider.

Remarks

Use wxScrolled for applications where the user scrolls by a fixed amount, and where a 'page' can be interpreted to be the current visible portion of the window. For more sophisticated applications, use the wxScrolled implementation as a guide to build your own scroll behaviour or use wxVScrolledWindow or its variants.

Since

The wxScrolled template exists since version 2.9.0. In older versions, only wxScrolledWindow (equivalent of wxScrolled<wxPanel>) was available.

  Translates the device coordinates to the logical ones.
- wxPoint CalcUnscrolledPosition (const wxPoint &pt) const
- bool Create (wxWindow *parent, wxWindowID id=-1, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, long style=wxHSCROLL|wxVSCROLL, const wxString &name="scrolledWindow")

  Creates the window for two-step construction.
- void DisableKeyboardScrolling ()

  Disable use of keyboard keys for scrolling.
- void DoPrepareDC (wxDC &dc)

  Call this function to prepare the device context for drawing a scrolled image.
- void EnableScrolling (bool xScrolling, bool yScrolling)

Enable or disable use of wxWindow::ScrollWindow() for scrolling.

- void ShowScrollbars (wxScrollbarVisibility horz, wxScrollbarVisibility vert)

  Set the scrollbar visibility.
- void GetScrollPixelsPerUnit (int *xUnit, int *yUnit) const

  Get the number of pixels per scroll unit (line), in each direction, as set by SetScrollbars().
- void GetViewStart (int *x, int *y) const

  Get the position at which the visible portion of the window starts.
- wxPoint GetViewStart () const

  This is a simple overload of GetViewStart(int,int*); see that function for more info.*
- void GetVirtualSize (int *x, int *y) const

  Gets the size in device units of the scrollable window area (as opposed to the client size, which is the area of the window currently visible).
- bool IsRetained () const

  Motif only: true if the window has a backing bitmap.
- virtual void OnDraw (wxDC &dc)

  Called by the default paint event handler to allow the application to define painting behaviour without having to worry about calling DoPrepareDC().
- void PrepareDC (wxDC &dc)

  This function is for backwards compatibility only and simply calls DoPrepareDC() now.
- void Scroll (int x, int y)

  Scrolls a window so the view start is at the given point.
- void Scroll (const wxPoint &pt)

  This is an overload of Scroll(int,int); see that function for more info.
- void SetScrollRate (int xstep, int ystep)

  Set the horizontal and vertical scrolling increment only.
- void SetScrollbars (int pixelsPerUnitX, int pixelsPerUnitY, int noUnitsX, int noUnitsY, int xPos=0, int yPos=0, bool noRefresh=false)

  Sets up vertical and/or horizontal scrollbars.
- void SetTargetWindow (wxWindow *window)

  Call this function to tell wxScrolled to perform the actual scrolling on a different window (and not on itself).
- wxWindow * GetTargetWindow () const
- void SetTargetRect (const wxRect &rect)
- wxRect GetTargetRect () const
- int GetScrollPageSize (int orient) const
- void SetScrollPageSize (int orient, int pageSize)
- int GetScrollLines (int orient) const
- void SetScale (double xs, double ys)
- double GetScaleX () const
- double GetScaleY () const
- virtual void AdjustScrollbars ()
- bool IsAutoScrolling () const

  Are we generating the autoscroll events?
- void StopAutoScrolling ()

  Stop generating the scroll events when mouse is held outside the window.
- virtual bool SendAutoScrollEvents (wxScrollWinEvent &event) const

  This method can be overridden in a derived class to forbid sending the auto scroll events - note that unlike StopAutoScrolling() it doesn't stop the timer, so it will be called repeatedly and will typically return different values depending on the current mouse position.

Protected Member Functions

- virtual wxSize GetSizeAvailableForScrollTarget (const wxSize &size)

  Function which must be overridden to implement the size available for the scroll target for the given size of the main window.

21.669.2 Constructor & Destructor Documentation

template<class T> wxScrolled< T >::wxScrolled ( )

Default constructor.

template<class T> wxScrolled< T >::wxScrolled (wxWindow * *parent*, wxWindowID *id* = -1, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, long *style* = wxHSCROLL|wxVSCROLL, const wxString & *name* = "scrolledWindow")

Constructor.

Parameters

parent	Parent window.
id	Window identifier. The value wxID_ANY indicates a default value.
pos	Window position. If a position of wxDefaultPosition is specified then a default position is chosen.
size	Window size. If a size of wxDefaultSize is specified then the window is sized appropriately.
style	Window style. See wxScrolled.
name	Window name.

Remarks

The window is initially created without visible scrollbars. Call SetScrollbars() to specify how big the virtual window size should be.

21.669.3 Member Function Documentation

template<class T> virtual void wxScrolled< T >::AdjustScrollbars ( ) [virtual]

template<class T> void wxScrolled< T >::CalcScrolledPosition (int *x*, int *y*, int * *xx*, int * *yy*) const

Translates the logical coordinates to the device ones.

For example, if a window is scrolled 10 pixels to the bottom, the device coordinates of the origin are (0, 0) (as always), but the logical coordinates are (0, 10) and so the call to CalcScrolledPosition(0, 10, xx, yy) will return 0 in yy.

wxPerl Note: In wxPerl this method takes two parameters and returns a 2-element list (xx, yy).

See also

CalcUnscrolledPosition()

template<class T> wxPoint wxScrolled< T >::CalcScrolledPosition (const wxPoint & *pt*) const

template<class T> void wxScrolled< T >::CalcUnscrolledPosition (int *x*, int *y*, int * *xx*, int * *yy*) const

Translates the device coordinates to the logical ones.

For example, if a window is scrolled 10 pixels to the bottom, the device coordinates of the origin are (0, 0) (as always), but the logical coordinates are (0, 10) and so the call to CalcUnscrolledPosition(0, 0, xx, yy) will return 10 in yy.

wxPerl Note: In wxPerl this method takes two parameters and returns a 2-element list (xx, yy).

See also

CalcScrolledPosition()

template<class T > wxPoint wxScrolled< T >::CalcUnscrolledPosition (const wxPoint & *pt*) const

template<class T > bool wxScrolled< T >::Create (wxWindow * *parent*, wxWindowID *id* = -1, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, long *style* = wxHSCROLL|wxVSCROLL, const wxString & *name* = "scrolledWindow")

Creates the window for two-step construction.

Derived classes should call or replace this function. See wxScrolled::wxScrolled() for details.

template<class T > void wxScrolled< T >::DisableKeyboardScrolling ( )

Disable use of keyboard keys for scrolling.

By default cursor movement keys (including Home, End, Page Up and Down) are used to scroll the window appropriately. If the derived class uses these keys for something else, e.g. changing the currently selected item, this function can be used to disable this behaviour as it's not only not necessary then but can actually be actively harmful if another object forwards a keyboard event corresponding to one of the above keys to us using ProcessWindowEvent() because the event will always be processed which can be undesirable.

Since

2.9.1

template<class T > void wxScrolled< T >::DoPrepareDC (wxDC & *dc*)

Call this function to prepare the device context for drawing a scrolled image.

It sets the device origin according to the current scroll position. DoPrepareDC() is called automatically within the default wxEVT_PAINT event handler, so your OnDraw() override will be passed an already 'pre-scrolled' device context. However, if you wish to draw from outside of OnDraw() (e.g. from your own wxEVT_PAINT handler), you must call this function yourself.

For example:

```
void MyWindow::OnEvent(wxMouseEvent& event)
{
  wxClientDC dc(this);
  DoPrepareDC(dc);

  dc.SetPen(*wxBLACK_PEN);
  float x, y;
  event.Position(&x, &y);
  if (xpos > -1 && ypos > -1 && event.Dragging())
  {
    dc.DrawLine(xpos, ypos, x, y);
  }
  xpos = x;
  ypos = y;
}
```

Notice that the function sets the origin by moving it relatively to the current origin position, so you shouldn't change the origin before calling DoPrepareDC() or, if you do, reset it to (0, 0) later. If you call DoPrepareDC() immediately after device context creation, as in the example above, this problem doesn't arise, of course, so it is customary to do it like this.

template<class T > void wxScrolled< T >::EnableScrolling (bool *xScrolling*, bool *yScrolling*)

Enable or disable use of wxWindow::ScrollWindow() for scrolling.

By default, when a scrolled window is logically scrolled, wxWindow::ScrollWindow() is called on the underlying window which scrolls the window contents and only invalidates the part of the window newly brought into view. If false is passed as an argument, then this "physical scrolling" is disabled and the window is entirely invalidated whenever it is scrolled by calling wxWindow::Refresh().

It should be rarely necessary to disable physical scrolling, so this method shouldn't be called in normal circumstances.

Parameters

xScrolling	If true, enables physical scrolling in the x direction.
yScrolling	If true, enables physical scrolling in the y direction.

template<class T > double wxScrolled< T >::GetScaleX ( ) const

template<class T > double wxScrolled< T >::GetScaleY ( ) const

template<class T > int wxScrolled< T >::GetScrollLines (int *orient*) const

template<class T > int wxScrolled< T >::GetScrollPageSize (int *orient*) const

template<class T > void wxScrolled< T >::GetScrollPixelsPerUnit (int * *xUnit*, int * *yUnit*) const

Get the number of pixels per scroll unit (line), in each direction, as set by SetScrollbars().

A value of zero indicates no scrolling in that direction.

Parameters

xUnit	Receives the number of pixels per horizontal unit.
yUnit	Receives the number of pixels per vertical unit.

wxPerl Note: In wxPerl this method takes no parameters and returns a 2-element list (xUnit, yUnit).

See also

SetScrollbars(), GetVirtualSize()

template<class T > virtual wxSize wxScrolled< T >::GetSizeAvailableForScrollTarget (const wxSize & *size*) [protected], [virtual]

Function which must be overridden to implement the size available for the scroll target for the given size of the main window.

This method must be overridden if SetTargetWindow() is used (it is never called otherwise). The implementation should decrease the *size* to account for the size of the non-scrollable parts of the main window and return only the size available for the scrollable window itself. E.g. in the example given in SetTargetWindow() documentation the function would subtract the height of the header window from the vertical component of *size*.

template<class T > wxRect wxScrolled< T >::GetTargetRect ( ) const

template<class T > wxWindow* wxScrolled< T >::GetTargetWindow ( ) const

template<class T > void wxScrolled< T >::GetViewStart (int * *x*, int * *y*) const

Get the position at which the visible portion of the window starts.

Parameters

x	Receives the first visible x position in scroll units.
y	Receives the first visible y position in scroll units.

Remarks

If either of the scrollbars is not at the home position, *x* and/or *y* will be greater than zero. Combined with wxWindow::GetClientSize(), the application can use this function to efficiently redraw only the visible portion of the window. The positions are in logical scroll units, not pixels, so to convert to pixels you will have to multiply by the number of pixels per scroll increment.

wxPerl Note: In wxPerl this method takes no parameters and returns a 2-element list (x, y).

See also

SetScrollbars(), Scroll()

template<class T > wxPoint wxScrolled< T >::GetViewStart ( ) const

This is a simple overload of GetViewStart(int*,int*); see that function for more info.

template<class T > void wxScrolled< T >::GetVirtualSize (int * *x*, int * *y*) const

Gets the size in device units of the scrollable window area (as opposed to the client size, which is the area of the window currently visible).

Parameters

x	Receives the length of the scrollable window, in pixels.
y	Receives the height of the scrollable window, in pixels.

Remarks

Use wxDC::DeviceToLogicalX() and wxDC::DeviceToLogicalY() to translate these units to logical units.

wxPerl Note: In wxPerl this method takes no parameters and returns a 2-element list (xUnit, yUnit).

See also

SetScrollbars(), GetScrollPixelsPerUnit()

template<class T > bool wxScrolled< T >::IsAutoScrolling ( ) const

Are we generating the autoscroll events?

template<class T > bool wxScrolled< T >::IsRetained ( ) const

Motif only: true if the window has a backing bitmap.

template<class T > virtual void wxScrolled< T >::OnDraw (wxDC & *dc*) [virtual]

Called by the default paint event handler to allow the application to define painting behaviour without having to worry about calling DoPrepareDC().

Instead of overriding this function you may also just process the paint event in the derived class as usual, but then you will have to call DoPrepareDC() yourself.

template<class T > void wxScrolled< T >::PrepareDC (wxDC & *dc*)

This function is for backwards compatibility only and simply calls DoPrepareDC() now.

Notice that it is not called by the default paint event handle (DoPrepareDC() is), so overriding this method in your derived class is useless.

template<class T > void wxScrolled< T >::Scroll (int *x*, int *y*)

Scrolls a window so the view start is at the given point.

Parameters

x	The x position to scroll to, in scroll units.
y	The y position to scroll to, in scroll units.

Remarks

The positions are in scroll units, not pixels, so to convert to pixels you will have to multiply by the number of pixels per scroll increment. If either parameter is wxDefaultCoord (-1), that position will be ignored (no change in that direction).

See also

SetScrollbars(), GetScrollPixelsPerUnit()

template<class T > void wxScrolled< T >::Scroll (const wxPoint & *pt*)

This is an overload of Scroll(int,int); see that function for more info.

template<class T > virtual bool wxScrolled< T >::SendAutoScrollEvents (wxScrollWinEvent & *event*) const `[virtual]`

This method can be overridden in a derived class to forbid sending the auto scroll events - note that unlike StopAutoScrolling() it doesn't stop the timer, so it will be called repeatedly and will typically return different values depending on the current mouse position.

The base class version just returns true.

template<class T > void wxScrolled< T >::SetScale (double *xs*, double *ys*)

template<class T > void wxScrolled< T >::SetScrollbars (int *pixelsPerUnitX*, int *pixelsPerUnitY*, int *noUnitsX*, int *noUnitsY*, int *xPos* = `0`, int *yPos* = `0`, bool *noRefresh* = `false`)

Sets up vertical and/or horizontal scrollbars.

The first pair of parameters give the number of pixels per 'scroll step', i.e. amount moved when the up or down scroll arrows are pressed. The second pair gives the length of scrollbar in scroll steps, which sets the size of the virtual window.

xPos and *yPos* optionally specify a position to scroll to immediately.

For example, the following gives a window horizontal and vertical scrollbars with 20 pixels per scroll step, and a size of 50 steps (1000 pixels) in each direction:

```
window->SetScrollbars(20, 20, 50, 50);
```

wxScrolled manages the page size itself, using the current client window size as the page size.

Note that for more sophisticated scrolling applications, for example where scroll steps may be variable according to the position in the document, it will be necessary to derive a new class from wxWindow, overriding OnSize() and adjusting the scrollbars appropriately.

Parameters

pixelsPerUnitX	Pixels per scroll unit in the horizontal direction.
pixelsPerUnitY	Pixels per scroll unit in the vertical direction.
noUnitsX	Number of units in the horizontal direction.
noUnitsY	Number of units in the vertical direction.
xPos	Position to initialize the scrollbars in the horizontal direction, in scroll units.
yPos	Position to initialize the scrollbars in the vertical direction, in scroll units.
noRefresh	Will not refresh window if true.

See also

wxWindow::SetVirtualSize()

template<class T > void wxScrolled< T >::SetScrollPageSize (int *orient,* int *pageSize*)

template<class T > void wxScrolled< T >::SetScrollRate (int *xstep,* int *ystep*)

Set the horizontal and vertical scrolling increment only.

See the pixelsPerUnit parameter in SetScrollbars().

template<class T > void wxScrolled< T >::SetTargetRect (const wxRect & *rect*)

template<class T > void wxScrolled< T >::SetTargetWindow (wxWindow * *window*)

Call this function to tell wxScrolled to perform the actual scrolling on a different window (and not on itself).

This method is useful when only a part of the window should be scrolled. A typical example is a control consisting of a fixed header and the scrollable contents window: the scrollbars are attached to the main window itself, hence it, and not the contents window must be derived from wxScrolled, but only the contents window scrolls when the scrollbars are used. To implement such setup, you need to call this method with the contents window as argument.

Notice that if this method is used, GetSizeAvailableForScrollTarget() method must be overridden.

template<class T > void wxScrolled< T >::ShowScrollbars (wxScrollbarVisibility *horz,* wxScrollbarVisibility *vert*)

Set the scrollbar visibility.

By default the scrollbar in the corresponding direction is only shown if it is needed, i.e. if the virtual size of the scrolled window in this direction is greater than the current physical window size. Using this function the scrollbar visibility can be changed to be:

- wxSHOW_SB_ALWAYS: To always show the scrollbar, even if it is not needed currently (wxALWAYS_SHOW_SB style can be used during the window creation to achieve the same effect but it applies in both directions).
- wxSHOW_SB_NEVER: To never show the scrollbar at all. In this case the program should presumably provide some other way for the user to scroll the window.
- wxSHOW_SB_DEFAULT: To restore the default behaviour described above.

Parameters

horz	The desired visibility for the horizontal scrollbar.
vert	The desired visibility for the vertical scrollbar.

Since

2.9.0

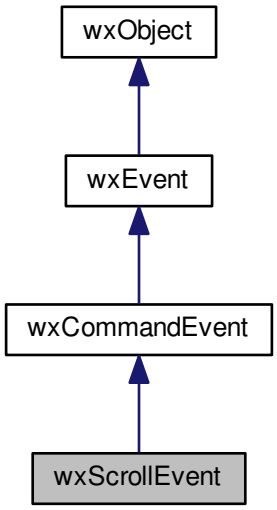
template<class T > void wxScrolled< T >::StopAutoScrolling ( )

Stop generating the scroll events when mouse is held outside the window.

21.670 wxScrollEvent Class Reference

`#include <wx/event.h>`

Inheritance diagram for wxScrollEvent:



21.670.1 Detailed Description

A scroll event holds information about events sent from stand-alone scrollbars (see wxScrollBar) and sliders (see wxSlider).

Note that scrolled windows send the wxScrollWinEvent which does not derive from wxCommandEvent, but from wxEvent directly - don't confuse these two kinds of events and use the event table macros mentioned below only for the scrollbar-like controls.

21.670.2 The difference between EVT_SCROLL_THUMBRELEASE and EVT_SCROLL_CHANGED

The EVT_SCROLL_THUMBRELEASE event is only emitted when actually dragging the thumb using the mouse and releasing it (This EVT_SCROLL_THUMBRELEASE event is also followed by an EVT_SCROLL_CHANGED event).

The EVT_SCROLL_CHANGED event also occurs when using the keyboard to change the thumb position, and when clicking next to the thumb (In all these cases the EVT_SCROLL_THUMBRELEASE event does not happen).

In short, the EVT_SCROLL_CHANGED event is triggered when scrolling/ moving has finished independently of the way it had started. Please see the widgets sample ("Slider" page) to see the difference between EVT_SCROLL_↩ THUMBRELEASE and EVT_SCROLL_CHANGED in action.

Remarks

Note that unless specifying a scroll control identifier, you will need to test for scrollbar orientation with wx↩ ScrollEvent::GetOrientation, since horizontal and vertical scroll events are processed using the same event handler.

Events using this class

The following event handler macros redirect the events to member function handlers '**func**' with prototypes like: void handlerFuncName(wxScrollEvent& event)

Event macros: You can use EVT_COMMAND_SCROLL... macros with window IDs for when intercepting scroll events from controls, or EVT_SCROLL... macros without window IDs for intercepting scroll events from the receiving window – except for this, the macros behave exactly the same.

- EVT_SCROLL(func): Process all scroll events.
- EVT_SCROLL_TOP(func): Process `wxEVT_SCROLL_TOP` scroll-to-top events (minimum position).
- EVT_SCROLL_BOTTOM(func): Process `wxEVT_SCROLL_BOTTOM` scroll-to-bottom events (maximum position).
- EVT_SCROLL_LINEUP(func): Process `wxEVT_SCROLL_LINEUP` line up events.
- EVT_SCROLL_LINEDOWN(func): Process `wxEVT_SCROLL_LINEDOWN` line down events.
- EVT_SCROLL_PAGEUP(func): Process `wxEVT_SCROLL_PAGEUP` page up events.
- EVT_SCROLL_PAGEDOWN(func): Process `wxEVT_SCROLL_PAGEDOWN` page down events.
- EVT_SCROLL_THUMBTRACK(func): Process `wxEVT_SCROLL_THUMBTRACK` thumbtrack events (frequent events sent as the user drags the thumbtrack).
- EVT_SCROLL_THUMBRELEASE(func): Process `wxEVT_SCROLL_THUMBRELEASE` thumb release events.
- EVT_SCROLL_CHANGED(func): Process `wxEVT_SCROLL_CHANGED` end of scrolling events (MSW only).
- EVT_COMMAND_SCROLL(id, func): Process all scroll events.
- EVT_COMMAND_SCROLL_TOP(id, func): Process `wxEVT_SCROLL_TOP` scroll-to-top events (minimum position).
- EVT_COMMAND_SCROLL_BOTTOM(id, func): Process `wxEVT_SCROLL_BOTTOM` scroll-to-bottom events (maximum position).
- EVT_COMMAND_SCROLL_LINEUP(id, func): Process `wxEVT_SCROLL_LINEUP` line up events.
- EVT_COMMAND_SCROLL_LINEDOWN(id, func): Process `wxEVT_SCROLL_LINEDOWN` line down events.

- EVT_COMMAND_SCROLL_PAGEUP(id, func): Process `wxEVT_SCROLL_PAGEUP` page up events.
- EVT_COMMAND_SCROLL_PAGEDOWN(id, func): Process `wxEVT_SCROLL_PAGEDOWN` page down events.
- EVT_COMMAND_SCROLL_THUMBTRACK(id, func): Process `wxEVT_SCROLL_THUMBTRACK` thumbtrack events (frequent events sent as the user drags the thumbtrack).
- EVT_COMMAND_SCROLL_THUMBRELEASE(func): Process `wxEVT_SCROLL_THUMBRELEASE` thumb release events.
- EVT_COMMAND_SCROLL_CHANGED(func): Process `wxEVT_SCROLL_CHANGED` end of scrolling events (MSW only).

Todo wxHORIZONTAL and wxVERTICAL should go in their own enum

int wxScrollWinEvent::GetPosition ( ) const

Returns the position of the scrollbar for the thumb track and release events.

Note that this field can't be used for the other events, you need to query the window itself for the current position in that case.

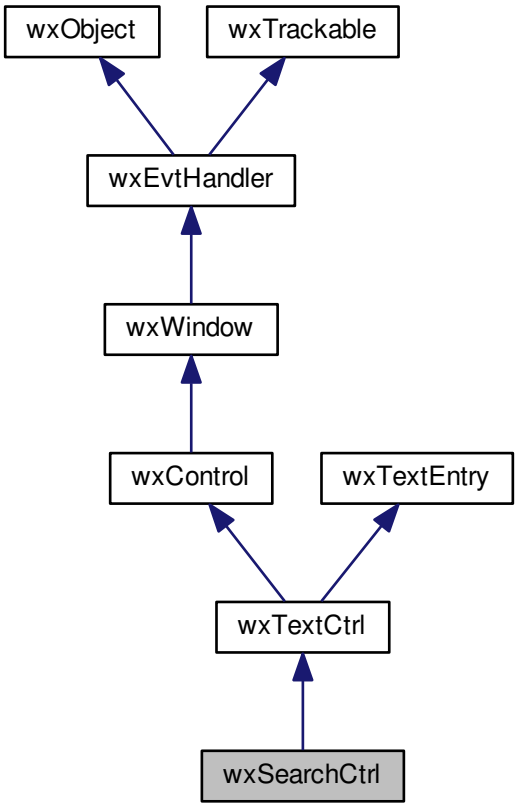
void wxScrollWinEvent::SetOrientation (int *orient*)

void wxScrollWinEvent::SetPosition (int *pos*)

21.672 wxSearchCtrl Class Reference

`#include <wx/srchctrl.h>`

Inheritance diagram for wxSearchCtrl:



21.672.1 Detailed Description

A search control is a composite control with a search button, a text control, and a cancel button.

Styles

This class supports the following styles:

- wxTE_PROCESS_ENTER: The control will generate the event `wxEVT_TEXT_ENTER` (otherwise pressing Enter key is either processed internally by the control or used for navigation between dialog controls).
- wxTE_PROCESS_TAB: The control will receive `wxEVT_CHAR` events for TAB pressed - normally, TAB is used for passing to the next control in a dialog instead. For the control created with this style, you can still use Ctrl-Enter to pass to the next control from the keyboard.
- wxTE_NOHIDESEL: By default, the Windows text control doesn't show the selection when it doesn't have focus - use this style to force it to always show it. It doesn't do anything under other platforms.

- wxTE_LEFT: The text in the control will be left-justified (default).
- wxTE_CENTRE: The text in the control will be centered (currently wxMSW and wxGTK2 only).
- wxTE_RIGHT: The text in the control will be right-justified (currently wxMSW and wxGTK2 only).
- wxTE_CAPITALIZE: On PocketPC and Smartphone, causes the first letter to be capitalized.

Events emitted by this class

The following event handler macros redirect the events to member function handlers '**func**' with prototypes like: void handlerFuncName(wxCommandEvent& event)

Event macros for events emitted by this class: To retrieve actual search queries, use EVT_TEXT and EVT_TEXT↩ _ENTER events, just as you would with wxTextCtrl.

- EVT_SEARCHCTRL_SEARCH_BTN(id, func): Respond to a `wxEVT_SEARCHCTRL_SEARCH_BT↩ N` event, generated when the search button is clicked. Note that this does not initiate a search on its own, you need to perform the appropriate action in your event handler. You may use

  ```
  event.GetString()
  ```

  to retrieve the string to search for in the event handler code.
- EVT_SEARCHCTRL_CANCEL_BTN(id, func): Respond to a `wxEVT_SEARCHCTRL_CANCEL_BTN` event, generated when the cancel button is clicked.

21.672.2 Constructor & Destructor Documentation

wxSearchCtrl::wxSearchCtrl ( )

Default constructor.

wxSearchCtrl::wxSearchCtrl (wxWindow * *parent*, wxWindowID *id*, const wxString & *value* = wxEmptyString, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, long *style* = 0, const wxValidator & *validator* = wxDefaultValidator, const wxString & *name* = wxSearchCtrlNameStr)

Constructor, creating and showing a text control.

Parameters

parent	Parent window. Should not be NULL.
id	Control identifier. A value of -1 denotes a default value.
value	Default text value.
pos	Text control position.
size	Text control size.
style	Window style. See wxSearchCtrl.
validator	Window validator.
name	Window name.

Destructor, destroying the search control.

21.672.3 Member Function Documentation

bool wxSearchCtrl::Create (wxWindow * *parent*, wxWindowID *id*, const wxString & *value* = wxEmptyString, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, long *style* = 0, const wxValidator & *validator* = wxDefaultValidator, const wxString & *name* = wxSearchCtrlNameStr)

wxString wxSearchCtrl::GetDescriptiveText ( ) const

Return the text displayed when there is not yet any user input.

virtual wxMenu* wxSearchCtrl::GetMenu ( ) [virtual]

Returns a pointer to the search control's menu object or NULL if there is no menu attached.

virtual bool wxSearchCtrl::IsCancelButtonVisible ( ) const [virtual]

Returns the cancel button's visibility state.

virtual bool wxSearchCtrl::IsSearchButtonVisible ( ) const [virtual]

Returns the search button visibility value.

If there is a menu attached, the search button will be visible regardless of the search button visibility value.

This always returns false in Mac OS X v10.3

void wxSearchCtrl::SetDescriptiveText (const wxString & *text*)

Set the text to be displayed in the search control when the user has not yet typed anything in it.

virtual void wxSearchCtrl::SetMenu (wxMenu * *menu*) [virtual]

Sets the search control's menu object.

If there is already a menu associated with the search control it is deleted.

Parameters

menu	Menu to attach to the search control.

virtual void wxSearchCtrl::ShowCancelButton (bool *show*) [virtual]

Shows or hides the cancel button.

virtual void wxSearchCtrl::ShowSearchButton (bool *show*) [virtual]

Sets the search button visibility value on the search control.

If there is a menu attached, the search button will be visible regardless of the search button visibility value.

This has no effect in Mac OS X v10.3

21.673 wxSemaphore Class Reference

`#include <wx/thread.h>`

21.673.1 Detailed Description

wxSemaphore is a counter limiting the number of threads concurrently accessing a shared resource.

This counter is always between 0 and the maximum value specified during the semaphore creation. When the counter is strictly greater than 0, a call to wxSemaphore::Wait() returns immediately and decrements the counter. As soon as it reaches 0, any subsequent calls to wxSemaphore::Wait block and only return when the semaphore counter becomes strictly positive again as the result of calling wxSemaphore::Post which increments the counter.

In general, semaphores are useful to restrict access to a shared resource which can only be accessed by some fixed number of clients at the same time. For example, when modeling a hotel reservation system a semaphore with the counter equal to the total number of available rooms could be created. Each time a room is reserved, the semaphore should be acquired by calling wxSemaphore::Wait and each time a room is freed it should be released by calling wxSemaphore::Post.

Library: wxBase

Category: Threading

Public Member Functions

- wxSemaphore (int initialcount=0, int maxcount=0)

  Specifying a maxcount of 0 actually makes wxSemaphore behave as if there is no upper limit.
- ~wxSemaphore ()

  Destructor is not virtual, don't use this class polymorphically.
- wxSemaError Post ()

  Increments the semaphore count and signals one of the waiting threads in an atomic way.
- wxSemaError TryWait ()

  Same as Wait(), but returns immediately.
- wxSemaError Wait ()

  Wait indefinitely until the semaphore count becomes strictly positive and then decrement it and return.
- wxSemaError WaitTimeout (unsigned long timeout_millis)

  Same as Wait(), but with a timeout limit.

21.673.2 Constructor & Destructor Documentation

wxSemaphore::wxSemaphore (int *initialcount* = 0, int *maxcount* = 0)

Specifying a *maxcount* of 0 actually makes wxSemaphore behave as if there is no upper limit.

If *maxcount* is 1, the semaphore behaves almost as a mutex (but unlike a mutex it can be released by a thread different from the one which acquired it).

initialcount is the initial value of the semaphore which must be between 0 and *maxcount* (if it is not set to 0).

wxSemaphore::~wxSemaphore ( )

Destructor is not virtual, don't use this class polymorphically.

21.673.3 Member Function Documentation

wxSemaError wxSemaphore::Post ( )

Increments the semaphore count and signals one of the waiting threads in an atomic way.

Returns *wxSEMA_OVERFLOW* if the count would increase the counter past the maximum.

Returns

One of:

- wxSEMA_NO_ERROR: There was no error.
- wxSEMA_INVALID : Semaphore hasn't been initialized successfully.
- wxSEMA_OVERFLOW: Post() would increase counter past the max.
- wxSEMA_MISC_ERROR: Miscellaneous error.

wxSemaError wxSemaphore::TryWait ( )

Same as Wait(), but returns immediately.

Returns

One of:

- wxSEMA_NO_ERROR: There was no error.
- wxSEMA_INVALID: Semaphore hasn't been initialized successfully.
- wxSEMA_BUSY: Returned by TryWait() if Wait() would block, i.e. the count is zero.
- wxSEMA_MISC_ERROR: Miscellaneous error.

wxSemaError wxSemaphore::Wait ( )

Wait indefinitely until the semaphore count becomes strictly positive and then decrement it and return.

Returns

One of:

- wxSEMA_NO_ERROR: There was no error.
- wxSEMA_INVALID: Semaphore hasn't been initialized successfully.
- wxSEMA_MISC_ERROR: Miscellaneous error.

wxSemaError wxSemaphore::WaitTimeout (unsigned long *timeout_millis*)

Same as Wait(), but with a timeout limit.

Returns

One of:

- wxSEMA_NO_ERROR: There was no error.
- wxSEMA_INVALID: Semaphore hasn't been initialized successfully.
- wxSEMA_TIMEOUT: Timeout occurred without receiving semaphore.
- wxSEMA_MISC_ERROR: Miscellaneous error.

21.674 wxServer Class Reference

`#include <wx/ipc.h>`

21.674.1 Detailed Description

A wxServer object represents the server part of a client-server DDE-like (Dynamic Data Exchange) conversation.

The actual DDE-based implementation using wxDDEServer is available on Windows only, but a platform-independent, socket-based version of this API is available using wxTCPServer, which has the same API.

To create a server which can communicate with a suitable client, you need to derive a class from wxConnection and another from wxServer. The custom wxConnection class will intercept communications in a 'conversation' with a client, and the custom wxServer is required so that a user-overridden wxServer::OnAcceptConnection member can return a wxConnection of the required class, when a connection is made. Look at the IPC sample and the Interprocess Communication for an example of how to do this.

Library: wxBase

Category: Interprocess Communication

See also

wxClient, wxConnection, IPC, Interprocess Communication

Public Member Functions

- wxServer ()

  Constructs a server object.
- bool Create (const wxString &service)

  Registers the server using the given service name.
- virtual wxConnectionBase * OnAcceptConnection (const wxString &topic)

  *When a client calls **MakeConnection**, the server receives the message and this member is called.*

21.674.2 Constructor & Destructor Documentation

wxServer::wxServer ( )

Constructs a server object.

21.674.3 Member Function Documentation

bool wxServer::Create (const wxString & *service*)

Registers the server using the given service name.

Under Unix, the service name may be either an integer port identifier in which case an Internet domain socket will be used for the communications, or a valid file name (which shouldn't exist and will be deleted afterwards) in which case a Unix domain socket is created.

false is returned if the call failed (for example, the port number is already in use).

virtual wxConnectionBase* wxServer::OnAcceptConnection (const wxString & *topic*) `[virtual]`

When a client calls **MakeConnection**, the server receives the message and this member is called.

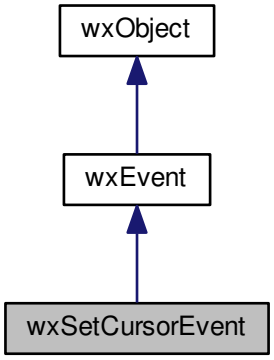
The application should derive a member to intercept this message and return a connection object of either the standard wxConnection type, or (more likely) of a user-derived type.

If the topic is **STDIO**, the application may wish to refuse the connection. Under UNIX, when a server is created the OnAcceptConnection() message is always sent for standard input and output, but in the context of DDE messages it doesn't make a lot of sense.

21.675 wxSetCursorEvent Class Reference

`#include <wx/event.h>`

Inheritance diagram for wxSetCursorEvent:



21.675.1 Detailed Description

A wxSetCursorEvent is generated from wxWindow when the mouse cursor is about to be set as a result of mouse motion.

This event gives the application the chance to perform specific mouse cursor processing based on the current position of the mouse within the window. Use wxSetCursorEvent::SetCursor to specify the cursor you want to be displayed.

Events using this class

The following event handler macros redirect the events to member function handlers '**func**' with prototypes like: void handlerFuncName(wxSetCursorEvent& event)

Event macros:

- EVT_SET_CURSOR(func): Process a `wxEVT_SET_CURSOR` event.

Library: wxCore

Category: Events

See also

wxSetCursor, wxWindow::SetCursor

Public Member Functions

- wxSetCursorEvent (wxCoord x=0, wxCoord y=0)

  Constructor, used by the library itself internally to initialize the event object.
- const wxCursor & GetCursor () const

  Returns a reference to the cursor specified by this event.
- wxCoord GetX () const

  Returns the X coordinate of the mouse in client coordinates.
- wxCoord GetY () const

  Returns the Y coordinate of the mouse in client coordinates.
- bool HasCursor () const

  Returns true if the cursor specified by this event is a valid cursor.
- void SetCursor (const wxCursor &cursor)

  Sets the cursor associated with this event.

Additional Inherited Members

21.675.2 Constructor & Destructor Documentation

wxSetCursorEvent::wxSetCursorEvent (wxCoord *x* = 0, wxCoord *y* = 0)

Constructor, used by the library itself internally to initialize the event object.

21.675.3 Member Function Documentation

const wxCursor& wxSetCursorEvent::GetCursor ( ) const

Returns a reference to the cursor specified by this event.

wxCoord wxSetCursorEvent::GetX ( ) const

Returns the X coordinate of the mouse in client coordinates.

wxCoord wxSetCursorEvent::GetY ( ) const

Returns the Y coordinate of the mouse in client coordinates.

bool wxSetCursorEvent::HasCursor ( ) const

Returns true if the cursor specified by this event is a valid cursor.

Remarks

You cannot specify wxNullCursor with this event, as it is not considered a valid cursor.

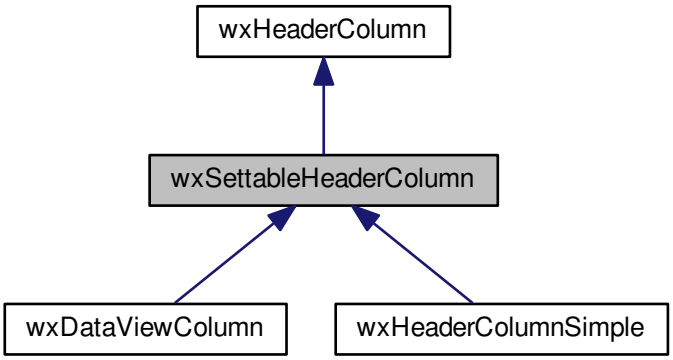
void wxSetCursorEvent::SetCursor (const wxCursor & *cursor*)

Sets the cursor associated with this event.

21.676 wxSettableHeaderColumn Class Reference

`#include <wx/headercol.h>`

Inheritance diagram for wxSettableHeaderColumn:



21.676.1 Detailed Description

Adds methods to set the column attributes to wxHeaderColumn.

This class adds setters for the column attributes defined by wxHeaderColumn. It is still an abstract base class and needs to be implemented before using it with wxHeaderCtrl.

Library: wxCore

Category: Controls

Public Member Functions

- virtual void SetTitle (const wxString &title)=0

  Set the text to display in the column header.
- virtual void SetBitmap (const wxBitmap &bitmap)=0

  Set the bitmap to be displayed in the column header.
- virtual void SetWidth (int width)=0

  Set the column width.
- virtual void SetMinWidth (int minWidth)=0

  Set the minimal column width.
- virtual void SetAlignment (wxAlignment align)=0

  Set the alignment of the column header.
- virtual void SetFlags (int flags)=0

  Set the column flags.
- void ChangeFlag (int flag, bool set)

  Set or clear the given flag.

- void SetFlag (int flag)

  Set the specified flag for the column.
- void ClearFlag (int flag)

  Clear the specified flag for the column.
- void ToggleFlag (int flag)

  Toggle the specified flag for the column.
- virtual void SetResizeable (bool resizable)

  Call this to enable or disable interactive resizing of the column by the user.
- virtual void SetSortable (bool sortable)

  Allow clicking the column to sort the control contents by the field in this column.
- virtual void SetReorderable (bool reorderable)

  Allow changing the column order by dragging it.
- virtual void SetHidden (bool hidden)

  Hide or show the column.
- void UnsetAsSortKey ()

  Don't use this column for sorting.
- virtual void SetSortOrder (bool ascending)=0

  Sets this column as the sort key for the associated control.
- void ToggleSortOrder ()

  Inverses the sort order.

21.676.2 Member Function Documentation

void wxSettableHeaderColumn::ChangeFlag (int *flag*, bool *set*)

Set or clear the given flag.

Parameters

flag	The flag to set or clear.
set	If true, set the flag, i.e. equivalent to calling SetFlag(), otherwise clear it, as ClearFlag().

See also

SetFlags()

void wxSettableHeaderColumn::ClearFlag (int *flag*)

Clear the specified flag for the column.

See also

SetFlags()

virtual void wxSettableHeaderColumn::SetAlignment (wxAlignment *align*) `[pure virtual]`

Set the alignment of the column header.

Parameters

align	The text alignment in horizontal direction only or wxALIGN_NOT to use the default alignment, The possible values here are wxALIGN_CENTRE, wxALIGN_LEFT or wxALIGN_RIGHT with wxALIGN_CENTRE_HORIZONTAL being also supported as synonym for wxALIGN_CEN↩ TRE for consistency (but notice that GetAlignment() never returns it).

Implemented in wxHeaderColumnSimple.

virtual void wxSettableHeaderColumn::SetBitmap (const wxBitmap & *bitmap*) `[pure virtual]`

Set the bitmap to be displayed in the column header.

Notice that the bitmaps displayed in different columns of the same control must all be of the same size.

Implemented in wxHeaderColumnSimple.

void wxSettableHeaderColumn::SetFlag (int *flag*)

Set the specified flag for the column.

See also

SetFlags()

virtual void wxSettableHeaderColumn::SetFlags (int *flags*) `[pure virtual]`

Set the column flags.

This method allows to set all flags at once, see also generic ChangeFlag(), SetFlag(), ClearFlag() and ToggleFlag() methods below as well as specific SetResizeable(), SetSortable(), SetReorderable() and SetHidden() ones.

Parameters

flags	Combination of wxCOL_RESIZABLE, wxCOL_SORTABLE, wxCOL_REORDERABLE and wxCOL_HIDDEN bit flags.

Implemented in wxHeaderColumnSimple.

virtual void wxSettableHeaderColumn::SetHidden (bool *hidden*) `[virtual]`

Hide or show the column.

By default all columns are shown but some of them can be completely hidden from view by calling this function.

Equivalent to ChangeFlag(wxCOL_HIDDEN, hidden).

virtual void wxSettableHeaderColumn::SetMinWidth (int *minWidth*) `[pure virtual]`

Set the minimal column width.

This method can be used with resizable columns (i.e. those for which wxCOL_RESIZABLE flag is set in GetFlags() or, alternatively, IsResizeable() returns true) to prevent the user from making them narrower than the given width.

Parameters

minWidth	The minimal column width in pixels, may be 0 to remove any previously set restrictions.

Implemented in wxHeaderColumnSimple.

virtual void wxSettableHeaderColumn::SetReorderable (bool *reorderable*) `[virtual]`

Allow changing the column order by dragging it.

Equivalent to ChangeFlag(wxCOL_REORDERABLE, reorderable).

virtual void wxSettableHeaderColumn::SetResizeable (bool *resizable*) `[virtual]`

Call this to enable or disable interactive resizing of the column by the user.

By default, the columns are resizable.

Equivalent to ChangeFlag(wxCOL_RESIZABLE, resizable).

virtual void wxSettableHeaderColumn::SetSortable (bool *sortable*) `[virtual]`

Allow clicking the column to sort the control contents by the field in this column.

By default, the columns are not sortable so you need to explicitly call this function to allow sorting by the field corresponding to this column.

Equivalent to ChangeFlag(wxCOL_SORTABLE, sortable).

virtual void wxSettableHeaderColumn::SetSortOrder (bool *ascending*) `[pure virtual]`

Sets this column as the sort key for the associated control.

This function indicates that this column is currently used for sorting the control and also sets the sorting direction. Notice that actual sorting is only done in the control associated with the header, this function doesn't do any sorting on its own.

Don't confuse this function with SetSortable() which should be used to indicate that the column *may* be used for sorting while this one is used to indicate that it currently *is* used for sorting. Of course, SetSortOrder() can be only called for sortable columns.

Parameters

ascending	If true, sort in ascending order, otherwise in descending order.

Implemented in wxHeaderColumnSimple.

virtual void wxSettableHeaderColumn::SetTitle (const wxString & *title*) `[pure virtual]`

Set the text to display in the column header.

Implemented in wxHeaderColumnSimple.

virtual void wxSettableHeaderColumn::SetWidth (int *width*) `[pure virtual]`

Set the column width.

Parameters

width	The column width in pixels or the special wxCOL_WIDTH_DEFAULT (meaning to use default width) or wxCOL_WIDTH_AUTOSIZE (size to fit the content) value.

Implemented in wxHeaderColumnSimple.

void wxSettableHeaderColumn::ToggleFlag (int *flag*)

Toggle the specified flag for the column.

If the flag is currently set, equivalent to ClearFlag(), otherwise – to SetFlag().

See also

SetFlags()

void wxSettableHeaderColumn::ToggleSortOrder ( )

Inverses the sort order.

This function is typically called when the user clicks on a column used for sorting to change sort order from ascending to descending or vice versa.

See also

SetSortOrder(), IsSortOrderAscending()

void wxSettableHeaderColumn::UnsetAsSortKey ( )

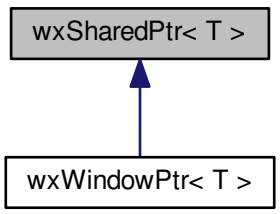
Don't use this column for sorting.

This is the reverse of SetSortOrder() and is called to indicate that this column is not used for sorting any longer.

21.677 wxSharedPtr< T > Class Template Reference

`#include <wx/sharedptr.h>`

Inheritance diagram for wxSharedPtr< T >:



21.677.1 Detailed Description

template<typename T>class wxSharedPtr< T >

A smart pointer with non-intrusive reference counting.

It is modelled after `boost::shared_ptr<>` and can be used with STL containers and wxVector<T> unlike `std::auto_ptr<>` and wxScopedPtr<T>.

Library: wxBase

Category: Smart Pointers

See also

wxScopedPtr<T>, wxWeakRef<T>, wxObjectDataPtr<T>

Public Member Functions

- wxEXPLICIT wxSharedPtr (T *ptr=NULL)

  Constructor.
- template<typename Deleter >
  wxEXPLICIT wxSharedPtr (T *ptr, Deleter d)

  Constructor.
- wxSharedPtr (const wxSharedPtr< T > &tocopy)

  Copy constructor.
- ~wxSharedPtr ()

  Destructor.
- T * get () const

  Returns pointer to its object or NULL.
- operator unspecified_bool_type () const

  Conversion to a boolean expression (in a variant which is not convertible to anything but a boolean expression).
- T operator* () const

  Returns a reference to the object.
- T * operator-> () const

  Smart pointer member access.
- wxSharedPtr< T > & operator= (T *ptr)

  Assignment operator.
- wxSharedPtr< T > & operator= (const wxSharedPtr< T > &tocopy)

  Assignment operator.
- void reset (T *ptr=NULL)

  Reset pointer to ptr.
- template<typename Deleter >
  void reset (T *ptr, Deleter d)

  Reset pointer to ptr.
- bool unique () const

  Returns true if this is the only pointer pointing to its object.
- long use_count () const

  Returns the number of pointers pointing to its object.

21.677.2 Constructor & Destructor Documentation

template<typename T > wxEXPLICIT wxSharedPtr< T >::wxSharedPtr (T * *ptr* = NULL)

Constructor.

Creates shared pointer from the raw pointer *ptr* and takes ownership of it.

template<typename T > template<typename Deleter > wxEXPLICIT wxSharedPtr< T >::wxSharedPtr (T * *ptr*, Deleter *d*)

Constructor.

Creates shared pointer from the raw pointer *ptr* and deleter *d* and takes ownership of it.

Parameters

ptr	The raw pointer.
d	Deleter - a functor that is called instead of delete to free the *ptr* raw pointer when its reference count drops to zero.

Since

3.0

template<typename T > wxSharedPtr< T >::wxSharedPtr (const wxSharedPtr< T > & *tocopy*)

Copy constructor.

template<typename T > wxSharedPtr< T >::~wxSharedPtr ( )

Destructor.

21.677.3 Member Function Documentation

template<typename T > T* wxSharedPtr< T >::get ( ) const

Returns pointer to its object or NULL.

template<typename T > wxSharedPtr< T >::operator unspecified_bool_type ( ) const

Conversion to a boolean expression (in a variant which is not convertible to anything but a boolean expression).

If this class contains a valid pointer it will return true, if it contains a NULL pointer it will return false.

template<typename T > T wxSharedPtr< T >::operator* ( ) const

Returns a reference to the object.

If the internal pointer is NULL this method will cause an assert in debug mode.

template<typename T > T* wxSharedPtr< T >::operator-> ( ) const

Smart pointer member access.

Returns pointer to its object.

If the internal pointer is NULL this method will cause an assert in debug mode.

template<typename T > wxSharedPtr<T>& wxSharedPtr< T >::operator= (T * *ptr*)

Assignment operator.

Releases any previously held pointer and creates a reference to *ptr*.

template<typename T > wxSharedPtr<T>& wxSharedPtr< T >::operator= (const wxSharedPtr< T > & *tocopy*)

Assignment operator.

Releases any previously held pointer and creates a reference to the same object as *topcopy*.

template<typename T > void wxSharedPtr< T >::reset (T * *ptr* = NULL)

Reset pointer to *ptr*.

If the reference count of the previously owned pointer was 1 it will be deleted.

template<typename T > template<typename Deleter > void wxSharedPtr< T >::reset (T * *ptr,* Deleter *d*)

Reset pointer to *ptr*.

If the reference count of the previously owned pointer was 1 it will be deleted.

Parameters

ptr	The new raw pointer.
d	Deleter - a functor that is called instead of delete to free the *ptr* raw pointer when its reference count drops to zero.

Since

3.0

template<typename T > bool wxSharedPtr< T >::unique ( ) const

Returns true if this is the only pointer pointing to its object.

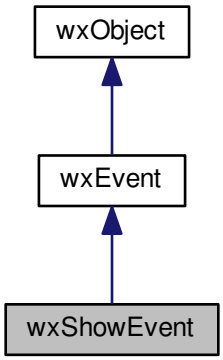
template<typename T > long wxSharedPtr< T >::use_count ( ) const

Returns the number of pointers pointing to its object.

21.678 wxShowEvent Class Reference

```
#include <wx/event.h>
```

Inheritance diagram for wxShowEvent:



21.678.1 Detailed Description

An event being sent when the window is shown or hidden.

The event is triggered by calls to wxWindow::Show(), and any user action showing a previously hidden window or vice versa (if allowed by the current platform and/or window manager). Notice that the event is not triggered when the application is iconized (minimized) or restored under wxMSW.

Availability: only available for the wxMSW, wxGTK ports.

Events using this class

The following event handler macros redirect the events to member function handlers '**func**' with prototypes like: void handlerFuncName(wxShowEvent& event)

Event macros:

- EVT_SHOW(func): Process a `wxEVT_SHOW` event.

Library: wxCore

Category: Events

See also

Events and Event Handling, wxWindow::Show, wxWindow::IsShown

Public Member Functions

- wxShowEvent (int winid=0, bool show=false)

  Constructor.
- void SetShow (bool show)

  Set whether the windows was shown or hidden.

- bool IsShown () const

  Return true if the window has been shown, false if it has been hidden.

- bool GetShow () const

Additional Inherited Members

21.678.2 Constructor & Destructor Documentation

wxShowEvent::wxShowEvent (int *winid* = `0`, bool *show* = `false`)

Constructor.

21.678.3 Member Function Documentation

bool wxShowEvent::GetShow ( ) const

Deprecated This function is deprecated in favour of IsShown().

bool wxShowEvent::IsShown ( ) const

Return true if the window has been shown, false if it has been hidden.

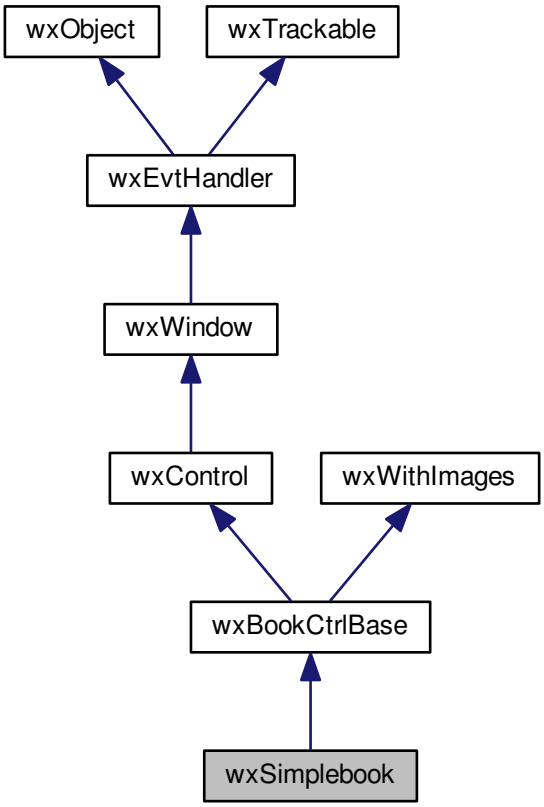
void wxShowEvent::SetShow (bool *show*)

Set whether the windows was shown or hidden.

21.679 wxSimplebook Class Reference

```
#include <wx/simplebook.h>
```

Inheritance diagram for wxSimplebook:



21.679.1 Detailed Description

wxSimplebook is a control showing exactly one of its several pages.

It implements wxBookCtrlBase class interface but doesn't allow the user to change the page being displayed, unlike all the other book control classes, only the program can do it.

This class is created in the same manner as any other wxBookCtrl but then the program will typically call ChangeSelection() to show different pages. See the Notebook Sample for an example of wxSimplebook in action.

Notice that is often convenient to use ShowNewPage() instead of the base class AddPage().

There are no special styles defined for this class as it has no visual appearance of its own.

There are also no special events, this class reuses `wxEVT_BOOKCTRL_PAGE_CHANGING` and `wxEVT_BOOKCTRL_PAGE_CHANGED` events for the events it generates if the program calls SetSelection().

Library: wxCore

Category: Book Controls

See also

wxBookCtrl, wxNotebook, Notebook Sample

Since

2.9.5

Public Member Functions

- wxSimplebook ()

  Default constructor.
- wxSimplebook (wxWindow *parent, wxWindowID id=wxID_ANY, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, long style=0, const wxString &name=wxEmptyString)

  Constructs a simple book control.
- bool Create (wxWindow *parent, wxWindowID id=wxID_ANY, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, long style=0, const wxString &name=wxEmptyString)

  Really create the window of an object created using default constructor.
- void SetEffects (wxShowEffect showEffect, wxShowEffect hideEffect)

  Set the effects to use for showing and hiding the pages.
- void SetEffect (wxShowEffect effect)

  Set the same effect to use for both showing and hiding the pages.
- void SetEffectsTimeouts (unsigned showTimeout, unsigned hideTimeout)

  Set the effect timeout to use for showing and hiding the pages.
- void SetEffectTimeout (unsigned timeout)

  Set the same effect timeout to use for both showing and hiding the pages.
- bool ShowNewPage (wxWindow *page)

  Add a new page and show it immediately.

Additional Inherited Members

21.679.2 Constructor & Destructor Documentation

wxSimplebook::wxSimplebook ( )

Default constructor.

Use Create() later to really create the control.

wxSimplebook::wxSimplebook (wxWindow * *parent*, wxWindowID *id* = wxID_ANY, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, long *style* = 0, const wxString & *name* = wxEmptyString)

Constructs a simple book control.

21.679.3 Member Function Documentation

bool wxSimplebook::Create (wxWindow * *parent*, wxWindowID *id* = wxID_ANY, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, long *style* = 0, const wxString & *name* = wxEmptyString)

Really create the window of an object created using default constructor.

Since

3.0.2

void wxSimplebook::SetEffect (wxShowEffect *effect*)

Set the same effect to use for both showing and hiding the pages.

This is the same as `SetEffects(effect, effect)`.

See also

SetEffectTimeout()

void wxSimplebook::SetEffects (wxShowEffect *showEffect*, wxShowEffect *hideEffect*)

Set the effects to use for showing and hiding the pages.

This method allows to specify the effects passed to wxWindow::ShowWithEffect() and wxWindow::HideWithEffect() respectively when the pages need to be shown or hidden.

By default, no effects are used, but as the pages are only changed by the program and not the user himself, it may be useful to use some visual effects to make the changes more noticeable.

Parameters

showEffect	The effect to use for showing the newly selected page.
hideEffect	The effect to use for hiding the previously selected page.

See also

SetEffectsTimeouts()

void wxSimplebook::SetEffectsTimeouts (unsigned *showTimeout*, unsigned *hideTimeout*)

Set the effect timeout to use for showing and hiding the pages.

This method allows to configure the timeout arguments passed to wxWindow::ShowWithEffect() and wxWindow::↩ HideWithEffect() if a non-default effect is used.

If this method is not called, default, system-dependent timeout is used.

Parameters

showTimeout	Timeout of the show effect, in milliseconds.
hideTimeout	Timeout of the hide effect, in milliseconds.

See also

SetEffects()

void wxSimplebook::SetEffectTimeout (unsigned *timeout*)

Set the same effect timeout to use for both showing and hiding the pages.

This is the same as `SetEffectsTimeouts(timeout, timeout)`.

See also

SetEffect()

bool wxSimplebook::ShowNewPage (wxWindow * *page*)

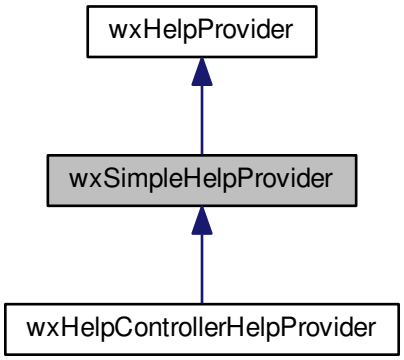
Add a new page and show it immediately.

This is simply a thin wrapper around the base class wxBookCtrlBase::AddPage() method using empty label (which is unused by this class anyhow) and selecting the new page immediately.

21.680 wxSimpleHelpProvider Class Reference

`#include <wx/cshelp.h>`

Inheritance diagram for wxSimpleHelpProvider:



21.680.1 Detailed Description

wxSimpleHelpProvider is an implementation of wxHelpProvider which supports only plain text help strings, and shows the string associated with the control (if any) in a tooltip.

Library: wxCore

Category: Help

See also

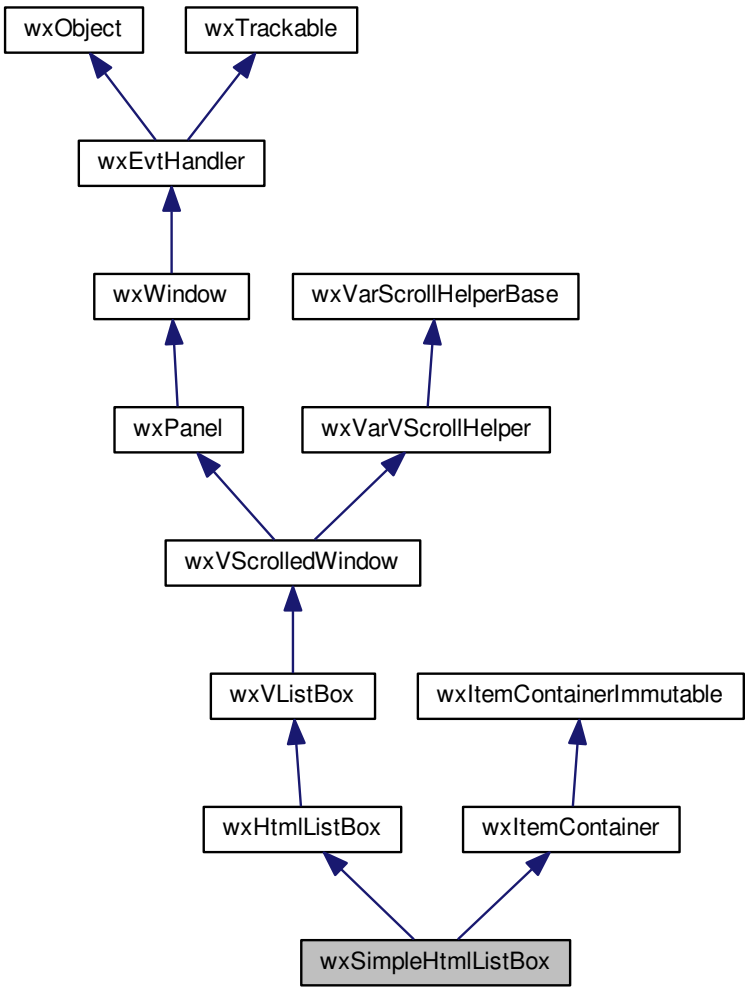
wxHelpProvider, wxHelpControllerHelpProvider, wxContextHelp, wxWindow::SetHelpText()(, wxWindow::↩ GetHelpTextAtPoint()

Additional Inherited Members

21.681 wxSimpleHtmlListBox Class Reference

`#include <wx/htmllbox.h>`

Inheritance diagram for wxSimpleHtmlListBox:



21.681.1 Detailed Description

wxSimpleHtmlListBox is an implementation of wxHtmlListBox which shows HTML content in the listbox rows.

Unlike wxHtmlListBox, this is not an abstract class and thus it has the advantage that you can use it without deriving your own class from it. However, it also has the disadvantage that this is not a virtual control and thus it's not well-suited for those cases where you need to show a huge number of items: every time you add/insert a string, it will be stored internally and thus will take memory.

The interface exposed by wxSimpleHtmlListBox fully implements the wxControlWithItems interface, thus you should refer to wxControlWithItems's documentation for the API reference for adding/removing/retrieving items in the listbox. Also note that the wxVListBox::SetItemCount function is `protected` in wxSimpleHtmlListBox's context so that you cannot call it directly, wxSimpleHtmlListBox will do it for you.

Note: in case you need to append a lot of items to the control at once, make sure to use the Append(const wx↩ ArrayString&) function.

Thus the only difference between a wxListBox and a wxSimpleHtmlListBox is that the latter stores strings which can contain HTML fragments (see the list of tags supported by wxHTML).

Note that the HTML strings you fetch to wxSimpleHtmlListBox should not contain the <html> or <body> tags.

Styles

This class supports the following styles:

- wxHLB_DEFAULT_STYLE: The default style: wxBORDER_SUNKEN
- wxHLB_MULTIPLE: Multiple-selection list: the user can toggle multiple items on and off.

A wxSimpleHtmlListBox emits the same events used by wxListBox and by wxHtmlListBox.

Events emitted by this class

Event macros for events emitted by this class:

- EVT_LISTBOX(id, func): Process a wxEVT_LISTBOX event, when an item on the list is selected. See wxCommandEvent.
- EVT_LISTBOX_DCLICK(id, func): Process a wxEVT_LISTBOX_DCLICK event, when the listbox is double-clicked. See wxCommandEvent.
- EVT_HTML_CELL_CLICKED(id, func): A wxHtmlCell was clicked. See wxHtmlCellEvent.
- EVT_HTML_CELL_HOVER(id, func): The mouse passed over a wxHtmlCell. See wxHtmlCellEvent.
- EVT_HTML_LINK_CLICKED(id, func): A wxHtmlCell which contains an hyperlink was clicked. See wxHtmlLinkEvent

Library: wxHTML

- wxSimpleHtmlListBox (wxWindow *parent, wxWindowID id, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, int n=0, const wxString choices[]=NULL, long style=wxHLB_DEFAULT_STYLE, const wxValidator &validator=wxDefaultValidator, const wxString &name=wxSimpleHtmlListBoxNameStr)

  Constructor, creating and showing the HTML list box.
- wxSimpleHtmlListBox (wxWindow *parent, wxWindowID id, const wxPoint &pos, const wxSize &size, const wxArrayString &choices, long style=wxHLB_DEFAULT_STYLE, const wxValidator &validator=wxDefaultValidator, const wxString &name=wxSimpleHtmlListBoxNameStr)

  Constructor, creating and showing the HTML list box.
- wxSimpleHtmlListBox ()

  Default constructor, you must call Create() later.
- virtual ~wxSimpleHtmlListBox ()

  Frees the array of stored items and relative client data.

- bool Create (wxWindow *parent, wxWindowID id, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, int n=0, const wxString choices[]=NULL, long style=wxHLB_DEFAULT_STYLE, const wxValidator &validator=wxDefaultValidator, const wxString &name=wxSimpleHtmlListBoxNameStr)

Creates the HTML listbox for two-step construction.

- bool Create (wxWindow *parent, wxWindowID id, const wxPoint &pos, const wxSize &size, const wxArrayString &choices, long style=wxHLB_DEFAULT_STYLE, const wxValidator &validator=wxDefaultValidator, const wxString &name=wxSimpleHtmlListBoxNameStr)

  Creates the HTML listbox for two-step construction.

Additional Inherited Members

21.681.2 Constructor & Destructor Documentation

wxSimpleHtmlListBox::wxSimpleHtmlListBox (wxWindow * *parent*, wxWindowID *id*, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, int *n* = 0, const wxString *choices[]* = NULL, long *style* = wxHLB_DEFAULT_STYLE, const wxValidator & *validator* = wxDefaultValidator, const wxString & *name* = wxSimpleHtmlListBoxNameStr)

Constructor, creating and showing the HTML list box.

Parameters

parent	Parent window. Must not be NULL.
id	Window identifier. A value of -1 indicates a default value.
pos	Window position. If wxDefaultPosition is specified then a default position is chosen.
size	Window size. If wxDefaultSize is specified then the window is sized appropriately.
n	Number of strings with which to initialise the control.
choices	An array of strings with which to initialise the control.
style	Window style. See wxHLB_* flags.
validator	Window validator.
name	Window name.

wxSimpleHtmlListBox::wxSimpleHtmlListBox (wxWindow * *parent*, wxWindowID *id*, const wxPoint & *pos*, const wxSize & *size*, const wxArrayString & *choices*, long *style* = wxHLB_DEFAULT_STYLE, const wxValidator & *validator* = wxDefaultValidator, const wxString & *name* = wxSimpleHtmlListBoxNameStr)

Constructor, creating and showing the HTML list box.

Parameters

parent	Parent window. Must not be NULL.
id	Window identifier. A value of -1 indicates a default value.
pos	Window position.
size	Window size. If wxDefaultSize is specified then the window is sized appropriately.
choices	An array of strings with which to initialise the control.
style	Window style. See wxHLB_* flags.
validator	Window validator.
name	Window name.

wxSimpleHtmlListBox::wxSimpleHtmlListBox ( )

Default constructor, you must call Create() later.

virtual wxSimpleHtmlListBox::~wxSimpleHtmlListBox ( ) [virtual]

Frees the array of stored items and relative client data.

21.681.3 Member Function Documentation

bool wxSimpleHtmlListBox::Create (wxWindow * *parent*, wxWindowID *id*, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, int *n* = 0, const wxString *choices[]* = NULL, long *style* = wxHLB_DEFAULT_STYLE, const wxValidator & *validator* = wxDefaultValidator, const wxString & *name* = wxSimpleHtmlListBoxNameStr)

Creates the HTML listbox for two-step construction.

See wxSimpleHtmlListBox() for further details.

bool wxSimpleHtmlListBox::Create (wxWindow * *parent*, wxWindowID *id*, const wxPoint & *pos*, const wxSize & *size*, const wxArrayString & *choices*, long *style* = wxHLB_DEFAULT_STYLE, const wxValidator & *validator* = wxDefaultValidator, const wxString & *name* = wxSimpleHtmlListBoxNameStr)

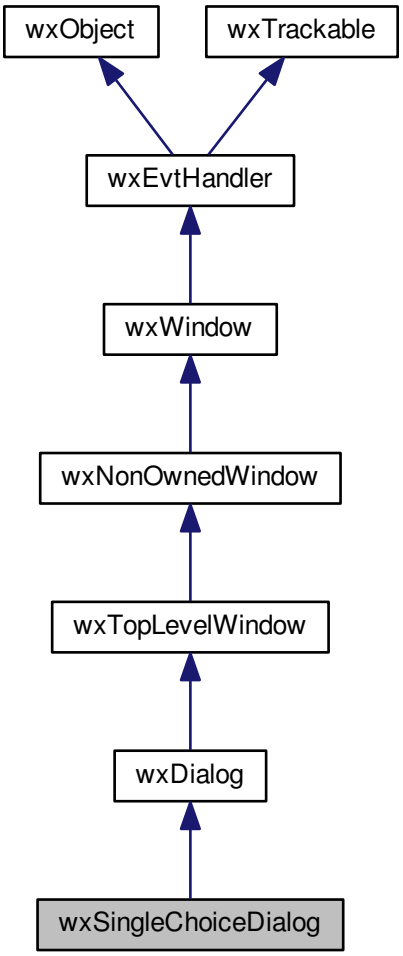
Creates the HTML listbox for two-step construction.

See wxSimpleHtmlListBox() for further details.

21.682 wxSingleChoiceDialog Class Reference

```
#include <wx/choicdlg.h>
```

Inheritance diagram for wxSingleChoiceDialog:



21.682.1 Detailed Description

This class represents a dialog that shows a list of strings, and allows the user to select one.

Double-clicking on a list item is equivalent to single-clicking and then pressing OK.

Styles

This class supports the following styles:

- wxOK: Show an OK button.
- wxCANCEL: Show a Cancel button.
- wxCENTRE: Centre the message. Not Windows.

Library: wxBase

Category: Common Dialogs

See also

wxSingleChoiceDialog Overview, wxMultiChoiceDialog

Public Member Functions

- int GetSelection () const

  Returns the index of selected item.
- void * GetSelectionData () const

  Returns the client data associated with the selection.
- wxString GetStringSelection () const

  Returns the selected string.
- void SetSelection (int selection)

  Sets the index of the initially selected item.
- int ShowModal ()

  Shows the dialog, returning either wxID_OK or wxID_CANCEL.

- wxSingleChoiceDialog (wxWindow *parent, const wxString &message, const wxString &caption, int n, const wxString *choices, void **clientData=NULL, long style=wxCHOICEDLG_STYLE, const wxPoint &pos=wxDefaultPosition)

  Constructor, taking an array of wxString choices and optional client data.
- wxSingleChoiceDialog (wxWindow *parent, const wxString &message, const wxString &caption, const wxArrayString &choices, void **clientData=NULL, long style=wxCHOICEDLG_STYLE, const wxPoint &pos=wxDefaultPosition)

  Constructor, taking an array of wxString choices and optional client data.

Additional Inherited Members

21.682.2 Constructor & Destructor Documentation

wxSingleChoiceDialog::wxSingleChoiceDialog (wxWindow * *parent,* const wxString & *message,* const wxString & *caption,* int *n,* const wxString * *choices,* void ** *clientData* = NULL, long *style* = wxCHOICEDLG_STYLE, const wxPoint & *pos* = wxDefaultPosition)

Constructor, taking an array of wxString choices and optional client data.

Parameters

parent	Parent window.
message	Message to show on the dialog.
caption	The dialog caption.
n	The number of choices.
choices	An array of strings, or a string list, containing the choices.
clientData	An array of client data to be associated with the items. See GetSelectionData().

style	A dialog style (bitlist) containing flags chosen from standard dialog styles and the ones listed in the class documentation. The default value is equivalent to wxDEFAULT_DIALOG_STYLE | wxRESIZE_BORDER | wxOK | wxCANCEL | wxCENTRE.
pos	Dialog position. Not Windows.

Remarks

Use ShowModal() to show the dialog.

wxPerl Note: Not supported by wxPerl.

wxSingleChoiceDialog::wxSingleChoiceDialog (wxWindow * *parent*, const wxString & *message*, const wxString & *caption*, const wxArrayString & *choices*, void ** *clientData* = NULL, long *style* = wxCHOICEDLG_STYLE, const wxPoint & *pos* = wxDefaultPosition)

Constructor, taking an array of wxString choices and optional client data.

Parameters

parent	Parent window.
message	Message to show on the dialog.
caption	The dialog caption.
choices	An array of strings, or a string list, containing the choices.
clientData	An array of client data to be associated with the items. See GetSelectionData().
style	A dialog style (bitlist) containing flags chosen from standard dialog styles and the ones listed in the class documentation. The default value is equivalent to wxDEFAULT_DIALOG_STYLE | wxRESIZE_BORDER | wxOK | wxCANCEL | wxCENTRE.
pos	Dialog position. Not Windows.

Remarks

Use ShowModal() to show the dialog.

wxPerl Note: Use an array reference for the *choices* parameter.

21.682.3 Member Function Documentation

int wxSingleChoiceDialog::GetSelection ( ) const

Returns the index of selected item.

void* wxSingleChoiceDialog::GetSelectionData ( ) const

Returns the client data associated with the selection.

Since

2.9.4

wxString wxSingleChoiceDialog::GetStringSelection ( ) const

Returns the selected string.

void wxSingleChoiceDialog::SetSelection (int *selection*)

Sets the index of the initially selected item.

int wxSingleChoiceDialog::ShowModal ( ) [virtual]

Shows the dialog, returning either wxID_OK or wxID_CANCEL.

Reimplemented from wxDialog.

21.683 wxSingleInstanceChecker Class Reference

`#include <wx/snglinst.h>`

21.683.1 Detailed Description

wxSingleInstanceChecker class allows to check that only a single instance of a program is running.

To do it, you should create an object of this class. As long as this object is alive, calls to wxSingleInstanceChecker::IsAnotherRunning from other processes will return true.

As the object should have the life span as big as possible, it makes sense to create it either as a global or in wxApp::OnInit. For example:

```
bool MyApp::OnInit()
{
    m_checker = new wxSingleInstanceChecker;
    if ( m_checker->IsAnotherRunning() )
    {
        wxLogError(_("Another program instance is already running, aborting."));

        delete m_checker; // OnExit() won't be called if we return false
        m_checker = NULL;

        return false;
    }

    ... more initializations ...

    return true;
}

int MyApp::OnExit()
{
    delete m_checker;

    return 0;
}
```

Note that by default wxSingleInstanceChecker::CreateDefault() is used to create the checker meaning that it will be initialized differently for different users and thus will allow different users to run the application concurrently which is usually the required behaviour. However if only a single instance of a program should be running system-wide, you need to call Create() with a custom name which does *not* include wxGetUserId().

This class is implemented for Win32 and Unix platforms (supporting `fcntl()` system call, but almost all of modern Unix systems do) only.

Library: wxBase

Category: Application and Process Management

Public Member Functions

- wxSingleInstanceChecker ()

  Default constructor.
- wxSingleInstanceChecker (const wxString &name, const wxString &path=wxEmptyString)

Constructor calling Create().

- ~wxSingleInstanceChecker ()

  Destructor frees the associated resources.

- bool Create (const wxString &name, const wxString &path=wxEmptyString)

  Initialize the object if it had been created using the default constructor.

- bool CreateDefault ()

  Calls Create() with default name.

- bool IsAnotherRunning () const

  Returns true if another copy of this program is already running and false otherwise.

21.683.2 Constructor & Destructor Documentation

wxSingleInstanceChecker::wxSingleInstanceChecker ( )

Default constructor.

You may call Create() after using it or directly call IsAnotherRunning() in which case CreateDefault() will be implicitly used.

wxSingleInstanceChecker::wxSingleInstanceChecker (const wxString & *name*, const wxString & *path* = wxEmptyString)

Constructor calling Create().

This constructor does exactly the same thing as Create() but doesn't allow to check for errors.

wxSingleInstanceChecker::~wxSingleInstanceChecker ( )

Destructor frees the associated resources.

Note that it is not virtual, this class is not meant to be used polymorphically.

21.683.3 Member Function Documentation

bool wxSingleInstanceChecker::Create (const wxString & *name*, const wxString & *path* = wxEmptyString)

Initialize the object if it had been created using the default constructor.

Note that you can't call Create() more than once, so calling it if the non default ctor had been used is an error.

Parameters

name	Must be given and be as unique as possible. It is used as the mutex name under Win32 and the lock file name under Unix. wxApp::GetAppName() and wxGetUserId() are commonly used to construct this parameter.
path	The path is optional and is ignored under Win32 and used as the directory to create the lock file in under Unix (default is wxGetHomeDir()).

Returns

Returns false if initialization failed, it doesn't mean that another instance is running – use IsAnotherRunning() to check for it.

Note

One of possible reasons while Create() may fail on Unix is that the lock file used for checking already exists but was not created by the user. Therefore applications shouldn't treat failure of this function as fatal condition, because doing so would open them to the possibility of a Denial of Service attack. Instead, they should alert the user about the problem and offer to continue execution without checking if another instance is running.

bool wxSingleInstanceChecker::CreateDefault ( )

Calls Create() with default name.

This method simply calls Create() with a string composed of wxApp::GetAppName() and wxGetUserId().

Because this method uses wxApp::GetAppName(), it may only be called after the global application was constructed.

Since

2.9.1

bool wxSingleInstanceChecker::IsAnotherRunning ( ) const

Returns true if another copy of this program is already running and false otherwise.

Notice that if the object was created using the default constructor Create() hadn't been called before this method, it will call CreateDefault() automatically.

21.684 wxSize Class Reference

```
#include <wx/gdicmn.h>
```

21.684.1 Detailed Description

A wxSize is a useful data structure for graphics operations.

It simply contains integer *width* and *height* members.

Note that the width and height stored inside a wxSize object may be negative and that wxSize functions do not perform any check against negative values (this is used to e.g. store the special -1 value in wxDefaultSize instance). See also IsFullySpecified() and SetDefaults() for utility functions regarding the special -1 value.

wxSize is used throughout wxWidgets as well as wxPoint which, although almost equivalent to wxSize, has a different meaning: wxPoint represents a position while wxSize represents the size.

Library: wxCore

Category: Data Structures

Predefined objects/pointers: wxDefaultSize

See also

wxPoint, wxRealPoint

Public Member Functions

- wxSize ()

  Initializes this size object with zero width and height.
- wxSize (int width, int height)

  Initializes this size object with the given width and height.
- void DecTo (const wxSize &size)

  Decrements this object so that both of its dimensions are not greater than the corresponding dimensions of the size.
- void DecToIfSpecified (const wxSize &size)

  Decrements this object to be not bigger than the given size ignoring non-specified components.
- int GetHeight () const

  Gets the height member.
- int GetWidth () const

  Gets the width member.
- void IncTo (const wxSize &size)

  Increments this object so that both of its dimensions are not less than the corresponding dimensions of the size.
- bool IsFullySpecified () const

  Returns true if neither of the size object components is equal to -1, which is used as default for the size values in wxWidgets (hence the predefined wxDefaultSize has both of its components equal to -1).
- wxSize & Scale (float xscale, float yscale)

  Scales the dimensions of this object by the given factors.
- void Set (int width, int height)

  Sets the width and height members.
- void SetDefaults (const wxSize &sizeDefault)

  Combine this size object with another one replacing the default (i.e. equal to -1) components of this object with those of the other.
- void SetHeight (int height)

  Sets the height.
- void SetWidth (int width)

  Sets the width.

- void DecBy (const wxPoint &pt)

  Decreases the size in both x and y directions.
- void DecBy (const wxSize &size)

  Decreases the size in both x and y directions.
- void DecBy (int dx, int dy)

  Decreases the size in both x and y directions.
- void DecBy (int d)

  Decreases the size in both x and y directions.

- void IncBy (const wxPoint &pt)

  Increases the size in both x and y directions.
- void IncBy (const wxSize &size)

  Increases the size in both x and y directions.
- void IncBy (int dx, int dy)

  Increases the size in both x and y directions.
- void IncBy (int d)

  Increases the size in both x and y directions.

Miscellaneous operators

Note that these operators are documented as class members (to make them easier to find) but, as their prototype shows, they are implemented as global operators; note that this is transparent to the user but it helps to understand why the following functions are documented to take the wxSize they operate on as an explicit argument.

- wxSize & operator= (const wxSize &sz)
- bool operator== (const wxSize &s1, const wxSize &s2)
- bool operator!= (const wxSize &s1, const wxSize &s2)
- wxSize operator+ (const wxSize &s1, const wxSize &s2)
- wxSize operator- (const wxSize &s1, const wxSize &s2)
- wxSize & operator+= (const wxSize &sz)
- wxSize & operator-= (const wxSize &sz)
- wxSize operator/ (const wxSize &sz, int factor)
- wxSize operator* (const wxSize &sz, int factor)
- wxSize operator* (int factor, const wxSize &sz)
- wxSize & operator/= (int factor)
- wxSize & operator*= (int factor)

21.684.2 Constructor & Destructor Documentation

wxSize::wxSize ( )

Initializes this size object with zero width and height.

wxSize::wxSize (int *width*, int *height*)

Initializes this size object with the given *width* and *height*.

21.684.3 Member Function Documentation

void wxSize::DecBy (const wxPoint & *pt*)

Decreases the size in both x and y directions.

See also

IncBy()

void wxSize::DecBy (const wxSize & *size*)

Decreases the size in both x and y directions.

See also

IncBy()

void wxSize::DecBy (int *dx*, int *dy*)

Decreases the size in both x and y directions.

See also

IncBy()

void wxSize::DecBy (int *d*)

Decreases the size in both x and y directions.

See also

IncBy()

void wxSize::DecTo (const wxSize & *size*)

Decrements this object so that both of its dimensions are not greater than the corresponding dimensions of the *size*.

See also

IncTo()

void wxSize::DecToIfSpecified (const wxSize & *size*)

Decrements this object to be not bigger than the given size ignoring non-specified components.

This is similar to DecTo() but doesn't do anything for x or y component if the same component of *size* is not specified, i.e. set to wxDefaultCoord.

Since

2.9.5

int wxSize::GetHeight ( ) const

Gets the height member.

int wxSize::GetWidth ( ) const

Gets the width member.

void wxSize::IncBy (const wxPoint & *pt*)

Increases the size in both x and y directions.

See also

DecBy()

void wxSize::IncBy (const wxSize & *size*)

Increases the size in both x and y directions.

See also

DecBy()

void wxSize::IncBy (int *dx,* int *dy*)

Increases the size in both x and y directions.

See also

DecBy()

void wxSize::IncBy (int *d*)

Increases the size in both x and y directions.

See also

DecBy()

void wxSize::IncTo (const wxSize & *size*)

Increments this object so that both of its dimensions are not less than the corresponding dimensions of the *size*.

See also

DecTo()

bool wxSize::IsFullySpecified ( ) const

Returns true if neither of the size object components is equal to -1, which is used as default for the size values in wxWidgets (hence the predefined wxDefaultSize has both of its components equal to -1).

This method is typically used before calling SetDefaults().

bool wxSize::operator!= (const wxSize & *s1,* const wxSize & *s2*)

wxSize wxSize::operator∗ (const wxSize & *sz,* int *factor*)

wxSize wxSize::operator∗ (int *factor,* const wxSize & *sz*)

wxSize& wxSize::operator∗= (int *factor*)

wxSize wxSize::operator+ (const wxSize & *s1,* const wxSize & *s2*)

wxSize& wxSize::operator+= (const wxSize & *sz*)

wxSize wxSize::operator- (const wxSize & *s1,* const wxSize & *s2*)

wxSize& wxSize::operator-= (const wxSize & *sz*)

wxSize wxSize::operator/ (const wxSize & *sz,* int *factor*)

wxSize& wxSize::operator/= (int *factor*)

wxSize& wxSize::operator= (const wxSize & *sz*)

bool wxSize::operator== (const wxSize & *s1,* const wxSize & *s2*)

wxSize& wxSize::Scale (float *xscale,* float *yscale*)

Scales the dimensions of this object by the given factors.

If you want to scale both dimensions by the same factor you can also use operator*=().

Returns

A reference to this object (so that you can concatenate other operations in the same line).

void wxSize::Set (int *width,* int *height*)

Sets the width and height members.

void wxSize::SetDefaults (const wxSize & *sizeDefault*)

Combine this size object with another one replacing the default (i.e. equal to -1) components of this object with those of the other.

It is typically used like this:

```
if ( !size.IsFullySpecified() )
{
    size.SetDefaults(GetDefaultSize());
}
```

See also

IsFullySpecified()

void wxSize::SetHeight (int *height*)

Sets the height.

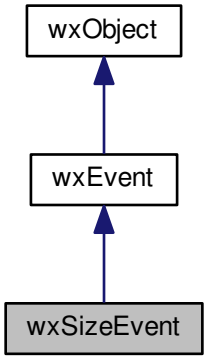
void wxSize::SetWidth (int *width*)

Sets the width.

21.685 wxSizeEvent Class Reference

`#include <wx/event.h>`

Inheritance diagram for wxSizeEvent:



21.685.1 Detailed Description

A size event holds information about size change events of wxWindow.

The EVT_SIZE handler function will be called when the window has been resized.

You may wish to use this for frames to resize their child windows as appropriate.

Note that the size passed is of the whole window: call wxWindow::GetClientSize() for the area which may be used by the application.

When a window is resized, usually only a small part of the window is damaged and you may only need to repaint that area. However, if your drawing depends on the size of the window, you may need to clear the DC explicitly and repaint the whole window. In which case, you may need to call wxWindow::Refresh to invalidate the entire window.

Important : Sizers (see Sizers Overview) rely on size events to function correctly. Therefore, in a sizer-based layout, do not forget to call Skip on all size events you catch (and don't catch size events at all when you don't need to).

Events using this class

The following event handler macros redirect the events to member function handlers '**func**' with prototypes like: void handlerFuncName(wxSizeEvent& event)

Event macros:

- EVT_SIZE(func): Process a `wxEVT_SIZE` event.

Library: wxCore

Category: Events

See also

wxSize, Events and Event Handling

Public Member Functions

- wxSizeEvent (const wxSize &sz, int id=0)

  Constructor.

- wxSize GetSize () const

  Returns the entire size of the window generating the size change event.

- void SetSize (wxSize size)
- wxRect GetRect () const
- void SetRect (wxRect rect)

Additional Inherited Members

21.685.2 Constructor & Destructor Documentation

wxSizeEvent::wxSizeEvent (const wxSize & *sz*, int *id* = 0)

Constructor.

21.685.3 Member Function Documentation

wxRect wxSizeEvent::GetRect ( ) const

wxSize wxSizeEvent::GetSize ( ) const

Returns the entire size of the window generating the size change event.

This is the new total size of the window, i.e. the same size as would be returned by wxWindow::GetSize() if it were called now. Use wxWindow::GetClientSize() if you catch this event in a top level window such as wxFrame to find the size available for the window contents.

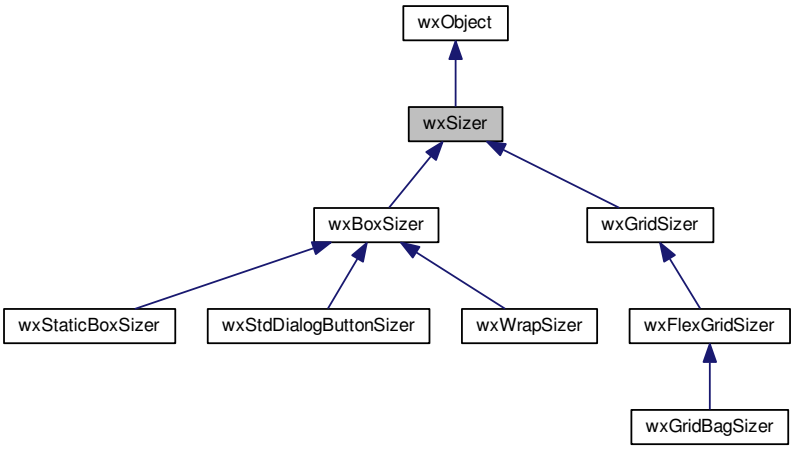
void wxSizeEvent::SetRect (wxRect *rect*)

void wxSizeEvent::SetSize (wxSize *size*)

21.686 wxSizer Class Reference

`#include <wx/sizer.h>`

Inheritance diagram for wxSizer:



21.686.1 Detailed Description

wxSizer is the abstract base class used for laying out subwindows in a window.

You cannot use wxSizer directly; instead, you will have to use one of the sizer classes derived from it. Currently there are wxBoxSizer, wxStaticBoxSizer, wxGridSizer, wxFlexGridSizer, wxWrapSizer and wxGridBagSizer.

The layout algorithm used by sizers in wxWidgets is closely related to layout in other GUI toolkits, such as Java's AWT, the GTK toolkit or the Qt toolkit. It is based upon the idea of the individual subwindows reporting their minimal required size and their ability to get stretched if the size of the parent window has changed.

This will most often mean that the programmer does not set the original size of a dialog in the beginning, rather the dialog will be assigned a sizer and this sizer will be queried about the recommended size. The sizer in turn will query its children, which can be normal windows, empty space or other sizers, so that a hierarchy of sizers can be constructed. Note that wxSizer does not derive from wxWindow and thus does not interfere with tab ordering and requires very little resources compared to a real window on screen.

What makes sizers so well fitted for use in wxWidgets is the fact that every control reports its own minimal size and the algorithm can handle differences in font sizes or different window (dialog item) sizes on different platforms without problems. If e.g. the standard font as well as the overall design of Motif widgets requires more space than on Windows, the initial dialog size will automatically be bigger on Motif than on Windows.

Sizers may also be used to control the layout of custom drawn items on the window. The wxSizer::Add(), wxSizer::Insert(), and wxSizer::Prepend() functions return a pointer to the newly added wxSizerItem. Just add empty space of the desired size and attributes, and then use the wxSizerItem::GetRect() method to determine where the drawing operations should take place.

Please notice that sizers, like child windows, are owned by the library and will be deleted by it which implies that they must be allocated on the heap. However if you create a sizer and do not add it to another sizer or window, the library wouldn't be able to delete such an orphan sizer and in this, and only this, case it should be deleted explicitly.

21.686.2 wxSizer flags

The "flag" argument accepted by wxSizeItem constructors and other functions, e.g. wxSizer::Add(), is OR-combination of the following flags. Two main behaviours are defined using these flags. One is the border around a window: the border parameter determines the border width whereas the flags given here determine which side(s) of the item that the border will be added. The other flags determine how the sizer item behaves when the space

allotted to the sizer changes, and is somewhat dependent on the specific kind of sizer used.

wxTOP wxBOTTOM wxLEFT wxRIGHT wxALL	These flags are used to specify which side(s) of the sizer item the border width will apply to.
wxEXPAND	The item will be expanded to fill the space assigned to the item.
wxSHAPED	The item will be expanded as much as possible while also maintaining its aspect ratio.
wxFIXED_MINSIZE	Normally wxSizers will use GetAdjustedBestSize() to determine what the minimal size of window items should be, and will use that size to calculate the layout. This allows layouts to adjust when an item changes and its best size becomes different. If you would rather have a window item stay the size it started with then use `wxFIXED_MINSIZE`.
wxRESERVE_SPACE_EVEN_IF_HIDDEN	Normally wxSizers don't allocate space for hidden windows or other items. This flag overrides this behaviour so that sufficient space is allocated for the window even if it isn't visible. This makes it possible to dynamically show and hide controls without resizing parent dialog, for example. (Available since 2.8.8.)
wxALIGN_CENTER wxALIGN_CENTRE wxALIGN_LEFT wxALIGN_RIGHT wxALIGN_TOP wxALIGN_BOTTOM wxALIGN_CENTER_VERTICAL wxALIGN_CENTRE_VERTICAL wxALIGN_CENTER_HORIZONTAL wxALIGN_CENTRE_HORIZONTAL	The `wxALIGN_*` flags allow you to specify the alignment of the item within the space allotted to it by the sizer, adjusted for the border if any.

Library: wxCore

Category: Window Layout

Sizers Overview

Public Member Functions

- wxSizer ()

  The constructor.
- virtual ~wxSizer ()

  The destructor.
- wxSizerItem * Add (wxWindow *window, const wxSizerFlags &flags)

  Appends a child to the sizer.
- wxSizerItem * Add (wxWindow *window, int proportion=0, int flag=0, int border=0, wxObject *userData=NULL)

  Appends a child to the sizer.
- wxSizerItem * Add (wxSizer *sizer, const wxSizerFlags &flags)

  Appends a child to the sizer.
- wxSizerItem * Add (wxSizer *sizer, int proportion=0, int flag=0, int border=0, wxObject *userData=NULL)

Appends a child to the sizer.

- wxSizerItem * Add (int width, int height, int proportion=0, int flag=0, int border=0, wxObject *userData=NULL)

  Appends a spacer child to the sizer.
- wxSizerItem * Add (int width, int height, const wxSizerFlags &flags)

  Appends a spacer child to the sizer.
- wxSizerItem * Add (wxSizerItem *item)
- virtual wxSizerItem * AddSpacer (int size)

  This base function adds non-stretchable space to both the horizontal and vertical orientation of the sizer.
- wxSizerItem * AddStretchSpacer (int prop=1)

  Adds stretchable space to the sizer.
- virtual wxSize CalcMin ()=0

  This method is abstract and has to be overwritten by any derived class.
- virtual void Clear (bool delete_windows=false)

  Detaches all children from the sizer.
- wxSize ComputeFittingClientSize (wxWindow *window)

  Computes client area size for window so that it matches the sizer's minimal size.
- wxSize ComputeFittingWindowSize (wxWindow *window)

  Like ComputeFittingClientSize(), but converts the result into window size.
- virtual bool Detach (wxWindow *window)

  Detach the child window from the sizer without destroying it.
- virtual bool Detach (wxSizer *sizer)

  Detach the child sizer from the sizer without destroying it.
- virtual bool Detach (int index)

  Detach a item at position index from the sizer without destroying it.
- wxSize Fit (wxWindow *window)

  Tell the sizer to resize the window so that its client area matches the sizer's minimal size (ComputeFittingClientSize() is called to determine it).
- void FitInside (wxWindow *window)

  Tell the sizer to resize the virtual size of the window to match the sizer's minimal size.
- virtual bool InformFirstDirection (int direction, int size, int availableOtherDir)

  Inform sizer about the first direction that has been decided (by parent item).
- wxWindow * GetContainingWindow () const

  Returns the window this sizer is used in or NULL if none.
- void SetContainingWindow (wxWindow *window)

  Set the window this sizer is used in.
- size_t GetItemCount () const

  Returns the number of items in the sizer.
- wxSizerItem * GetItem (wxWindow *window, bool recursive=false)

  Finds wxSizerItem which holds the given window.
- wxSizerItem * GetItem (wxSizer *sizer, bool recursive=false)

  Finds wxSizerItem which holds the given sizer.
- wxSizerItem * GetItem (size_t index)

  Finds wxSizerItem which is located in the sizer at position index.
- wxSizerItem * GetItemById (int id, bool recursive=false)

  Finds item of the sizer which has the given id.
- wxSize GetMinSize ()

  Returns the minimal size of the sizer.
- wxPoint GetPosition () const

  Returns the current position of the sizer.
- wxSize GetSize () const

  Returns the current size of the sizer.

- bool Hide (wxWindow *window, bool recursive=false)

  Hides the child window.
- bool Hide (wxSizer *sizer, bool recursive=false)

  Hides the child sizer.
- bool Hide (size_t index)

  Hides the item at position index.
- wxSizerItem * Insert (size_t index, wxWindow *window, const wxSizerFlags &flags)

  Insert a child into the sizer before any existing item at index.
- wxSizerItem * Insert (size_t index, wxWindow *window, int proportion=0, int flag=0, int border=0, wxObject *userData=NULL)

  Insert a child into the sizer before any existing item at index.
- wxSizerItem * Insert (size_t index, wxSizer *sizer, const wxSizerFlags &flags)

  Insert a child into the sizer before any existing item at index.
- wxSizerItem * Insert (size_t index, wxSizer *sizer, int proportion=0, int flag=0, int border=0, wxObject *user↩ Data=NULL)

  Insert a child into the sizer before any existing item at index.
- wxSizerItem * Insert (size_t index, int width, int height, int proportion=0, int flag=0, int border=0, wxObject *userData=NULL)

  Insert a child into the sizer before any existing item at index.
- wxSizerItem * Insert (size_t index, int width, int height, const wxSizerFlags &flags)

  Insert a child into the sizer before any existing item at index.
- wxSizerItem * Insert (size_t index, wxSizerItem *item)
- wxSizerItem * InsertSpacer (size_t index, int size)

  Inserts non-stretchable space to the sizer.
- wxSizerItem * InsertStretchSpacer (size_t index, int prop=1)

  Inserts stretchable space to the sizer.
- bool IsEmpty () const

  Return true if the sizer has no elements.
- bool IsShown (wxWindow *window) const

  Returns true if the window is shown.
- bool IsShown (wxSizer *sizer) const

  Returns true if the sizer is shown.
- bool IsShown (size_t index) const

  Returns true if the item at index is shown.
- virtual void Layout ()

  Call this to force layout of the children anew, e.g. after having added a child to or removed a child (window, other sizer or space) from the sizer while keeping the current dimension.
- wxSizerItem * Prepend (wxWindow *window, const wxSizerFlags &flags)

  Same as Add(), but prepends the items to the beginning of the list of items (windows, subsizers or spaces) owned by this sizer.
- wxSizerItem * Prepend (wxWindow *window, int proportion=0, int flag=0, int border=0, wxObject *user↩ Data=NULL)

  Same as Add(), but prepends the items to the beginning of the list of items (windows, subsizers or spaces) owned by this sizer.
- wxSizerItem * Prepend (wxSizer *sizer, const wxSizerFlags &flags)

  Same as Add(), but prepends the items to the beginning of the list of items (windows, subsizers or spaces) owned by this sizer.
- wxSizerItem * Prepend (wxSizer *sizer, int proportion=0, int flag=0, int border=0, wxObject *userData=NULL)

  Same as Add(), but prepends the items to the beginning of the list of items (windows, subsizers or spaces) owned by this sizer.
- wxSizerItem * Prepend (int width, int height, int proportion=0, int flag=0, int border=0, wxObject *user↩ Data=NULL)

Same as Add(), but prepends the items to the beginning of the list of items (windows, subsizers or spaces) owned by this sizer.

- wxSizerItem * Prepend (int width, int height, const wxSizerFlags &flags)

  Same as Add(), but prepends the items to the beginning of the list of items (windows, subsizers or spaces) owned by this sizer.
- wxSizerItem * Prepend (wxSizerItem *item)
- wxSizerItem * PrependSpacer (int size)

  Prepends non-stretchable space to the sizer.
- wxSizerItem * PrependStretchSpacer (int prop=1)

  Prepends stretchable space to the sizer.
- virtual void RecalcSizes ()=0

  This method is abstract and has to be overwritten by any derived class.
- virtual bool Remove (wxWindow *window)

  *Removes a child window from the sizer, but does **not** destroy it (because windows are owned by their parent window, not the sizer).*
- virtual bool Remove (wxSizer *sizer)

  Removes a sizer child from the sizer and destroys it.
- virtual bool Remove (int index)

  Removes a child from the sizer and destroys it if it is a sizer or a spacer, but not if it is a window (because windows are owned by their parent window, not the sizer).
- virtual bool Replace (wxWindow *oldwin, wxWindow *newwin, bool recursive=false)

  Detaches the given oldwin from the sizer and replaces it with the given newwin.
- virtual bool Replace (wxSizer *oldsz, wxSizer *newsz, bool recursive=false)

  Detaches the given oldsz from the sizer and replaces it with the given newsz.
- virtual bool Replace (size_t index, wxSizerItem *newitem)

  Detaches the given item at position index from the sizer and replaces it with the given wxSizerItem newitem.
- void SetDimension (int x, int y, int width, int height)

  Call this to force the sizer to take the given dimension and thus force the items owned by the sizer to resize themselves according to the rules defined by the parameter in the Add() and Prepend() methods.
- void SetDimension (const wxPoint &pos, const wxSize &size)

  This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.
- void SetMinSize (const wxSize &size)

  Call this to give the sizer a minimal size.
- void SetMinSize (int width, int height)

  This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.
- void SetSizeHints (wxWindow *window)

  This method first calls Fit() and then wxTopLevelWindow::SetSizeHints() on the window passed to it.
- void SetVirtualSizeHints (wxWindow *window)

  Tell the sizer to set the minimal size of the window virtual area to match the sizer's minimal size.
- bool Show (wxWindow *window, bool show=true, bool recursive=false)

  Shows or hides the window.
- bool Show (wxSizer *sizer, bool show=true, bool recursive=false)

  Shows or hides sizer.
- bool Show (size_t index, bool show=true)

  Shows the item at index.
- virtual void ShowItems (bool show)

  Show or hide all items managed by the sizer.

- wxSizerItemList & GetChildren ()

  Returns the list of the items in this sizer.

- const wxSizerItemList & GetChildren () const

  Returns the list of the items in this sizer.

- bool SetItemMinSize (wxWindow *window, int width, int height)

  Set an item's minimum size by window, sizer, or position.
- bool SetItemMinSize (wxWindow *window, const wxSize &size)

  Set an item's minimum size by window, sizer, or position.
- bool SetItemMinSize (wxSizer *sizer, int width, int height)

  Set an item's minimum size by window, sizer, or position.
- bool SetItemMinSize (wxSizer *sizer, const wxSize &size)

  Set an item's minimum size by window, sizer, or position.
- bool SetItemMinSize (size_t index, int width, int height)

  Set an item's minimum size by window, sizer, or position.
- bool SetItemMinSize (size_t index, const wxSize &size)

  Set an item's minimum size by window, sizer, or position.

Additional Inherited Members

21.686.3 Constructor & Destructor Documentation

wxSizer::wxSizer ( )

The constructor.

Note that wxSizer is an abstract base class and may not be instantiated.

virtual wxSizer::~wxSizer ( ) [virtual]

The destructor.

21.686.4 Member Function Documentation

wxSizerItem* wxSizer::Add (wxWindow * *window,* const wxSizerFlags & *flags*)

Appends a child to the sizer.

wxSizer itself is an abstract class, but the parameters are equivalent in the derived classes that you will instantiate to use it so they are described here:

Parameters

window	The window to be added to the sizer. Its initial size (either set explicitly by the user or calculated internally when using wxDefaultSize) is interpreted as the minimal and in many cases also the initial size.
flags	A wxSizerFlags object that enables you to specify most of the above parameters more conveniently.

wxSizerItem* wxSizer::Add (wxWindow * *window,* int *proportion* = 0, int *flag* = 0, int *border* = 0, wxObject * *userData* = NULL)

Appends a child to the sizer.

wxSizer itself is an abstract class, but the parameters are equivalent in the derived classes that you will instantiate to use it so they are described here:

Parameters

window	The window to be added to the sizer. Its initial size (either set explicitly by the user or calculated internally when using wxDefaultSize) is interpreted as the minimal and in many cases also the initial size.
proportion	Although the meaning of this parameter is undefined in wxSizer, it is used in wxBoxSizer to indicate if a child of a sizer can change its size in the main orientation of the wxBoxSizer - where 0 stands for not changeable and a value of more than zero is interpreted relative to the value of other children of the same wxBoxSizer. For example, you might have a horizontal wxBoxSizer with three children, two of which are supposed to change their size with the sizer. Then the two stretchable windows would get a value of 1 each to make them grow and shrink equally with the sizer's horizontal dimension.
flag	OR-combination of flags affecting sizer's behaviour. See wxSizer flags list for details.
border	Determines the border width, if the flag parameter is set to include any border flag.
userData	Allows an extra object to be attached to the sizer item, for use in derived classes when sizing information is more complex than the proportion and flag will allow for.

wxSizerItem* wxSizer::Add (wxSizer * *sizer,* const wxSizerFlags & *flags*)

Appends a child to the sizer.

wxSizer itself is an abstract class, but the parameters are equivalent in the derived classes that you will instantiate to use it so they are described here:

Parameters

sizer	The (child-)sizer to be added to the sizer. This allows placing a child sizer in a sizer and thus to create hierarchies of sizers (typically a vertical box as the top sizer and several horizontal boxes on the level beneath).
flags	A wxSizerFlags object that enables you to specify most of the above parameters more conveniently.

wxSizerItem* wxSizer::Add (wxSizer * *sizer,* int *proportion* = `0`, int *flag* = `0`, int *border* = `0`, wxObject * *userData* = `NULL`)

Appends a child to the sizer.

wxSizer itself is an abstract class, but the parameters are equivalent in the derived classes that you will instantiate to use it so they are described here:

Parameters

sizer	The (child-)sizer to be added to the sizer. This allows placing a child sizer in a sizer and thus to create hierarchies of sizers (typically a vertical box as the top sizer and several horizontal boxes on the level beneath).
proportion	Although the meaning of this parameter is undefined in wxSizer, it is used in wxBoxSizer to indicate if a child of a sizer can change its size in the main orientation of the wxBoxSizer - where 0 stands for not changeable and a value of more than zero is interpreted relative to the value of other children of the same wxBoxSizer. For example, you might have a horizontal wxBoxSizer with three children, two of which are supposed to change their size with the sizer. Then the two stretchable windows would get a value of 1 each to make them grow and shrink equally with the sizer's horizontal dimension.

flag	OR-combination of flags affecting sizer's behaviour. See wxSizer flags list for details.
border	Determines the border width, if the flag parameter is set to include any border flag.
userData	Allows an extra object to be attached to the sizer item, for use in derived classes when sizing information is more complex than the proportion and flag will allow for.

wxSizerItem* wxSizer::Add (int *width*, int *height*, int *proportion* = 0, int *flag* = 0, int *border* = 0, wxObject * *userData* = NULL)

Appends a spacer child to the sizer.

wxSizer itself is an abstract class, but the parameters are equivalent in the derived classes that you will instantiate to use it so they are described here.

width and *height* specify the dimension of a spacer to be added to the sizer. Adding spacers to sizers gives more flexibility in the design of dialogs; imagine for example a horizontal box with two buttons at the bottom of a dialog: you might want to insert a space between the two buttons and make that space stretchable using the proportion flag and the result will be that the left button will be aligned with the left side of the dialog and the right button with the right side - the space in between will shrink and grow with the dialog.

Parameters

width	Width of the spacer.
height	Height of the spacer.
proportion	Although the meaning of this parameter is undefined in wxSizer, it is used in wxBoxSizer to indicate if a child of a sizer can change its size in the main orientation of the wxBoxSizer - where 0 stands for not changeable and a value of more than zero is interpreted relative to the value of other children of the same wxBoxSizer. For example, you might have a horizontal wxBoxSizer with three children, two of which are supposed to change their size with the sizer. Then the two stretchable windows would get a value of 1 each to make them grow and shrink equally with the sizer's horizontal dimension.
flag	OR-combination of flags affecting sizer's behaviour. See wxSizer flags list for details.
border	Determines the border width, if the flag parameter is set to include any border flag.
userData	Allows an extra object to be attached to the sizer item, for use in derived classes when sizing information is more complex than the proportion and flag will allow for.

wxSizerItem* wxSizer::Add (int *width*, int *height*, const wxSizerFlags & *flags*)

Appends a spacer child to the sizer.

Parameters

width	Width of the spacer.
height	Height of the spacer.
flags	A wxSizerFlags object that enables you to specify most of the other parameters more conveniently.

wxSizerItem* wxSizer::Add (wxSizerItem * *item*)

virtual wxSizerItem* wxSizer::AddSpacer (int *size*) [virtual]

This base function adds non-stretchable space to both the horizontal and vertical orientation of the sizer.

More readable way of calling:

```
wxSizer::Add(size, size, 0).
```

See also

wxBoxSizer::AddSpacer()

Reimplemented in wxBoxSizer.

wxSizerItem* wxSizer::AddStretchSpacer (int *prop* = 1)

Adds stretchable space to the sizer.

More readable way of calling:

```
wxSizer::Add(0, 0, prop).
```

virtual wxSize wxSizer::CalcMin ( ) [pure virtual]

This method is abstract and has to be overwritten by any derived class.

Here, the sizer will do the actual calculation of its children's minimal sizes.

Implemented in wxBoxSizer, wxStaticBoxSizer, wxGridSizer, wxFlexGridSizer, wxStdDialogButtonSizer, wxGridBagSizer, and wxWrapSizer.

virtual void wxSizer::Clear (bool *delete_windows* = false) [virtual]

Detaches all children from the sizer.

If *delete_windows* is true then child windows will also be deleted.

Notice that child sizers are always deleted, as a general consequence of the principle that sizers own their sizer children, but don't own their window children (because they are already owned by their parent windows).

wxSize wxSizer::ComputeFittingClientSize (wxWindow * *window*)

Computes client area size for *window* so that it matches the sizer's minimal size.

Unlike GetMinSize(), this method accounts for other constraints imposed on *window*, namely display's size (returned size will never be too large for the display) and maximum window size if previously set by wxWindow::SetMaxSize().

The returned value is suitable for passing to wxWindow::SetClientSize() or wxWindow::SetMinClientSize().

Since

2.8.8

See also

ComputeFittingWindowSize(), Fit()

wxSize wxSizer::ComputeFittingWindowSize (wxWindow * *window*)

Like ComputeFittingClientSize(), but converts the result into window size.

The returned value is suitable for passing to wxWindow::SetSize() or wxWindow::SetMinSize().

Since

2.8.8

See also

ComputeFittingClientSize(), Fit()

virtual bool wxSizer::Detach (wxWindow * *window*) [virtual]

Detach the child *window* from the sizer without destroying it.

This method does not cause any layout or resizing to take place, call Layout() to update the layout "on screen" after detaching a child from the sizer.

Returns true if the child item was found and detached, false otherwise.

See also

Remove()

virtual bool wxSizer::Detach (wxSizer * *sizer*) [virtual]

Detach the child *sizer* from the sizer without destroying it.

This method does not cause any layout or resizing to take place, call Layout() to update the layout "on screen" after detaching a child from the sizer.

Returns true if the child item was found and detached, false otherwise.

See also

Remove()

virtual bool wxSizer::Detach (int *index*) [virtual]

Detach a item at position *index* from the sizer without destroying it.

This method does not cause any layout or resizing to take place, call Layout() to update the layout "on screen" after detaching a child from the sizer. Returns true if the child item was found and detached, false otherwise.

See also

Remove()

wxSize wxSizer::Fit (wxWindow * *window*)

Tell the sizer to resize the *window* so that its client area matches the sizer's minimal size (ComputeFittingClientSize() is called to determine it).

This is commonly done in the constructor of the window itself, see sample in the description of wxBoxSizer.

Returns

The new window size.

See also

ComputeFittingClientSize(), ComputeFittingWindowSize()

void wxSizer::FitInside (wxWindow * *window*)

Tell the sizer to resize the virtual size of the *window* to match the sizer's minimal size.

This will not alter the on screen size of the window, but may cause the addition/removal/alteration of scrollbars required to view the virtual area in windows which manage it.

See also

wxScrolled::SetScrollbars(), SetVirtualSizeHints()

wxSizerItemList& wxSizer::GetChildren ( )

Returns the list of the items in this sizer.

The elements of type-safe wxList `wxSizerItemList` are pointers to objects of type wxSizerItem.

const wxSizerItemList& wxSizer::GetChildren ( ) const

Returns the list of the items in this sizer.

The elements of type-safe wxList `wxSizerItemList` are pointers to objects of type wxSizerItem.

wxWindow* wxSizer::GetContainingWindow ( ) const

Returns the window this sizer is used in or NULL if none.

wxSizerItem* wxSizer::GetItem (wxWindow * *window*, bool *recursive* = `false`)

Finds wxSizerItem which holds the given *window*.

Use parameter *recursive* to search in subsizers too. Returns pointer to item or NULL.

wxSizerItem* wxSizer::GetItem (wxSizer * *sizer*, bool *recursive* = `false`)

Finds wxSizerItem which holds the given *sizer*.

Use parameter *recursive* to search in subsizers too. Returns pointer to item or NULL.

wxSizerItem* wxSizer::GetItem (size_t *index*)

Finds wxSizerItem which is located in the sizer at position *index*.

Use parameter *recursive* to search in subsizers too. Returns pointer to item or NULL.

wxSizerItem* wxSizer::GetItemById (int *id*, bool *recursive* = `false`)

Finds item of the sizer which has the given *id*.

This *id* is not the window id but the id of the wxSizerItem itself. This is mainly useful for retrieving the sizers created from XRC resources. Use parameter *recursive* to search in subsizers too. Returns pointer to item or NULL.

size_t wxSizer::GetItemCount ( ) const

Returns the number of items in the sizer.

If you just need to test whether the sizer is empty or not you can also use IsEmpty() function.

wxSize wxSizer::GetMinSize ( )

Returns the minimal size of the sizer.

This is either the combined minimal size of all the children and their borders or the minimal size set by SetMinSize(), depending on which is bigger. Note that the returned value is client size, not window size. In particular, if you use the value to set toplevel window's minimal or actual size, use wxWindow::SetMinClientSize() or wxWindow::SetClientSize(), not wxWindow::SetMinSize() or wxWindow::SetSize().

wxPoint wxSizer::GetPosition ( ) const

Returns the current position of the sizer.

wxSize wxSizer::GetSize ( ) const

Returns the current size of the sizer.

bool wxSizer::Hide (wxWindow * *window,* bool *recursive* = `false`)

Hides the child *window*.

To make a sizer item disappear, use Hide() followed by Layout().

Use parameter *recursive* to hide elements found in subsizers. Returns true if the child item was found, false otherwise.

See also

IsShown(), Show()

bool wxSizer::Hide (wxSizer * *sizer,* bool *recursive* = `false`)

Hides the child *sizer*.

To make a sizer item disappear, use Hide() followed by Layout().

Use parameter *recursive* to hide elements found in subsizers. Returns true if the child item was found, false otherwise.

See also

IsShown(), Show()

bool wxSizer::Hide (size_t *index*)

Hides the item at position *index*.

To make a sizer item disappear, use Hide() followed by Layout().

Use parameter *recursive* to hide elements found in subsizers. Returns true if the child item was found, false otherwise.

See also

IsShown(), Show()

virtual bool wxSizer::InformFirstDirection (int *direction,* int *size,* int *availableOtherDir*) `[virtual]`

Inform sizer about the first direction that has been decided (by parent item).

Returns true if it made use of the information (and recalculated min size).

Reimplemented in wxWrapSizer.

wxSizerItem* wxSizer::Insert (size_t *index,* wxWindow * *window,* const wxSizerFlags & *flags*)

Insert a child into the sizer before any existing item at *index*.

See Add() for the meaning of the other parameters.

wxSizerItem* wxSizer::Insert (size_t *index,* wxWindow * *window,* int *proportion* = 0, int *flag* = 0, int *border* = 0, wxObject * *userData* = NULL)

Insert a child into the sizer before any existing item at *index*.

See Add() for the meaning of the other parameters.

wxSizerItem* wxSizer::Insert (size_t *index,* wxSizer * *sizer,* const wxSizerFlags & *flags*)

Insert a child into the sizer before any existing item at *index*.

See Add() for the meaning of the other parameters.

wxSizerItem* wxSizer::Insert (size_t *index,* wxSizer * *sizer,* int *proportion* = 0, int *flag* = 0, int *border* = 0, wxObject * *userData* = NULL)

Insert a child into the sizer before any existing item at *index*.

See Add() for the meaning of the other parameters.

wxSizerItem* wxSizer::Insert (size_t *index,* int *width,* int *height,* int *proportion* = 0, int *flag* = 0, int *border* = 0, wxObject * *userData* = NULL)

Insert a child into the sizer before any existing item at *index*.

See Add() for the meaning of the other parameters.

wxSizerItem* wxSizer::Insert (size_t *index,* int *width,* int *height,* const wxSizerFlags & *flags*)

Insert a child into the sizer before any existing item at *index*.

See Add() for the meaning of the other parameters.

wxSizerItem* wxSizer::Insert (size_t *index,* wxSizerItem * *item*)

wxSizerItem* wxSizer::InsertSpacer (size_t *index,* int *size*)

Inserts non-stretchable space to the sizer.

More readable way of calling wxSizer::Insert(index, size, size).

wxSizerItem* wxSizer::InsertStretchSpacer (size_t *index*, int *prop* = 1)

Inserts stretchable space to the sizer.

More readable way of calling wxSizer::Insert(0, 0, prop).

bool wxSizer::IsEmpty ( ) const

Return true if the sizer has no elements.

See also

GetItemCount()

bool wxSizer::IsShown (wxWindow * *window*) const

Returns true if the *window* is shown.

See also

Hide(), Show(), wxSizerItem::IsShown()

bool wxSizer::IsShown (wxSizer * *sizer*) const

Returns true if the *sizer* is shown.

See also

Hide(), Show(), wxSizerItem::IsShown()

bool wxSizer::IsShown (size_t *index*) const

Returns true if the item at *index* is shown.

See also

Hide(), Show(), wxSizerItem::IsShown()

virtual void wxSizer::Layout ( ) [virtual]

Call this to force layout of the children anew, e.g. after having added a child to or removed a child (window, other sizer or space) from the sizer while keeping the current dimension.

wxSizerItem* wxSizer::Prepend (wxWindow * *window*, const wxSizerFlags & *flags*)

Same as Add(), but prepends the items to the beginning of the list of items (windows, subsizers or spaces) owned by this sizer.

wxSizerItem* wxSizer::Prepend (wxWindow * *window*, int *proportion* = 0, int *flag* = 0, int *border* = 0, wxObject * *userData* = NULL)

Same as Add(), but prepends the items to the beginning of the list of items (windows, subsizers or spaces) owned by this sizer.

wxSizerItem* wxSizer::Prepend (wxSizer * *sizer,* const wxSizerFlags & *flags*)

Same as Add(), but prepends the items to the beginning of the list of items (windows, subsizers or spaces) owned by this sizer.

wxSizerItem* wxSizer::Prepend (wxSizer * *sizer,* int *proportion* = 0, int *flag* = 0, int *border* = 0, wxObject * *userData* = NULL)

Same as Add(), but prepends the items to the beginning of the list of items (windows, subsizers or spaces) owned by this sizer.

wxSizerItem* wxSizer::Prepend (int *width,* int *height,* int *proportion* = 0, int *flag* = 0, int *border* = 0, wxObject * *userData* = NULL)

Same as Add(), but prepends the items to the beginning of the list of items (windows, subsizers or spaces) owned by this sizer.

wxSizerItem* wxSizer::Prepend (int *width,* int *height,* const wxSizerFlags & *flags*)

Same as Add(), but prepends the items to the beginning of the list of items (windows, subsizers or spaces) owned by this sizer.

wxSizerItem* wxSizer::Prepend (wxSizerItem * *item*)

wxSizerItem* wxSizer::PrependSpacer (int *size*)

Prepends non-stretchable space to the sizer.

More readable way of calling wxSizer::Prepend(size, size, 0).

wxSizerItem* wxSizer::PrependStretchSpacer (int *prop* = 1)

Prepends stretchable space to the sizer.

More readable way of calling wxSizer::Prepend(0, 0, prop).

virtual void wxSizer::RecalcSizes ( ) [pure virtual]

This method is abstract and has to be overwritten by any derived class.

Here, the sizer will do the actual calculation of its children's positions and sizes.

Implemented in wxBoxSizer, wxStaticBoxSizer, wxGridSizer, wxFlexGridSizer, wxStdDialogButtonSizer, wxGridBagSizer, and wxWrapSizer.

virtual bool wxSizer::Remove (wxWindow * *window*) [virtual]

Removes a child window from the sizer, but does **not** destroy it (because windows are owned by their parent window, not the sizer).

Deprecated The overload of this method taking a wxWindow* parameter is deprecated as it does not destroy the window as would usually be expected from Remove(). You should use Detach() in new code instead. There is currently no wxSizer method that will both detach and destroy a wxWindow item.

Note

This method does not cause any layout or resizing to take place, call Layout() to update the layout "on screen" after removing a child from the sizer.

Returns

true if the child item was found and removed, false otherwise.

virtual bool wxSizer::Remove (wxSizer * *sizer*) [virtual]

Removes a sizer child from the sizer and destroys it.

Note

This method does not cause any layout or resizing to take place, call Layout() to update the layout "on screen" after removing a child from the sizer.

Parameters

sizer	The wxSizer to be removed.

Returns

true if the child item was found and removed, false otherwise.

virtual bool wxSizer::Remove (int *index*) [virtual]

Removes a child from the sizer and destroys it if it is a sizer or a spacer, but not if it is a window (because windows are owned by their parent window, not the sizer).

Note

This method does not cause any layout or resizing to take place, call Layout() to update the layout "on screen" after removing a child from the sizer.

Parameters

index	The position of the child in the sizer, e.g. 0 for the first item.

Returns

true if the child item was found and removed, false otherwise.

virtual bool wxSizer::Replace (wxWindow * *oldwin*, wxWindow * *newwin*, bool *recursive* = false) [virtual]

Detaches the given *oldwin* from the sizer and replaces it with the given *newwin*.

The detached child window is **not** deleted (because windows are owned by their parent window, not the sizer).

Use parameter *recursive* to search the given element recursively in subsizers.

This method does not cause any layout or resizing to take place, call Layout() to update the layout "on screen" after replacing a child from the sizer.

Returns true if the child item was found and removed, false otherwise.

virtual bool wxSizer::Replace (wxSizer * *oldsz*, wxSizer * *newsz*, bool *recursive* = false) [virtual]

Detaches the given *oldsz* from the sizer and replaces it with the given *newsz*.

The detached child sizer is deleted.

Use parameter *recursive* to search the given element recursively in subsizers.

This method does not cause any layout or resizing to take place, call Layout() to update the layout "on screen" after replacing a child from the sizer.

Returns true if the child item was found and removed, false otherwise.

virtual bool wxSizer::Replace (size_t *index*, wxSizerItem * *newitem*) [virtual]

Detaches the given item at position *index* from the sizer and replaces it with the given wxSizerItem *newitem*.

The detached child is deleted **only** if it is a sizer or a spacer (but not if it is a wxWindow because windows are owned by their parent window, not the sizer).

This method does not cause any layout or resizing to take place, call Layout() to update the layout "on screen" after replacing a child from the sizer.

Returns true if the child item was found and removed, false otherwise.

void wxSizer::SetContainingWindow (wxWindow * *window*)

Set the window this sizer is used in.

void wxSizer::SetDimension (int *x*, int *y*, int *width*, int *height*)

Call this to force the sizer to take the given dimension and thus force the items owned by the sizer to resize themselves according to the rules defined by the parameter in the Add() and Prepend() methods.

void wxSizer::SetDimension (const wxPoint & *pos*, const wxSize & *size*)

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.

bool wxSizer::SetItemMinSize (wxWindow * *window*, int *width*, int *height*)

Set an item's minimum size by window, sizer, or position.

This function enables an application to set the size of an item after initial creation.

The *window* or *sizer* will be found recursively in the sizer's descendants.

See also

wxSizerItem::SetMinSize()

Returns

true if the minimal size was successfully set or false if the item was not found.

bool wxSizer::SetItemMinSize (wxWindow * *window,* const wxSize & *size*)

Set an item's minimum size by window, sizer, or position.

This function enables an application to set the size of an item after initial creation.

The *window* or *sizer* will be found recursively in the sizer's descendants.

See also

wxSizerItem::SetMinSize()

Returns

true if the minimal size was successfully set or false if the item was not found.

bool wxSizer::SetItemMinSize (wxSizer * *sizer,* int *width,* int *height*)

Set an item's minimum size by window, sizer, or position.

This function enables an application to set the size of an item after initial creation.

The *window* or *sizer* will be found recursively in the sizer's descendants.

See also

wxSizerItem::SetMinSize()

Returns

true if the minimal size was successfully set or false if the item was not found.

bool wxSizer::SetItemMinSize (wxSizer * *sizer,* const wxSize & *size*)

Set an item's minimum size by window, sizer, or position.

This function enables an application to set the size of an item after initial creation.

The *window* or *sizer* will be found recursively in the sizer's descendants.

See also

wxSizerItem::SetMinSize()

Returns

true if the minimal size was successfully set or false if the item was not found.

bool wxSizer::SetItemMinSize (size_t *index,* int *width,* int *height*)

Set an item's minimum size by window, sizer, or position.

This function enables an application to set the size of an item after initial creation.

The *window* or *sizer* will be found recursively in the sizer's descendants.

See also

wxSizerItem::SetMinSize()

Returns

true if the minimal size was successfully set or false if the item was not found.

bool wxSizer::SetItemMinSize (size_t *index*, const wxSize & *size*)

Set an item's minimum size by window, sizer, or position.

This function enables an application to set the size of an item after initial creation.

The *window* or *sizer* will be found recursively in the sizer's descendants.

See also

wxSizerItem::SetMinSize()

Returns

true if the minimal size was successfully set or false if the item was not found.

void wxSizer::SetMinSize (const wxSize & *size*)

Call this to give the sizer a minimal size.

Normally, the sizer will calculate its minimal size based purely on how much space its children need. After calling this method GetMinSize() will return either the minimal size as requested by its children or the minimal size set here, depending on which is bigger.

void wxSizer::SetMinSize (int *width*, int *height*)

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.

void wxSizer::SetSizeHints (wxWindow * *window*)

This method first calls Fit() and then wxTopLevelWindow::SetSizeHints() on the *window* passed to it.

This only makes sense when *window* is actually a wxTopLevelWindow such as a wxFrame or a wxDialog, since SetSizeHints only has any effect in these classes. It does nothing in normal windows or controls.

This method is implicitly used by wxWindow::SetSizerAndFit() which is commonly invoked in the constructor of a toplevel window itself (see the sample in the description of wxBoxSizer) if the toplevel window is resizable.

void wxSizer::SetVirtualSizeHints (wxWindow * *window*)

Tell the sizer to set the minimal size of the *window* virtual area to match the sizer's minimal size.

For windows with managed scrollbars this will set them appropriately.

Deprecated This is exactly the same as FitInside() in wxWidgets 2.9 and later, please replace calls to it with FitInside().

See also

wxScrolled::SetScrollbars()

bool wxSizer::Show (wxWindow * *window*, bool *show* = `true`, bool *recursive* = `false`)

Shows or hides the *window*.

To make a sizer item disappear or reappear, use Show() followed by Layout().

Use parameter *recursive* to show or hide elements found in subsizers.

Returns true if the child item was found, false otherwise.

See also

Hide(), IsShown()

bool wxSizer::Show (wxSizer * *sizer*, bool *show* = `true`, bool *recursive* = `false`)

Shows or hides *sizer*.

To make a sizer item disappear or reappear, use Show() followed by Layout().

Use parameter *recursive* to show or hide elements found in subsizers.

Returns true if the child item was found, false otherwise.

See also

Hide(), IsShown()

bool wxSizer::Show (size_t *index*, bool *show* = `true`)

Shows the item at *index*.

To make a sizer item disappear or reappear, use Show() followed by Layout().

Returns true if the child item was found, false otherwise.

See also

Hide(), IsShown()

virtual void wxSizer::ShowItems (bool *show*) `[virtual]`

Show or hide all items managed by the sizer.

21.687 wxSizerFlags Class Reference

`#include <wx/sizer.h>`

21.687.1 Detailed Description

Container for sizer items flags providing readable names for them.

Normally, when you add an item to a sizer via wxSizer::Add, you have to specify a lot of flags and parameters which can be unwieldy. This is where wxSizerFlags comes in: it allows you to specify all parameters using the named methods instead. For example, instead of

```
sizer->Add(ctrl, 0, wxEXPAND | wxALL, 10);
```

you can now write

```
sizer->Add(ctrl, wxSizerFlags().Expand().Border(wxALL, 10));
```

This is more readable and also allows you to create wxSizerFlags objects which can be reused for several sizer items.

```
wxSizerFlags flagsExpand(1);
    flagsExpand.Expand().Border(wxALL, 10);

    sizer->Add(ctrl1, flagsExpand);
    sizer->Add(ctrl2, flagsExpand);
```

Note that by specification, all methods of wxSizerFlags return the wxSizerFlags object itself to allowing chaining multiple methods calls like in the examples above.

Library: wxCore

Category: Window Layout

See also

wxSizer

Public Member Functions

- wxSizerFlags (int proportion=0)

  Creates the wxSizer with the proportion specified by proportion.
- wxSizerFlags & Align (int alignment)

  Sets the alignment of this wxSizerFlags to align.
- wxSizerFlags & Border (int direction, int borderinpixels)

  Sets the wxSizerFlags to have a border of a number of pixels specified by borderinpixels with the directions specified by direction.
- wxSizerFlags & Border (int direction=wxALL)

  Sets the wxSizerFlags to have a border with size as returned by GetDefaultBorder().
- wxSizerFlags & Bottom ()

  Aligns the object to the bottom, similar for `Align(wxALIGN_BOTTOM)`.
- wxSizerFlags & Center ()

  Sets the object of the wxSizerFlags to center itself in the area it is given.
- wxSizerFlags & Centre ()

  Center() for people with the other dialect of English.
- wxSizerFlags & DoubleBorder (int direction=wxALL)

  Sets the border in the given direction having twice the default border size.
- wxSizerFlags & DoubleHorzBorder ()

  Sets the border in left and right directions having twice the default border size.
- wxSizerFlags & Expand ()

  Sets the object of the wxSizerFlags to expand to fill as much area as it can.
- wxSizerFlags & FixedMinSize ()

  Set the `wxFIXED_MINSIZE` flag which indicates that the initial size of the window should be also set as its minimal size.
- wxSizerFlags & ReserveSpaceEvenIfHidden ()

  Set the `wxRESERVE_SPACE_EVEN_IF_HIDDEN` flag.
- wxSizerFlags & Left ()

Aligns the object to the left, similar for `Align(wxALIGN_LEFT)`.

- wxSizerFlags & Proportion (int proportion)

  Sets the proportion of this wxSizerFlags to proportion.

- wxSizerFlags & Right ()

  Aligns the object to the right, similar for `Align(wxALIGN_RIGHT)`.

- wxSizerFlags & Shaped ()

  Set the `wx_SHAPED` flag which indicates that the elements should always keep the fixed width to height ratio equal to its original value.

- wxSizerFlags & Top ()

  Aligns the object to the top, similar for `Align(wxALIGN_TOP)`.

- wxSizerFlags & TripleBorder (int direction=wxALL)

  Sets the border in the given direction having thrice the default border size.

Static Public Member Functions

- static int GetDefaultBorder ()

  Returns the border used by default in Border() method.

21.687.2 Constructor & Destructor Documentation

wxSizerFlags::wxSizerFlags (int *proportion* = `0`)

Creates the wxSizer with the proportion specified by *proportion*.

21.687.3 Member Function Documentation

wxSizerFlags& wxSizerFlags::Align (int *alignment*)

Sets the alignment of this wxSizerFlags to *align*.

This method replaces the previously set alignment with the specified one.

Parameters

alignment	Combination of `wxALIGN_XXX` bit masks.

See also

Top(), Left(), Right(), Bottom(), Centre()

wxSizerFlags& wxSizerFlags::Border (int *direction*, int *borderinpixels*)

Sets the wxSizerFlags to have a border of a number of pixels specified by *borderinpixels* with the directions specified by *direction*.

wxSizerFlags& wxSizerFlags::Border (int *direction* = wxALL)

Sets the wxSizerFlags to have a border with size as returned by GetDefaultBorder().

Parameters

direction	Direction(s) to apply the border in.

wxSizerFlags& wxSizerFlags::Bottom ( )

Aligns the object to the bottom, similar for `Align(wxALIGN_BOTTOM)`.

Unlike Align(), this method doesn't change the horizontal alignment of the item.

wxSizerFlags& wxSizerFlags::Center ( )

Sets the object of the wxSizerFlags to center itself in the area it is given.

wxSizerFlags& wxSizerFlags::Centre ( )

Center() for people with the other dialect of English.

wxSizerFlags& wxSizerFlags::DoubleBorder (int *direction* = **wxALL**)

Sets the border in the given *direction* having twice the default border size.

wxSizerFlags& wxSizerFlags::DoubleHorzBorder ( )

Sets the border in left and right directions having twice the default border size.

wxSizerFlags& wxSizerFlags::Expand ( )

Sets the object of the wxSizerFlags to expand to fill as much area as it can.

wxSizerFlags& wxSizerFlags::FixedMinSize ( )

Set the `wxFIXED_MINSIZE` flag which indicates that the initial size of the window should be also set as its minimal size.

static int wxSizerFlags::GetDefaultBorder ( ) [static]

Returns the border used by default in Border() method.

wxSizerFlags& wxSizerFlags::Left ( )

Aligns the object to the left, similar for `Align(wxALIGN_LEFT)`.

Unlike Align(), this method doesn't change the vertical alignment of the item.

wxSizerFlags& wxSizerFlags::Proportion (int *proportion*)

Sets the proportion of this wxSizerFlags to *proportion*.

wxSizerFlags& wxSizerFlags::ReserveSpaceEvenIfHidden ( )

Set the `wxRESERVE_SPACE_EVEN_IF_HIDDEN` flag.

Normally wxSizers don't allocate space for hidden windows or other items. This flag overrides this behaviour so that sufficient space is allocated for the window even if it isn't visible. This makes it possible to dynamically show and hide controls without resizing parent dialog, for example.

Since

2.8.8

wxSizerFlags& wxSizerFlags::Right ( )

Aligns the object to the right, similar for `Align(wxALIGN_RIGHT)`.

Unlike Align(), this method doesn't change the vertical alignment of the item.

wxSizerFlags& wxSizerFlags::Shaped ( )

Set the `wx_SHAPED` flag which indicates that the elements should always keep the fixed width to height ratio equal to its original value.

wxSizerFlags& wxSizerFlags::Top ( )

Aligns the object to the top, similar for `Align(wxALIGN_TOP)`.

Unlike Align(), this method doesn't change the horizontal alignment of the item.

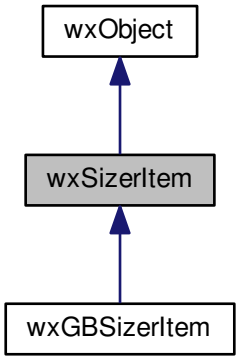
wxSizerFlags& wxSizerFlags::TripleBorder (int *direction* = wxALL)

Sets the border in the given *direction* having thrice the default border size.

21.688 wxSizerItem Class Reference

`#include <wx/sizer.h>`

Inheritance diagram for wxSizerItem:



21.688.1 Detailed Description

The wxSizerItem class is used to track the position, size and other attributes of each item managed by a wxSizer.

It is not usually necessary to use this class because the sizer elements can also be identified by their positions or window or sizer pointers but sometimes it may be more convenient to use it directly.

Library: wxCore

Category: Window Layout

Public Member Functions

- wxSizerItem (int width, int height, int proportion=0, int flag=0, int border=0, wxObject ∗userData=NULL)

  Construct a sizer item for tracking a spacer.
- virtual ∼wxSizerItem ()

  Deletes the user data and subsizer, if any.
- void AssignWindow (wxWindow ∗window)

  Set the window to be tracked by this item.
- void AssignSizer (wxSizer ∗sizer)

  Set the sizer tracked by this item.
- virtual wxSize CalcMin ()

  Calculates the minimum desired size for the item, including any space needed by borders.
- virtual void DeleteWindows ()

  Destroy the window or the windows in a subsizer, depending on the type of item.
- void DetachSizer ()

  Enable deleting the SizerItem without destroying the contained sizer.
- int GetBorder () const

  Return the border attribute.
- int GetFlag () const

Return the flags attribute.

- int GetId () const

  Return the numeric id of wxSizerItem, or `wxID_NONE` if the id has not been set.

- wxSize GetMinSize () const

  Get the minimum size needed for the item.

- void SetMinSize (const wxSize &size)

  Sets the minimum size to be allocated for this item.

- void SetMinSize (int x, int y)

  This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.

- wxPoint GetPosition () const

  What is the current position of the item, as set in the last Layout.

- int GetProportion () const

  Get the proportion item attribute.

- float GetRatio () const

  Get the ration item attribute.

- virtual wxRect GetRect ()

  Get the rectangle of the item on the parent window, excluding borders.

- virtual wxSize GetSize () const

  Get the current size of the item, as set in the last Layout.

- wxSizer * GetSizer () const

  If this item is tracking a sizer, return it.

- wxSize GetSpacer () const

  If this item is tracking a spacer, return its size.

- wxObject * GetUserData () const

  Get the userData item attribute.

- wxWindow * GetWindow () const

  If this item is tracking a window then return it.

- bool IsShown () const

  Returns true if this item is a window or a spacer and it is shown or if this item is a sizer and not all of its elements are hidden.

- bool IsSizer () const

  Is this item a sizer?

- bool IsSpacer () const

  Is this item a spacer?

- bool IsWindow () const

  Is this item a window?

- void SetBorder (int border)

  Set the border item attribute.

- virtual void SetDimension (const wxPoint &pos, const wxSize &size)

  Set the position and size of the space allocated to the sizer, and adjust the position and size of the item to be within that space taking alignment and borders into account.

- void SetFlag (int flag)

  Set the flag item attribute.

- void SetId (int id)

  Sets the numeric id of the wxSizerItem to id.

- void SetInitSize (int x, int y)

- void SetProportion (int proportion)

  Set the proportion item attribute.

- void SetSizer (wxSizer *sizer)

  Set the sizer tracked by this item.

- void SetSpacer (const wxSize &size)

  Set the size of the spacer tracked by this item.
- void SetUserData (wxObject *userData)
- void SetWindow (wxWindow *window)

  Set the window to be tracked by this item.
- void Show (bool show)

  Set the show item attribute, which sizers use to determine if the item is to be made part of the layout or not.

- wxSizerItem (wxWindow *window, const wxSizerFlags &flags)

  Construct a sizer item for tracking a window.
- wxSizerItem (wxWindow *window, int proportion=0, int flag=0, int border=0, wxObject *userData=NULL)

  Construct a sizer item for tracking a window.

- wxSizerItem (wxSizer *sizer, const wxSizerFlags &flags)

  Construct a sizer item for tracking a subsizer.
- wxSizerItem (wxSizer *sizer, int proportion=0, int flag=0, int border=0, wxObject *userData=NULL)

  Construct a sizer item for tracking a subsizer.

- void AssignSpacer (const wxSize &size)

  Set the size of the spacer tracked by this item.
- void AssignSpacer (int w, int h)

  Set the size of the spacer tracked by this item.

- void SetRatio (int width, int height)

  Set the ratio item attribute.
- void SetRatio (wxSize size)

  Set the ratio item attribute.
- void SetRatio (float ratio)

  Set the ratio item attribute.

Additional Inherited Members

21.688.2 Constructor & Destructor Documentation

wxSizerItem::wxSizerItem (int *width*, int *height*, int *proportion* = 0, int *flag* = 0, int *border* = 0, wxObject * *userData* = NULL)

Construct a sizer item for tracking a spacer.

wxSizerItem::wxSizerItem (wxWindow * *window*, const wxSizerFlags & *flags*)

Construct a sizer item for tracking a window.

wxSizerItem::wxSizerItem (wxWindow * *window*, int *proportion* = 0, int *flag* = 0, int *border* = 0, wxObject * *userData* = NULL)

Construct a sizer item for tracking a window.

wxSizerItem::wxSizerItem (wxSizer * *sizer*, const wxSizerFlags & *flags*)

Construct a sizer item for tracking a subsizer.

wxSizerItem::wxSizerItem (wxSizer * *sizer,* int *proportion* = 0, int *flag* = 0, int *border* = 0, wxObject * *userData* = NULL)

Construct a sizer item for tracking a subsizer.

virtual wxSizerItem::~wxSizerItem ( ) [virtual]

Deletes the user data and subsizer, if any.

21.688.3 Member Function Documentation

void wxSizerItem::AssignSizer (wxSizer * *sizer*)

Set the sizer tracked by this item.

Old sizer, if any, is deleted.

void wxSizerItem::AssignSpacer (const wxSize & *size*)

Set the size of the spacer tracked by this item.

Old spacer, if any, is deleted.

void wxSizerItem::AssignSpacer (int *w,* int *h*)

Set the size of the spacer tracked by this item.

Old spacer, if any, is deleted.

void wxSizerItem::AssignWindow (wxWindow * *window*)

Set the window to be tracked by this item.

The old window isn't deleted as it is now owned by the sizer item.

virtual wxSize wxSizerItem::CalcMin ( ) [virtual]

Calculates the minimum desired size for the item, including any space needed by borders.

virtual void wxSizerItem::DeleteWindows ( ) [virtual]

Destroy the window or the windows in a subsizer, depending on the type of item.

void wxSizerItem::DetachSizer ( )

Enable deleting the SizerItem without destroying the contained sizer.

int wxSizerItem::GetBorder ( ) const

Return the border attribute.

int wxSizerItem::GetFlag ( ) const

Return the flags attribute.

See wxSizer flags list for details.

int wxSizerItem::GetId ( ) const

Return the numeric id of wxSizerItem, or `wxID_NONE` if the id has not been set.

wxSize wxSizerItem::GetMinSize ( ) const

Get the minimum size needed for the item.

wxPoint wxSizerItem::GetPosition ( ) const

What is the current position of the item, as set in the last Layout.

int wxSizerItem::GetProportion ( ) const

Get the proportion item attribute.

float wxSizerItem::GetRatio ( ) const

Get the ration item attribute.

virtual wxRect wxSizerItem::GetRect ( ) [virtual]

Get the rectangle of the item on the parent window, excluding borders.

virtual wxSize wxSizerItem::GetSize ( ) const [virtual]

Get the current size of the item, as set in the last Layout.

wxSizer* wxSizerItem::GetSizer ( ) const

If this item is tracking a sizer, return it.

NULL otherwise.

wxSize wxSizerItem::GetSpacer ( ) const

If this item is tracking a spacer, return its size.

wxObject* wxSizerItem::GetUserData ( ) const

Get the userData item attribute.

wxWindow* wxSizerItem::GetWindow ( ) const

If this item is tracking a window then return it.

NULL otherwise.

bool wxSizerItem::IsShown ( ) const

Returns true if this item is a window or a spacer and it is shown or if this item is a sizer and not all of its elements are hidden.

In other words, for sizer items, all of the child elements must be hidden for the sizer itself to be considered hidden.

As an exception, if the `wxRESERVE_SPACE_EVEN_IF_HIDDEN` flag was used for this sizer item, then IsShown() always returns true for it (see wxSizerFlags::ReserveSpaceEvenIfHidden()).

bool wxSizerItem::IsSizer ( ) const

Is this item a sizer?

bool wxSizerItem::IsSpacer ( ) const

Is this item a spacer?

bool wxSizerItem::IsWindow ( ) const

Is this item a window?

void wxSizerItem::SetBorder (int *border*)

Set the border item attribute.

virtual void wxSizerItem::SetDimension (const wxPoint & *pos*, const wxSize & *size*) [virtual]

Set the position and size of the space allocated to the sizer, and adjust the position and size of the item to be within that space taking alignment and borders into account.

void wxSizerItem::SetFlag (int *flag*)

Set the flag item attribute.

void wxSizerItem::SetId (int *id*)

Sets the numeric id of the wxSizerItem to *id*.

void wxSizerItem::SetInitSize (int *x*, int *y*)

Todo docme.

void wxSizerItem::SetMinSize (const wxSize & *size*)

Sets the minimum size to be allocated for this item.

If this item is a window, the *size* is also passed to wxWindow::SetMinSize().

void wxSizerItem::SetMinSize (int *x,* int *y*)

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.

void wxSizerItem::SetProportion (int *proportion*)

Set the proportion item attribute.

void wxSizerItem::SetRatio (int *width,* int *height*)

Set the ratio item attribute.

void wxSizerItem::SetRatio (wxSize *size*)

Set the ratio item attribute.

void wxSizerItem::SetRatio (float *ratio*)

Set the ratio item attribute.

void wxSizerItem::SetSizer (wxSizer * *sizer*)

Set the sizer tracked by this item.

Deprecated This function does not free the old sizer which may result in memory leaks, use AssignSizer() which does free it instead.

void wxSizerItem::SetSpacer (const wxSize & *size*)

Set the size of the spacer tracked by this item.

Deprecated This function does not free the old spacer which may result in memory leaks, use AssignSpacer() which does free it instead.

void wxSizerItem::SetUserData (wxObject * *userData*)

void wxSizerItem::SetWindow (wxWindow * *window*)

Set the window to be tracked by this item.

Deprecated

Todo provide deprecation description

void wxSizerItem::Show (bool *show*)

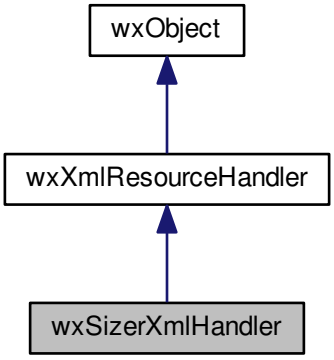
Set the show item attribute, which sizers use to determine if the item is to be made part of the layout or not.

If the item is tracking a window then it is shown or hidden as needed.

21.689 wxSizerXmlHandler Class Reference

`#include <wx/xrc/xh_sizer.h>`

Inheritance diagram for wxSizerXmlHandler:



Public Member Functions

- wxSizerXmlHandler ()

  Constructor.
- virtual wxObject * DoCreateResource ()

  Creates a sizer, sizeritem or spacer object, depending on the current handled node.
- virtual bool CanHandle (wxXmlNode *node)

  Returns true if the given node can be handled by this class.

Protected Member Functions

- virtual wxSizer * DoCreateSizer (const wxString &name)

  Creates an object of type wxSizer from the XML node content.
- virtual bool IsSizerNode (wxXmlNode *node) const

  Used by CanHandle() to know if the given node contains a sizer supported by this class.

Additional Inherited Members

21.689.1 Constructor & Destructor Documentation

wxSizerXmlHandler::wxSizerXmlHandler ( )

Constructor.

Initializes the attributes and adds the supported styles.

21.689.2 Member Function Documentation

virtual bool wxSizerXmlHandler::CanHandle (wxXmlNode * *node*) [virtual]

Returns true if the given node can be handled by this class.

If the node concerns a sizer object, the method IsSizerNode is called to know if the class is managed or not. If the node concerns a sizer item or a spacer, true is returned. Otherwise false is returned.

See also

wxXmlResourceHandler::CanHandle().

Implements wxXmlResourceHandler.

virtual wxObject* wxSizerXmlHandler::DoCreateResource ( ) [virtual]

Creates a sizer, sizeritem or spacer object, depending on the current handled node.

See also

wxXmlResourceHandler::DoCreateResource().

Implements wxXmlResourceHandler.

virtual wxSizer* wxSizerXmlHandler::DoCreateSizer (const wxString & *name*) [protected], [virtual]

Creates an object of type wxSizer from the XML node content.

This virtual method can be overridden to add support for custom sizer classes to the derived handler.

Notice that if you override this method you would typically overload IsSizerNode() as well.

Example of use of this method:

```
class MySizerXmlHandler : public wxSizerXmlHandler
{
    ...

protected:
    bool IsSizerNode(wxXmlNode *node) const
    {
        return IsOfClass(node, "MySizer") ||
               wxSizerXmlHandler::IsSizerNode(node));
    }

    void DoCreateSizer(const wxString& name)
    {
        if ( name == "MySizer" )
            return Handle_MySizer();
        else
            return wxSizerXmlHandler::DoCreateSizer(name);
    }

private:
    wxSizer* Handle_MySizer()
    {
        // Create your own sizer here from XRC content (see
        // wxXmlResource methods) and return the instance.
    }
};
```

Since

2.9.2

virtual bool wxSizerXmlHandler::IsSizerNode (wxXmlNode * *node*) const `[protected], [virtual]`

Used by CanHandle() to know if the given node contains a sizer supported by this class.

This method should be overridden to allow this handler to be used for the custom sizer types.

See the example in DoCreateSizer() description for how it can be used.

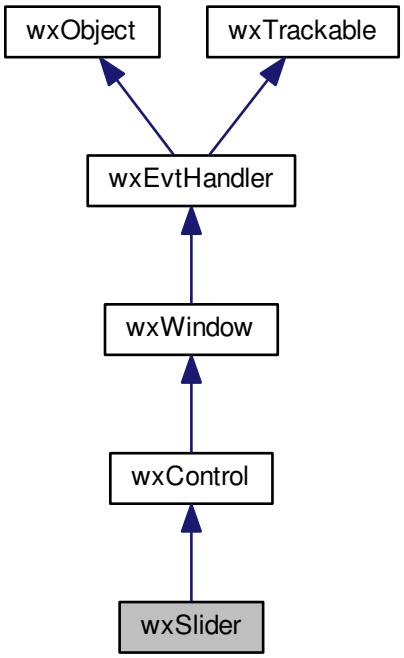
Since

2.9.2

21.690 wxSlider Class Reference

`#include <wx/slider.h>`

Inheritance diagram for wxSlider:



21.690.1 Detailed Description

A slider is a control with a handle which can be pulled back and forth to change the value.

On Windows, the track bar control is used.

Slider generates the same events as wxScrollBar but in practice the most convenient way to process wxSlider updates is by handling the slider-specific `wxEVT_SLIDER` event which carries wxCommandEvent containing just the latest slider position.

Styles

This class supports the following styles:

- wxSL_HORIZONTAL: Displays the slider horizontally (this is the default).
- wxSL_VERTICAL: Displays the slider vertically.
- wxSL_AUTOTICKS: Displays tick marks. Windows only.
- wxSL_MIN_MAX_LABELS: Displays minimum, maximum labels (new since wxWidgets 2.9.1).
- wxSL_VALUE_LABEL: Displays value label (new since wxWidgets 2.9.1).
- wxSL_LABELS: Displays minimum, maximum and value labels (same as wxSL_VALUE_LABEL and wxSL↩ _MIN_MAX_LABELS together).
- wxSL_LEFT: Displays ticks on the left and forces the slider to be vertical.
- wxSL_RIGHT: Displays ticks on the right and forces the slider to be vertical.
- wxSL_TOP: Displays ticks on the top.
- wxSL_BOTTOM: Displays ticks on the bottom (this is the default).
- wxSL_SELRANGE: Allows the user to select a range on the slider. Windows only.
- wxSL_INVERSE: Inverses the minimum and maximum endpoints on the slider. Not compatible with wxSL↩ _SELRANGE.

Notice that `wxSL_LEFT`, `wxSL_TOP`, `wxSL_RIGHT` and `wxSL_BOTTOM` specify the position of the slider ticks in MSW implementation and that the slider labels, if any, are positioned on the opposite side. So, to have a label on the left side of a vertical slider, **wxSL_RIGHT** must be used (or none of these styles at all should be specified as left and top are default positions for the vertical and horizontal sliders respectively).

Events emitted by this class

The following event handler macros redirect the events to member function handlers '**func**' with prototypes like: void handlerFuncName(wxScrollEvent& event)

Event macros for events emitted by this class: You can use EVT_COMMAND_SCROLL... macros with window IDs for when intercepting scroll events from controls, or EVT_SCROLL... macros without window IDs for intercepting scroll events from the receiving window – except for this, the macros behave exactly the same.

- EVT_SCROLL(func): Process all scroll events.
- EVT_SCROLL_TOP(func): Process `wxEVT_SCROLL_TOP` scroll-to-top events (minimum position).
- EVT_SCROLL_BOTTOM(func): Process `wxEVT_SCROLL_BOTTOM` scroll-to-bottom events (maximum position).
- EVT_SCROLL_LINEUP(func): Process `wxEVT_SCROLL_LINEUP` line up events.
- EVT_SCROLL_LINEDOWN(func): Process `wxEVT_SCROLL_LINEDOWN` line down events.
- EVT_SCROLL_PAGEUP(func): Process `wxEVT_SCROLL_PAGEUP` page up events.
- EVT_SCROLL_PAGEDOWN(func): Process `wxEVT_SCROLL_PAGEDOWN` page down events.

- EVT_SCROLL_THUMBTRACK(func): Process `wxEVT_SCROLL_THUMBTRACK` thumbtrack events (frequent events sent as the user drags the thumbtrack).
- EVT_SCROLL_THUMBRELEASE(func): Process `wxEVT_SCROLL_THUMBRELEASE` thumb release events.
- EVT_SCROLL_CHANGED(func): Process `wxEVT_SCROLL_CHANGED` end of scrolling events (MSW only).
- EVT_COMMAND_SCROLL(id, func): Process all scroll events.
- EVT_COMMAND_SCROLL_TOP(id, func): Process `wxEVT_SCROLL_TOP` scroll-to-top events (minimum position).
- EVT_COMMAND_SCROLL_BOTTOM(id, func): Process `wxEVT_SCROLL_BOTTOM` scroll-to-bottom events (maximum position).
- EVT_COMMAND_SCROLL_LINEUP(id, func): Process `wxEVT_SCROLL_LINEUP` line up events.
- EVT_COMMAND_SCROLL_LINEDOWN(id, func): Process `wxEVT_SCROLL_LINEDOWN` line down events.
- EVT_COMMAND_SCROLL_PAGEUP(id, func): Process `wxEVT_SCROLL_PAGEUP` page up events.
- EVT_COMMAND_SCROLL_PAGEDOWN(id, func): Process `wxEVT_SCROLL_PAGEDOWN` page down events.
- EVT_COMMAND_SCROLL_THUMBTRACK(id, func): Process `wxEVT_SCROLL_THUMBTRACK` thumbtrack events (frequent events sent as the user drags the thumbtrack).
- EVT_COMMAND_SCROLL_THUMBRELEASE(func): Process `wxEVT_SCROLL_THUMBRELEASE` thumb release events.
- EVT_COMMAND_SCROLL_CHANGED(func): Process `wxEVT_SCROLL_CHANGED` end of scrolling events (MSW only).
- EVT_SLIDER(id, func): Process `wxEVT_SLIDER` which is generated after any change of wxSlider position in addition to one of the events above. Notice that the handler of this event receives a wxCommandEvent as argument and not wxScrollEvent, as all the other handlers.

21.690.2 The difference between EVT_SCROLL_THUMBRELEASE and EVT_SCROLL_CHANGED

The EVT_SCROLL_THUMBRELEASE event is only emitted when actually dragging the thumb using the mouse and releasing it (This EVT_SCROLL_THUMBRELEASE event is also followed by an EVT_SCROLL_CHANGED event).

The EVT_SCROLL_CHANGED event also occurs when using the keyboard to change the thumb position, and when clicking next to the thumb (In all these cases the EVT_SCROLL_THUMBRELEASE event does not happen). In short, the EVT_SCROLL_CHANGED event is triggered when scrolling/ moving has finished independently of the way it had started. Please see the widgets sample ("Slider" page) to see the difference between EVT_SCROLL_↩ THUMBRELEASE and EVT_SCROLL_CHANGED in action.

21.690.3 Constructor & Destructor Documentation

wxSlider::wxSlider ( )

Default constructor.

wxSlider::wxSlider (wxWindow * *parent*, wxWindowID *id*, int *value*, int *minValue*, int *maxValue*, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, long *style* = wxSL_HORIZONTAL, const wxValidator & *validator* = wxDefaultValidator, const wxString & *name* = `wxSliderNameStr`)

Constructor, creating and showing a slider.

Parameters

parent	Parent window. Must not be NULL.
id	Window identifier. The value wxID_ANY indicates a default value.
value	Initial position for the slider.
minValue	Minimum slider position.
maxValue	Maximum slider position.
pos	Window position. If wxDefaultPosition is specified then a default position is chosen.
size	Window size. If wxDefaultSize is specified then a default size is chosen.
style	Window style. See wxSlider.
validator	Window validator.
name	Window name.

SetTickFreq()

virtual int wxSlider::GetValue ( ) const [virtual]

Gets the current slider value.

See also

GetMin(), GetMax(), SetValue()

virtual void wxSlider::SetLineSize (int *lineSize*) [virtual]

Sets the line size for the slider.

Parameters

lineSize	The number of steps the slider moves when the user moves it up or down a line.

See also

GetLineSize()

void wxSlider::SetMax (int *maxValue*)

Sets the maximum slider value.

Parameters

maxValue	The new top end of the slider range.

See also

GetMax(), SetRange()

void wxSlider::SetMin (int *minValue*)

Sets the minimum slider value.

Parameters

minValue	The new bottom end of the slider range.

See also

GetMin(), SetRange()

virtual void wxSlider::SetPageSize (int *pageSize*) `[virtual]`

Sets the page size for the slider.

Parameters

pageSize	The number of steps the slider moves when the user pages up or down.

See also

GetPageSize()

virtual void wxSlider::SetRange (int *minValue*, int *maxValue*) `[virtual]`

Sets the minimum and maximum slider values.

See also

GetMin(), GetMax()

virtual void wxSlider::SetSelection (int *startPos*, int *endPos*) `[virtual]`

Sets the selection.

Parameters

startPos	The selection start position.
endPos	The selection end position.

Availability: only available for the wxMSW port.

See also

GetSelStart(), GetSelEnd()

virtual void wxSlider::SetThumbLength (int *len*) `[virtual]`

Sets the slider thumb length.

Parameters

len	The thumb length.

Availability: only available for the wxMSW port.

See also

GetThumbLength()

virtual void wxSlider::SetTick (int *tickPos*) [virtual]

Sets a tick position.

Parameters

tickPos	The tick position.

Availability: only available for the wxMSW port.

See also

SetTickFreq()

virtual void wxSlider::SetTickFreq (int *n*) [virtual]

Sets the tick mark frequency and position.

Parameters

n	Frequency. For example, if the frequency is set to two, a tick mark is displayed for every other increment in the slider's range.

Availability: only available for the wxMSW port.

See also

GetTickFreq()

virtual void wxSlider::SetValue (int *value*) [virtual]

Sets the slider position.

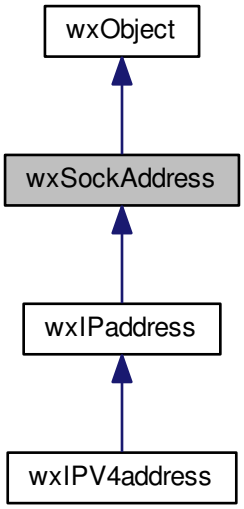
Parameters

value	The slider position.

21.691 wxSockAddress Class Reference

```
#include <wx/socket.h>
```

Inheritance diagram for wxSockAddress:



21.691.1 Detailed Description

You are unlikely to need to use this class: only wxSocketBase uses it.

Public Member Functions

- wxSockAddress ()

  Default constructor.
- virtual ~wxSockAddress ()

  Default destructor.
- virtual void Clear ()

  Delete all information about the address.
- int SockAddrLen ()

  Returns the length of the socket address.
- const sockaddr * GetAddressData () const

  Returns the pointer to the low-level representation of the address.
- int GetAddressDataLen () const

  Returns the length of the buffer retrieved by GetAddressData().

Additional Inherited Members

21.691.2 Constructor & Destructor Documentation

wxSockAddress::wxSockAddress ( )

Default constructor.

virtual wxSockAddress::~wxSockAddress ( ) [virtual]

Default destructor.

21.691.3 Member Function Documentation

virtual void wxSockAddress::Clear ( ) [virtual]

Delete all information about the address.

const sockaddr* wxSockAddress::GetAddressData ( ) const

Returns the pointer to the low-level representation of the address.

This can be used to pass socket address information to a 3rd party library.

Returns

Pointer to a sockaddr-derived struct.

int wxSockAddress::GetAddressDataLen ( ) const

Returns the length of the buffer retrieved by GetAddressData().

Returns

The size of the sockaddr-derived struct corresponding to this address.

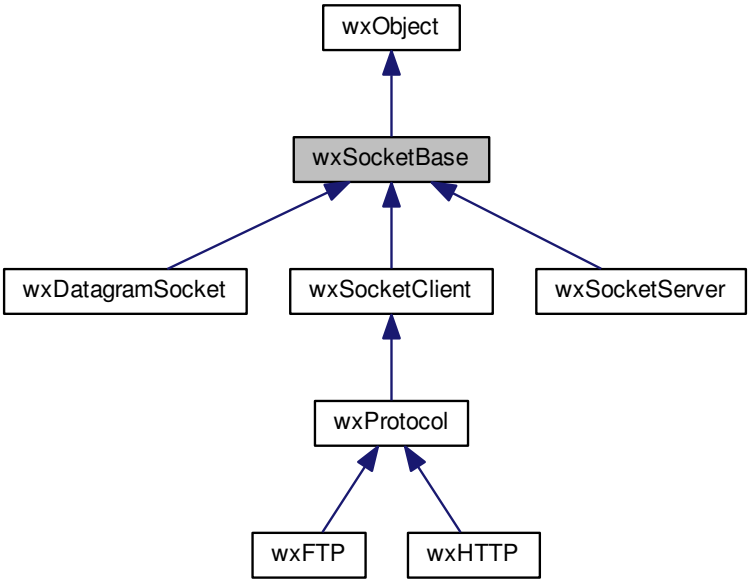
int wxSockAddress::SockAddrLen ( )

Returns the length of the socket address.

21.692 wxSocketBase Class Reference

```
#include <wx/socket.h>
```

Inheritance diagram for wxSocketBase:



21.692.1 Detailed Description

wxSocketBase is the base class for all socket-related objects, and it defines all basic IO functionality.

Note

When using wxSocket from multiple threads, even implicitly (e.g. by using wxFTP or wxHTTP in another thread) you must initialize the sockets from the main thread by calling Initialize() before creating the other ones.

Events emitted by this class

The following event handler macros redirect the events to member function handlers '**func**' with prototypes like: void handlerFuncName(wxSocketEvent& event)

Event macros for events emitted by this class:

- EVT_SOCKET(id, func): Process a `wxEVT_SOCKET` event. See wxSocketEventFlags and wxSocketFlags for more info.

Library: wxNet

Category: Networking

Construction and Destruction

- wxSocketBase ()

  Default constructor.
- virtual ~wxSocketBase ()

  Destructor.
- bool Destroy ()

  Destroys the socket safely.
- static bool Initialize ()

  Perform the initialization needed in order to use the sockets.
- static void Shutdown ()

  Shut down the sockets.

Public Member Functions

Socket State

- bool Error () const

  Returns true if an error occurred in the last IO operation.
- virtual bool GetLocal (wxSockAddress &addr) const

  Return the local address of the socket.
- virtual bool GetPeer (wxSockAddress &addr) const

  Return the peer address field of the socket.
- long GetTimeout () const

  Return the socket timeout in seconds.
- bool IsConnected () const

  Returns true if the socket is connected.
- bool IsData ()

  Check if the socket can be currently read or written.
- bool IsDisconnected () const

  Returns true if the socket is not connected.
- bool IsOk () const

  Returns true if the socket is initialized and ready and false in other cases.
- wxUint32 LastCount () const

  Returns the number of bytes read or written by the last IO call.
- wxUint32 LastReadCount () const

  Returns the number of bytes read by the last Read() or ReadMsg() call (receive direction only).
- wxUint32 LastWriteCount () const

  Returns the number of bytes written by the last Write() or WriteMsg() call (transmit direction only).
- wxSocketError LastError () const

  Returns the last wxSocket error.
- void RestoreState ()

  Restore the previous state of the socket, as saved with SaveState().
- void SaveState ()

  Save the current state of the socket in a stack.

Basic I/O

See also: wxSocketServer::WaitForAccept(), wxSocketClient::WaitOnConnect()

- virtual bool Close ()

  Shut down the socket, disabling further transmission and reception of data and disable events for the socket and frees the associated system resources.
- void ShutdownOutput ()

  Shuts down the writing end of the socket.
- wxSocketBase & Discard ()

  Delete all bytes in the incoming queue.
- wxSocketFlags GetFlags () const

Returns current IO flags, as set with SetFlags()

- void InterruptWait ()

  Use this function to interrupt any wait operation currently in progress.
- wxSocketBase & Peek (void *buffer, wxUint32 nbytes)

  Peek into the socket by copying the next bytes which would be read by Read() into the provided buffer.
- wxSocketBase & Read (void *buffer, wxUint32 nbytes)

  Read up to the given number of bytes from the socket.
- wxSocketBase & ReadMsg (void *buffer, wxUint32 nbytes)

  Receive a message sent by WriteMsg().
- void SetFlags (wxSocketFlags flags)

  Use SetFlags to customize IO operation for this socket.
- virtual bool SetLocal (const wxIPV4address &local)

  Set the local address and port to use.
- void SetTimeout (long seconds)

  Set the default socket timeout in seconds.
- wxSocketBase & Unread (const void *buffer, wxUint32 nbytes)

  Put the specified data into the input queue.
- bool Wait (long seconds=-1, long millisecond=0)

  Wait for any socket event.
- bool WaitForLost (long seconds=-1, long millisecond=0)

  Wait until the connection is lost.
- bool WaitForRead (long seconds=-1, long millisecond=0)

  Wait until the socket is readable.
- bool WaitForWrite (long seconds=-1, long millisecond=0)

  Wait until the socket becomes writable.
- wxSocketBase & Write (const void *buffer, wxUint32 nbytes)

  Write up to the given number of bytes to the socket.
- wxSocketBase & WriteMsg (const void *buffer, wxUint32 nbytes)

  Sends a buffer which can be read using ReadMsg().

Handling Socket Events

- void * GetClientData () const

  Returns a pointer of the client data for this socket, as set with SetClientData()
- void Notify (bool notify)

  According to the notify value, this function enables or disables socket events.
- void SetClientData (void *data)

  Sets user-supplied client data for this socket.
- void SetEventHandler (wxEvtHandler &handler, int id=-1)

  Sets an event handler to be called when a socket event occurs.
- void SetNotify (wxSocketEventFlags flags)

  Specifies which socket events are to be sent to the event handler.
- wxSOCKET_T GetSocket () const

  Returns the native socket descriptor.

Additional Inherited Members

21.692.2 Constructor & Destructor Documentation

wxSocketBase::wxSocketBase ( )

Default constructor.

Don't use it directly; instead, use wxSocketClient to construct a socket client, or wxSocketServer to construct a socket server.

virtual wxSocketBase::~wxSocketBase ( ) [virtual]

Destructor.

Do not destroy a socket using the delete operator directly; use Destroy() instead. Also, do not create socket objects in the stack.

21.692.3 Member Function Documentation

virtual bool wxSocketBase::Close ( ) [virtual]

Shut down the socket, disabling further transmission and reception of data and disable events for the socket and frees the associated system resources.

Upon socket destruction, Close() is automatically called, so in most cases you won't need to do it yourself, unless you explicitly want to shut down the socket, typically to notify the peer that you are closing the connection.

Remarks

Although Close() immediately disables events for the socket, it is possible that event messages may be waiting in the application's event queue. The application must therefore be prepared to handle socket event messages even after calling Close().

Reimplemented in wxFTP.

bool wxSocketBase::Destroy ( )

Destroys the socket safely.

Use this function instead of the delete operator, since otherwise socket events could reach the application even after the socket has been destroyed. To prevent this problem, this function appends the wxSocket to a list of object to be deleted on idle time, after all events have been processed. For the same reason, you should avoid creating socket objects in the stack.

Destroy() calls Close() automatically.

Returns

Always true.

wxSocketBase& wxSocketBase::Discard ( )

Delete all bytes in the incoming queue.

This function always returns immediately and its operation is not affected by IO flags.

Use LastCount() to verify the number of bytes actually discarded.

If you use Error(), it will always return false.

bool wxSocketBase::Error ( ) const

Returns true if an error occurred in the last IO operation.

Use this function to check for an error condition after one of the following calls: Discard(), Peek(), Read(), ReadMsg(), Unread(), Write(), WriteMsg().

void* wxSocketBase::GetClientData ( ) const

Returns a pointer of the client data for this socket, as set with SetClientData()

wxSocketFlags wxSocketBase::GetFlags ( ) const

Returns current IO flags, as set with SetFlags()

virtual bool wxSocketBase::GetLocal (wxSockAddress & *addr*) const [virtual]

Return the local address of the socket.

Returns

true if no error happened, false otherwise.

virtual bool wxSocketBase::GetPeer (wxSockAddress & *addr*) const [virtual]

Return the peer address field of the socket.

Returns

true if no error happened, false otherwise.

wxSOCKET_T wxSocketBase::GetSocket ( ) const

Returns the native socket descriptor.

This is intended to use with rarely used specific platform features that can only be accessed via the actual socket descriptor.

Do not use this for reading or writing data from or to the socket as this would almost surely interfere with wxSocket code logic and result in unexpected behaviour.

The socket must be successfully initialized, e.g. connected for client sockets, before this method can be called.

Returns

Returns the native socket descriptor.

Since

2.9.5

long wxSocketBase::GetTimeout ( ) const

Return the socket timeout in seconds.

The timeout can be set using SetTimeout() and is 10 minutes by default.

static bool wxSocketBase::Initialize ( ) [static]

Perform the initialization needed in order to use the sockets.

This function is called from wxSocket constructor implicitly and so normally doesn't need to be called explicitly. There is however one important exception: as this function must be called from the main (UI) thread, if you use wxSocket from multiple threads you must call Initialize() from the main thread before creating wxSocket objects in the other ones.

It is safe to call this function multiple times (only the first call does anything) but you must call Shutdown() exactly once for every call to Initialize().

This function should only be called from the main thread.

Returns

true if the sockets can be used, false if the initialization failed and sockets are not available at all.

void wxSocketBase::InterruptWait ( )

Use this function to interrupt any wait operation currently in progress.

Note that this is not intended as a regular way to interrupt a Wait call, but only as an escape mechanism for exceptional situations where it is absolutely necessary to use it, for example to abort an operation due to some exception or abnormal problem. InterruptWait is automatically called when you Close() a socket (and thus also upon socket destruction), so you don't need to use it in these cases.

See also

Wait(), WaitForLost(), WaitForRead(), WaitForWrite(), wxSocketServer::WaitForAccept(), wxSocketClient::↩ WaitOnConnect()

bool wxSocketBase::IsConnected ( ) const

Returns true if the socket is connected.

bool wxSocketBase::IsData ( )

Check if the socket can be currently read or written.

This might mean that queued data is available for reading or, for streamed sockets, that the connection has been closed, so that a read operation will complete immediately without blocking (unless the **wxSOCKET_WAITALL** flag is set, in which case the operation might still block).

bool wxSocketBase::IsDisconnected ( ) const

Returns true if the socket is not connected.

bool wxSocketBase::IsOk ( ) const

Returns true if the socket is initialized and ready and false in other cases.

Remarks

For wxSocketClient, IsOk() won't return true unless the client is connected to a server. For wxSocketServer, IsOk() will return true if the server could bind to the specified address and is already listening for new connections. IsOk() does not check for IO errors; use Error() instead for that purpose.

wxUint32 wxSocketBase::LastCount ( ) const

Returns the number of bytes read or written by the last IO call.

Use this function to get the number of bytes actually transferred after using one of the following IO calls: Discard(), Peek(), Read(), ReadMsg(), Unread(), Write(), WriteMsg().

Deprecated This function is kept mostly for backwards compatibility. Use LastReadCount() or LastWriteCount() instead. LastCount() is still needed for use with less commonly used functions: Discard(), Peek(), and Unread().

wxSocketError wxSocketBase::LastError ( ) const

Returns the last wxSocket error.

See wxSocketError .

Note

This function merely returns the last error code, but it should not be used to determine if an error has occurred (this is because successful operations do not change the LastError value). Use Error() first, in order to determine if the last IO call failed. If this returns true, use LastError() to discover the cause of the error.

wxUint32 wxSocketBase::LastReadCount ( ) const

Returns the number of bytes read by the last Read() or ReadMsg() call (receive direction only).

This function is thread-safe, in case Read() is executed in a different thread than Write(). Use LastReadCount() instead of LastCount() for this reason.

Unlike LastCount(), the functions Discard(), Peek(), and Unread() are currently not supported by LastReadCount().

Since

2.9.5

wxUint32 wxSocketBase::LastWriteCount ( ) const

Returns the number of bytes written by the last Write() or WriteMsg() call (transmit direction only).

This function is thread-safe, in case Write() is executed in a different thread than Read(). Use LastWriteCount() instead of LastCount() for this reason.

Since

2.9.5

void wxSocketBase::Notify (bool *notify*)

According to the *notify* value, this function enables or disables socket events.

If *notify* is true, the events configured with SetNotify() will be sent to the application. If *notify* is false; no events will be sent.

wxSocketBase& wxSocketBase::Peek (void * *buffer,* wxUint32 *nbytes*)

Peek into the socket by copying the next bytes which would be read by Read() into the provided buffer.

Peeking a buffer doesn't delete it from the socket input queue, i.e. calling Read() will return the same data.

Use LastCount() to verify the number of bytes actually peeked.

Use Error() to determine if the operation succeeded.

Parameters

buffer	Buffer where to put peeked data.
nbytes	Number of bytes.

Returns

Returns a reference to the current object.

Remarks

The exact behaviour of Peek() depends on the combination of flags being used. For a detailed explanation, see SetFlags()

See also

Error(), LastError(), LastCount(), SetFlags()

wxSocketBase& wxSocketBase::Read (void * *buffer*, wxUint32 *nbytes*)

Read up to the given number of bytes from the socket.

Use LastReadCount() to verify the number of bytes actually read. Use Error() to determine if the operation succeeded.

Parameters

buffer	Buffer where to put read data.
nbytes	Number of bytes.

Returns

Returns a reference to the current object.

Remarks

The exact behaviour of Read() depends on the combination of flags being used. For a detailed explanation, see SetFlags()

See also

Error(), LastError(), LastReadCount(), SetFlags()

wxSocketBase& wxSocketBase::ReadMsg (void * *buffer*, wxUint32 *nbytes*)

Receive a message sent by WriteMsg().

If the buffer passed to the function isn't big enough, the remaining bytes will be discarded. This function always waits for the buffer to be entirely filled, unless an error occurs.

Use LastReadCount() to verify the number of bytes actually read.

Use Error() to determine if the operation succeeded.

Parameters

buffer	Buffer where to put read data.
nbytes	Size of the buffer.

Returns

Returns a reference to the current object.

Remarks

ReadMsg() will behave as if the **wxSOCKET_WAITALL** flag was always set and it will always ignore the **wx↩ SOCKET_NOWAIT** flag. The exact behaviour of ReadMsg() depends on the **wxSOCKET_BLOCK** flag. For a detailed explanation, see SetFlags(). For thread safety, in case ReadMsg() and WriteMsg() are called in different threads, it is a good idea to call SetFlags(wxSOCKET_WAITALL|wx_SOCKET_BLOCK) before the first calls to ReadMsg() and WriteMsg() in different threads, as each of these functions will call SetFlags() which performs read/modify/write. By setting these flags before the multi-threading, it will ensure that they don't get reset by thread race conditions.

See also

Error(), LastError(), LastReadCount(), SetFlags(), WriteMsg()

void wxSocketBase::RestoreState ( )

Restore the previous state of the socket, as saved with SaveState().

Calls to SaveState() and RestoreState() can be nested.

See also

SaveState()

void wxSocketBase::SaveState ( )

Save the current state of the socket in a stack.

Socket state includes flags, as set with SetFlags(), event mask, as set with SetNotify() and Notify(), user data, as set with SetClientData(). Calls to SaveState and RestoreState can be nested.

See also

RestoreState()

void wxSocketBase::SetClientData (void * *data*)

Sets user-supplied client data for this socket.

All socket events will contain a pointer to this data, which can be retrieved with the wxSocketEvent::GetClientData() function.

void wxSocketBase::SetEventHandler (**wxEvtHandler** & *handler,* int *id* = -1)

Sets an event handler to be called when a socket event occurs.

The handler will be called for those events for which notification is enabled with SetNotify() and Notify().

Parameters

handler	Specifies the event handler you want to use.
id	The id of socket event.

See also

SetNotify(), Notify(), wxSocketEvent, wxEvtHandler

void wxSocketBase::SetFlags (wxSocketFlags *flags*)

Use SetFlags to customize IO operation for this socket.

The *flags* parameter may be a combination of flags ORed together. Notice that not all combinations of flags affecting the IO calls (Read() and Write()) make sense, e.g. **wxSOCKET_NOWAIT** can't be combined with **wxSOCKET_WAITALL** nor with **wxSOCKET_BLOCK**.

The following flags can be used:

- wxSOCKET_NONE: Default mode: the socket will read some data in the IO calls and will process events to avoid blocking UI while waiting for the data to become available.
- wxSOCKET_NOWAIT: Don't wait for the socket to become ready in IO calls, read as much data as is available – potentially 0 bytes – and return immediately.
- wxSOCKET_WAITALL: Don't return before the entire amount of data specified in IO calls is read or written unless an error occurs. If this flag is not specified, the IO calls return as soon as any amount of data, even less than the total number of bytes, is processed.
- wxSOCKET_BLOCK: Don't process the UI events while waiting for the socket to become ready. This means that UI will be unresponsive during socket IO.
- wxSOCKET_REUSEADDR: Allows the use of an in-use port (wxServerSocket only).
- wxSOCKET_BROADCAST: Switches the socket to broadcast mode.
- wxSOCKET_NOBIND: Stops the socket from being bound to a specific adapter (normally used in conjunction with **wxSOCKET_BROADCAST**).

For more information on socket events see wxSocketFlags .

virtual bool wxSocketBase::SetLocal (const wxIPV4address & *local*) [virtual]

Set the local address and port to use.

This function must always be called for the server sockets but may also be called for client sockets, if it is, **bind()** is called before **connect()**.

void wxSocketBase::SetNotify (wxSocketEventFlags *flags*)

Specifies which socket events are to be sent to the event handler.

The *flags* parameter may be combination of flags ORed together. The following flags can be used:

- wxSOCKET_INPUT_FLAG: to receive **wxSOCKET_INPUT**.
- wxSOCKET_OUTPUT_FLAG: to receive **wxSOCKET_OUTPUT**.
- wxSOCKET_CONNECTION_FLAG: to receive **wxSOCKET_CONNECTION**.
- wxSOCKET_LOST_FLAG: to receive **wxSOCKET_LOST**.

For example:

```
sock.SetNotify(wxSOCKET_INPUT_FLAG | wxSOCKET_LOST_FLAG);
sock.Notify(true);
```

In this example, the user will be notified about incoming socket data and whenever the connection is closed.

For more information on socket events see wxSocketEventFlags .

void wxSocketBase::SetTimeout (long *seconds*)

Set the default socket timeout in seconds.

This timeout applies to all IO calls, and also to the Wait() family of functions if you don't specify a wait interval. Initially, the default timeout is 10 minutes.

static void wxSocketBase::Shutdown ( ) [static]

Shut down the sockets.

This function undoes the call to Initialize() and must be called after every successful call to Initialize().

This function should only be called from the main thread, just as Initialize().

void wxSocketBase::ShutdownOutput ( )

Shuts down the writing end of the socket.

This function simply calls the standard shutdown() function on the underlying socket, indicating that nothing will be written to this socket any more.

wxSocketBase& wxSocketBase::Unread (const void * *buffer*, wxUint32 *nbytes*)

Put the specified data into the input queue.

The data in the buffer will be returned by the next call to Read().

This function is not affected by wxSocket flags.

If you use LastCount(), it will always return *nbytes*.

If you use Error(), it will always return false.

Parameters

buffer	Buffer to be unread.
nbytes	Number of bytes.

Returns

Returns a reference to the current object.

See also

Error(), LastCount(), LastError()

bool wxSocketBase::Wait (long *seconds* = -1, long *millisecond* = 0)

Wait for any socket event.

Possible socket events are:

- The socket becomes readable.
- The socket becomes writable.
- An ongoing connection request has completed (wxSocketClient only)
- An incoming connection request has arrived (wxSocketServer only)
- The connection has been closed.

Note that it is recommended to use the individual **WaitForXXX()** functions to wait for the required condition, instead of this one.

Parameters

seconds	Number of seconds to wait. If -1, it will wait for the default timeout, as set with SetTimeout().
millisecond	Number of milliseconds to wait.

Returns

true when any of the above conditions is satisfied or false if the timeout was reached.

See also

InterruptWait(), wxSocketServer::WaitForAccept(), WaitForLost(), WaitForRead(), WaitForWrite(), wxSocketClient::WaitOnConnect()

bool wxSocketBase::WaitForLost (long *seconds* = -1, long *millisecond* = 0)

Wait until the connection is lost.

This may happen if the peer gracefully closes the connection or if the connection breaks.

Parameters

seconds	Number of seconds to wait. If -1, it will wait for the default timeout, as set with SetTimeout().
millisecond	Number of milliseconds to wait.

Returns

Returns true if the connection was lost, false if the timeout was reached.

See also

InterruptWait(), Wait()

bool wxSocketBase::WaitForRead (long *seconds* = -1, long *millisecond* = 0)

Wait until the socket is readable.

This might mean that queued data is available for reading or, for streamed sockets, that the connection has been closed, so that a read operation will complete immediately without blocking (unless the **wxSOCKET_WAITALL** flag is set, in which case the operation might still block).

Notice that this function should not be called if there is already data available for reading on the socket.

Parameters

seconds	Number of seconds to wait. If -1, it will wait for the default timeout, as set with SetTimeout().
millisecond	Number of milliseconds to wait.

Returns

Returns true if the socket becomes readable, false on timeout.

See also

InterruptWait(), Wait()

bool wxSocketBase::WaitForWrite (long *seconds* = -1, long *millisecond* = 0)

Wait until the socket becomes writable.

This might mean that the socket is ready to send new data, or for streamed sockets, that the connection has been closed, so that a write operation is guaranteed to complete immediately (unless the **wxSOCKET_WAITALL** flag is set, in which case the operation might still block).

Notice that this function should not be called if the socket is already writable.

Parameters

seconds	Number of seconds to wait. If -1, it will wait for the default timeout, as set with SetTimeout().
millisecond	Number of milliseconds to wait.

Returns

Returns true if the socket becomes writable, false on timeout.

See also

InterruptWait(), Wait()

wxSocketBase& wxSocketBase::Write (const void * *buffer*, wxUint32 *nbytes*)

Write up to the given number of bytes to the socket.

Use LastWriteCount() to verify the number of bytes actually written.

Use Error() to determine if the operation succeeded.

Parameters

buffer	Buffer with the data to be sent.
nbytes	Number of bytes.

Returns

Returns a reference to the current object.

Remarks

The exact behaviour of Write() depends on the combination of flags being used. For a detailed explanation, see SetFlags().

See also

Error(), LastError(), LastWriteCount(), SetFlags()

wxSocketBase& wxSocketBase::WriteMsg (const void * *buffer*, wxUint32 *nbytes*)

Sends a buffer which can be read using ReadMsg().

WriteMsg() sends a short header before the data so that ReadMsg() knows how much data should be actually read.

This function always waits for the entire buffer to be sent, unless an error occurs.

Use LastWriteCount() to verify the number of bytes actually written.

Use Error() to determine if the operation succeeded.

Parameters

buffer	Buffer with the data to be sent.
nbytes	Number of bytes to send.

Returns

Returns a reference to the current object.

Remarks

WriteMsg() will behave as if the **wxSOCKET_WAITALL** flag was always set and it will always ignore the **wxSOCKET_NOWAIT** flag. The exact behaviour of WriteMsg() depends on the **wxSOCKET_BLOCK** flag. For a detailed explanation, see SetFlags(). For thread safety, in case ReadMsg() and WriteMsg() are called in different threads, it is a good idea to call

```
SetFlags(wxSOCKET_WAITALL|wx_SOCKET_BLOCK)
```

before the first calls to ReadMsg() and WriteMsg() in different threads, as each of these functions calls SetFlags() which performs read/modify/write. By setting these flags before the multi-threading, it will ensure that they don't get reset by thread race conditions.

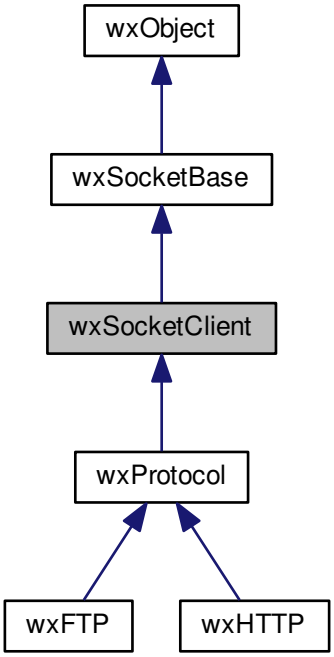
Error(), LastError(), LastWriteCount(), SetFlags(), ReadMsg()

21.693 wxSocketClient Class Reference

```
#include <wx/socket.h>
```

Inheritance diagram for wxSocketClient:



21.693.1 Detailed Description

Todo describe me.

Library: wxNet

Category: Networking

Public Member Functions

- wxSocketClient (wxSocketFlags flags=wxSOCKET_NONE)

  Constructor.
- virtual ~wxSocketClient ()

  Destructor.
- virtual bool Connect (const wxSockAddress &address, bool wait=true)

  Connects to a server using the specified address.
- bool Connect (const wxSockAddress &address, const wxSockAddress &local, bool wait=true)

  Connects to a server using the specified address.
- bool WaitOnConnect (long seconds=-1, long milliseconds=0)

  Wait until a connection request completes, or until the specified timeout elapses.

Additional Inherited Members

21.693.2 Constructor & Destructor Documentation

wxSocketClient::wxSocketClient (wxSocketFlags *flags* = wxSOCKET_NONE)

Constructor.

Parameters

flags	Socket flags (See wxSocketBase::SetFlags())

virtual wxSocketClient::~wxSocketClient ( ) [virtual]

Destructor.

Please see wxSocketBase::Destroy().

21.693.3 Member Function Documentation

virtual bool wxSocketClient::Connect (const wxSockAddress & *address*, bool *wait* = true) [virtual]

Connects to a server using the specified address.

If *wait* is true, Connect() will wait until the connection completes.

Warning

This method will block the GUI.

If *wait* is false, Connect() will try to establish the connection and return immediately, without blocking the GUI. When used this way, even if Connect() returns false, the connection request can be completed later. To detect this, use WaitOnConnect(), or catch **wxSOCKET_CONNECTION** events (for successful establishment) and **wxSOCKET_LOST** events (for connection failure).

Parameters

address	Address of the server.
wait	If true, waits for the connection to complete.

Returns

true if the connection is established and no error occurs. If *wait* was true, and Connect() returns false, an error occurred and the connection failed. If *wait* was false, and Connect() returns false, you should still be prepared to handle the completion of this connection request, either with WaitOnConnect() or by watching wxSOCKET_CONNECTION and wxSOCKET_LOST events.

See also

WaitOnConnect(), wxSocketBase::SetNotify(), wxSocketBase::Notify()

Reimplemented in wxHTTP.

bool wxSocketClient::Connect (const wxSockAddress & *address*, const wxSockAddress & *local*, bool *wait* = true)

Connects to a server using the specified address.

If *wait* is true, Connect() will wait until the connection completes. **Warning:** This will block the GUI.

If *wait* is false, Connect() will try to establish the connection and return immediately, without blocking the GUI. When used this way, even if Connect() returns false, the connection request can be completed later. To detect this, use WaitOnConnect(), or catch **wxSOCKET_CONNECTION** events (for successful establishment) and **wxSOCKET_LOST** events (for connection failure).

Parameters

address	Address of the server.
local	Bind to the specified local address and port before connecting. The local address and port can also be set using SetLocal(), and then using the 2-parameter Connect() method.
wait	If true, waits for the connection to complete.

Returns

true if the connection is established and no error occurs. If *wait* was true, and Connect() returns false, an error occurred and the connection failed. If *wait* was false, and Connect() returns false, you should still be prepared to handle the completion of this connection request, either with WaitOnConnect() or by watching wxSOCKET_CONNECTION and wxSOCKET_LOST events.

See also

WaitOnConnect(), wxSocketBase::SetNotify(), wxSocketBase::Notify()

bool wxSocketClient::WaitOnConnect (long *seconds* = -1, long *milliseconds* = 0)

Wait until a connection request completes, or until the specified timeout elapses.

Use this function after issuing a call to Connect() with *wait* set to false.

Parameters

seconds	Number of seconds to wait. If -1, it will wait for the default timeout, as set with wxSocketBase::SetTimeout().
milliseconds	Number of milliseconds to wait.

Returns

WaitOnConnect() returns true if the connection request completes. This does not necessarily mean that the connection was successfully established; it might also happen that the connection was refused by the peer. Use wxSocketBase::IsConnected() to distinguish between these two situations.

If the timeout elapses, WaitOnConnect() returns false.

These semantics allow code like this:

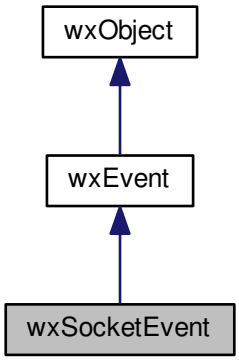
```
// Issue the connection request
client->Connect(addr, false);

// Wait until the request completes or until we decide to give up
bool waitmore = true;
while ( !client->WaitOnConnect(seconds, millis) && waitmore )
{
    // possibly give some feedback to the user,
    // and update waitmore as needed.
}
bool success = client->IsConnected();
```

21.694 wxSocketEvent Class Reference

`#include <wx/socket.h>`

Inheritance diagram for wxSocketEvent:



21.694.1 Detailed Description

This event class contains information about socket events.

This kind of events are sent to the event handler specified with wxSocketBase::SetEventHandler.

Events using this class

The following event handler macros redirect the events to member function handlers '**func**' with prototypes like: void handlerFuncName(wxSocketEvent& event)

Event macros:

- EVT_SOCKET(id, func): Process a socket event, supplying the member function.

Library: wxNet

Category: Networking

See also

wxSocketBase, wxSocketClient, wxSocketServer

Public Member Functions

- wxSocketEvent (int id=0)

  Constructor.
- void * GetClientData () const

  Gets the client data of the socket which generated this event, as set with wxSocketBase::SetClientData().
- wxSocketBase * GetSocket () const

  Returns the socket object to which this event refers to.
- wxSocketNotify GetSocketEvent () const

  Returns the socket event type.

Additional Inherited Members

21.694.2 Constructor & Destructor Documentation

wxSocketEvent::wxSocketEvent (int *id* = 0)

Constructor.

21.694.3 Member Function Documentation

void* wxSocketEvent::GetClientData ( ) const

Gets the client data of the socket which generated this event, as set with wxSocketBase::SetClientData().

wxSocketBase* wxSocketEvent::GetSocket ( ) const

Returns the socket object to which this event refers to.

This makes it possible to use the same event handler for different sockets.

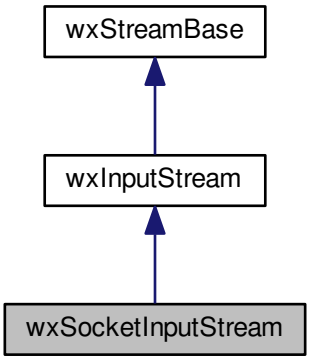
wxSocketNotify wxSocketEvent::GetSocketEvent ( ) const

Returns the socket event type.

21.695 wxSocketInputStream Class Reference

`#include <wx/sckstrm.h>`

Inheritance diagram for wxSocketInputStream:



21.695.1 Detailed Description

This class implements an input stream which reads data from a connected socket.

Note that this stream is purely sequential and it does not support seeking.

Library: wxNet

Category: Networking, Streams

See also

wxSocketBase

Public Member Functions

- wxSocketInputStream (wxSocketBase &s)

  Creates a new read-only socket stream using the specified initialized socket connection.

Additional Inherited Members

21.695.2 Constructor & Destructor Documentation

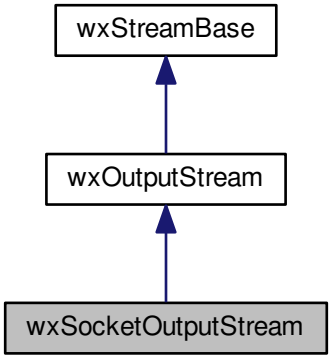
wxSocketInputStream::wxSocketInputStream (wxSocketBase & *s*)

Creates a new read-only socket stream using the specified initialized socket connection.

21.696 wxSocketOutputStream Class Reference

`#include <wx/sckstrm.h>`

Inheritance diagram for wxSocketOutputStream:



21.696.1 Detailed Description

This class implements an output stream which writes data from a connected socket.

Note that this stream is purely sequential and it does not support seeking.

Library: wxNet

Category: Networking, Streams

See also

wxSocketBase

Public Member Functions

- wxSocketOutputStream (wxSocketBase &s)

  Creates a new write-only socket stream using the specified initialized socket connection.

Additional Inherited Members

21.696.2 Constructor & Destructor Documentation

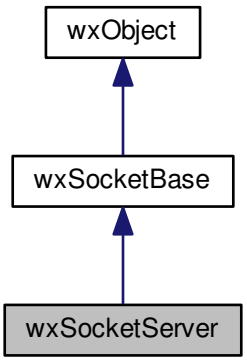
wxSocketOutputStream::wxSocketOutputStream (wxSocketBase & *s*)

Creates a new write-only socket stream using the specified initialized socket connection.

21.697 wxSocketServer Class Reference

```
#include <wx/socket.h>
```

Inheritance diagram for wxSocketServer:



21.697.1 Detailed Description

Todo describe me.

Library: wxNet

Category: Networking

Public Member Functions

- wxSocketServer (const wxSockAddress &address, wxSocketFlags flags=wxSOCKET_NONE)

  Constructs a new server and tries to bind to the specified address.
- virtual ~wxSocketServer ()

  Destructor (it doesn't close the accepted connections).
- wxSocketBase * Accept (bool wait=true)

  Accepts an incoming connection request, and creates a new wxSocketBase object which represents the server-side of the connection.
- bool AcceptWith (wxSocketBase &socket, bool wait=true)

  Accept an incoming connection using the specified socket object.
- bool WaitForAccept (long seconds=-1, long millisecond=0)

  Wait for an incoming connection.

Additional Inherited Members

21.697.2 Constructor & Destructor Documentation

wxSocketServer::wxSocketServer (const wxSockAddress & *address*, wxSocketFlags *flags* = wxSOCKET_NONE)

Constructs a new server and tries to bind to the specified *address*.

Before trying to accept new connections, remember to test whether it succeeded with wxSocketBase:IsOk().

Parameters

address	Specifies the local address for the server (e.g. port number).
flags	Socket flags (See wxSocketBase::SetFlags()).

virtual wxSocketServer::~wxSocketServer ( ) [virtual]

Destructor (it doesn't close the accepted connections).

21.697.3 Member Function Documentation

wxSocketBase* wxSocketServer::Accept (bool *wait* = true)

Accepts an incoming connection request, and creates a new wxSocketBase object which represents the server-side of the connection.

If *wait* is true and there are no pending connections to be accepted, it will wait for the next incoming connection to arrive.

Warning

This method will block the GUI.

If *wait* is false, it will try to accept a pending connection if there is one, but it will always return immediately without blocking the GUI. If you want to use Accept() in this way, you can either check for incoming connections with WaitForAccept() or catch **wxSOCKET_CONNECTION** events, then call Accept() once you know that there is an incoming connection waiting to be accepted.

Returns

Returns an opened socket connection, or NULL if an error occurred or if the wait parameter was false and there were no pending connections.

See also

WaitForAccept(), wxSocketBase::SetNotify(), wxSocketBase::Notify(), AcceptWith()

bool wxSocketServer::AcceptWith (wxSocketBase & *socket*, bool *wait* = `true`)

Accept an incoming connection using the specified socket object.

Parameters

socket	Socket to be initialized
wait	See Accept() for more info.

Returns

Returns true on success, or false if an error occurred or if the wait parameter was false and there were no pending connections.

See also

WaitForAccept(), wxSocketBase::SetNotify(), wxSocketBase::Notify(), Accept()

bool wxSocketServer::WaitForAccept (long *seconds* = `-1`, long *millisecond* = `0`)

Wait for an incoming connection.

Use it if you want to call Accept() or AcceptWith() with *wait* set to false, to detect when an incoming connection is waiting to be accepted.

Parameters

seconds	Number of seconds to wait. If -1, it will wait for the default timeout, as set with wxSocketBase::SetTimeout().
millisecond	Number of milliseconds to wait.

Returns

true if an incoming connection arrived, false if the timeout elapsed.

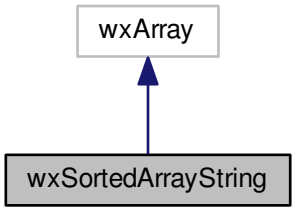
See also

Accept(), AcceptWith(), wxSocketBase::InterruptWait()

21.698 wxSortedArrayString Class Reference

`#include <wx/arrstr.h>`

Inheritance diagram for wxSortedArrayString:



21.698.1 Detailed Description

wxSortedArrayString is an efficient container for storing wxString objects which always keeps the string in alphabetical order.

wxSortedArrayString uses binary search in its wxSortedArrayString::Index() method (instead of linear search for wxArrayString::Index()) which makes it much more efficient if you add strings to the array rarely (because, of course, you have to pay for Index() efficiency by having Add() be slower) but search for them often. Several methods should not be used with sorted array (basically, all those which break the order of items) which is mentioned in their description.

Library: wxBase

Category: Containers

See also

wxArray, wxString, wxString Overview

Public Member Functions

- wxSortedArrayString ()

  Default constructor.
- wxSortedArrayString (CompareFunction compareFunction)

  Constructs a sorted array using the specified compareFunction for item comparison.
- wxSortedArrayString (const wxArrayString &array)

  Conversion constructor.
- size_t Add (const wxString &str, size_t copies=1)

  Appends the given number of copies of the new item str to the array and returns the index of the first new item in the array.
- int Index (const wxString &sz, bool bCase=true, bool bFromEnd=false) const

  Search the element in the array, starting from the beginning if bFromEnd is false or from end otherwise.
- void Insert (const wxString &str, size_t nIndex, size_t copies=1)

- void Sort (bool reverseOrder=false)
- void Sort (CompareFunction compareFunction)

21.698.2 Constructor & Destructor Documentation

wxSortedArrayString::wxSortedArrayString ( )

Default constructor.

The elements of the array are kept sorted in alphabetical order.

wxSortedArrayString::wxSortedArrayString (CompareFunction *compareFunction*)

Constructs a sorted array using the specified *compareFunction* for item comparison.

See also

wxStringSortAscending(), wxDictionaryStringSortAscending()

Since

3.1.0

wxSortedArrayString::wxSortedArrayString (const wxArrayString & *array*)

Conversion constructor.

Constructs a sorted array with the same contents as the (possibly unsorted) "array" argument.

21.698.3 Member Function Documentation

size_t wxSortedArrayString::Add (const wxString & *str*, size_t *copies* = `1`)

Appends the given number of *copies* of the new item *str* to the array and returns the index of the first new item in the array.

See also

Insert()

Warning

For sorted arrays, the index of the inserted item will not be, in general, equal to GetCount() - 1 because the item is inserted at the correct position to keep the array sorted and not appended.

int wxSortedArrayString::Index (const wxString & *sz*, bool *bCase* = `true`, bool *bFromEnd* = `false`) const

Search the element in the array, starting from the beginning if *bFromEnd* is false or from end otherwise.

If *bCase*, comparison is case sensitive (default), otherwise the case is ignored.

This function uses linear search for wxArrayString. Returns index of the first item matched or `wxNOT_FOUND` if there is no match.

This function uses binary search for wxSortedArrayString, but it ignores the *bCase* and *bFromEnd* parameters.

void wxSortedArrayString::Insert (const wxString & *str,* size_t *nIndex,* size_t *copies* = `1`)

Warning

This function should not be used with sorted arrays because it could break the order of items and, for example, subsequent calls to Index() would then not work!
In STL mode, Insert is private and simply invokes wxFAIL_MSG.

void wxSortedArrayString::Sort (bool *reverseOrder* = `false`)

Warning

This function should not be used with sorted array because it could break the order of items and, for example, subsequent calls to Index() would then not work! Also, sorting a wxSortedArrayString doesn't make sense because its elements are always already sorted.
In STL mode, Sort is private and simply invokes wxFAIL_MSG.

void wxSortedArrayString::Sort (CompareFunction *compareFunction*)

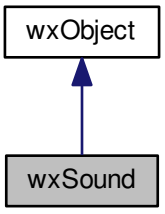
Warning

This function should not be used with sorted array because it could break the order of items and, for example, subsequent calls to Index() would then not work! Also, sorting a wxSortedArrayString doesn't make sense because its elements are always already sorted.
In STL mode, Sort is private and simply invokes wxFAIL_MSG.

21.699 wxSound Class Reference

`#include <wx/sound.h>`

Inheritance diagram for wxSound:



21.699.1 Detailed Description

This class represents a short sound (loaded from Windows WAV file), that can be stored in memory and played.

Currently this class is implemented on Windows and Unix (and uses either Open Sound System or Simple Direct↩ Media Layer).

Library: wxAdvanced

Category: Multimedia

- bool Play (unsigned flags=wxSOUND_ASYNC) const

  Plays the sound file.
- static bool Play (const wxString &filename, unsigned flags=wxSOUND_ASYNC)

  Plays the sound file.

Public Member Functions

- wxSound ()

  Default ctor.
- wxSound (const wxString &fileName, bool isResource=false)

  Constructs a wave object from a file or, under Windows, from a Windows resource.
- wxSound (size_t size, const void *data)

  Constructs a wave object from in-memory data.
- virtual ~wxSound ()

  Destroys the wxSound object.
- bool Create (const wxString &fileName, bool isResource=false)

  Constructs a wave object from a file or resource.
- bool Create (size_t size, const void *data)

  Constructs a wave object from in-memory data.
- bool IsOk () const

  Returns true if the object contains a successfully loaded file or resource, false otherwise.

Static Public Member Functions

- static bool IsPlaying ()

  Returns true if a sound is played at the moment.
- static void Stop ()

  If a sound is played, this function stops it.

Additional Inherited Members

21.699.2 Constructor & Destructor Documentation

wxSound::wxSound ( )

Default ctor.

wxSound::wxSound (const wxString & *fileName*, bool *isResource* = `false`)

Constructs a wave object from a file or, under Windows, from a Windows resource.

Call IsOk() to determine whether this succeeded.

Parameters

fileName	The filename or Windows resource.
isResource	true if fileName is a resource, false if it is a filename.

wxSound::wxSound (size_t *size*, const void * *data*)

Constructs a wave object from in-memory data.

Parameters

size	Size of the buffer pointer to by *data*.
data	The buffer containing the sound data in WAV format.

virtual wxSound::~wxSound ( ) [virtual]

Destroys the wxSound object.

21.699.3 Member Function Documentation

bool wxSound::Create (const wxString & *fileName*, bool *isResource* = false)

Constructs a wave object from a file or resource.

Parameters

fileName	The filename or Windows resource.
isResource	true if fileName is a resource, false if it is a filename.

Returns

true if the call was successful, false otherwise.

bool wxSound::Create (size_t *size*, const void * *data*)

Constructs a wave object from in-memory data.

Parameters

size	Size of the buffer pointer to by *data*.
data	The buffer containing the sound data in WAV format.

bool wxSound::IsOk ( ) const

Returns true if the object contains a successfully loaded file or resource, false otherwise.

static bool wxSound::IsPlaying ( ) [static]

Returns true if a sound is played at the moment.

This method is currently not available under Windows and may not be always implemented in Unix ports depending on the compilation options used (in this case it just always returns false).

Availability: only available for the wxGTK, wxOSX ports.

bool wxSound::Play (unsigned *flags* = wxSOUND_ASYNC) const

Plays the sound file.

If another sound is playing, it will be interrupted.

Returns true on success, false otherwise. Note that in general it is possible to delete the object which is being asynchronously played any time after calling this function and the sound would continue playing, however this currently doesn't work under Windows for sound objects loaded from memory data.

The possible values for *flags* are:

- wxSOUND_SYNC: `Play` will block and wait until the sound is replayed.
- wxSOUND_ASYNC: Sound is played asynchronously, `Play` returns immediately.
- wxSOUND_ASYNC|wxSOUND_LOOP: Sound is played asynchronously and loops until another sound is played, Stop() is called or the program terminates.

The static form is shorthand for this code:

```
wxSound(filename).Play(flags);
```

static bool wxSound::Play (const wxString & *filename*, unsigned *flags* = wxSOUND_ASYNC) [static]

Plays the sound file.

If another sound is playing, it will be interrupted.

Returns true on success, false otherwise. Note that in general it is possible to delete the object which is being asynchronously played any time after calling this function and the sound would continue playing, however this currently doesn't work under Windows for sound objects loaded from memory data.

The possible values for *flags* are:

- wxSOUND_SYNC: `Play` will block and wait until the sound is replayed.
- wxSOUND_ASYNC: Sound is played asynchronously, `Play` returns immediately.
- wxSOUND_ASYNC|wxSOUND_LOOP: Sound is played asynchronously and loops until another sound is played, Stop() is called or the program terminates.

The static form is shorthand for this code:

```
wxSound(filename).Play(flags);
```

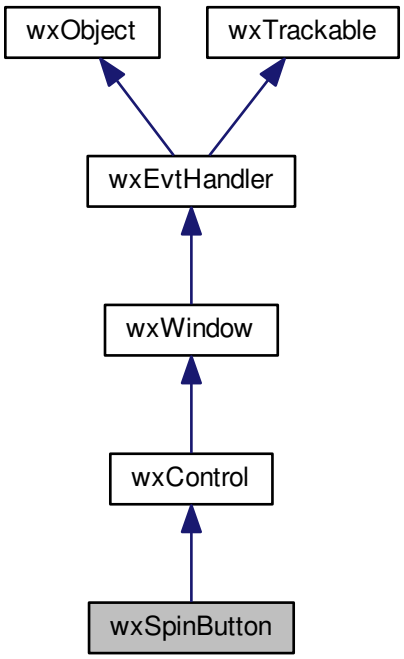
static void wxSound::Stop ( ) [static]

If a sound is played, this function stops it.

21.700 wxSpinButton Class Reference

`#include <wx/spinbutt.h>`

Inheritance diagram for wxSpinButton:



21.700.1 Detailed Description

A wxSpinButton has two small up and down (or left and right) arrow buttons.

It is often used next to a text control for increment and decrementing a value. Portable programs should try to use wxSpinCtrl instead as wxSpinButton is not implemented for all platforms but wxSpinCtrl is as it degenerates to a simple wxTextCtrl on such platforms.

Note

the range supported by this control (and wxSpinCtrl) depends on the platform but is at least `-0x8000` to `0x7fff`. Under GTK and Win32 with sufficiently new version of `comctrl32.dll` (at least 4.71 is required, 5.80 is recommended) the full 32 bit range is supported.

Styles

This class supports the following styles:

- wxSP_HORIZONTAL: Specifies a horizontal spin button (note that this style is not supported in wxGTK).
- wxSP_VERTICAL: Specifies a vertical spin button.
- wxSP_ARROW_KEYS: The user can use arrow keys to change the value.
- wxSP_WRAP: The value wraps at the minimum and maximum.

Events emitted by this class

The following event handler macros redirect the events to member function handlers '**func**' with prototypes like: void handlerFuncName(wxSpinEvent& event)

Event macros for events emitted by this class:

- EVT_SPIN(id, func): Generated whenever an arrow is pressed.
- EVT_SPIN_UP(id, func): Generated when left/up arrow is pressed.
- EVT_SPIN_DOWN(id, func): Generated when right/down arrow is pressed.

Note that if you handle both SPIN and UP or DOWN events, you will be notified about each of them twice: first the UP/DOWN event will be received and then, if it wasn't vetoed, the SPIN event will be sent.

Library: wxCore

Category: Controls

See also

wxSpinCtrl

Public Member Functions

- wxSpinButton ()

  Default constructor.
- wxSpinButton (wxWindow *parent, wxWindowID id=-1, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, long style=wxSP_VERTICAL, const wxString &name="spinButton")

  Constructor, creating and showing a spin button.
- virtual ~wxSpinButton ()

  Destructor, destroys the spin button control.
- bool Create (wxWindow *parent, wxWindowID id=-1, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, long style=wxSP_VERTICAL, const wxString &name="wxSpinButton")

  Scrollbar creation function called by the spin button constructor.
- virtual int GetMax () const

  Returns the maximum permissible value.
- virtual int GetMin () const

  Returns the minimum permissible value.
- virtual int GetValue () const

  Returns the current spin button value.
- virtual void SetRange (int min, int max)

  Sets the range of the spin button.
- virtual void SetValue (int value)

  Sets the value of the spin button.

Additional Inherited Members

21.700.2 Constructor & Destructor Documentation

wxSpinButton::wxSpinButton ( )

Default constructor.

wxSpinButton::wxSpinButton (wxWindow * *parent*, wxWindowID *id* = -1, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, long *style* = wxSP_VERTICAL, const wxString & *name* = "spinButton")

Constructor, creating and showing a spin button.

Parameters

parent	Parent window. Must not be NULL.
id	Window identifier. The value wxID_ANY indicates a default value.
pos	Window position. If wxDefaultPosition is specified then a default position is chosen.
size	Window size. If wxDefaultSize is specified then a default size is chosen.
style	Window style. See wxSpinButton class description.
name	Window name.

See also

Create()

virtual wxSpinButton::~wxSpinButton ( ) [virtual]

Destructor, destroys the spin button control.

21.700.3 Member Function Documentation

bool wxSpinButton::Create (wxWindow * *parent*, wxWindowID *id* = -1, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, long *style* = wxSP_VERTICAL, const wxString & *name* = "wxSpinButton")

Scrollbar creation function called by the spin button constructor.

See wxSpinButton() for details.

virtual int wxSpinButton::GetMax ( ) const [virtual]

Returns the maximum permissible value.

See also

SetRange()

virtual int wxSpinButton::GetMin ( ) const [virtual]

Returns the minimum permissible value.

See also

SetRange()

virtual int wxSpinButton::GetValue ( ) const [virtual]

Returns the current spin button value.

See also

SetValue()

virtual void wxSpinButton::SetRange (int *min*, int *max*) [virtual]

Sets the range of the spin button.

Parameters

min	The minimum value for the spin button.
max	The maximum value for the spin button.

See also

GetMin(), GetMax()

virtual void wxSpinButton::SetValue (int *value*) [virtual]

Sets the value of the spin button.

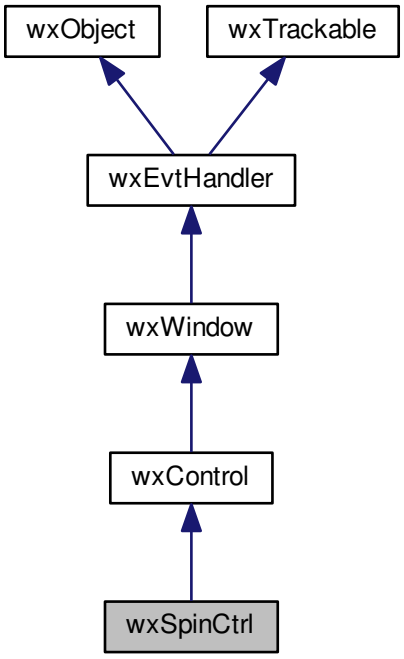
Parameters

value	The value for the spin button.

21.701 wxSpinCtrl Class Reference

`#include <wx/spinctrl.h>`

Inheritance diagram for wxSpinCtrl:



21.701.1 Detailed Description

wxSpinCtrl combines wxTextCtrl and wxSpinButton in one control.

Styles

This class supports the following styles:

- wxSP_ARROW_KEYS: The user can use arrow keys to change the value.
- wxSP_WRAP: The value wraps at the minimum and maximum.
- wxTE_PROCESS_ENTER: Indicates that the control should generate `wxEVT_TEXT_ENTER` events. Using this style will prevent the user from using the Enter key for dialog navigation (e.g. activating the default button in the dialog) under MSW.
- wxALIGN_LEFT: Same as wxTE_LEFT for wxTextCtrl: the text is left aligned.
- wxALIGN_CENTRE_HORIZONTAL: Same as wxTE_CENTRE for wxTextCtrl: the text is centered.
- wxALIGN_RIGHT: Same as wxTE_RIGHT for wxTextCtrl: the text is right aligned (this is the default).

Events emitted by this class

The following event handler macros redirect the events to member function handlers '**func**' with prototypes like: void handlerFuncName(wxSpinEvent& event)

Event macros for events emitted by this class:

- EVT_SPINCTRL(id, func): Process a wxEVT_SPINCTRL event, which is generated whenever the numeric value of the spin control is updated.

You may also use the wxSpinButton event macros, however the corresponding events will not be generated under all platforms. Finally, if the user modifies the text in the edit part of the spin control directly, the EVT_TEXT is generated, like for the wxTextCtrl. When the use enters text into the text area, the text is not validated until the control loses focus (e.g. by using the TAB key). The value is then adjusted to the range and a wxSpinEvent sent then if the value is different from the last value sent.

Library: wxCore

Category: Controls

wxSpinButton, wxSpinCtrlDouble, wxControl

Public Member Functions

- wxSpinCtrl ()

  Default constructor.
- wxSpinCtrl (wxWindow *parent, wxWindowID id=wxID_ANY, const wxString &value=wxEmptyString, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, long style=wxSP_ARROW_KEYS, int min=0, int max=100, int initial=0, const wxString &name="wxSpinCtrl")

  Constructor, creating and showing a spin control.
- bool Create (wxWindow *parent, wxWindowID id=wxID_ANY, const wxString &value=wxEmptyString, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, long style=wxSP_ARROW_KEYS, int min=0, int max=100, int initial=0, const wxString &name="wxSpinCtrl")

  Creation function called by the spin control constructor.
- int GetBase () const

  Returns the numerical base being currently used, 10 by default.

- int GetMax () const

  Gets maximal allowable value.
- int GetMin () const

  Gets minimal allowable value.
- int GetValue () const

  Gets the value of the spin control.
- bool SetBase (int base)

  Sets the base to use for the numbers in this control.
- void SetRange (int minVal, int maxVal)

  Sets range of allowable values.
- virtual void SetSelection (long from, long to)

  Select the text in the text part of the control between positions from (inclusive) and to (exclusive).
- virtual void SetValue (const wxString &text)

  Sets the value of the spin control.
- void SetValue (int value)

  Sets the value of the spin control.

Additional Inherited Members

21.701.2 Constructor & Destructor Documentation

wxSpinCtrl::wxSpinCtrl ( )

Default constructor.

wxSpinCtrl::wxSpinCtrl (wxWindow * *parent*, wxWindowID *id* = wxID_ANY, const wxString & *value* = wxEmptyString, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, long *style* = wxSP_ARROW_KEYS, int *min* = 0, int *max* = 100, int *initial* = 0, const wxString & *name* = "wxSpinCtrl")

Constructor, creating and showing a spin control.

If *value* is non-empty, it will be shown in the text entry part of the control and if it has numeric value, the initial numeric value of the control, as returned by GetValue() will also be determined by it instead of by *initial*. Hence, it only makes sense to specify *initial* if *value* is an empty string or is not convertible to a number, otherwise *initial* is simply ignored and the number specified by *value* is used.

Parameters

parent	Parent window. Must not be NULL.
value	Default value (as text).
id	Window identifier. The value wxID_ANY indicates a default value.
pos	Window position. If wxDefaultPosition is specified then a default position is chosen.
size	Window size. If wxDefaultSize is specified then a default size is chosen.
style	Window style. See wxSpinButton.
min	Minimal value.
max	Maximal value.
initial	Initial value.
name	Window name.

See also

Create()

21.701.3 Member Function Documentation

bool wxSpinCtrl::Create (wxWindow * *parent*, wxWindowID *id* = wxID_ANY, const wxString & *value* = wxEmptyString, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, long *style* = wxSP_ARROW_KEYS, int *min* = 0, int *max* = 100, int *initial* = 0, const wxString & *name* = "wxSpinCtrl")

Creation function called by the spin control constructor.

See wxSpinCtrl() for details.

int wxSpinCtrl::GetBase ( ) const

Returns the numerical base being currently used, 10 by default.

See also

SetBase()

Since

2.9.5

int wxSpinCtrl::GetMax ( ) const

Gets maximal allowable value.

int wxSpinCtrl::GetMin ( ) const

Gets minimal allowable value.

int wxSpinCtrl::GetValue ( ) const

Gets the value of the spin control.

bool wxSpinCtrl::SetBase (int *base*)

Sets the base to use for the numbers in this control.

Currently the only supported values are 10 (which is the default) and 16.

Changing the base allows the user to enter the numbers in the specified base, e.g. with "0x" prefix for hexadecimal numbers, and also displays the numbers in the specified base when they are changed using the spin control arrows.

Parameters

base	Numeric base, currently only 10 and 16 are supported.

Returns

true if the base was successfully changed or false if it failed, usually meaning that either the base is not 10 or 16.

Since

2.9.5

void wxSpinCtrl::SetRange (int *minVal,* int *maxVal*)

Sets range of allowable values.

Notice that calling this method may change the value of the control if it's not inside the new valid range, e.g. it will become *minVal* if it is less than it now. However no `wxEVT_SPINCTRL` event is generated, even if it the value does change.

virtual void wxSpinCtrl::SetSelection (long *from,* long *to*) `[virtual]`

Select the text in the text part of the control between positions *from* (inclusive) and *to* (exclusive).

This is similar to wxTextCtrl::SetSelection().

Note

this is currently only implemented for Windows and generic versions of the control.

virtual void wxSpinCtrl::SetValue (const wxString & *text*) `[virtual]`

Sets the value of the spin control.

It is recommended to use the overload taking an integer value instead.

Notice that, unlike wxTextCtrl::SetValue(), but like most of the other setter methods in wxWidgets, calling this method does not generate any events as events are only generated for the user actions.

void wxSpinCtrl::SetValue (int *value*)

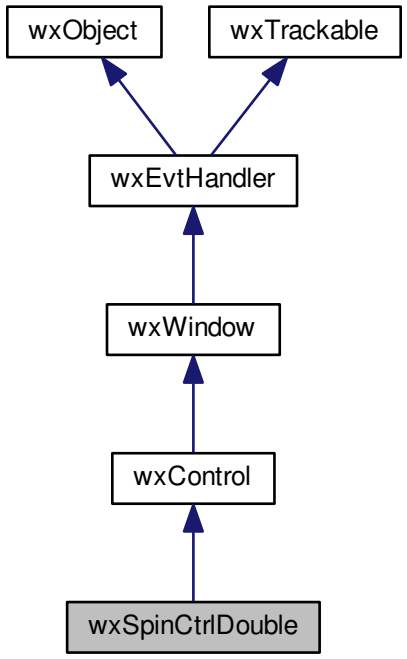
Sets the value of the spin control.

Calling this method doesn't generate any `wxEVT_SPINCTRL` events.

21.702 wxSpinCtrlDouble Class Reference

```
#include <wx/spinctrl.h>
```

Inheritance diagram for wxSpinCtrlDouble:



21.702.1 Detailed Description

wxSpinCtrlDouble combines wxTextCtrl and wxSpinButton in one control and displays a real number.

(wxSpinCtrl displays an integer.)

Styles

This class supports the following styles:

- wxSP_ARROW_KEYS: The user can use arrow keys to change the value.
- wxSP_WRAP: The value wraps at the minimum and maximum.

Events emitted by this class

The following event handler macros redirect the events to member function handlers '**func**' with prototypes like: void handlerFuncName(wxSpinDoubleEvent& event)

Event macros for events emitted by this class:

- EVT_SPINCTRLDOUBLE(id, func): Generated whenever the numeric value of the spin control is changed, that is, when the up/down spin button is clicked, when ENTER is pressed, or the control loses focus and the new value is different from the last. See wxSpinDoubleEvent.

Library: wxCore

wxSpinButton, wxSpinCtrl, wxControl

Public Member Functions

- wxSpinCtrlDouble ()

  Default constructor.
- wxSpinCtrlDouble (wxWindow *parent, wxWindowID id=-1, const wxString &value=wxEmptyString, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, long style=wxSP_ARROW_KEYS, double min=0, double max=100, double initial=0, double inc=1, const wxString &name=wxT("wxSpinCtrlDouble"))

  Constructor, creating and showing a spin control.
- bool Create (wxWindow *parent, wxWindowID id=wxID_ANY, const wxString &value=wxEmptyString, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, long style=wxSP_ARROW_KEYS, double min=0, double max=100, double initial=0, double inc=1, const wxString &name="wxSpinCtrlDouble")

  Creation function called by the spin control constructor.
- unsigned int GetDigits () const

  Gets the number of digits in the display.
- double GetIncrement () const

  Gets the increment value.
- double GetMax () const

  Gets maximal allowable value.
- double GetMin () const

  Gets minimal allowable value.
- double GetValue () const

  Gets the value of the spin control.
- void SetDigits (unsigned int digits)

  Sets the number of digits in the display.
- void SetIncrement (double inc)

  Sets the increment value.
- void SetRange (double minVal, double maxVal)

  Sets range of allowable values.
- virtual void SetValue (const wxString &text)

  Sets the value of the spin control.
- void SetValue (double value)

  Sets the value of the spin control.

Additional Inherited Members

21.702.2 Constructor & Destructor Documentation

wxSpinCtrlDouble::wxSpinCtrlDouble ( )

Default constructor.

wxSpinCtrlDouble::wxSpinCtrlDouble (wxWindow * *parent*, wxWindowID *id* = -1, const wxString & *value* = wxEmptyString, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, long *style* = wxSP_ARROW_KEYS, double *min* = 0, double *max* = 100, double *initial* = 0, double *inc* = 1, const wxString & *name* = wxT("wxSpinCtrlDouble"))

Constructor, creating and showing a spin control.

Parameters

parent	Parent window. Must not be NULL.
value	Default value (as text).
id	Window identifier. The value wxID_ANY indicates a default value.
pos	Window position. If wxDefaultPosition is specified then a default position is chosen.
size	Window size. If wxDefaultSize is specified then a default size is chosen.
style	Window style. See wxSpinButton.
min	Minimal value.
max	Maximal value.
initial	Initial value.
inc	Increment value.
name	Window name.

Creation function called by the spin control constructor.

See wxSpinCtrlDouble() for details.

unsigned int wxSpinCtrlDouble::GetDigits ( ) const

Gets the number of digits in the display.

double wxSpinCtrlDouble::GetIncrement ( ) const

Gets the increment value.

double wxSpinCtrlDouble::GetMax ( ) const

Gets maximal allowable value.

double wxSpinCtrlDouble::GetMin ( ) const

Gets minimal allowable value.

double wxSpinCtrlDouble::GetValue ( ) const

Gets the value of the spin control.

void wxSpinCtrlDouble::SetDigits (unsigned int *digits*)

Sets the number of digits in the display.

void wxSpinCtrlDouble::SetIncrement (double *inc*)

Sets the increment value.

Note

You may also need to increase the number of visible digits using SetDigits

void wxSpinCtrlDouble::SetRange (double *minVal,* double *maxVal*)

Sets range of allowable values.

virtual void wxSpinCtrlDouble::SetValue (const wxString & *text*) `[virtual]`

Sets the value of the spin control.

It is recommended to use the overload taking a double value instead.

Notice that, unlike wxTextCtrl::SetValue(), but like most of the other setter methods in wxWidgets, calling this method does not generate any events as events are only generated for the user actions.

void wxSpinCtrlDouble::SetValue (double *value*)

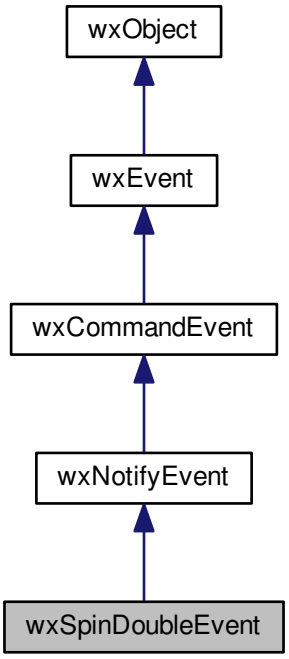
Sets the value of the spin control.

Calling this method doesn't generate any `wxEVT_SPINCTRLDOUBLE` events.

21.703 wxSpinDoubleEvent Class Reference

`#include <wx/spinctrl.h>`

Inheritance diagram for wxSpinDoubleEvent:



21.703.1 Detailed Description

This event class is used for the events generated by wxSpinCtrlDouble.

Events using this class

The following event handler macros redirect the events to member function handlers '**func**' with prototypes like: void handlerFuncName(wxSpinDoubleEvent& event)

Event macros:

- EVT_SPINCTRLDOUBLE(id, func): Generated whenever the numeric value of the spin control is changed, that is, when the up/down spin button is clicked, when ENTER is pressed, or the control loses focus and the new value is different from the last. See wxSpinDoubleEvent.

wxSpinCtrlDouble

Public Member Functions

- wxSpinDoubleEvent (wxEventType commandType=wxEVT_NULL, int winid=0, double value=0)

  The constructor.

- wxSpinDoubleEvent (const wxSpinDoubleEvent &event)

  The copy constructor.

- double GetValue () const

  Returns the value associated with this spin control event.

- void SetValue (double value)

  Set the value associated with the event.

Additional Inherited Members

21.703.2 Constructor & Destructor Documentation

wxSpinDoubleEvent::wxSpinDoubleEvent (wxEventType *commandType* = wxEVT_NULL, int *winid* = 0, double *value* = 0)

The constructor.

Not normally used by the user code.

wxSpinDoubleEvent::wxSpinDoubleEvent (const wxSpinDoubleEvent & *event*)

The copy constructor.

21.703.3 Member Function Documentation

double wxSpinDoubleEvent::GetValue ( ) const

Returns the value associated with this spin control event.

void wxSpinDoubleEvent::SetValue (double *value*)

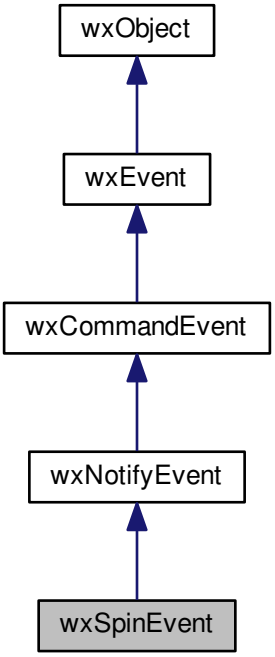
Set the value associated with the event.

(Not normally used by user code.)

21.704 wxSpinEvent Class Reference

`#include <wx/spinbutt.h>`

Inheritance diagram for wxSpinEvent:



21.704.1 Detailed Description

This event class is used for the events generated by wxSpinButton and wxSpinCtrl.

Events using this class

The following event handler macros redirect the events to member function handlers '**func**' with prototypes like: void handlerFuncName(wxSpinEvent& event)

Event macros:

- EVT_SPIN(id, func): Generated whenever an arrow is pressed.
- EVT_SPIN_UP(id, func): Generated when left/up arrow is pressed.
- EVT_SPIN_DOWN(id, func): Generated when right/down arrow is pressed.

Note that if you handle both SPIN and UP or DOWN events, you will be notified about each of them twice: first the UP/DOWN event will be received and then, if it wasn't vetoed, the SPIN event will be sent.

Library: wxCore

Category: Events

int wxSpinEvent::GetPosition ( ) const

Retrieve the current spin button or control value.

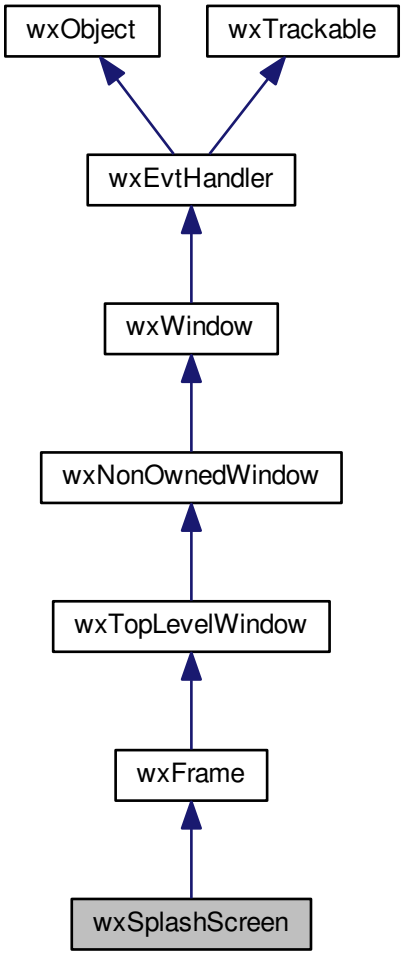
void wxSpinEvent::SetPosition (int *pos*)

Set the value associated with the event.

21.705 wxSplashScreen Class Reference

`#include <wx/splash.h>`

Inheritance diagram for wxSplashScreen:



21.705.1 Detailed Description

wxSplashScreen shows a window with a thin border, displaying a bitmap describing your application.

Show it in application initialisation, and then either explicitly destroy it or let it time-out.

Example usage:

```
wxBitmap bitmap;
if (bitmap.LoadFile("splash16.png", wxBITMAP_TYPE_PNG))
{
    wxSplashScreen* splash = new wxSplashScreen(bitmap,
        wxSPLASH_CENTRE_ON_SCREEN|wxSPLASH_TIMEOUT,
        6000, NULL, -1, wxDefaultPosition, wxDefaultSize,
        wxBORDER_SIMPLE|wxSTAY_ON_TOP);
}
wxYield();
```

Library: wxAdvanced

Category: Managed Windows

Public Member Functions

- wxSplashScreen (const wxBitmap &bitmap, long splashStyle, int milliseconds, wxWindow *parent, wxWindowID id, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, long style=wxBORDER_SIMPLE|wxFRAME_NO_TASKBAR|wxSTAY_ON_TOP)

  Construct the splash screen passing a bitmap, a style, a timeout, a window id, optional position and size, and a window style.
- virtual ~wxSplashScreen ()

  Destroys the splash screen.
- long GetSplashStyle () const

  Returns the splash style (see wxSplashScreen() for details).
- wxSplashScreenWindow * GetSplashWindow () const

  Returns the window used to display the bitmap.
- int GetTimeout () const

  Returns the timeout in milliseconds.
- void OnCloseWindow (wxCloseEvent &event)

  Reimplement this event handler if you want to set an application variable on window destruction, for example.

Additional Inherited Members

21.705.2 Constructor & Destructor Documentation

wxSplashScreen::wxSplashScreen (const wxBitmap & *bitmap,* long *splashStyle,* int *milliseconds,* wxWindow * *parent,* wxWindowID *id,* const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, long *style* = wxBORDER_SIMPLE|wxFRAME_NO_TASKBAR|wxSTAY_ON_TOP)

Construct the splash screen passing a bitmap, a style, a timeout, a window id, optional position and size, and a window style.

splashStyle is a bitlist of some of the following:

- wxSPLASH_CENTRE_ON_PARENT
- wxSPLASH_CENTRE_ON_SCREEN
- wxSPLASH_NO_CENTRE
- wxSPLASH_TIMEOUT
- wxSPLASH_NO_TIMEOUT

milliseconds is the timeout in milliseconds.

virtual wxSplashScreen::~wxSplashScreen ( ) [virtual]

Destroys the splash screen.

21.705.3 Member Function Documentation

long wxSplashScreen::GetSplashStyle ( ) const

Returns the splash style (see wxSplashScreen() for details).

wxSplashScreenWindow* wxSplashScreen::GetSplashWindow ( ) const

Returns the window used to display the bitmap.

int wxSplashScreen::GetTimeout ( ) const

Returns the timeout in milliseconds.

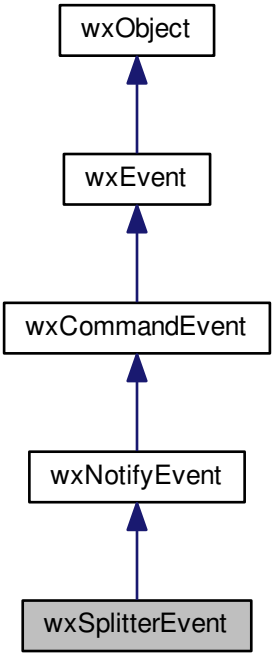
void wxSplashScreen::OnCloseWindow (wxCloseEvent & *event*)

Reimplement this event handler if you want to set an application variable on window destruction, for example.

21.706 wxSplitterEvent Class Reference

`#include <wx/splitter.h>`

Inheritance diagram for wxSplitterEvent:



21.706.1 Detailed Description

This class represents the events generated by a splitter control.

Also there is only one event class, the data associated to the different events is not the same and so not all accessor functions may be called for each event. The documentation mentions the kind of event(s) for which the given accessor function makes sense: calling it for other types of events will result in assert failure (in debug mode) and will return meaningless results.

Events using this class

The following event handler macros redirect the events to member function handlers '**func**' with prototypes like: void handlerFuncName(wxSplitterEvent& event)

Event macros:

- EVT_SPLITTER_SASH_POS_CHANGING(id, func): The sash position is in the process of being changed. May be used to modify the position of the tracking bar to properly reflect the position that would be set if the drag were to be completed at this point. Processes a `wxEVT_SPLITTER_SASH_POS_CHANGING` event.
- EVT_SPLITTER_SASH_POS_CHANGED(id, func): The sash position was changed. May be used to modify the sash position before it is set, or to prevent the change from taking place. Processes a `wxEVT_SPLITTER_SASH_POS_CHANGED` event.
- EVT_SPLITTER_UNSPLIT(id, func): The splitter has been just unsplit. Processes a `wxEVT_SPLITTER_UNSPLIT` event.
- EVT_SPLITTER_DCLICK(id, func): The sash was double clicked. The default behaviour is to unsplit the window when this happens (unless the minimum pane size has been set to a value greater than zero). Processes a `wxEVT_SPLITTER_DOUBLECLICKED` event.

Library: wxCore

Category: Events

See also

wxSplitterWindow, Events and Event Handling

Public Member Functions

- wxSplitterEvent (wxEventType eventType=wxEVT_NULL, wxSplitterWindow *splitter=NULL)

  Constructor.
- int GetSashPosition () const

  Returns the new sash position.
- wxWindow * GetWindowBeingRemoved () const

  Returns a pointer to the window being removed when a splitter window is unsplit.
- int GetX () const

  Returns the x coordinate of the double-click point.
- int GetY () const

  Returns the y coordinate of the double-click point.
- void SetSashPosition (int pos)

  In the case of `wxEVT_SPLITTER_SASH_POS_CHANGED` events, sets the new sash position.

Additional Inherited Members

21.706.2 Constructor & Destructor Documentation

wxSplitterEvent::wxSplitterEvent (wxEventType *eventType* = wxEVT_NULL, wxSplitterWindow * *splitter* = `NULL`)

Constructor.

Used internally by wxWidgets only.

21.706.3 Member Function Documentation

int wxSplitterEvent::GetSashPosition ( ) const

Returns the new sash position.

May only be called while processing `wxEVT_SPLITTER_SASH_POS_CHANGING` and `wxEVT_SPLITTER_SASH_POS_CHANGED` events.

wxWindow* wxSplitterEvent::GetWindowBeingRemoved ( ) const

Returns a pointer to the window being removed when a splitter window is unsplit.

May only be called while processing `wxEVT_SPLITTER_UNSPLIT` events.

int wxSplitterEvent::GetX ( ) const

Returns the x coordinate of the double-click point.

May only be called while processing `wxEVT_SPLITTER_DOUBLECLICKED` events.

int wxSplitterEvent::GetY ( ) const

Returns the y coordinate of the double-click point.

May only be called while processing `wxEVT_SPLITTER_DOUBLECLICKED` events.

void wxSplitterEvent::SetSashPosition (int *pos*)

In the case of `wxEVT_SPLITTER_SASH_POS_CHANGED` events, sets the new sash position.

In the case of `wxEVT_SPLITTER_SASH_POS_CHANGING` events, sets the new tracking bar position so visual feedback during dragging will represent that change that will actually take place. Set to -1 from the event handler code to prevent repositioning.

May only be called while processing `wxEVT_SPLITTER_SASH_POS_CHANGING` and `wxEVT_SPLITTER_SASH_POS_CHANGED` events.

Parameters

pos	New sash position.

21.707 wxSplitterRenderParams Struct Reference

`#include <wx/renderer.h>`

21.707.1 Detailed Description

This is just a simple `struct` used as a return value of wxRendererNative::GetSplitterParams().

It doesn't have any methods and all of its fields are constant, so they can only be examined but not modified.

Library: wxCore

Category: Graphics Device Interface (GDI)

Public Member Functions

- wxSplitterRenderParams (wxCoord widthSash_, wxCoord border_, bool isSens_)

  The only way to initialize this struct is by using this ctor.

Public Attributes

- const wxCoord border

  The width of the border drawn by the splitter inside it, may be 0.
- const bool isHotSensitive

  true if the sash changes appearance when the mouse passes over it, false otherwise.
- const wxCoord widthSash

  The width of the splitter sash.

21.707.2 Constructor & Destructor Documentation

wxSplitterRenderParams::wxSplitterRenderParams (wxCoord *widthSash_*, wxCoord *border_*, bool *isSens_*)

The only way to initialize this struct is by using this ctor.

21.707.3 Member Data Documentation

const wxCoord wxSplitterRenderParams::border

The width of the border drawn by the splitter inside it, may be 0.

const bool wxSplitterRenderParams::isHotSensitive

true if the sash changes appearance when the mouse passes over it, false otherwise.

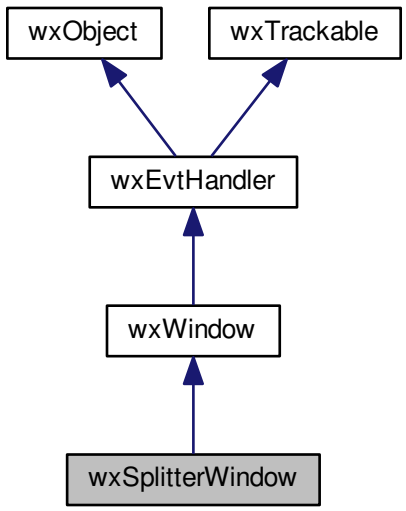
const wxCoord wxSplitterRenderParams::widthSash

The width of the splitter sash.

21.708 wxSplitterWindow Class Reference

`#include <wx/splitter.h>`

Inheritance diagram for wxSplitterWindow:



21.708.1 Detailed Description

This class manages up to two subwindows.

The current view can be split into two programmatically (perhaps from a menu command), and unsplit either programmatically or via the wxSplitterWindow user interface.

Styles

This class supports the following styles:

- wxSP_3D: Draws a 3D effect border and sash.
- wxSP_THIN_SASH: Draws a thin sash.
- wxSP_3DSASH: Draws a 3D effect sash (part of default style).
- wxSP_3DBORDER: Synonym for wxSP_BORDER.
- wxSP_BORDER: Draws a standard border.
- wxSP_NOBORDER: No border (default).
- wxSP_NO_XP_THEME: Under Windows XP, switches off the attempt to draw the splitter using Windows XP theming, so the borders and sash will take on the pre-XP look.
- wxSP_PERMIT_UNSPLIT: Always allow to unsplit, even with the minimum pane size other than zero.
- wxSP_LIVE_UPDATE: Don't draw XOR line but resize the child windows immediately.

Events emitted by this class

The following event handler macros redirect the events to member function handlers '**func**' with prototypes like: void handlerFuncName(wxSplitterEvent& event)

Event macros for events emitted by this class:

- EVT_SPLITTER_SASH_POS_CHANGING(id, func): The sash position is in the process of being changed. May be used to modify the position of the tracking bar to properly reflect the position that would be set if the drag were to be completed at this point. Processes a `wxEVT_SPLITTER_SASH_POS_CHANGING` event.
- EVT_SPLITTER_SASH_POS_CHANGED(id, func): The sash position was changed. May be used to modify the sash position before it is set, or to prevent the change from taking place. Processes a `wxEVT_SPLITTER_SASH_POS_CHANGED` event.
- EVT_SPLITTER_UNSPLIT(id, func): The splitter has been just unsplit. Processes a `wxEVT_SPLITTER_UNSPLIT` event.
- EVT_SPLITTER_DCLICK(id, func): The sash was double clicked. The default behaviour is to unsplit the window when this happens (unless the minimum pane size has been set to a value greater than zero). Processes a `wxEVT_SPLITTER_DOUBLECLICKED` event.

wxSplitterEvent, wxSplitterWindow Overview

Public Member Functions

- wxSplitterWindow ()

  Default constructor.
- wxSplitterWindow (wxWindow *parent, wxWindowID id=wxID_ANY, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, long style=wxSP_3D, const wxString &name="splitterWindow")

  Constructor for creating the window.
- virtual ~wxSplitterWindow ()

  Destroys the wxSplitterWindow and its children.
- bool Create (wxWindow *parent, wxWindowID id=wxID_ANY, const wxPoint &point=wxDefaultPosition, const wxSize &size=wxDefaultSize, long style=wxSP_3D, const wxString &name="splitter")

  Creation function, for two-step construction.
- int GetMinimumPaneSize () const

  Returns the current minimum pane size (defaults to zero).
- double GetSashGravity () const

  Returns the current sash gravity.
- int GetSashPosition () const

  Returns the current sash position.
- int GetSashSize () const

  Returns the default sash size in pixels or 0 if it is invisible.
- int GetDefaultSashSize () const

  Returns the default sash size in pixels.
- wxSplitMode GetSplitMode () const

  Gets the split mode.

- wxWindow * GetWindow1 () const

  Returns the left/top or only pane.
- wxWindow * GetWindow2 () const

  Returns the right/bottom pane.
- void Initialize (wxWindow *window)

  Initializes the splitter window to have one pane.
- bool IsSashInvisible () const

  Returns true if the sash is invisible even when the window is split, false otherwise.
- bool IsSplit () const

  Returns true if the window is split, false otherwise.
- virtual void OnDoubleClickSash (int x, int y)

  Application-overridable function called when the sash is double-clicked with the left mouse button.
- virtual bool OnSashPositionChange (int newSashPosition)

  Application-overridable function called when the sash position is changed by user.
- virtual void OnUnsplit (wxWindow *removed)

  Application-overridable function called when the window is unsplit, either programmatically or using the wxSplitterWindow user interface.
- bool ReplaceWindow (wxWindow *winOld, wxWindow *winNew)

  This function replaces one of the windows managed by the wxSplitterWindow with another one.
- void SetMinimumPaneSize (int paneSize)

  Sets the minimum pane size.
- void SetSashGravity (double gravity)

  Sets the sash gravity.
- void SetSashPosition (int position, bool redraw=true)

  Sets the sash position.
- void SetSplitMode (int mode)

  Sets the split mode.
- void SetSashInvisible (bool invisible=true)

  Sets whether the sash should be invisible, even when the window is split.
- virtual bool SplitHorizontally (wxWindow *window1, wxWindow *window2, int sashPosition=0)

  Initializes the top and bottom panes of the splitter window.
- virtual bool SplitVertically (wxWindow *window1, wxWindow *window2, int sashPosition=0)

  Initializes the left and right panes of the splitter window.
- bool Unsplit (wxWindow *toRemove=NULL)

  Unsplits the window.
- void UpdateSize ()

  Causes any pending sizing of the sash and child panes to take place immediately.

Additional Inherited Members

21.708.2 Constructor & Destructor Documentation

wxSplitterWindow::wxSplitterWindow ( )

Default constructor.

wxSplitterWindow::wxSplitterWindow (wxWindow * *parent*, wxWindowID *id* = wxID_ANY, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, long *style* = wxSP_3D, const wxString & *name* = "splitterWindow")

Constructor for creating the window.

Parameters

parent	The parent of the splitter window.
id	The window identifier.
pos	The window position.
size	The window size.
style	The window style. See wxSplitterWindow.
name	The window name.

Remarks

After using this constructor, you must create either one or two subwindows with the splitter window as parent, and then call one of Initialize(), SplitVertically() and SplitHorizontally() in order to set the pane(s). You can create two windows, with one hidden when not being shown; or you can create and delete the second pane on demand.

See also

Initialize(), SplitVertically(), SplitHorizontally(), Create()

virtual wxSplitterWindow::~wxSplitterWindow ( ) [virtual]

Destroys the wxSplitterWindow and its children.

21.708.3 Member Function Documentation

bool wxSplitterWindow::Create (wxWindow * *parent*, wxWindowID *id* = wxID_ANY, const wxPoint & *point* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, long *style* = wxSP_3D, const wxString & *name* = "splitter")

Creation function, for two-step construction.

See wxSplitterWindow() for details.

int wxSplitterWindow::GetDefaultSashSize ( ) const

Returns the default sash size in pixels.

The size of the sash is its width for a vertically split window and its height for a horizontally split one. Its other direction is the same as the client size of the window in the corresponding direction.

The default sash size is platform-dependent because it conforms to the current platform look-and-feel and cannot be changed.

Since

2.9.4

int wxSplitterWindow::GetMinimumPaneSize ( ) const

Returns the current minimum pane size (defaults to zero).

See also

SetMinimumPaneSize()

double wxSplitterWindow::GetSashGravity ( ) const

Returns the current sash gravity.

See also

SetSashGravity()

int wxSplitterWindow::GetSashPosition ( ) const

Returns the current sash position.

See also

SetSashPosition()

int wxSplitterWindow::GetSashSize ( ) const

Returns the default sash size in pixels or 0 if it is invisible.

See also

GetDefaultSashSize(), IsSashInvisible()

wxSplitMode wxSplitterWindow::GetSplitMode ( ) const

Gets the split mode.

See also

SetSplitMode(), SplitVertically(), SplitHorizontally().

wxWindow* wxSplitterWindow::GetWindow1 ( ) const

Returns the left/top or only pane.

wxWindow* wxSplitterWindow::GetWindow2 ( ) const

Returns the right/bottom pane.

void wxSplitterWindow::Initialize (wxWindow * *window*)

Initializes the splitter window to have one pane.

The child window is shown if it is currently hidden.

Parameters

window	The pane for the unsplit window.

Remarks

This should be called if you wish to initially view only a single pane in the splitter window.

See also

SplitVertically(), SplitHorizontally()

bool wxSplitterWindow::IsSashInvisible ( ) const

Returns true if the sash is invisible even when the window is split, false otherwise.

Remarks

This is a shortcut for HasFlag(wxSP_NOSASH)

See also

SetSashInvisible()

Since

2.9.4

bool wxSplitterWindow::IsSplit ( ) const

Returns true if the window is split, false otherwise.

virtual void wxSplitterWindow::OnDoubleClickSash (int *x*, int *y*) [virtual]

Application-overridable function called when the sash is double-clicked with the left mouse button.

Parameters

x	The x position of the mouse cursor.
y	The y position of the mouse cursor.

Remarks

The default implementation of this function calls Unsplit if the minimum pane size is zero.

See also

Unsplit()

virtual bool wxSplitterWindow::OnSashPositionChange (int *newSashPosition*) [virtual]

Application-overridable function called when the sash position is changed by user.

It may return false to prevent the change or true to allow it.

Parameters

newSash↩ Position	The new sash position (always positive or zero)

Remarks

The default implementation of this function verifies that the sizes of both panes of the splitter are greater than minimum pane size.

virtual void wxSplitterWindow::OnUnsplit (wxWindow * *removed*) [virtual]

Application-overridable function called when the window is unsplit, either programmatically or using the wxSplitter↩ Window user interface.

Parameters

removed	The window being removed.

Remarks

The default implementation of this function simply hides removed. You may wish to delete the window.

bool wxSplitterWindow::ReplaceWindow (wxWindow * *winOld,* wxWindow * *winNew*)

This function replaces one of the windows managed by the wxSplitterWindow with another one.

It is in general better to use it instead of calling Unsplit() and then resplitting the window back because it will provoke much less flicker (if any). It is valid to call this function whether the splitter has two windows or only one.

Both parameters should be non-NULL and *winOld* must specify one of the windows managed by the splitter. If the parameters are incorrect or the window couldn't be replaced, false is returned. Otherwise the function will return true, but please notice that it will not delete the replaced window and you may wish to do it yourself.

See also

GetMinimumPaneSize()

void wxSplitterWindow::SetMinimumPaneSize (int *paneSize*)

Sets the minimum pane size.

Parameters

paneSize	Minimum pane size in pixels.

Remarks

The default minimum pane size is zero, which means that either pane can be reduced to zero by dragging the sash, thus removing one of the panes. To prevent this behaviour (and veto out-of-range sash dragging), set a minimum size, for example 20 pixels. If the wxSP_PERMIT_UNSPLIT style is used when a splitter window is created, the window may be unsplit even if minimum size is non-zero.

See also

GetMinimumPaneSize()

void wxSplitterWindow::SetSashGravity (double *gravity*)

Sets the sash gravity.

Parameters

gravity	The sash gravity. Value between 0.0 and 1.0.

Remarks

Gravity is real factor which controls position of sash while resizing wxSplitterWindow. Gravity tells wxSplitter↩ Window how much will left/top window grow while resizing. Example values:

- 0.0: only the bottom/right window is automatically resized
- 0.5: both windows grow by equal size

- 1.0: only left/top window grows Gravity should be a real value between 0.0 and 1.0. Default value of sash gravity is 0.0. That value is compatible with previous (before gravity was introduced) behaviour of wxSplitterWindow.

Notice that when sash gravity for a newly created splitter window, it is often necessary to explicitly set the splitter size using SetSize() to ensure that is big enough for its initial sash position. Otherwise, i.e. if the window is created with the default tiny size and only resized to its correct size later, the initial sash position will be affected by the gravity and typically result in sash being at the rightmost position for the gravity of 1. See the example code creating wxSplitterWindow in the splitter sample for more details.

See also

GetSashGravity()

void wxSplitterWindow::SetSashInvisible (bool *invisible* = `true`)

Sets whether the sash should be invisible, even when the window is split.

When the sash is invisible, it doesn't appear on the screen at all and, in particular, doesn't allow the user to resize the windows.

Remarks

Only sets the internal variable; does not update the display.

Parameters

invisible	If true, the sash is always invisible, else it is shown when the window is split.

See also

IsSashInvisible()

Since

2.9.4

void wxSplitterWindow::SetSashPosition (int *position*, bool *redraw* = `true`)

Sets the sash position.

Parameters

position	The sash position in pixels.
redraw	If true, resizes the panes and redraws the sash and border.

Remarks

Does not currently check for an out-of-range value.

See also

GetSashPosition()

void wxSplitterWindow::SetSplitMode (int *mode*)

Sets the split mode.

Parameters

mode	Can be wxSPLIT_VERTICAL or wxSPLIT_HORIZONTAL.

Remarks

Only sets the internal variable; does not update the display.

See also

GetSplitMode(), SplitVertically(), SplitHorizontally().

virtual bool wxSplitterWindow::SplitHorizontally (wxWindow * *window1*, wxWindow * *window2*, int *sashPosition* = 0) [virtual]

Initializes the top and bottom panes of the splitter window.

The child windows are shown if they are currently hidden.

Parameters

window1	The top pane.
window2	The bottom pane.
sashPosition	The initial position of the sash. If this value is positive, it specifies the size of the upper pane. If it is negative, its absolute value gives the size of the lower pane. Finally, specify 0 (default) to choose the default position (half of the total window height).

Returns

true if successful, false otherwise (the window was already split).

Remarks

This should be called if you wish to initially view two panes. It can also be called at any subsequent time, but the application should check that the window is not currently split using IsSplit().

See also

SplitVertically(), IsSplit(), Unsplit()

virtual bool wxSplitterWindow::SplitVertically (wxWindow * *window1*, wxWindow * *window2*, int *sashPosition* = 0) [virtual]

Initializes the left and right panes of the splitter window.

The child windows are shown if they are currently hidden.

Parameters

window1	The left pane.
window2	The right pane.
sashPosition	The initial position of the sash. If this value is positive, it specifies the size of the left pane. If it is negative, it is absolute value gives the size of the right pane. Finally, specify 0 (default) to choose the default position (half of the total window width).

Returns

true if successful, false otherwise (the window was already split).

Remarks

This should be called if you wish to initially view two panes. It can also be called at any subsequent time, but the application should check that the window is not currently split using IsSplit().

See also

SplitHorizontally(), IsSplit(), Unsplit().

bool wxSplitterWindow::Unsplit (wxWindow * *toRemove* = NULL)

Unsplits the window.

Parameters

toRemove	The pane to remove, or NULL to remove the right or bottom pane.

Returns

true if successful, false otherwise (the window was not split).

Remarks

This call will not actually delete the pane being removed; it calls OnUnsplit() which can be overridden for the desired behaviour. By default, the pane being removed is hidden.

See also

SplitHorizontally(), SplitVertically(), IsSplit(), OnUnsplit()

void wxSplitterWindow::UpdateSize ( )

Causes any pending sizing of the sash and child panes to take place immediately.

Such resizing normally takes place in idle time, in order to wait for layout to be completed. However, this can cause unacceptable flicker as the panes are resized after the window has been shown. To work around this, you can perform window layout (for example by sending a size event to the parent window), and then call this function, before showing the top-level window.

21.709 wxStack< T > Class Template Reference

`#include <wx/stack.h>`

21.709.1 Detailed Description

template<typename T>class wxStack< T >

wxStack<T> is similar to `std::stack` and can be used exactly like it.

If wxWidgets is compiled in STL mode, wxStack will just be a typedef to `std::stack` but the advantage of this class is that it is also available on the (rare) platforms where STL is not, so using it makes the code marginally more portable. If you only target the standard desktop platforms, please always use `std::stack` directly instead.

The main difference of this class compared to the standard version is that it always uses wxVector<T> as the underlying container and doesn't allow specifying an alternative container type. Another missing part is that the comparison operators between wxStacks are not currently implemented. Other than that, this class is exactly the same as `std::stack`, so please refer to the STL documentation for further information.

Library: None; this class implementation is entirely header-based.

Category: Containers

See also

Container Classes, wxVector<T>

Since

2.9.2

Public Types

- typedef wxVector< T > container_type
  Type of the underlying container used.
- typedef container_type::size_type size_type
  Type returned by size() method.
- typedef container_type::value_type value_type
  Type of the elements stored in the stack.

Public Member Functions

- bool empty () const
  Return whether the stack is currently empty.
- size_type size () const
  Return the number of elements in the stack.
- void push (const value_type &val)
  Adds an element to the stack.
- void pop ()
  Removes the element currently on top of the stack.

- wxStack ()
  Stack can be created either empty or initialized with the contents of an existing compatible container.
- wxStack (const container_type &cont)
  Stack can be created either empty or initialized with the contents of an existing compatible container.

- value_type & top ()
  Return the element on top of the stack.
- const value_type & top ()
  Return the element on top of the stack.

21.709.2 Member Typedef Documentation

template<typename T > typedef wxVector<T> wxStack< T >::container_type

Type of the underlying container used.

template<typename T > typedef container_type::size_type wxStack< T >::size_type

Type returned by size() method.

template<typename T > typedef container_type::value_type wxStack< T >::value_type

Type of the elements stored in the stack.

21.709.3 Constructor & Destructor Documentation

template<typename T > wxStack< T >::wxStack ( )

Stack can be created either empty or initialized with the contents of an existing compatible container.

template<typename T > wxStack< T >::wxStack (const container_type & *cont*) `[explicit]`

Stack can be created either empty or initialized with the contents of an existing compatible container.

21.709.4 Member Function Documentation

template<typename T > bool wxStack< T >::empty ( ) const

Return whether the stack is currently empty.

template<typename T > void wxStack< T >::pop ( )

Removes the element currently on top of the stack.

template<typename T > void wxStack< T >::push (const value_type & *val*)

Adds an element to the stack.

template<typename T > size_type wxStack< T >::size ( ) const

Return the number of elements in the stack.

template<typename T > value_type& wxStack< T >::top ( )

Return the element on top of the stack.

template<typename T > const value_type& wxStack< T >::top ( )

Return the element on top of the stack.

21.710 wxStackFrame Class Reference

`#include <wx/stackwalk.h>`

21.710.1 Detailed Description

wxStackFrame represents a single stack frame, or a single function in the call stack, and is used exclusively together with wxStackWalker, see there for a more detailed discussion.

Library: wxBase

Category: Debugging

See also

wxStackWalker

Public Member Functions

- void * GetAddress () const

  Return the address of this frame.
- wxString GetFileName () const

  Return the name of the file containing this frame, empty if unavailable (typically because debug info is missing).
- size_t GetLevel () const

  Get the level of this frame (deepest/innermost one is 0).
- size_t GetLine () const

  Return the line number of this frame, 0 if unavailable.
- wxString GetModule () const

  Get the module this function belongs to (empty if not available).
- wxString GetName () const

  Return the unmangled (if possible) name of the function containing this frame.
- size_t GetOffset () const

  Return the return address of this frame.
- virtual bool GetParam (size_t n, wxString *type, wxString *name, wxString *value) const

  Get the name, type and value (in text form) of the given parameter.
- virtual size_t GetParamCount () const

  Return the number of parameters of this function (may return 0 if we can't retrieve the parameters info even although the function does have parameters).
- bool HasSourceLocation () const

  Return true if we have the file name and line number for this frame.

21.710.2 Member Function Documentation

void* wxStackFrame::GetAddress ( ) const

Return the address of this frame.

wxString wxStackFrame::GetFileName ( ) const

Return the name of the file containing this frame, empty if unavailable (typically because debug info is missing).

Use HasSourceLocation() to check whether the file name is available.

size_t wxStackFrame::GetLevel ( ) const

Get the level of this frame (deepest/innermost one is 0).

size_t wxStackFrame::GetLine ( ) const

Return the line number of this frame, 0 if unavailable.

See also

GetFileName()

wxString wxStackFrame::GetModule ( ) const

Get the module this function belongs to (empty if not available).

wxString wxStackFrame::GetName ( ) const

Return the unmangled (if possible) name of the function containing this frame.

size_t wxStackFrame::GetOffset ( ) const

Return the return address of this frame.

virtual bool wxStackFrame::GetParam (size_t *n*, wxString * *type*, wxString * *name*, wxString * *value*) const `[virtual]`

Get the name, type and value (in text form) of the given parameter.

Any pointer may be NULL if you're not interested in the corresponding value.

Return true if at least some values could be retrieved. This function currently is only implemented under Win32 and requires a PDB file.

virtual size_t wxStackFrame::GetParamCount ( ) const `[virtual]`

Return the number of parameters of this function (may return 0 if we can't retrieve the parameters info even although the function does have parameters).

bool wxStackFrame::HasSourceLocation ( ) const

Return true if we have the file name and line number for this frame.

21.711 wxStackWalker Class Reference

`#include <wx/stackwalk.h>`

21.711.1 Detailed Description

wxStackWalker allows an application to enumerate, or walk, the stack frames (the function callstack).

It is mostly useful in only two situations: inside wxApp::OnFatalException function to programmatically get the location of the crash and, in debug builds, in wxApp::OnAssertFailure to report the caller of the failed assert.

wxStackWalker works by repeatedly calling the wxStackWalker::OnStackFrame method for each frame in the stack, so to use it you must derive your own class from it and override this method.

This class will not return anything except raw stack frame addresses if the debug information is not available. Under Win32 this means that the PDB file matching the program being executed should be present. Note that if you use Microsoft Visual C++ compiler, you can create PDB files even for the programs built in release mode and it doesn't affect the program size (at least if you don't forget to add `/opt`:ref option which is suppressed by using `/debug` linker option by default but should be always enabled for release builds). Under Unix, you need to compile your program with debugging information (usually using `-g` compiler and linker options) to get the file and line numbers information, however function names should be available even without it. Of course, all this is only true if you build using a recent enough version of GNU libc which provides the `backtrace()` function needed to walk the stack.

See Debugging for how to make it available.

Library: wxBase

Category: Debugging

See also

wxStackFrame

Public Member Functions

- wxStackWalker (const char *argv0=NULL)

  Constructor does nothing, use Walk() to walk the stack.
- virtual ~wxStackWalker ()

  Destructor does nothing neither but should be virtual as this class is used as a base one.
- virtual void Walk (size_t skip=1, size_t maxDepth=wxSTACKWALKER_MAX_DEPTH)

  Enumerate stack frames from the current location, skipping the initial number of them (this can be useful when Walk() is called from some known location and you don't want to see the first few frames anyhow; also notice that Walk() frame itself is not included if skip = 1).
- virtual void WalkFromException (size_t maxDepth=wxSTACKWALKER_MAX_DEPTH)

  Enumerate stack frames from the location of uncaught exception.

Protected Member Functions

- virtual void OnStackFrame (const wxStackFrame &frame)=0

  This function must be overidden to process the given frame.

21.711.2 Constructor & Destructor Documentation

wxStackWalker::wxStackWalker (const char * *argv0* = `NULL`)

Constructor does nothing, use Walk() to walk the stack.

virtual wxStackWalker::~wxStackWalker ( ) `[virtual]`

Destructor does nothing neither but should be virtual as this class is used as a base one.

21.711.3 Member Function Documentation

virtual void wxStackWalker::OnStackFrame (const wxStackFrame & *frame*) `[protected], [pure virtual]`

This function must be overidden to process the given frame.

virtual void wxStackWalker::Walk (size_t *skip* = 1, size_t *maxDepth* = wxSTACKWALKER_MAX_DEPTH) `[virtual]`

Enumerate stack frames from the current location, skipping the initial number of them (this can be useful when Walk() is called from some known location and you don't want to see the first few frames anyhow; also notice that Walk() frame itself is not included if skip = 1).

Up to *maxDepth* frames are walked from the innermost to the outermost one. It defaults to wxSTACKWALKER_MAX_DEPTH.

virtual void wxStackWalker::WalkFromException (size_t *maxDepth* = wxSTACKWALKER_MAX_DEPTH) `[virtual]`

Enumerate stack frames from the location of uncaught exception.

This method can only be called from wxApp::OnFatalException().

Up to *maxDepth* frames are walked from the innermost to the outermost one. It defaults to wxSTACKWALKER_MAX_DEPTH.

21.712 wxStandardPaths Class Reference

`#include <wx/stdpaths.h>`

21.712.1 Detailed Description

wxStandardPaths returns the standard locations in the file system and should be used by applications to find their data files in a portable way.

Note that you must not create objects of class wxStandardPaths directly, but use the global standard paths object returned by wxStandardPaths::Get() (which can be of a type derived from wxStandardPaths and not of exactly this type) and call the methods you need on it. The object returned by Get() may be customized by overriding wxAppTraits::GetStandardPaths() methods.

In the description of the methods below, the example return values are given for the Unix, Windows and Mac OS X systems, however please note that these are just the examples and the actual values may differ. For example, under Windows: the system administrator may change the standard directories locations, e.g. the Windows directory may be named `"W:\Win2003"` instead of the default `"C:\Windows"`.

Notice that in the examples below the string `appinfo` may be either just the application name (as returned by wxApp::GetAppName()) or a combination of the vendor name (wxApp::GetVendorName()) and the application name, with a path separator between them. By default, only the application name is used, use UseAppInfo() to change this.

The other placeholders should be self-explanatory: the string `username` should be replaced with the value the name of the currently logged in user. and `prefix` is only used under Unix and is `/usr/local` by default but may be changed using wxStandardPaths::SetInstallPrefix().

The directories returned by the methods of this class may or may not exist. If they don't exist, it's up to the caller to create them, wxStandardPaths doesn't do it.

Finally note that these functions only work with standardly packaged applications. I.e. under Unix you should follow the standard installation conventions and under Mac you should create your application bundle according to the Apple guidelines. Again, this class doesn't help you to do it.

This class is MT-safe: its methods may be called concurrently from different threads without additional locking.

Library: wxBase

Category: File Handling

wxFileConfig

Public Types

- enum ResourceCat {
  ResourceCat_None,
  ResourceCat_Messages }

  Possible values for category parameter of GetLocalizedResourcesDir().

Public Member Functions

- void DontIgnoreAppSubDir ()

  MSW-specific function undoing the effect of IgnoreAppSubDir() calls.
- virtual wxString GetAppDocumentsDir () const

  Return the directory for the document files used by this application.
- virtual wxString GetConfigDir () const

  Return the directory containing the system config files.
- virtual wxString GetDataDir () const

  Return the location of the applications global, i.e. not user-specific, data files.
- virtual wxString GetDocumentsDir () const

  Return the directory containing the current user's documents.
- virtual wxString GetExecutablePath () const

  Return the directory and the filename for the current executable.
- wxString GetInstallPrefix () const

  Return the program installation prefix, e.g. `/usr`, `/opt` or `/home/zeitlin`.
- virtual wxString GetLocalDataDir () const

  Return the location for application data files which are host-specific and can't, or shouldn't, be shared with the other machines.
- virtual wxString GetLocalizedResourcesDir (const wxString &lang, ResourceCat category=ResourceCat_None) const

  Return the localized resources directory containing the resource files of the specified category for the given language.
- virtual wxString GetPluginsDir () const

  Return the directory where the loadable modules (plugins) live.
- virtual wxString GetResourcesDir () const

  Return the directory where the application resource files are located.
- virtual wxString GetTempDir () const

  Return the directory for storing temporary files.
- virtual wxString GetUserConfigDir () const

  Return the directory for the user config files:
- virtual wxString GetUserDataDir () const

  Return the directory for the user-dependent application data files:
- virtual wxString GetUserLocalDataDir () const

  Return the directory for user data files which shouldn't be shared with the other machines.
- void IgnoreAppSubDir (const wxString &subdirPattern)

  MSW-specific function to customize application directory detection.

- void IgnoreAppBuildSubDirs ()

  MSW-specific function to ignore all common build directories.
- void SetInstallPrefix (const wxString &prefix)

  Lets wxStandardPaths know about the real program installation prefix on a Unix system.
- void UseAppInfo (int info)

  Controls what application information is used when constructing paths that should be unique to this program, such as the application data directory, the plugins directory on Unix, etc.

Static Public Member Functions

- static wxStandardPaths & Get ()

  Returns reference to the unique global standard paths object.
- static wxString MSWGetShellDir (int csidl)

  Returns location of Windows shell special folder.

Protected Member Functions

- wxStandardPaths ()

  Protected default constructor.

21.712.2 Member Enumeration Documentation

enum wxStandardPaths::ResourceCat

Possible values for category parameter of GetLocalizedResourcesDir().

Enumerator

ResourceCat_None No special category, this is the default.

ResourceCat_Messages Message catalog resources category.

21.712.3 Constructor & Destructor Documentation

wxStandardPaths::wxStandardPaths ( ) [protected]

Protected default constructor.

This constructor is protected in order to prevent creation of objects of this class as Get() should be used instead to access the unique global wxStandardPaths object of the correct type.

21.712.4 Member Function Documentation

void wxStandardPaths::DontIgnoreAppSubDir ( )

MSW-specific function undoing the effect of IgnoreAppSubDir() calls.

After a call to this function the program directory will be exactly the directory containing the main application binary, i.e. it undoes the effect of any previous IgnoreAppSubDir() calls including the ones done indirectly by IgnoreApp↩ BuildSubDirs() called from the class constructor.

Since

2.9.1

static wxStandardPaths& wxStandardPaths::Get ( ) [static]

Returns reference to the unique global standard paths object.

virtual wxString wxStandardPaths::GetAppDocumentsDir ( ) const [virtual]

Return the directory for the document files used by this application.

If the application-specific directory doesn't exist, this function returns GetDocumentsDir().

Example return values:

- Unix: ~/appinfo
- Windows: "C:\Documents and Settings\username\My Documents\appinfo"
- Mac: ~/Documents/appinfo

Since

2.9.0

virtual wxString wxStandardPaths::GetConfigDir ( ) const [virtual]

Return the directory containing the system config files.

Example return values:

- Unix: /etc
- Windows: "C:\Documents and Settings\All Users\Application Data"
- Mac: /Library/Preferences

See also

wxFileConfig

virtual wxString wxStandardPaths::GetDataDir ( ) const [virtual]

Return the location of the applications global, i.e. not user-specific, data files.

Example return values:

- Unix: prefix/share/appinfo
- Windows: the directory where the executable file is located
- Mac: appinfo.app/Contents/SharedSupport bundle subdirectory

Under Unix (only) it is possible to override the default value returned from this function by setting the value of WX_APPNAME_DATA_DIR environment variable to the directory to use (where APPNAME is the upper-cased value of wxApp::GetAppName()). This is useful in order to be able to run applications using this function without installing them as you can simply set this environment variable to the source directory location to allow the application to find its files there.

See also

GetLocalDataDir()

virtual wxString wxStandardPaths::GetDocumentsDir ( ) const `[virtual]`

Return the directory containing the current user's documents.

Example return values:

- Unix: ~ (the home directory)
- Windows: `"C:\Documents and Settings\username\My Documents"`
- Mac: `~/Documents`

Since

2.7.0

See also

GetAppDocumentsDir()

virtual wxString wxStandardPaths::GetExecutablePath ( ) const `[virtual]`

Return the directory and the filename for the current executable.

Example return values:

- Unix: `/usr/local/bin/exename`
- Windows: `"C:\Programs\AppFolder\exename.exe"`
- Mac: `/Applications/exename`.app/Contents/MacOS/exename

wxString wxStandardPaths::GetInstallPrefix ( ) const

Return the program installation prefix, e.g. `/usr`, `/opt` or `/home/zeitlin`.

If the prefix had been previously by SetInstallPrefix(), returns that value, otherwise tries to determine it automatically (Linux only right now) and finally returns the default `/usr/local` value if it failed.

Note

This function is only available under Unix platforms (but not limited to wxGTK mentioned below).

Availability: only available for the wxGTK port.

virtual wxString wxStandardPaths::GetLocalDataDir ( ) const `[virtual]`

Return the location for application data files which are host-specific and can't, or shouldn't, be shared with the other machines.

This is the same as GetDataDir() except under Unix where it returns `/etc/appinfo`.

virtual wxString wxStandardPaths::GetLocalizedResourcesDir (const wxString & *lang*, ResourceCat *category* = ResourceCat_None) const `[virtual]`

Return the localized resources directory containing the resource files of the specified category for the given language.

In general this is just the same as *lang* subdirectory of GetResourcesDir() (or `lang.lproj` under Mac OS X) but is something quite different for message catalog category under Unix where it returns the standard `prefix/share/locale/lang/LC_MESSAGES` directory.

Since

2.7.0

virtual wxString wxStandardPaths::GetPluginsDir ( ) const `[virtual]`

Return the directory where the loadable modules (plugins) live.

Example return values:

- Unix: `prefix/lib/appinfo`
- Windows: the directory of the executable file
- Mac: `appinfo.app/Contents/PlugIns` bundle subdirectory

See also

wxDynamicLibrary

virtual wxString wxStandardPaths::GetResourcesDir ( ) const `[virtual]`

Return the directory where the application resource files are located.

The resources are the auxiliary data files needed for the application to run and include, for example, image and sound files it might use.

This function is the same as GetDataDir() for all platforms except Mac OS X. Example return values:

- Unix: `prefix/share/appinfo`
- Windows: the directory where the executable file is located
- Mac: `appinfo.app/Contents/Resources` bundle subdirectory

Since

2.7.0

See also

GetLocalizedResourcesDir()

virtual wxString wxStandardPaths::GetTempDir ( ) const `[virtual]`

Return the directory for storing temporary files.

To create unique temporary files, it is best to use wxFileName::CreateTempFileName for correct behaviour when multiple processes are attempting to create temporary files.

Since

2.7.2

virtual wxString wxStandardPaths::GetUserConfigDir ( ) const `[virtual]`

Return the directory for the user config files:

- Unix: ~ (the home directory)
- Windows: "C:\Documents and Settings\username\Application Data"
- Mac: ~/Library/Preferences

Only use this method if you have a single configuration file to put in this directory, otherwise GetUserDataDir() is more appropriate as the latter adds `appinfo` to the path, unlike this function.

virtual wxString wxStandardPaths::GetUserDataDir ( ) const `[virtual]`

Return the directory for the user-dependent application data files:

- Unix: ~/.appinfo
- Windows: "C:\Documents and Settings\username\Application Data\appinfo"
- Mac: "~/Library/Application Support/appinfo"

virtual wxString wxStandardPaths::GetUserLocalDataDir ( ) const `[virtual]`

Return the directory for user data files which shouldn't be shared with the other machines.

This is the same as GetUserDataDir() for all platforms except Windows where it returns "C:\Documents and Settings\username\Local Settings\Application Data\appinfo"

void wxStandardPaths::IgnoreAppBuildSubDirs ( )

MSW-specific function to ignore all common build directories.

This function calls IgnoreAppSubDir() with all common values for build directory, e.g. "debug" and "release".

It is called by the class constructor and so the build directories are always ignored by default. You may use DontIgnoreAppSubDir() to avoid ignoring them if this is inappropriate for your application.

Since

2.9.1

void wxStandardPaths::IgnoreAppSubDir (const wxString & *subdirPattern*)

MSW-specific function to customize application directory detection.

This class supposes that data, plugins &c files are located under the program directory which is the directory containing the application binary itself. But sometimes this binary may be in a subdirectory of the main program directory, e.g. this happens in at least the following common cases:

- The program is in "bin" subdirectory of the installation directory.
- The program is in "debug" subdirectory of the directory containing sources and data files during development

By calling this function you instruct the class to remove the last component of the path if it matches its argument. Notice that it may be called more than once, e.g. you can call both IgnoreAppSubDir("bin") and IgnoreAppSub↩ Dir("debug") to take care of both production and development cases above but that each call will only remove the last path component. Finally note that the argument can contain wild cards so you can also call IgnoreAppSub↩ Dir("vc∗msw∗") to ignore all build directories at once when using wxWidgets-inspired output directories names.

Since

2.9.1

See also

IgnoreAppBuildSubDirs()

Parameters

subdirPattern	The subdirectory containing the application binary which should be ignored when determining the top application directory. The pattern is case-insensitive and may contain wild card characters '?' and '∗'.

static wxString wxStandardPaths::MSWGetShellDir (int *csidl*) [static]

Returns location of Windows shell special folder.

This function is, by definition, MSW-specific. It can be used to access pre-defined shell directories not covered by the existing methods of this class, e.g.:

```
#ifdef __WXMSW__
    // get the location of files waiting to be burned on a CD
    wxString cdburnArea =
        wxStandardPaths::MSWGetShellDir(CSIDL_CDBURN_AREA);
#endif // __WXMSW__
```

Parameters

csidl	

Since

2.9.1

void wxStandardPaths::SetInstallPrefix (const wxString & *prefix*)

Lets wxStandardPaths know about the real program installation prefix on a Unix system.

By default, the value returned by GetInstallPrefix() is used.

Although under Linux systems the program prefix may usually be determined automatically, portable programs should call this function. Usually the prefix is set during program configuration if using GNU autotools and so it is enough to pass its value defined in config.h to this function.

Note

This function is only available under Unix platforms (but not limited to wxGTK mentioned below).

Availability: only available for the wxGTK port.

void wxStandardPaths::UseAppInfo (int *info*)

Controls what application information is used when constructing paths that should be unique to this program, such as the application data directory, the plugins directory on Unix, etc.

Valid values for *info* are:

- `AppInfo_None`: don't use neither application nor vendor name in the paths.
- `AppInfo_AppName`: use the application name in the paths.
- `AppInfo_VendorName`: use the vendor name in the paths, usually used combined with AppInfo_App↩ Name, i.e. as

```
AppInfo_AppName |
   AppInfo_VendorName
```

By default, only the application name is used.

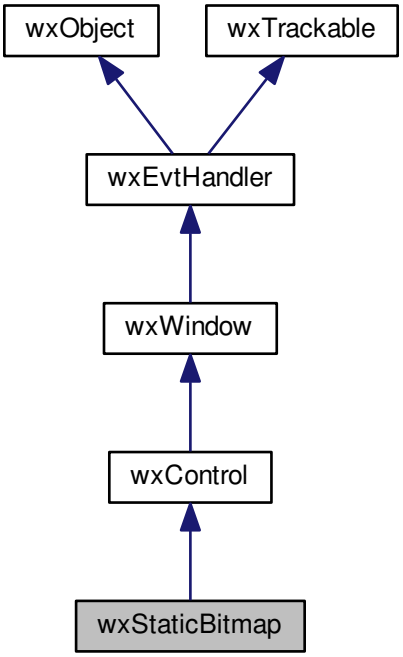
Since

2.9.0

21.713 wxStaticBitmap Class Reference

`#include <wx/statbmp.h>`

Inheritance diagram for wxStaticBitmap:



21.713.1 Detailed Description

A static bitmap control displays a bitmap.

Native implementations on some platforms are only meant for display of the small icons in the dialog boxes. In particular, under Windows 9x the size of bitmap is limited to 64∗64 pixels.

If you want to display larger images portably, you may use generic implementation wxGenericStaticBitmap declared in <wx/generic/statbmpg.h>.

Notice that for the best results, the size of the control should be the same as the size of the image displayed in it, as happens by default if it's not resized explicitly. Otherwise, behaviour depends on the platform: under MSW, the bitmap is drawn centred inside the control, while elsewhere it is drawn at the origin of the control.

Library: wxCore

Category: Controls

wxBitmap

Public Member Functions

- wxStaticBitmap ()

Default constructor.

- wxStaticBitmap (wxWindow *parent, wxWindowID id, const wxBitmap &label, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, long style=0, const wxString &name=wxStaticBitmapNameStr)

  Constructor, creating and showing a static bitmap control.

- bool Create (wxWindow *parent, wxWindowID id, const wxBitmap &label, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, long style=0, const wxString &name=wxStaticBitmapNameStr)

  Creation function, for two-step construction.

- virtual wxBitmap GetBitmap () const

  Returns the bitmap currently used in the control.

- virtual wxIcon GetIcon () const

  Returns the icon currently used in the control.

- virtual void SetBitmap (const wxBitmap &label)

  Sets the bitmap label.

- virtual void SetIcon (const wxIcon &label)

  Sets the label to the given icon.

Additional Inherited Members

21.713.2 Constructor & Destructor Documentation

wxStaticBitmap::wxStaticBitmap ( )

Default constructor.

wxStaticBitmap::wxStaticBitmap (wxWindow * *parent*, wxWindowID *id*, const wxBitmap & *label*, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, long *style* = `0`, const wxString & *name* = `wxStaticBitmapNameStr`)

Constructor, creating and showing a static bitmap control.

Parameters

parent	Parent window. Should not be NULL.
id	Control identifier. A value of -1 denotes a default value.
label	Bitmap label.
pos	Window position.
size	Window size.
style	Window style. See wxStaticBitmap.
name	Window name.

See also

Create()

21.713.3 Member Function Documentation

bool wxStaticBitmap::Create (wxWindow * *parent*, wxWindowID *id*, const wxBitmap & *label*, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, long *style* = `0`, const wxString & *name* = `wxStaticBitmapNameStr`)

Creation function, for two-step construction.

For details see wxStaticBitmap().

virtual wxBitmap wxStaticBitmap::GetBitmap ( ) const `[virtual]`

Returns the bitmap currently used in the control.

Notice that this method can be called even if SetIcon() had been used.

See also

SetBitmap()

virtual wxIcon wxStaticBitmap::GetIcon ( ) const `[virtual]`

Returns the icon currently used in the control.

Notice that this method can only be called if SetIcon() had been used: an icon can't be retrieved from the control if a bitmap had been set (using wxStaticBitmap::SetBitmap).

See also

SetIcon()

virtual void wxStaticBitmap::SetBitmap (const wxBitmap & *label*) `[virtual]`

Sets the bitmap label.

Parameters

label	The new bitmap.

See also

GetBitmap()

virtual void wxStaticBitmap::SetIcon (const wxIcon & *label*) `[virtual]`

Sets the label to the given icon.

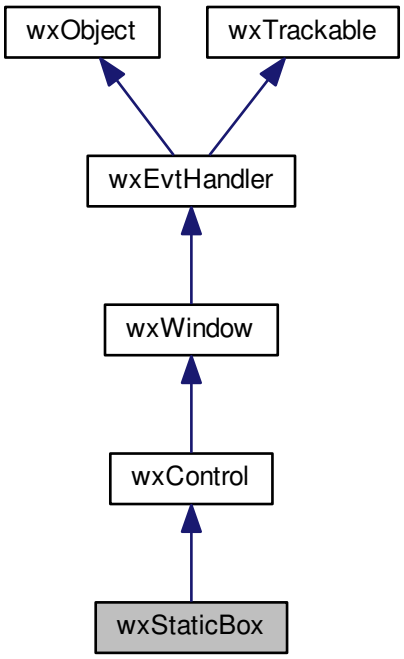
Parameters

label	The new icon.

21.714 wxStaticBox Class Reference

```
#include <wx/statbox.h>
```

Inheritance diagram for wxStaticBox:



21.714.1 Detailed Description

A static box is a rectangle drawn around other windows to denote a logical grouping of items.

Note that while the previous versions required that windows appearing inside a static box be created as its siblings (i.e. use the same parent as the static box itself), since wxWidgets 2.9.1 it is also possible to create them as children of wxStaticBox itself and you are actually encouraged to do it like this if compatibility with the previous versions is not important.

So the new recommended way to create static box is:

```
void MyFrame::CreateControls()
{
    wxPanel *panel = new wxPanel(this);
    wxStaticBox *box = new wxStaticBox(panel, wxID_ANY, "StaticBox");

    new wxStaticText(box, wxID_ANY "This window is a child of the staticbox");
    ...
}
```

While the compatible – and now deprecated – way is

```
wxStaticBox *box = new wxStaticBox(panel, wxID_ANY, "StaticBox");

new wxStaticText(panel, wxID_ANY "This window is a child of the panel");
...
```

Also note that there is a specialized wxSizer class (wxStaticBoxSizer) which can be used as an easier way to pack items into a static box.

Library: wxCore

Category: Controls

wxStaticText, wxStaticBoxSizer

Public Member Functions

- wxStaticBox ()

  Default constructor.
- wxStaticBox (wxWindow *parent, wxWindowID id, const wxString &label, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, long style=0, const wxString &name=wxStaticBoxNameStr)

  Constructor, creating and showing a static box.
- virtual ~wxStaticBox ()

  Destructor, destroying the group box.
- bool Create (wxWindow *parent, wxWindowID id, const wxString &label, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, long style=0, const wxString &name=wxStaticBoxNameStr)

  Creates the static box for two-step construction.

Additional Inherited Members

21.714.2 Constructor & Destructor Documentation

wxStaticBox::wxStaticBox ( )

Default constructor.

wxStaticBox::wxStaticBox (wxWindow * *parent*, wxWindowID *id*, const wxString & *label*, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, long *style* = 0, const wxString & *name* = wxStaticBoxNameStr)

Constructor, creating and showing a static box.

Parameters

parent	Parent window. Must not be NULL.
id	Window identifier. The value wxID_ANY indicates a default value.
label	Text to be displayed in the static box, the empty string for no label.
pos	Window position. If wxDefaultPosition is specified then a default position is chosen.
size	Checkbox size. If wxDefaultSize is specified then a default size is chosen.
style	Window style. See wxStaticBox.
name	Window name.

See also

Create()

virtual wxStaticBox::~wxStaticBox ( ) [virtual]

Destructor, destroying the group box.

21.714.3 Member Function Documentation

bool wxStaticBox::Create (wxWindow * *parent*, wxWindowID *id*, const wxString & *label*, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, long *style* = `0`, const wxString & *name* = `wxStaticBoxNameStr`)

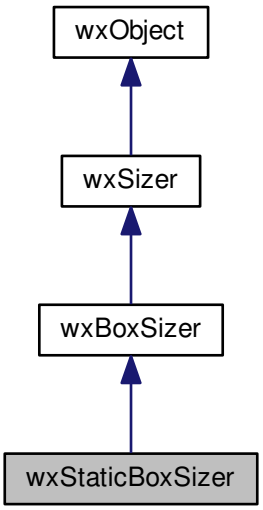
Creates the static box for two-step construction.

See wxStaticBox() for further details.

21.715 wxStaticBoxSizer Class Reference

`#include <wx/sizer.h>`

Inheritance diagram for wxStaticBoxSizer:



21.715.1 Detailed Description

wxStaticBoxSizer is a sizer derived from wxBoxSizer but adds a static box around the sizer.

The static box may be either created independently or the sizer may create it itself as a convenience. In any case, the sizer owns the wxStaticBox control and will delete it in the wxStaticBoxSizer destructor.

Note that since wxWidgets 2.9.1 you are encouraged to create the windows which are added to wxStaticBoxSizer as children of wxStaticBox itself, see this class documentation for more details.

Example of use of this class:

```
void MyFrame::CreateControls()
{
    wxPanel *panel = new wxPanel(this);
    ...
    wxStaticBoxSizer *sz = new wxStaticBoxSizer(
      wxVERTICAL, panel, "Box");
    sz->Add(new wxStaticText(sz->GetStaticBox(),
      wxID_ANY,
                             "This window is a child of the staticbox"));
```

```
    ...
}
```

wxSizer, wxStaticBox, wxBoxSizer, Sizers Overview

Public Member Functions

- wxStaticBoxSizer (wxStaticBox *box, int orient)

  This constructor uses an already existing static box.
- wxStaticBoxSizer (int orient, wxWindow *parent, const wxString &label=wxEmptyString)

  This constructor creates a new static box with the given label and parent window.
- wxStaticBox * GetStaticBox () const

  Returns the static box associated with the sizer.
- virtual wxSize CalcMin ()

  Implements the calculation of a box sizer's minimal.
- virtual void RecalcSizes ()

  Implements the calculation of a box sizer's dimensions and then sets the size of its children (calling wxWindow::SetSize if the child is a window).

Additional Inherited Members

21.715.2 Constructor & Destructor Documentation

wxStaticBoxSizer::wxStaticBoxSizer (wxStaticBox * *box,* int *orient*)

This constructor uses an already existing static box.

Parameters

box	The static box to associate with the sizer (which will take its ownership).
orient	Can be either `wxVERTICAL` or `wxHORIZONTAL`.

wxStaticBoxSizer::wxStaticBoxSizer (int *orient,* wxWindow * *parent,* const wxString & *label* = wxEmptyString)

This constructor creates a new static box with the given label and parent window.

21.715.3 Member Function Documentation

virtual wxSize wxStaticBoxSizer::CalcMin ( ) `[virtual]`

Implements the calculation of a box sizer's minimal.

It is used internally only and must not be called by the user. Documented for information.

Reimplemented from wxBoxSizer.

wxStaticBox* wxStaticBoxSizer::GetStaticBox ( ) const

Returns the static box associated with the sizer.

virtual void wxStaticBoxSizer::RecalcSizes ( ) [virtual]

Implements the calculation of a box sizer's dimensions and then sets the size of its children (calling wxWindow::SetSize if the child is a window).

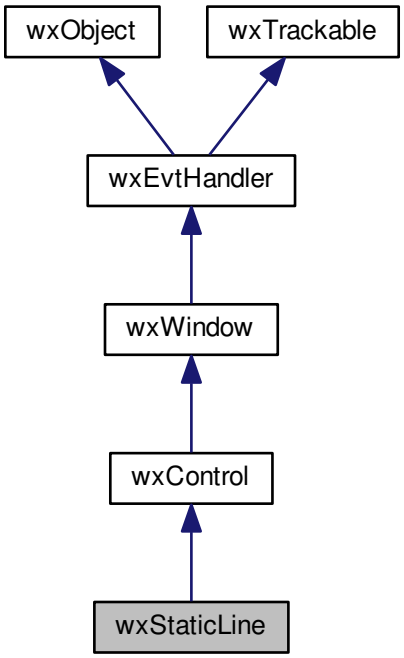
It is used internally only and must not be called by the user (call Layout() if you want to resize). Documented for information.

Reimplemented from wxBoxSizer.

21.716 wxStaticLine Class Reference

`#include <wx/statline.h>`

Inheritance diagram for wxStaticLine:



21.716.1 Detailed Description

A static line is just a line which may be used in a dialog to separate the groups of controls.

The line may be only vertical or horizontal. Moreover, not all ports (notably not wxGTK) support specifying the transversal direction of the line (e.g. height for a horizontal line) so for maximal portability you should specify it as wxDefaultCoord.

Styles

This class supports the following styles:

- wxLI_HORIZONTAL: Creates a horizontal line.
- wxLI_VERTICAL: Creates a vertical line.

Library: wxCore

Category: Controls

See also

wxStaticBox

Public Member Functions

- wxStaticLine ()

  Default constructor.
- wxStaticLine (wxWindow *parent, wxWindowID id=wxID_ANY, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, long style=wxLI_HORIZONTAL, const wxString &name=wxStaticLineNameStr)

  Constructor, creating and showing a static line.
- bool Create (wxWindow *parent, wxWindowID id=wxID_ANY, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, long style=wxLI_HORIZONTAL, const wxString &name=wxStaticLineNameStr)

  Creates the static line for two-step construction.
- bool IsVertical () const

  Returns true if the line is vertical, false if horizontal.

Static Public Member Functions

- static int GetDefaultSize ()

  This static function returns the size which will be given to the smaller dimension of the static line, i.e.

Additional Inherited Members

21.716.2 Constructor & Destructor Documentation

wxStaticLine::wxStaticLine ( )

Default constructor.

wxStaticLine::wxStaticLine (wxWindow * *parent*, wxWindowID *id* = wxID_ANY, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, long *style* = wxLI_HORIZONTAL, const wxString & *name* = `wxStaticLineNameStr`)

Constructor, creating and showing a static line.

Parameters

parent	Parent window. Must not be NULL.
id	Window identifier. The value wxID_ANY indicates a default value.
pos	Window position. If wxDefaultPosition is specified then a default position is chosen.
size	Size. Note that either the height or the width (depending on whether the line if horizontal or vertical) is ignored.
style	Window style (either wxLI_HORIZONTAL or wxLI_VERTICAL).
name	Window name.

See also

Create()

21.716.3 Member Function Documentation

bool wxStaticLine::Create (wxWindow * *parent*, wxWindowID *id* = wxID_ANY, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, long *style* = wxLI_HORIZONTAL, const wxString & *name* = `wxStaticLineNameStr`)

Creates the static line for two-step construction.

See wxStaticLine() for further details.

static int wxStaticLine::GetDefaultSize ( ) `[static]`

This static function returns the size which will be given to the smaller dimension of the static line, i.e.

its height for a horizontal line or its width for a vertical one.

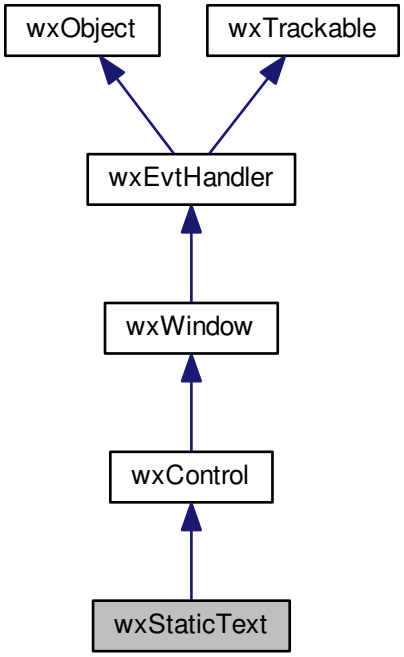
bool wxStaticLine::IsVertical ( ) const

Returns true if the line is vertical, false if horizontal.

21.717 wxStaticText Class Reference

`#include <wx/stattext.h>`

Inheritance diagram for wxStaticText:



21.717.1 Detailed Description

A static text control displays one or more lines of read-only text.

wxStaticText supports the three classic text alignments, label ellipsization i.e. replacing parts of the text with the ellipsis ("...") if the label doesn't fit into the provided space and also formatting markup with wxControl::SetLabel↩ Markup().

Styles

This class supports the following styles:

- wxALIGN_LEFT: Align the text to the left.
- wxALIGN_RIGHT: Align the text to the right.
- wxALIGN_CENTRE_HORIZONTAL: Center the text (horizontally).
- wxST_NO_AUTORESIZE: By default, the control will adjust its size to exactly fit to the size of the text when SetLabel() is called. If this style flag is given, the control will not change its size (this style is especially useful with controls which also have the `wxALIGN_RIGHT` or the `wxALIGN_CENTRE_HORIZONTAL` style because otherwise they won't make sense any longer after a call to SetLabel()).
- wxST_ELLIPSIZE_START: If the labeltext width exceeds the control width, replace the beginning of the label with an ellipsis; uses wxControl::Ellipsize.
- wxST_ELLIPSIZE_MIDDLE: If the label text width exceeds the control width, replace the middle of the label with an ellipsis; uses wxControl::Ellipsize.

- wxST_ELLIPSIZE_END: If the label text width exceeds the control width, replace the end of the label with an ellipsis; uses wxControl::Ellipsize.

Library: wxCore

Category: Controls

wxStaticBitmap, wxStaticBox

Public Member Functions

- wxStaticText ()

  Default constructor.
- wxStaticText (wxWindow *parent, wxWindowID id, const wxString &label, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, long style=0, const wxString &name=wxStaticTextNameStr)

  Constructor, creating and showing a text control.
- bool Create (wxWindow *parent, wxWindowID id, const wxString &label, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, long style=0, const wxString &name=wxStaticTextNameStr)

  Creation function, for two-step construction.
- bool IsEllipsized () const

  Returns true if the window styles for this control contains one of the `wxST_ELLIPSIZE_START`, `wxST_ELLIPSIZE_MIDDLE` or `wxST_ELLIPSIZE_END` styles.
- void Wrap (int width)

  This functions wraps the controls label so that each of its lines becomes at most width pixels wide if possible (the lines are broken at words boundaries so it might not be the case if words are too long).

Additional Inherited Members

21.717.2 Constructor & Destructor Documentation

wxStaticText::wxStaticText ( )

Default constructor.

wxStaticText::wxStaticText (wxWindow * *parent*, wxWindowID *id*, const wxString & *label*, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, long *style* = `0`, const wxString & *name* = `wxStaticTextNameStr`)

Constructor, creating and showing a text control.

Parameters

parent	Parent window. Should not be NULL.
id	Control identifier. A value of -1 denotes a default value.
label	Text label.
pos	Window position.

size	Window size.
style	Window style. See wxStaticText.
name	Window name.

See also

Create()

21.717.3 Member Function Documentation

bool wxStaticText::Create (wxWindow * *parent*, wxWindowID *id*, const wxString & *label*, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, long *style* = `0`, const wxString & *name* = `wxStaticTextNameStr`)

Creation function, for two-step construction.

For details see wxStaticText().

bool wxStaticText::IsEllipsized ( ) const

Returns true if the window styles for this control contains one of the `wxST_ELLIPSIZE_START`, `wxST_ELLIPSIZE_MIDDLE` or `wxST_ELLIPSIZE_END` styles.

void wxStaticText::Wrap (int *width*)

This functions wraps the controls label so that each of its lines becomes at most *width* pixels wide if possible (the lines are broken at words boundaries so it might not be the case if words are too long).

If *width* is negative, no wrapping is done. Note that this width is not necessarily the total width of the control, since a few pixels for the border (depending on the controls border style) may be added.

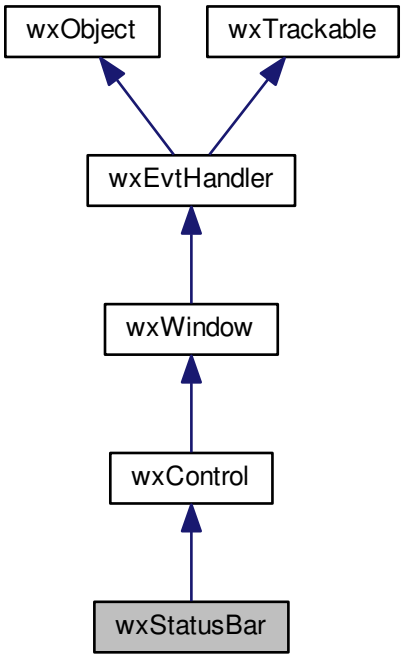
Since

2.6.2

21.718 wxStatusBar Class Reference

`#include <wx/statusbr.h>`

Inheritance diagram for wxStatusBar:



21.718.1 Detailed Description

A status bar is a narrow window that can be placed along the bottom of a frame to give small amounts of status information.

It can contain one or more fields, one or more of which can be variable length according to the size of the window.

wxStatusBar also maintains an independent stack of status texts for each field (see PushStatusText() and PopStatusText()).

Note that in wxStatusBar context, the terms *pane* and *field* are synonyms.

Styles

This class supports the following styles:

- wxSTB_SIZEGRIP: Displays a gripper at the right-hand side of the status bar which can be used to resize the parent window.
- wxSTB_SHOW_TIPS: Displays tooltips for those panes whose status text has been ellipsized/truncated because the status text doesn't fit the pane width. Note that this style has effect only on wxGTK (with GTK+ >= 2.12) currently.
- wxSTB_ELLIPSIZE_START: Replace the beginning of the status texts with an ellipsis when the status text widths exceed the status bar pane's widths (uses wxControl::Ellipsize).
- wxSTB_ELLIPSIZE_MIDDLE: Replace the middle of the status texts with an ellipsis when the status text widths exceed the status bar pane's widths (uses wxControl::Ellipsize).

- wxSTB_ELLIPSIZE_END: Replace the end of the status texts with an ellipsis when the status text widths exceed the status bar pane's widths (uses wxControl::Ellipsize).
- wxSTB_DEFAULT_STYLE: The default style: includes `wxSTB_SIZEGRIP|wxSTB_SHOW_TIPS|wxSTB_ELLIPSIZE_END|wxFULL_REPAINT_ON_RESIZE`.

Remarks

It is possible to create controls and other windows on the status bar. Position these windows from an OnSize() event handler.
Notice that only the first 127 characters of a string will be shown in status bar fields under pre-XP MSW systems (or even under later systems if a proper manifest indicating that the program uses version 6 of common controls library is not used). This is a limitation of the native control on these platforms.

Library: wxCore

wxStatusBarPane, wxFrame, Status Bar Sample

Public Member Functions

- wxStatusBar ()

  Default ctor.
- wxStatusBar (wxWindow *parent, wxWindowID id=wxID_ANY, long style=wxSTB_DEFAULT_STYLE, const wxString &name=wxStatusBarNameStr)

  Constructor, creating the window.
- virtual ~wxStatusBar ()

  Destructor.
- bool Create (wxWindow *parent, wxWindowID id=wxID_ANY, long style=wxSTB_DEFAULT_STYLE, const wxString &name=wxStatusBarNameStr)

  Creates the window, for two-step construction.
- virtual bool GetFieldRect (int i, wxRect &rect) const

  Returns the size and position of a field's internal bounding rectangle.
- int GetFieldsCount () const

  Returns the number of fields in the status bar.
- const wxStatusBarPane & GetField (int n) const

  Returns the wxStatusBarPane representing the n-th field.
- wxSize GetBorders () const

  Returns the horizontal and vertical borders used when rendering the field text inside the field area.
- virtual wxString GetStatusText (int i=0) const

  Returns the string associated with a status bar field.
- int GetStatusWidth (int n) const

  Returns the width of the n-th field.
- int GetStatusStyle (int n) const

  Returns the style of the n-th field.
- void PopStatusText (int field=0)

  Restores the text to the value it had before the last call to PushStatusText().
- void PushStatusText (const wxString &string, int field=0)

  Saves the current field text in a per-field stack, and sets the field text to the string passed as argument.

- virtual void SetFieldsCount (int number=1, const int ∗widths=NULL)

  Sets the number of fields, and optionally the field widths.
- virtual void SetMinHeight (int height)

  Sets the minimal possible height for the status bar.
- virtual void SetStatusStyles (int n, const int ∗styles)

  Sets the styles of the fields in the status line which can make fields appear flat or raised instead of the standard sunken 3D border.
- virtual void SetStatusText (const wxString &text, int i=0)

  Sets the status text for the i-th field.
- virtual void SetStatusWidths (int n, const int ∗widths_field)

  Sets the widths of the fields in the status line.

Additional Inherited Members

21.718.2 Constructor & Destructor Documentation

wxStatusBar::wxStatusBar ( )

Default ctor.

wxStatusBar::wxStatusBar (wxWindow ∗ *parent*, wxWindowID *id* = wxID_ANY, long *style* = wxSTB_DEFAULT_STYLE, const wxString & *name* = `wxStatusBarNameStr`)

Constructor, creating the window.

Parameters

parent	The window parent, usually a frame.
id	The window identifier. It may take a value of -1 to indicate a default value.
style	The window style. See wxStatusBar.
name	The name of the window. This parameter is used to associate a name with the item, allowing the application user to set Motif resource values for individual windows.

See also

Create()

virtual wxStatusBar::∼wxStatusBar ( ) `[virtual]`

Destructor.

21.718.3 Member Function Documentation

bool wxStatusBar::Create (wxWindow ∗ *parent*, wxWindowID *id* = wxID_ANY, long *style* = wxSTB_DEFAULT_STYLE, const wxString & *name* = `wxStatusBarNameStr`)

Creates the window, for two-step construction.

See wxStatusBar() for details.

wxSize wxStatusBar::GetBorders ( ) const

Returns the horizontal and vertical borders used when rendering the field text inside the field area.

Note that the rect returned by GetFieldRect() already accounts for the presence of horizontal and vertical border returned by this function.

const wxStatusBarPane& wxStatusBar::GetField (int *n*) const

Returns the wxStatusBarPane representing the *n-th* field.

virtual bool wxStatusBar::GetFieldRect (int *i*, wxRect & *rect*) const [virtual]

Returns the size and position of a field's internal bounding rectangle.

Parameters

i	The field in question.
rect	The rectangle values are placed in this variable.

Returns

true if the field index is valid, false otherwise.

wxPerl Note: In wxPerl this function returns a `Wx::Rect` if the field index is valid, `undef` otherwise.

See also

wxRect

int wxStatusBar::GetFieldsCount ( ) const

Returns the number of fields in the status bar.

int wxStatusBar::GetStatusStyle (int *n*) const

Returns the style of the *n-th* field.

See wxStatusBarPane::GetStyle() for more info.

virtual wxString wxStatusBar::GetStatusText (int *i* = 0) const [virtual]

Returns the string associated with a status bar field.

Parameters

i	The number of the status field to retrieve, starting from zero.

Returns

The status field string if the field is valid, otherwise the empty string.

See also

SetStatusText()

int wxStatusBar::GetStatusWidth (int *n*) const

Returns the width of the *n-th* field.

See wxStatusBarPane::GetWidth() for more info.

void wxStatusBar::PopStatusText (int *field* = 0)

Restores the text to the value it had before the last call to PushStatusText().

Notice that if SetStatusText() had been called in the meanwhile, PopStatusText() will not change the text, i.e. it does not override explicit changes to status text but only restores the saved text if it hadn't been changed since.

See also

PushStatusText()

void wxStatusBar::PushStatusText (const wxString & *string,* int *field* = 0)

Saves the current field text in a per-field stack, and sets the field text to the string passed as argument.

See also

PopStatusText()

virtual void wxStatusBar::SetFieldsCount (int *number* = 1, const int * *widths* = NULL) [virtual]

Sets the number of fields, and optionally the field widths.

Parameters

number	The number of fields. If this is greater than the previous number, then new fields with empty strings will be added to the status bar.
widths	An array of n integers interpreted in the same way as in SetStatusWidths().

wxPerl Note: In wxPerl this function accepts only the *number* parameter. Use SetStatusWidths to set the field widths.

virtual void wxStatusBar::SetMinHeight (int *height*) [virtual]

Sets the minimal possible height for the status bar.

The real height may be bigger than the height specified here depending on the size of the font used by the status bar.

virtual void wxStatusBar::SetStatusStyles (int *n,* const int * *styles*) [virtual]

Sets the styles of the fields in the status line which can make fields appear flat or raised instead of the standard sunken 3D border.

Parameters

n	The number of fields in the status bar. Must be equal to the number passed to SetFields↩ Count() the last time it was called.

styles	Contains an array of *n* integers with the styles for each field. There are four possible styles: • `wxSB_NORMAL` (default): The field appears with the default native border. • `wxSB_FLAT`: No border is painted around the field so that it appears flat. • `wxSB_RAISED`: A raised 3D border is painted around the field. • `wxSB_SUNKEN`: A sunken 3D border is painted around the field (this style is new since wxWidgets 2.9.5).

virtual void wxStatusBar::SetStatusText (const wxString & *text*, int *i* = 0) [virtual]

Sets the status text for the *i-th* field.

The given text will replace the current text.

Note that if PushStatusText() had been called before the new text will also replace the last saved value to make sure that the next call to PopStatusText() doesn't restore the old value, which was overwritten by the call to this function.

Parameters

text	The text to be set. Use an empty string ("") to clear the field.
i	The field to set, starting from zero.

See also

GetStatusText(), wxFrame::SetStatusText

virtual void wxStatusBar::SetStatusWidths (int *n*, const int * *widths_field*) [virtual]

Sets the widths of the fields in the status line.

There are two types of fields: **fixed** widths and **variable** width fields. For the fixed width fields you should specify their (constant) width in pixels. For the variable width fields, specify a negative number which indicates how the field should expand: the space left for all variable width fields is divided between them according to the absolute value of this number. A variable width field with width of -2 gets twice as much of it as a field with width -1 and so on.

For example, to create one fixed width field of width 100 in the right part of the status bar and two more fields which get 66% and 33% of the remaining space correspondingly, you should use an array containing -2, -1 and 100.

Parameters

n	The number of fields in the status bar. Must be equal to the number passed to SetFields↩ Count() the last time it was called.
widths_field	Contains an array of n integers, each of which is either an absolute status field width in pixels if positive or indicates a variable width field if negative. The special value NULL means that all fields should get the same width.

Remarks

The widths of the variable fields are calculated from the total width of all fields, minus the sum of widths of the non-variable fields, divided by the number of variable fields.

wxPerl Note: In wxPerl this method takes as parameters the field widths.

SetFieldsCount(), wxFrame::SetStatusWidths()

21.719 wxStatusBarPane Class Reference

```
#include <wx/statusbr.h>
```

21.719.1 Detailed Description

A status bar pane data container used by wxStatusBar.

Library: wxCore

Category: Data Structures

See also

wxStatusBar

Public Member Functions

- wxStatusBarPane (int style=wxSB_NORMAL, int width=0)

  Constructs the pane with the given style and width.
- int GetWidth () const

  Returns the pane width; it maybe negative, indicating a variable-width field.
- int GetStyle () const

  Returns the pane style.
- wxString GetText () const

  Returns the text currently shown in this pane.

21.719.2 Constructor & Destructor Documentation

wxStatusBarPane::wxStatusBarPane (int *style* = wxSB_NORMAL, int *width* = 0)

Constructs the pane with the given *style* and *width*.

21.719.3 Member Function Documentation

int wxStatusBarPane::GetStyle ( ) const

Returns the pane style.

wxString wxStatusBarPane::GetText ( ) const

Returns the text currently shown in this pane.

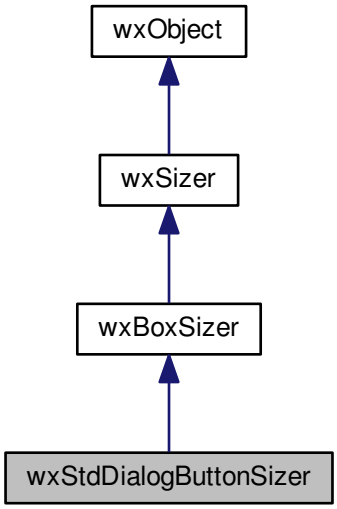
int wxStatusBarPane::GetWidth ( ) const

Returns the pane width; it maybe negative, indicating a variable-width field.

21.720 wxStdDialogButtonSizer Class Reference

`#include <wx/sizer.h>`

Inheritance diagram for wxStdDialogButtonSizer:



21.720.1 Detailed Description

This class creates button layouts which conform to the standard button spacing and ordering defined by the platform or toolkit's user interface guidelines (if such things exist).

By using this class, you can ensure that all your standard dialogs look correct on all major platforms. Currently it conforms to the Windows, GTK+ and Mac OS X human interface guidelines.

When there aren't interface guidelines defined for a particular platform or toolkit, wxStdDialogButtonSizer reverts to the Windows implementation.

To use this class, first add buttons to the sizer by calling wxStdDialogButtonSizer::AddButton (or wxStdDialogButtonSizer::SetAffirmativeButton, wxStdDialogButtonSizer::SetNegativeButton or wxStdDialogButtonSizer::SetCancelButton) and then call Realize in order to create the actual button layout used. Other than these special operations, this sizer works like any other sizer.

If you add a button with wxID_SAVE, on Mac OS X the button will be renamed to "Save" and the wxID_NO button will be renamed to "Don't Save" in accordance with the Mac OS X Human Interface Guidelines.

Library: wxCore

Category: Window Layout

See also

wxSizer, Sizers Overview, wxDialog::CreateButtonSizer

Public Member Functions

- wxStdDialogButtonSizer ()

  Constructor for a wxStdDialogButtonSizer.
- void AddButton (wxButton ∗button)

  Adds a button to the wxStdDialogButtonSizer.
- void Realize ()

  Rearranges the buttons and applies proper spacing between buttons to make them match the platform or toolkit's interface guidelines.
- void SetAffirmativeButton (wxButton ∗button)

  Sets the affirmative button for the sizer.
- void SetCancelButton (wxButton ∗button)

  Sets the cancel button for the sizer.
- void SetNegativeButton (wxButton ∗button)

  Sets the negative button for the sizer.
- virtual void RecalcSizes ()

  Implements the calculation of a box sizer's dimensions and then sets the size of its children (calling wxWindow::SetSize if the child is a window).
- virtual wxSize CalcMin ()

  Implements the calculation of a box sizer's minimal.

Additional Inherited Members

21.720.2 Constructor & Destructor Documentation

wxStdDialogButtonSizer::wxStdDialogButtonSizer ( )

Constructor for a wxStdDialogButtonSizer.

21.720.3 Member Function Documentation

void wxStdDialogButtonSizer::AddButton (wxButton ∗ *button*)

Adds a button to the wxStdDialogButtonSizer.

The *button* must have one of the following identifiers:

- wxID_OK
- wxID_YES
- wxID_SAVE
- wxID_APPLY
- wxID_CLOSE
- wxID_NO
- wxID_CANCEL
- wxID_HELP
- wxID_CONTEXT_HELP

virtual wxSize wxStdDialogButtonSizer::CalcMin ( ) [virtual]

Implements the calculation of a box sizer's minimal.

It is used internally only and must not be called by the user. Documented for information.

Reimplemented from wxBoxSizer.

void wxStdDialogButtonSizer::Realize ( )

Rearranges the buttons and applies proper spacing between buttons to make them match the platform or toolkit's interface guidelines.

virtual void wxStdDialogButtonSizer::RecalcSizes ( ) [virtual]

Implements the calculation of a box sizer's dimensions and then sets the size of its children (calling wxWindow::SetSize if the child is a window).

It is used internally only and must not be called by the user (call Layout() if you want to resize). Documented for information.

Reimplemented from wxBoxSizer.

void wxStdDialogButtonSizer::SetAffirmativeButton (wxButton * *button*)

Sets the affirmative button for the sizer.

This allows you to use identifiers other than the standard identifiers outlined above.

void wxStdDialogButtonSizer::SetCancelButton (wxButton * *button*)

Sets the cancel button for the sizer.

This allows you to use identifiers other than the standard identifiers outlined above.

void wxStdDialogButtonSizer::SetNegativeButton (wxButton * *button*)

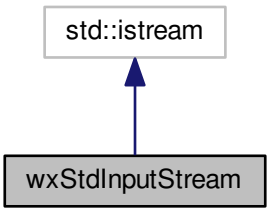
Sets the negative button for the sizer.

This allows you to use identifiers other than the standard identifiers outlined above.

21.721 wxStdInputStream Class Reference

```
#include <wx/stdstream.h>
```

Inheritance diagram for wxStdInputStream:



21.721.1 Detailed Description

wxStdInputStream is a std::istream derived stream which reads from a wxInputStream.

Example:

```
wxFFileInputStream file("words.txt");
wxStdInputStream in(file);
std::vector<std::string> words;

// read words from words.txt
std::copy(std::istream_iterator<std::string>(in),
          std::istream_iterator<std::string>(),
          std::back_inserter(words));

// sort and remove duplicates
std::sort(words.begin(), words.end());
words.resize(std::unique(words.begin(), words.end()) - words.begin());

// print words
std::copy(words.begin(), words.end(),
          std::ostream_iterator<std::string>(std::cout, "\n"));
```

Library: wxBase

Category: Streams

See also

wxInputStream, wxStdInputStreamBuffer

Public Member Functions

- wxStdInputStream (wxInputStream &stream)

  Creates a std::istream derived stream which reads from a wxInputStream.
- virtual ~wxStdInputStream ()

  Destructor.

21.721.2 Constructor & Destructor Documentation

wxStdInputStream::wxStdInputStream (wxInputStream & *stream*)

Creates a std::istream derived stream which reads from a wxInputStream.

Parameters

stream	Stream to read from.

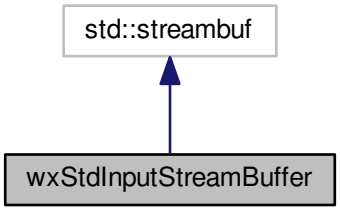
virtual wxStdInputStream::~wxStdInputStream ( ) [inline], [virtual]

Destructor.

21.722 wxStdInputStreamBuffer Class Reference

`#include <wx/stdstream.h>`

Inheritance diagram for wxStdInputStreamBuffer:



21.722.1 Detailed Description

wxStdInputStreamBuffer is a std::streambuf derived stream buffer which reads from a wxInputStream.

Example:

```
wxFFileInputStream file("input.txt.gz");
wxZlibInputStream gzipInput(file, wxZLIB_GZIP);
wxStdInputStreamBuffer gzipStreamBuffer(gzipInput);

// redirect std::cin to read from compressed file
std::streambuf* streamBufferOld = std::cin.rdbuf(&gzipStreamBuffer);

// prompt for integer
int number;
std::cout << "Enter an integer: " << std::flush;
std::cin >> number;
std::cout << std::endl;
std::cout << "You entered the integer " << number << "." << std::endl;

// restore std::cin
std::cin.rdbuf(streamBufferOld);
```

Library: wxBase

Category: Streams

See also

wxInputStream, wxStdInputStream

Public Member Functions

- wxStdInputStreamBuffer (wxInputStream &stream)

  Creates a std::steambuf derived stream buffer which reads from a wxInputStream.
- virtual ~wxStdInputStreamBuffer ()

  Destructor.

21.722.2 Constructor & Destructor Documentation

wxStdInputStreamBuffer::wxStdInputStreamBuffer (wxInputStream & *stream*)

Creates a std::steambuf derived stream buffer which reads from a wxInputStream.

Parameters

stream	Stream to read from.

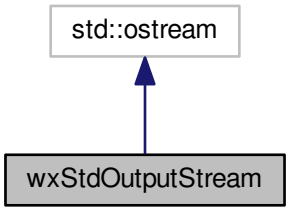
virtual wxStdInputStreamBuffer::~wxStdInputStreamBuffer ( ) [inline], [virtual]

Destructor.

21.723 wxStdOutputStream Class Reference

`#include <wx/stdstream.h>`

Inheritance diagram for wxStdOutputStream:



21.723.1 Detailed Description

wxStdOutputStream is a std::ostream derived stream which writes to a wxOutputStream.

Example:

```
wxFFileOutputStream file("out.txt.gz");
wxZlibOutputStream gzipOutput(file, -1, wxZLIB_GZIP);
wxStdOutputStream out(gzipOutput);

out << "Hello world!" << std::endl;
```

  Creates a std::steambuf derived stream buffer which writes to a wxOutputStream.
- virtual ~wxStdOutputStreamBuffer ()

  Destructor.

21.724.2 Constructor & Destructor Documentation

wxStdOutputStreamBuffer::wxStdOutputStreamBuffer (wxOutputStream & *stream*)

Creates a std::steambuf derived stream buffer which writes to a wxOutputStream.

Parameters

stream	Stream to write to.

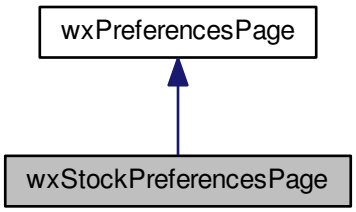
virtual wxStdOutputStreamBuffer::~wxStdOutputStreamBuffer ( ) [inline], [virtual]

Destructor.

21.725 wxStockPreferencesPage Class Reference

```
#include <wx/preferences.h>
```

Inheritance diagram for wxStockPreferencesPage:



21.725.1 Detailed Description

Specialization of wxPreferencesPage useful for certain commonly used preferences page.

On OS X, preferences pages named "General" and "Advanced" are commonly used in apps and the OS provides stock icons for them that should be used. Instead of reimplementing this behavior yourself, you can inherit from wxStockPreferencesPage and get correct title and icon.

Notice that this class only implements GetName() and GetLargeIcon(), you still have to provide the rest of wxPreferencesPage implementation.

Library: wxCore

Since

2.9.5

Public Types

- enum Kind {
  Kind_General,
  Kind_Advanced }

  Kinds of stock pages.

Public Member Functions

- wxStockPreferencesPage (Kind kind)

  Constructor.
- Kind GetKind () const

  Returns the page's kind.
- virtual wxString GetName () const

  Reimplemented to return suitable name for the page's kind.
- virtual wxBitmap GetLargeIcon () const

  Reimplemented to return stock icon on OS X.

21.725.2 Member Enumeration Documentation

enum wxStockPreferencesPage::Kind

Kinds of stock pages.

Enumerator

Kind_General The "General" page.

Kind_Advanced The "Advanced" page.

21.725.3 Constructor & Destructor Documentation

wxStockPreferencesPage::wxStockPreferencesPage (Kind *kind*)

Constructor.

21.725.4 Member Function Documentation

Kind wxStockPreferencesPage::GetKind ( ) const

Returns the page's kind.

virtual wxBitmap wxStockPreferencesPage::GetLargeIcon ( ) const `[virtual]`

Reimplemented to return stock icon on OS X.

Implements wxPreferencesPage.

virtual wxString wxStockPreferencesPage::GetName ( ) const `[virtual]`

Reimplemented to return suitable name for the page's kind.

Implements wxPreferencesPage.

21.726 wxStopWatch Class Reference

`#include <wx/stopwatch.h>`

21.726.1 Detailed Description

The wxStopWatch class allow you to measure time intervals.

For example, you may use it to measure the time elapsed by some function:

```
wxStopWatch sw;
CallLongRunningFunction();
wxLogMessage("The long running function took %ldms to execute",
             sw.Time());
sw.Pause();
... stopwatch is stopped now ...
sw.Resume();
CallLongRunningFunction();
wxLogMessage("And calling it twice took %ldms in all", sw.Time());
```

Since wxWidgets 2.9.3 this class uses `QueryPerformanceCounter()` function under MSW to measure the elapsed time. It provides higher precision than the usual timer functions but can suffer from bugs in its implementation in some Windows XP versions. If you encounter such problems, installing a Microsoft hot fix from `http://support.microsoft.com/?id=896256` could be necessary.

Library: wxBase

Category: Miscellaneous

See also

wxTimer

Public Member Functions

- wxStopWatch ()

  Constructor.
- void Pause ()

  Pauses the stop watch.
- void Resume ()

  Resumes the stop watch which had been paused with Pause().
- void Start (long milliseconds=0)

  (Re)starts the stop watch with a given initial value.
- long Time () const

  Returns the time in milliseconds since the start (or restart) or the last call of Pause().
- wxLongLong TimeInMicro () const

  Returns elapsed time in microseconds.

21.726.2 Constructor & Destructor Documentation

wxStopWatch::wxStopWatch ( )

Constructor.

This starts the stop watch.

21.726.3 Member Function Documentation

void wxStopWatch::Pause ( )

Pauses the stop watch.

Call Resume() to resume time measuring again.

If this method is called several times, `Resume()` must be called the same number of times to really resume the stop watch. You may, however, call Start() to resume it unconditionally.

void wxStopWatch::Resume ( )

Resumes the stop watch which had been paused with Pause().

void wxStopWatch::Start (long *milliseconds* = 0)

(Re)starts the stop watch with a given initial value.

The stopwatch will always be running after calling Start(), even if Pause() had been called before and even if it had been called multiple times.

long wxStopWatch::Time ( ) const

Returns the time in milliseconds since the start (or restart) or the last call of Pause().

See also

TimeInMicro()

wxLongLong wxStopWatch::TimeInMicro ( ) const

Returns elapsed time in microseconds.

This method is similar to Time() but returns the elapsed time in microseconds and not milliseconds. Notice that not all platforms really can measure times with this precision.

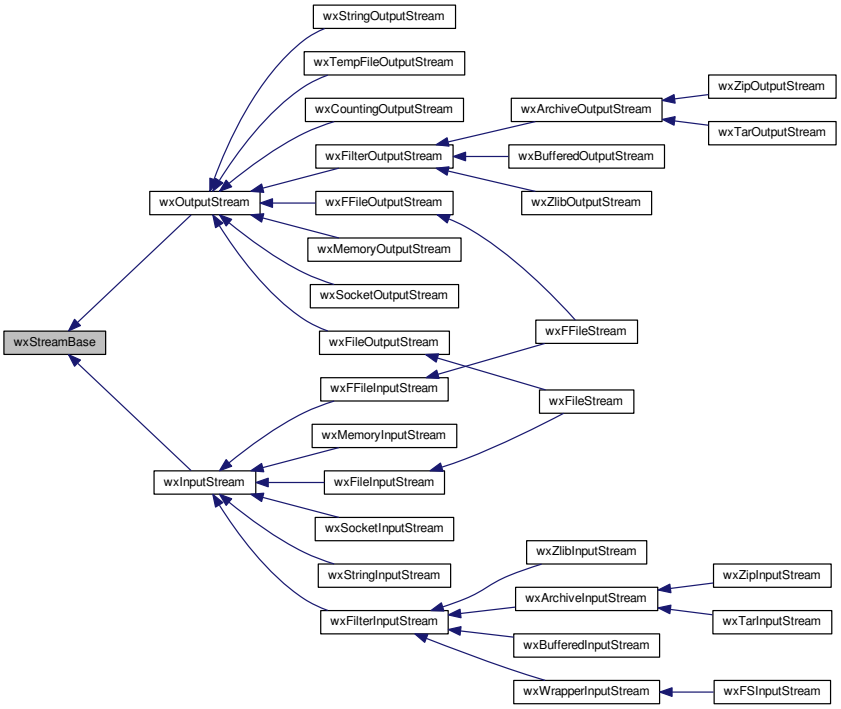
Since

2.9.3

21.727 wxStreamBase Class Reference

`#include <wx/stream.h>`

Inheritance diagram for wxStreamBase:



21.727.1 Detailed Description

This class is the base class of most stream related classes in wxWidgets.

It must not be used directly.

Library: wxBase

Category: Streams

See also

wxStreamBuffer

Public Member Functions

- wxStreamBase ()

  Creates a dummy stream object.
- virtual ~wxStreamBase ()

  Destructor.
- wxStreamError GetLastError () const

  This function returns the last error.
- virtual wxFileOffset GetLength () const

  Returns the length of the stream in bytes.
- virtual size_t GetSize () const

  This function returns the size of the stream.
- virtual bool IsOk () const

  Returns true if no error occurred on the stream.
- virtual bool IsSeekable () const

  Returns true if the stream supports seeking to arbitrary offsets.
- void Reset (wxStreamError error=wxSTREAM_NO_ERROR)

  Resets the stream state.
- bool operator! () const

  Returns the opposite of IsOk().

Protected Member Functions

- virtual wxFileOffset OnSysSeek (wxFileOffset pos, wxSeekMode mode)

  Internal function.
- virtual wxFileOffset OnSysTell () const

  Internal function.

21.727.2 Constructor & Destructor Documentation

wxStreamBase::wxStreamBase ( )

Creates a dummy stream object.

It doesn't do anything.

virtual wxStreamBase::~wxStreamBase ( ) [virtual]

Destructor.

21.727.3 Member Function Documentation

wxStreamError wxStreamBase::GetLastError ( ) const

This function returns the last error.

virtual wxFileOffset wxStreamBase::GetLength ( ) const [virtual]

Returns the length of the stream in bytes.

If the length cannot be determined (this is always the case for socket streams for example), returns wxInvalidOffset.

Since

2.5.4

Reimplemented in wxCountingOutputStream.

virtual size_t wxStreamBase::GetSize ( ) const [virtual]

This function returns the size of the stream.

For example, for a file it is the size of the file.

Warning

There are streams which do not have size by definition, such as socket streams. In that cases, GetSize() returns 0 so you should always test its return value.

virtual bool wxStreamBase::IsOk ( ) const [virtual]

Returns true if no error occurred on the stream.

See also

GetLastError()

Reimplemented in wxFSInputStream, wxFileStream, wxFFileStream, wxFFileInputStream, wxFileInputStream, wxFileOutputStream, and wxFFileOutputStream.

virtual bool wxStreamBase::IsSeekable ( ) const [virtual]

Returns true if the stream supports seeking to arbitrary offsets.

virtual wxFileOffset wxStreamBase::OnSysSeek (wxFileOffset *pos*, wxSeekMode *mode*) [protected], [virtual]

Internal function.

It is called when the stream needs to change the current position.

Parameters

pos	Offset to seek to.
mode	One of the wxSeekMode enumeration values.

Returns

The new stream position or wxInvalidOffset on error.

virtual wxFileOffset wxStreamBase::OnSysTell ( ) const `[protected], [virtual]`

Internal function.

It is called when the stream needs to know the real position.

Returns

The current stream position.

bool wxStreamBase::operator! ( ) const

Returns the opposite of IsOk().

You can use this function to test the validity of the stream as if it was a pointer:

```
bool DoSomething(wxInputStream& stream)
{
    wxInt32 data;
    if (!stream.Read(&data, 4))
        return false;
    ...
}
```

void wxStreamBase::Reset (wxStreamError *error* = wxSTREAM_NO_ERROR)

Resets the stream state.

By default, resets the stream to good state, i.e. clears any errors. Since wxWidgets 2.9.3 can be also used to explicitly set the state to the specified error (the *error* argument didn't exist in the previous versions).

See also

GetLastError()

21.728 wxStreamBuffer Class Reference

`#include <wx/stream.h>`

21.728.1 Detailed Description

wxStreamBuffer is a cache manager for wxStreamBase: it manages a stream buffer linked to a stream.

Each stream always has one autoinitialized stream buffer, but you may attach more of them to the same stream.

Library: wxBase

Category: Streams

See also

wxStreamBase, Stream Classes Overview

Public Types

- enum BufMode {
  read,
  write,
  read_write }

  BufMode flags.

Public Member Functions

- wxStreamBuffer (wxStreamBase &stream, BufMode mode)

  Constructor, creates a new stream buffer using stream as a parent stream and mode as the IO mode.
- wxStreamBuffer (size_t bufsize, wxInputStream &stream)

  Constructor for an input buffer of the specified size.
- wxStreamBuffer (size_t bufsize, wxOutputStream &stream)

  Constructor for an output buffer of the specified size.
- wxStreamBuffer (BufMode mode)

  Constructor; creates a new empty stream buffer which won't flush any data to a stream.
- wxStreamBuffer (const wxStreamBuffer &buffer)

  Copy constructor.
- ~wxStreamBuffer ()

  Destructor.
- bool FillBuffer ()

  Fill the IO buffer.
- void Fixed (bool fixed)

  Toggles the fixed flag.
- bool FlushBuffer ()

  Flushes the IO buffer.
- void Flushable (bool flushable)

  Toggles the flushable flag.
- void * GetBufferEnd () const

  Returns a pointer on the end of the stream buffer.
- void * GetBufferPos () const

  Returns a pointer on the current position of the stream buffer.
- size_t GetBufferSize () const

  Returns the size of the buffer.
- void * GetBufferStart () const

  Returns a pointer on the start of the stream buffer.
- virtual char GetChar ()

  Gets a single char from the stream buffer.
- size_t GetDataLeft ()

  Returns the amount of available data in the buffer.

- size_t GetIntPosition () const

  Returns the current position (counted in bytes) in the stream buffer.
- size_t GetLastAccess () const

  Returns the amount of bytes read during the last IO call to the parent stream.
- virtual void PutChar (char c)

  Puts a single char to the stream buffer.
- virtual size_t Read (void ∗buffer, size_t size)

  Reads a block of the specified size and stores the data in buffer.
- size_t Read (wxStreamBuffer ∗buffer)

  Copies data to buffer.
- void ResetBuffer ()

  Resets to the initial state variables concerning the buffer.
- virtual wxFileOffset Seek (wxFileOffset pos, wxSeekMode mode)

  Changes the current position.
- void SetBufferIO (void ∗start, void ∗end, bool takeOwnership=false)

  Specifies which pointers to use for stream buffering.
- void SetBufferIO (size_t bufsize)

  Destroys or invalidates the previous IO buffer and allocates a new one of the specified size.
- void SetIntPosition (size_t pos)

  Sets the current position (in bytes) in the stream buffer.
- wxStreamBase ∗ Stream ()

  Returns the parent stream of the stream buffer.
- virtual wxFileOffset Tell () const

  Gets the current position in the stream.
- void Truncate ()

  Truncates the buffer to the current position.
- virtual size_t Write (const void ∗buffer, size_t size)

  Writes a block of the specified size using data of buffer.
- size_t Write (wxStreamBuffer ∗buffer)

  See Read().

21.728.2 Member Enumeration Documentation

enum wxStreamBuffer::BufMode

BufMode flags.

Enumerator

read

write

read_write

21.728.3 Constructor & Destructor Documentation

wxStreamBuffer::wxStreamBuffer (wxStreamBase & *stream*, BufMode *mode*)

Constructor, creates a new stream buffer using *stream* as a parent stream and mode as the IO mode.

Parameters

stream	The parent stream.
mode	Can be: wxStreamBuffer::read, wxStreamBuffer::write, wxStreamBuffer::read_write.

One stream can have many stream buffers but only one is used internally to pass IO call (e.g. wxInputStream::Read() -> wxStreamBuffer::Read()), but you can call directly wxStreamBuffer::Read without any problems. Note that all errors and messages linked to the stream are stored in the stream, not the stream buffers:

```
streambuffer.Read(...);
streambuffer2.Read(...);
    // This call erases previous error messages set by 'streambuffer'
    // assuming that both instances are stream buffers for the same stream
```

See also

SetBufferIO()

wxStreamBuffer::wxStreamBuffer (size_t *bufsize,* **wxInputStream** & *stream*)

Constructor for an input buffer of the specified size.

Using it is equivalent to using the constructor above with read mode and calling SetBufferIO() but is more convenient.

Since

2.9.0

Parameters

bufsize	The size of buffer in bytes.
stream	The associated input stream, the buffer will be used in read mode.

wxStreamBuffer::wxStreamBuffer (size_t *bufsize,* **wxOutputStream** & *stream*)

Constructor for an output buffer of the specified size.

Using it is equivalent to using the constructor above with write mode and calling SetBufferIO() but is more convenient.

Since

2.9.0

Parameters

bufsize	The size of buffer in bytes.
stream	The associated output stream, the buffer will be used in write mode.

wxStreamBuffer::wxStreamBuffer (**BufMode** *mode*)

Constructor; creates a new empty stream buffer which won't flush any data to a stream.

mode specifies the type of the buffer (read, write, read_write).

This stream buffer has the advantage to be stream independent and to work only on memory buffers but it is still compatible with the rest of the wxStream classes. You can write, read to this special stream and it will grow (if it is allowed by the user) its internal buffer. Briefly, it has all functionality of a "normal" stream.

Warning

The "read_write" mode doesn't currently work for standalone stream buffers.

See also

SetBufferIO()

wxStreamBuffer::wxStreamBuffer (const wxStreamBuffer & *buffer*)

Copy constructor.

This method initializes the stream buffer with the data of the specified stream buffer. The new stream buffer has the same attributes, size, position and they share the same buffer. This will cause problems if the stream to which the stream buffer belong is destroyed and the newly cloned stream buffer continues to be used, trying to call functions in the (destroyed) stream. It is advised to use this feature only in very local area of the program.

wxStreamBuffer::~wxStreamBuffer ( )

Destructor.

It finalizes all IO calls and frees all internal buffers if necessary.

21.728.4 Member Function Documentation

bool wxStreamBuffer::FillBuffer ( )

Fill the IO buffer.

void wxStreamBuffer::Fixed (bool *fixed*)

Toggles the fixed flag.

Usually this flag is toggled at the same time as *flushable*. This flag allows (when it has the false value) or forbids (when it has the true value) the stream buffer to resize dynamically the IO buffer.

See also

SetBufferIO()

void wxStreamBuffer::Flushable (bool *flushable*)

Toggles the flushable flag.

If *flushable* is disabled, no data are sent to the parent stream.

bool wxStreamBuffer::FlushBuffer ( )

Flushes the IO buffer.

void* wxStreamBuffer::GetBufferEnd ( ) const

Returns a pointer on the end of the stream buffer.

void* wxStreamBuffer::GetBufferPos ( ) const

Returns a pointer on the current position of the stream buffer.

size_t wxStreamBuffer::GetBufferSize ( ) const

Returns the size of the buffer.

void* wxStreamBuffer::GetBufferStart ( ) const

Returns a pointer on the start of the stream buffer.

virtual char wxStreamBuffer::GetChar ( ) [virtual]

Gets a single char from the stream buffer.

It acts like the Read() call.

Warning

You aren't directly notified if an error occurred during the IO call.

See also

Read()

size_t wxStreamBuffer::GetDataLeft ( )

Returns the amount of available data in the buffer.

size_t wxStreamBuffer::GetIntPosition ( ) const

Returns the current position (counted in bytes) in the stream buffer.

size_t wxStreamBuffer::GetLastAccess ( ) const

Returns the amount of bytes read during the last IO call to the parent stream.

virtual void wxStreamBuffer::PutChar (char *c*) [virtual]

Puts a single char to the stream buffer.

Warning

You aren't directly notified if an error occurred during the IO call.

See also

Read()

virtual size_t wxStreamBuffer::Read (void * *buffer,* size_t *size*) [virtual]

Reads a block of the specified size and stores the data in buffer.

This function tries to read from the buffer first and if more data has been requested, reads more data from the associated stream and updates the buffer accordingly until all requested data is read.

Returns

It returns the size of the data read. If the returned size is different of the specified size, an error has occurred and should be tested using GetLastError().

size_t wxStreamBuffer::Read (wxStreamBuffer * *buffer*)

Copies data to *buffer*.

The function returns when *buffer* is full or when there isn't any more data in the current buffer.

See also

Write()

void wxStreamBuffer::ResetBuffer ( )

Resets to the initial state variables concerning the buffer.

virtual wxFileOffset wxStreamBuffer::Seek (wxFileOffset *pos,* wxSeekMode *mode*) [virtual]

Changes the current position.

Parameter *mode* may be one of the following:

- **wxFromStart:** The position is counted from the start of the stream.
- **wxFromCurrent:** The position is counted from the current position of the stream.
- **wxFromEnd:** The position is counted from the end of the stream.

Returns

Upon successful completion, it returns the new offset as measured in bytes from the beginning of the stream. Otherwise, it returns wxInvalidOffset.

void wxStreamBuffer::SetBufferIO (void * *start,* void * *end,* bool *takeOwnership* = false)

Specifies which pointers to use for stream buffering.

You need to pass a pointer on the start of the buffer end and another on the end. The object will use this buffer to cache stream data. It may be used also as a source/destination buffer when you create an empty stream buffer (See wxStreamBuffer::wxStreamBuffer).

Remarks

When you use this function, you will have to destroy the IO buffers yourself after the stream buffer is destroyed or don't use it anymore. In the case you use it with an empty buffer, the stream buffer will not resize it when it is full.

See also

wxStreamBuffer(), Fixed(), Flushable()

void wxStreamBuffer::SetBufferIO (size_t *bufsize*)

Destroys or invalidates the previous IO buffer and allocates a new one of the specified size.

Warning

All previous pointers aren't valid anymore.

Remarks

The created IO buffer is growable by the object.

See also

Fixed(), Flushable()

void wxStreamBuffer::SetIntPosition (size_t *pos*)

Sets the current position (in bytes) in the stream buffer.

Warning

Since it is a very low-level function, there is no check on the position: specifying an invalid position can induce unexpected results.

wxStreamBase* wxStreamBuffer::Stream ( )

Returns the parent stream of the stream buffer.

Deprecated use GetStream() instead

virtual wxFileOffset wxStreamBuffer::Tell ( ) const `[virtual]`

Gets the current position in the stream.

This position is calculated from the *real* position in the stream and from the internal buffer position: so it gives you the position in the *real* stream counted from the start of the stream.

Returns

Returns the current position in the stream if possible, wxInvalidOffset in the other case.

void wxStreamBuffer::Truncate ( )

Truncates the buffer to the current position.

Note

Truncate() cannot be used to enlarge the buffer. This is usually not needed since the buffer expands automatically.

virtual size_t wxStreamBuffer::Write (const void * *buffer*, size_t *size*) `[virtual]`

Writes a block of the specified size using data of buffer.

The data are cached in a buffer before being sent in one block to the stream.

size_t wxStreamBuffer::Write (wxStreamBuffer * *buffer*)

See Read().

21.729 wxStreamToTextRedirector Class Reference

`#include <wx/textctrl.h>`

21.729.1 Detailed Description

This class can be used to (temporarily) redirect all output sent to a C++ ostream object to a wxTextCtrl instead.

Note

Some compilers and/or build configurations don't support multiply inheriting wxTextCtrl from `std::streambuf` in which case this class is not compiled in. You also must have `wxUSE_STD_IOSTREAM` option on (i.e. set to 1) in your `setup.h` to be able to use it. Under Unix, specify `-enable-std_iostreams` switch when running configure for this.

Example of usage:

```
using namespace std;
wxTextCtrl* text = new wxTextCtrl(...);
{
    wxStreamToTextRedirector redirect(text);

    // this goes to the text control
    cout << "Hello, text!" << endl;
}
// this goes somewhere else, presumably to stdout
cout << "Hello, console!" << endl;
```

Library: wxCore

Category: Logging

See also

wxTextCtrl

Public Member Functions

- wxStreamToTextRedirector (wxTextCtrl *text, ostream *ostr)

  The constructor starts redirecting output sent to ostr or cout for the default parameter value to the text control text.
- ~wxStreamToTextRedirector ()

  When a wxStreamToTextRedirector object is destroyed, the redirection is ended and any output sent to the C++ ostream which had been specified at the time of the object construction will go to its original destination.

21.729.2 Constructor & Destructor Documentation

wxStreamToTextRedirector::wxStreamToTextRedirector (wxTextCtrl * *text,* ostream * *ostr*)

The constructor starts redirecting output sent to *ostr* or *cout* for the default parameter value to the text control *text*.

Parameters

text	The text control to append output too, must be non-NULL
ostr	The C++ stream to redirect, cout is used if it is NULL

wxStreamToTextRedirector::~wxStreamToTextRedirector ( )

When a wxStreamToTextRedirector object is destroyed, the redirection is ended and any output sent to the C++ ostream which had been specified at the time of the object construction will go to its original destination.

21.730 wxString Class Reference

`#include <wx/string.h>`

21.730.1 Detailed Description

String class for passing textual data to or receiving it from wxWidgets.

Note

> While the use of wxString is unavoidable in wxWidgets program, you are encouraged to use the standard string classes `std::string` or `std::wstring` in your applications and convert them to and from wxString only when interacting with wxWidgets.

wxString is a class representing a Unicode character string but with methods taking or returning both `wchar_t` wide characters and `wchar_t*` wide strings and traditional `char` characters and `char*` strings. The dual nature of wxString API makes it simple to use in all cases and, importantly, allows the code written for either ANSI or Unicode builds of the previous wxWidgets versions to compile and work correctly with the single unified Unicode build of wxWidgets 3.0. It is also mostly transparent when using wxString with the few exceptions described below.

21.730.2 API overview

wxString tries to be similar to both `std::string` and `std::wstring` and can mostly be used as either class. It provides practically all of the methods of these classes, which behave exactly the same as in the standard C++, and so are not documented here (please see any standard library documentation, for example `http://en.cppreference.com/w/cpp/string` for more details).

In addition to these standard methods, wxString adds functions dealing with the conversions between different string encodings, described below, as well as many extra helpers such as functions for formatted output (Printf(), Format(), ...), case conversion (MakeUpper(), Capitalize(), ...) and various others (Trim(), StartsWith(), Matches(), ...). All of the non-standard methods follow wxWidgets "CamelCase" naming convention and are documented here.

Notice that some wxString methods exist in several versions for compatibility reasons. For example all of length(), Length() and Len() are provided. In such cases it is recommended to use the standard string-like method, i.e. length() in this case.

21.730.3 Converting to and from wxString

wxString can be created from:

- ASCII string guaranteed to contain only 7 bit characters using wxString::FromAscii().
- Narrow `char*` string in the current locale encoding using implicit wxString::wxString(const char*) constructor.

- Narrow `char*` string in UTF-8 encoding using wxString::FromUTF8().
- Narrow `char*` string in the given encoding using wxString::wxString(const char*, const wxMBConv&) constructor passing a wxCSConv corresponding to the encoding as the second argument.
- Standard `std::string` using implicit wxString::wxString(const std::string&) constructor. Notice that this constructor supposes that the string contains data in the current locale encoding, use FromUTF8() or the constructor taking wxMBConv if this is not the case.
- Wide `wchar_t*` string using implicit wxString::wxString(const wchar_t*) constructor.
- Standard `std::wstring` using implicit wxString::wxString(const std::wstring&) constructor.

Notice that many of the constructors are implicit, meaning that you don't even need to write them at all to pass the existing string to some wxWidgets function taking a wxString.

Similarly, wxString can be converted to:

- ASCII string using wxString::ToAscii(). This is a potentially destructive operation as all non-ASCII string characters are replaced with a placeholder character.
- String in the current locale encoding implicitly or using c_str() or mb_str() methods. This is a potentially destructive operation as an *empty* string is returned if the conversion fails.
- String in UTF-8 encoding using wxString::utf8_str().
- String in any given encoding using mb_str() with the appropriate wxMBConv object. This is also a potentially destructive operation.
- Standard `std::string` using wxString::ToStdString(). The contents of the returned string use the current locale encoding, so this conversion is potentially destructive as well.
- Wide C string using wxString::wc_str().
- Standard `std::wstring` using wxString::ToStdWstring().

Note

If you built wxWidgets with `wxUSE_STL` set to 1, the implicit conversions to both narrow and wide C strings are disabled and replaced with implicit conversions to `std::string` and `std::wstring`.

Please notice that the conversions marked as "potentially destructive" above can result in loss of data if their result is not checked, so you need to verify that converting the contents of a non-empty Unicode string to a non-UTF-8 multibyte encoding results in non-empty string. The simplest and best way to ensure that the conversion never fails is to always use UTF-8.

21.730.4 Traps for the unwary

As mentioned above, wxString tries to be compatible with both narrow and wide standard string classes and mostly does it transparently, but there are some exceptions.

String element access

Some problems are caused by wxString::operator[]() which returns an object of a special proxy class allowing to assign either a simple `char` or a `wchar_t` to the given index. Because of this, the return type of this operator is neither `char` nor `wchar_t` nor a reference to one of these types but wxUniCharRef which is not a primitive type and hence can't be used in the `switch` statement. So the following code does *not* compile

```
wxString s(...);
switch ( s[n] ) {
    case 'A':
        ...
        break;
}
```

and you need to use

```
switch ( s[n].GetValue() ) {
    ...
}
```

instead. Alternatively, you can use an explicit cast:

```
switch ( static_cast<char>(s[n]) ) {
    ...
}
```

but notice that this will result in an assert failure if the character at the given position is not representable as a single `char` in the current encoding, so you may want to cast to `int` instead if non-ASCII values can be used.

Another consequence of this unusual return type arises when it is used with template deduction or C++11 `auto` keyword. Unlike with the normal references which are deduced to be of the referenced type, the deduced type for wxUniCharRef is wxUniCharRef itself. This results in potentially unexpected behaviour, for example:

```
wxString s("abc");
auto c = s[0];
c = 'x';             // Modifies the string!
wxASSERT( s == "xbc" );
```

Due to this, either explicitly specify the variable type:

```
int c = s[0];
c = 'x';             // Doesn't modify the string any more.
wxASSERT( s == "abc" );
```

or explicitly convert the return value:

```
auto c = s[0].GetValue();
c = 'x';             // Doesn't modify the string neither.
wxASSERT( s == "abc" );
```

Conversion to C string

A different class of problems happens due to the dual nature of the return value of wxString::c_str() method, which is also used for implicit conversions. The result of calls to this method is convertible to either narrow `char*` string or wide `wchar_t*` string and so, again, has neither the former nor the latter type. Usually, the correct type will be chosen depending on how you use the result but sometimes the compiler can't choose it because of an ambiguity, e.g.:

```
// Some non-wxWidgets functions existing for both narrow and wide
// strings:
void dump_text(const char* text);       // Version (1)
void dump_text(const wchar_t* text);    // Version (2)

wxString s(...);
dump_text(s);           // ERROR: ambiguity.
dump_text(s.c_str());   // ERROR: still ambiguous.
```

In this case you need to explicitly convert to the type that you need to use or use a different, non-ambiguous, conversion function (which is usually the best choice):

```
dump_text(static_cast<const char*>(s));            // OK, calls (1)
dump_text(static_cast<const wchar_t*>(s.c_str())); // OK, calls (2)
dump_text(s.mb_str());                             // OK, calls (1)
dump_text(s.wc_str());                             // OK, calls (2)
dump_text(s.wx_str());                             // OK, calls ???
```

Using wxString with vararg functions

A special subclass of the problems arising due to the polymorphic nature of wxString::c_str() result type happens when using functions taking an arbitrary number of arguments, such as the standard `printf()`. Due to the rules of the C++ language, the types for the "variable" arguments of such functions are not specified and hence the compiler cannot convert wxString objects, or the objects returned by wxString::c_str(), to these unknown types automatically. Hence neither wxString objects nor the results of most of the conversion functions can be passed as vararg arguments:

```
// ALL EXAMPLES HERE DO NOT WORK, DO NOT USE THEM!
printf("Don't do this: %s", s);
printf("Don't do that: %s", s.c_str());
printf("Nor even this: %s", s.mb_str());
wprintf("And even not always this: %s", s.wc_str());
```

Instead you need to either explicitly cast to the needed type:

```
// These examples work but are not the best solution, see below.
printf("You can do this: %s", static_cast<const char*>(s));
printf("Or this: %s", static_cast<const char*>(s.c_str()));
printf("And this: %s", static_cast<const char*>(s.mb_str()));
wprintf("Or this: %s", static_cast<const wchar_t*>(s.wc_str()));
```

But a better solution is to use wxWidgets-provided functions, if possible, as is the case for `printf` family of functions:

```
// This is the recommended way.
wxPrintf("You can do just this: %s", s);
wxPrintf("And this (but it is redundant): %s", s.c_str());
wxPrintf("And this (not using Unicode): %s", s.mb_str());
wxPrintf("And this (always Unicode): %s", s.wc_str());
```

Notice that wxPrintf() replaces both `printf()` and `wprintf()` and accepts wxString objects, results of c_str() calls but also `char*` and `wchar_t*` strings directly.

wxWidgets provides wx-prefixed equivalents to all the standard vararg functions and a few more, notably wxString::Format(), wxLogMessage(), wxLogError() and other log functions. But if you can't use one of those functions and need to pass wxString objects to non-wx vararg functions, you need to use the explicit casts as explained above.

21.730.5 Performance characteristics

wxString uses `std::basic_string` internally to store its content (unless this is not supported by the compiler or disabled specifically when building wxWidgets) and it therefore inherits many features from `std::basic_string`. In particular, most modern implementations of `std::basic_string` are thread-safe and don't use reference counting (making copying large strings potentially expensive) and so wxString has the same characteristics.

By default, wxString uses `std::basic_string` specialized for the platform-dependent `wchar_t` type, meaning that it is not memory-efficient for ASCII strings, especially under Unix platforms where every ASCII character, normally fitting in a byte, is represented by a 4 byte `wchar_t`.

It is possible to build wxWidgets with `wxUSE_UNICODE_UTF8` set to 1 in which case an UTF-8-encoded string representation is stored in `std::basic_string` specialized for `char`, i.e. the usual `std::string`. In this case the memory efficiency problem mentioned above doesn't arise but run-time performance of many wxString methods changes dramatically, in particular accessing the N-th character of the string becomes an operation taking O(N) time instead of O(1), i.e. constant, time by default. Thus, if you do use this so called UTF-8 build, you should avoid using indices to access the strings whenever possible and use the iterators instead. As an example, traversing the string using iterators is an O(N), where N is the string length, operation in both the normal ("wchar_t") and UTF-8 builds but doing it using indices becomes O(N^2) in UTF-8 case meaning that simply checking every character of a reasonably long (e.g. a couple of millions elements) string can take an unreasonably long time.

However, if you do use iterators, UTF-8 build can be a better choice than the default build, especially for the memory-constrained embedded systems. Notice also that GTK+ and DirectFB use UTF-8 internally, so using this build not only saves memory for ASCII strings but also avoids conversions between wxWidgets and the underlying toolkit.

21.730.6 Index of the member groups

Links for quick access to the various categories of wxString functions:

Public Types

Standard types

Types used with wxString.

- typedef wxUniChar value_type
- typedef wxUniChar char_type
- typedef wxUniCharRef reference
- typedef wxChar * pointer
- typedef const wxChar * const_pointer
- typedef size_t size_type
- typedef wxUniChar const_reference

Public Member Functions

Constructors and assignment operators

A string may be constructed either from a C string, (some number of copies of) a single character or a wide (Unicode) string.

For all constructors (except the default which creates an empty string) there is also a corresponding assignment operator.

See also the assign() STL-like function.

- wxString ()
  Default constructor.
- wxString (const wxString &stringSrc)
  Creates a string from another string.
- wxString (wxUniChar ch, size_t nRepeat=1)
  Construct a string consisting of nRepeat copies of ch.
- wxString (wxUniCharRef ch, size_t nRepeat=1)
  Construct a string consisting of nRepeat copies of ch.
- wxString (char ch, size_t nRepeat=1)
  Construct a string consisting of nRepeat copies of ch converted to Unicode using the current locale encoding.
- wxString (wchar_t ch, size_t nRepeat=1)
  Construct a string consisting of nRepeat copies of ch.
- wxString (const char *psz)
  Constructs a string from the string literal psz using the current locale encoding to convert it to Unicode (wxConv↩ Libc).
- wxString (const char *psz, const wxMBConv &conv)
  Constructs a string from the string literal psz using conv to convert it Unicode.
- wxString (const char *psz, size_t nLength)
  Constructs a string from the first nLength character of the string literal psz using the current locale encoding to convert it to Unicode (wxConvLibc).
- wxString (const char *psz, const wxMBConv &conv, size_t nLength)
  Constructs a string from the first nLength character of the string literal psz using conv to convert it Unicode.
- wxString (const wchar_t *pwz)
  Constructs a string from the string literal pwz.
- wxString (const wchar_t *pwz, size_t nLength)
  Constructs a string from the first nLength characters of the string literal pwz.
- wxString (const wxCharBuffer &buf)
  Constructs a string from buf using the using the current locale encoding to convert it to Unicode.
- wxString (const wxWCharBuffer &buf)
  Constructs a string from buf.
- wxString (const std::string &str)
  Constructs a string from str using the using the current locale encoding to convert it to Unicode (wxConvLibc).
- wxString (const std::wstring &str)
  Constructs a string from str.
- ~wxString ()
  String destructor.
- wxString operator= (const wxString &str)
  Assignment: see the relative wxString constructor.
- wxString operator= (wxUniChar c)
  Assignment: see the relative wxString constructor.

String length

These functions return the string length and/or check whether the string is empty.

See also the length(), size() or empty() STL-like functions.

- size_t Len () const
  Returns the length of the string.
- size_t Length () const
  Returns the length of the string (same as Len).

- bool IsEmpty () const
  Returns true if the string is empty.
- bool IsNull () const
  Returns true if the string is empty (same as wxString::IsEmpty).
- bool operator! () const
  Empty string is false, so !string will only return true if the string is empty.

Character access

Many functions below take a character index in the string.

As with C strings and arrays, the indices start from 0, so the first character of a string is string[0]. An attempt to access a character beyond the end of the string (which may even be 0 if the string is empty) will provoke an assert failure in debug builds, but no checks are done in release builds.

- wxUniChar GetChar (size_t n) const
  Returns the character at position n (read-only).
- const wxCStrData GetData () const
  wxWidgets compatibility conversion.
- wxUniCharRef GetWritableChar (size_t n)
  Returns a reference to the character at position n.
- wxStringCharType * GetWriteBuf (size_t len)
  Returns a writable buffer of at least len bytes.
- void UngetWriteBuf ()
  Puts the string back into a reasonable state (in which it can be used normally), after GetWriteBuf() was called.
- void UngetWriteBuf (size_t len)
  This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.
- void SetChar (size_t n, wxUniChar ch)
  Sets the character at position n.
- wxUniChar Last () const
  Returns the last character.
- wxUniCharRef Last ()
  Returns a reference to the last character (writable).
- wxUniChar operator[] (size_t i) const
  Returns the i-th character of the string.
- wxUniCharRef operator[] (size_t i)
  Returns a writable reference to the i-th character of the string.

Conversions

This section contains both implicit and explicit conversions to C style strings.

Although implicit conversion is quite convenient, you are advised to use wc_str() for the sake of clarity.

- wxCStrData c_str () const
  Returns a lightweight intermediate class which is in turn implicitly convertible to both `const char*` and to `const wchar_t*`.
- wxWritableCharBuffer char_str (const wxMBConv &conv=wxConvLibc) const
  Returns an object with string data that is implicitly convertible to `char*` pointer.
- template<typename T >
  wxCharTypeBuffer< T > tchar_str (size_t *len=NULL) const
  Returns buffer of the specified type containing the string data.
- const wchar_t * fn_str () const
  Returns a string representation suitable for passing to OS' functions for file handling.
- const char * fn_str () const
  This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.
- const wxCharBuffer fn_str () const
  This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.
- const wxCharBuffer mb_str (const wxMBConv &conv=wxConvLibc) const

Returns the multibyte (C string) representation of the string using conv's wxMBConv::cWC2MB method and returns wxCharBuffer.

- const wxScopedCharBuffer utf8_str () const

  Converts the strings contents to UTF-8 and returns it either as a temporary wxCharBuffer object or as a pointer to the internal string contents in UTF-8 build.
- const wchar_t * wc_str () const

  Converts the strings contents to the wide character representation and returns it as a temporary wxWCharBuffer object (Unix and OS X) or returns a pointer to the internal string contents in wide character mode (Windows).
- const wxWCharBuffer wc_str () const

  This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.
- wxWritableWCharBuffer wchar_str () const

  Returns an object with string data that is implicitly convertible to `char*` pointer.
- const wxStringCharType * wx_str () const

  Explicit conversion to C string in the internal representation (either wchar_t or UTF-8-encoded char*, depending on the build).*
- const wxScopedCharBuffer To8BitData () const

  Converts the string to an 8-bit string in ISO-8859-1 encoding in the form of a wxCharBuffer (Unicode builds only).
- const char * ToAscii () const

  Converts the string to an ASCII, 7-bit string in the form of a wxCharBuffer (Unicode builds only) or a C string (ANSI builds).
- const wxCharBuffer ToAscii () const

  This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.
- std::string ToStdString () const

  Return the string as an std::string in current locale encoding.
- std::wstring ToStdWstring () const

  Return the string as an std::wstring.
- const wxScopedCharBuffer ToUTF8 () const

  Same as utf8_str().

Concatenation

Almost anything may be concatenated (appended to) with a string!

Note that the various operator<<() overloads work as C++ stream insertion operators. They insert the given value into the string. Precision and format cannot be set using them. Use Printf() instead.

See also the insert() and append() STL-like functions.

- wxString & Append (const char *psz)

  Appends the string literal psz.
- wxString & Append (const wchar_t *pwz)

  Appends the wide string literal pwz.
- wxString & Append (const char *psz, size_t nLen)

  Appends the string literal psz with max length nLen.
- wxString & Append (const wchar_t *pwz, size_t nLen)

  Appends the wide string literal psz with max length nLen.
- wxString & Append (const wxString &s)

  Appends the string s.
- wxString & Append (wxUniChar ch, size_t count=1u)

  Appends the character ch count times.
- wxString & Prepend (const wxString &str)

  Prepends str to this string, returning a reference to this string.
- wxString operator+ (const wxString &x, const wxString &y)

  Concatenation: returns a new string equal to the concatenation of the operands.
- wxString operator+ (const wxString &x, wxUniChar y)

  This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.
- wxString & operator<< (const wxString &s)

  Appends the string literal psz.
- wxString & operator<< (const char *psz)

Appends the string literal psz.

- wxString & operator<< (const wchar_t *pwz)

  Appends the string literal psz.
- wxString & operator<< (const wxCStrData &psz)

  Appends the string literal psz.
- wxString & operator<< (char ch)

  Appends the string literal psz.
- wxString & operator<< (unsigned char ch)

  Appends the string literal psz.
- wxString & operator<< (wchar_t ch)

  Appends the string literal psz.
- wxString & operator<< (const wxCharBuffer &s)

  Appends the string literal psz.
- wxString & operator<< (const wxWCharBuffer &s)

  Appends the string literal psz.
- wxString & operator<< (wxUniChar ch)

  Appends the string literal psz.
- wxString & operator<< (wxUniCharRef ch)

  Appends the string literal psz.
- wxString & operator<< (unsigned int ui)

  Appends the string literal psz.
- wxString & operator<< (long l)

  Appends the string literal psz.
- wxString & operator<< (unsigned long ul)

  Appends the string literal psz.
- wxString & operator<< (wxLongLong_t ll)

  Appends the string literal psz.
- wxString & operator<< (wxULongLong_t ul)

  Appends the string literal psz.
- wxString & operator<< (float f)

  Appends the string literal psz.
- wxString & operator<< (double d)

  Appends the string literal psz.
- void operator+= (const wxString &str)

  Concatenation in place: the argument is appended to the string.
- void operator+= (wxUniChar c)

  This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.

Comparison

The default comparison function Cmp() is case-sensitive and so is the default version of IsSameAs().

For case insensitive comparisons you should use CmpNoCase() or give a second parameter to IsSameAs(). This last function is maybe more convenient if only equality of the strings matters because it returns a boolean true value if the strings are the same and not 0 (which is usually false in C) as Cmp() does.

Matches() is a poor man's regular expression matcher: it only understands '' and '?' metacharacters in the sense of DOS command line interpreter.*

StartsWith() is helpful when parsing a line of text which should start with some predefined prefix and is more efficient than doing direct string comparison as you would also have to precalculate the length of the prefix.

See also the compare() STL-like function.

- int Cmp (const wxString &s) const

  Case-sensitive comparison.
- int CmpNoCase (const wxString &s) const

  Case-insensitive comparison.
- bool IsSameAs (const wxString &s, bool caseSensitive=true) const

  Test whether the string is equal to another string s.
- bool IsSameAs (wxUniChar ch, bool caseSensitive=true) const

Test whether the string is equal to the single character ch.

- bool Matches (const wxString &mask) const

  Returns true if the string contents matches a mask containing '' and '?'.*
- bool StartsWith (const wxString &prefix, wxString *rest=NULL) const

  This function can be used to test if the string starts with the specified prefix.
- bool EndsWith (const wxString &suffix, wxString *rest=NULL) const

  This function can be used to test if the string ends with the specified suffix.

Substring extraction

These functions allow you to extract a substring from the string.

The original string is not modified and the function returns the extracted substring.

See also the at() and the substr() STL-like functions.

- wxString Mid (size_t first, size_t nCount=wxString::npos) const

  Returns a substring starting at first, with length count, or the rest of the string if count is the default value.
- wxString SubString (size_t from, size_t to) const

  Returns the part of the string between the indices from and to inclusive.
- wxString operator() (size_t start, size_t len) const

  Same as Mid() (substring extraction).
- wxString Left (size_t count) const

  Returns the first count characters of the string.
- wxString Right (size_t count) const

  Returns the last count characters.
- wxString AfterFirst (wxUniChar ch) const

  Gets all the characters after the first occurrence of ch.
- wxString AfterLast (wxUniChar ch) const

  Gets all the characters after the last occurrence of ch.
- wxString BeforeFirst (wxUniChar ch, wxString *rest=NULL) const

  Gets all characters before the first occurrence of ch.
- wxString BeforeLast (wxUniChar ch, wxString *rest=NULL) const

  Gets all characters before the last occurrence of ch.

Case conversion

The MakeXXX() variants modify the string in place, while the other functions return a new string which contains the original text converted to the upper or lower case and leave the original string unchanged.

- wxString Capitalize () const

  Return the copy of the string with the first string character in the upper case and the subsequent ones in the lower case.
- wxString Lower () const

  Returns this string converted to the lower case.
- void LowerCase ()

  Same as MakeLower.
- wxString & MakeCapitalized ()

  Converts the first characters of the string to the upper case and all the subsequent ones to the lower case and returns the result.
- wxString & MakeLower ()

  Converts all characters to lower case and returns the reference to the modified string.
- wxString & MakeUpper ()

  Converts all characters to upper case and returns the reference to the modified string.
- wxString Upper () const

  Returns this string converted to upper case.
- void UpperCase ()

  The same as MakeUpper().

Searching and replacing

These functions replace the standard `strchr()` and `strstr()` functions.

See also the find(), rfind(), replace() STL-like functions.

- int Find (wxUniChar ch, bool fromEnd=false) const
  Searches for the given character ch.
- int Find (const wxString &sub) const
  Searches for the given string sub.
- int First (wxUniChar ch) const
  Same as Find().
- int First (const wxString &str) const
  Same as Find().
- size_t Replace (const wxString &strOld, const wxString &strNew, bool replaceAll=true)
  Replace first (or all) occurrences of substring with another one.

Conversion to numbers

The string provides functions for conversion to signed and unsigned integer and floating point numbers.

*All functions take a pointer to the variable to put the numeric value in and return true if the **entire** string could be converted to a number. Notice if there is a valid number in the beginning of the string, it is returned in the output parameter even if the function returns false because there is more text following it.*

- bool ToDouble (double ∗val) const
  Attempts to convert the string to a floating point number.
- bool ToCDouble (double ∗val) const
  Variant of ToDouble() always working in "C" locale.
- bool ToLong (long ∗val, int base=10) const
  Attempts to convert the string to a signed integer in base base.
- bool ToCLong (long ∗val, int base=10) const
  Variant of ToLong() always working in "C" locale.
- bool ToLongLong (wxLongLong_t ∗val, int base=10) const
  This is exactly the same as ToLong() but works with 64 bit integer numbers.
- bool ToULong (unsigned long ∗val, int base=10) const
  Attempts to convert the string to an unsigned integer in base base.
- bool ToCULong (unsigned long ∗val, int base=10) const
  Variant of ToULong() always working in "C" locale.
- bool ToULongLong (wxULongLong_t ∗val, int base=10) const
  This is exactly the same as ToULong() but works with 64 bit integer numbers.

Formatting and printing

Both formatted versions (Printf/() and stream-like insertion operators exist (for basic types only).

See also the static Format() and FormatV() functions.

- int Printf (const wxString &pszFormat,...)
  Similar to the standard function sprintf().
- int PrintfV (const wxString &pszFormat, va_list argPtr)
  Similar to vprintf.

Memory management

The following are "advanced" functions and they will be needed rarely.

Alloc() and Shrink() are only interesting for optimization purposes. wxStringBuffer and wxStringBufferLength classes may be very useful when working with some external API which requires the caller to provide a writable buffer.

See also the reserve() and resize() STL-like functions.

- bool Alloc (size_t nLen)
  Preallocate enough space for wxString to store nLen characters.
- bool Shrink ()
  Minimizes the string's memory.
- wxString Clone () const
  Returns a deep copy of the string.
- void Clear ()

Empties the string and frees memory occupied by it.

Miscellaneous

Miscellaneous other string functions.

- bool Contains (const wxString &str) const
  Returns true if target appears anywhere in wxString; else false.
- void Empty ()
  Makes the string empty, but doesn't free memory occupied by the string.
- int Freq (wxUniChar ch) const
  Returns the number of occurrences of ch in the string.
- bool IsAscii () const
  Returns true if the string contains only ASCII characters.
- bool IsNumber () const
  Returns true if the string is an integer (with possible sign).
- bool IsWord () const
  Returns true if the string is a word.
- wxString & Pad (size_t count, wxUniChar chPad= ' ', bool fromRight=true)
  Adds count copies of chPad to the beginning, or to the end of the string (the default).
- wxString & Remove (size_t pos)
  Removes all characters from the string starting at pos.
- wxString & Remove (size_t pos, size_t len)
  Removes len characters from the string, starting at pos.
- wxString & RemoveLast (size_t n=1)
  Removes the last character.
- wxString Strip (stripType s=trailing) const
  Strip characters at the front and/or end.
- wxString & Trim (bool fromRight=true)
  Removes white-space (space, tabs, form feed, newline and carriage return) from the left or from the right end of the string (right is default).
- wxString & Truncate (size_t len)
  Truncate the string to the given length.

Iterator interface

These methods return iterators to the beginning or end of the string.

Please see any STL reference (e.g. http://www.cppreference.com/wiki/string/start*) for their documentation.*

- const_iterator begin () const
- iterator begin ()
- const_iterator end () const
- iterator end ()
- const_reverse_iterator rbegin () const
- reverse_iterator rbegin ()
- const_reverse_iterator rend () const
- reverse_iterator rend ()

STL interface

The supported STL functions are listed here.

Please see any STL reference (e.g. http://www.cppreference.com/wiki/string/start*) for their documentation.*

- wxString & append (const wxString &str, size_t pos, size_t n)
- wxString & append (const wxString &str)
- wxString & append (const char *sz, size_t n)
- wxString & append (const wchar_t *sz, size_t n)
- wxString & append (size_t n, wxUniChar ch)
- wxString & append (const_iterator first, const_iterator last)
- wxString & assign (const wxString &str, size_t pos, size_t n)

- wxString & assign (const wxString &str)
- wxString & assign (const char *sz, size_t n)
- wxString & assign (const wchar_t *sz, size_t n)
- wxString & assign (size_t n, wxUniChar ch)
- wxString & assign (const_iterator first, const_iterator last)
- wxUniChar at (size_t n) const
- wxUniCharRef at (size_t n)
- void clear ()
- size_type capacity () const
- int compare (const wxString &str) const
- int compare (size_t nStart, size_t nLen, const wxString &str) const
- int compare (size_t nStart, size_t nLen, const wxString &str, size_t nStart2, size_t nLen2) const
- int compare (size_t nStart, size_t nLen, const char *sz, size_t nCount=npos) const
- int compare (size_t nStart, size_t nLen, const wchar_t *sz, size_t nCount=npos) const
- wxCStrData data () const
- bool empty () const
- wxString & erase (size_type pos=0, size_type n=npos)
- iterator erase (iterator first, iterator last)
- iterator erase (iterator first)
- size_t find (const wxString &str, size_t nStart=0) const
- size_t find (const char *sz, size_t nStart=0, size_t n=npos) const
- size_t find (const wchar_t *sz, size_t nStart=0, size_t n=npos) const
- size_t find (wxUniChar ch, size_t nStart=0) const
- size_t find_first_of (const char *sz, size_t nStart=0) const
- size_t find_first_of (const wchar_t *sz, size_t nStart=0) const
- size_t find_first_of (const char *sz, size_t nStart, size_t n) const
- size_t find_first_of (const wchar_t *sz, size_t nStart, size_t n) const
- size_t find_first_of (wxUniChar c, size_t nStart=0) const
- size_t find_last_of (const wxString &str, size_t nStart=npos) const
- size_t find_last_of (const char *sz, size_t nStart=npos) const
- size_t find_last_of (const wchar_t *sz, size_t nStart=npos) const
- size_t find_last_of (const char *sz, size_t nStart, size_t n) const
- size_t find_last_of (const wchar_t *sz, size_t nStart, size_t n) const
- size_t find_last_of (wxUniChar c, size_t nStart=npos) const
- size_t find_first_not_of (const wxString &str, size_t nStart=0) const
- size_t find_first_not_of (const char *sz, size_t nStart=0) const
- size_t find_first_not_of (const wchar_t *sz, size_t nStart=0) const
- size_t find_first_not_of (const char *sz, size_t nStart, size_t n) const
- size_t find_first_not_of (const wchar_t *sz, size_t nStart, size_t n) const
- size_t find_first_not_of (wxUniChar ch, size_t nStart=0) const
- size_t find_last_not_of (const wxString &str, size_t nStart=npos) const
- size_t find_last_not_of (const char *sz, size_t nStart=npos) const
- size_t find_last_not_of (const wchar_t *sz, size_t nStart=npos) const
- size_t find_last_not_of (const char *sz, size_t nStart, size_t n) const
- size_t find_last_not_of (const wchar_t *sz, size_t nStart, size_t n) const
- wxString & insert (size_t nPos, const wxString &str)
- wxString & insert (size_t nPos, const wxString &str, size_t nStart, size_t n)
- wxString & insert (size_t nPos, const char *sz, size_t n)
- wxString & insert (size_t nPos, const wchar_t *sz, size_t n)
- wxString & insert (size_t nPos, size_t n, wxUniChar ch)
- iterator insert (iterator it, wxUniChar ch)
- void insert (iterator it, const_iterator first, const_iterator last)
- void insert (iterator it, size_type n, wxUniChar ch)
- size_t length () const
- size_type max_size () const
- void reserve (size_t sz)
- void resize (size_t nSize, wxUniChar ch= '\0')
- wxString & replace (size_t nStart, size_t nLen, const wxString &str)
- wxString & replace (size_t nStart, size_t nLen, size_t nCount, wxUniChar ch)
- wxString & replace (size_t nStart, size_t nLen, const wxString &str, size_t nStart2, size_t nLen2)
- wxString & replace (size_t nStart, size_t nLen, const char *sz, size_t nCount)
- wxString & replace (size_t nStart, size_t nLen, const wchar_t *sz, size_t nCount)
- wxString & replace (size_t nStart, size_t nLen, const wxString &s, size_t nCount)
- wxString & replace (iterator first, iterator last, const wxString &s)

- wxString & replace (iterator first, iterator last, const char *s, size_type n)
- wxString & replace (iterator first, iterator last, const wchar_t *s, size_type n)
- wxString & replace (iterator first, iterator last, size_type n, wxUniChar ch)
- wxString & replace (iterator first, iterator last, const_iterator first1, const_iterator last1)
- wxString & replace (iterator first, iterator last, const char *first1, const char *last1)
- wxString & replace (iterator first, iterator last, const wchar_t *first1, const wchar_t *last1)
- size_t rfind (const wxString &str, size_t nStart=npos) const
- size_t rfind (const char *sz, size_t nStart=npos, size_t n=npos) const
- size_t rfind (const wchar_t *sz, size_t nStart=npos, size_t n=npos) const
- size_t rfind (wxUniChar ch, size_t nStart=npos) const
- size_type size () const
- wxString substr (size_t nStart=0, size_t nLen=npos) const
- void swap (wxString &str)

Static Public Member Functions

- static wxString Format (const wxString &format,...)

  This static function returns the string containing the result of calling Printf() with the passed parameters on it.
- static wxString FormatV (const wxString &format, va_list argptr)

  This static function returns the string containing the result of calling PrintfV() with the passed parameters on it.
- static wxString FromCDouble (double val, int precision=-1)

  Returns a string with the textual representation of the number in C locale.
- static wxString FromDouble (double val, int precision=-1)

  Returns a string with the textual representation of the number.

- static wxString From8BitData (const char *buf, size_t len)

  Converts given buffer of binary data from 8-bit string to wxString.
- static wxString From8BitData (const char *buf)

  Converts given buffer of binary data from 8-bit string to wxString.

- static wxString FromAscii (const char *s)

  Converts the string or character from an ASCII, 7-bit form to the native wxString representation.
- static wxString FromAscii (const unsigned char *s)

  Converts the string or character from an ASCII, 7-bit form to the native wxString representation.
- static wxString FromAscii (const char *s, size_t len)

  Converts the string or character from an ASCII, 7-bit form to the native wxString representation.
- static wxString FromAscii (const unsigned char *s, size_t len)

  Converts the string or character from an ASCII, 7-bit form to the native wxString representation.
- static wxString FromAscii (char c)

  Converts the string or character from an ASCII, 7-bit form to the native wxString representation.

- static wxString FromUTF8 (const char *s)

  Converts C string encoded in UTF-8 to wxString.
- static wxString FromUTF8 (const char *s, size_t len)

  Converts C string encoded in UTF-8 to wxString.

- static wxString FromUTF8Unchecked (const char *s)

  Converts C string encoded in UTF-8 to wxString without checking its validity.
- static wxString FromUTF8Unchecked (const char *s, size_t len)

  Converts C string encoded in UTF-8 to wxString without checking its validity.

Static Public Attributes

- static const size_t npos

  An 'invalid' value for string index.

21.730.7 Member Typedef Documentation

typedef wxUniChar wxString::char_type

typedef const wxChar* wxString::const_pointer

typedef wxUniChar wxString::const_reference

typedef wxChar* wxString::pointer

typedef wxUniCharRef wxString::reference

typedef size_t wxString::size_type

typedef wxUniChar wxString::value_type

21.730.8 Constructor & Destructor Documentation

wxString::wxString ( )

Default constructor.

wxString::wxString (const wxString & *stringSrc*)

Creates a string from another string.

Just increases the ref count by 1.

wxString::wxString (wxUniChar *ch*, size_t *nRepeat* = 1)

Construct a string consisting of *nRepeat* copies of ch.

wxString::wxString (wxUniCharRef *ch*, size_t *nRepeat* = 1)

Construct a string consisting of *nRepeat* copies of ch.

wxString::wxString (char *ch*, size_t *nRepeat* = 1)

Construct a string consisting of *nRepeat* copies of ch converted to Unicode using the current locale encoding.

wxString::wxString (wchar_t *ch*, size_t *nRepeat* = 1)

Construct a string consisting of *nRepeat* copies of ch.

wxString::wxString (const char * *psz*)

Constructs a string from the string literal *psz* using the current locale encoding to convert it to Unicode (wxConvLibc).

wxString::wxString (const char * *psz*, const wxMBConv & *conv*)

Constructs a string from the string literal *psz* using *conv* to convert it Unicode.

wxString::wxString (const char * *psz*, size_t *nLength*)

Constructs a string from the first *nLength* character of the string literal *psz* using the current locale encoding to convert it to Unicode (wxConvLibc).

wxString::wxString (const char * *psz*, const wxMBConv & *conv*, size_t *nLength*)

Constructs a string from the first *nLength* character of the string literal *psz* using *conv* to convert it Unicode.

wxString::wxString (const wchar_t * *pwz*)

Constructs a string from the string literal *pwz*.

wxString::wxString (const wchar_t * *pwz*, size_t *nLength*)

Constructs a string from the first *nLength* characters of the string literal *pwz*.

wxString::wxString (const wxCharBuffer & *buf*)

Constructs a string from *buf* using the using the current locale encoding to convert it to Unicode.

wxString::wxString (const wxWCharBuffer & *buf*)

Constructs a string from *buf*.

wxString::wxString (const std::string & *str*)

Constructs a string from *str* using the using the current locale encoding to convert it to Unicode (wxConvLibc).

See also

ToStdString()

wxString::wxString (const std::wstring & *str*)

Constructs a string from *str*.

See also

ToStdWstring()

wxString::~wxString ( )

String destructor.

Note that this is not virtual, so wxString must not be inherited from.

21.730.9 Member Function Documentation

wxString wxString::AfterFirst (wxUniChar *ch*) const

Gets all the characters after the first occurrence of *ch*.

Returns the empty string if *ch* is not found.

wxString wxString::AfterLast (wxUniChar *ch*) const

Gets all the characters after the last occurrence of *ch*.

Returns the whole string if *ch* is not found.

bool wxString::Alloc (size_t *nLen*)

Preallocate enough space for wxString to store *nLen* characters.

Please note that this method does the same thing as the standard reserve() one and shouldn't be used in new code.

This function may be used to increase speed when the string is constructed by repeated concatenation as in

```
// delete all vowels from the string
wxString DeleteAllVowels(const wxString& original)
{
    wxString result;

    size_t len = original.length();

    result.Alloc(len);

    for ( size_t n = 0; n < len; n++ )
    {
        if ( strchr("aeuio", tolower(original[n])) == NULL )
            result += original[n];
    }

    return result;
}
```

because it will avoid the need to reallocate string memory many times (in case of long strings). Note that it does not set the maximal length of a string – it will still expand if more than *nLen* characters are stored in it. Also, it does not truncate the existing string (use Truncate() for this) even if its current length is greater than *nLen*.

Returns

true if memory was successfully allocated, false otherwise.

wxString& wxString::Append (const char * *psz*)

Appends the string literal *psz*.

wxString& wxString::Append (const wchar_t * *pwz*)

Appends the wide string literal *pwz*.

wxString& wxString::Append (const char * *psz*, size_t *nLen*)

Appends the string literal *psz* with max length *nLen*.

wxString& wxString::Append (const wchar_t * *pwz*, size_t *nLen*)

Appends the wide string literal *psz* with max length *nLen*.

wxString& wxString::Append (const wxString & *s*)

Appends the string *s*.

wxString& wxString::Append (wxUniChar *ch*, size_t *count* = `1u`)

Appends the character *ch count* times.

wxString& wxString::append (const wxString & *str*, size_t *pos*, size_t *n*)

wxString& wxString::append (const wxString & *str*)

wxString& wxString::append (const char * *sz*, size_t *n*)

wxString& wxString::append (const wchar_t * *sz*, size_t *n*)

wxString& wxString::append (size_t *n*, wxUniChar *ch*)

wxString& wxString::append (const_iterator *first*, const_iterator *last*)

wxString& wxString::assign (const wxString & *str*, size_t *pos*, size_t *n*)

wxString& wxString::assign (const wxString & *str*)

wxString& wxString::assign (const char * *sz*, size_t *n*)

wxString& wxString::assign (const wchar_t * *sz*, size_t *n*)

wxString& wxString::assign (size_t *n*, wxUniChar *ch*)

wxString& wxString::assign (const_iterator *first*, const_iterator *last*)

wxUniChar wxString::at (size_t *n*) const

wxUniCharRef wxString::at (size_t *n*)

wxString wxString::BeforeFirst (wxUniChar *ch*, wxString * *rest* = `NULL`) const

Gets all characters before the first occurrence of *ch*.

Returns the whole string if *ch* is not found.

Parameters

ch	The character to look for.
rest	Filled with the part of the string following the first occurrence of *ch* or cleared if it was not found. The same string is returned by AfterFirst() but it is more efficient to use this output parameter if both the "before" and "after" parts are needed than calling both functions one after the other. This parameter is available in wxWidgets version 2.9.2 and later only.

Returns

Part of the string before the first occurrence of *ch*.

wxString wxString::BeforeLast (wxUniChar *ch*, wxString * *rest* = NULL) const

Gets all characters before the last occurrence of *ch*.

Returns the empty string if *ch* is not found.

Parameters

ch	The character to look for.
rest	Filled with the part of the string following the last occurrence of *ch* or the copy of this string if it was not found. The same string is returned by AfterLast() but it is more efficient to use this output parameter if both the "before" and "after" parts are needed than calling both functions one after the other. This parameter is available in wxWidgets version 2.9.2 and later only.

Returns

Part of the string before the last occurrence of *ch*.

const_iterator wxString::begin ( ) const

iterator wxString::begin ( )

wxCStrData wxString::c_str ( ) const

Returns a lightweight intermediate class which is in turn implicitly convertible to both `const char*` and to `const wchar_t*`.

Given this ambiguity it is mostly better to use wc_str(), mb_str() or utf8_str() instead.

Please see the Unicode Support in wxWidgets for more information about it.

Note that the returned value is not convertible to `char*` or `wchar_t*`, use char_str() or wchar_str() if you need to pass string value to a function expecting non-const pointer.

See also

wc_str(), utf8_str(), c_str(), mb_str(), fn_str()

size_type wxString::capacity ( ) const

wxString wxString::Capitalize ( ) const

Return the copy of the string with the first string character in the upper case and the subsequent ones in the lower case.

Since

2.9.0

See also

MakeCapitalized()

wxWritableCharBuffer wxString::char_str (const wxMBConv & *conv* = `wxConvLibc`) const

Returns an object with string data that is implicitly convertible to `char*` pointer.

Note that any change to the returned buffer is lost and so this function is only usable for passing strings to legacy libraries that don't have const-correct API. Use wxStringBuffer if you want to modify the string.

See also

c_str()

void wxString::Clear ( )

Empties the string and frees memory occupied by it.

See also

Empty()

void wxString::clear ( )

wxString wxString::Clone ( ) const

Returns a deep copy of the string.

That is, the returned string is guaranteed to not share data with this string when using reference-counted wxString implementation.

This method is primarily useful for passing strings between threads (because wxString is not thread-safe). Unlike creating a copy using `wxString(c_str())`, Clone() handles embedded NULs correctly.

Since

2.9.0

int wxString::Cmp (const wxString & *s*) const

Case-sensitive comparison.

Returns a positive value if the string is greater than the argument, zero if it is equal to it or a negative value if it is less than the argument (same semantics as the standard `strcmp()` function).

See also

CmpNoCase(), IsSameAs().

int wxString::CmpNoCase (const wxString & *s*) const

Case-insensitive comparison.

Returns a positive value if the string is greater than the argument, zero if it is equal to it or a negative value if it is less than the argument (same semantics as the standard `strcmp()` function).

See also

Cmp(), IsSameAs().

int wxString::compare (const wxString & *str*) const

int wxString::compare (size_t *nStart*, size_t *nLen*, const wxString & *str*) const

int wxString::compare (size_t *nStart*, size_t *nLen*, const wxString & *str*, size_t *nStart2*, size_t *nLen2*) const

int wxString::compare (size_t *nStart*, size_t *nLen*, const char * *sz*, size_t *nCount* = npos) const

int wxString::compare (size_t *nStart*, size_t *nLen*, const wchar_t * *sz*, size_t *nCount* = npos) const

bool wxString::Contains (const wxString & *str*) const

Returns true if target appears anywhere in wxString; else false.

This is a wxWidgets 1.xx compatibility function; you should not use it in new code.

wxCStrData wxString::data ( ) const

void wxString::Empty ( )

Makes the string empty, but doesn't free memory occupied by the string.

See also

Clear().

bool wxString::empty ( ) const

const_iterator wxString::end ( ) const

iterator wxString::end ( )

bool wxString::EndsWith (const wxString & *suffix*, wxString * *rest* = NULL) const

This function can be used to test if the string ends with the specified *suffix*.

If it does, the function will return true and put the beginning of the string before the suffix into *rest* string if it is not NULL. Otherwise, the function returns false and doesn't modify the *rest*.

wxString& wxString::erase (size_type *pos* = 0, size_type *n* = npos)

iterator wxString::erase (iterator *first*, iterator *last*)

iterator wxString::erase (iterator *first*)

int wxString::Find (wxUniChar *ch*, bool *fromEnd* = false) const

Searches for the given character *ch*.

Returns the position or wxNOT_FOUND if not found.

int wxString::Find (const wxString & *sub*) const

Searches for the given string *sub*.

Returns the starting position or wxNOT_FOUND if not found.

size_t wxString::find (const wxString & *str,* size_t *nStart* = 0) const

size_t wxString::find (const char * *sz,* size_t *nStart* = 0, size_t *n* = npos) const

size_t wxString::find (const wchar_t * *sz,* size_t *nStart* = 0, size_t *n* = npos) const

size_t wxString::find (wxUniChar *ch,* size_t *nStart* = 0) const

size_t wxString::find_first_not_of (const wxString & *str,* size_t *nStart* = 0) const

size_t wxString::find_first_not_of (const char * *sz,* size_t *nStart* = 0) const

size_t wxString::find_first_not_of (const wchar_t * *sz,* size_t *nStart* = 0) const

size_t wxString::find_first_not_of (const char * *sz,* size_t *nStart,* size_t *n*) const

size_t wxString::find_first_not_of (const wchar_t * *sz,* size_t *nStart,* size_t *n*) const

size_t wxString::find_first_not_of (wxUniChar *ch,* size_t *nStart* = 0) const

size_t wxString::find_first_of (const char * *sz,* size_t *nStart* = 0) const

size_t wxString::find_first_of (const wchar_t * *sz,* size_t *nStart* = 0) const

size_t wxString::find_first_of (const char * *sz,* size_t *nStart,* size_t *n*) const

size_t wxString::find_first_of (const wchar_t * *sz,* size_t *nStart,* size_t *n*) const

size_t wxString::find_first_of (wxUniChar *c,* size_t *nStart* = 0) const

size_t wxString::find_last_not_of (const wxString & *str,* size_t *nStart* = npos) const

size_t wxString::find_last_not_of (const char * *sz,* size_t *nStart* = npos) const

size_t wxString::find_last_not_of (const wchar_t * *sz,* size_t *nStart* = npos) const

size_t wxString::find_last_not_of (const char * *sz,* size_t *nStart,* size_t *n*) const

size_t wxString::find_last_not_of (const wchar_t * *sz,* size_t *nStart,* size_t *n*) const

size_t wxString::find_last_of (const wxString & *str,* size_t *nStart* = npos) const

size_t wxString::find_last_of (const char * *sz,* size_t *nStart* = npos) const

size_t wxString::find_last_of (const wchar_t * *sz,* size_t *nStart* = npos) const

size_t wxString::find_last_of (const char * *sz,* size_t *nStart,* size_t *n*) const

size_t wxString::find_last_of (const wchar_t * *sz,* size_t *nStart,* size_t *n*) const

size_t wxString::find_last_of (wxUniChar *c,* size_t *nStart* = npos) const

int wxString::First (wxUniChar *ch*) const

Same as Find().

This is a wxWidgets 1.xx compatibility function; you should not use it in new code.

int wxString::First (const wxString & *str*) const

Same as Find().

This is a wxWidgets 1.xx compatibility function; you should not use it in new code.

const wchar_t* wxString::fn_str ( ) const

Returns a string representation suitable for passing to OS' functions for file handling.

const char* wxString::fn_str ( ) const

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.

const wxCharBuffer wxString::fn_str ( ) const

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.

static wxString wxString::Format (const wxString & *format, ...*) [static]

This static function returns the string containing the result of calling Printf() with the passed parameters on it.

See also

FormatV(), Printf()

static wxString wxString::FormatV (const wxString & *format,* va_list *argptr*) [static]

This static function returns the string containing the result of calling PrintfV() with the passed parameters on it.

See also

Format(), PrintfV()

int wxString::Freq (wxUniChar *ch*) const

Returns the number of occurrences of *ch* in the string.

This is a wxWidgets 1.xx compatibility function; you should not use it in new code.

static wxString wxString::From8BitData (const char * *buf,* size_t *len*) [static]

Converts given buffer of binary data from 8-bit string to wxString.

In Unicode build, the string is interpreted as being in ISO-8859-1 encoding. The version without *len* parameter takes NUL-terminated data.

This is a convenience method useful when storing binary data in wxString. It should be used *only* for that purpose and only in conjunction with To8BitData(). Use mb_str() for conversion of character data to known encoding.

Since

2.8.4

See also

wxString::To8BitData()

static wxString wxString::From8BitData (const char * *buf*) [static]

Converts given buffer of binary data from 8-bit string to wxString.

In Unicode build, the string is interpreted as being in ISO-8859-1 encoding. The version without *len* parameter takes NUL-terminated data.

This is a convenience method useful when storing binary data in wxString. It should be used *only* for that purpose and only in conjunction with To8BitData(). Use mb_str() for conversion of character data to known encoding.

Since

2.8.4

See also

wxString::To8BitData()

static wxString wxString::FromAscii (const char * *s*) [static]

Converts the string or character from an ASCII, 7-bit form to the native wxString representation.

static wxString wxString::FromAscii (const unsigned char * *s*) [static]

Converts the string or character from an ASCII, 7-bit form to the native wxString representation.

static wxString wxString::FromAscii (const char * *s*, size_t *len*) [static]

Converts the string or character from an ASCII, 7-bit form to the native wxString representation.

static wxString wxString::FromAscii (const unsigned char * *s*, size_t *len*) [static]

Converts the string or character from an ASCII, 7-bit form to the native wxString representation.

static wxString wxString::FromAscii (char *c*) [static]

Converts the string or character from an ASCII, 7-bit form to the native wxString representation.

static wxString wxString::FromCDouble (double *val*, int *precision* = -1) [static]

Returns a string with the textual representation of the number in C locale.

Unlike FromDouble() the string returned by this function always uses the period character as decimal separator, independently of the current locale. Otherwise its behaviour is identical to the other function.

Since

2.9.1

See also

ToCDouble()

static wxString wxString::FromDouble (double *val,* int *precision* = -1) [static]

Returns a string with the textual representation of the number.

For the default value of *precision*, this function behaves as a simple wrapper for

```
wxString::Format("%g", val)
```

. If *precision* is positive (or zero), the %.Nf format is used with the given precision value.

Notice that the string returned by this function uses the decimal separator appropriate for the current locale, e.g. "," and not a period in French locale. Use FromCDouble() if this is unwanted.

Parameters

val	The value to format.
precision	The number of fractional digits to use in or -1 to use the most appropriate format. This parameter is new in wxWidgets 2.9.2.

Since

2.9.1

See also

ToDouble()

static wxString wxString::FromUTF8 (const char * *s*) [static]

Converts C string encoded in UTF-8 to wxString.

If *s* is not a valid UTF-8 string, an empty string is returned.

Notice that when using UTF-8 wxWidgets build there is a more efficient alternative to this function called FromUTF8Unchecked() which, unlike this one, doesn't check that the input string is valid.

Since

2.8.4

static wxString wxString::FromUTF8 (const char * *s,* size_t *len*) [static]

Converts C string encoded in UTF-8 to wxString.

If *s* is not a valid UTF-8 string, an empty string is returned.

Notice that when using UTF-8 wxWidgets build there is a more efficient alternative to this function called FromUTF8Unchecked() which, unlike this one, doesn't check that the input string is valid.

Since

2.8.4

static wxString wxString::FromUTF8Unchecked (const char * *s*) [static]

Converts C string encoded in UTF-8 to wxString without checking its validity.

This method assumes that *s* is a valid UTF-8 sequence and doesn't do any validation (although an assert failure is triggered in debug builds if the string is invalid). Only use it if you are absolutely sure that *s* is a correct UTF-8 string (e.g. because it comes from another library using UTF-8) and if the performance matters, otherwise use slower (in UTF-8 build) but safer FromUTF8(). Passing a bad UTF-8 string to this function will result in creating a corrupted wxString and all the subsequent operations on it will be undefined.

Since

2.8.9

static wxString wxString::FromUTF8Unchecked (const char * *s*, size_t *len*) [static]

Converts C string encoded in UTF-8 to wxString without checking its validity.

This method assumes that *s* is a valid UTF-8 sequence and doesn't do any validation (although an assert failure is triggered in debug builds if the string is invalid). Only use it if you are absolutely sure that *s* is a correct UTF-8 string (e.g. because it comes from another library using UTF-8) and if the performance matters, otherwise use slower (in UTF-8 build) but safer FromUTF8(). Passing a bad UTF-8 string to this function will result in creating a corrupted wxString and all the subsequent operations on it will be undefined.

Since

2.8.9

wxUniChar wxString::GetChar (size_t *n*) const

Returns the character at position *n* (read-only).

const wxCStrData wxString::GetData ( ) const

wxWidgets compatibility conversion.

Same as c_str().

wxUniCharRef wxString::GetWritableChar (size_t *n*)

Returns a reference to the character at position *n*.

wxStringCharType* wxString::GetWriteBuf (size_t *len*)

Returns a writable buffer of at least *len* bytes.

It returns a pointer to a new memory block, and the existing data will not be copied. Call UngetWriteBuf() as soon as possible to put the string back into a reasonable state.

This method is deprecated, please use wxStringBuffer or wxStringBufferLength instead.

wxString& wxString::insert (size_t *nPos*, const wxString & *str*)

wxString& wxString::insert (size_t *nPos*, const wxString & *str*, size_t *nStart*, size_t *n*)

wxString& wxString::insert (size_t *nPos,* const char * *sz,* size_t *n*)

wxString& wxString::insert (size_t *nPos,* const wchar_t * *sz,* size_t *n*)

wxString& wxString::insert (size_t *nPos,* size_t *n,* wxUniChar *ch*)

iterator wxString::insert (iterator *it,* wxUniChar *ch*)

void wxString::insert (iterator *it,* const_iterator *first,* const_iterator *last*)

void wxString::insert (iterator *it,* size_type *n,* wxUniChar *ch*)

bool wxString::IsAscii ( ) const

Returns true if the string contains only ASCII characters.

See wxUniChar::IsAscii for more details.

This is a wxWidgets 1.xx compatibility function; you should not use it in new code.

bool wxString::IsEmpty ( ) const

Returns true if the string is empty.

bool wxString::IsNull ( ) const

Returns true if the string is empty (same as wxString::IsEmpty).

This is a wxWidgets 1.xx compatibility function; you should not use it in new code.

bool wxString::IsNumber ( ) const

Returns true if the string is an integer (with possible sign).

This is a wxWidgets 1.xx compatibility function; you should not use it in new code.

bool wxString::IsSameAs (const wxString & *s,* bool *caseSensitive* = `true`) const

Test whether the string is equal to another string *s*.

The test is case-sensitive if *caseSensitive* is true (default) or not if it is false.

Returns

true if the string is equal to the other one, false otherwise.

See also

Cmp(), CmpNoCase()

bool wxString::IsSameAs (wxUniChar *ch,* bool *caseSensitive* = `true`) const

Test whether the string is equal to the single character *ch*.

The test is case-sensitive if *caseSensitive* is true (default) or not if it is false.

Returns

true if the string is equal to this character, false otherwise.

See also

Cmp(), CmpNoCase()

bool wxString::IsWord ( ) const

Returns true if the string is a word.

This is a wxWidgets 1.xx compatibility function; you should not use it in new code.

wxUniChar wxString::Last ( ) const

Returns the last character.

This is a wxWidgets 1.xx compatibility function; you should not use it in new code.

wxUniCharRef wxString::Last ( )

Returns a reference to the last character (writable).

This is a wxWidgets 1.xx compatibility function; you should not use it in new code.

wxString wxString::Left (size_t *count*) const

Returns the first *count* characters of the string.

size_t wxString::Len ( ) const

Returns the length of the string.

size_t wxString::Length ( ) const

Returns the length of the string (same as Len).

This is a wxWidgets 1.xx compatibility function; you should not use it in new code.

size_t wxString::length ( ) const

wxString wxString::Lower ( ) const

Returns this string converted to the lower case.

See also

MakeLower()

void wxString::LowerCase ( )

Same as MakeLower.

This is a wxWidgets 1.xx compatibility function; you should not use it in new code.

wxString& wxString::MakeCapitalized ( )

Converts the first characters of the string to the upper case and all the subsequent ones to the lower case and returns the result.

Since

2.9.0

See also

Capitalize()

wxString& wxString::MakeLower ( )

Converts all characters to lower case and returns the reference to the modified string.

See also

Lower()

wxString& wxString::MakeUpper ( )

Converts all characters to upper case and returns the reference to the modified string.

See also

Upper()

bool wxString::Matches (const wxString & *mask*) const

Returns true if the string contents matches a mask containing '*' and '?'.

size_type wxString::max_size ( ) const

const wxCharBuffer wxString::mb_str (const wxMBConv & *conv* = `wxConvLibc`) const

Returns the multibyte (C string) representation of the string using *conv's* wxMBConv::cWC2MB method and returns wxCharBuffer.

See also

wc_str(), utf8_str(), c_str(), wxMBConv

wxString wxString::Mid (size_t *first*, size_t *nCount* = wxString::npos) const

Returns a substring starting at *first*, with length *count*, or the rest of the string if *count* is the default value.

bool wxString::operator! ( ) const

Empty string is false, so !string will only return true if the string is empty.

See also

IsEmpty().

wxString wxString::operator() (size_t *start,* size_t *len*) const

Same as Mid() (substring extraction).

wxString wxString::operator+ (const wxString & *x,* const wxString & *y*)

Concatenation: returns a new string equal to the concatenation of the operands.

wxString wxString::operator+ (const wxString & *x,* wxUniChar *y*)

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.

void wxString::operator+= (const wxString & *str*)

Concatenation in place: the argument is appended to the string.

void wxString::operator+= (wxUniChar *c*)

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.

wxString& wxString::operator<< (const wxString & *s*)

Appends the string literal *psz*.

wxString& wxString::operator<< (const char * *psz*)

Appends the string literal *psz*.

wxString& wxString::operator<< (const wchar_t * *pwz*)

Appends the string literal *psz*.

wxString& wxString::operator<< (const wxCStrData & *psz*)

Appends the string literal *psz*.

wxString& wxString::operator<< (char *ch*)

Appends the string literal *psz*.

wxString& wxString::operator<< (unsigned char *ch*)

Appends the string literal *psz*.

wxString& wxString::operator<< (wchar_t *ch*)

Appends the string literal *psz*.

wxString& wxString::operator<< (const wxCharBuffer & *s*)

Appends the string literal *psz*.

wxString& wxString::operator<< (const wxWCharBuffer & *s*)

Appends the string literal *psz*.

wxString& wxString::operator<< (wxUniChar *ch*)

Appends the string literal *psz*.

wxString& wxString::operator<< (wxUniCharRef *ch*)

Appends the string literal *psz*.

wxString& wxString::operator<< (unsigned int *ui*)

Appends the string literal *psz*.

wxString& wxString::operator<< (long *l*)

Appends the string literal *psz*.

wxString& wxString::operator<< (unsigned long *ul*)

Appends the string literal *psz*.

wxString& wxString::operator<< (wxLongLong_t *ll*)

Appends the string literal *psz*.

wxString& wxString::operator<< (wxULongLong_t *ul*)

Appends the string literal *psz*.

wxString& wxString::operator<< (float *f*)

Appends the string literal *psz*.

wxString& wxString::operator<< (double *d*)

Appends the string literal *psz*.

wxString wxString::operator= (const wxString & *str*)

Assignment: see the relative wxString constructor.

wxString wxString::operator= (wxUniChar *c*)

Assignment: see the relative wxString constructor.

wxUniChar wxString::operator[] (size_t *i*) const

Returns the *i-th* character of the string.

wxUniCharRef wxString::operator[] (size_t *i*)

Returns a writable reference to the *i-th* character of the string.

wxString& wxString::Pad (size_t *count*, wxUniChar *chPad* = ' ', bool *fromRight* = true)

Adds *count* copies of *chPad* to the beginning, or to the end of the string (the default).

Removes spaces from the left or from the right (default).

wxString& wxString::Prepend (const wxString & *str*)

Prepends *str* to this string, returning a reference to this string.

int wxString::Printf (const wxString & *pszFormat*, ...)

Similar to the standard function *sprintf()*.

Returns the number of characters written, or an integer less than zero on error. Note that if wxUSE_PRINTF_POS_PARAMS is set to 1, then this function supports Unix98-style positional parameters:

```
wxString str;

str.Printf(wxT("%d %d %d"), 1, 2, 3);
// str now contains "1 2 3"

str.Printf(wxT("%2$d %3$d %1$d"), 1, 2, 3);
// str now contains "2 3 1"
```

Note

This function will use a safe version of *vsprintf()* (usually called *vsnprintf()*) whenever available to always allocate the buffer of correct size. Unfortunately, this function is not available on all platforms and the dangerous *vsprintf()* will be used then which may lead to buffer overflows.

int wxString::PrintfV (const wxString & *pszFormat*, va_list *argPtr*)

Similar to vprintf.

Returns the number of characters written, or an integer less than zero on error.

const_reverse_iterator wxString::rbegin ( ) const

reverse_iterator wxString::rbegin ( )

wxString& wxString::Remove (size_t *pos*)

Removes all characters from the string starting at *pos*.

Use Truncate() as a more readable alternative.

This is a wxWidgets 1.xx compatibility function; you should not use it in new code.

wxString& wxString::Remove (size_t *pos*, size_t *len*)

Removes *len* characters from the string, starting at *pos*.

This is a wxWidgets 1.xx compatibility function; you should not use it in new code.

wxString& wxString::RemoveLast (size_t *n* = `1`)

Removes the last character.

const_reverse_iterator wxString::rend ( ) const

reverse_iterator wxString::rend ( )

size_t wxString::Replace (const wxString & *strOld*, const wxString & *strNew*, bool *replaceAll* = `true`)

Replace first (or all) occurrences of substring with another one.

Parameters

strOld	The string to search for replacing.
strNew	The substitution string.
replaceAll	If true a global replace will be done (default), otherwise only the first occurrence will be replaced.

Returns the number of replacements made.

wxString& wxString::replace (size_t *nStart*, size_t *nLen*, const wxString & *str*)

wxString& wxString::replace (size_t *nStart*, size_t *nLen*, size_t *nCount*, wxUniChar *ch*)

wxString& wxString::replace (size_t *nStart*, size_t *nLen*, const wxString & *str*, size_t *nStart2*, size_t *nLen2*)

wxString& wxString::replace (size_t *nStart*, size_t *nLen*, const char * *sz*, size_t *nCount*)

wxString& wxString::replace (size_t *nStart*, size_t *nLen*, const wchar_t * *sz*, size_t *nCount*)

wxString& wxString::replace (size_t *nStart*, size_t *nLen*, const wxString & *s*, size_t *nCount*)

wxString& wxString::replace (iterator *first*, iterator *last*, const wxString & *s*)

wxString& wxString::replace (iterator *first*, iterator *last*, const char * *s*, size_type *n*)

wxString& wxString::replace (iterator *first*, iterator *last*, const wchar_t * *s*, size_type *n*)

wxString& wxString::replace (iterator *first*, iterator *last*, size_type *n*, wxUniChar *ch*)

wxString& wxString::replace (iterator *first*, iterator *last*, const_iterator *first1*, const_iterator *last1*)

wxString& wxString::replace (iterator *first*, iterator *last*, const char * *first1*, const char * *last1*)

wxString& wxString::replace (iterator *first*, iterator *last*, const wchar_t * *first1*, const wchar_t * *last1*)

void wxString::reserve (size_t *sz*)

void wxString::resize (size_t *nSize,* wxUniChar *ch* = '\0')

size_t wxString::rfind (const wxString & *str,* size_t *nStart* = npos) const

size_t wxString::rfind (const char * *sz,* size_t *nStart* = npos, size_t *n* = npos) const

size_t wxString::rfind (const wchar_t * *sz,* size_t *nStart* = npos, size_t *n* = npos) const

size_t wxString::rfind (wxUniChar *ch,* size_t *nStart* = npos) const

wxString wxString::Right (size_t *count*) const

Returns the last *count* characters.

void wxString::SetChar (size_t *n,* wxUniChar *ch*)

Sets the character at position *n*.

bool wxString::Shrink ( )

Minimizes the string's memory.

This can be useful after a call to Alloc() if too much memory were preallocated.

size_type wxString::size ( ) const

bool wxString::StartsWith (const wxString & *prefix,* wxString * *rest* = NULL) const

This function can be used to test if the string starts with the specified *prefix*.

If it does, the function will return true and put the rest of the string (i.e. after the prefix) into *rest* string if it is not NULL. Otherwise, the function returns false and doesn't modify the *rest*.

wxString wxString::Strip (stripType *s* = trailing) const

Strip characters at the front and/or end.

This is the same as Trim() except that it doesn't change this string.

This is a wxWidgets 1.xx compatibility function; you should not use it in new code.

wxString wxString::substr (size_t *nStart* = 0, size_t *nLen* = npos) const

wxString wxString::SubString (size_t *from,* size_t *to*) const

Returns the part of the string between the indices *from* and *to* inclusive.

This is a wxWidgets 1.xx compatibility function, use Mid() instead (but note that parameters have different meaning).

void wxString::swap (wxString & *str*)

template<typename T > wxCharTypeBuffer<T> wxString::tchar_str (size_t * *len* = NULL) const

Returns buffer of the specified type containing the string data.

This method is only useful in template code, otherwise you should directly call mb_str() or wc_str() if you need to retrieve a narrow or wide string from this wxString. The template parameter *t* should be either `char` or `wchar_t`.

Notice that retrieving a char buffer in UTF-8 build will return the internal string representation in UTF-8 while in wchar_t build the char buffer will contain the conversion of the string to the encoding of the current locale (and so can fail).

Parameters

len	If non-NULL, filled with the length of the returned buffer.

Returns

buffer containing the string contents in the specified type, notice that it may be NULL if the conversion failed (e.g. Unicode string couldn't be converted to the current encoding when *T* is `char`).

const wxScopedCharBuffer wxString::To8BitData ( ) const

Converts the string to an 8-bit string in ISO-8859-1 encoding in the form of a wxCharBuffer (Unicode builds only).

This is a convenience method useful when storing binary data in wxString. It should be used *only* for this purpose. It is only valid to call this method on strings created using From8BitData().

Since

2.8.4

See also

wxString::From8BitData()

const char* wxString::ToAscii ( ) const

Converts the string to an ASCII, 7-bit string in the form of a wxCharBuffer (Unicode builds only) or a C string (ANSI builds).

Note that this conversion is only lossless if the string contains only ASCII characters as all the non-ASCII ones are replaced with the `'_'` (underscore) character.

Use mb_str() or utf8_str() to convert to other encodings.

const wxCharBuffer wxString::ToAscii ( ) const

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.

bool wxString::ToCDouble (double * *val*) const

Variant of ToDouble() always working in "C" locale.

Works like ToDouble() but unlike it this function expects the floating point number to be formatted always with the rules dictated by the "C" locale (in particular, the decimal point must be a dot), independently from the current application-wide locale (see wxLocale).

See also

ToDouble(), ToLong(), ToULong()

bool wxString::ToCLong (long * *val,* int *base* = 10) const

Variant of ToLong() always working in "C" locale.

Works like ToLong() but unlike it this function expects the integer number to be formatted always with the rules dictated by the "C" locale, independently from the current application-wide locale (see wxLocale).

See also

ToDouble(), ToLong(), ToULong()

bool wxString::ToCULong (unsigned long * *val,* int *base* = 10) const

Variant of ToULong() always working in "C" locale.

Works like ToULong() but unlike it this function expects the integer number to be formatted always with the rules dictated by the "C" locale, independently from the current application-wide locale (see wxLocale).

See also

ToDouble(), ToLong(), ToULong()

bool wxString::ToDouble (double * *val*) const

Attempts to convert the string to a floating point number.

Returns true on success (the number is stored in the location pointed to by *val*) or false if the string does not represent such number (the value of *val* may still be modified in this case).

Note that unlike ToCDouble() this function uses a localized version of `wxStrtod()` and thus needs as decimal point (and thousands separator) the locale-specific decimal point. Thus you should use this function only when you are sure that this string contains a floating point number formatted with the rules of the locale currently in use (see wxLocale).

Also notice that even this function is locale-specific it does not support strings with thousands separators in them, even if the current locale uses digits grouping. You may use wxNumberFormatter::FromString() to parse such strings.

Please refer to the documentation of the standard function `strtod()` for more details about the supported syntax.

ToCDouble(), ToLong(), ToULong()

bool wxString::ToLong (long * *val,* int *base* = 10) const

Attempts to convert the string to a signed integer in base *base*.

Returns true on success in which case the number is stored in the location pointed to by *val* or false if the string does not represent a valid number in the given base (the value of *val* may still be modified in this case).

The value of *base* must be comprised between 2 and 36, inclusive, or be a special value 0 which means that the usual rules of `C` numbers are applied: if the number starts with `0x` it is considered to be in base 16, if it starts with `0` - in base 8 and in base 10 otherwise. Note that you may not want to specify the base 0 if you are parsing the numbers which may have leading zeroes as they can yield unexpected (to the user not familiar with C) results.

Note that unlike ToCLong() this function uses a localized version of `wxStrtol()`. Thus you should use this function only when you are sure that this string contains an integer number formatted with the rules of the locale currently in use (see wxLocale).

As with ToDouble(), this function does not support strings containing thousands separators even if the current locale uses digits grouping. You may use wxNumberFormatter::FromString() to parse such strings.

Please refer to the documentation of the standard function `strtol()` for more details about the supported syntax.

ToCDouble(), ToDouble(), ToULong()

bool wxString::ToLongLong (wxLongLong_t * *val,* int *base* = `10`) const

This is exactly the same as ToLong() but works with 64 bit integer numbers.

Notice that currently it doesn't work (always returns false) if parsing of 64 bit numbers is not supported by the underlying C run-time library. Compilers with C99 support and Microsoft Visual C++ version 7 and higher do support this.

See also

ToLong(), ToULongLong()

std::string wxString::ToStdString ( ) const

Return the string as an std::string in current locale encoding.

Note that if the conversion of (Unicode) string contents to the current locale fails, the return string will be empty. Be sure to check for this to avoid silent data loss.

Instead of using this function it's also possible to write

```
std::string s;
wxString wxs;
...
s = std::string(wxs);
```

but using ToStdString() may make the code more clear.

Since

2.9.1

std::wstring wxString::ToStdWstring ( ) const

Return the string as an std::wstring.

Unlike ToStdString(), there is no danger of data loss when using this function.

Since

2.9.1

bool wxString::ToULong (unsigned long * *val*, int *base* = `10`) const

Attempts to convert the string to an unsigned integer in base *base*.

Returns true on success in which case the number is stored in the location pointed to by *val* or false if the string does not represent a valid number in the given base (the value of *val* may still be modified in this case).

Please notice that this function behaves in the same way as the standard `strtoul()` and so it simply converts negative numbers to unsigned representation instead of rejecting them (e.g. -1 is returned as `ULONG_MAX`).

See ToLong() for the more detailed description of the *base* parameter (and of the locale-specific behaviour of this function).

See also

ToCULong(), ToDouble(), ToLong()

bool wxString::ToULongLong (wxULongLong_t * *val*, int *base* = `10`) const

This is exactly the same as ToULong() but works with 64 bit integer numbers.

Please see ToLongLong() for additional remarks.

const wxScopedCharBuffer wxString::ToUTF8 ( ) const

Same as utf8_str().

wxString& wxString::Trim (bool *fromRight* = `true`)

Removes white-space (space, tabs, form feed, newline and carriage return) from the left or from the right end of the string (right is default).

wxString& wxString::Truncate (size_t *len*)

Truncate the string to the given length.

void wxString::UngetWriteBuf ( )

Puts the string back into a reasonable state (in which it can be used normally), after GetWriteBuf() was called.

The version of the function without the *len* parameter will calculate the new string length itself assuming that the string is terminated by the first `NUL` character in it while the second one will use the specified length and thus is the only version which should be used with the strings with embedded `NUL`s (it is also slightly more efficient as `strlen()` doesn't have to be called).

This method is deprecated, please use wxStringBuffer or wxStringBufferLength instead.

void wxString::UngetWriteBuf (size_t *len*)

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.

wxString wxString::Upper ( ) const

Returns this string converted to upper case.

See also

MakeUpper()

void wxString::UpperCase ( )

The same as MakeUpper().

This is a wxWidgets 1.xx compatibility function; you should not use it in new code.

const wxScopedCharBuffer wxString::utf8_str ( ) const
