Please note that the easiest way to use drag and drop and the clipboard with multiple formats is by using wxDataObjectComposite, but it is not the most efficient one as each wxDataObjectSimple would contain the whole data in its respective formats. Now imagine that you want to paste 200 pages of text in your proprietary format, as well as Word, RTF, HTML, Unicode and plain text to the clipboard and even today's computers are in trouble. For this case, you will have to derive from wxDataObject directly and make it enumerate its formats and provide the data in the requested format on demand.

Note that neither the GTK+ data transfer mechanisms for clipboard and drag and drop, nor OLE data transfer, *copies* any data until another application actually requests the data. This is in contrast to the 'feel' offered to the user of a program who would normally think that the data resides in the clipboard after having pressed 'Copy' - in reality it is only declared to be *available*.

You may also derive your own data object classes from wxCustomDataObject for user-defined types. The format of user-defined data is given as a mime-type string literal, such as "application/word" or "image/png". These strings are used as they are under Unix (so far only GTK+) to identify a format and are translated into their Windows equivalent under Win32 (using the OLE IDataObject for data exchange to and from the clipboard and for drag and drop). Note that the format string translation under Windows is not yet finished.

Each class derived directly from wxDataObject must override and implement all of its functions which are pure virtual in the base class. The data objects which only render their data or only set it (i.e. work in only one direction), should return 0 from GetFormatCount().

wxPerl Note: This class is not currently usable from wxPerl; you may use Wx::PlDataObjectSimple instead.

Public Types

- enum Direction {
  Get = 0x01,
  Set = 0x02,
  Both = 0x03 }

Public Member Functions

- wxDataObject ()

  Constructor.
- virtual ~wxDataObject ()

  Destructor.
- virtual void GetAllFormats (wxDataFormat *formats, Direction dir=Get) const =0

  Copies all formats supported in the given direction dir to the array pointed to by formats.
- virtual bool GetDataHere (const wxDataFormat &format, void *buf) const =0

  The method will write the data of the format format to the buffer buf.
- virtual size_t GetDataSize (const wxDataFormat &format) const =0

  Returns the data size of the given format format.
- virtual size_t GetFormatCount (Direction dir=Get) const =0

  Returns the number of available formats for rendering or setting the data.
- virtual wxDataFormat GetPreferredFormat (Direction dir=Get) const =0

  Returns the preferred format for either rendering the data (if dir is `Get`, its default value) or for setting it.
- virtual bool SetData (const wxDataFormat &format, size_t len, const void *buf)

  Set the data in the format format of the length len provided in the buffer buf.
- bool IsSupported (const wxDataFormat &format, Direction dir=Get) const

  Returns true if this format is supported.

21.137.2 Member Enumeration Documentation

enum wxDataObject::Direction

Enumerator

Get Format is supported by GetDataHere()

Set Format is supported by SetData()

Both Format is supported by both GetDataHere() and SetData() (unused currently)

21.137.3 Constructor & Destructor Documentation

wxDataObject::wxDataObject ( )

Constructor.

virtual wxDataObject::~wxDataObject ( ) [virtual]

Destructor.

21.137.4 Member Function Documentation

virtual void wxDataObject::GetAllFormats (wxDataFormat * *formats,* Direction *dir* = Get) const [pure virtual]

Copies all formats supported in the given direction *dir* to the array pointed to by *formats*.

There must be enough space for GetFormatCount(dir) formats in it.

wxPerl Note: In wxPerl this method only takes the *dir* parameter. In scalar context it returns the first format in the list, in list context it returns a list containing all the supported formats.

Implemented in wxTextDataObject.

virtual bool wxDataObject::GetDataHere (const wxDataFormat & *format,* void * *buf*) const [pure virtual]

The method will write the data of the format *format* to the buffer *buf*.

In other words, copy the data from this object in the given format to the supplied buffer. Returns true on success, false on failure.

Implemented in wxRichTextBufferDataObject.

virtual size_t wxDataObject::GetDataSize (const wxDataFormat & *format*) const [pure virtual]

Returns the data size of the given format *format*.

Implemented in wxRichTextBufferDataObject.

virtual size_t wxDataObject::GetFormatCount (Direction *dir* = Get) const [pure virtual]

Returns the number of available formats for rendering or setting the data.

Implemented in wxTextDataObject.

virtual wxDataFormat wxDataObject::GetPreferredFormat (Direction *dir* = Get) const [pure virtual]

Returns the preferred format for either rendering the data (if *dir* is `Get`, its default value) or for setting it.

Usually this will be the native format of the wxDataObject.

Implemented in wxRichTextBufferDataObject.

bool wxDataObject::IsSupported (const wxDataFormat & *format,* Direction *dir* = Get) const

Returns true if this format is supported.

virtual bool wxDataObject::SetData (const wxDataFormat & *format,* size_t *len,* const void * *buf*) [virtual]

Set the data in the format *format* of the length *len* provided in the buffer *buf*.

In other words, copy length bytes of data from the buffer to this data object.

Parameters

format	The format for which to set the data.

len	The size of data in bytes.
buf	Non-NULL pointer to the data.

Returns

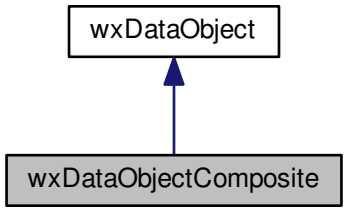
true on success, false on failure.

Reimplemented in wxRichTextBufferDataObject.

21.138 wxDataObjectComposite Class Reference

`#include <wx/dataobj.h>`

Inheritance diagram for wxDataObjectComposite:



21.138.1 Detailed Description

wxDataObjectComposite is the simplest wxDataObject derivation which may be used to support multiple formats.

It contains several wxDataObjectSimple objects and supports any format supported by at least one of them. Only one of these data objects is *preferred* (the first one if not explicitly changed by using the second parameter of Add()) and its format determines the preferred format of the composite data object as well.

See wxDataObject documentation for the reasons why you might prefer to use wxDataObject directly instead of wxDataObjectComposite for efficiency reasons.

This example shows how a composite data object capable of storing either bitmaps or file names (presumably of bitmap files) can be initialized and used:

```
MyDropTarget::MyDropTarget()
{
    wxDataObjectComposite* dataobj = new
      wxDataObjectComposite();
    dataobj->Add(new wxBitmapDataObject(), true);
    dataobj->Add(new wxFileDataObject());
    SetDataObject(dataobj);
}

wxDragResult MyDropTarget::OnData(wxCoord x, wxCoord y,
                                  wxDragResult defaultDragResult)
{
    wxDragResult dragResult = wxDropTarget::OnData(x, y, defaultDragResult)
      ;
    if ( dragResult == defaultDragResult )
    {
        wxDataObjectComposite *
            dataobjComp = static_cast<wxDataObjectComposite *>(GetDataObject());

        wxDataFormat format = dataObjects->GetReceivedFormat();
```

```
        wxDataObject *dataobj = dataobjComp->GetObject(format);
        switch ( format.GetType() )
        {
            case wxDF_BITMAP:
                {
                    wxBitmapDataObject *
                        dataobjBitmap = static_cast<wxBitmapDataObject *>(dataobj);

                    ... use dataobj->GetBitmap() ...
                }
                break;

            case wxDF_FILENAME:
                {
                    wxFileDataObject *
                        dataobjFile = static_cast<wxFileDataObject *>(dataobj);

                    ... use dataobj->GetFilenames() ...
                }
                break;

            default:
                wxFAIL_MSG( "unexpected data object format" );
        }
    }

    return dragResult;
}
```

Drag and Drop Overview, wxDataObject, wxDataObjectSimple, wxFileDataObject, wxTextDataObject, wxBitmapDataObject

Public Member Functions

- wxDataObjectComposite ()

  The default constructor.
- void Add (wxDataObjectSimple *dataObject, bool preferred=false)

  Adds the dataObject to the list of supported objects and it becomes the preferred object if preferred is true.
- wxDataFormat GetReceivedFormat () const

  Report the format passed to the SetData() method.
- wxDataObjectSimple * GetObject (const wxDataFormat &format, wxDataObject::Direction dir=wxDataObject::Get) const

  Returns the pointer to the object which supports the passed format for the specified direction.

Additional Inherited Members

21.138.2 Constructor & Destructor Documentation

wxDataObjectComposite::wxDataObjectComposite ( )

The default constructor.

21.138.3 Member Function Documentation

void wxDataObjectComposite::Add (wxDataObjectSimple * *dataObject*, bool *preferred* = `false`)

Adds the *dataObject* to the list of supported objects and it becomes the preferred object if *preferred* is true.

wxDataObjectSimple* wxDataObjectComposite::GetObject (const wxDataFormat & *format*, wxDataObject::Direction *dir* = wxDataObject::Get) const

Returns the pointer to the object which supports the passed format for the specified direction.

NULL is returned if the specified *format* is not supported for this direction *dir*. The returned pointer is owned by wxDataObjectComposite itself and shouldn't be deleted by caller.

Since

2.9.1

wxDataFormat wxDataObjectComposite::GetReceivedFormat ( ) const

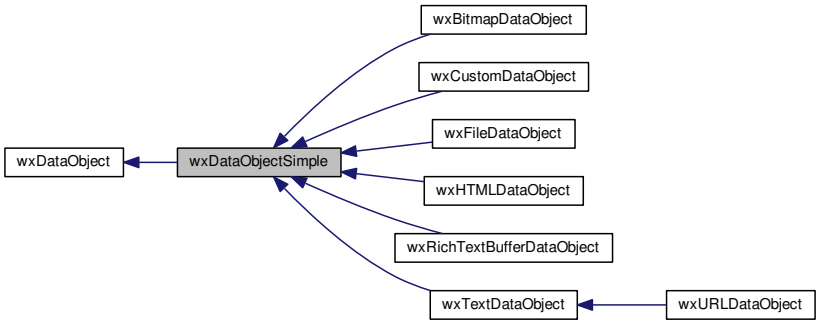
Report the format passed to the SetData() method.

This should be the format of the data object within the composite that received data from the clipboard or the DnD operation. You can use this method to find out what kind of data object was received.

21.139 wxDataObjectSimple Class Reference

`#include <wx/dataobj.h>`

Inheritance diagram for wxDataObjectSimple:



21.139.1 Detailed Description

This is the simplest possible implementation of the wxDataObject class.

The data object of (a class derived from) this class only supports **one format**, so the number of virtual functions to be implemented is reduced.

Notice that this is still an abstract base class and cannot be used directly, it must be derived. The objects supporting rendering the data must override GetDataSize() and GetDataHere() while the objects which may be set must override SetData(). Of course, the objects supporting both operations must override all three methods.

wxPerl Note: In wxPerl, you need to derive your data object class from Wx::PlDataObjectSimple.

Public Member Functions

- wxDataObjectSimple (const wxDataFormat &format=wxFormatInvalid)

  Constructor accepts the supported format (none by default) which may also be set later with SetFormat().
- virtual bool GetDataHere (void ∗buf) const

  Copy the data to the buffer, return true on success.
- virtual size_t GetDataSize () const

  Gets the size of our data.
- const wxDataFormat & GetFormat () const

  Returns the (one and only one) format supported by this object.
- virtual bool SetData (size_t len, const void ∗buf)

  Copy the data from the buffer, return true on success.
- void SetFormat (const wxDataFormat &format)

  Sets the supported format.

Additional Inherited Members

21.139.2 Constructor & Destructor Documentation

wxDataObjectSimple::wxDataObjectSimple (const wxDataFormat & *format* = wxFormatInvalid)

Constructor accepts the supported format (none by default) which may also be set later with SetFormat().

21.139.3 Member Function Documentation

virtual bool wxDataObjectSimple::GetDataHere (void ∗ *buf*) const `[virtual]`

Copy the data to the buffer, return true on success.

Must be implemented in the derived class if the object supports rendering its data.

Reimplemented in wxRichTextBufferDataObject.

virtual size_t wxDataObjectSimple::GetDataSize ( ) const `[virtual]`

Gets the size of our data.

Must be implemented in the derived class if the object supports rendering its data.

Reimplemented in wxRichTextBufferDataObject.

const wxDataFormat& wxDataObjectSimple::GetFormat ( ) const

Returns the (one and only one) format supported by this object.

It is assumed that the format is supported in both directions.

virtual bool wxDataObjectSimple::SetData (size_t *len,* const void * *buf*) `[virtual]`

Copy the data from the buffer, return true on success.

Must be implemented in the derived class if the object supports setting its data.

Reimplemented in wxRichTextBufferDataObject, and wxCustomDataObject.

void wxDataObjectSimple::SetFormat (const wxDataFormat & *format*)

Sets the supported format.

21.140 wxDataOutputStream Class Reference

`#include <wx/datstrm.h>`

21.140.1 Detailed Description

This class provides functions that write binary data types in a portable way.

Data can be written in either big-endian or little-endian format, little-endian being the default on all architectures but BigEndianOrdered() can be used to change this. The default format for the floating point types is 80 bit "extended precision" unless `wxUSE_APPLE_IEEE` was turned off during the library compilation, in which case extended precision is not available at all. You can call UseBasicPrecisions() to change this and use the standard IEEE 754 32 bit single precision format for floats and standard 64 bit double precision format for doubles. This is recommended for the new code for better interoperability with other software that typically uses standard IEEE 754 formats for its data, the use of extended precision by default is solely due to backwards compatibility.

If you want to write data to text files (or streams) use wxTextOutputStream instead.

The "<<" operator is overloaded and you can use this class like a standard C++ iostream. See wxDataInputStream for its usage and caveats.

Library: wxBase

Category: Streams

See also

wxDataInputStream

Public Member Functions

- wxDataOutputStream (wxOutputStream &stream, const wxMBConv &conv=wxConvUTF8)

  Constructs a datastream object from an output stream.
- ~wxDataOutputStream ()

  Destroys the wxDataOutputStream object.
- void BigEndianOrdered (bool be_order)

  If be_order is true, all data will be written in big-endian order, e.g.
- wxMBConv * GetConv () const

  Returns the current text conversion class used for writing strings.
- void SetConv (const wxMBConv &conv)

  Sets the text conversion class used for writing strings.

- void UseBasicPrecisions ()

  Disables the use of extended precision format for floating point numbers.
- void UseExtendedPrecision ()

  Explicitly request the use of extended precision for floating point numbers.
- void Write8 (wxUint8 i8)

  Writes the single byte i8 to the stream.
- void Write8 (const wxUint8 *buffer, size_t size)

  Writes an array of bytes to the stream.
- void Write16 (wxUint16 i16)

  Writes the 16 bit unsigned integer i16 to the stream.
- void Write16 (const wxUint16 *buffer, size_t size)

  Writes an array of 16 bit unsigned integer to the stream.
- void Write32 (wxUint32 i32)

  Writes the 32 bit unsigned integer i32 to the stream.
- void Write32 (const wxUint32 *buffer, size_t size)

  Writes an array of 32 bit unsigned integer to the stream.
- void Write64 (wxUint64 i64)

  Writes the 64 bit unsigned integer i64 to the stream.
- void Write64 (const wxUint64 *buffer, size_t size)

  Writes an array of 64 bit unsigned integer to the stream.
- void WriteFloat (float f)

  Writes the float f to the stream.
- void WriteFloat (const float *buffer, size_t size)

  Writes an array of float to the stream.
- void WriteDouble (double d)

  Writes the double d to the stream.
- void WriteDouble (const double *buffer, size_t size)

  Writes an array of double to the stream.
- void WriteString (const wxString &string)

  Writes string to the stream.

21.140.2 Constructor & Destructor Documentation

wxDataOutputStream::wxDataOutputStream (wxOutputStream & *stream*, const wxMBConv & *conv* = wxConvUTF8)

Constructs a datastream object from an output stream.

Only write methods will be available.

Note that the *conv* parameter is only available in Unicode builds of wxWidgets.

Parameters

stream	The output stream.
conv	Charset conversion object used to encoding Unicode strings before writing them to the stream in Unicode mode (see WriteString() for a detailed description). Note that you must not destroy *conv* before you destroy this wxDataOutputStream instance! It is recommended to use the default value (UTF-8).

wxDataOutputStream::~wxDataOutputStream ( )

Destroys the wxDataOutputStream object.

21.140.3 Member Function Documentation

void wxDataOutputStream::BigEndianOrdered (bool *be_order*)

If *be_order* is true, all data will be written in big-endian order, e.g.

for reading on a Sparc or from Java-Streams (which always use big-endian order), otherwise data will be written in little-endian order.

wxMBConv* wxDataOutputStream::GetConv ( ) const

Returns the current text conversion class used for writing strings.

void wxDataOutputStream::SetConv (const wxMBConv & *conv*)

Sets the text conversion class used for writing strings.

void wxDataOutputStream::UseBasicPrecisions ( )

Disables the use of extended precision format for floating point numbers.

This method disables the use of 80 bit extended precision format for the `float` and `double` values written to the stream, which is used by default (unless `wxUSE_APPLE_IEEE` was set to `0` when building the library, in which case the extended format support is not available at all and this function does nothing).

After calling it, `float` values will be written out in one of IEEE 754 "basic formats", i.e. 32 bit single precision format for floats and 64 bit double precision format for doubles.

Since

2.9.5

void wxDataOutputStream::UseExtendedPrecision ( )

Explicitly request the use of extended precision for floating point numbers.

This function allows the application code to explicitly request the use of 80 bit extended precision format for the floating point numbers. This is the case by default but using this function explicitly ensures that the compilation of code relying on producing the output stream using extended precision would fail when using a version of wxWidgets compiled with `wxUSE_APPLE_IEEE==0` and so not supporting this format at all.

Since

2.9.5

void wxDataOutputStream::Write16 (wxUint16 *i16*)

Writes the 16 bit unsigned integer *i16* to the stream.

void wxDataOutputStream::Write16 (const wxUint16 * *buffer*, size_t *size*)

Writes an array of 16 bit unsigned integer to the stream.

The number of 16 bit unsigned integer to write is specified with the *size* variable.

void wxDataOutputStream::Write32 (wxUint32 *i32*)

Writes the 32 bit unsigned integer *i32* to the stream.

void wxDataOutputStream::Write32 (const wxUint32 * *buffer*, size_t *size*)

Writes an array of 32 bit unsigned integer to the stream.

The number of 32 bit unsigned integer to write is specified with the *size* variable.

void wxDataOutputStream::Write64 (wxUint64 *i64*)

Writes the 64 bit unsigned integer *i64* to the stream.

void wxDataOutputStream::Write64 (const wxUint64 * *buffer*, size_t *size*)

Writes an array of 64 bit unsigned integer to the stream.

The number of 64 bit unsigned integer to write is specified with the *size* variable.

void wxDataOutputStream::Write8 (wxUint8 *i8*)

Writes the single byte *i8* to the stream.

void wxDataOutputStream::Write8 (const wxUint8 * *buffer*, size_t *size*)

Writes an array of bytes to the stream.

The number of bytes to write is specified with the *size* variable.

void wxDataOutputStream::WriteDouble (double *d*)

Writes the double *d* to the stream.

The output format is either 80 bit extended precision or, if UseBasicPrecisions() had been called, standard IEEE 754 64 bit double precision.

void wxDataOutputStream::WriteDouble (const double * *buffer*, size_t *size*)

Writes an array of double to the stream.

The number of doubles to write is specified by the *size* variable.

void wxDataOutputStream::WriteFloat (float *f*)

Writes the float *f* to the stream.

If UseBasicPrecisions() had been called, the value is written out using the standard IEEE 754 32 bit single precision format. Otherwise, this method uses the same format as WriteDouble(), i.e. 80 bit extended precision representation.

Since

2.9.5

void wxDataOutputStream::WriteFloat (const float * *buffer*, size_t *size*)

Writes an array of float to the stream.

The number of floats to write is specified by the *size* variable.

Since

2.9.5

void wxDataOutputStream::WriteString (const wxString & *string*)

Writes *string* to the stream.

Actually, this method writes the size of the string before writing *string* itself.

In ANSI build of wxWidgets, the string is written to the stream in exactly same way it is represented in memory. In Unicode build, however, the string is first converted to multibyte representation with *conv* object passed to stream's constructor (consequently, ANSI applications can read data written by Unicode application, as long as they agree on encoding) and this representation is written to the stream. UTF-8 is used by default.

21.141 wxDataViewBitmapRenderer Class Reference

`#include <wx/dataview.h>`

Inheritance diagram for wxDataViewBitmapRenderer:

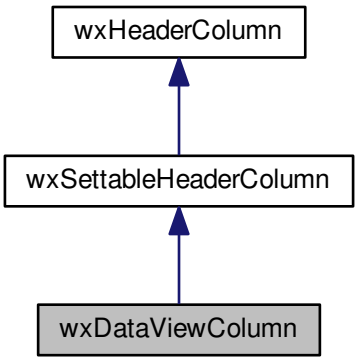
21.144 wxDataViewColumn Class Reference

`#include <wx/dataview.h>`

Inheritance diagram for wxDataViewColumn:



21.144.1 Detailed Description

This class represents a column in a wxDataViewCtrl.

One wxDataViewColumn is bound to one column in the data model to which the wxDataViewCtrl has been associated.

An instance of wxDataViewRenderer is used by this class to render its data.

Library: wxAdvanced

Category: wxDataViewCtrl Related Classes

Public Member Functions

- wxDataViewColumn (const wxString &title, wxDataViewRenderer *renderer, unsigned int model_column, int width=wxDVC_DEFAULT_WIDTH, wxAlignment align=wxALIGN_CENTER, int flags=wxDATAVIEW_COL_RESIZABLE)

  Constructs a text column.
- wxDataViewColumn (const wxBitmap &bitmap, wxDataViewRenderer *renderer, unsigned int model_column, int width=wxDVC_DEFAULT_WIDTH, wxAlignment align=wxALIGN_CENTER, int flags=wxDATAVIEW_COL_RESIZABLE)

  Constructs a bitmap column.
- unsigned int GetModelColumn () const

  Returns the index of the column of the model, which this wxDataViewColumn is displaying.
- wxDataViewCtrl * GetOwner () const

  Returns the owning wxDataViewCtrl.
- wxDataViewRenderer * GetRenderer () const

  Returns the renderer of this wxDataViewColumn.

21.144.2 Constructor & Destructor Documentation

wxDataViewColumn::wxDataViewColumn (const wxString & *title*, wxDataViewRenderer * *renderer*, unsigned int *model_column*, int *width* = wxDVC_DEFAULT_WIDTH, wxAlignment *align* = wxALIGN_CENTER, int *flags* = wxDATAVIEW_COL_RESIZABLE)

Constructs a text column.

Parameters

title	The title of the column.
renderer	The class which will render the contents of this column.
model_column	The index of the model's column which is associated with this object.
width	The width of the column. The `wxDVC_DEFAULT_WIDTH` value is the fixed default value.
align	The alignment of the column title.
flags	One or more flags of the wxDataViewColumnFlags enumeration.

wxDataViewColumn::wxDataViewColumn (const wxBitmap & *bitmap*, wxDataViewRenderer * *renderer*, unsigned int *model_column*, int *width* = wxDVC_DEFAULT_WIDTH, wxAlignment *align* = wxALIGN_CENTER, int *flags* = wxDATAVIEW_COL_RESIZABLE)

Constructs a bitmap column.

Parameters

bitmap	The bitmap of the column.
renderer	The class which will render the contents of this column.
model_column	The index of the model's column which is associated with this object.
width	The width of the column. The `wxDVC_DEFAULT_WIDTH` value is the fixed default value.
align	The alignment of the column title.
flags	One or more flags of the wxDataViewColumnFlags enumeration.

21.144.3 Member Function Documentation

unsigned int wxDataViewColumn::GetModelColumn ( ) const

Returns the index of the column of the model, which this wxDataViewColumn is displaying.

wxDataViewCtrl* wxDataViewColumn::GetOwner ( ) const

Returns the owning wxDataViewCtrl.

wxDataViewRenderer* wxDataViewColumn::GetRenderer ( ) const

Returns the renderer of this wxDataViewColumn.

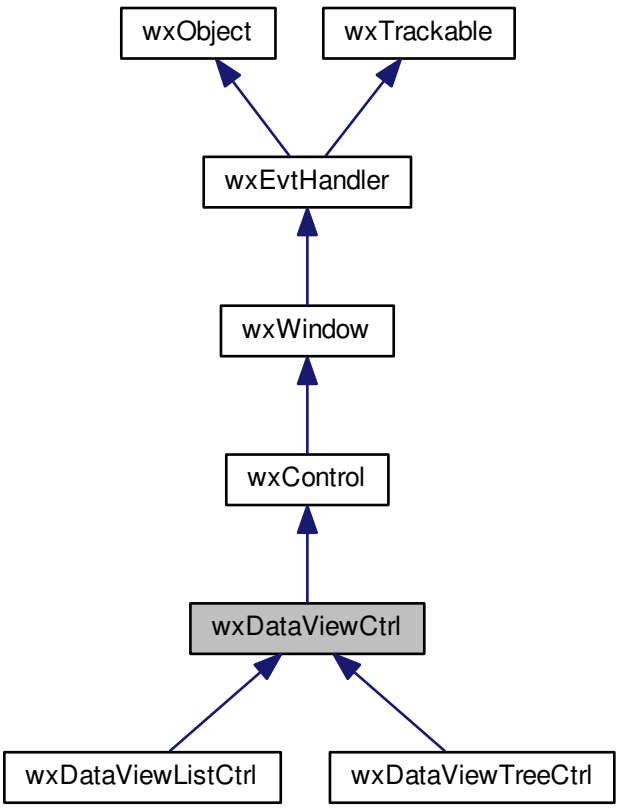
See also

wxDataViewRenderer.

21.145 wxDataViewCtrl Class Reference

`#include <wx/dataview.h>`

Inheritance diagram for wxDataViewCtrl:



21.145.1 Detailed Description

wxDataViewCtrl is a control to display data either in a tree like fashion or in a tabular form or both.

If you only need to display a simple tree structure with an API more like the older wxTreeCtrl class, then the specialized wxDataViewTreeCtrl can be used. Likewise, if you only want to display simple table structure you can use the specialized wxDataViewListCtrl class. Both wxDataViewTreeCtrl and wxDataViewListCtrl can be used without defining your own wxDataViewModel.

A wxDataViewItem is used to represent a (visible) item in the control.

Unlike wxListCtrl, wxDataViewCtrl doesn't get its data from the user through virtual functions or by setting it directly. Instead you need to write your own wxDataViewModel and associate it with this control. Then you need to add a number of wxDataViewColumn to this control to define what each column shall display. Each wxDataViewColumn in turn owns 1 instance of a wxDataViewRenderer to render its cells.

A number of standard renderers for rendering text, dates, images, toggle, a progress bar etc. are provided. Additionally, the user can write custom renderers deriving from wxDataViewCustomRenderer for displaying anything.

All data transfer from the control to the model and the user code is done through wxVariant which can be extended to support more data formats as necessary. Accordingly, all type information uses the strings returned from wxVariant::GetType.

This control supports single column sorting and on some platforms (currently only those using the generic version, i.e. not wxGTK nor wxOSX) also sorting by multiple columns at once. The latter must be explicitly enabled using AllowMultiColumnSort(), which will also indicate whether this feature is supported, as it changes the default behaviour of right clicking the column header to add or remove it to the set of columns used for sorting. If this behaviour is not appropriate, you may handle `wxEVT_DATAVIEW_COLUMN_HEADER_RIGHT_CLICK` event yourself to prevent it from happening. In this case you would presumably call ToggleSortByColumn() from some other event handler to still allow the user to configure sort order somehow.

Styles

This class supports the following styles:

- wxDV_SINGLE: Single selection mode. This is the default.
- wxDV_MULTIPLE: Multiple selection mode.
- wxDV_ROW_LINES: Use alternating colours for rows if supported by platform and theme. Currently only supported by the native GTK and OS X implementations but not by the generic one.
- wxDV_HORIZ_RULES: Display the separator lines between rows.
- wxDV_VERT_RULES: Display the separator lines between columns.
- wxDV_VARIABLE_LINE_HEIGHT: Allow variable line heights. This can be inefficient when displaying large number of items.
- wxDV_NO_HEADER: Do not show column headers (which are shown by default).

Events emitted by this class

The following event handler macros redirect the events to member function handlers '**func**' with prototypes like: void handlerFuncName(wxDataViewEvent& event)

Event macros for events emitted by this class:

- EVT_DATAVIEW_SELECTION_CHANGED(id, func): Process a `wxEVT_DATAVIEW_SELECTION_CHANGED` event.

- EVT_DATAVIEW_ITEM_ACTIVATED(id, func): Process a `wxEVT_DATAVIEW_ITEM_ACTIVATED` event. This event is triggered by double clicking an item or pressing some special key (usually "Enter") when it is focused.
- EVT_DATAVIEW_ITEM_START_EDITING(id, func): Process a `wxEVT_DATAVIEW_ITEM_START_EDITING` event. This event can be vetoed in order to prevent editing on an item by item basis.
- EVT_DATAVIEW_ITEM_EDITING_STARTED(id, func): Process a `wxEVT_DATAVIEW_ITEM_EDITING_STARTED` event.
- EVT_DATAVIEW_ITEM_EDITING_DONE(id, func): Process a `wxEVT_DATAVIEW_ITEM_EDITING_DONE` event.
- EVT_DATAVIEW_ITEM_COLLAPSING(id, func): Process a `wxEVT_DATAVIEW_ITEM_COLLAPSING` event.
- EVT_DATAVIEW_ITEM_COLLAPSED(id, func): Process a `wxEVT_DATAVIEW_ITEM_COLLAPSED` event.
- EVT_DATAVIEW_ITEM_EXPANDING(id, func): Process a `wxEVT_DATAVIEW_ITEM_EXPANDING` event.
- EVT_DATAVIEW_ITEM_EXPANDED(id, func): Process a `wxEVT_DATAVIEW_ITEM_EXPANDED` event.
- EVT_DATAVIEW_ITEM_VALUE_CHANGED(id, func): Process a `wxEVT_DATAVIEW_ITEM_VALUE_CHANGED` event.
- EVT_DATAVIEW_ITEM_CONTEXT_MENU(id, func): Process a `wxEVT_DATAVIEW_ITEM_CONTEXT_MENU` event generated when the user right clicks inside the control. Notice that this menu is generated even if the click didn't occur on any valid item, in this case wxDataViewEvent::GetItem() simply returns an invalid item.
- EVT_DATAVIEW_COLUMN_HEADER_CLICK(id, func): Process a `wxEVT_DATAVIEW_COLUMN_HEADER_CLICK` event.
- EVT_DATAVIEW_COLUMN_HEADER_RIGHT_CLICK(id, func): Process a `wxEVT_DATAVIEW_COLUMN_HEADER_RIGHT_CLICK` event. Notice that currently this event is not generated in the native OS X versions of the control.
- EVT_DATAVIEW_COLUMN_SORTED(id, func): Process a `wxEVT_DATAVIEW_COLUMN_SORTED` event.
- EVT_DATAVIEW_COLUMN_REORDERED(id, func): Process a `wxEVT_DATAVIEW_COLUMN_REORDERED` event.
- EVT_DATAVIEW_ITEM_BEGIN_DRAG(id, func): Process a `wxEVT_DATAVIEW_ITEM_BEGIN_DRAG` event.
- EVT_DATAVIEW_ITEM_DROP_POSSIBLE(id, func): Process a `wxEVT_DATAVIEW_ITEM_DROP_POSSIBLE` event.
- EVT_DATAVIEW_ITEM_DROP(id, func): Process a `wxEVT_DATAVIEW_ITEM_DROP` event.

Notice that this control doesn't allow to process generic mouse events such as `wxEVT_LEFT_DOWN` in all ports (notably it doesn't work in wxGTK). If you need to handle any mouse events not covered by the ones above, consider using a custom renderer for the cells that must handle them.

Category: Controls, wxDataViewCtrl Related Classes

Public Member Functions

- wxDataViewCtrl ()

  Default Constructor.
- wxDataViewCtrl (wxWindow *parent, wxWindowID id, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, long style=0, const wxValidator &validator=wxDefaultValidator, const wxString &name=wxDataViewCtrlNameStr)

  Constructor.
- virtual ~wxDataViewCtrl ()

  Destructor.
- bool AllowMultiColumnSort (bool allow)

  Call to allow using multiple columns for sorting.
- bool Create (wxWindow *parent, wxWindowID id, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, long style=0, const wxValidator &validator=wxDefaultValidator, const wxString &name=wxDataViewCtrlNameStr)

  Create the control.
- virtual bool AppendColumn (wxDataViewColumn *col)

  Appends a wxDataViewColumn to the control.
- virtual bool PrependColumn (wxDataViewColumn *col)

  Prepends a wxDataViewColumn to the control.
- virtual bool InsertColumn (unsigned int pos, wxDataViewColumn *col)

  Inserts a wxDataViewColumn to the control.
- virtual bool AssociateModel (wxDataViewModel *model)

  Associates a wxDataViewModel with the control.
- virtual bool ClearColumns ()

  Removes all columns.
- virtual void Collapse (const wxDataViewItem &item)

  Collapses the item.
- virtual bool DeleteColumn (wxDataViewColumn *column)

  Deletes given column.
- virtual void EditItem (const wxDataViewItem &item, const wxDataViewColumn *column)

  Programmatically starts editing given cell of item.
- virtual bool EnableDragSource (const wxDataFormat &format)

  Enable drag operations using the given format.
- virtual bool EnableDropTarget (const wxDataFormat &format)

  Enable drop operations using the given format.
- virtual void EnsureVisible (const wxDataViewItem &item, const wxDataViewColumn *column=NULL)

  Call this to ensure that the given item is visible.
- virtual void Expand (const wxDataViewItem &item)

  Expands the item.
- virtual void ExpandAncestors (const wxDataViewItem &item)

  Expands all ancestors of the item.
- virtual wxDataViewColumn * GetColumn (unsigned int pos) const

  Returns pointer to the column.
- virtual unsigned int GetColumnCount () const

  Returns the number of columns.
- virtual int GetColumnPosition (const wxDataViewColumn *column) const

  Returns the position of the column or -1 if not found in the control.
- wxDataViewColumn * GetExpanderColumn () const

  Returns column containing the expanders.
- wxDataViewItem GetCurrentItem () const

Returns the currently focused item.

- wxDataViewColumn * GetCurrentColumn () const

  Returns the column that currently has focus.

- int GetIndent () const

  Returns indentation.

- virtual wxRect GetItemRect (const wxDataViewItem &item, const wxDataViewColumn *col=NULL) const

  Returns item rectangle.

- wxDataViewModel * GetModel ()

  Returns pointer to the data model associated with the control (if any).

- virtual int GetSelectedItemsCount () const

  Returns the number of currently selected items.

- virtual wxDataViewItem GetSelection () const

  Returns first selected item or an invalid item if none is selected.

- virtual int GetSelections (wxDataViewItemArray &sel) const

  Fills sel with currently selected items and returns their number.

- virtual wxDataViewColumn * GetSortingColumn () const

  Returns the wxDataViewColumn currently responsible for sorting or NULL if none has been selected.

- virtual wxVector
  < wxDataViewColumn * > GetSortingColumns () const

  Returns the columns which should be used for sorting the data in this control.

- bool HasSelection () const

  Returns true if any items are currently selected.

- virtual void HitTest (const wxPoint &point, wxDataViewItem &item, wxDataViewColumn *&col) const

  Hittest.

- virtual bool IsExpanded (const wxDataViewItem &item) const

  Return true if the item is expanded.

- bool IsMultiColumnSortAllowed () const

  Return true if using more than one column for sorting is allowed.

- virtual bool IsSelected (const wxDataViewItem &item) const

  Return true if the item is selected.

- virtual void Select (const wxDataViewItem &item)

  Select the given item.

- virtual void SelectAll ()

  Select all items.

- void SetExpanderColumn (wxDataViewColumn *col)

  Set which column shall contain the tree-like expanders.

- void SetCurrentItem (const wxDataViewItem &item)

  Changes the currently focused item.

- void SetIndent (int indent)

  Sets the indentation.

- virtual void SetSelections (const wxDataViewItemArray &sel)

  Sets the selection to the array of wxDataViewItems.

- virtual void Unselect (const wxDataViewItem &item)

  Unselect the given item.

- virtual void UnselectAll ()

  Unselect all item.

- virtual bool SetRowHeight (int rowHeight)

  Sets the row height.

- virtual void ToggleSortByColumn (int column)

  Toggle sorting by the given column.

- wxDataViewColumn * AppendBitmapColumn (const wxString &label, unsigned int model_column, wxDataViewCellMode mode=wxDATAVIEW_CELL_INERT, int width=-1, wxAlignment align=wxALIGN_CENTER, int flags=wxDATAVIEW_COL_RESIZABLE)

  Appends a column for rendering a bitmap.
- wxDataViewColumn * AppendBitmapColumn (const wxBitmap &label, unsigned int model_column, wxDataViewCellMode mode=wxDATAVIEW_CELL_INERT, int width=-1, wxAlignment align=wxALIGN_CENTER, int flags=wxDATAVIEW_COL_RESIZABLE)

  Appends a column for rendering a bitmap.

- wxDataViewColumn * PrependBitmapColumn (const wxString &label, unsigned int model_column, wxDataViewCellMode mode=wxDATAVIEW_CELL_INERT, int width=-1, wxAlignment align=wxALIGN_CENTER, int flags=wxDATAVIEW_COL_RESIZABLE)

  Prepends a column for rendering a bitmap.
- wxDataViewColumn * PrependBitmapColumn (const wxBitmap &label, unsigned int model_column, wxDataViewCellMode mode=wxDATAVIEW_CELL_INERT, int width=-1, wxAlignment align=wxALIGN_CENTER, int flags=wxDATAVIEW_COL_RESIZABLE)

  Prepends a column for rendering a bitmap.

- wxDataViewColumn * AppendDateColumn (const wxString &label, unsigned int model_column, wxDataViewCellMode mode=wxDATAVIEW_CELL_ACTIVATABLE, int width=-1, wxAlignment align=wxALIGN_NOT, int flags=wxDATAVIEW_COL_RESIZABLE)

  Appends a column for rendering a date.
- wxDataViewColumn * AppendDateColumn (const wxBitmap &label, unsigned int model_column, wxDataViewCellMode mode=wxDATAVIEW_CELL_ACTIVATABLE, int width=-1, wxAlignment align=wxALIGN_NOT, int flags=wxDATAVIEW_COL_RESIZABLE)

  Appends a column for rendering a date.

- wxDataViewColumn * PrependDateColumn (const wxString &label, unsigned int model_column, wxDataViewCellMode mode=wxDATAVIEW_CELL_ACTIVATABLE, int width=-1, wxAlignment align=wxALIGN_NOT, int flags=wxDATAVIEW_COL_RESIZABLE)

  Prepends a column for rendering a date.
- wxDataViewColumn * PrependDateColumn (const wxBitmap &label, unsigned int model_column, wxDataViewCellMode mode=wxDATAVIEW_CELL_ACTIVATABLE, int width=-1, wxAlignment align=wxALIGN_NOT, int flags=wxDATAVIEW_COL_RESIZABLE)

  Prepends a column for rendering a date.

- wxDataViewColumn * AppendIconTextColumn (const wxString &label, unsigned int model_column, wxDataViewCellMode mode=wxDATAVIEW_CELL_INERT, int width=-1, wxAlignment align=wxALIGN_NOT, int flags=wxDATAVIEW_COL_RESIZABLE)

  Appends a column for rendering text with an icon.
- wxDataViewColumn * AppendIconTextColumn (const wxBitmap &label, unsigned int model_column, wxDataViewCellMode mode=wxDATAVIEW_CELL_INERT, int width=-1, wxAlignment align=wxALIGN_NOT, int flags=wxDATAVIEW_COL_RESIZABLE)

  Appends a column for rendering text with an icon.

- wxDataViewColumn * PrependIconTextColumn (const wxString &label, unsigned int model_column, wxDataViewCellMode mode=wxDATAVIEW_CELL_INERT, int width=-1, wxAlignment align=wxALIGN_NOT, int flags=wxDATAVIEW_COL_RESIZABLE)

  Prepends a column for rendering text with an icon.
- wxDataViewColumn * PrependIconTextColumn (const wxBitmap &label, unsigned int model_column, wxDataViewCellMode mode=wxDATAVIEW_CELL_INERT, int width=-1, wxAlignment align=wxALIGN_NOT, int flags=wxDATAVIEW_COL_RESIZABLE)

  Prepends a column for rendering text with an icon.

- wxDataViewColumn * AppendProgressColumn (const wxString &label, unsigned int model_column, wxDataViewCellMode mode=wxDATAVIEW_CELL_INERT, int width=80, wxAlignment align=wxALIGN_CENTER, int flags=wxDATAVIEW_COL_RESIZABLE)

  Appends a column for rendering a progress indicator.
- wxDataViewColumn * AppendProgressColumn (const wxBitmap &label, unsigned int model_column, wxDataViewCellMode mode=wxDATAVIEW_CELL_INERT, int width=80, wxAlignment align=wxALIGN_CENTER, int flags=wxDATAVIEW_COL_RESIZABLE)

  Appends a column for rendering a progress indicator.

- wxDataViewColumn * PrependProgressColumn (const wxString &label, unsigned int model_column, wxDataViewCellMode mode=wxDATAVIEW_CELL_INERT, int width=80, wxAlignment align=wxALIGN_CENTER, int flags=wxDATAVIEW_COL_RESIZABLE)

  Prepends a column for rendering a progress indicator.
- wxDataViewColumn * PrependProgressColumn (const wxBitmap &label, unsigned int model_column, wxDataViewCellMode mode=wxDATAVIEW_CELL_INERT, int width=80, wxAlignment align=wxALIGN_CENTER, int flags=wxDATAVIEW_COL_RESIZABLE)

  Prepends a column for rendering a progress indicator.

- wxDataViewColumn * AppendTextColumn (const wxString &label, unsigned int model_column, wxDataViewCellMode mode=wxDATAVIEW_CELL_INERT, int width=-1, wxAlignment align=wxALIGN_NOT, int flags=wxDATAVIEW_COL_RESIZABLE)

  Appends a column for rendering text.
- wxDataViewColumn * AppendTextColumn (const wxBitmap &label, unsigned int model_column, wxDataViewCellMode mode=wxDATAVIEW_CELL_INERT, int width=-1, wxAlignment align=wxALIGN_NOT, int flags=wxDATAVIEW_COL_RESIZABLE)

  Appends a column for rendering text.

- wxDataViewColumn * PrependTextColumn (const wxString &label, unsigned int model_column, wxDataViewCellMode mode=wxDATAVIEW_CELL_INERT, int width=-1, wxAlignment align=wxALIGN_NOT, int flags=wxDATAVIEW_COL_RESIZABLE)

  Prepends a column for rendering text.
- wxDataViewColumn * PrependTextColumn (const wxBitmap &label, unsigned int model_column, wxDataViewCellMode mode=wxDATAVIEW_CELL_INERT, int width=-1, wxAlignment align=wxALIGN_NOT, int flags=wxDATAVIEW_COL_RESIZABLE)

  Prepends a column for rendering text.

- wxDataViewColumn * AppendToggleColumn (const wxString &label, unsigned int model_column, wxDataViewCellMode mode=wxDATAVIEW_CELL_INERT, int width=30, wxAlignment align=wxALIGN_CENTER, int flags=wxDATAVIEW_COL_RESIZABLE)

  Appends a column for rendering a toggle.
- wxDataViewColumn * AppendToggleColumn (const wxBitmap &label, unsigned int model_column, wxDataViewCellMode mode=wxDATAVIEW_CELL_INERT, int width=30, wxAlignment align=wxALIGN_CENTER, int flags=wxDATAVIEW_COL_RESIZABLE)

  Appends a column for rendering a toggle.

- wxDataViewColumn * PrependToggleColumn (const wxString &label, unsigned int model_column, wxDataViewCellMode mode=wxDATAVIEW_CELL_INERT, int width=30, wxAlignment align=wxALIGN_CENTER, int flags=wxDATAVIEW_COL_RESIZABLE)

  Prepends a column for rendering a toggle.
- wxDataViewColumn * PrependToggleColumn (const wxBitmap &label, unsigned int model_column, wxDataViewCellMode mode=wxDATAVIEW_CELL_INERT, int width=30, wxAlignment align=wxALIGN_CENTER, int flags=wxDATAVIEW_COL_RESIZABLE)

  Prepends a column for rendering a toggle.

Additional Inherited Members

21.145.2 Constructor & Destructor Documentation

wxDataViewCtrl::wxDataViewCtrl ( )

Default Constructor.

wxDataViewCtrl::wxDataViewCtrl (wxWindow * *parent*, wxWindowID *id*, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, long *style* = 0, const wxValidator & *validator* = wxDefaultValidator, const wxString & *name* = wxDataViewCtrlNameStr)

Constructor.

Calls Create().

virtual wxDataViewCtrl::~wxDataViewCtrl ( ) [virtual]

Destructor.

21.145.3 Member Function Documentation

bool wxDataViewCtrl::AllowMultiColumnSort (bool *allow*)

Call to allow using multiple columns for sorting.

When using multiple column for sorting, GetSortingColumns() method should be used to retrieve all the columns which should be used to effectively sort the data when processing the sorted event.

Currently multiple column sort is only implemented in the generic version, i.e. this functionality is not available when using the native wxDataViewCtrl implementation in wxGTK nor wxOSX.

Returns

true if sorting by multiple columns could be enabled, false otherwise, typically because this feature is not supported.

Since

3.1.0

wxDataViewColumn* wxDataViewCtrl::AppendBitmapColumn (const wxString & *label*, unsigned int *model_column*, wxDataViewCellMode *mode* = wxDATAVIEW_CELL_INERT, int *width* = -1, wxAlignment *align* = wxALIGN_CENTER, int *flags* = wxDATAVIEW_COL_RESIZABLE)

Appends a column for rendering a bitmap.

Returns the wxDataViewColumn created in the function or NULL on failure.

wxDataViewColumn* wxDataViewCtrl::AppendBitmapColumn (const wxBitmap & *label*, unsigned int *model_column*, wxDataViewCellMode *mode* = wxDATAVIEW_CELL_INERT, int *width* = -1, wxAlignment *align* = wxALIGN_CENTER, int *flags* = wxDATAVIEW_COL_RESIZABLE)

Appends a column for rendering a bitmap.

Returns the wxDataViewColumn created in the function or NULL on failure.

virtual bool wxDataViewCtrl::AppendColumn (**wxDataViewColumn** * *col*) [virtual]

Appends a wxDataViewColumn to the control.

Returns true on success.

Note that there is a number of short cut methods which implicitly create a wxDataViewColumn and a wxDataViewRenderer for it (see below).

Reimplemented in wxDataViewListCtrl.

wxDataViewColumn* wxDataViewCtrl::AppendDateColumn (const **wxString** & *label*, unsigned int *model_column*, **wxDataViewCellMode** *mode* = **wxDATAVIEW_CELL_ACTIVATABLE**, int *width* = -1, **wxAlignment** *align* = **wxALIGN_NOT**, int *flags* = **wxDATAVIEW_COL_RESIZABLE**)

Appends a column for rendering a date.

Returns the wxDataViewColumn created in the function or NULL on failure.

Note

The *align* parameter is applied to both the column header and the column renderer.

wxDataViewColumn* wxDataViewCtrl::AppendDateColumn (const **wxBitmap** & *label*, unsigned int *model_column*, **wxDataViewCellMode** *mode* = **wxDATAVIEW_CELL_ACTIVATABLE**, int *width* = -1, **wxAlignment** *align* = **wxALIGN_NOT**, int *flags* = **wxDATAVIEW_COL_RESIZABLE**)

Appends a column for rendering a date.

Returns the wxDataViewColumn created in the function or NULL on failure.

Note

The *align* parameter is applied to both the column header and the column renderer.

wxDataViewColumn* wxDataViewCtrl::AppendIconTextColumn (const **wxString** & *label*, unsigned int *model_column*, **wxDataViewCellMode** *mode* = **wxDATAVIEW_CELL_INERT**, int *width* = -1, **wxAlignment** *align* = **wxALIGN_NOT**, int *flags* = **wxDATAVIEW_COL_RESIZABLE**)

Appends a column for rendering text with an icon.

Returns the wxDataViewColumn created in the function or NULL on failure. This method uses the wxDataViewIconTextRenderer class.

Note

The *align* parameter is applied to both the column header and the column renderer.

wxDataViewColumn* wxDataViewCtrl::AppendIconTextColumn (const **wxBitmap** & *label*, unsigned int *model_column*, **wxDataViewCellMode** *mode* = **wxDATAVIEW_CELL_INERT**, int *width* = -1, **wxAlignment** *align* = **wxALIGN_NOT**, int *flags* = **wxDATAVIEW_COL_RESIZABLE**)

Appends a column for rendering text with an icon.

Returns the wxDataViewColumn created in the function or NULL on failure. This method uses the wxDataViewIconTextRenderer class.

Note

The *align* parameter is applied to both the column header and the column renderer.

wxDataViewColumn* wxDataViewCtrl::AppendProgressColumn (**const wxString &** *label*, **unsigned int** *model_column*, **wxDataViewCellMode** *mode* = **wxDATAVIEW_CELL_INERT**, **int** *width* = 80, **wxAlignment** *align* = **wxALIGN_CENTER**, **int** *flags* = **wxDATAVIEW_COL_RESIZABLE**)

Appends a column for rendering a progress indicator.

Returns the wxDataViewColumn created in the function or NULL on failure.

Note

The *align* parameter is applied to both the column header and the column renderer.

wxDataViewColumn* wxDataViewCtrl::AppendProgressColumn (**const wxBitmap &** *label*, **unsigned int** *model_column*, **wxDataViewCellMode** *mode* = **wxDATAVIEW_CELL_INERT**, **int** *width* = 80, **wxAlignment** *align* = **wxALIGN_CENTER**, **int** *flags* = **wxDATAVIEW_COL_RESIZABLE**)

Appends a column for rendering a progress indicator.

Returns the wxDataViewColumn created in the function or NULL on failure.

Note

The *align* parameter is applied to both the column header and the column renderer.

wxDataViewColumn* wxDataViewCtrl::AppendTextColumn (**const wxString &** *label*, **unsigned int** *model_column*, **wxDataViewCellMode** *mode* = **wxDATAVIEW_CELL_INERT**, **int** *width* = -1, **wxAlignment** *align* = **wxALIGN_NOT**, **int** *flags* = **wxDATAVIEW_COL_RESIZABLE**)

Appends a column for rendering text.

Returns the wxDataViewColumn created in the function or NULL on failure.

Note

The *align* parameter is applied to both the column header and the column renderer.

wxDataViewColumn* wxDataViewCtrl::AppendTextColumn (**const wxBitmap &** *label*, **unsigned int** *model_column*, **wxDataViewCellMode** *mode* = **wxDATAVIEW_CELL_INERT**, **int** *width* = -1, **wxAlignment** *align* = **wxALIGN_NOT**, **int** *flags* = **wxDATAVIEW_COL_RESIZABLE**)

Appends a column for rendering text.

Returns the wxDataViewColumn created in the function or NULL on failure.

Note

The *align* parameter is applied to both the column header and the column renderer.

wxDataViewColumn* wxDataViewCtrl::AppendToggleColumn (**const wxString &** *label*, **unsigned int** *model_column*, **wxDataViewCellMode** *mode* = **wxDATAVIEW_CELL_INERT**, **int** *width* = 30, **wxAlignment** *align* = **wxALIGN_CENTER**, **int** *flags* = **wxDATAVIEW_COL_RESIZABLE**)

Appends a column for rendering a toggle.

Returns the wxDataViewColumn created in the function or NULL on failure.

Note

The *align* parameter is applied to both the column header and the column renderer.

wxDataViewColumn* **wxDataViewCtrl::AppendToggleColumn** (**const wxBitmap &** *label*, **unsigned int** *model_column*, **wxDataViewCellMode** *mode* = **wxDATAVIEW_CELL_INERT**, **int** *width* = `30`, **wxAlignment** *align* = **wxALIGN_CENTER**, **int** *flags* = **wxDATAVIEW_COL_RESIZABLE**)

Appends a column for rendering a toggle.

Returns the wxDataViewColumn created in the function or NULL on failure.

Note

The *align* parameter is applied to both the column header and the column renderer.

virtual bool wxDataViewCtrl::AssociateModel (**wxDataViewModel** * *model*) `[virtual]`

Associates a wxDataViewModel with the control.

This increases the reference count of the model by 1.

virtual bool wxDataViewCtrl::ClearColumns ( ) `[virtual]`

Removes all columns.

virtual void wxDataViewCtrl::Collapse (**const wxDataViewItem &** *item*) `[virtual]`

Collapses the item.

bool wxDataViewCtrl::Create (**wxWindow** * *parent*, **wxWindowID** *id*, **const wxPoint &** *pos* = **wxDefaultPosition**, **const wxSize &** *size* = **wxDefaultSize**, **long** *style* = `0`, **const wxValidator &** *validator* = **wxDefaultValidator**, **const wxString &** *name* = `wxDataViewCtrlNameStr`)

Create the control.

Useful for two step creation.

virtual bool wxDataViewCtrl::DeleteColumn (**wxDataViewColumn** * *column*) `[virtual]`

Deletes given column.

virtual void wxDataViewCtrl::EditItem (**const wxDataViewItem &** *item*, **const wxDataViewColumn** * *column*) `[virtual]`

Programmatically starts editing given cell of *item*.

Doesn't do anything if the item or this column is not editable.

Note

Currently not implemented in wxOSX/Carbon.

Since

2.9.4

virtual bool wxDataViewCtrl::EnableDragSource (const wxDataFormat & *format*) [virtual]

Enable drag operations using the given *format*.

virtual bool wxDataViewCtrl::EnableDropTarget (const wxDataFormat & *format*) [virtual]

Enable drop operations using the given *format*.

virtual void wxDataViewCtrl::EnsureVisible (const wxDataViewItem & *item*, const wxDataViewColumn * *column* = NULL) [virtual]

Call this to ensure that the given item is visible.

virtual void wxDataViewCtrl::Expand (const wxDataViewItem & *item*) [virtual]

Expands the item.

virtual void wxDataViewCtrl::ExpandAncestors (const wxDataViewItem & *item*) [virtual]

Expands all ancestors of the *item*.

This method also ensures that the item itself as well as all ancestor items have been read from the model by the control.

virtual wxDataViewColumn* wxDataViewCtrl::GetColumn (unsigned int *pos*) const [virtual]

Returns pointer to the column.

pos refers to the position in the control which may change after reordering columns by the user.

virtual unsigned int wxDataViewCtrl::GetColumnCount ( ) const [virtual]

Returns the number of columns.

virtual int wxDataViewCtrl::GetColumnPosition (const wxDataViewColumn * *column*) const [virtual]

Returns the position of the column or -1 if not found in the control.

wxDataViewColumn* wxDataViewCtrl::GetCurrentColumn ( ) const

Returns the column that currently has focus.

If the focus is set to individual cell within the currently focused item (as opposed to being on the item as a whole), then this is the column that the focus is on.

Returns NULL if no column currently has focus.

See also

GetCurrentItem()

Since

2.9.4

wxDataViewItem wxDataViewCtrl::GetCurrentItem ( ) const

Returns the currently focused item.

This is the item that the keyboard commands apply to. It may be invalid if there is no focus currently.

This method is mostly useful for the controls with `wxDV_MULTIPLE` style as in the case of single selection it returns the same thing as GetSelection().

Notice that under all platforms except Mac OS X the currently focused item may be selected or not but under OS X the current item is always selected.

See also

SetCurrentItem(), GetCurrentColumn()

Since

2.9.2

wxDataViewColumn* wxDataViewCtrl::GetExpanderColumn ( ) const

Returns column containing the expanders.

int wxDataViewCtrl::GetIndent ( ) const

Returns indentation.

virtual wxRect wxDataViewCtrl::GetItemRect (const wxDataViewItem & *item*, const wxDataViewColumn * *col* = `NULL`) const `[virtual]`

Returns item rectangle.

This method is currently not implemented at all in wxGTK and only implemented for non-NULL *col* argument in wxOSX. It is fully implemented in the generic version of the control.

Parameters

item	A valid item.
col	If non-NULL, the rectangle returned corresponds to the intersection of the item with the specified column. If NULL, the rectangle spans all the columns.

wxDataViewModel* wxDataViewCtrl::GetModel ( )

Returns pointer to the data model associated with the control (if any).

virtual int wxDataViewCtrl::GetSelectedItemsCount ( ) const `[virtual]`

Returns the number of currently selected items.

This method may be called for both the controls with single and multiple selections and returns the number of selected item, possibly 0, in any case.

Since

2.9.3

virtual wxDataViewItem wxDataViewCtrl::GetSelection ( ) const `[virtual]`

Returns first selected item or an invalid item if none is selected.

This method may be called for both the controls with single and multiple selections but returns an invalid item if more than one item is selected in the latter case, use HasSelection() to determine if there are any selected items when using multiple selection.

virtual int wxDataViewCtrl::GetSelections (wxDataViewItemArray & *sel*) const `[virtual]`

Fills *sel* with currently selected items and returns their number.

This method may be called for both the controls with single and multiple selections. In the single selection case it returns the array with at most one element in it.

See also

GetSelectedItemsCount()

virtual wxDataViewColumn* wxDataViewCtrl::GetSortingColumn ( ) const `[virtual]`

Returns the wxDataViewColumn currently responsible for sorting or NULL if none has been selected.

virtual wxVector<wxDataViewColumn *> wxDataViewCtrl::GetSortingColumns ( ) const `[virtual]`

Returns the columns which should be used for sorting the data in this control.

This method is only useful when sorting by multiple columns had been enabled using AllowMultiColumnSort() previously, otherwise GetSortingColumn() is more convenient.

Returns

A possibly empty vector containing all the columns used selected by the user for sorting. The sort order can be retrieved from each column object separately.

Since

3.1.0

bool wxDataViewCtrl::HasSelection ( ) const

Returns true if any items are currently selected.

This method may be called for both the controls with single and multiple selections.

Calling this method is equivalent to calling GetSelectedItemsCount() and comparing its result with 0 but is more clear and might also be implemented more efficiently in the future.

Since

2.9.3

virtual void wxDataViewCtrl::HitTest (const wxPoint & *point,* wxDataViewItem & *item,* wxDataViewColumn *& *col*) const `[virtual]`

Hittest.

virtual bool wxDataViewCtrl::InsertColumn (unsigned int *pos*, **wxDataViewColumn** * *col*) [virtual]

Inserts a wxDataViewColumn to the control.

Returns true on success.

Reimplemented in wxDataViewListCtrl.

virtual bool wxDataViewCtrl::IsExpanded (const **wxDataViewItem** & *item*) const [virtual]

Return true if the item is expanded.

bool wxDataViewCtrl::IsMultiColumnSortAllowed ( ) const

Return true if using more than one column for sorting is allowed.

See AllowMultiColumnSort() and GetSortingColumns().

Since

3.1.0

virtual bool wxDataViewCtrl::IsSelected (const **wxDataViewItem** & *item*) const [virtual]

Return true if the item is selected.

wxDataViewColumn* wxDataViewCtrl::PrependBitmapColumn (const **wxString** & *label*, unsigned int *model_column*, **wxDataViewCellMode** *mode* = **wxDATAVIEW_CELL_INERT**, int *width* = −1, **wxAlignment** *align* = **wxALIGN_CENTER**, int *flags* = **wxDATAVIEW_COL_RESIZABLE**)

Prepends a column for rendering a bitmap.

Returns the wxDataViewColumn created in the function or NULL on failure.

wxDataViewColumn* wxDataViewCtrl::PrependBitmapColumn (const **wxBitmap** & *label*, unsigned int *model_column*, **wxDataViewCellMode** *mode* = **wxDATAVIEW_CELL_INERT**, int *width* = −1, **wxAlignment** *align* = **wxALIGN_CENTER**, int *flags* = **wxDATAVIEW_COL_RESIZABLE**)

Prepends a column for rendering a bitmap.

Returns the wxDataViewColumn created in the function or NULL on failure.

virtual bool wxDataViewCtrl::PrependColumn (**wxDataViewColumn** * *col*) [virtual]

Prepends a wxDataViewColumn to the control.

Returns true on success.

Note that there is a number of short cut methods which implicitly create a wxDataViewColumn and a wxDataView↩ Renderer for it.

Reimplemented in wxDataViewListCtrl.

wxDataViewColumn* wxDataViewCtrl::PrependDateColumn (const **wxString** & *label*, unsigned int *model_column*, **wxDataViewCellMode** *mode* = **wxDATAVIEW_CELL_ACTIVATABLE**, int *width* = −1, **wxAlignment** *align* = **wxALIGN_NOT**, int *flags* = **wxDATAVIEW_COL_RESIZABLE**)

Prepends a column for rendering a date.

Returns the wxDataViewColumn created in the function or NULL on failure.

Note

The *align* parameter is applied to both the column header and the column renderer.

wxDataViewColumn* **wxDataViewCtrl::PrependDateColumn** (**const wxBitmap &** *label*, **unsigned int** *model_column*, **wxDataViewCellMode** *mode* = **wxDATAVIEW_CELL_ACTIVATABLE**, **int** *width* = `-1`, **wxAlignment** *align* = **wxALIGN_NOT**, **int** *flags* = **wxDATAVIEW_COL_RESIZABLE**)

Prepends a column for rendering a date.

Returns the wxDataViewColumn created in the function or NULL on failure.

Note

The *align* parameter is applied to both the column header and the column renderer.

wxDataViewColumn* **wxDataViewCtrl::PrependIconTextColumn** (**const wxString &** *label*, **unsigned int** *model_column*, **wxDataViewCellMode** *mode* = **wxDATAVIEW_CELL_INERT**, **int** *width* = `-1`, **wxAlignment** *align* = **wxALIGN_NOT**, **int** *flags* = **wxDATAVIEW_COL_RESIZABLE**)

Prepends a column for rendering text with an icon.

Returns the wxDataViewColumn created in the function or NULL on failure. This method uses the wxDataViewIconTextRenderer class.

Note

The *align* parameter is applied to both the column header and the column renderer.

wxDataViewColumn* **wxDataViewCtrl::PrependIconTextColumn** (**const wxBitmap &** *label*, **unsigned int** *model_column*, **wxDataViewCellMode** *mode* = **wxDATAVIEW_CELL_INERT**, **int** *width* = `-1`, **wxAlignment** *align* = **wxALIGN_NOT**, **int** *flags* = **wxDATAVIEW_COL_RESIZABLE**)

Prepends a column for rendering text with an icon.

Returns the wxDataViewColumn created in the function or NULL on failure. This method uses the wxDataViewIconTextRenderer class.

Note

The *align* parameter is applied to both the column header and the column renderer.

wxDataViewColumn* **wxDataViewCtrl::PrependProgressColumn** (**const wxString &** *label*, **unsigned int** *model_column*, **wxDataViewCellMode** *mode* = **wxDATAVIEW_CELL_INERT**, **int** *width* = `80`, **wxAlignment** *align* = **wxALIGN_CENTER**, **int** *flags* = **wxDATAVIEW_COL_RESIZABLE**)

Prepends a column for rendering a progress indicator.

Returns the wxDataViewColumn created in the function or NULL on failure.

Note

The *align* parameter is applied to both the column header and the column renderer.

wxDataViewColumn* wxDataViewCtrl::PrependProgressColumn (const **wxBitmap** & *label*, unsigned int *model_column*, **wxDataViewCellMode** *mode* = **wxDATAVIEW_CELL_INERT**, int *width* = 80, **wxAlignment** *align* = **wxALIGN_CENTER**, int *flags* = **wxDATAVIEW_COL_RESIZABLE**)

Prepends a column for rendering a progress indicator.

Returns the wxDataViewColumn created in the function or NULL on failure.

Note

The *align* parameter is applied to both the column header and the column renderer.

wxDataViewColumn* wxDataViewCtrl::PrependTextColumn (const **wxString** & *label*, unsigned int *model_column*, **wxDataViewCellMode** *mode* = **wxDATAVIEW_CELL_INERT**, int *width* = -1, **wxAlignment** *align* = **wxALIGN_NOT**, int *flags* = **wxDATAVIEW_COL_RESIZABLE**)

Prepends a column for rendering text.

Returns the wxDataViewColumn created in the function or NULL on failure.

Note

The *align* parameter is applied to both the column header and the column renderer.

wxDataViewColumn* wxDataViewCtrl::PrependTextColumn (const **wxBitmap** & *label*, unsigned int *model_column*, **wxDataViewCellMode** *mode* = **wxDATAVIEW_CELL_INERT**, int *width* = -1, **wxAlignment** *align* = **wxALIGN_NOT**, int *flags* = **wxDATAVIEW_COL_RESIZABLE**)

Prepends a column for rendering text.

Returns the wxDataViewColumn created in the function or NULL on failure.

Note

The *align* parameter is applied to both the column header and the column renderer.

wxDataViewColumn* wxDataViewCtrl::PrependToggleColumn (const **wxString** & *label*, unsigned int *model_column*, **wxDataViewCellMode** *mode* = **wxDATAVIEW_CELL_INERT**, int *width* = 30, **wxAlignment** *align* = **wxALIGN_CENTER**, int *flags* = **wxDATAVIEW_COL_RESIZABLE**)

Prepends a column for rendering a toggle.

Returns the wxDataViewColumn created in the function or NULL on failure.

Note

The *align* parameter is applied to both the column header and the column renderer.

wxDataViewColumn* wxDataViewCtrl::PrependToggleColumn (const **wxBitmap** & *label*, unsigned int *model_column*, **wxDataViewCellMode** *mode* = **wxDATAVIEW_CELL_INERT**, int *width* = 30, **wxAlignment** *align* = **wxALIGN_CENTER**, int *flags* = **wxDATAVIEW_COL_RESIZABLE**)

Prepends a column for rendering a toggle.

Returns the wxDataViewColumn created in the function or NULL on failure.

Note

The *align* parameter is applied to both the column header and the column renderer.

virtual void wxDataViewCtrl::Select (const wxDataViewItem & *item*) [virtual]

Select the given item.

In single selection mode this changes the (unique) currently selected item. In multi selection mode, the *item* is selected and the previously selected items remain selected.

virtual void wxDataViewCtrl::SelectAll ( ) [virtual]

Select all items.

void wxDataViewCtrl::SetCurrentItem (const wxDataViewItem & *item*)

Changes the currently focused item.

The *item* parameter must be valid, there is no way to remove the current item from the control.

In single selection mode, calling this method is the same as calling Select() and is thus not very useful. In multiple selection mode this method only moves the current item however without changing the selection except under OS X where the current item is always selected, so calling SetCurrentItem() selects *item* if it hadn't been selected before.

See also

GetCurrentItem()

Since

2.9.2

void wxDataViewCtrl::SetExpanderColumn (wxDataViewColumn * *col*)

Set which column shall contain the tree-like expanders.

void wxDataViewCtrl::SetIndent (int *indent*)

Sets the indentation.

virtual bool wxDataViewCtrl::SetRowHeight (int *rowHeight*) [virtual]

Sets the row height.

This function can only be used when all rows have the same height, i.e. when wxDV_VARIABLE_LINE_HEIGHT flag is not used.

Currently this is implemented in the generic and native GTK versions only and nothing is done (and false returned) when using OS X port.

Also notice that this method can only be used to increase the row height compared with the default one (as determined by the return value of wxDataViewRenderer::GetSize()), if it is set to a too small value then the minimum required by the renderers will be used.

Returns

true if the line height was changed or false otherwise.

Since

2.9.2

virtual void wxDataViewCtrl::SetSelections (const wxDataViewItemArray & *sel*) `[virtual]`

Sets the selection to the array of wxDataViewItems.

virtual void wxDataViewCtrl::ToggleSortByColumn (int *column*) `[virtual]`

Toggle sorting by the given column.

This method should only be used when sorting by multiple columns is allowed, see AllowMultiColumnSort(), and does nothing otherwise.

Since

3.1.0

virtual void wxDataViewCtrl::Unselect (const wxDataViewItem & *item*) `[virtual]`

Unselect the given item.

virtual void wxDataViewCtrl::UnselectAll ( ) `[virtual]`

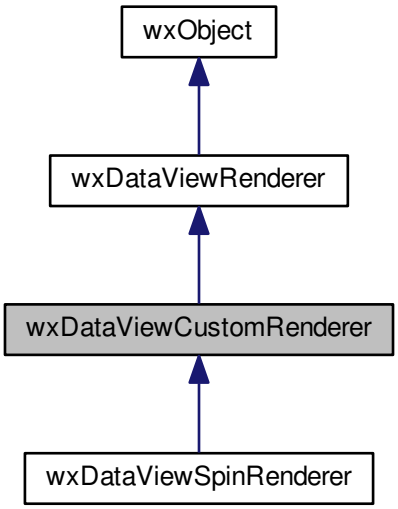
Unselect all item.

This method only has effect if multiple selections are allowed.

21.146 wxDataViewCustomRenderer Class Reference

`#include <wx/dataview.h>`

Inheritance diagram for wxDataViewCustomRenderer:



21.146.1 Detailed Description

You need to derive a new class from wxDataViewCustomRenderer in order to write a new renderer.

You need to override at least wxDataViewRenderer::SetValue, wxDataViewRenderer::GetValue, wxDataViewCustomRenderer::GetSize and wxDataViewCustomRenderer::Render.

If you want your renderer to support in-place editing then you also need to override wxDataViewCustomRenderer::HasEditorCtrl, wxDataViewCustomRenderer::CreateEditorCtrl and wxDataViewCustomRenderer::GetValueFromEditorCtrl.

Note that a special event handler will be pushed onto that editor control which handles <*ENTER*> and focus out events in order to end the editing.

Library: wxAdvanced

Category: wxDataViewCtrl Related Classes

Public Member Functions

- wxDataViewCustomRenderer (const wxString &varianttype=GetDefaultType(), wxDataViewCellMode mode=wxDATAVIEW_CELL_INERT, int align=wxDVR_DEFAULT_ALIGNMENT)

  Constructor.
- virtual ~wxDataViewCustomRenderer ()

  Destructor.
- virtual bool ActivateCell (const wxRect &cell, wxDataViewModel *model, const wxDataViewItem &item, unsigned int col, const wxMouseEvent *mouseEvent)

  Override this to react to cell activation.
- virtual wxWindow * CreateEditorCtrl (wxWindow *parent, wxRect labelRect, const wxVariant &value)

  Override this to create the actual editor control once editing is about to start.
- const wxDataViewItemAttr & GetAttr () const

  Return the attribute to be used for rendering.
- virtual wxSize GetSize () const =0

  Return size required to show content.
- virtual bool GetValueFromEditorCtrl (wxWindow *editor, wxVariant &value)

  Override this so that the renderer can get the value from the editor control (pointed to by editor):
- virtual bool HasEditorCtrl () const

  Override this and make it return true in order to indicate that this renderer supports in-place editing.
- virtual bool LeftClick (wxPoint cursor, wxRect cell, wxDataViewModel *model, const wxDataViewItem &item, unsigned int col)

  Override this to react to a left click.
- virtual bool Activate (wxRect cell, wxDataViewModel *model, const wxDataViewItem &item, unsigned int col)

  Override this to react to the activation of a cell.
- virtual bool Render (wxRect cell, wxDC *dc, int state)=0

  Override this to render the cell.
- void RenderText (const wxString &text, int xoffset, wxRect cell, wxDC *dc, int state)

  This method should be called from within Render() whenever you need to render simple text.
- virtual bool StartDrag (const wxPoint &cursor, const wxRect &cell, wxDataViewModel *model, const wxDataViewItem &item, unsigned int col)

  Override this to start a drag operation.

Static Public Member Functions

- static wxString GetDefaultType ()

  Returns the wxVariant type used with this renderer.

Protected Member Functions

- wxSize GetTextExtent (const wxString &str) const

  Helper for GetSize() implementations, respects attributes.

Additional Inherited Members

21.146.2 Constructor & Destructor Documentation

wxDataViewCustomRenderer::wxDataViewCustomRenderer (const wxString & *varianttype* = GetDefaultType () , wxDataViewCellMode *mode* = wxDATAVIEW_CELL_INERT, int *align* = wxDVR_DEFAULT_ALIGNMENT)

Constructor.

virtual wxDataViewCustomRenderer::~wxDataViewCustomRenderer ( ) [virtual]

Destructor.

21.146.3 Member Function Documentation

virtual bool wxDataViewCustomRenderer::Activate (wxRect *cell*, wxDataViewModel * *model*, const wxDataViewItem & *item*, unsigned int *col*) [virtual]

Override this to react to the activation of a cell.

Deprecated Use ActivateCell instead.

virtual bool wxDataViewCustomRenderer::ActivateCell (const wxRect & *cell*, wxDataViewModel * *model*, const wxDataViewItem & *item*, unsigned int *col*, const wxMouseEvent * *mouseEvent*) [virtual]

Override this to react to cell *activation*.

Activating a cell is an alternative to showing inline editor when the value can be edited in a simple way that doesn't warrant full editor control. The most typical use of cell activation is toggling the checkbox in wxDataViewToggleRenderer; others would be e.g. an embedded volume slider or a five-star rating column.

The exact means of activating a cell are platform-dependent, but they are usually similar to those used for inline editing of values. Typically, a cell would be activated by Space or Enter keys or by left mouse click.

This method will only be called if the cell has the wxDATAVIEW_CELL_ACTIVATABLE mode.

Parameters

cell	Coordinates of the activated cell's area.
model	The model to manipulate in response.
item	Activated item.
col	Activated column of *item*.
mouseEvent	If the activation was triggered by mouse click, contains the corresponding event. Is NULL otherwise (for keyboard activation). Mouse coordinates are adjusted to be relative to the cell.

Since

2.9.3

Note

Do not confuse this method with item activation in wxDataViewCtrl and the wxEVT_DATAVIEW_ITEM_ACTIVATED event. That one is used for activating the item (or, to put it differently, the entire row) similarly to analogous messages in wxTreeCtrl and wxListCtrl, and the effect differs (play a song, open a file etc.). Cell activation, on the other hand, is all about interacting with the individual cell.

See also

CreateEditorCtrl()

virtual wxWindow* wxDataViewCustomRenderer::CreateEditorCtrl (wxWindow * *parent*, wxRect *labelRect*, const wxVariant & *value*) [virtual]

Override this to create the actual editor control once editing is about to start.

This method will only be called if the cell has the wxDATAVIEW_CELL_EDITABLE mode. Editing is typically triggered by slowly double-clicking the cell or by a platform-dependent keyboard shortcut (F2 is typical on Windows, Space and/or Enter is common elsewhere and supported on Windows too).

Parameters

parent	The parent of the editor control.
labelRect	Indicates the position and size of the editor control. The control should be created in place of the cell and *labelRect* should be respected as much as possible.
value	Initial value of the editor.

An example:

```
{
    long l = value;
    return new wxSpinCtrl( parent, wxID_ANY, wxEmptyString,
                labelRect.GetTopLeft(), labelRect.GetSize(), 0, 0, 100, l );
}
```

See also

ActivateCell()

Reimplemented from wxDataViewRenderer.

const wxDataViewItemAttr& wxDataViewCustomRenderer::GetAttr ( ) const

Return the attribute to be used for rendering.

This function may be called from Render() implementation to use the attributes defined for the item if the renderer supports them.

Notice that when Render() is called, the wxDC object passed to it is already set up to use the correct attributes (e.g. its font is set to bold or italic version if wxDataViewItemAttr::GetBold() or GetItalic() returns true) so it may not be necessary to call it explicitly if you only want to render text using the items attributes.

Since

2.9.1

static wxString wxDataViewCustomRenderer::GetDefaultType ( ) [static]

Returns the wxVariant type used with this renderer.

Since

3.1.0

virtual wxSize wxDataViewCustomRenderer::GetSize ( ) const [pure virtual]

Return size required to show content.

wxSize wxDataViewCustomRenderer::GetTextExtent (const wxString & *str*) const [protected]

Helper for GetSize() implementations, respects attributes.

virtual bool wxDataViewCustomRenderer::GetValueFromEditorCtrl (wxWindow * *editor*, wxVariant & *value*) [virtual]

Override this so that the renderer can get the value from the editor control (pointed to by *editor*):

```
{
    wxSpinCtrl *sc = (wxSpinCtrl*) editor;
    long l = sc->GetValue();
    value = l;
    return true;
}
```

Reimplemented from wxDataViewRenderer.

virtual bool wxDataViewCustomRenderer::HasEditorCtrl ( ) const [virtual]

Override this and make it return true in order to indicate that this renderer supports in-place editing.

Reimplemented from wxDataViewRenderer.

virtual bool wxDataViewCustomRenderer::LeftClick (wxPoint *cursor*, wxRect *cell*, wxDataViewModel * *model*, const wxDataViewItem & *item*, unsigned int *col*) [virtual]

Override this to react to a left click.

This method will only be called in `wxDATAVIEW_CELL_ACTIVATABLE` mode.

Deprecated Use ActivateCell instead.

virtual bool wxDataViewCustomRenderer::Render (wxRect *cell*, wxDC * *dc*, int *state*) [pure virtual]

Override this to render the cell.

Before this is called, wxDataViewRenderer::SetValue was called so that this instance knows what to render.

void wxDataViewCustomRenderer::RenderText (const wxString & *text*, int *xoffset*, wxRect *cell*, wxDC * *dc*, int *state*)

This method should be called from within Render() whenever you need to render simple text.

This will ensure that the correct colour, font and vertical alignment will be chosen so the text will look the same as text drawn by native renderers.

virtual bool wxDataViewCustomRenderer::StartDrag (const wxPoint & *cursor,* const wxRect & *cell,* wxDataViewModel * *model,* const wxDataViewItem & *item,* unsigned int *col*) [virtual]

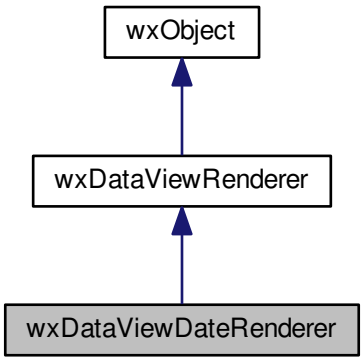
Override this to start a drag operation.

Not yet supported.

21.147 wxDataViewDateRenderer Class Reference

`#include <wx/dataview.h>`

Inheritance diagram for wxDataViewDateRenderer:



21.147.1 Detailed Description

This class is used by wxDataViewCtrl to render calendar controls.

Library: wxAdvanced

Returns the wxVariant type used with this renderer.

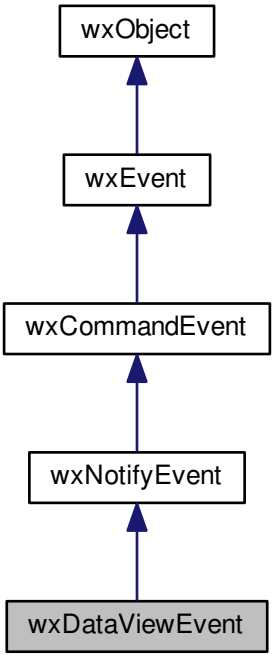
Since

3.1.0

21.148 wxDataViewEvent Class Reference

`#include <wx/dataview.h>`

Inheritance diagram for wxDataViewEvent:



21.148.1 Detailed Description

This is the event class for the wxDataViewCtrl notifications.

Events using this class

The following event handler macros redirect the events to member function handlers '**func**' with prototypes like: void handlerFuncName(wxDataViewEvent& event)

Event macros:

- EVT_DATAVIEW_SELECTION_CHANGED(id, func): Process a `wxEVT_DATAVIEW_SELECTION_CHANGED` event.
- EVT_DATAVIEW_ITEM_ACTIVATED(id, func): Process a `wxEVT_DATAVIEW_ITEM_ACTIVATED` event.
- EVT_DATAVIEW_ITEM_EDITING_STARTED(id, func): Process a `wxEVT_DATAVIEW_ITEM_EDITING_STARTED` event.
- EVT_DATAVIEW_ITEM_EDITING_DONE(id, func): Process a `wxEVT_DATAVIEW_ITEM_EDITING_DONE` event.
- EVT_DATAVIEW_ITEM_COLLAPSING(id, func): Process a `wxEVT_DATAVIEW_ITEM_COLLAPSING` event.
- EVT_DATAVIEW_ITEM_COLLAPSED(id, func): Process a `wxEVT_DATAVIEW_ITEM_COLLAPSED` event.
- EVT_DATAVIEW_ITEM_EXPANDING(id, func): Process a `wxEVT_DATAVIEW_ITEM_EXPANDING` event.
- EVT_DATAVIEW_ITEM_EXPANDED(id, func): Process a `wxEVT_DATAVIEW_ITEM_EXPANDED` event.
- EVT_DATAVIEW_ITEM_VALUE_CHANGED(id, func): Process a `wxEVT_DATAVIEW_ITEM_VALUE_CHANGED` event.
- EVT_DATAVIEW_ITEM_CONTEXT_MENU(id, func): Process a `wxEVT_DATAVIEW_ITEM_CONTEXT_MENU` event.
- EVT_DATAVIEW_COLUMN_HEADER_CLICK(id, func): Process a `wxEVT_DATAVIEW_COLUMN_HEADER_CLICK` event.
- EVT_DATAVIEW_COLUMN_HEADER_RIGHT_CLICK(id, func): Process a `wxEVT_DATAVIEW_COLUMN_HEADER_RIGHT_CLICK` event.
- EVT_DATAVIEW_COLUMN_SORTED(id, func): Process a `wxEVT_DATAVIEW_COLUMN_SORTED` event.
- EVT_DATAVIEW_COLUMN_REORDERED(id, func): Process a `wxEVT_DATAVIEW_COLUMN_REORDERED` event. Currently this even is only generated when using the native OSX version.
- EVT_DATAVIEW_ITEM_BEGIN_DRAG(id, func): Process a `wxEVT_DATAVIEW_ITEM_BEGIN_DRAG` event.
- EVT_DATAVIEW_ITEM_DROP_POSSIBLE(id, func): Process a `wxEVT_DATAVIEW_ITEM_DROP_POSSIBLE` event.
- EVT_DATAVIEW_ITEM_DROP(id, func): Process a `wxEVT_DATAVIEW_ITEM_DROP` event.
- EVT_DATAVIEW_CACHE_HINT(id, func): Process a `wxEVT_DATAVIEW_CACHE_HINT` event.

Library: wxAdvanced

Category: Events, wxDataViewCtrl Related Classes

Public Member Functions

- wxDataViewEvent (wxEventType commandType=wxEVT_NULL, int winid=0)

  Constructor.
- int GetColumn () const

  Returns the position of the column in the control or -1 if no column field was set by the event emitter.
- wxDataViewColumn * GetDataViewColumn () const

  Returns a pointer to the wxDataViewColumn from which the event was emitted or NULL.
- wxDataViewModel * GetModel () const

  Returns the wxDataViewModel associated with the event.
- wxPoint GetPosition () const

  Returns the position of a context menu event in screen coordinates.
- const wxVariant & GetValue () const

  Returns a reference to a value.
- bool IsEditCancelled () const

  Can be used to determine whether the new value is going to be accepted in wxEVT_DATAVIEW_ITEM_EDITING↩ _DONE handler.
- void SetColumn (int col)

  Sets the column index associated with this event.
- void SetDataViewColumn (wxDataViewColumn *col)

  For `wxEVT_DATAVIEW_COLUMN_HEADER_CLICK` only.
- void SetModel (wxDataViewModel *model)

  Sets the dataview model associated with this event.
- void SetValue (const wxVariant &value)

  Sets the value associated with this event.
- void SetDataObject (wxDataObject *obj)

  Set wxDataObject for data transfer within a drag operation.
- wxDataFormat GetDataFormat () const

  Gets the wxDataFormat during a drop operation.
- size_t GetDataSize () const

  Gets the data size for a drop data transfer.
- void * GetDataBuffer () const

  Gets the data buffer for a drop data transfer.
- void SetDragFlags (int flags)

  Specify the kind of the drag operation to perform.
- wxDragResult GetDropEffect () const

  Returns the effect the user requested to happen to the dropped data.
- int GetCacheFrom () const

  Return the first row that will be displayed.
- int GetCacheTo () const

  Return the last row that will be displayed.
- wxDataViewItem GetItem () const

  Returns the item affected by the event.
- void SetItem (const wxDataViewItem &item)
- void SetEditCanceled (bool editCancelled)
- void SetPosition (int x, int y)

- void SetCache (int from, int to)
- wxDataObject * GetDataObject () const
- void SetDataFormat (const wxDataFormat &format)
- void SetDataSize (size_t size)
- void SetDataBuffer (void *buf)
- int GetDragFlags () const
- void SetDropEffect (wxDragResult effect)

Additional Inherited Members

21.148.2 Constructor & Destructor Documentation

wxDataViewEvent::wxDataViewEvent (wxEventType *commandType* = wxEVT_NULL, int *winid* = 0)

Constructor.

Typically used by wxWidgets internals only.

21.148.3 Member Function Documentation

int wxDataViewEvent::GetCacheFrom ( ) const

Return the first row that will be displayed.

int wxDataViewEvent::GetCacheTo ( ) const

Return the last row that will be displayed.

int wxDataViewEvent::GetColumn ( ) const

Returns the position of the column in the control or -1 if no column field was set by the event emitter.

void* wxDataViewEvent::GetDataBuffer ( ) const

Gets the data buffer for a drop data transfer.

wxDataFormat wxDataViewEvent::GetDataFormat ( ) const

Gets the wxDataFormat during a drop operation.

wxDataObject* wxDataViewEvent::GetDataObject ( ) const

size_t wxDataViewEvent::GetDataSize ( ) const

Gets the data size for a drop data transfer.

wxDataViewColumn* wxDataViewEvent::GetDataViewColumn ( ) const

Returns a pointer to the wxDataViewColumn from which the event was emitted or NULL.

int wxDataViewEvent::GetDragFlags ( ) const

wxDragResult wxDataViewEvent::GetDropEffect ( ) const

Returns the effect the user requested to happen to the dropped data.

This function can be used inside wxEVT_DATAVIEW_ITEM_DROP_POSSIBLE and wxEVT_DATAVIEW_ITEM_DROP handlers and returns whether the user is trying to copy (the return value is wxDragCopy) or move (if the return value is wxDragMove) the data.

Currently this is only available when using the generic version of wxDataViewCtrl (used e.g. under MSW) and always returns wxDragNone in the GTK and OS X native versions.

Since

2.9.4

wxDataViewItem wxDataViewEvent::GetItem ( ) const

Returns the item affected by the event.

Notice that for `wxEVT_DATAVIEW_ITEM_DROP_POSSIBLE` and `wxEVT_DATAVIEW_ITEM_DROP` event handlers, the item may be invalid, indicating that the drop is about to happen outside of the item area.

wxDataViewModel* wxDataViewEvent::GetModel ( ) const

Returns the wxDataViewModel associated with the event.

wxPoint wxDataViewEvent::GetPosition ( ) const

Returns the position of a context menu event in screen coordinates.

const wxVariant& wxDataViewEvent::GetValue ( ) const

Returns a reference to a value.

bool wxDataViewEvent::IsEditCancelled ( ) const

Can be used to determine whether the new value is going to be accepted in wxEVT_DATAVIEW_ITEM_EDITING_DONE handler.

Returns true if editing the item was cancelled or if the user tried to enter an invalid value (refused by wxDataViewRenderer::Validate()). If this method returns false, it means that the value in the model is about to be changed to the new one.

Notice that wxEVT_DATAVIEW_ITEM_EDITING_DONE event handler can call wxNotifyEvent::Veto() to prevent this from happening.

Currently support for setting this field and for vetoing the change is only available in the generic version of wxDataViewCtrl, i.e. under MSW but not GTK nor OS X.

Since

2.9.3

void wxDataViewEvent::SetCache (int *from,* int *to*)

void wxDataViewEvent::SetColumn (int *col*)

Sets the column index associated with this event.

void wxDataViewEvent::SetDataBuffer (void * *buf*)

void wxDataViewEvent::SetDataFormat (const wxDataFormat & *format*)

void wxDataViewEvent::SetDataObject (wxDataObject * *obj*)

Set wxDataObject for data transfer within a drag operation.

void wxDataViewEvent::SetDataSize (size_t *size*)

void wxDataViewEvent::SetDataViewColumn (wxDataViewColumn * *col*)

For `wxEVT_DATAVIEW_COLUMN_HEADER_CLICK` only.

void wxDataViewEvent::SetDragFlags (int *flags*)

Specify the kind of the drag operation to perform.

This method can be used inside a wxEVT_DATAVIEW_ITEM_BEGIN_DRAG handler in order to configure the drag operation. Valid values are wxDrag_CopyOnly (default), wxDrag_AllowMove (allow the data to be moved) and wxDrag_DefaultMove.

Currently it is only honoured by the generic version of wxDataViewCtrl (used e.g. under MSW) and not supported by the native GTK and OS X versions.

See also

GetDropEffect()

Since

2.9.4

void wxDataViewEvent::SetDropEffect (wxDragResult *effect*)

void wxDataViewEvent::SetEditCanceled (bool *editCancelled*)

void wxDataViewEvent::SetItem (const wxDataViewItem & *item*)

void wxDataViewEvent::SetModel (wxDataViewModel * *model*)

Sets the dataview model associated with this event.

void wxDataViewEvent::SetPosition (int *x,* int *y*)

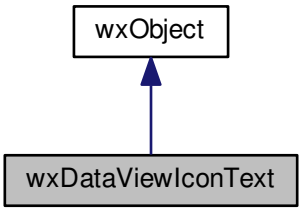
void wxDataViewEvent::SetValue (const wxVariant & *value*)

Sets the value associated with this event.

21.149 wxDataViewIconText Class Reference

`#include <wx/dataview.h>`

Inheritance diagram for wxDataViewIconText:



21.149.1 Detailed Description

wxDataViewIconText is used by wxDataViewIconTextRenderer for data transfer.

This class can be converted to and from a wxVariant.

Library: wxAdvanced

Category: wxDataViewCtrl Related Classes

Public Member Functions

- const wxIcon & GetIcon () const

  Gets the icon.

wxDataViewIconText::wxDataViewIconText (const wxDataViewIconText & *other*)

Constructor.

21.149.3 Member Function Documentation

const wxIcon& wxDataViewIconText::GetIcon ( ) const

Gets the icon.

wxString wxDataViewIconText::GetText ( ) const

Gets the text.

void wxDataViewIconText::SetIcon (const wxIcon & *icon*)

Set the icon.

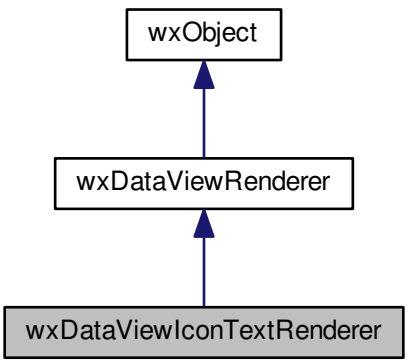
void wxDataViewIconText::SetText (const wxString & *text*)

Set the text.

21.150 wxDataViewIconTextRenderer Class Reference

`#include <wx/dataview.h>`

Inheritance diagram for wxDataViewIconTextRenderer:



21.150.1 Detailed Description

The wxDataViewIconTextRenderer class is used to display text with a small icon next to it as it is typically done in a file manager.

This classes uses the wxDataViewIconText helper class to store its data. wxDataViewIconText can be converted to and from a wxVariant using the left shift operator.

Public Member Functions

- wxDataViewIconTextRenderer (const wxString &varianttype=GetDefaultType(), wxDataViewCellMode mode=wxDATAVIEW_CELL_INERT, int align=wxDVR_DEFAULT_ALIGNMENT)

  The ctor.

Static Public Member Functions

- static wxString GetDefaultType ()

  Returns the wxVariant type used with this renderer.

Additional Inherited Members

21.150.2 Constructor & Destructor Documentation

wxDataViewIconTextRenderer::wxDataViewIconTextRenderer (const wxString & *varianttype* = GetDefaultType (), wxDataViewCellMode *mode* = wxDATAVIEW_CELL_INERT, int *align* = wxDVR_DEFAULT_ALIGNMENT)

The ctor.

21.150.3 Member Function Documentation

static wxString wxDataViewIconTextRenderer::GetDefaultType ( ) `[static]`

Returns the wxVariant type used with this renderer.

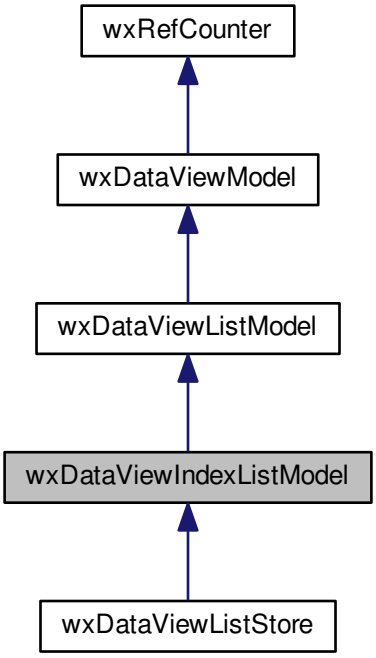
Since

3.1.0

21.151 wxDataViewIndexListModel Class Reference

```
#include <wx/dataview.h>
```

Inheritance diagram for wxDataViewIndexListModel:



21.151.1 Detailed Description

wxDataViewIndexListModel is a specialized data model which lets you address an item by its position (row) rather than its wxDataViewItem (which you can obtain from this class).

This model also provides its own wxDataViewIndexListModel::Compare method which sorts the model's data by the index.

This model is not a virtual model since the control stores each wxDataViewItem. Use wxDataViewVirtualListModel if you need to display millions of items or have other reason to use a virtual control.

See also

wxDataViewListModel for the API.

Library: wxAdvanced

Category: wxDataViewCtrl Related Classes

Public Member Functions

- wxDataViewIndexListModel (unsigned int initial_size=0)

  Constructor.
- wxDataViewItem GetItem (unsigned int row) const

Returns the wxDataViewItem at the given row.

- void Reset (unsigned int new_size)

  Call this after if the data has to be read again from the model.
- void RowAppended ()

  Call this after a row has been appended to the model.
- void RowChanged (unsigned int row)

  Call this after a row has been changed.
- void RowDeleted (unsigned int row)

  Call this after a row has been deleted.
- void RowInserted (unsigned int before)

  Call this after a row has been inserted at the given position.
- void RowPrepended ()

  Call this after a row has been prepended to the model.
- void RowValueChanged (unsigned int row, unsigned int col)

  Call this after a value has been changed.
- void RowsDeleted (const wxArrayInt &rows)

  Call this after rows have been deleted.

Additional Inherited Members

21.151.2 Constructor & Destructor Documentation

wxDataViewIndexListModel::wxDataViewIndexListModel (unsigned int *initial_size* = 0)

Constructor.

21.151.3 Member Function Documentation

wxDataViewItem wxDataViewIndexListModel::GetItem (unsigned int *row*) const

Returns the wxDataViewItem at the given *row*.

void wxDataViewIndexListModel::Reset (unsigned int *new_size*)

Call this after if the data has to be read again from the model.

This is useful after major changes when calling the methods below (possibly thousands of times) doesn't make sense.

void wxDataViewIndexListModel::RowAppended ( )

Call this after a row has been appended to the model.

void wxDataViewIndexListModel::RowChanged (unsigned int *row*)

Call this after a row has been changed.

void wxDataViewIndexListModel::RowDeleted (unsigned int *row*)

Call this after a row has been deleted.

void wxDataViewIndexListModel::RowInserted (unsigned int *before*)

Call this after a row has been inserted at the given position.

void wxDataViewIndexListModel::RowPrepended ( )

Call this after a row has been prepended to the model.

void wxDataViewIndexListModel::RowsDeleted (const wxArrayInt & *rows*)

Call this after rows have been deleted.

The array will internally get copied and sorted in descending order so that the rows with the highest position will be deleted first.

void wxDataViewIndexListModel::RowValueChanged (unsigned int *row,* unsigned int *col*)

Call this after a value has been changed.

21.152 wxDataViewItem Class Reference

`#include <wx/dataview.h>`

21.152.1 Detailed Description

wxDataViewItem is a small opaque class that represents an item in a wxDataViewCtrl in a persistent way, i.e.

independent of the position of the item in the control or changes to its contents.

It must hold a unique ID of type *void*∗ in its only field and can be converted to and from it.

If the ID is NULL the wxDataViewItem is invalid and wxDataViewItem::IsOk will return false which used in many places in the API of wxDataViewCtrl to indicate that e.g. no item was found. An ID of NULL is also used to indicate the invisible root. Examples for this are wxDataViewModel::GetParent and wxDataViewModel::GetChildren.

Library: wxAdvanced

Category: wxDataViewCtrl Related Classes

Public Member Functions

- void ∗ GetID () const
  Returns the ID.
- bool IsOk () const
  Returns true if the ID is not NULL.

- wxDataViewItem ()
  Constructor.
- wxDataViewItem (const wxDataViewItem &item)
  Constructor.
- wxDataViewItem (void ∗id)
  Constructor.

21.152.2 Constructor & Destructor Documentation

wxDataViewItem::wxDataViewItem ( )

Constructor.

wxDataViewItem::wxDataViewItem (const wxDataViewItem & *item*)

Constructor.

wxDataViewItem::wxDataViewItem (void * *id*) `[explicit]`

Constructor.

21.152.3 Member Function Documentation

void* wxDataViewItem::GetID ( ) const

Returns the ID.

bool wxDataViewItem::IsOk ( ) const

Returns true if the ID is not NULL.

21.153 wxDataViewItemAttr Class Reference

`#include <wx/dataview.h>`

21.153.1 Detailed Description

This class is used to indicate to a wxDataViewCtrl that a certain item (see wxDataViewItem) has extra font attributes for its renderer.

For this, it is required to override wxDataViewModel::GetAttr.

Attributes are currently only supported by wxDataViewTextRendererText.

Library: wxAdvanced

Category: wxDataViewCtrl Related Classes

Public Member Functions

- wxDataViewItemAttr ()

  Constructor.
- void SetBold (bool set)

  Call this to indicate that the item shall be displayed in bold text.
- void SetColour (const wxColour &colour)

  Call this to indicate that the item shall be displayed with that colour.

- void SetBackgroundColour (const wxColour &colour)

  Call this to set the background colour to use.
- void SetItalic (bool set)

  Call this to indicate that the item shall be displayed in italic text.
- bool HasColour () const

  Returns true if the colour property has been set.
- const wxColour & GetColour () const

  Returns this attribute's colour.
- bool HasFont () const

  Returns true if any property affecting the font has been set.
- bool GetBold () const

  Returns value of the bold property.
- bool GetItalic () const

  Returns value of the italics property.
- bool HasBackgroundColour () const

  Returns true if the background colour property has been set.
- const wxColour & GetBackgroundColour () const

  Returns the colour to be used for the background.
- bool IsDefault () const

  Returns true if none of the properties have been set.
- wxFont GetEffectiveFont (const wxFont &font) const

  Return the font based on the given one with this attribute applied to it.

21.153.2 Constructor & Destructor Documentation

wxDataViewItemAttr::wxDataViewItemAttr ( )

Constructor.

21.153.3 Member Function Documentation

const wxColour& wxDataViewItemAttr::GetBackgroundColour ( ) const

Returns the colour to be used for the background.

bool wxDataViewItemAttr::GetBold ( ) const

Returns value of the bold property.

const wxColour& wxDataViewItemAttr::GetColour ( ) const

Returns this attribute's colour.

wxFont wxDataViewItemAttr::GetEffectiveFont (const wxFont & *font*) const

Return the font based on the given one with this attribute applied to it.

bool wxDataViewItemAttr::GetItalic ( ) const

Returns value of the italics property.

bool wxDataViewItemAttr::HasBackgroundColour ( ) const

Returns true if the background colour property has been set.

bool wxDataViewItemAttr::HasColour ( ) const

Returns true if the colour property has been set.

bool wxDataViewItemAttr::HasFont ( ) const

Returns true if any property affecting the font has been set.

bool wxDataViewItemAttr::IsDefault ( ) const

Returns true if none of the properties have been set.

void wxDataViewItemAttr::SetBackgroundColour (const wxColour & *colour*)

Call this to set the background colour to use.

Currently this attribute is only supported in the generic version of wxDataViewCtrl and ignored by the native GTK+ and OS X implementations.

Since

2.9.4

void wxDataViewItemAttr::SetBold (bool *set*)

Call this to indicate that the item shall be displayed in bold text.

void wxDataViewItemAttr::SetColour (const wxColour & *colour*)

Call this to indicate that the item shall be displayed with that colour.

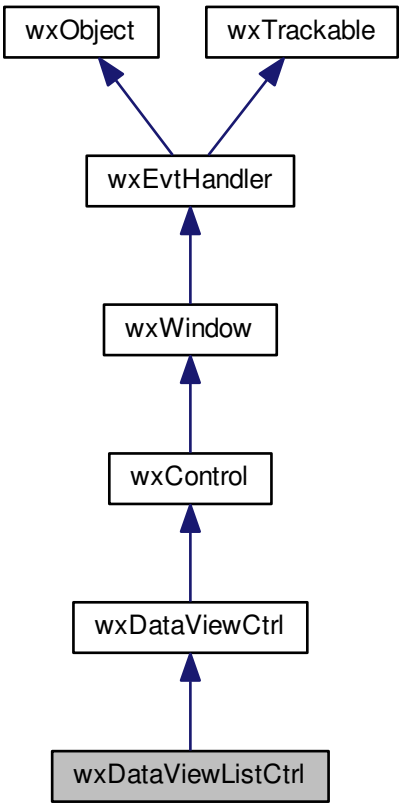
void wxDataViewItemAttr::SetItalic (bool *set*)

Call this to indicate that the item shall be displayed in italic text.

21.154 wxDataViewListCtrl Class Reference

`#include <wx/dataview.h>`

Inheritance diagram for wxDataViewListCtrl:



21.154.1 Detailed Description

This class is a wxDataViewCtrl which internally uses a wxDataViewListStore and forwards most of its API to that class.

The purpose of this class is to offer a simple way to display and edit a small table of data without having to write your own wxDataViewModel.

```
wxDataViewListCtrl *listctrl = new wxDataViewListCtrl( parent,
      wxID_ANY );

listctrl->AppendToggleColumn( "Toggle" );
listctrl->AppendTextColumn( "Text" );

wxVector<wxVariant> data;
data.push_back( wxVariant(true) );
data.push_back( wxVariant("row 1") );
listctrl->AppendItem( data );

data.clear();
data.push_back( wxVariant(false) );
data.push_back( wxVariant("row 3") );
listctrl->AppendItem( data );
```

Styles

This class supports the following styles:

See wxDataViewCtrl for the list of supported styles.

Events emitted by this class

Event macros for events emitted by this class:

See wxDataViewCtrl for the list of events emitted by this class.

Library: wxAdvanced

Category: Controls, wxDataViewCtrl Related Classes

Since

2.9.0

Public Member Functions

- wxDataViewListCtrl ()

  Default ctor.
- wxDataViewListCtrl (wxWindow *parent, wxWindowID id, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, long style=wxDV_ROW_LINES, const wxValidator &validator=wxDefaultValidator)

  Constructor.
- ~wxDataViewListCtrl ()

  Destructor.
- bool Create (wxWindow *parent, wxWindowID id, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, long style=wxDV_ROW_LINES, const wxValidator &validator=wxDefaultValidator)

  Creates the control and a wxDataViewListStore as its internal model.
- int ItemToRow (const wxDataViewItem &item) const

  Returns the position of given item or wxNOT_FOUND if it's not a valid item.
- wxDataViewItem RowToItem (int row) const

  Returns the wxDataViewItem at the given row.

- wxDataViewListStore * GetStore ()

  Returns the store.
- const wxDataViewListStore * GetStore () const

  Returns the store.

Selection handling functions

- int GetSelectedRow () const

  Returns index of the selected row or wxNOT_FOUND.
- void SelectRow (unsigned row)

  Selects given row.
- void UnselectRow (unsigned row)

  Unselects given row.
- bool IsRowSelected (unsigned row) const

  Returns true if row is selected.

Column management functions

- virtual bool AppendColumn (wxDataViewColumn *column)

  Appends a column to the control and additionally appends a column to the store with the type string.

- void AppendColumn (wxDataViewColumn *column, const wxString &varianttype)

  Appends a column to the control and additionally appends a column to the list store with the type varianttype.
- wxDataViewColumn * AppendTextColumn (const wxString &label, wxDataViewCellMode mode=wxDATAVIEW_CELL_INERT, int width=-1, wxAlignment align=wxALIGN_LEFT, int flags=wxDATAVIEW_COL_RESIZABLE)

  Appends a text column to the control and the store.
- wxDataViewColumn * AppendToggleColumn (const wxString &label, wxDataViewCellMode mode=wxDATAVIEW_CELL_ACTIVATABLE, int width=-1, wxAlignment align=wxALIGN_LEFT, int flags=wxDATAVIEW_COL_RESIZABLE)

  Appends a toggle column to the control and the store.
- wxDataViewColumn * AppendProgressColumn (const wxString &label, wxDataViewCellMode mode=wxDATAVIEW_CELL_INERT, int width=-1, wxAlignment align=wxALIGN_LEFT, int flags=wxDATAVIEW_COL_RESIZABLE)

  Appends a progress column to the control and the store.
- wxDataViewColumn * AppendIconTextColumn (const wxString &label, wxDataViewCellMode mode=wxDATAVIEW_CELL_INERT, int width=-1, wxAlignment align=wxALIGN_LEFT, int flags=wxDATAVIEW_COL_RESIZABLE)

  Appends an icon-and-text column to the control and the store.
- virtual bool InsertColumn (unsigned int pos, wxDataViewColumn *column)

  Inserts a column to the control and additionally inserts a column to the store with the type string.
- void InsertColumn (unsigned int pos, wxDataViewColumn *column, const wxString &varianttype)

  Inserts a column to the control and additionally inserts a column to the list store with the type varianttype.
- virtual bool PrependColumn (wxDataViewColumn *column)

  Prepends a column to the control and additionally prepends a column to the store with the type string.
- void PrependColumn (wxDataViewColumn *column, const wxString &varianttype)

  Prepends a column to the control and additionally prepends a column to the list store with the type varianttype.

Item management functions

- void AppendItem (const wxVector< wxVariant > &values, wxUIntPtr data=NULL)

  Appends an item (=row) to the control and store.
- void PrependItem (const wxVector< wxVariant > &values, wxUIntPtr data=NULL)

  Prepends an item (=row) to the control and store.
- void InsertItem (unsigned int row, const wxVector< wxVariant > &values, wxUIntPtr data=NULL)

  Inserts an item (=row) to the control and store.
- void DeleteItem (unsigned row)

  Delete the row at position row.
- void DeleteAllItems ()

  Delete all items (= all rows).
- unsigned int GetItemCount () const

  Returns the number of items (=rows) in the control.
- wxUIntPtr GetItemData (const wxDataViewItem &item) const

  Returns the client data associated with the item.
- void SetValue (const wxVariant &value, unsigned int row, unsigned int col)

  Sets the value in the store and update the control.
- void GetValue (wxVariant &value, unsigned int row, unsigned int col)

  Returns the value from the store.
- void SetTextValue (const wxString &value, unsigned int row, unsigned int col)

  Sets the value in the store and update the control.
- wxString GetTextValue (unsigned int row, unsigned int col) const

  Returns the value from the store.
- void SetToggleValue (bool value, unsigned int row, unsigned int col)

  Sets the value in the store and update the control.
- bool GetToggleValue (unsigned int row, unsigned int col) const

  Returns the value from the store.
- void SetItemData (const wxDataViewItem &item, wxUIntPtr data)

  Associates a client data pointer with the given item.

Additional Inherited Members

21.154.2 Constructor & Destructor Documentation

wxDataViewListCtrl::wxDataViewListCtrl ( )

Default ctor.

wxDataViewListCtrl::wxDataViewListCtrl (wxWindow * *parent*, wxWindowID *id*, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, long *style* = wxDV_ROW_LINES, const wxValidator & *validator* = wxDefaultValidator)

Constructor.

Calls Create().

wxDataViewListCtrl::~wxDataViewListCtrl ( )

Destructor.

Deletes the image list if any.

21.154.3 Member Function Documentation

virtual bool wxDataViewListCtrl::AppendColumn (wxDataViewColumn * *column*) [virtual]

Appends a column to the control and additionally appends a column to the store with the type string.

Reimplemented from wxDataViewCtrl.

void wxDataViewListCtrl::AppendColumn (wxDataViewColumn * *column*, const wxString & *varianttype*)

Appends a column to the control and additionally appends a column to the list store with the type *varianttype*.

wxDataViewColumn* wxDataViewListCtrl::AppendIconTextColumn (const wxString & *label*, wxDataViewCellMode *mode* = wxDATAVIEW_CELL_INERT, int *width* = -1, wxAlignment *align* = wxALIGN_LEFT, int *flags* = wxDATAVIEW_COL_RESIZABLE)

Appends an icon-and-text column to the control and the store.

See wxDataViewColumn::wxDataViewColumn for more info about the parameters.

void wxDataViewListCtrl::AppendItem (const wxVector< wxVariant > & *values*, wxUIntPtr *data* = NULL)

Appends an item (=row) to the control and store.

wxDataViewColumn* wxDataViewListCtrl::AppendProgressColumn (const wxString & *label*, wxDataViewCellMode *mode* = wxDATAVIEW_CELL_INERT, int *width* = -1, wxAlignment *align* = wxALIGN_LEFT, int *flags* = wxDATAVIEW_COL_RESIZABLE)

Appends a progress column to the control and the store.

See wxDataViewColumn::wxDataViewColumn for more info about the parameters.

wxDataViewColumn* **wxDataViewListCtrl::AppendTextColumn** (**const wxString &** *label*, **wxDataViewCellMode** *mode* = **wxDATAVIEW_CELL_INERT**, **int** *width* = **-1**, **wxAlignment** *align* = **wxALIGN_LEFT**, **int** *flags* = **wxDATAVIEW_COL_RESIZABLE**)

Appends a text column to the control and the store.

See wxDataViewColumn::wxDataViewColumn for more info about the parameters.

wxDataViewColumn* **wxDataViewListCtrl::AppendToggleColumn** (**const wxString &** *label*, **wxDataViewCellMode** *mode* = **wxDATAVIEW_CELL_ACTIVATABLE**, **int** *width* = **-1**, **wxAlignment** *align* = **wxALIGN_LEFT**, **int** *flags* = **wxDATAVIEW_COL_RESIZABLE**)

Appends a toggle column to the control and the store.

See wxDataViewColumn::wxDataViewColumn for more info about the parameters.

bool wxDataViewListCtrl::Create (**wxWindow** * *parent*, **wxWindowID** *id*, **const wxPoint &** *pos* = **wxDefaultPosition**, **const wxSize &** *size* = **wxDefaultSize**, **long** *style* = **wxDV_ROW_LINES**, **const wxValidator &** *validator* = **wxDefaultValidator**)

Creates the control and a wxDataViewListStore as its internal model.

void wxDataViewListCtrl::DeleteAllItems ( )

Delete all items (= all rows).

void wxDataViewListCtrl::DeleteItem (**unsigned** *row*)

Delete the row at position *row*.

unsigned int wxDataViewListCtrl::GetItemCount ( ) **const**

Returns the number of items (=rows) in the control.

Since

2.9.4

wxUIntPtr wxDataViewListCtrl::GetItemData (**const wxDataViewItem &** *item*) **const**

Returns the client data associated with the item.

See also

SetItemData()

Since

2.9.4

int wxDataViewListCtrl::GetSelectedRow ( ) const

Returns index of the selected row or wxNOT_FOUND.

See also

wxDataViewCtrl::GetSelection()

Since

2.9.2

wxDataViewListStore* wxDataViewListCtrl::GetStore ( )

Returns the store.

const wxDataViewListStore* wxDataViewListCtrl::GetStore ( ) const

Returns the store.

wxString wxDataViewListCtrl::GetTextValue (unsigned int *row*, unsigned int *col*) const

Returns the value from the store.

This method assumes that the string is stored in respective column.

bool wxDataViewListCtrl::GetToggleValue (unsigned int *row*, unsigned int *col*) const

Returns the value from the store.

This method assumes that the boolean value is stored in respective column.

void wxDataViewListCtrl::GetValue (wxVariant & *value*, unsigned int *row*, unsigned int *col*)

Returns the value from the store.

virtual bool wxDataViewListCtrl::InsertColumn (unsigned int *pos*, wxDataViewColumn * *column*) [virtual]

Inserts a column to the control and additionally inserts a column to the store with the type string.

Reimplemented from wxDataViewCtrl.

void wxDataViewListCtrl::InsertColumn (unsigned int *pos*, wxDataViewColumn * *column*, const wxString & *varianttype*)

Inserts a column to the control and additionally inserts a column to the list store with the type *varianttype*.

void wxDataViewListCtrl::InsertItem (unsigned int *row*, const wxVector< wxVariant > & *values*, wxUIntPtr *data* = NULL)

Inserts an item (=row) to the control and store.

bool wxDataViewListCtrl::IsRowSelected (unsigned *row*) const

Returns true if *row* is selected.

See also

wxDataViewCtrl::IsSelected()

Since

2.9.2

int wxDataViewListCtrl::ItemToRow (const wxDataViewItem & *item*) const

Returns the position of given *item* or wxNOT_FOUND if it's not a valid item.

Since

2.9.2

virtual bool wxDataViewListCtrl::PrependColumn (wxDataViewColumn * *column*) [virtual]

Prepends a column to the control and additionally prepends a column to the store with the type string.

Reimplemented from wxDataViewCtrl.

void wxDataViewListCtrl::PrependColumn (wxDataViewColumn * *column,* const wxString & *varianttype*)

Prepends a column to the control and additionally prepends a column to the list store with the type *varianttype*.

void wxDataViewListCtrl::PrependItem (const wxVector< wxVariant > & *values,* wxUIntPtr *data* = NULL)

Prepends an item (=row) to the control and store.

wxDataViewItem wxDataViewListCtrl::RowToItem (int *row*) const

Returns the wxDataViewItem at the given *row*.

Since

2.9.2

void wxDataViewListCtrl::SelectRow (unsigned *row*)

Selects given row.

See also

wxDataViewCtrl::Select()

Since

2.9.2

void wxDataViewListCtrl::SetItemData (const wxDataViewItem & *item,* wxUIntPtr *data*)

Associates a client data pointer with the given item.

Notice that the control does *not* take ownership of the pointer for compatibility with wxListCtrl. I.e. it will *not* delete the pointer (if it is a pointer and not a number) itself, it is up to you to do it.

See also

GetItemData()

Since

2.9.4

void wxDataViewListCtrl::SetTextValue (const wxString & *value,* unsigned int *row,* unsigned int *col*)

Sets the value in the store and update the control.

This method assumes that the string is stored in respective column.

void wxDataViewListCtrl::SetToggleValue (bool *value,* unsigned int *row,* unsigned int *col*)

Sets the value in the store and update the control.

This method assumes that the boolean value is stored in respective column.

void wxDataViewListCtrl::SetValue (const wxVariant & *value,* unsigned int *row,* unsigned int *col*)

Sets the value in the store and update the control.

void wxDataViewListCtrl::UnselectRow (unsigned *row*)

Unselects given row.

See also

wxDataViewCtrl::Unselect()

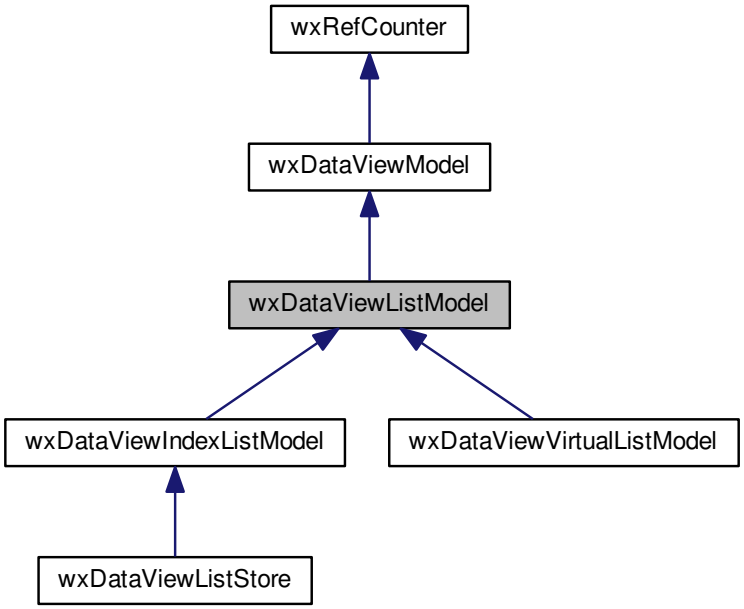
Since

2.9.2

21.155 wxDataViewListModel Class Reference

`#include <wx/dataview.h>`

Inheritance diagram for wxDataViewListModel:



21.155.1 Detailed Description

Base class with abstract API for wxDataViewIndexListModel and wxDataViewVirtualListModel.

Library: wxAdvanced

Category: wxDataViewCtrl Related Classes

Public Member Functions

- virtual ~wxDataViewListModel ()

  Destructor.
- int Compare (const wxDataViewItem &item1, const wxDataViewItem &item2, unsigned int column, bool ascending) const

  Compare method that sorts the items by their index.
- virtual bool GetAttrByRow (unsigned int row, unsigned int col, wxDataViewItemAttr &attr) const

  Override this to indicate that the row has special font attributes.
- virtual bool IsEnabledByRow (unsigned int row, unsigned int col) const

  Override this if you want to disable specific items.
- unsigned int GetCount () const =0

  Returns the number of items (or rows) in the list.
- unsigned int GetRow (const wxDataViewItem &item) const =0

  Returns the position of given item.

- virtual void GetValueByRow (wxVariant &variant, unsigned int row, unsigned int col) const =0

  Override this to allow getting values from the model.
- virtual bool SetValueByRow (const wxVariant &variant, unsigned int row, unsigned int col)=0

  Called in order to set a value in the model.

Additional Inherited Members

21.155.2 Constructor & Destructor Documentation

virtual wxDataViewListModel::~wxDataViewListModel ( ) [virtual]

Destructor.

21.155.3 Member Function Documentation

int wxDataViewListModel::Compare (const wxDataViewItem & *item1,* const wxDataViewItem & *item2,* unsigned int *column,* bool *ascending*) const [virtual]

Compare method that sorts the items by their index.

Reimplemented from wxDataViewModel.

virtual bool wxDataViewListModel::GetAttrByRow (unsigned int *row,* unsigned int *col,* wxDataViewItemAttr & *attr*) const [virtual]

Override this to indicate that the row has special font attributes.

This only affects the wxDataViewTextRendererText() renderer.

The base class version always simply returns false.

See also

wxDataViewItemAttr.

Parameters

row	The row for which the attribute is requested.
col	The column for which the attribute is requested.
attr	The attribute to be filled in if the function returns true.

Returns

true if this item has an attribute or false otherwise.

unsigned int wxDataViewListModel::GetCount ( ) const [pure virtual]

Returns the number of items (or rows) in the list.

unsigned int wxDataViewListModel::GetRow (const wxDataViewItem & *item*) const [pure virtual]

Returns the position of given *item*.

virtual void wxDataViewListModel::GetValueByRow (wxVariant & *variant,* unsigned int *row,* unsigned int *col*) const `[pure virtual]`

Override this to allow getting values from the model.

Implemented in wxDataViewListStore.

virtual bool wxDataViewListModel::IsEnabledByRow (unsigned int *row,* unsigned int *col*) const `[virtual]`

Override this if you want to disable specific items.

The base class version always returns true, thus making all items enabled by default.

Parameters

row	The row of the item whose enabled status is requested.
col	The column of the item whose enabled status is requested.

Returns

true if the item at this row and column should be enabled, false otherwise.

Note

See wxDataViewModel::IsEnabled() for the current status of support for disabling the items under different platforms.

Since

2.9.2

virtual bool wxDataViewListModel::SetValueByRow (const wxVariant & *variant,* unsigned int *row,* unsigned int *col*) `[pure virtual]`

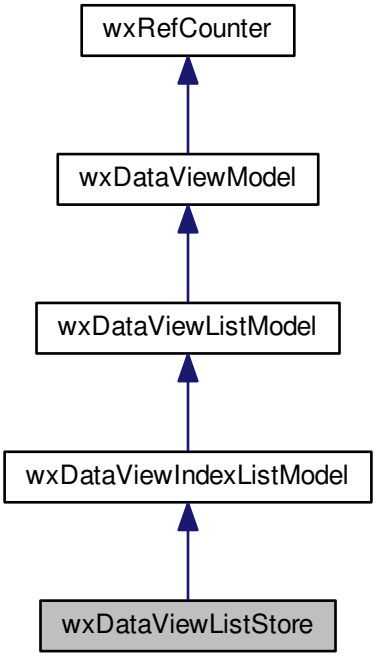
Called in order to set a value in the model.

Implemented in wxDataViewListStore.

21.156 wxDataViewListStore Class Reference

`#include <wx/dataview.h>`

Inheritance diagram for wxDataViewListStore:



21.156.1 Detailed Description

wxDataViewListStore is a specialised wxDataViewModel for storing a simple table of data.

Since it derives from wxDataViewIndexListModel its data is be accessed by row (i.e. by index) instead of only by wxDataViewItem.

This class actually stores the values (therefore its name) and implements all virtual methods from the base classes so it can be used directly without having to derive any class from it, but it is mostly used from within wxDataView↩ ListCtrl.

Library: wxAdvanced

Category: wxDataViewCtrl Related Classes

Public Member Functions

- wxDataViewListStore ()

  Constructor.
- ∼wxDataViewListStore ()

  Destructor.
- void PrependColumn (const wxString &varianttype)

  Prepends a data column.

- void InsertColumn (unsigned int pos, const wxString &varianttype)

  Inserts a data column before pos.
- void AppendColumn (const wxString &varianttype)

  Appends a data column.
- void AppendItem (const wxVector< wxVariant > &values, wxUIntPtr data=NULL)

  Appends an item (=row) and fills it with values.
- void PrependItem (const wxVector< wxVariant > &values, wxUIntPtr data=NULL)

  Prepends an item (=row) and fills it with values.
- void InsertItem (unsigned int row, const wxVector< wxVariant > &values, wxUIntPtr data=NULL)

  Inserts an item (=row) and fills it with values.
- void DeleteItem (unsigned pos)

  Delete the item (=row) at position pos.
- void DeleteAllItems ()

  Delete all item (=all rows) in the store.
- unsigned int GetItemCount () const

  Returns the number of items (=rows) in the control.
- wxUIntPtr GetItemData (const wxDataViewItem &item) const

  Returns the client data associated with the item.
- virtual unsigned int GetColumnCount () const

  Overridden from wxDataViewModel.
- virtual wxString GetColumnType (unsigned int col) const

  Overridden from wxDataViewModel.
- void SetItemData (const wxDataViewItem &item, wxUIntPtr data)

  Sets the client data associated with the item.
- virtual void GetValueByRow (wxVariant &value, unsigned int row, unsigned int col) const

  Overridden from wxDataViewIndexListModel.
- virtual bool SetValueByRow (const wxVariant &value, unsigned int row, unsigned int col)

  Overridden from wxDataViewIndexListModel.

Additional Inherited Members

21.156.2 Constructor & Destructor Documentation

wxDataViewListStore::wxDataViewListStore ( )

Constructor.

wxDataViewListStore::~wxDataViewListStore ( )

Destructor.

21.156.3 Member Function Documentation

void wxDataViewListStore::AppendColumn (const wxString & *varianttype*)

Appends a data column.

variantype indicates the type of values store in the column.

This does not automatically fill in any (default) values in rows which exist in the store already.

void wxDataViewListStore::AppendItem (const wxVector< wxVariant > & *values*, wxUIntPtr *data* = NULL)

Appends an item (=row) and fills it with *values*.

The values must match the values specifies in the column in number and type. No (default) values are filled in automatically.

void wxDataViewListStore::DeleteAllItems ( )

Delete all item (=all rows) in the store.

void wxDataViewListStore::DeleteItem (unsigned *pos*)

Delete the item (=row) at position *pos*.

virtual unsigned int wxDataViewListStore::GetColumnCount ( ) const [virtual]

Overridden from wxDataViewModel.

Implements wxDataViewModel.

virtual wxString wxDataViewListStore::GetColumnType (unsigned int *col*) const [virtual]

Overridden from wxDataViewModel.

Implements wxDataViewModel.

unsigned int wxDataViewListStore::GetItemCount ( ) const

Returns the number of items (=rows) in the control.

Since

2.9.4

wxUIntPtr wxDataViewListStore::GetItemData (const wxDataViewItem & *item*) const

Returns the client data associated with the item.

See also

SetItemData()

Since

2.9.4

virtual void wxDataViewListStore::GetValueByRow (wxVariant & *value*, unsigned int *row*, unsigned int *col*) const [virtual]

Overridden from wxDataViewIndexListModel.

Implements wxDataViewListModel.

void wxDataViewListStore::InsertColumn (unsigned int *pos*, const wxString & *varianttype*)

Inserts a data column before *pos*.

variantype indicates the type of values store in the column.

This does not automatically fill in any (default) values in rows which exist in the store already.

void wxDataViewListStore::InsertItem (unsigned int *row*, const wxVector< wxVariant > & *values*, wxUIntPtr *data* = NULL)

Inserts an item (=row) and fills it with *values*.

The values must match the values specifies in the column in number and type. No (default) values are filled in automatically.

void wxDataViewListStore::PrependColumn (const wxString & *varianttype*)

Prepends a data column.

variantype indicates the type of values store in the column.

This does not automatically fill in any (default) values in rows which exist in the store already.

void wxDataViewListStore::PrependItem (const wxVector< wxVariant > & *values*, wxUIntPtr *data* = NULL)

Prepends an item (=row) and fills it with *values*.

The values must match the values specifies in the column in number and type. No (default) values are filled in automatically.

void wxDataViewListStore::SetItemData (const wxDataViewItem & *item*, wxUIntPtr *data*)

Sets the client data associated with the item.

Notice that this class does *not* take ownership of the passed in pointer and will not delete it.

See also

GetItemData()

Since

2.9.4

virtual bool wxDataViewListStore::SetValueByRow (const wxVariant & *value*, unsigned int *row*, unsigned int *col*) [virtual]

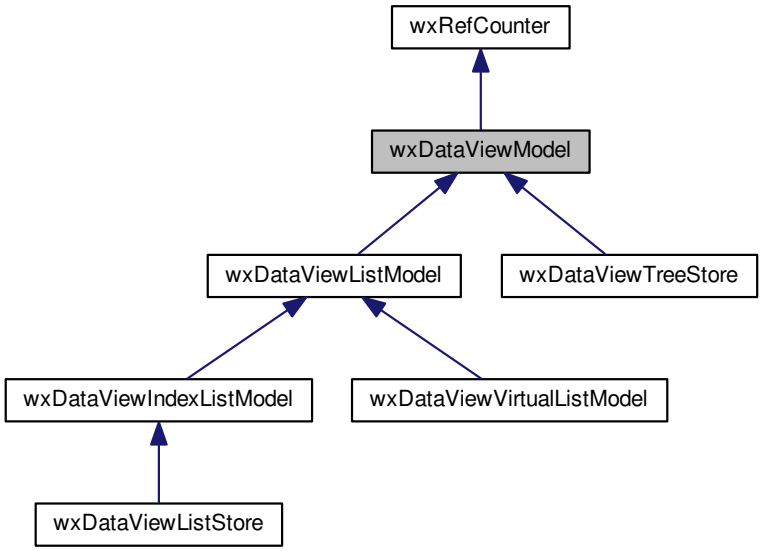
Overridden from wxDataViewIndexListModel.

Implements wxDataViewListModel.

21.157 wxDataViewModel Class Reference

```
#include <wx/dataview.h>
```

Inheritance diagram for wxDataViewModel:



21.157.1 Detailed Description

wxDataViewModel is the base class for all data model to be displayed by a wxDataViewCtrl.

All other models derive from it and must implement its pure virtual functions in order to define a complete data model. In detail, you need to override wxDataViewModel::IsContainer, wxDataViewModel::GetParent, wxDataViewModel::GetChildren, wxDataViewModel::GetColumnCount, wxDataViewModel::GetColumnType and wxDataViewModel::GetValue in order to define the data model which acts as an interface between your actual data and the wxDataViewCtrl.

Note that wxDataViewModel does not define the position or index of any item in the control because different controls might display the same data differently. wxDataViewModel does provide a wxDataViewModel::Compare method which the wxDataViewCtrl may use to sort the data either in conjunction with a column header or without (see wxDataViewModel::HasDefaultCompare).

wxDataViewModel (as indeed the entire wxDataViewCtrl code) is using wxVariant to store data and its type in a generic way. wxVariant can be extended to contain almost any data without changes to the original class. To a certain extent, you can use (the somewhat more elegant) wxAny instead of wxVariant as there is code to convert between the two, but it is unclear what impact this will have on performance.

Since you will usually allow the wxDataViewCtrl to change your data through its graphical interface, you will also have to override wxDataViewModel::SetValue which the wxDataViewCtrl will call when a change to some data has been committed.

If the data represented by the model is changed by something else than its associated wxDataViewCtrl, the control has to be notified about the change. Depending on what happened you need to call one of the following methods:

- wxDataViewModel::ValueChanged,
- wxDataViewModel::ItemAdded,
- wxDataViewModel::ItemDeleted,
- wxDataViewModel::ItemChanged,

- wxDataViewModel::Cleared.

There are plural forms for notification of addition, change or removal of several item at once. See:

- wxDataViewModel::ItemsAdded,
- wxDataViewModel::ItemsDeleted,
- wxDataViewModel::ItemsChanged.

This class maintains a list of wxDataViewModelNotifier which link this class to the specific implementations on the supported platforms so that e.g. calling wxDataViewModel::ValueChanged on this model will just call wxDataViewModelNotifier::ValueChanged for each notifier that has been added. You can also add your own notifier in order to get informed about any changes to the data in the list model.

Currently wxWidgets provides the following models apart from the base model: wxDataViewIndexListModel, wxDataViewVirtualListModel, wxDataViewTreeStore, wxDataViewListStore.

Note that wxDataViewModel is reference counted, derives from wxRefCounter and cannot be deleted directly as it can be shared by several wxDataViewCtrls. This implies that you need to decrease the reference count after associating the model with a control like this:

```
wxDataViewCtrl *musicCtrl = new wxDataViewCtrl( this,
      wxID_ANY );
wxDataViewModel *musicModel = new MyMusicModel;
m_musicCtrl->AssociateModel( musicModel );
musicModel->DecRef();  // avoid memory leak !!

// add columns now
```

A potentially better way to avoid memory leaks is to use wxObjectDataPtr

```
wxObjectDataPtr<MyMusicModel> musicModel;

wxDataViewCtrl *musicCtrl = new wxDataViewCtrl( this,
      wxID_ANY );
musicModel = new MyMusicModel;
m_musicCtrl->AssociateModel( musicModel.get() );

// add columns now
```

Library: wxAdvanced

Category: wxDataViewCtrl Related Classes

Public Member Functions

- wxDataViewModel ()

  Constructor.
- void AddNotifier (wxDataViewModelNotifier *notifier)

  Adds a wxDataViewModelNotifier to the model.
- bool ChangeValue (const wxVariant &variant, const wxDataViewItem &item, unsigned int col)

  Change the value of the given item and update the control to reflect it.
- virtual bool Cleared ()

  Called to inform the model that all data has been cleared.
- virtual int Compare (const wxDataViewItem &item1, const wxDataViewItem &item2, unsigned int column, bool ascending) const

  The compare function to be used by control.
- virtual bool GetAttr (const wxDataViewItem &item, unsigned int col, wxDataViewItemAttr &attr) const

Override this to indicate that the item has special font attributes.

- virtual bool IsEnabled (const wxDataViewItem &item, unsigned int col) const

  Override this to indicate that the item should be disabled.
- virtual unsigned int GetChildren (const wxDataViewItem &item, wxDataViewItemArray &children) const =0

  Override this so the control can query the child items of an item.
- virtual unsigned int GetColumnCount () const =0

  Override this to indicate the number of columns in the model.
- virtual wxString GetColumnType (unsigned int col) const =0

  Override this to indicate what type of data is stored in the column specified by col.
- virtual wxDataViewItem GetParent (const wxDataViewItem &item) const =0

  Override this to indicate which wxDataViewItem representing the parent of item or an invalid wxDataViewItem if the root item is the parent item.
- virtual void GetValue (wxVariant &variant, const wxDataViewItem &item, unsigned int col) const =0

  Override this to indicate the value of item.
- virtual bool HasContainerColumns (const wxDataViewItem &item) const

  Override this method to indicate if a container item merely acts as a headline (or for categorisation) or if it also acts a normal item with entries for further columns.
- virtual bool HasDefaultCompare () const

  Override this to indicate that the model provides a default compare function that the control should use if no wxDataViewColumn has been chosen for sorting.
- bool HasValue (const wxDataViewItem &item, unsigned col) const

  Return true if there is a value in the given column of this item.
- virtual bool IsContainer (const wxDataViewItem &item) const =0

  Override this to indicate of item is a container, i.e. if it can have child items.
- bool ItemAdded (const wxDataViewItem &parent, const wxDataViewItem &item)

  Call this to inform the model that an item has been added to the data.
- bool ItemChanged (const wxDataViewItem &item)

  Call this to inform the model that an item has changed.
- bool ItemDeleted (const wxDataViewItem &parent, const wxDataViewItem &item)

  Call this to inform the model that an item has been deleted from the data.
- bool ItemsAdded (const wxDataViewItem &parent, const wxDataViewItemArray &items)

  Call this to inform the model that several items have been added to the data.
- bool ItemsChanged (const wxDataViewItemArray &items)

  Call this to inform the model that several items have changed.
- bool ItemsDeleted (const wxDataViewItem &parent, const wxDataViewItemArray &items)

  Call this to inform the model that several items have been deleted.
- void RemoveNotifier (wxDataViewModelNotifier *notifier)

  Remove the notifier from the list of notifiers.
- virtual void Resort ()

  Call this to initiate a resort after the sort function has been changed.
- virtual bool SetValue (const wxVariant &variant, const wxDataViewItem &item, unsigned int col)=0

  This gets called in order to set a value in the data model.
- virtual bool ValueChanged (const wxDataViewItem &item, unsigned int col)

  Call this to inform this model that a value in the model has been changed.
- virtual bool IsListModel () const
- virtual bool IsVirtualListModel () const

Protected Member Functions

- virtual ~wxDataViewModel ()

  Destructor.

21.157.2 Constructor & Destructor Documentation

wxDataViewModel::wxDataViewModel ( )

Constructor.

virtual wxDataViewModel::~wxDataViewModel ( ) [protected], [virtual]

Destructor.

This should not be called directly. Use DecRef() instead.

21.157.3 Member Function Documentation

void wxDataViewModel::AddNotifier (wxDataViewModelNotifier * *notifier*)

Adds a wxDataViewModelNotifier to the model.

bool wxDataViewModel::ChangeValue (const wxVariant & *variant*, const wxDataViewItem & *item*, unsigned int *col*)

Change the value of the given item and update the control to reflect it.

This function simply calls SetValue() and, if it succeeded, ValueChanged().

Since

2.9.1

Parameters

variant	The new value.
item	The item (row) to update.
col	The column to update.

Returns

true if both SetValue() and ValueChanged() returned true.

virtual bool wxDataViewModel::Cleared ( ) [virtual]

Called to inform the model that all data has been cleared.

The control will reread the data from the model again.

virtual int wxDataViewModel::Compare (const wxDataViewItem & *item1*, const wxDataViewItem & *item2*, unsigned int *column*, bool *ascending*) const [virtual]

The compare function to be used by control.

The default compare function sorts by container and other items separately and in ascending order. Override this for a different sorting behaviour.

See also

HasDefaultCompare().

Reimplemented in wxDataViewListModel.

virtual bool wxDataViewModel::GetAttr (const wxDataViewItem & *item,* unsigned int *col,* wxDataViewItemAttr & *attr*) const `[virtual]`

Override this to indicate that the item has special font attributes.

This only affects the wxDataViewTextRendererText renderer.

The base class version always simply returns false.

See also

wxDataViewItemAttr.

Parameters

item	The item for which the attribute is requested.
col	The column of the item for which the attribute is requested.
attr	The attribute to be filled in if the function returns true.

Returns

true if this item has an attribute or false otherwise.

virtual unsigned int wxDataViewModel::GetChildren (const wxDataViewItem & *item,* wxDataViewItemArray & *children*) const `[pure virtual]`

Override this so the control can query the child items of an item.

Returns the number of items.

virtual unsigned int wxDataViewModel::GetColumnCount ( ) const `[pure virtual]`

Override this to indicate the number of columns in the model.

Implemented in wxDataViewListStore.

virtual wxString wxDataViewModel::GetColumnType (unsigned int *col*) const `[pure virtual]`

Override this to indicate what type of data is stored in the column specified by *col*.

This should return a string indicating the type of data as reported by wxVariant.

Implemented in wxDataViewListStore.

virtual wxDataViewItem wxDataViewModel::GetParent (const wxDataViewItem & *item*) const `[pure virtual]`

Override this to indicate which wxDataViewItem representing the parent of *item* or an invalid wxDataViewItem if the root item is the parent item.

virtual void wxDataViewModel::GetValue (wxVariant & *variant,* const wxDataViewItem & *item,* unsigned int *col*) const `[pure virtual]`

Override this to indicate the value of *item*.

A wxVariant is used to store the data.

virtual bool wxDataViewModel::HasContainerColumns (const wxDataViewItem & *item*) const [virtual]

Override this method to indicate if a container item merely acts as a headline (or for categorisation) or if it also acts a normal item with entries for further columns.

By default returns false.

virtual bool wxDataViewModel::HasDefaultCompare ( ) const [virtual]

Override this to indicate that the model provides a default compare function that the control should use if no wxDataViewColumn has been chosen for sorting.

Usually, the user clicks on a column header for sorting, the data will be sorted alphanumerically.

If any other order (e.g. by index or order of appearance) is required, then this should be used. See wxDataViewIndexListModel for a model which makes use of this.

bool wxDataViewModel::HasValue (const wxDataViewItem & *item*, unsigned *col*) const

Return true if there is a value in the given column of this item.

All normal items have values in all columns but the container items only show their label in the first column (*col* == 0) by default (but see HasContainerColumns()). So this function always returns true for the first column while for the other ones it returns true only if the item is not a container or HasContainerColumns() was overridden to return true for it.

Since

2.9.1

virtual bool wxDataViewModel::IsContainer (const wxDataViewItem & *item*) const [pure virtual]

Override this to indicate of *item* is a container, i.e. if it can have child items.

virtual bool wxDataViewModel::IsEnabled (const wxDataViewItem & *item*, unsigned int *col*) const [virtual]

Override this to indicate that the item should be disabled.

Disabled items are displayed differently (e.g. grayed out) and cannot be interacted with.

The base class version always returns true, thus making all items enabled by default.

Parameters

item	The item whose enabled status is requested.
col	The column of the item whose enabled status is requested.

Returns

true if this item should be enabled, false otherwise.

Note

Currently disabling items is not supported by the wxOSX/Carbon implementation.

Since

2.9.2

virtual bool wxDataViewModel::IsListModel ( ) const `[virtual]`

virtual bool wxDataViewModel::IsVirtualListModel ( ) const `[virtual]`

bool wxDataViewModel::ItemAdded (const wxDataViewItem & *parent,* const wxDataViewItem & *item*)

Call this to inform the model that an item has been added to the data.

bool wxDataViewModel::ItemChanged (const wxDataViewItem & *item*)

Call this to inform the model that an item has changed.

This will eventually emit a `wxEVT_DATAVIEW_ITEM_VALUE_CHANGED` event (in which the column fields will not be set) to the user.

bool wxDataViewModel::ItemDeleted (const wxDataViewItem & *parent,* const wxDataViewItem & *item*)

Call this to inform the model that an item has been deleted from the data.

bool wxDataViewModel::ItemsAdded (const wxDataViewItem & *parent,* const wxDataViewItemArray & *items*)

Call this to inform the model that several items have been added to the data.

bool wxDataViewModel::ItemsChanged (const wxDataViewItemArray & *items*)

Call this to inform the model that several items have changed.

This will eventually emit `wxEVT_DATAVIEW_ITEM_VALUE_CHANGED` events (in which the column fields will not be set) to the user.

bool wxDataViewModel::ItemsDeleted (const wxDataViewItem & *parent,* const wxDataViewItemArray & *items*)

Call this to inform the model that several items have been deleted.

void wxDataViewModel::RemoveNotifier (wxDataViewModelNotifier * *notifier*)

Remove the *notifier* from the list of notifiers.

virtual void wxDataViewModel::Resort ( ) `[virtual]`

Call this to initiate a resort after the sort function has been changed.

virtual bool wxDataViewModel::SetValue (const wxVariant & *variant,* const wxDataViewItem & *item,* unsigned int *col*) `[pure virtual]`

This gets called in order to set a value in the data model.

The most common scenario is that the wxDataViewCtrl calls this method after the user changed some data in the view.

This is the function you need to override in your derived class but if you want to call it, ChangeValue() is usually more convenient as otherwise you need to manually call ValueChanged() to update the control itself.

virtual bool wxDataViewModel::ValueChanged (const wxDataViewItem & *item,* unsigned int *col*) `[virtual]`

Call this to inform this model that a value in the model has been changed.

This is also called from wxDataViewCtrl's internal editing code, e.g. when editing a text field in the control.

This will eventually emit a `wxEVT_DATAVIEW_ITEM_VALUE_CHANGED` event to the user.

21.158 wxDataViewModelNotifier Class Reference

`#include <wx/dataview.h>`

21.158.1 Detailed Description

A wxDataViewModelNotifier instance is owned by a wxDataViewModel and mirrors its notification interface.

See the documentation of that class for further information.

Library: wxAdvanced

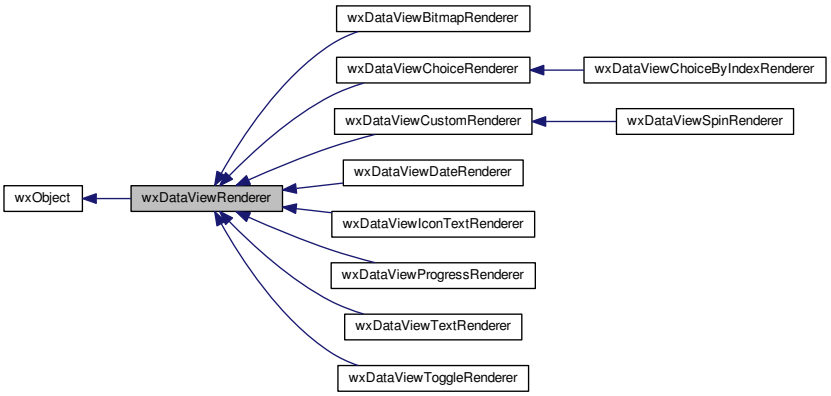
21.160 wxDataViewRenderer Class Reference

`#include <wx/dataview.h>`

Inheritance diagram for wxDataViewRenderer:



21.160.1 Detailed Description

This class is used by wxDataViewCtrl to render the individual cells.

One instance of a renderer class is owned by a wxDataViewColumn. There is a number of ready-to-use renderers provided:

- wxDataViewTextRenderer,
- wxDataViewIconTextRenderer,
- wxDataViewToggleRenderer,

- wxDataViewProgressRenderer,
- wxDataViewBitmapRenderer,
- wxDataViewDateRenderer,
- wxDataViewSpinRenderer.
- wxDataViewChoiceRenderer.

Additionally, the user can write their own renderers by deriving from wxDataViewCustomRenderer.

The wxDataViewCellMode and wxDataViewCellRenderState flags accepted by the constructors respectively controls what actions the cell data allows and how the renderer should display its contents in a cell.

Library: wxAdvanced

Category: wxDataViewCtrl Related Classes

Public Member Functions

- wxDataViewRenderer (const wxString &varianttype, wxDataViewCellMode mode=wxDATAVIEW_CELL_INERT, int align=wxDVR_DEFAULT_ALIGNMENT)

  Constructor.
- void EnableEllipsize (wxEllipsizeMode mode=wxELLIPSIZE_MIDDLE)

  Enable or disable replacing parts of the item text with ellipsis to make it fit the column width.
- void DisableEllipsize ()

  Disable replacing parts of the item text with ellipsis.
- virtual int GetAlignment () const

  Returns the alignment.
- wxEllipsizeMode GetEllipsizeMode () const

  Returns the ellipsize mode used by the renderer.
- virtual wxDataViewCellMode GetMode () const

  Returns the cell mode.
- wxDataViewColumn * GetOwner () const

  Returns pointer to the owning wxDataViewColumn.
- virtual bool GetValue (wxVariant &value) const =0

  This methods retrieves the value from the renderer in order to transfer the value back to the data model.
- wxString GetVariantType () const

  Returns a string with the type of the wxVariant supported by this renderer.
- virtual void SetAlignment (int align)

  Sets the alignment of the renderer's content.
- void SetOwner (wxDataViewColumn *owner)

  Sets the owning wxDataViewColumn.
- virtual bool SetValue (const wxVariant &value)=0

  Set the value of the renderer (and thus its cell) to value.
- virtual bool Validate (wxVariant &value)

  Before data is committed to the data model, it is passed to this method where it can be checked for validity.
- virtual bool HasEditorCtrl () const
- virtual wxWindow * CreateEditorCtrl (wxWindow *parent, wxRect labelRect, const wxVariant &value)
- virtual bool GetValueFromEditorCtrl (wxWindow *editor, wxVariant &value)
- virtual bool StartEditing (const wxDataViewItem &item, wxRect labelRect)
- virtual void CancelEditing ()
- virtual bool FinishEditing ()
- wxWindow * GetEditorCtrl ()

Protected Member Functions

- wxDataViewCtrl * GetView () const

Additional Inherited Members

21.160.2 Constructor & Destructor Documentation

wxDataViewRenderer::wxDataViewRenderer (const wxString & *varianttype,* wxDataViewCellMode *mode* = wxDATAVIEW_CELL_INERT, int *align* = wxDVR_DEFAULT_ALIGNMENT)

Constructor.

21.160.3 Member Function Documentation

virtual void wxDataViewRenderer::CancelEditing ( ) [virtual]

virtual wxWindow* wxDataViewRenderer::CreateEditorCtrl (wxWindow * *parent,* wxRect *labelRect,* const wxVariant & *value*) [virtual]

Reimplemented in wxDataViewCustomRenderer.

void wxDataViewRenderer::DisableEllipsize ( )

Disable replacing parts of the item text with ellipsis.

If ellipsizing is disabled, the string will be truncated if it doesn't fit.

This is the same as

```
EnableEllipsize(wxELLIPSIZE_NONE)
```

.

Since

2.9.1

void wxDataViewRenderer::EnableEllipsize (wxEllipsizeMode *mode* = wxELLIPSIZE_MIDDLE)

Enable or disable replacing parts of the item text with ellipsis to make it fit the column width.

This method only makes sense for the renderers working with text, such as wxDataViewTextRenderer or wxDataViewIconTextRenderer.

By default wxELLIPSIZE_MIDDLE is used.

Parameters

mode	Ellipsization mode, use wxELLIPSIZE_NONE to disable.

Since

2.9.1

virtual bool wxDataViewRenderer::FinishEditing ( ) [virtual]

virtual int wxDataViewRenderer::GetAlignment ( ) const [virtual]

Returns the alignment.

See SetAlignment()

wxWindow* wxDataViewRenderer::GetEditorCtrl ( )

wxEllipsizeMode wxDataViewRenderer::GetEllipsizeMode ( ) const

Returns the ellipsize mode used by the renderer.

If the return value is wxELLIPSIZE_NONE, the text is simply truncated if it doesn't fit.

See also

EnableEllipsize()

virtual wxDataViewCellMode wxDataViewRenderer::GetMode ( ) const [virtual]

Returns the cell mode.

wxDataViewColumn* wxDataViewRenderer::GetOwner ( ) const

Returns pointer to the owning wxDataViewColumn.

virtual bool wxDataViewRenderer::GetValue (wxVariant & *value*) const [pure virtual]

This methods retrieves the value from the renderer in order to transfer the value back to the data model.

Returns false on failure.

virtual bool wxDataViewRenderer::GetValueFromEditorCtrl (wxWindow * *editor*, wxVariant & *value*) [virtual]

Reimplemented in wxDataViewCustomRenderer.

wxString wxDataViewRenderer::GetVariantType ( ) const

Returns a string with the type of the wxVariant supported by this renderer.

wxDataViewCtrl* wxDataViewRenderer::GetView ( ) const [protected]

virtual bool wxDataViewRenderer::HasEditorCtrl ( ) const [virtual]

Reimplemented in wxDataViewCustomRenderer.

virtual void wxDataViewRenderer::SetAlignment (int *align*) [virtual]

Sets the alignment of the renderer's content.

The default value of `wxDVR_DEFAULT_ALIGMENT` indicates that the content should have the same alignment as the column header.

The method is not implemented under OS X and the renderer always aligns its contents as the column header on that platform. The other platforms support both vertical and horizontal alignment.

void wxDataViewRenderer::SetOwner (wxDataViewColumn * *owner*)

Sets the owning wxDataViewColumn.

This is usually called from within wxDataViewColumn.

virtual bool wxDataViewRenderer::SetValue (const wxVariant & *value*) `[pure virtual]`

Set the value of the renderer (and thus its cell) to *value*.

The internal code will then render this cell with this data.

virtual bool wxDataViewRenderer::StartEditing (const wxDataViewItem & *item*, wxRect *labelRect*) `[virtual]`

virtual bool wxDataViewRenderer::Validate (wxVariant & *value*) `[virtual]`

Before data is committed to the data model, it is passed to this method where it can be checked for validity.

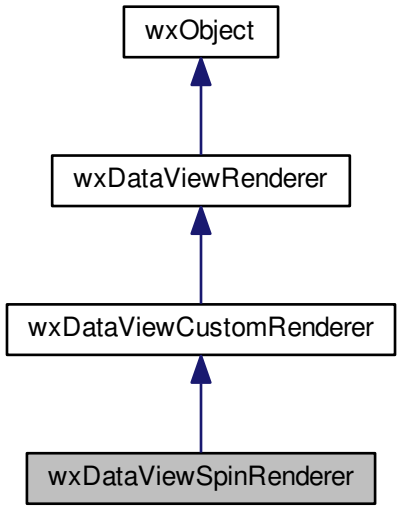
This can also be used for checking a valid range or limiting the user input in a certain aspect (e.g. max number of characters or only alphanumeric input, ASCII only etc.). Return false if the value is not valid.

Please note that due to implementation limitations, this validation is done after the editing control already is destroyed and the editing process finished.

21.161 wxDataViewSpinRenderer Class Reference

`#include <wx/dataview.h>`

Inheritance diagram for wxDataViewSpinRenderer:



21.161.1 Detailed Description

This is a specialized renderer for rendering integer values.

It supports modifying the values in-place by using a wxSpinCtrl. The renderer only support variants of type *long*.

Library: wxAdvanced

Category: wxDataViewCtrl Related Classes

Public Member Functions

- wxDataViewSpinRenderer (int min, int max, wxDataViewCellMode mode=wxDATAVIEW_CELL_EDITABLE, int align=wxDVR_DEFAULT_ALIGNMENT)

  Constructor.

Additional Inherited Members

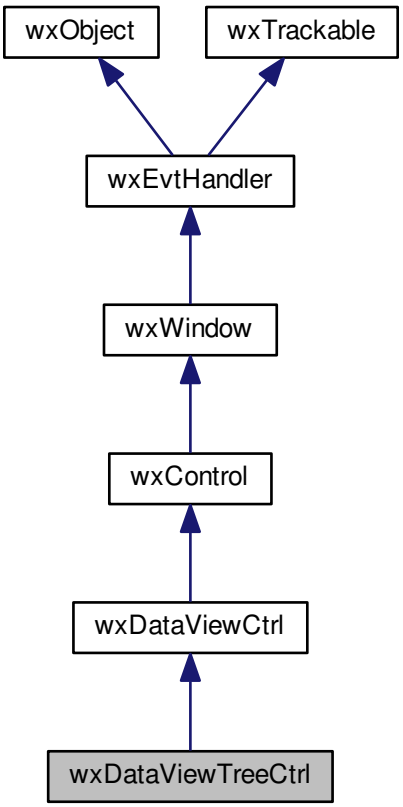
21.164 wxDataViewTreeCtrl Class Reference

`#include <wx/dataview.h>`

Inheritance diagram for wxDataViewTreeCtrl:



21.164.1 Detailed Description

This class is a wxDataViewCtrl which internally uses a wxDataViewTreeStore and forwards most of its API to that class.

Additionally, it uses a wxImageList to store a list of icons.

The main purpose of this class is to provide a simple upgrade path for code using wxTreeCtrl.

Styles

This class supports the following styles:

See wxDataViewCtrl for the list of supported styles.

2.9.0

Public Member Functions

- wxDataViewTreeCtrl ()

  Default ctor.
- wxDataViewTreeCtrl (wxWindow *parent, wxWindowID id, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, long style=wxDV_NO_HEADER|wxDV_ROW_LINES, const wxValidator &validator=wxDefaultValidator)

  Constructor.
- virtual ~wxDataViewTreeCtrl ()

  Destructor.
- wxDataViewItem AppendContainer (const wxDataViewItem &parent, const wxString &text, int icon=-1, int expanded=-1, wxClientData *data=NULL)

  Appends a container to the given parent.
- wxDataViewItem AppendItem (const wxDataViewItem &parent, const wxString &text, int icon=-1, wxClientData *data=NULL)

  Appends an item to the given parent.
- bool Create (wxWindow *parent, wxWindowID id, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, long style=wxDV_NO_HEADER|wxDV_ROW_LINES, const wxValidator &validator=wxDefaultValidator)

  Creates the control and a wxDataViewTreeStore as its internal model.
- void DeleteAllItems ()

  Calls the identical method from wxDataViewTreeStore.
- void DeleteChildren (const wxDataViewItem &item)

  Calls the identical method from wxDataViewTreeStore.
- void DeleteItem (const wxDataViewItem &item)

  Calls the identical method from wxDataViewTreeStore.
- int GetChildCount (const wxDataViewItem &parent) const

  Calls the identical method from wxDataViewTreeStore.
- wxImageList * GetImageList ()

  Returns the image list.
- wxClientData * GetItemData (const wxDataViewItem &item) const

  Calls the identical method from wxDataViewTreeStore.

- const wxIcon & GetItemExpandedIcon (const wxDataViewItem &item) const

  Calls the identical method from wxDataViewTreeStore.
- const wxIcon & GetItemIcon (const wxDataViewItem &item) const

  Calls the identical method from wxDataViewTreeStore.
- wxString GetItemText (const wxDataViewItem &item) const

  Calls the identical method from wxDataViewTreeStore.
- wxDataViewItem GetNthChild (const wxDataViewItem &parent, unsigned int pos) const

  Calls the identical method from wxDataViewTreeStore.
- wxDataViewItem InsertContainer (const wxDataViewItem &parent, const wxDataViewItem &previous, const wxString &text, int icon=-1, int expanded=-1, wxClientData *data=NULL)

  Calls the same method from wxDataViewTreeStore but uses an index position in the image list instead of a wxIcon.
- wxDataViewItem InsertItem (const wxDataViewItem &parent, const wxDataViewItem &previous, const wxString &text, int icon=-1, wxClientData *data=NULL)

  Calls the same method from wxDataViewTreeStore but uses an index position in the image list instead of a wxIcon.
- bool IsContainer (const wxDataViewItem &item)

  Returns true if item is a container.
- wxDataViewItem PrependContainer (const wxDataViewItem &parent, const wxString &text, int icon=-1, int expanded=-1, wxClientData *data=NULL)

  Calls the same method from wxDataViewTreeStore but uses an index position in the image list instead of a wxIcon.
- wxDataViewItem PrependItem (const wxDataViewItem &parent, const wxString &text, int icon=-1, wxClientData *data=NULL)

  Calls the same method from wxDataViewTreeStore but uses an index position in the image list instead of a wxIcon.
- void SetImageList (wxImageList *imagelist)

  Sets the image list.
- void SetItemData (const wxDataViewItem &item, wxClientData *data)

  Calls the identical method from wxDataViewTreeStore.
- void SetItemExpandedIcon (const wxDataViewItem &item, const wxIcon &icon)

  Calls the identical method from wxDataViewTreeStore.
- void SetItemIcon (const wxDataViewItem &item, const wxIcon &icon)

  Calls the identical method from wxDataViewTreeStore.
- void SetItemText (const wxDataViewItem &item, const wxString &text)

  Calls the identical method from wxDataViewTreeStore.

- wxDataViewTreeStore * GetStore ()

  Returns the store.
- const wxDataViewTreeStore * GetStore () const

  Returns the store.

21.164.2 Constructor & Destructor Documentation

wxDataViewTreeCtrl::wxDataViewTreeCtrl ( )

Default ctor.

wxDataViewTreeCtrl::wxDataViewTreeCtrl (wxWindow * *parent*, wxWindowID *id*, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, long *style* = wxDV_NO_HEADER|wxDV_ROW_LINES, const wxValidator & *validator* = wxDefaultValidator)

Constructor.

Calls Create().

virtual wxDataViewTreeCtrl::~wxDataViewTreeCtrl ( ) [virtual]

Destructor.

Deletes the image list if any.

21.164.3 Member Function Documentation

wxDataViewItem wxDataViewTreeCtrl::AppendContainer (const **wxDataViewItem** & *parent*, const **wxString** & *text*, int *icon* = −1, int *expanded* = −1, **wxClientData** ∗ *data* = NULL)

Appends a container to the given *parent*.

wxDataViewItem wxDataViewTreeCtrl::AppendItem (const **wxDataViewItem** & *parent*, const **wxString** & *text*, int *icon* = −1, **wxClientData** ∗ *data* = NULL)

Appends an item to the given *parent*.

bool wxDataViewTreeCtrl::Create (**wxWindow** ∗ *parent*, **wxWindowID** *id*, const **wxPoint** & *pos* = **wxDefaultPosition**, const **wxSize** & *size* = **wxDefaultSize**, long *style* = **wxDV_NO_HEADER**|**wxDV_ROW_LINES**, const **wxValidator** & *validator* = **wxDefaultValidator**)

Creates the control and a wxDataViewTreeStore as its internal model.

The default tree column created by this method is an editable column using wxDataViewIconTextRenderer as its renderer.

void wxDataViewTreeCtrl::DeleteAllItems ( )

Calls the identical method from wxDataViewTreeStore.

void wxDataViewTreeCtrl::DeleteChildren (const **wxDataViewItem** & *item*)

Calls the identical method from wxDataViewTreeStore.

void wxDataViewTreeCtrl::DeleteItem (const **wxDataViewItem** & *item*)

Calls the identical method from wxDataViewTreeStore.

int wxDataViewTreeCtrl::GetChildCount (const **wxDataViewItem** & *parent*) const

Calls the identical method from wxDataViewTreeStore.

wxImageList∗ wxDataViewTreeCtrl::GetImageList ( )

Returns the image list.

wxClientData∗ wxDataViewTreeCtrl::GetItemData (const **wxDataViewItem** & *item*) const

Calls the identical method from wxDataViewTreeStore.

const wxIcon& wxDataViewTreeCtrl::GetItemExpandedIcon (const wxDataViewItem & *item*) const

Calls the identical method from wxDataViewTreeStore.

const wxIcon& wxDataViewTreeCtrl::GetItemIcon (const wxDataViewItem & *item*) const

Calls the identical method from wxDataViewTreeStore.

wxString wxDataViewTreeCtrl::GetItemText (const wxDataViewItem & *item*) const

Calls the identical method from wxDataViewTreeStore.

wxDataViewItem wxDataViewTreeCtrl::GetNthChild (const wxDataViewItem & *parent,* unsigned int *pos*) const

Calls the identical method from wxDataViewTreeStore.

wxDataViewTreeStore* wxDataViewTreeCtrl::GetStore ( )

Returns the store.

const wxDataViewTreeStore* wxDataViewTreeCtrl::GetStore ( ) const

Returns the store.

wxDataViewItem wxDataViewTreeCtrl::InsertContainer (const wxDataViewItem & *parent,* const wxDataViewItem & *previous,* const wxString & *text,* int *icon* = -1, int *expanded* = -1, wxClientData * *data* = NULL)

Calls the same method from wxDataViewTreeStore but uses an index position in the image list instead of a wxIcon.

wxDataViewItem wxDataViewTreeCtrl::InsertItem (const wxDataViewItem & *parent,* const wxDataViewItem & *previous,* const wxString & *text,* int *icon* = -1, wxClientData * *data* = NULL)

Calls the same method from wxDataViewTreeStore but uses an index position in the image list instead of a wxIcon.

bool wxDataViewTreeCtrl::IsContainer (const wxDataViewItem & *item*)

Returns true if item is a container.

wxDataViewItem wxDataViewTreeCtrl::PrependContainer (const wxDataViewItem & *parent,* const wxString & *text,* int *icon* = -1, int *expanded* = -1, wxClientData * *data* = NULL)

Calls the same method from wxDataViewTreeStore but uses an index position in the image list instead of a wxIcon.

wxDataViewItem wxDataViewTreeCtrl::PrependItem (const wxDataViewItem & *parent,* const wxString & *text,* int *icon* = -1, wxClientData * *data* = NULL)

Calls the same method from wxDataViewTreeStore but uses an index position in the image list instead of a wxIcon.

void wxDataViewTreeCtrl::SetImageList (wxImageList * *imagelist*)

Sets the image list.

void wxDataViewTreeCtrl::SetItemData (const wxDataViewItem & *item,* wxClientData * *data*)

Calls the identical method from wxDataViewTreeStore.

void wxDataViewTreeCtrl::SetItemExpandedIcon (const wxDataViewItem & *item,* const wxIcon & *icon*)

Calls the identical method from wxDataViewTreeStore.

void wxDataViewTreeCtrl::SetItemIcon (const wxDataViewItem & *item,* const wxIcon & *icon*)

Calls the identical method from wxDataViewTreeStore.

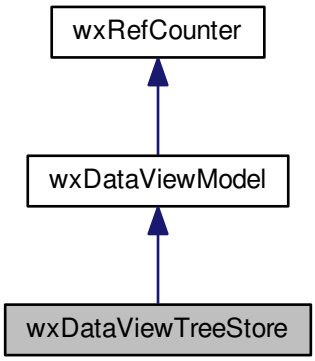
void wxDataViewTreeCtrl::SetItemText (const wxDataViewItem & *item,* const wxString & *text*)

Calls the identical method from wxDataViewTreeStore.

21.165 wxDataViewTreeStore Class Reference

`#include <wx/dataview.h>`

Inheritance diagram for wxDataViewTreeStore:



21.165.1 Detailed Description

wxDataViewTreeStore is a specialised wxDataViewModel for storing simple trees very much like wxTreeCtrl does and it offers a similar API.

This class actually stores the entire tree and the values (therefore its name) and implements all virtual methods from the base class so it can be used directly without having to derive any class from it, but it is mostly used from within wxDataViewTreeCtrl.

Library: wxAdvanced

Category: wxDataViewCtrl Related Classes

Public Member Functions

- wxDataViewTreeStore ()

  Constructor.
- virtual ~wxDataViewTreeStore ()

  Destructor.
- wxDataViewItem AppendContainer (const wxDataViewItem &parent, const wxString &text, const wxIcon &icon=wxNullIcon, const wxIcon &expanded=wxNullIcon, wxClientData *data=NULL)

  Append a container.
- wxDataViewItem AppendItem (const wxDataViewItem &parent, const wxString &text, const wxIcon &icon=wxNullIcon, wxClientData *data=NULL)

  Append an item.
- void DeleteAllItems ()

  Delete all item in the model.
- void DeleteChildren (const wxDataViewItem &item)

  Delete all children of the item, but not the item itself.
- void DeleteItem (const wxDataViewItem &item)

  Delete this item.
- int GetChildCount (const wxDataViewItem &parent) const

  Return the number of children of item.
- wxClientData * GetItemData (const wxDataViewItem &item) const

  Returns the client data associated with the item.
- const wxIcon & GetItemExpandedIcon (const wxDataViewItem &item) const

  Returns the icon to display in expanded containers.
- const wxIcon & GetItemIcon (const wxDataViewItem &item) const

  Returns the icon of the item.
- wxString GetItemText (const wxDataViewItem &item) const

  Returns the text of the item.
- wxDataViewItem GetNthChild (const wxDataViewItem &parent, unsigned int pos) const

  Returns the nth child item of item.
- wxDataViewItem InsertContainer (const wxDataViewItem &parent, const wxDataViewItem &previous, const wxString &text, const wxIcon &icon=wxNullIcon, const wxIcon &expanded=wxNullIcon, wxClientData *data=NULL)

  Inserts a container after previous.
- wxDataViewItem InsertItem (const wxDataViewItem &parent, const wxDataViewItem &previous, const wxString &text, const wxIcon &icon=wxNullIcon, wxClientData *data=NULL)

  Inserts an item after previous.
- wxDataViewItem PrependContainer (const wxDataViewItem &parent, const wxString &text, const wxIcon &icon=wxNullIcon, const wxIcon &expanded=wxNullIcon, wxClientData *data=NULL)

  Inserts a container before the first child item or parent.
- wxDataViewItem PrependItem (const wxDataViewItem &parent, const wxString &text, const wxIcon &icon=wxNullIcon, wxClientData *data=NULL)

  Inserts an item before the first child item or parent.
- void SetItemData (const wxDataViewItem &item, wxClientData *data)

  Sets the client data associated with the item.
- void SetItemExpandedIcon (const wxDataViewItem &item, const wxIcon &icon)

  Sets the expanded icon for the item.
- void SetItemIcon (const wxDataViewItem &item, const wxIcon &icon)

  Sets the icon for the item.

Additional Inherited Members

wxDataViewItem wxDataViewTreeStore::AppendContainer (const wxDataViewItem & *parent,* const wxString & *text,* const wxIcon & *icon* = wxNullIcon, const wxIcon & *expanded* = wxNullIcon, wxClientData * *data* = NULL)

Append a container.

wxDataViewItem wxDataViewTreeStore::AppendItem (const wxDataViewItem & *parent,* const wxString & *text,* const wxIcon & *icon* = wxNullIcon, wxClientData * *data* = NULL)

Append an item.

void wxDataViewTreeStore::DeleteAllItems ( )

Delete all item in the model.

void wxDataViewTreeStore::DeleteChildren (const wxDataViewItem & *item*)

Delete all children of the item, but not the item itself.

void wxDataViewTreeStore::DeleteItem (const wxDataViewItem & *item*)

Delete this item.

int wxDataViewTreeStore::GetChildCount (const wxDataViewItem & *parent*) const

Return the number of children of item.

wxClientData* wxDataViewTreeStore::GetItemData (const wxDataViewItem & *item*) const

Returns the client data associated with the item.

const wxIcon& wxDataViewTreeStore::GetItemExpandedIcon (const wxDataViewItem & *item*) const

Returns the icon to display in expanded containers.

const wxIcon& wxDataViewTreeStore::GetItemIcon (const wxDataViewItem & *item*) const

Returns the icon of the item.

wxString wxDataViewTreeStore::GetItemText (const wxDataViewItem & *item*) const

Returns the text of the item.

wxDataViewItem wxDataViewTreeStore::GetNthChild (const wxDataViewItem & *parent,* unsigned int *pos*) const

Returns the nth child item of item.

wxDataViewItem wxDataViewTreeStore::InsertContainer (const wxDataViewItem & *parent,* const wxDataViewItem & *previous,* const wxString & *text,* const wxIcon & *icon* = wxNullIcon, const wxIcon & *expanded* = wxNullIcon, wxClientData * *data* = NULL)

Inserts a container after *previous*.

wxDataViewItem wxDataViewTreeStore::InsertItem (const wxDataViewItem & *parent,* const wxDataViewItem & *previous,* const wxString & *text,* const wxIcon & *icon* = wxNullIcon, wxClientData * *data* = NULL)

Inserts an item after *previous*.

wxDataViewItem wxDataViewTreeStore::PrependContainer (const wxDataViewItem & *parent,* const wxString & *text,* const wxIcon & *icon* = wxNullIcon, const wxIcon & *expanded* = wxNullIcon, wxClientData * *data* = NULL)

Inserts a container before the first child item or *parent*.

wxDataViewItem wxDataViewTreeStore::PrependItem (const wxDataViewItem & *parent,* const wxString & *text,* const wxIcon & *icon* = wxNullIcon, wxClientData * *data* = NULL)

Inserts an item before the first child item or *parent*.

void wxDataViewTreeStore::SetItemData (const wxDataViewItem & *item,* wxClientData * *data*)

Sets the client data associated with the item.

void wxDataViewTreeStore::SetItemExpandedIcon (const wxDataViewItem & *item,* const wxIcon & *icon*)

Sets the expanded icon for the item.

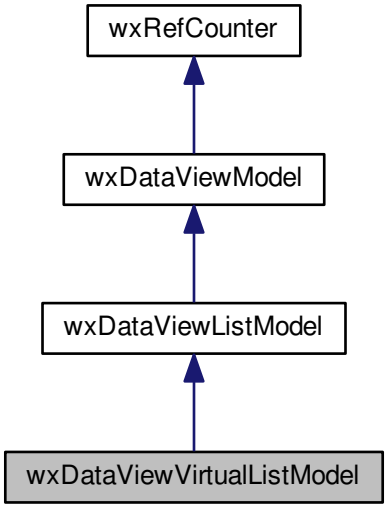
void wxDataViewTreeStore::SetItemIcon (const wxDataViewItem & *item,* const wxIcon & *icon*)

Sets the icon for the item.

21.166 wxDataViewVirtualListModel Class Reference

```
#include <wx/dataview.h>
```

Inheritance diagram for wxDataViewVirtualListModel:



21.166.1 Detailed Description

wxDataViewVirtualListModel is a specialized data model which lets you address an item by its position (row) rather than its wxDataViewItem and as such offers the exact same interface as wxDataViewIndexListModel.

The important difference is that under platforms other than OS X, using this model will result in a truly virtual control able to handle millions of items as the control doesn't store any item (a feature not supported by OS X).

See also

wxDataViewListModel for the API.

Library: wxAdvanced

Category: wxDataViewCtrl Related Classes

Public Member Functions

- wxDataViewVirtualListModel (unsigned int initial_size=0)

  Constructor.
- wxDataViewItem GetItem (unsigned int row) const

  Returns the wxDataViewItem at the given row.
- void Reset (unsigned int new_size)

  Call this after if the data has to be read again from the model.
- void RowAppended ()

  Call this after a row has been appended to the model.
- void RowChanged (unsigned int row)

Call this after a row has been changed.

- void RowDeleted (unsigned int row)

  Call this after a row has been deleted.

- void RowInserted (unsigned int before)

  Call this after a row has been inserted at the given position.

- void RowPrepended ()

  Call this after a row has been prepended to the model.

- void RowValueChanged (unsigned int row, unsigned int col)

  Call this after a value has been changed.

- void RowsDeleted (const wxArrayInt &rows)

  Call this after rows have been deleted.

Additional Inherited Members

21.166.2 Constructor & Destructor Documentation

wxDataViewVirtualListModel::wxDataViewVirtualListModel (unsigned int *initial_size* = 0)

Constructor.

21.166.3 Member Function Documentation

wxDataViewItem wxDataViewVirtualListModel::GetItem (unsigned int *row*) const

Returns the wxDataViewItem at the given *row*.

void wxDataViewVirtualListModel::Reset (unsigned int *new_size*)

Call this after if the data has to be read again from the model.

This is useful after major changes when calling the methods below (possibly thousands of times) doesn't make sense.

void wxDataViewVirtualListModel::RowAppended ( )

Call this after a row has been appended to the model.

void wxDataViewVirtualListModel::RowChanged (unsigned int *row*)

Call this after a row has been changed.

void wxDataViewVirtualListModel::RowDeleted (unsigned int *row*)

Call this after a row has been deleted.

void wxDataViewVirtualListModel::RowInserted (unsigned int *before*)

Call this after a row has been inserted at the given position.

void wxDataViewVirtualListModel::RowPrepended ( )

Call this after a row has been prepended to the model.

void wxDataViewVirtualListModel::RowsDeleted (const wxArrayInt & *rows*)

Call this after rows have been deleted.

The array will internally get copied and sorted in descending order so that the rows with the highest position will be deleted first.

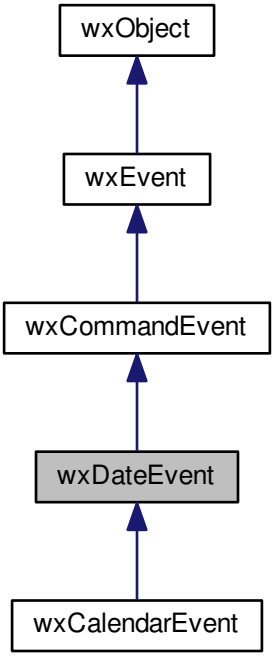
void wxDataViewVirtualListModel::RowValueChanged (unsigned int *row*, unsigned int *col*)

Call this after a value has been changed.

21.167 wxDateEvent Class Reference

`#include <wx/dateevt.h>`

Inheritance diagram for wxDateEvent:



21.167.1 Detailed Description

This event class holds information about a date change and is used together with wxDatePickerCtrl.

It also serves as a base class for wxCalendarEvent.

Library: wxAdvanced

Category: Events

Public Member Functions

- wxDateEvent ()
- wxDateEvent (wxWindow *win, const wxDateTime &dt, wxEventType type)
- const wxDateTime & GetDate () const

  Returns the date.
- void SetDate (const wxDateTime &date)

  Sets the date carried by the event, normally only used by the library internally.

Additional Inherited Members

21.167.2 Constructor & Destructor Documentation

wxDateEvent::wxDateEvent ( )

wxDateEvent::wxDateEvent (wxWindow * *win,* const wxDateTime & *dt,* wxEventType *type*)

21.167.3 Member Function Documentation

const wxDateTime& wxDateEvent::GetDate ( ) const

Returns the date.

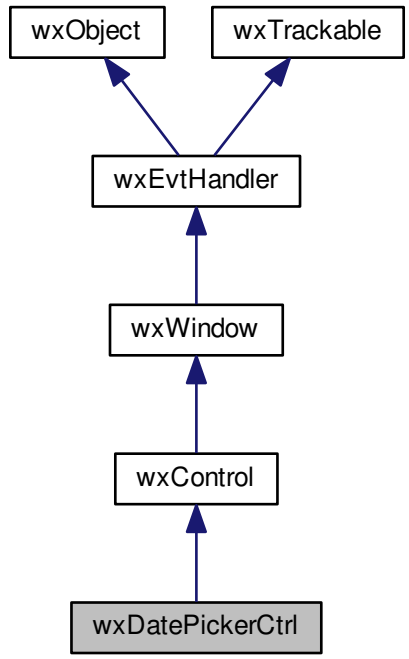
void wxDateEvent::SetDate (const wxDateTime & *date*)

Sets the date carried by the event, normally only used by the library internally.

21.168 wxDatePickerCtrl Class Reference

```
#include <wx/datectrl.h>
```

Inheritance diagram for wxDatePickerCtrl:



21.168.1 Detailed Description

This control allows the user to select a date.

Unlike wxCalendarCtrl, which is a relatively big control, wxDatePickerCtrl is implemented as a small window showing the currently selected date. The control can be edited using the keyboard, and can also display a popup window for more user-friendly date selection, depending on the styles used and the platform.

It is only available if `wxUSE_DATEPICKCTRL` is set to 1.

Styles

This class supports the following styles:

- wxDP_SPIN: Creates a control without a month calendar drop down but with spin-control-like arrows to change individual date components. This style is not supported by the generic version.
- wxDP_DROPDOWN: Creates a control with a month calendar drop-down part from which the user can select a date. This style is not supported in OSX/Cocoa native version.
- wxDP_DEFAULT: Creates a control with the style that is best supported for the current platform (currently wxDP_SPIN under Windows and OSX/Cocoa and wxDP_DROPDOWN elsewhere).
- wxDP_ALLOWNONE: With this style, the control allows the user to not enter any valid date at all. Without it - the default - the control always has some valid date. This style is not supported in OSX/Cocoa native version.
- wxDP_SHOWCENTURY: Forces display of the century in the default date format. Without this style the century could be displayed, or not, depending on the default date representation in the system. This style is not supported in OSX/Cocoa native version currently.

As can be seen from the remarks above, most of the control style are only supported in the native MSW implementation. In portable code it's recommended to use `wxDP_DEFAULT` style only, possibly combined with `wxDP_SHOWCENTURY` (this is also the style used by default if none is specified).

Events emitted by this class

The following event handler macros redirect the events to member function handlers '**func**' with prototypes like: void handlerFuncName(wxDateEvent& event)

Event macros for events emitted by this class:

- EVT_DATE_CHANGED(id, func): This event fires when the user changes the current selection in the control.

Library: wxAdvanced

Category: Picker Controls

See also

wxCalendarCtrl, wxDateEvent

Public Member Functions

- wxDatePickerCtrl ()

  Default constructor.
- wxDatePickerCtrl (wxWindow *parent, wxWindowID id, const wxDateTime &dt=wxDefaultDateTime, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, long style=wxDP_DEFAULT|wxDP_SHOWCENTURY, const wxValidator &validator=wxDefaultValidator, const wxString &name="datectrl")

  Initializes the object and calls Create() with all the parameters.
- bool Create (wxWindow *parent, wxWindowID id, const wxDateTime &dt=wxDefaultDateTime, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, long style=wxDP_DEFAULT|wxDP_SHOWCENTURY, const wxValidator &validator=wxDefaultValidator, const wxString &name="datectrl")

  Create the control window.
- virtual bool GetRange (wxDateTime *dt1, wxDateTime *dt2) const

  If the control had been previously limited to a range of dates using SetRange(), returns the lower and upper bounds of this range.
- virtual wxDateTime GetValue () const

  Returns the currently entered date.
- virtual void SetRange (const wxDateTime &dt1, const wxDateTime &dt2)

  Sets the valid range for the date selection.
- virtual void SetValue (const wxDateTime &dt)

  Changes the current value of the control.

Additional Inherited Members

21.168.2 Constructor & Destructor Documentation

wxDatePickerCtrl::wxDatePickerCtrl ( )

Default constructor.

wxDatePickerCtrl::wxDatePickerCtrl (wxWindow * *parent*, wxWindowID *id*, const wxDateTime & *dt* = wxDefaultDateTime, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, long *style* = wxDP_DEFAULT|wxDP_SHOWCENTURY, const wxValidator & *validator* = wxDefaultValidator, const wxString & *name* = "datectrl")

Initializes the object and calls Create() with all the parameters.

21.168.3 Member Function Documentation

bool wxDatePickerCtrl::Create (wxWindow * *parent*, wxWindowID *id*, const wxDateTime & *dt* = wxDefaultDateTime, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, long *style* = wxDP_DEFAULT|wxDP_SHOWCENTURY, const wxValidator & *validator* = wxDefaultValidator, const wxString & *name* = "datectrl")

Create the control window.

This method should only be used for objects created using default constructor.

Parameters

parent	Parent window, must not be non-NULL.
id	The identifier for the control.
dt	The initial value of the control, if an invalid date (such as the default value) is used, the control is set to today.
pos	Initial position.
size	Initial size. If left at default value, the control chooses its own best size by using the height approximately equal to a text control and width large enough to show the date string fully.
style	The window style, see the description of the styles in the class documentation.
validator	Validator which can be used for additional date checks.
name	Control name.

Returns

true if the control was successfully created or false if creation failed.

virtual bool wxDatePickerCtrl::GetRange (wxDateTime * *dt1*, wxDateTime * *dt2*) const `[virtual]`

If the control had been previously limited to a range of dates using SetRange(), returns the lower and upper bounds of this range.

If no range is set (or only one of the bounds is set), *dt1* and/or *dt2* are set to be invalid.

Notice that when using a native MSW implementation of this control the lower range is always set, even if SetRange() hadn't been called explicitly, as the native control only supports dates later than year 1601.

Parameters

dt1	Pointer to the object which receives the lower range limit or becomes invalid if it is not set. May be NULL if the caller is not interested in lower limit.
dt2	Same as above but for the upper limit.

Returns

false if no range limits are currently set, true if at least one bound is set.

virtual wxDateTime wxDatePickerCtrl::GetValue ( ) const `[virtual]`

Returns the currently entered date.

For a control with wxDP_ALLOWNONE style the returned value may be invalid if no date is entered, otherwise it is always valid.

virtual void wxDatePickerCtrl::SetRange (const wxDateTime & *dt1*, const wxDateTime & *dt2*) [virtual]

Sets the valid range for the date selection.

If *dt1* is valid, it becomes the earliest date (inclusive) accepted by the control. If *dt2* is valid, it becomes the latest possible date.

Remarks

If the current value of the control is outside of the newly set range bounds, the behaviour is undefined.

virtual void wxDatePickerCtrl::SetValue (const wxDateTime & *dt*) [virtual]

Changes the current value of the control.

The date should be valid unless the control was created with wxDP_ALLOWNONE style and included in the currently selected range, if any.

Calling this method does not result in a date change event.

21.169 wxDateSpan Class Reference

`#include <wx/datetime.h>`

21.169.1 Detailed Description

This class is a "logical time span" and is useful for implementing program logic for such things as "add one month to the date" which, in general, doesn't mean to add 60∗60∗24∗31 seconds to it, but to take the same date the next month (to understand that this is indeed different consider adding one month to Feb, 15 – we want to get Mar, 15, of course).

When adding a month to the date, all lesser components (days, hours, ...) won't be changed unless the resulting date would be invalid: for example, Jan 31 + 1 month will be Feb 28, not (non-existing) Feb 31.

Because of this feature, adding and subtracting back again the same wxDateSpan will **not**, in general, give back the original date: Feb 28 - 1 month will be Jan 28, not Jan 31!

wxDateSpan objects can be either positive or negative. They may be multiplied by scalars which multiply all deltas by the scalar: i.e. 2∗(1 month and 1 day) is 2 months and 2 days. They can be added together with wxDateTime or wxTimeSpan, but the type of result is different for each case.

Warning

If you specify both weeks and days, the total number of days added will be 7∗weeks + days! See also GetTotalDays().

Equality operators are defined for wxDateSpans. Two wxDateSpans are equal if and only if they both give the same target date when added to **every** source date. Thus wxDateSpan::Months(1) is not equal to wxDateSpan::Days(30), because they don't give the same date when added to Feb 1st. But wxDateSpan::Days(14) is equal to wxDateSpan::Weeks(2).

Finally, notice that for adding hours, minutes and so on you don't need this class at all: wxTimeSpan will do the job because there are no subtleties associated with those (we don't support leap seconds).

Public Member Functions

- wxDateSpan (int years=0, int months=0, int weeks=0, int days=0)

  Constructs the date span object for the given number of years, months, weeks and days.
- wxDateSpan Add (const wxDateSpan &other) const

  Returns the sum of two date spans.
- wxDateSpan & Add (const wxDateSpan &other)

  Adds the given wxDateSpan to this wxDateSpan and returns a reference to itself.
- int GetDays () const

  Returns the number of days (not counting the weeks component) in this date span.
- int GetMonths () const

  Returns the number of the months (not counting the years) in this date span.
- int GetTotalMonths () const

  Returns the combined number of months in this date span, counting both years and months.
- int GetTotalDays () const

  Returns the combined number of days in this date span, counting both weeks and days.
- int GetWeeks () const

  Returns the number of weeks in this date span.
- int GetYears () const

  Returns the number of years in this date span.
- wxDateSpan Multiply (int factor) const

  Returns the product of the date span by the specified factor.
- wxDateSpan & Multiply (int factor)

  Multiplies this date span by the specified factor.
- wxDateSpan & Neg ()

  Changes the sign of this date span.
- wxDateSpan Negate () const

  Returns a date span with the opposite sign.
- wxDateSpan & SetDays (int n)

  Sets the number of days (without modifying any other components) in this date span.
- wxDateSpan & SetMonths (int n)

  Sets the number of months (without modifying any other components) in this date span.
- wxDateSpan & SetWeeks (int n)

  Sets the number of weeks (without modifying any other components) in this date span.
- wxDateSpan & SetYears (int n)

  Sets the number of years (without modifying any other components) in this date span.
- wxDateSpan Subtract (const wxDateSpan &other) const

  Returns the difference of two date spans.
- wxDateSpan & Subtract (const wxDateSpan &other)

  Subtracts the given wxDateSpan to this wxDateSpan and returns a reference to itself.
- wxDateSpan & operator+= (const wxDateSpan &other)

  Adds the given wxDateSpan to this wxDateSpan and returns the result.

- wxDateSpan & operator-= (const wxDateSpan &other)

  Subtracts the given wxDateSpan to this wxDateSpan and returns the result.
- wxDateSpan & operator- ()

  Changes the sign of this date span.
- wxDateSpan & operator*= (int factor)

  Multiplies this date span by the specified factor.
- bool operator!= (const wxDateSpan &other) const

  Returns true if this date span is different from the other one.
- bool operator== (const wxDateSpan &other) const

  Returns true if this date span is equal to the other one.

Static Public Member Functions

- static wxDateSpan Day ()

  Returns a date span object corresponding to one day.
- static wxDateSpan Days (int days)

  Returns a date span object corresponding to the given number of days.
- static wxDateSpan Month ()

  Returns a date span object corresponding to one month.
- static wxDateSpan Months (int mon)

  Returns a date span object corresponding to the given number of months.
- static wxDateSpan Week ()

  Returns a date span object corresponding to one week.
- static wxDateSpan Weeks (int weeks)

  Returns a date span object corresponding to the given number of weeks.
- static wxDateSpan Year ()

  Returns a date span object corresponding to one year.
- static wxDateSpan Years (int years)

  Returns a date span object corresponding to the given number of years.

21.169.2 Constructor & Destructor Documentation

wxDateSpan::wxDateSpan (int *years* = 0, int *months* = 0, int *weeks* = 0, int *days* = 0)

Constructs the date span object for the given number of years, months, weeks and days.

Note that the weeks and days add together if both are given.

21.169.3 Member Function Documentation

wxDateSpan wxDateSpan::Add (const wxDateSpan & *other*) const

Returns the sum of two date spans.

Returns

A new wxDateSpan object with the result.

wxDateSpan& wxDateSpan::Add (const wxDateSpan & *other*)

Adds the given wxDateSpan to this wxDateSpan and returns a reference to itself.

static wxDateSpan wxDateSpan::Day ( ) [static]

Returns a date span object corresponding to one day.

See also

Days()

static wxDateSpan wxDateSpan::Days (int *days*) [static]

Returns a date span object corresponding to the given number of days.

See also

Day()

int wxDateSpan::GetDays ( ) const

Returns the number of days (not counting the weeks component) in this date span.

See also

GetTotalDays()

int wxDateSpan::GetMonths ( ) const

Returns the number of the months (not counting the years) in this date span.

int wxDateSpan::GetTotalDays ( ) const

Returns the combined number of days in this date span, counting both weeks and days.

This doesn't take months or years into account.

See also

GetWeeks(), GetDays()

int wxDateSpan::GetTotalMonths ( ) const

Returns the combined number of months in this date span, counting both years and months.

See also

GetYears(), GetMonths()

Since

2.9.5

int wxDateSpan::GetWeeks ( ) const

Returns the number of weeks in this date span.

See also

GetTotalDays()

int wxDateSpan::GetYears ( ) const

Returns the number of years in this date span.

static wxDateSpan wxDateSpan::Month ( ) [static]

Returns a date span object corresponding to one month.

See also

Months()

static wxDateSpan wxDateSpan::Months (int *mon*) [static]

Returns a date span object corresponding to the given number of months.

See also

Month()

wxDateSpan wxDateSpan::Multiply (int *factor*) const

Returns the product of the date span by the specified *factor*.

The product is computed by multiplying each of the components by the *factor*.

Returns

A new wxDateSpan object with the result.

wxDateSpan& wxDateSpan::Multiply (int *factor*)

Multiplies this date span by the specified *factor*.

The product is computed by multiplying each of the components by the *factor*.

Returns

A reference to this wxDateSpan object modified in place.

wxDateSpan& wxDateSpan::Neg ( )

Changes the sign of this date span.

See also

Negate()

wxDateSpan wxDateSpan::Negate ( ) const

Returns a date span with the opposite sign.

See also

Neg()

bool wxDateSpan::operator!= (const wxDateSpan & *other*) const

Returns true if this date span is different from the other one.

wxDateSpan& wxDateSpan::operator*= (int *factor*)

Multiplies this date span by the specified *factor*.

The product is computed by multiplying each of the components by the *factor*.

Returns

A reference to this wxDateSpan object modified in place.

wxDateSpan& wxDateSpan::operator+= (const wxDateSpan & *other*)

Adds the given wxDateSpan to this wxDateSpan and returns the result.

wxDateSpan& wxDateSpan::operator- ( )

Changes the sign of this date span.

See also

Negate()

wxDateSpan& wxDateSpan::operator-= (const wxDateSpan & *other*)

Subtracts the given wxDateSpan to this wxDateSpan and returns the result.

bool wxDateSpan::operator== (const wxDateSpan & *other*) const

Returns true if this date span is equal to the other one.

Two date spans are considered equal if and only if they have the same number of years and months and the same total number of days (counting both days and weeks).

wxDateSpan& wxDateSpan::SetDays (int *n*)

Sets the number of days (without modifying any other components) in this date span.

wxDateSpan& wxDateSpan::SetMonths (int *n*)

Sets the number of months (without modifying any other components) in this date span.

wxDateSpan& wxDateSpan::SetWeeks (int *n*)

Sets the number of weeks (without modifying any other components) in this date span.

wxDateSpan& wxDateSpan::SetYears (int *n*)

Sets the number of years (without modifying any other components) in this date span.

wxDateSpan wxDateSpan::Subtract (const wxDateSpan & *other*) const

Returns the difference of two date spans.

Returns

A new wxDateSpan object with the result.

wxDateSpan& wxDateSpan::Subtract (const wxDateSpan & *other*)

Subtracts the given wxDateSpan to this wxDateSpan and returns a reference to itself.

static wxDateSpan wxDateSpan::Week ( ) [static]

Returns a date span object corresponding to one week.

See also

Weeks()

static wxDateSpan wxDateSpan::Weeks (int *weeks*) [static]

Returns a date span object corresponding to the given number of weeks.

See also

Week()

static wxDateSpan wxDateSpan::Year ( ) [static]

Returns a date span object corresponding to one year.

See also

Years()

static wxDateSpan wxDateSpan::Years (int *years*) [static]

Returns a date span object corresponding to the given number of years.

See also

Year()

21.170 wxDateTime Class Reference

`#include <wx/datetime.h>`

21.170.1 Detailed Description

wxDateTime class represents an absolute moment in time.

The type `wxDateTime_t` is typedefed as `unsigned short` and is used to contain the number of years, hours, minutes, seconds and milliseconds.

Global constant wxDefaultDateTime and synonym for it wxInvalidDateTime are defined. This constant will be different from any valid wxDateTime object.

21.170.2 Static Functions

All static functions either set or return the static variables of wxDateSpan (the country), return the current moment, year, month or number of days in it, or do some general calendar-related actions.

Please note that although several function accept an extra Calendar parameter, it is currently ignored as only the Gregorian calendar is supported. Future versions will support other calendars.

21.170.3 Date Formatting and Parsing

The date formatting and parsing functions convert wxDateTime objects to and from text. The conversions to text are mostly trivial: you can either do it using the default date and time representations for the current locale (FormatDate() and FormatTime()), using the international standard representation defined by ISO 8601 (FormatISODate(), FormatISOTime() and FormatISOCombined()) or by specifying any format at all and using Format() directly.

The conversions from text are more interesting, as there are much more possibilities to care about. The simplest cases can be taken care of with ParseFormat() which can parse any date in the given (rigid) format. ParseRfc822Date() is another function for parsing dates in predefined format – the one of RFC 822 which (still...) defines the format of email messages on the Internet. This format cannot be described with `strptime(3)-like` format strings used by Format(), hence the need for a separate function.

But the most interesting functions are ParseTime(), ParseDate() and ParseDateTime(). They try to parse the date and time (or only one of them) in 'free' format, i.e. allow them to be specified in any of possible ways. These functions will usually be used to parse the (interactive) user input which is not bound to be in any predefined format. As an example, ParseDate() can parse the strings such as "tomorrow", "March first" and even "next Sunday".

Finally notice that each of the parsing functions is available in several overloads: if the input string is a narrow (`char *`) string, then a narrow pointer is returned. If the input string is a wide string, a wide char pointer is returned. Finally, if the input parameter is a wxString, a narrow char pointer is also returned for backwards compatibility but there is also an additional argument of wxString::const_iterator type in which, if it is not NULL, an iterator pointing to the end of the scanned string part is returned.

Library: wxBase

Category: Data Structures

Predefined objects/pointers:

- wxDefaultDateTime

See also

Date and Time, wxTimeSpan, wxDateSpan, wxCalendarCtrl

Classes

- class TimeZone

  Class representing a time zone.

- struct Tm

  Contains broken down date-time representation.

Public Types

- enum TZ {
  Local,
  GMT_12,
  GMT_11,
  GMT_10,
  GMT_9,
  GMT_8,
  GMT_7,
  GMT_6,
  GMT_5,
  GMT_4,
  GMT_3,
  GMT_2,
  GMT_1,
  GMT0,
  GMT1,
  GMT2,
  GMT3,
  GMT4,
  GMT5,
  GMT6,
  GMT7,
  GMT8,
  GMT9,
  GMT10,
  GMT11,
  GMT12,
  GMT13,
  WET = GMT0,
  WEST = GMT1,
  CET = GMT1,
  CEST = GMT2,
  EET = GMT2,
  EEST = GMT3,
  MSK = GMT3,
  MSD = GMT4,
  AST = GMT_4,
  ADT = GMT_3,
  EST = GMT_5,
  EDT = GMT_4,
  CST = GMT_6,
  CDT = GMT_5,
  MST = GMT_7,
  MDT = GMT_6,
  PST = GMT_8,
  PDT = GMT_7,
  HST = GMT_10,
  AKST = GMT_9,
  AKDT = GMT_8,
  A_WST = GMT8,
  A_CST = GMT13 + 1,
  A_EST = GMT10,
  A_ESST = GMT11,
  NZST = GMT12,
  NZDT = GMT13,
  UTC = GMT0 }

Time zone symbolic names.

- enum Calendar {
  Gregorian,
  Julian }

  Several functions accept an extra parameter specifying the calendar to use (although most of them only support now the Gregorian calendar).
- enum Country {
  Country_Unknown,
  Country_Default,
  Country_WesternEurope_Start,
  Country_EEC = Country_WesternEurope_Start,
  France,
  Germany,
  UK,
  Country_WesternEurope_End = UK,
  Russia,
  USA }

  Date calculations often depend on the country and wxDateTime allows to set the country whose conventions should be used using SetCountry().
- enum Month {
  Jan,
  Feb,
  Mar,
  Apr,
  May,
  Jun,
  Jul,
  Aug,
  Sep,
  Oct,
  Nov,
  Dec,
  Inv_Month }

  symbolic names for the months
- enum WeekDay {
  Sun,
  Mon,
  Tue,
  Wed,
  Thu,
  Fri,
  Sat,
  Inv_WeekDay }

  symbolic names for the weekdays
- enum Year { Inv_Year = SHRT_MIN }

  invalid value for the year
- enum NameFlags {
  Name_Full = 0x01,
  Name_Abbr = 0x02 }

  Flags to be used with GetMonthName() and GetWeekDayName() functions.
- enum WeekFlags {
  Default_First,
  Monday_First,
  Sunday_First }

  Different parts of the world use different conventions for the week start.
- typedef unsigned short wxDateTime_t

  A small unsigned integer type for storing things like minutes, seconds &c.

Public Member Functions

Constructors, Assignment Operators and Setters

Constructors and various Set() methods are collected here.

If you construct a date object from separate values for day, month and year, you should use IsValid() method to check that the values were correct as constructors cannot return an error code.

- wxDateTime ()
  Default constructor.
- wxDateTime (const wxDateTime &date)
  Copy constructor.
- wxDateTime (time_t timet)
  Same as Set().
- wxDateTime (const struct tm &tm)
  Same as Set().
- wxDateTime (double jdn)
  Same as Set().
- wxDateTime (wxDateTime_t hour, wxDateTime_t minute=0, wxDateTime_t second=0, wxDateTime_t millisec=0)
  Same as Set().
- wxDateTime (wxDateTime_t day, Month month, int year=Inv_Year, wxDateTime_t hour=0, wxDateTime_t minute=0, wxDateTime_t second=0, wxDateTime_t millisec=0)
  Same as Set().
- wxDateTime (const struct _SYSTEMTIME &st)
  Same as SetFromMSWSysTime.
- wxDateTime & ResetTime ()
  Reset time to midnight (00:00:00) without changing the date.
- wxDateTime & Set (time_t timet)
  Constructs the object from timet value holding the number of seconds since Jan 1, 1970 UTC.
- wxDateTime & Set (const struct tm &tm)
  Sets the date and time from the broken down representation in the standard tm structure.
- wxDateTime & Set (const Tm &tm)
  Sets the date and time from the broken down representation in the wxDateTime::Tm structure.
- wxDateTime & Set (double jdn)
  Sets the date from the so-called Julian Day Number.
- wxDateTime & Set (wxDateTime_t hour, wxDateTime_t minute=0, wxDateTime_t second=0, wxDateTime_t millisec=0)
  Sets the date to be equal to Today() and the time from supplied parameters.
- wxDateTime & Set (wxDateTime_t day, Month month, int year=Inv_Year, wxDateTime_t hour=0, wxDateTime_t minute=0, wxDateTime_t second=0, wxDateTime_t millisec=0)
  Sets the date and time from the parameters.
- wxDateTime & SetDay (unsigned short day)
  Sets the day without changing other date components.
- wxDateTime & SetFromDOS (unsigned long ddt)
  Sets the date from the date and time in DOS format.
- wxDateTime & SetHour (unsigned short hour)
  Sets the hour without changing other date components.
- wxDateTime & SetMillisecond (unsigned short millisecond)
  Sets the millisecond without changing other date components.
- wxDateTime & SetMinute (unsigned short minute)
  Sets the minute without changing other date components.
- wxDateTime & SetMonth (Month month)
  Sets the month without changing other date components.
- wxDateTime & SetSecond (unsigned short second)
  Sets the second without changing other date components.
- wxDateTime & SetToCurrent ()
  Sets the date and time of to the current values.
- wxDateTime & SetYear (int year)
  Sets the year without changing other date components.

- wxDateTime & operator= (time_t timet)
  Same as Set().
- wxDateTime & operator= (const struct tm &tm)
  Same as Set().

Accessors

Here are the trivial accessors.

Other functions, which might have to perform some more complicated calculations to find the answer are under the "Date Arithmetics" section.

- unsigned long GetAsDOS () const
  Returns the date and time in DOS format.
- wxDateTime & SetFromMSWSysTime (const struct _SYSTEMTIME &st)
  Initialize using the Windows SYSTEMTIME structure.
- void GetAsMSWSysTime (struct _SYSTEMTIME *st) const
  Returns the date and time in the Windows SYSTEMTIME format.
- int GetCentury (const TimeZone &tz=Local) const
  Returns the century of this date.
- wxDateTime GetDateOnly () const
  Returns the object having the same date component as this one but time of 00:00:00.
- unsigned short GetDay (const TimeZone &tz=Local) const
  Returns the day in the given timezone (local one by default).
- unsigned short GetDayOfYear (const TimeZone &tz=Local) const
  Returns the day of the year (in 1-366 range) in the given timezone (local one by default).
- unsigned short GetHour (const TimeZone &tz=Local) const
  Returns the hour in the given timezone (local one by default).
- unsigned short GetMillisecond (const TimeZone &tz=Local) const
  Returns the milliseconds in the given timezone (local one by default).
- unsigned short GetMinute (const TimeZone &tz=Local) const
  Returns the minute in the given timezone (local one by default).
- Month GetMonth (const TimeZone &tz=Local) const
  Returns the month in the given timezone (local one by default).
- unsigned short GetSecond (const TimeZone &tz=Local) const
  Returns the seconds in the given timezone (local one by default).
- time_t GetTicks () const
  Returns the number of seconds since Jan 1, 1970 UTC.
- Tm GetTm (const TimeZone &tz=Local) const
  Returns broken down representation of the date and time.
- WeekDay GetWeekDay (const TimeZone &tz=Local) const
  Returns the week day in the given timezone (local one by default).
- int GetWeekBasedYear (const TimeZone &tz) const
  Returns the year to which the week containing this date belongs.
- wxDateTime_t GetWeekOfMonth (WeekFlags flags=Monday_First, const TimeZone &tz=Local) const
  Returns the ordinal number of the week in the month (in 1-5 range).
- wxDateTime_t GetWeekOfYear (WeekFlags flags=Monday_First, const TimeZone &tz=Local) const
  Returns the number of the week of the year this date is in.
- int GetYear (const TimeZone &tz=Local) const
  Returns the year in the given timezone (local one by default).
- bool IsValid () const
  Returns true if the object represents a valid time moment.
- bool IsWorkDay (Country country=Country_Default) const
  Returns true is this day is not a holiday in the given country.

Date Comparison

There are several functions to allow date comparison.

To supplement them, a few global operators, etc taking wxDateTime are defined.

- bool IsEarlierThan (const wxDateTime &datetime) const

Returns true if this date precedes the given one.

- bool IsEqualTo (const wxDateTime &datetime) const

  Returns true if the two dates are strictly identical.
- bool IsEqualUpTo (const wxDateTime &dt, const wxTimeSpan &ts) const

  Returns true if the date is equal to another one up to the given time interval, i.e. if the absolute difference between the two dates is less than this interval.
- bool IsLaterThan (const wxDateTime &datetime) const

  Returns true if this date is later than the given one.
- bool IsSameDate (const wxDateTime &dt) const

  Returns true if the date is the same without comparing the time parts.
- bool IsSameTime (const wxDateTime &dt) const

  Returns true if the time is the same (although dates may differ).
- bool IsStrictlyBetween (const wxDateTime &t1, const wxDateTime &t2) const

  Returns true if this date lies strictly between the two given dates.
- bool IsBetween (const wxDateTime &t1, const wxDateTime &t2) const

  Returns true if IsStrictlyBetween() is true or if the date is equal to one of the limit values.

Date Arithmetics

These functions carry out arithmetics on the wxDateTime objects.

As explained in the overview, either wxTimeSpan or wxDateSpan may be added to wxDateTime, hence all functions are overloaded to accept both arguments.

Also, both Add() and Subtract() have both const and non-const version. The first one returns a new object which represents the sum/difference of the original one with the argument while the second form modifies the object to which it is applied. The operators "-=" and "+=" are defined to be equivalent to the second forms of these functions.

- wxDateTime Add (const wxDateSpan &diff) const

  Adds the given date span to this object.
- wxDateTime & Add (const wxDateSpan &diff)

  Adds the given date span to this object.
- wxDateTime Add (const wxTimeSpan &diff) const

  Adds the given time span to this object.
- wxDateTime & Add (const wxTimeSpan &diff)

  Adds the given time span to this object.
- wxDateTime Subtract (const wxTimeSpan &diff) const

  Subtracts the given time span from this object.
- wxDateTime & Subtract (const wxTimeSpan &diff)

  Subtracts the given time span from this object.
- wxDateTime Subtract (const wxDateSpan &diff) const

  Subtracts the given date span from this object.
- wxDateTime & Subtract (const wxDateSpan &diff)

  Subtracts the given date span from this object.
- wxTimeSpan Subtract (const wxDateTime &dt) const

  Subtracts another date from this one and returns the difference between them as a wxTimeSpan.
- wxDateSpan DiffAsDateSpan (const wxDateTime &dt) const

  Returns the difference between this object and dt as a wxDateSpan.
- wxDateTime & operator+= (const wxDateSpan &diff)

  Adds the given date span to this object.
- wxDateTime operator+ (const wxDateSpan &ds) const

  Adds the given date span to this object.
- wxDateTime & operator-= (const wxDateSpan &diff)

  Subtracts the given date span from this object.
- wxDateTime operator- (const wxDateSpan &ds) const

  Subtracts the given date span from this object.
- wxDateTime & operator+= (const wxTimeSpan &diff)

  Adds the given time span to this object.
- wxDateTime operator+ (const wxTimeSpan &ts) const

  Adds the given time span to this object.

- wxDateTime & operator-= (const wxTimeSpan &diff)
  Subtracts the given time span from this object.
- wxDateTime operator- (const wxTimeSpan &ts) const
  Subtracts the given time span from this object.
- wxTimeSpan operator- (const wxDateTime &dt2) const
  Subtracts another date from this one and returns the difference between them as a wxTimeSpan.

Date Formatting and Parsing

See Date Formatting and Parsing

- wxString Format (const wxString &format=wxDefaultDateTimeFormat, const TimeZone &tz=Local) const
  This function does the same as the standard ANSI C `strftime(3)` function (http://www.cplusplus.com/reference/clibrary/ctime/strftime.html).
- wxString FormatDate () const
  Identical to calling Format() with `"%x"` argument (which means "preferred date representation for the current locale").
- wxString FormatISOCombined (char sep= 'T') const
  Returns the combined date-time representation in the ISO 8601 format `"YYYY-MM-DDTHH:MM:SS"`.
- wxString FormatISODate () const
  This function returns the date representation in the ISO 8601 format `"YYYY-MM-DD"`.
- wxString FormatISOTime () const
  This function returns the time representation in the ISO 8601 format `"HH:MM:SS"`.
- wxString FormatTime () const
  Identical to calling Format() with `"%X"` argument (which means "preferred time representation for the current locale").
- bool ParseDate (const wxString &date, wxString::const_iterator *end)
  This function is like ParseDateTime(), but it only allows the date to be specified.
- bool ParseDateTime (const wxString &datetime, wxString::const_iterator *end)
  Parses the string datetime containing the date and time in free format.
- bool ParseFormat (const wxString &date, const wxString &format, const wxDateTime &dateDef, wxString::const_iterator *end)
  This function parses the string date according to the given format.
- bool ParseFormat (const wxString &date, const wxString &format, wxString::const_iterator *end)
  This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.
- bool ParseFormat (const wxString &date, wxString::const_iterator *end)
  This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.
- bool ParseISOCombined (const wxString &date, char sep= 'T')
  This function parses the string containing the date and time in ISO 8601 combined format `"YYYY-MM-DDTHH:MM:SS"`.
- bool ParseISODate (const wxString &date)
  This function parses the date in ISO 8601 format `"YYYY-MM-DD"`.
- bool ParseISOTime (const wxString &date)
  This function parses the time in ISO 8601 format `"HH:MM:SS"`.
- bool ParseRfc822Date (const wxString &date, wxString::const_iterator *end)
  Parses the string date looking for a date formatted according to the RFC 822 in it.
- bool ParseTime (const wxString &time, wxString::const_iterator *end)
  This functions is like ParseDateTime(), but only allows the time to be specified in the input string.

Calendar Calculations

The functions in this section perform the basic calendar calculations, mostly related to the week days.

They allow to find the given week day in the week with given number (either in the month or in the year) and so on.

None of the functions in this section modify the time part of the wxDateTime, they only work with the date part of it.

- wxDateTime GetLastMonthDay (Month month=Inv_Month, int year=Inv_Year) const

Returns the copy of this object to which SetToLastMonthDay() was applied.

- wxDateTime GetLastWeekDay (WeekDay weekday, Month month=Inv_Month, int year=Inv_Year)

  Returns the copy of this object to which SetToLastWeekDay() was applied.
- wxDateTime GetNextWeekDay (WeekDay weekday) const

  Returns the copy of this object to which SetToNextWeekDay() was applied.
- wxDateTime GetPrevWeekDay (WeekDay weekday) const

  Returns the copy of this object to which SetToPrevWeekDay() was applied.
- wxDateTime GetWeekDay (WeekDay weekday, int n=1, Month month=Inv_Month, int year=Inv_Year) const

  Returns the copy of this object to which SetToWeekDay() was applied.
- wxDateTime GetWeekDayInSameWeek (WeekDay weekday, WeekFlags flags=Monday_First) const

  Returns the copy of this object to which SetToWeekDayInSameWeek() was applied.
- wxDateTime GetYearDay (wxDateTime_t yday) const

  Returns the copy of this object to which SetToYearDay() was applied.
- wxDateTime & SetToLastMonthDay (Month month=Inv_Month, int year=Inv_Year)

  Sets the date to the last day in the specified month (the current one by default).
- bool SetToLastWeekDay (WeekDay weekday, Month month=Inv_Month, int year=Inv_Year)

  The effect of calling this function is the same as of calling `SetToWeekDay`(-1, weekday, month, year).
- wxDateTime & SetToNextWeekDay (WeekDay weekday)

  Sets the date so that it will be the first weekday following the current date.
- wxDateTime & SetToPrevWeekDay (WeekDay weekday)

  Sets the date so that it will be the last weekday before the current date.
- bool SetToWeekDay (WeekDay weekday, int n=1, Month month=Inv_Month, int year=Inv_Year)

  Sets the date to the n-th weekday in the given month of the given year (the current month and year are used by default).
- wxDateTime & SetToWeekDayInSameWeek (WeekDay weekday, WeekFlags flags=Monday_First)

  Adjusts the date so that it will still lie in the same week as before, but its week day will be the given one.
- wxDateTime & SetToYearDay (wxDateTime_t yday)

  Sets the date to the day number yday in the same year (i.e. unlike the other functions, this one does not use the current year).

Astronomical/Historical Functions

Some degree of support for the date units used in astronomy and/or history is provided.

You can construct a wxDateTime object from a JDN and you may also get its JDN, MJD or Rata Die number from it.

Related functions in other groups: wxDateTime(double), Set(double)

- double GetJDN () const

  Synonym for GetJulianDayNumber().
- double GetJulianDayNumber () const

  Returns the JDN corresponding to this date.
- double GetMJD () const

  Synonym for GetModifiedJulianDayNumber().
- double GetModifiedJulianDayNumber () const

  Returns the "Modified Julian Day Number" (MJD) which is, by definition, is equal to JDN - 2400000.5.
- double GetRataDie () const

  Return the Rata Die number of this date.

Time Zone and DST Support

Please see the time zone overview for more information about time zones.

Normally, these functions should be rarely used.

Related functions in other groups: GetBeginDST(), GetEndDST()

- wxDateTime FromTimezone (const TimeZone &tz, bool noDST=false) const

  Transform the date from the given time zone to the local one.
- int IsDST (Country country=Country_Default) const

  Returns true if the DST is applied for this date in the given country.
- wxDateTime & MakeFromTimezone (const TimeZone &tz, bool noDST=false)

Same as FromTimezone() but modifies the object in place.

- wxDateTime & MakeTimezone (const TimeZone &tz, bool noDST=false)

  Modifies the object in place to represent the date in another time zone.
- wxDateTime & MakeUTC (bool noDST=false)

  This is the same as calling MakeTimezone() with the argument `GMT0`.
- wxDateTime ToTimezone (const TimeZone &tz, bool noDST=false) const

  Transform the date to the given time zone.
- wxDateTime ToUTC (bool noDST=false) const

  This is the same as calling ToTimezone() with the argument `GMT0`.

Static Public Member Functions

- static int ConvertYearToBC (int year)

  Converts the year in absolute notation (i.e. a number which can be negative, positive or zero) to the year in BC/AD notation.
- static void GetAmPmStrings (wxString *am, wxString *pm)

  Returns the translations of the strings `AM` and `PM` used for time formatting for the current locale.
- static wxDateTime GetBeginDST (int year=Inv_Year, Country country=Country_Default)

  Get the beginning of DST for the given country in the given year (current one by default).
- static wxDateTime GetEndDST (int year=Inv_Year, Country country=Country_Default)

  Returns the end of DST for the given country in the given year (current one by default).
- static int GetCentury (int year)

  Get the current century, i.e. first two digits of the year, in given calendar (only Gregorian is currently supported).
- static Country GetCountry ()

  Returns the current default country.
- static Month GetCurrentMonth (Calendar cal=Gregorian)

  Get the current month in given calendar (only Gregorian is currently supported).
- static int GetCurrentYear (Calendar cal=Gregorian)

  Get the current year in given calendar (only Gregorian is currently supported).
- static wxString GetEnglishMonthName (Month month, NameFlags flags=Name_Full)

  Return the standard English name of the given month.
- static wxString GetEnglishWeekDayName (WeekDay weekday, NameFlags flags=Name_Full)

  Return the standard English name of the given week day.
- static wxString GetMonthName (Month month, NameFlags flags=Name_Full)

  Gets the full (default) or abbreviated name of the given month.
- static wxDateTime_t GetNumberOfDays (int year, Calendar cal=Gregorian)

  Returns the number of days in the given year.
- static wxDateTime_t GetNumberOfDays (Month month, int year=Inv_Year, Calendar cal=Gregorian)

  Returns the number of days in the given month of the given year.
- static time_t GetTimeNow ()

  Returns the current time.
- static tm * GetTmNow (struct tm *tm)

  Returns the current time broken down using the buffer whose address is passed to the function with tm to store the result.
- static tm * GetTmNow ()

  Returns the current time broken down.
- static wxString GetWeekDayName (WeekDay weekday, NameFlags flags=Name_Full)

  Gets the full (default) or abbreviated name of the given week day.
- static bool IsDSTApplicable (int year=Inv_Year, Country country=Country_Default)

  Returns true if DST was used in the given year (the current one by default) in the given country.
- static bool IsLeapYear (int year=Inv_Year, Calendar cal=Gregorian)

  Returns true if the year is a leap one in the specified calendar.

- static bool IsWestEuropeanCountry (Country country=Country_Default)

  This function returns true if the specified (or default) country is one of Western European ones.
- static wxDateTime Now ()

  Returns the object corresponding to the current time.
- static void SetCountry (Country country)

  Sets the country to use by default.
- static wxDateTime SetToWeekOfYear (int year, wxDateTime_t numWeek, WeekDay weekday=Mon)

  Set the date to the given weekday in the week number numWeek of the given year .
- static wxDateTime Today ()

  Returns the object corresponding to the midnight of the current day (i.e. the same as Now(), but the time part is set to 0).
- static wxDateTime UNow ()

  Returns the object corresponding to the current UTC time including the milliseconds.

21.170.4 Member Typedef Documentation

typedef unsigned short wxDateTime::wxDateTime_t

A small unsigned integer type for storing things like minutes, seconds &c.

It should be at least short (i.e. not char) to contain the number of milliseconds - it may also be 'int' because there is no size penalty associated with it in our code, we don't store any data in this format.

21.170.5 Member Enumeration Documentation

enum wxDateTime::Calendar

Several functions accept an extra parameter specifying the calendar to use (although most of them only support now the Gregorian calendar).

This parameters is one of the following values.

Enumerator

Gregorian calendar currently in use in Western countries

Julian calendar in use since -45 until the 1582 (or later)

enum wxDateTime::Country

Date calculations often depend on the country and wxDateTime allows to set the country whose conventions should be used using SetCountry().

It takes one of the following values as parameter.

Enumerator

Country_Unknown no special information for this country

Country_Default set the default country with SetCountry() method or use the default country with any other

Country_WesternEurope_Start

Country_EEC

France

Germany

UK

Country_WesternEurope_End

Russia

USA

enum wxDateTime::Month

symbolic names for the months

Enumerator

Jan

Feb

Mar

Apr

May

Jun

Jul

Aug

Sep

Oct

Nov

Dec

Inv_Month Invalid month value.

enum wxDateTime::NameFlags

Flags to be used with GetMonthName() and GetWeekDayName() functions.

Enumerator

Name_Full return full name

Name_Abbr return abbreviated name

enum wxDateTime::TZ

Time zone symbolic names.

Enumerator

Local the time in the current time zone

GMT_12 zones from GMT (= Greenwich Mean Time): they're guaranteed to be consequent numbers, so writing something like 'GMT0 + offset' is safe if abs(offset) <= 12

GMT_11 zones from GMT (= Greenwich Mean Time): they're guaranteed to be consequent numbers, so writing something like 'GMT0 + offset' is safe if abs(offset) <= 12

GMT_10 zones from GMT (= Greenwich Mean Time): they're guaranteed to be consequent numbers, so writing something like 'GMT0 + offset' is safe if abs(offset) <= 12

GMT_9 zones from GMT (= Greenwich Mean Time): they're guaranteed to be consequent numbers, so writing something like 'GMT0 + offset' is safe if abs(offset) <= 12

GMT_8 zones from GMT (= Greenwich Mean Time): they're guaranteed to be consequent numbers, so writing something like 'GMT0 + offset' is safe if abs(offset) <= 12

GMT_7 zones from GMT (= Greenwich Mean Time): they're guaranteed to be consequent numbers, so writing something like 'GMT0 + offset' is safe if abs(offset) <= 12

GMT_6 zones from GMT (= Greenwich Mean Time): they're guaranteed to be consequent numbers, so writing something like 'GMT0 + offset' is safe if abs(offset) <= 12

GMT_5 zones from GMT (= Greenwich Mean Time): they're guaranteed to be consequent numbers, so writing something like 'GMT0 + offset' is safe if abs(offset) <= 12

GMT_4 zones from GMT (= Greenwich Mean Time): they're guaranteed to be consequent numbers, so writing something like 'GMT0 + offset' is safe if abs(offset) <= 12

GMT_3 zones from GMT (= Greenwich Mean Time): they're guaranteed to be consequent numbers, so writing something like 'GMT0 + offset' is safe if abs(offset) <= 12

GMT_2 zones from GMT (= Greenwich Mean Time): they're guaranteed to be consequent numbers, so writing something like 'GMT0 + offset' is safe if abs(offset) <= 12

GMT_1 zones from GMT (= Greenwich Mean Time): they're guaranteed to be consequent numbers, so writing something like 'GMT0 + offset' is safe if abs(offset) <= 12

GMT0 zones from GMT (= Greenwich Mean Time): they're guaranteed to be consequent numbers, so writing something like 'GMT0 + offset' is safe if abs(offset) <= 12

GMT1 zones from GMT (= Greenwich Mean Time): they're guaranteed to be consequent numbers, so writing something like 'GMT0 + offset' is safe if abs(offset) <= 12

GMT2 zones from GMT (= Greenwich Mean Time): they're guaranteed to be consequent numbers, so writing something like 'GMT0 + offset' is safe if abs(offset) <= 12

GMT3 zones from GMT (= Greenwich Mean Time): they're guaranteed to be consequent numbers, so writing something like 'GMT0 + offset' is safe if abs(offset) <= 12

GMT4 zones from GMT (= Greenwich Mean Time): they're guaranteed to be consequent numbers, so writing something like 'GMT0 + offset' is safe if abs(offset) <= 12

GMT5 zones from GMT (= Greenwich Mean Time): they're guaranteed to be consequent numbers, so writing something like 'GMT0 + offset' is safe if abs(offset) <= 12

GMT6 zones from GMT (= Greenwich Mean Time): they're guaranteed to be consequent numbers, so writing something like 'GMT0 + offset' is safe if abs(offset) <= 12

GMT7 zones from GMT (= Greenwich Mean Time): they're guaranteed to be consequent numbers, so writing something like 'GMT0 + offset' is safe if abs(offset) <= 12

GMT8 zones from GMT (= Greenwich Mean Time): they're guaranteed to be consequent numbers, so writing something like 'GMT0 + offset' is safe if abs(offset) <= 12

GMT9 zones from GMT (= Greenwich Mean Time): they're guaranteed to be consequent numbers, so writing something like 'GMT0 + offset' is safe if abs(offset) <= 12

GMT10 zones from GMT (= Greenwich Mean Time): they're guaranteed to be consequent numbers, so writing something like 'GMT0 + offset' is safe if abs(offset) <= 12

GMT11 zones from GMT (= Greenwich Mean Time): they're guaranteed to be consequent numbers, so writing something like 'GMT0 + offset' is safe if abs(offset) <= 12

GMT12 zones from GMT (= Greenwich Mean Time): they're guaranteed to be consequent numbers, so writing something like 'GMT0 + offset' is safe if abs(offset) <= 12

GMT13 zones from GMT (= Greenwich Mean Time): they're guaranteed to be consequent numbers, so writing something like 'GMT0 + offset' is safe if abs(offset) <= 12

enum wxDateTime::WeekDay

symbolic names for the weekdays

Enumerator

Sun

Mon

Tue

Wed

Thu

Fri

Sat

Inv_WeekDay Invalid week day value.

enum wxDateTime::WeekFlags

Different parts of the world use different conventions for the week start.

In some countries, the week starts on Sunday, while in others – on Monday. The ISO standard doesn't address this issue, so we support both conventions in the functions whose result depends on it (GetWeekOfYear() and GetWeekOfMonth()).

The desired behaviour may be specified by giving one of the following constants as argument to these functions.

Enumerator

Default_First Sunday_First for US, Monday_First for the rest.

Monday_First week starts with a Monday

Sunday_First week starts with a Sunday

enum wxDateTime::Year

invalid value for the year

Enumerator

Inv_Year

21.170.6 Constructor & Destructor Documentation

wxDateTime::wxDateTime ( )

Default constructor.

Use one of the Set() functions to initialize the object later.

wxDateTime::wxDateTime (const wxDateTime & *date*)

Copy constructor.

wxDateTime::wxDateTime (time_t *timet*)

Same as Set().

wxDateTime::wxDateTime (const struct tm & *tm*)

Same as Set().

wxDateTime::wxDateTime (double *jdn*)

Same as Set().

wxDateTime::wxDateTime (wxDateTime_t *hour*, wxDateTime_t *minute* = 0, wxDateTime_t *second* = 0, wxDateTime_t *millisec* = 0)

Same as Set().

wxDateTime::wxDateTime (wxDateTime_t *day*, Month *month*, int *year* = Inv_Year, wxDateTime_t *hour* = 0, wxDateTime_t *minute* = 0, wxDateTime_t *second* = 0, wxDateTime_t *millisec* = 0)

Same as Set().

wxDateTime::wxDateTime (const struct _SYSTEMTIME & *st*)

Same as SetFromMSWSysTime.

Parameters

st	Input, Windows SYSTEMTIME reference

Since

2.9.0

Remarks

MSW only Availability: only available for the wxMSW port.

21.170.7 Member Function Documentation

wxDateTime wxDateTime::Add (const wxDateSpan & *diff*) const

Adds the given date span to this object.

wxDateTime& wxDateTime::Add (const wxDateSpan & *diff*)

Adds the given date span to this object.

wxDateTime wxDateTime::Add (const wxTimeSpan & *diff*) const

Adds the given time span to this object.

wxDateTime& wxDateTime::Add (const wxTimeSpan & *diff*)

Adds the given time span to this object.

static int wxDateTime::ConvertYearToBC (int *year*) [static]

Converts the year in absolute notation (i.e. a number which can be negative, positive or zero) to the year in BC/AD notation.

For the positive years, nothing is done, but the year 0 is year 1 BC and so for other years there is a difference of 1.

This function should be used like this:

```
wxDateTime dt(...);
int y = dt.GetYear();
printf("The year is %d%s", wxDateTime::ConvertYearToBC(y), y > 0 ? "AD" : "BC");
```

wxDateSpan wxDateTime::DiffAsDateSpan (const wxDateTime & *dt*) const

Returns the difference between this object and *dt* as a wxDateSpan.

This method allows to find the number of entire years, months, weeks and days between *dt* and this date.

Since

2.9.5

wxString wxDateTime::Format (const wxString & *format* = wxDefaultDateTimeFormat, const TimeZone & *tz* = Local) const

This function does the same as the standard ANSI C `strftime(3)` function (http://www.cplusplus.com/reference/clibrary/ctime/strftime.html).

Please see its description for the meaning of *format* parameter.

Notice that POSIX `"%g"`, `"%G"`, `"%V"` and `"%z"` format specifiers are supported even if the standard library doesn't support them (e.g. MSVC).

It also accepts a few wxWidgets-specific extensions: you can optionally specify the width of the field to follow using `printf(3)`-like syntax and the format specification `"%l"` can be used to get the number of milliseconds.

See also

ParseFormat()

wxString wxDateTime::FormatDate ( ) const

Identical to calling Format() with "%x" argument (which means "preferred date representation for the current locale").

wxString wxDateTime::FormatISOCombined (char *sep* = 'T') const

Returns the combined date-time representation in the ISO 8601 format "YYYY-MM-DDTHH:MM:SS".

The *sep* parameter default value produces the result exactly corresponding to the ISO standard, but it can also be useful to use a space as separator if a more human-readable combined date-time representation is needed.

See also

FormatISODate(), FormatISOTime(), ParseISOCombined()

wxString wxDateTime::FormatISODate ( ) const

This function returns the date representation in the ISO 8601 format "YYYY-MM-DD".

wxString wxDateTime::FormatISOTime ( ) const

This function returns the time representation in the ISO 8601 format "HH:MM:SS".

wxString wxDateTime::FormatTime ( ) const

Identical to calling Format() with "%X" argument (which means "preferred time representation for the current locale").

wxDateTime wxDateTime::FromTimezone (const TimeZone & *tz*, bool *noDST* = false) const

Transform the date from the given time zone to the local one.

If *noDST* is true, no DST adjustments will be made.

Returns

The date in the local time zone.

static void wxDateTime::GetAmPmStrings (wxString * *am*, wxString * *pm*) [static]

Returns the translations of the strings AM and PM used for time formatting for the current locale.

Either of the pointers may be NULL if the corresponding value is not needed.

unsigned long wxDateTime::GetAsDOS ( ) const

Returns the date and time in DOS format.

void wxDateTime::GetAsMSWSysTime (struct _SYSTEMTIME * *st*) const

Returns the date and time in the Windows SYSTEMTIME format.

Parameters

st	Output, pointer to Windows SYSTEMTIME

Since

2.9.0

Remarks

MSW only Availability: only available for the wxMSW port.

static wxDateTime wxDateTime::GetBeginDST (int *year* = Inv_Year, Country *country* = Country_Default) [static]

Get the beginning of DST for the given country in the given year (current one by default).

This function suffers from limitations described in the DST overview.

See also

GetEndDST()

int wxDateTime::GetCentury (const TimeZone & *tz* = Local) const

Returns the century of this date.

static int wxDateTime::GetCentury (int *year*) [static]

Get the current century, i.e. first two digits of the year, in given calendar (only Gregorian is currently supported).

static Country wxDateTime::GetCountry ( ) [static]

Returns the current default country.

The default country is used for DST calculations, for example.

See also

SetCountry()

static Month wxDateTime::GetCurrentMonth (Calendar *cal* = Gregorian) [static]

Get the current month in given calendar (only Gregorian is currently supported).

static int wxDateTime::GetCurrentYear (Calendar *cal* = Gregorian) [static]

Get the current year in given calendar (only Gregorian is currently supported).

wxDateTime wxDateTime::GetDateOnly ( ) const

Returns the object having the same date component as this one but time of 00:00:00.

Since

2.8.2

See also

ResetTime()

unsigned short wxDateTime::GetDay (const TimeZone & *tz* = Local) const

Returns the day in the given timezone (local one by default).

unsigned short wxDateTime::GetDayOfYear (const TimeZone & *tz* = Local) const

Returns the day of the year (in 1-366 range) in the given timezone (local one by default).

static wxDateTime wxDateTime::GetEndDST (int *year* = Inv_Year, Country *country* = Country_Default) [static]

Returns the end of DST for the given country in the given year (current one by default).

See also

GetBeginDST()

static wxString wxDateTime::GetEnglishMonthName (Month *month*, NameFlags *flags* = Name_Full) [static]

Return the standard English name of the given month.

This function always returns "January" or "Jan" for January, use GetMonthName() to retrieve the name of the month in the users current locale.

Parameters

month	One of wxDateTime::Jan, ..., wxDateTime::Dec values.
flags	Either Name_Full (default) or Name_Abbr.

See also

GetEnglishWeekDayName()

Since

2.9.0

static wxString wxDateTime::GetEnglishWeekDayName (WeekDay *weekday*, NameFlags *flags* = Name_Full) [static]

Return the standard English name of the given week day.

This function always returns "Monday" or "Mon" for Monday, use GetWeekDayName() to retrieve the name of the month in the users current locale.

Parameters

weekday	One of wxDateTime::Sun, ..., wxDateTime::Sat values.
flags	Either Name_Full (default) or Name_Abbr.

See also

GetEnglishMonthName()

Since

2.9.0

unsigned short wxDateTime::GetHour (const TimeZone & *tz* = Local) const

Returns the hour in the given timezone (local one by default).

double wxDateTime::GetJDN ( ) const

Synonym for GetJulianDayNumber().

double wxDateTime::GetJulianDayNumber ( ) const

Returns the JDN corresponding to this date.

Beware of rounding errors!

See also

GetModifiedJulianDayNumber()

wxDateTime wxDateTime::GetLastMonthDay (Month *month* = Inv_Month, int *year* = Inv_Year) const

Returns the copy of this object to which SetToLastMonthDay() was applied.

wxDateTime wxDateTime::GetLastWeekDay (WeekDay *weekday*, Month *month* = Inv_Month, int *year* = Inv_Year)

Returns the copy of this object to which SetToLastWeekDay() was applied.

unsigned short wxDateTime::GetMillisecond (const TimeZone & *tz* = Local) const

Returns the milliseconds in the given timezone (local one by default).

unsigned short wxDateTime::GetMinute (const TimeZone & *tz* = Local) const

Returns the minute in the given timezone (local one by default).

double wxDateTime::GetMJD ( ) const

Synonym for GetModifiedJulianDayNumber().

double wxDateTime::GetModifiedJulianDayNumber ( ) const

Returns the *"Modified Julian Day Number"* (MJD) which is, by definition, is equal to JDN - 2400000.5.

The MJDs are simpler to work with as the integral MJDs correspond to midnights of the dates in the Gregorian calendar and not the noons like JDN. The MJD 0 represents Nov 17, 1858.

Month wxDateTime::GetMonth (const TimeZone & *tz* = Local) const

Returns the month in the given timezone (local one by default).

static wxString wxDateTime::GetMonthName (Month *month*, NameFlags *flags* = Name_Full) [static]

Gets the full (default) or abbreviated name of the given month.

This function returns the name in the current locale, use GetEnglishMonthName() to get the untranslated name if necessary.

Parameters

month	One of wxDateTime::Jan, ..., wxDateTime::Dec values.
flags	Either Name_Full (default) or Name_Abbr.

See also

GetWeekDayName()

wxDateTime wxDateTime::GetNextWeekDay (WeekDay *weekday*) const

Returns the copy of this object to which SetToNextWeekDay() was applied.

static wxDateTime_t wxDateTime::GetNumberOfDays (int *year*, Calendar *cal* = Gregorian) [static]

Returns the number of days in the given year.

The only supported value for *cal* currently is `Gregorian`.

static wxDateTime_t wxDateTime::GetNumberOfDays (Month *month*, int *year* = Inv_Year, Calendar *cal* = Gregorian) [static]

Returns the number of days in the given month of the given year.

The only supported value for *cal* currently is `Gregorian`.

wxDateTime wxDateTime::GetPrevWeekDay (WeekDay *weekday*) const

Returns the copy of this object to which SetToPrevWeekDay() was applied.

double wxDateTime::GetRataDie ( ) const

Return the *Rata* Die number of this date.

By definition, the Rata Die number is a date specified as the number of days relative to a base date of December 31 of the year 0. Thus January 1 of the year 1 is Rata Die day 1.

unsigned short wxDateTime::GetSecond (const TimeZone & *tz* = Local) const

Returns the seconds in the given timezone (local one by default).

time_t wxDateTime::GetTicks ( ) const

Returns the number of seconds since Jan 1, 1970 UTC.

An assert failure will occur if the date is not in the range covered by `time_t` type, use GetValue() if you work with dates outside of it.

static time_t wxDateTime::GetTimeNow ( ) [static]

Returns the current time.

Tm wxDateTime::GetTm (const TimeZone & *tz* = Local) const

Returns broken down representation of the date and time.

static tm* wxDateTime::GetTmNow (struct tm * *tm*) [static]

Returns the current time broken down using the buffer whose address is passed to the function with *tm* to store the result.

static tm* wxDateTime::GetTmNow ( ) [static]

Returns the current time broken down.

Note that this function returns a pointer to a static buffer that's reused by calls to this function and certain C library functions (e.g. localtime). If there is any chance your code might be used in a multi-threaded application, you really should use GetTmNow(struct tm *) instead.

int wxDateTime::GetWeekBasedYear (const TimeZone & *tz*) const

Returns the year to which the week containing this date belongs.

The value returned by this function is the same as the year, except, possibly, for a few days at the very beginning and very end of the year if they belong to a week which is mostly (i.e. at least 4 days) is in another year in which case that other (previous or next) year is returned.

For example, January 1 in 2015 belongs to the first year of 2015, hence GetWeekOfYear() for it returns 1 and this function returns 2015. However January 1 in 2016 belongs to the last week of 2015 according to ISO 8601 standard rules and so GetWeekOfYear() returns 53 and this function returns 2015, although GetYear() returns 2016.

Since

3.1.0

WeekDay wxDateTime::GetWeekDay (const TimeZone & *tz* = Local) const

Returns the week day in the given timezone (local one by default).

wxDateTime wxDateTime::GetWeekDay (WeekDay *weekday,* int *n* = 1, Month *month* = Inv_Month, int *year* = Inv_Year) const

Returns the copy of this object to which SetToWeekDay() was applied.

wxDateTime wxDateTime::GetWeekDayInSameWeek (WeekDay *weekday,* WeekFlags *flags* = Monday_First) const

Returns the copy of this object to which SetToWeekDayInSameWeek() was applied.

static wxString wxDateTime::GetWeekDayName (WeekDay *weekday,* NameFlags *flags* = Name_Full) [static]

Gets the full (default) or abbreviated name of the given week day.

This function returns the name in the current locale, use GetEnglishWeekDayName() to get the untranslated name if necessary.

Parameters

weekday	One of wxDateTime::Sun, ..., wxDateTime::Sat values.
flags	Either Name_Full (default) or Name_Abbr.

See also

GetMonthName()

wxDateTime_t wxDateTime::GetWeekOfMonth (WeekFlags *flags* = Monday_First, const TimeZone & *tz* = Local) const

Returns the ordinal number of the week in the month (in 1-5 range).

As GetWeekOfYear(), this function supports both conventions for the week start.

wxDateTime_t wxDateTime::GetWeekOfYear (WeekFlags *flags* = Monday_First, const TimeZone & *tz* = Local) const

Returns the number of the week of the year this date is in.

The first week of the year is, according to international standards, the one containing Jan 4 or, equivalently, the first week which has Thursday in this year. Both of these definitions are the same as saying that the first week of the year must contain more than half of its days in this year. Accordingly, the week number will always be in 1-53 range (52 for non-leap years).

The function depends on the week start convention specified by the *flags* argument but its results for `Sunday_First` are not well-defined as the ISO definition quoted above applies to the weeks starting on Monday only.

See also

GetWeekBasedYear()

int wxDateTime::GetYear (const TimeZone & *tz* = Local) const

Returns the year in the given timezone (local one by default).

wxDateTime wxDateTime::GetYearDay (wxDateTime_t *yday*) const

Returns the copy of this object to which SetToYearDay() was applied.

bool wxDateTime::IsBetween (const wxDateTime & *t1*, const wxDateTime & *t2*) const

Returns true if IsStrictlyBetween() is true or if the date is equal to one of the limit values.

See also

IsStrictlyBetween()

int wxDateTime::IsDST (Country *country* = Country_Default) const

Returns true if the DST is applied for this date in the given country.

See also

GetBeginDST(), GetEndDST()

static bool wxDateTime::IsDSTApplicable (int *year* = Inv_Year, Country *country* = Country_Default) [static]

Returns true if DST was used in the given year (the current one by default) in the given country.

bool wxDateTime::IsEarlierThan (const wxDateTime & *datetime*) const

Returns true if this date precedes the given one.

bool wxDateTime::IsEqualTo (const wxDateTime & *datetime*) const

Returns true if the two dates are strictly identical.

bool wxDateTime::IsEqualUpTo (const wxDateTime & *dt*, const wxTimeSpan & *ts*) const

Returns true if the date is equal to another one up to the given time interval, i.e. if the absolute difference between the two dates is less than this interval.

bool wxDateTime::IsLaterThan (const wxDateTime & *datetime*) const

Returns true if this date is later than the given one.

static bool wxDateTime::IsLeapYear (int *year* = Inv_Year, Calendar *cal* = Gregorian) [static]

Returns true if the *year* is a leap one in the specified calendar.

This functions supports Gregorian and Julian calendars.

bool wxDateTime::IsSameDate (const wxDateTime & *dt*) const

Returns true if the date is the same without comparing the time parts.

bool wxDateTime::IsSameTime (const wxDateTime & *dt*) const

Returns true if the time is the same (although dates may differ).

bool wxDateTime::IsStrictlyBetween (const wxDateTime & *t1*, const wxDateTime & *t2*) const

Returns true if this date lies strictly between the two given dates.

See also

IsBetween()

bool wxDateTime::IsValid ( ) const

Returns true if the object represents a valid time moment.

static bool wxDateTime::IsWestEuropeanCountry (Country *country* = Country_Default) [static]

This function returns true if the specified (or default) country is one of Western European ones.

It is used internally by wxDateTime to determine the DST convention and date and time formatting rules.

bool wxDateTime::IsWorkDay (Country *country* = Country_Default) const

Returns true is this day is not a holiday in the given country.

wxDateTime& wxDateTime::MakeFromTimezone (const TimeZone & *tz*, bool *noDST* = false)

Same as FromTimezone() but modifies the object in place.

wxDateTime& wxDateTime::MakeTimezone (const TimeZone & *tz*, bool *noDST* = false)

Modifies the object in place to represent the date in another time zone.

If *noDST* is true, no DST adjustments will be made.

wxDateTime& wxDateTime::MakeUTC (bool *noDST* = false)

This is the same as calling MakeTimezone() with the argument GMT0.

static wxDateTime wxDateTime::Now ( ) [static]

Returns the object corresponding to the current time.

Example:

```
wxDateTime now = wxDateTime::Now();
printf("Current time in Paris:\t%s\n", now.Format("%c", wxDateTime::CET).
      c_str());
```

Note

This function is accurate up to seconds. UNow() can be used if better precision is required.

See also

Today()

wxDateTime wxDateTime::operator+ (const wxDateSpan & *ds*) const

Adds the given date span to this object.

wxDateTime wxDateTime::operator+ (const wxTimeSpan & *ts*) const

Adds the given time span to this object.

wxDateTime& wxDateTime::operator+= (const wxDateSpan & *diff*)

Adds the given date span to this object.

wxDateTime& wxDateTime::operator+= (const wxTimeSpan & *diff*)

Adds the given time span to this object.

wxDateTime wxDateTime::operator- (const wxDateSpan & *ds*) const

Subtracts the given date span from this object.

wxDateTime wxDateTime::operator- (const wxTimeSpan & *ts*) const

Subtracts the given time span from this object.

wxTimeSpan wxDateTime::operator- (const wxDateTime & *dt2*) const

Subtracts another date from this one and returns the difference between them as a wxTimeSpan.

wxDateTime& wxDateTime::operator-= (const wxDateSpan & *diff*)

Subtracts the given date span from this object.

wxDateTime& wxDateTime::operator-= (const wxTimeSpan & *diff*)

Subtracts the given time span from this object.

wxDateTime& wxDateTime::operator= (time_t *timet*)

Same as Set().

wxDateTime& wxDateTime::operator= (const struct tm & *tm*)

Same as Set().

bool wxDateTime::ParseDate (const wxString & *date,* wxString::const_iterator * *end*)

This function is like ParseDateTime(), but it only allows the date to be specified.

It is thus less flexible then ParseDateTime(), but also has less chances to misinterpret the user input.

See ParseFormat() for the description of function parameters and return value.

See also

Format()

bool wxDateTime::ParseDateTime (const wxString & *datetime,* wxString::const_iterator * *end*)

Parses the string *datetime* containing the date and time in free format.

This function tries as hard as it can to interpret the given string as date and time. Unlike ParseRfc822Date(), it will accept anything that may be accepted and will only reject strings which cannot be parsed in any way at all. Notice that the function will fail if either date or time part is present but not both, use ParseDate() or ParseTime() to parse strings containing just the date or time component.

See ParseFormat() for the description of function parameters and return value.

bool wxDateTime::ParseFormat (const wxString & *date,* const wxString & *format,* const wxDateTime & *dateDef,* wxString::const_iterator * *end*)

This function parses the string *date* according to the given *format*.

The system `strptime(3)` function is used whenever available, but even if it is not, this function is still implemented, although support for locale-dependent format specifiers such as `"%c"`, `"%x"` or `"%X"` may not be perfect and GNU extensions such as `"%z"` and `"%Z"` are not implemented. This function does handle the month and weekday names in the current locale on all platforms, however.

Please see the description of the ANSI C function `strftime(3)` for the syntax of the format string.

The *dateDef* parameter is used to fill in the fields which could not be determined from the format string. For example, if the format is `"%d"` (the day of the month), the month and the year are taken from *dateDef*. If it is not specified, Today() is used as the default date.

Example of using this function:

```
wxDateTime dt;
wxString str = "...";
wxString::const_iterator end;
if ( !dt.ParseFormat(str, "%Y-%m-%d", &end) )
    ... parsing failed ...
else if ( end == str.end() )
    ... entire string parsed ...
else
    ... wxString(end, str.end()) left over ...
```

Parameters

date	The string to be parsed.
format	strptime()-like format string.
dateDef	Used to fill in the date components not specified in the *date* string.
end	Will be filled with the iterator pointing to the location where the parsing stopped if the function returns true. If the entire string was consumed, it is set to `date.end()`. Notice that this argument must be non-NULL.

Returns

true if at least part of the string was parsed successfully, false otherwise.

See also

Format()

bool wxDateTime::ParseFormat (const wxString & *date,* const wxString & *format,* wxString::const_iterator * *end*)

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.

bool wxDateTime::ParseFormat (const wxString & *date,* wxString::const_iterator * *end*)

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.

bool wxDateTime::ParseISOCombined (const wxString & *date,* char *sep* = 'T')

This function parses the string containing the date and time in ISO 8601 combined format "YYYY-MM-DDTHH:↩MM:SS".

The separator between the date and time parts must be equal to *sep* for the function to succeed.

Returns

true if the entire string was parsed successfully, false otherwise.

bool wxDateTime::ParseISODate (const wxString & *date*)

This function parses the date in ISO 8601 format "YYYY-MM-DD".

Returns

true if the entire string was parsed successfully, false otherwise.

bool wxDateTime::ParseISOTime (const wxString & *date*)

This function parses the time in ISO 8601 format "HH:MM:SS".

Returns

true if the entire string was parsed successfully, false otherwise.

bool wxDateTime::ParseRfc822Date (const wxString & *date,* wxString::const_iterator * *end*)

Parses the string *date* looking for a date formatted according to the RFC 822 in it.

The exact description of this format may, of course, be found in the RFC (section 5), but, briefly, this is the format used in the headers of Internet email messages and one of the most common strings expressing date in this format may be something like "Sat, 18 Dec 1999 00:48:30 +0100".

Returns NULL if the conversion failed, otherwise return the pointer to the character immediately following the part of the string which could be parsed. If the entire string contains only the date in RFC 822 format, the returned pointer will be pointing to a NUL character.

This function is intentionally strict, it will return an error for any string which is not RFC 822 compliant. If you need to parse date formatted in more free ways, you should use ParseDateTime() or ParseDate() instead.

See ParseFormat() for the description of function parameters and return value.

bool wxDateTime::ParseTime (const wxString & *time*, wxString::const_iterator * *end*)

This functions is like ParseDateTime(), but only allows the time to be specified in the input string.

See ParseFormat() for the description of function parameters and return value.

wxDateTime& wxDateTime::ResetTime ( )

Reset time to midnight (00:00:00) without changing the date.

wxDateTime& wxDateTime::Set (time_t *timet*)

Constructs the object from *timet* value holding the number of seconds since Jan 1, 1970 UTC.

If *timet* is invalid, i.e.

```
(time_t)-1
```

, wxDateTime becomes invalid too, i.e. its IsValid() will return false.

wxDateTime& wxDateTime::Set (const struct tm & *tm*)

Sets the date and time from the broken down representation in the standard *tm* structure.

wxDateTime& wxDateTime::Set (const Tm & *tm*)

Sets the date and time from the broken down representation in the *wxDateTime::Tm* structure.

wxDateTime& wxDateTime::Set (double *jdn*)

Sets the date from the so-called Julian Day Number.

By definition, the Julian Day Number, usually abbreviated as JDN, of a particular instant is the fractional number of days since 12 hours Universal Coordinated Time (Greenwich mean noon) on January 1 of the year -4712 in the Julian proleptic calendar.

wxDateTime& wxDateTime::Set (wxDateTime_t *hour*, wxDateTime_t *minute* = 0, wxDateTime_t *second* = 0, wxDateTime_t *millisec* = 0)

Sets the date to be equal to Today() and the time from supplied parameters.

See the full Set() overload for the remarks about DST.

wxDateTime& wxDateTime::Set (wxDateTime_t *day*, Month *month*, int *year* = Inv_Year, wxDateTime_t *hour* = 0, wxDateTime_t *minute* = 0, wxDateTime_t *second* = 0, wxDateTime_t *millisec* = 0)

Sets the date and time from the parameters.

If the function parameters are invalid, e.g. *month* is February and *day* is 30, the object is left in an invalid state, i.e. IsValid() method will return false.

If the specified time moment is invalid due to DST, i.e. it falls into the "missing" hour on the date on which the DST starts, a valid wxDateTime object is still constructed but its hour component is moved forward to ensure that it corresponds to a valid moment in the local time zone. For example, in the CET time zone the DST started on 2013-03-31T02:00:00 in 2013 and so setting the object to 2:30 at this date actually sets the hour to 3, and not 2.

static void wxDateTime::SetCountry (Country *country*) `[static]`

Sets the country to use by default.

This setting influences the DST calculations, date formatting and other things.

See also

GetCountry()

wxDateTime& wxDateTime::SetDay (unsigned short *day*)

Sets the day without changing other date components.

wxDateTime& wxDateTime::SetFromDOS (unsigned long *ddt*)

Sets the date from the date and time in DOS format.

wxDateTime& wxDateTime::SetFromMSWSysTime (const struct _SYSTEMTIME & *st*)

Initialize using the Windows SYSTEMTIME structure.

Parameters

st	Input, Windows SYSTEMTIME reference

Since

2.9.0

Remarks

MSW only Availability: only available for the wxMSW port.

wxDateTime& wxDateTime::SetHour (unsigned short *hour*)

Sets the hour without changing other date components.

wxDateTime& wxDateTime::SetMillisecond (unsigned short *millisecond*)

Sets the millisecond without changing other date components.

wxDateTime& wxDateTime::SetMinute (unsigned short *minute*)

Sets the minute without changing other date components.

wxDateTime& wxDateTime::SetMonth (Month *month*)

Sets the month without changing other date components.

wxDateTime& wxDateTime::SetSecond (unsigned short *second*)

Sets the second without changing other date components.

wxDateTime& wxDateTime::SetToCurrent ( )

Sets the date and time of to the current values.

Same as assigning the result of Now() to this object.

wxDateTime& wxDateTime::SetToLastMonthDay (Month *month* = Inv_Month, int *year* = Inv_Year)

Sets the date to the last day in the specified month (the current one by default).

Returns

The reference to the modified object itself.

bool wxDateTime::SetToLastWeekDay (WeekDay *weekday*, Month *month* = Inv_Month, int *year* = Inv_Year)

The effect of calling this function is the same as of calling `SetToWeekDay`(-1, weekday, month, year).

The date will be set to the last *weekday* in the given month and year (the current ones by default). Always returns true.

wxDateTime& wxDateTime::SetToNextWeekDay (WeekDay *weekday*)

Sets the date so that it will be the first *weekday* following the current date.

Returns

The reference to the modified object itself.

wxDateTime& wxDateTime::SetToPrevWeekDay (WeekDay *weekday*)

Sets the date so that it will be the last *weekday* before the current date.

Returns

The reference to the modified object itself.

bool wxDateTime::SetToWeekDay (WeekDay *weekday*, int *n* = `1`, Month *month* = Inv_Month, int *year* = Inv_Year)

Sets the date to the *n-th weekday* in the given month of the given year (the current month and year are used by default).

The parameter *n* may be either positive (counting from the beginning of the month) or negative (counting from the end of it).

For example, SetToWeekDay(2, wxDateTime::Wed) will set the date to the second Wednesday in the current month and SetToWeekDay(-1, wxDateTime::Sun) will set the date to the last Sunday in the current month.

Returns

true if the date was modified successfully, false otherwise meaning that the specified date doesn't exist.

wxDateTime& wxDateTime::SetToWeekDayInSameWeek (WeekDay *weekday,* WeekFlags *flags* = Monday_First)

Adjusts the date so that it will still lie in the same week as before, but its week day will be the given one.

Returns

The reference to the modified object itself.

static wxDateTime wxDateTime::SetToWeekOfYear (int *year,* wxDateTime_t *numWeek,* WeekDay *weekday* = Mon) [static]

Set the date to the given *weekday* in the week number *numWeek* of the given *year* .

The number should be in range 1-53.

Note that the returned date may be in a different year than the one passed to this function because both the week 1 and week 52 or 53 (for leap years) contain days from different years. See GetWeekOfYear() for the explanation of how the year weeks are counted.

wxDateTime& wxDateTime::SetToYearDay (wxDateTime_t *yday*)

Sets the date to the day number *yday* in the same year (i.e. unlike the other functions, this one does not use the current year).

The day number should be in the range 1-366 for the leap years and 1-365 for the other ones.

Returns

The reference to the modified object itself.

wxDateTime& wxDateTime::SetYear (int *year*)

Sets the year without changing other date components.

wxDateTime wxDateTime::Subtract (const wxTimeSpan & *diff*) const

Subtracts the given time span from this object.

wxDateTime& wxDateTime::Subtract (const wxTimeSpan & *diff*)

Subtracts the given time span from this object.

wxDateTime wxDateTime::Subtract (const wxDateSpan & *diff*) const

Subtracts the given date span from this object.

wxDateTime& wxDateTime::Subtract (const wxDateSpan & *diff*)

Subtracts the given date span from this object.

wxTimeSpan wxDateTime::Subtract (const wxDateTime & *dt*) const

Subtracts another date from this one and returns the difference between them as a wxTimeSpan.

static wxDateTime wxDateTime::Today ( ) [static]

Returns the object corresponding to the midnight of the current day (i.e. the same as Now(), but the time part is set to 0).

See also

Now()

wxDateTime wxDateTime::ToTimezone (const TimeZone & *tz*, bool *noDST* = false) const

Transform the date to the given time zone.

If *noDST* is true, no DST adjustments will be made.

Returns

The date in the new time zone.

wxDateTime wxDateTime::ToUTC (bool *noDST* = false) const

This is the same as calling ToTimezone() with the argument GMT0.

static wxDateTime wxDateTime::UNow ( ) [static]

Returns the object corresponding to the current UTC time including the milliseconds.

Notice that unlike Now(), this method creates a wxDateTime object corresponding to UTC, not local, time.

See also

Now(), wxGetUTCTimeMillis()

21.171 wxDateTimeHolidayAuthority Class Reference

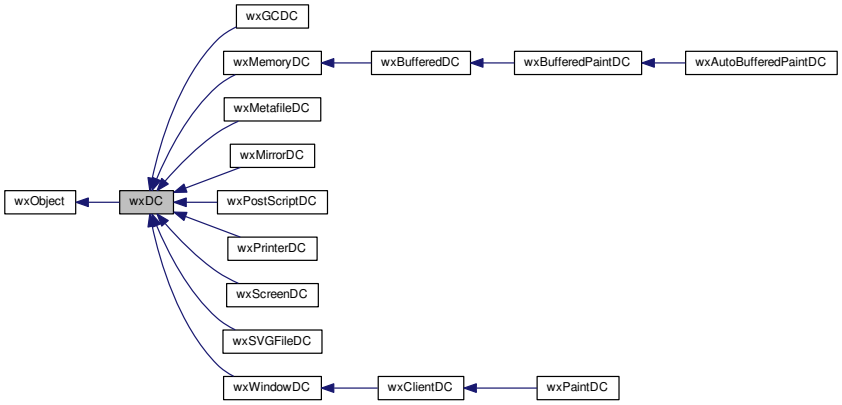
21.173 wxDC Class Reference

`#include <wx/dc.h>`

Inheritance diagram for wxDC:



21.173.1 Detailed Description

A wxDC is a *"device context"* onto which graphics and text can be drawn.

It is intended to represent different output devices and offers a common abstract API for drawing on any of them.

wxWidgets offers an alternative drawing API based on the modern drawing backends GDI+, CoreGraphics and Cairo. See wxGraphicsContext, wxGraphicsRenderer and related classes. There is also a wxGCDC linking the APIs by offering the wxDC API on top of a wxGraphicsContext.

wxDC is an abstract base class and cannot be created directly. Use wxPaintDC, wxClientDC, wxWindowDC, wxScreenDC, wxMemoryDC or wxPrinterDC. Notice that device contexts which are associated with windows (i.e. wxClientDC, wxWindowDC and wxPaintDC) use the window font and colours by default (starting with wxWidgets 2.9.0) but the other device context classes use system-default values so you always must set the appropriate fonts and colours before using them.

In addition to the versions of the methods documented below, there are also versions which accept single wxPoint parameter instead of the two wxCoord ones or wxPoint and wxSize instead of the four wxCoord parameters.

Beginning with wxWidgets 2.9.0 the entire wxDC code has been reorganized. All platform dependent code (actually all drawing code) has been moved into backend classes which derive from a common wxDCImpl class. The user-visible classes such as wxClientDC and wxPaintDC merely forward all calls to the backend implementation.

21.173.2 Device and logical units

In the wxDC context there is a distinction between *logical* units and *device* units.

Device units are the units native to the particular device; e.g. for a screen, a device unit is a *pixel*. For a printer, the device unit is defined by the resolution of the printer (usually given in `DPI:` dot-per-inch).

All wxDC functions use instead **logical** units, unless where explicitly stated. Logical units are arbitrary units mapped to device units using the current mapping mode (see wxDC::SetMapMode).

This mechanism allows to reuse the same code which prints on e.g. a window on the screen to print on e.g. a paper.

21.173.3 Support for Transparency / Alpha Channel

In general wxDC methods don't support alpha transparency and the alpha component of wxColour is simply ignored and you need to use wxGraphicsContext for full transparency support. There are, however, a few exceptions: first, under Mac OS X colours with alpha channel are supported in all the normal wxDC-derived classes as they use wxGraphicsContext internally. Second, under all platforms wxSVGFileDC also fully supports alpha channel. In both of these cases the instances of wxPen or wxBrush that are built from wxColour use the colour's alpha values when stroking or filling.

21.173.4 for Transformation Matrix

On some platforms (currently only under MSW and only on Windows NT, i.e. not Windows 9x/ME, systems) wxDC has support for applying an arbitrary affine transformation matrix to its coordinate system. Call CanUseTransform↩ Matrix() to check if this support is available and then call SetTransformMatrix() if it is. If the transformation matrix is not supported, SetTransformMatrix() always simply returns false and doesn't do anything.

Library: wxCore

Category: Device Contexts, Graphics Device Interface (GDI)

See also

Device Contexts, wxGraphicsContext, wxDCFontChanger, wxDCTextColourChanger, wxDCPenChanger, wxDCBrushChanger, wxDCClipper

Todo Precise definition of default/initial state.

Pixelwise definition of operations (e.g. last point of a line not drawn).

Public Member Functions

- void CopyAttributes (const wxDC &dc)

  Copy attributes from another DC.
- int GetDepth () const

  Returns the depth (number of bits/pixel) of this DC.
- wxPoint GetDeviceOrigin () const

  Returns the current device origin.
- wxRasterOperationMode GetLogicalFunction () const

  Gets the current logical function.
- wxMappingMode GetMapMode () const

  Gets the current mapping mode for the device context.

- bool GetPixel (wxCoord x, wxCoord y, wxColour *colour) const

  Gets in colour the colour at the specified location.
- wxSize GetPPI () const

  Returns the resolution of the device in pixels per inch.
- void GetSize (wxCoord *width, wxCoord *height) const

  Gets the horizontal and vertical extent of this device context in device units.
- wxSize GetSize () const

  This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.
- void GetSizeMM (wxCoord *width, wxCoord *height) const

  Returns the horizontal and vertical resolution in millimetres.
- wxSize GetSizeMM () const

  This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.
- void GetUserScale (double *x, double *y) const

  Gets the current user scale factor.
- bool IsOk () const

  Returns true if the DC is ok to use.
- void SetAxisOrientation (bool xLeftRight, bool yBottomUp)

  Sets the x and y axis orientation (i.e. the direction from lowest to highest values on the axis).
- void SetDeviceOrigin (wxCoord x, wxCoord y)

  Sets the device origin (i.e. the origin in pixels after scaling has been applied).
- void SetLogicalFunction (wxRasterOperationMode function)

  Sets the current logical function for the device context.
- void SetMapMode (wxMappingMode mode)

  The mapping mode of the device context defines the unit of measurement used to convert logical units to device units.
- void SetPalette (const wxPalette &palette)

  If this is a window DC or memory DC, assigns the given palette to the window or bitmap associated with the DC.
- void SetUserScale (double xScale, double yScale)

  Sets the user scaling factor, useful for applications which require 'zooming'.
- void * GetHandle () const

  Returns a value that can be used as a handle to the native drawing context, if this wxDC has something that could be thought of in that way.
- wxBitmap GetAsBitmap (const wxRect *subrect=NULL) const

  If supported by the platform and the type of DC, fetch the contents of the DC, or a subset of it, as a bitmap.
- void SetLogicalScale (double x, double y)
- void GetLogicalScale (double *x, double *y) const
- void SetLogicalOrigin (wxCoord x, wxCoord y)
- void GetLogicalOrigin (wxCoord *x, wxCoord *y) const
- wxPoint GetLogicalOrigin () const

Coordinate conversion functions

- wxCoord DeviceToLogicalX (wxCoord x) const

  Convert device X coordinate to logical coordinate, using the current mapping mode, user scale factor, device origin and axis orientation.
- wxCoord DeviceToLogicalXRel (wxCoord x) const

  Convert device X coordinate to relative logical coordinate, using the current mapping mode and user scale factor but ignoring the axis orientation.
- wxCoord DeviceToLogicalY (wxCoord y) const

  Converts device Y coordinate to logical coordinate, using the current mapping mode, user scale factor, device origin and axis orientation.
- wxCoord DeviceToLogicalYRel (wxCoord y) const

Convert device Y coordinate to relative logical coordinate, using the current mapping mode and user scale factor but ignoring the axis orientation.

- wxCoord LogicalToDeviceX (wxCoord x) const

  Converts logical X coordinate to device coordinate, using the current mapping mode, user scale factor, device origin and axis orientation.
- wxCoord LogicalToDeviceXRel (wxCoord x) const

  Converts logical X coordinate to relative device coordinate, using the current mapping mode and user scale factor but ignoring the axis orientation.
- wxCoord LogicalToDeviceY (wxCoord y) const

  Converts logical Y coordinate to device coordinate, using the current mapping mode, user scale factor, device origin and axis orientation.
- wxCoord LogicalToDeviceYRel (wxCoord y) const

  Converts logical Y coordinate to relative device coordinate, using the current mapping mode and user scale factor but ignoring the axis orientation.

Drawing functions

- void Clear ()

  Clears the device context using the current background brush.
- void DrawArc (wxCoord xStart, wxCoord yStart, wxCoord xEnd, wxCoord yEnd, wxCoord xc, wxCoord yc)

  Draws an arc from the given start to the given end point.
- void DrawArc (const wxPoint &ptStart, const wxPoint &ptEnd, const wxPoint &centre)

  This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.
- void DrawBitmap (const wxBitmap &bitmap, wxCoord x, wxCoord y, bool useMask=false)

  Draw a bitmap on the device context at the specified point.
- void DrawBitmap (const wxBitmap &bmp, const wxPoint &pt, bool useMask=false)

  This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.
- void DrawCheckMark (wxCoord x, wxCoord y, wxCoord width, wxCoord height)

  Draws a check mark inside the given rectangle.
- void DrawCheckMark (const wxRect &rect)

  This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.
- void DrawCircle (wxCoord x, wxCoord y, wxCoord radius)

  Draws a circle with the given centre and radius.
- void DrawCircle (const wxPoint &pt, wxCoord radius)

  This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.
- void DrawEllipse (wxCoord x, wxCoord y, wxCoord width, wxCoord height)

  Draws an ellipse contained in the rectangle specified either with the given top left corner and the given size or directly.
- void DrawEllipse (const wxPoint &pt, const wxSize &size)

  This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.
- void DrawEllipse (const wxRect &rect)

  This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.
- void DrawEllipticArc (wxCoord x, wxCoord y, wxCoord width, wxCoord height, double start, double end)

  Draws an arc of an ellipse.
- void DrawEllipticArc (const wxPoint &pt, const wxSize &sz, double sa, double ea)

  This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.
- void DrawIcon (const wxIcon &icon, wxCoord x, wxCoord y)

  Draw an icon on the display (does nothing if the device context is PostScript).
- void DrawIcon (const wxIcon &icon, const wxPoint &pt)

  This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.
- void DrawLabel (const wxString &text, const wxBitmap &bitmap, const wxRect &rect, int alignment=wxALIGN_LEFT|wxALIGN_TOP, int indexAccel=-1, wxRect *rectBounding=NULL)

Draw optional bitmap and the text into the given rectangle and aligns it as specified by alignment parameter; it also will emphasize the character with the given index if it is != -1 and return the bounding rectangle if required.

- void DrawLabel (const wxString &text, const wxRect &rect, int alignment=wxALIGN_LEFT|wxALIGN_TOP, int indexAccel=-1)

  This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.
- void DrawLine (wxCoord x1, wxCoord y1, wxCoord x2, wxCoord y2)

  Draws a line from the first point to the second.
- void DrawLine (const wxPoint &pt1, const wxPoint &pt2)

  This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.
- void DrawLines (int n, const wxPoint points[], wxCoord xoffset=0, wxCoord yoffset=0)

  Draws lines using an array of points of size n adding the optional offset coordinate.
- void DrawLines (const wxPointList *points, wxCoord xoffset=0, wxCoord yoffset=0)

  This method uses a list of wxPoints, adding the optional offset coordinate.
- void DrawPoint (wxCoord x, wxCoord y)

  Draws a point using the color of the current pen.
- void DrawPoint (const wxPoint &pt)

  This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.
- void DrawPolygon (int n, const wxPoint points[], wxCoord xoffset=0, wxCoord yoffset=0, wxPolygonFill↩ Mode fill_style=wxODDEVEN_RULE)

  Draws a filled polygon using an array of points of size n, adding the optional offset coordinate.
- void DrawPolygon (const wxPointList *points, wxCoord xoffset=0, wxCoord yoffset=0, wxPolygonFillMode fill_style=wxODDEVEN_RULE)

  This method draws a filled polygon using a list of wxPoints, adding the optional offset coordinate.
- void DrawPolyPolygon (int n, const int count[], const wxPoint points[], wxCoord xoffset=0, wxCoord yoffset=0, wxPolygonFillMode fill_style=wxODDEVEN_RULE)

  Draws two or more filled polygons using an array of points, adding the optional offset coordinates.
- void DrawRectangle (wxCoord x, wxCoord y, wxCoord width, wxCoord height)

  Draws a rectangle with the given top left corner, and with the given size.
- void DrawRectangle (const wxPoint &pt, const wxSize &sz)

  This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.
- void DrawRectangle (const wxRect &rect)

  This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.
- void DrawRotatedText (const wxString &text, wxCoord x, wxCoord y, double angle)

  Draws the text rotated by angle degrees (positive angles are counterclockwise; the full angle is 360 degrees).
- void DrawRotatedText (const wxString &text, const wxPoint &point, double angle)

  This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.
- void DrawRoundedRectangle (wxCoord x, wxCoord y, wxCoord width, wxCoord height, double radius)

  Draws a rectangle with the given top left corner, and with the given size.
- void DrawRoundedRectangle (const wxPoint &pt, const wxSize &sz, double radius)

  This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.
- void DrawRoundedRectangle (const wxRect &rect, double radius)

  This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.
- void DrawSpline (int n, const wxPoint points[])

  Draws a spline between all given points using the current pen.
- void DrawSpline (const wxPointList *points)

  This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.
- void DrawSpline (wxCoord x1, wxCoord y1, wxCoord x2, wxCoord y2, wxCoord x3, wxCoord y3)

  This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.
- void DrawText (const wxString &text, wxCoord x, wxCoord y)

Draws a text string at the specified point, using the current text font, and the current text foreground and background colours.

- void DrawText (const wxString &text, const wxPoint &pt)

  This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.
- void GradientFillConcentric (const wxRect &rect, const wxColour &initialColour, const wxColour &destColour)

  Fill the area specified by rect with a radial gradient, starting from initialColour at the centre of the circle and fading to destColour on the circle outside.
- void GradientFillConcentric (const wxRect &rect, const wxColour &initialColour, const wxColour &destColour, const wxPoint &circleCenter)

  Fill the area specified by rect with a radial gradient, starting from initialColour at the centre of the circle and fading to destColour on the circle outside.
- void GradientFillLinear (const wxRect &rect, const wxColour &initialColour, const wxColour &destColour, wxDirection nDirection=wxRIGHT)

  Fill the area specified by rect with a linear gradient, starting from initialColour and eventually fading to destColour.
- bool FloodFill (wxCoord x, wxCoord y, const wxColour &colour, wxFloodFillStyle style=wxFLOOD_SURFACE)

  Flood fills the device context starting from the given point, using the current brush colour, and using a style:
- bool FloodFill (const wxPoint &pt, const wxColour &col, wxFloodFillStyle style=wxFLOOD_SURFACE)

  This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.
- void CrossHair (wxCoord x, wxCoord y)

  Displays a cross hair using the current pen.
- void CrossHair (const wxPoint &pt)

  This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.

Clipping region functions

- void DestroyClippingRegion ()

  Destroys the current clipping region so that none of the DC is clipped.
- void GetClippingBox (wxCoord *x, wxCoord *y, wxCoord *width, wxCoord *height) const

  Gets the rectangle surrounding the current clipping region.
- void SetClippingRegion (wxCoord x, wxCoord y, wxCoord width, wxCoord height)

  Sets the clipping region for this device context to the intersection of the given region described by the parameters of this method and the previously set clipping region.
- void SetClippingRegion (const wxPoint &pt, const wxSize &sz)

  This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.
- void SetClippingRegion (const wxRect &rect)

  This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.
- void SetDeviceClippingRegion (const wxRegion &region)

  Sets the clipping region for this device context.

Text/character extent functions

- wxCoord GetCharHeight () const

  Gets the character height of the currently set font.
- wxCoord GetCharWidth () const

  Gets the average character width of the currently set font.
- wxFontMetrics GetFontMetrics () const

  Returns the various font characteristics.
- void GetMultiLineTextExtent (const wxString &string, wxCoord *w, wxCoord *h, wxCoord *heightLine=NULL, const wxFont *font=NULL) const

  Gets the dimensions of the string using the currently selected font.
- wxSize GetMultiLineTextExtent (const wxString &string) const

  Gets the dimensions of the string using the currently selected font.

- bool GetPartialTextExtents (const wxString &text, wxArrayInt &widths) const

  Fills the widths array with the widths from the beginning of text to the corresponding character of text.
- void GetTextExtent (const wxString &string, wxCoord *w, wxCoord *h, wxCoord *descent=NULL, wxCoord *externalLeading=NULL, const wxFont *font=NULL) const

  Gets the dimensions of the string using the currently selected font.
- wxSize GetTextExtent (const wxString &string) const

  This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.

Text properties functions

- int GetBackgroundMode () const

  Returns the current background mode: `wxPENSTYLE_SOLID` or `wxPENSTYLE_TRANSPARENT`.
- const wxFont & GetFont () const

  Gets the current font.
- wxLayoutDirection GetLayoutDirection () const

  Gets the current layout direction of the device context.
- const wxColour & GetTextBackground () const

  Gets the current text background colour.
- const wxColour & GetTextForeground () const

  Gets the current text foreground colour.
- void SetBackgroundMode (int mode)

  mode may be one of `wxPENSTYLE_SOLID` and `wxPENSTYLE_TRANSPARENT`.
- void SetFont (const wxFont &font)

  Sets the current font for the DC.
- void SetTextBackground (const wxColour &colour)

  Sets the current text background colour for the DC.
- void SetTextForeground (const wxColour &colour)

  Sets the current text foreground colour for the DC.
- void SetLayoutDirection (wxLayoutDirection dir)

  Sets the current layout direction for the device context.

Bounding box functions

- void CalcBoundingBox (wxCoord x, wxCoord y)

  Adds the specified point to the bounding box which can be retrieved with MinX(), MaxX() and MinY(), MaxY() functions.
- wxCoord MaxX () const

  Gets the maximum horizontal extent used in drawing commands so far.
- wxCoord MaxY () const

  Gets the maximum vertical extent used in drawing commands so far.
- wxCoord MinX () const

  Gets the minimum horizontal extent used in drawing commands so far.
- wxCoord MinY () const

  Gets the minimum vertical extent used in drawing commands so far.
- void ResetBoundingBox ()

  Resets the bounding box: after a call to this function, the bounding box doesn't contain anything.

Page and document start/end functions

- bool StartDoc (const wxString &message)

  Starts a document (only relevant when outputting to a printer).
- void StartPage ()

  Starts a document page (only relevant when outputting to a printer).
- void EndDoc ()

  Ends a document (only relevant when outputting to a printer).
- void EndPage ()

  Ends a document page (only relevant when outputting to a printer).

Bit-Block Transfer operations (blit)

- bool Blit (wxCoord xdest, wxCoord ydest, wxCoord width, wxCoord height, wxDC *source, wxCoord xsrc, wxCoord ysrc, wxRasterOperationMode logicalFunc=wxCOPY, bool useMask=false, wxCoord xsrcMask=wxDefaultCoord, wxCoord ysrcMask=wxDefaultCoord)
  Copy from a source DC to this DC.
- bool StretchBlit (wxCoord xdest, wxCoord ydest, wxCoord dstWidth, wxCoord dstHeight, wxDC *source, wxCoord xsrc, wxCoord ysrc, wxCoord srcWidth, wxCoord srcHeight, wxRasterOperationMode logicalFunc=wxCOPY, bool useMask=false, wxCoord xsrcMask=wxDefaultCoord, wxCoord ysrcMask=wxDefaultCoord)
  Copy from a source DC to this DC possibly changing the scale.

Background/foreground brush and pen

- const wxBrush & GetBackground () const
  Gets the brush used for painting the background.
- const wxBrush & GetBrush () const
  Gets the current brush.
- const wxPen & GetPen () const
  Gets the current pen.
- void SetBackground (const wxBrush &brush)
  Sets the current background brush for the DC.
- void SetBrush (const wxBrush &brush)
  Sets the current brush for the DC.
- void SetPen (const wxPen &pen)
  Sets the current pen for the DC.

Transformation matrix

See the notes about the availability of these functions in the class documentation.

- bool CanUseTransformMatrix () const
  Check if the use of transformation matrix is supported by the current system.
- bool SetTransformMatrix (const wxAffineMatrix2D &matrix)
  Set the transformation matrix.
- wxAffineMatrix2D GetTransformMatrix () const
  Return the transformation matrix used by this device context.
- void ResetTransformMatrix ()
  Revert the transformation matrix to identity matrix.

query capabilities

- bool CanDrawBitmap () const
  Does the DC support drawing bitmaps?
- bool CanGetTextExtent () const
  Does the DC support calculating the size required to draw text?

Additional Inherited Members

21.173.5 Member Function Documentation

bool wxDC::Blit (wxCoord *xdest*, wxCoord *ydest*, wxCoord *width*, wxCoord *height*, wxDC * *source*, wxCoord *xsrc*, wxCoord *ysrc*, wxRasterOperationMode *logicalFunc* = wxCOPY, bool *useMask* = `false`, wxCoord *xsrcMask* = wxDefaultCoord, wxCoord *ysrcMask* = wxDefaultCoord)

Copy from a source DC to this DC.

With this method you can specify the destination coordinates and the size of area to copy which will be the same for both the source and target DCs. If you need to apply scaling while copying, use StretchBlit().

Notice that source DC coordinates *xsrc* and *ysrc* are interpreted using the current source DC coordinate system, i.e. the scale, origin position and axis directions are taken into account when transforming them to physical (pixel) coordinates.

Parameters

xdest	Destination device context x position.
ydest	Destination device context y position.
width	Width of source area to be copied.
height	Height of source area to be copied.
source	Source device context.
xsrc	Source device context x position.
ysrc	Source device context y position.
logicalFunc	Logical function to use, see SetLogicalFunction().
useMask	If true, Blit does a transparent blit using the mask that is associated with the bitmap selected into the source device context. The Windows implementation does the following if MaskBlt cannot be used: 1. Creates a temporary bitmap and copies the destination area into it. 2. Copies the source area into the temporary bitmap using the specified logical function. 3. Sets the masked area in the temporary bitmap to BLACK by ANDing the mask bitmap with the temp bitmap with the foreground colour set to WHITE and the bg colour set to BLACK. 4. Sets the unmasked area in the destination area to BLACK by ANDing the mask bitmap with the destination area with the foreground colour set to BLACK and the background colour set to WHITE. 5. ORs the temporary bitmap with the destination area. 6. Deletes the temporary bitmap. This sequence of operations ensures that the source's transparent area need not be black, and logical functions are supported. **Note:** on Windows, blitting with masks can be speeded up considerably by compiling wx↩ Widgets with the wxUSE_DC_CACHEING option enabled. You can also influence whether MaskBlt or the explicit mask blitting code above is used, by using wxSystemOptions and setting the `no-maskblt` option to 1.

xsrcMask	Source x position on the mask. If both xsrcMask and ysrcMask are `-1`, xsrc and ysrc will be assumed for the mask source position. Currently only implemented on Windows.
ysrcMask	Source y position on the mask. If both xsrcMask and ysrcMask are `-1`, xsrc and ysrc will be assumed for the mask source position. Currently only implemented on Windows.

Remarks

There is partial support for Blit() in wxPostScriptDC, under X.

See also

StretchBlit(), wxMemoryDC, wxBitmap, wxMask

void wxDC::CalcBoundingBox (wxCoord *x*, wxCoord *y*)

Adds the specified point to the bounding box which can be retrieved with MinX(), MaxX() and MinY(), MaxY() functions.

See also

ResetBoundingBox()

bool wxDC::CanDrawBitmap ( ) const

Does the DC support drawing bitmaps?

bool wxDC::CanGetTextExtent ( ) const

Does the DC support calculating the size required to draw text?

bool wxDC::CanUseTransformMatrix ( ) const

Check if the use of transformation matrix is supported by the current system.

Currently this function always returns false for non-MSW platforms and may return false for old (Windows 9x/ME) Windows systems. Normally support for the transformation matrix is always available in any relatively recent Windows versions.

Since

2.9.2

void wxDC::Clear ( )

Clears the device context using the current background brush.

void wxDC::CopyAttributes (const wxDC & *dc*)

Copy attributes from another DC.

The copied attributes currently are:

- Font

- Text foreground and background colours
- Background brush
- Layout direction

Parameters

dc	A valid (i.e. its IsOk() must return true) source device context.

void wxDC::CrossHair (wxCoord *x*, wxCoord *y*)

Displays a cross hair using the current pen.

This is a vertical and horizontal line the height and width of the window, centred on the given point.

void wxDC::CrossHair (const wxPoint & *pt*)

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.

void wxDC::DestroyClippingRegion ( )

Destroys the current clipping region so that none of the DC is clipped.

See also

SetClippingRegion()

wxCoord wxDC::DeviceToLogicalX (wxCoord *x*) const

Convert *device* X coordinate to logical coordinate, using the current mapping mode, user scale factor, device origin and axis orientation.

wxCoord wxDC::DeviceToLogicalXRel (wxCoord *x*) const

Convert *device* X coordinate to relative logical coordinate, using the current mapping mode and user scale factor but ignoring the axis orientation.

Use this for converting a width, for example.

wxCoord wxDC::DeviceToLogicalY (wxCoord *y*) const

Converts *device* Y coordinate to logical coordinate, using the current mapping mode, user scale factor, device origin and axis orientation.

wxCoord wxDC::DeviceToLogicalYRel (wxCoord *y*) const

Convert *device* Y coordinate to relative logical coordinate, using the current mapping mode and user scale factor but ignoring the axis orientation.

Use this for converting a height, for example.

void wxDC::DrawArc (wxCoord *xStart,* wxCoord *yStart,* wxCoord *xEnd,* wxCoord *yEnd,* wxCoord *xc,* wxCoord *yc*)

Draws an arc from the given start to the given end point.

Note

DrawEllipticArc() has more clear semantics and it is recommended to use it instead of this function.

The arc drawn is an arc of the circle centered at (*xc*, *yc*). Its start point is (*xStart*, *yStart*) whereas its end point is the point of intersection of the line passing by (*xc*, *yc*) and (*xEnd*, *yEnd*) with the circle passing by (*xStart*, *yStart*).

The arc is drawn in a counter-clockwise direction between the start and the end points.

The current pen is used for the outline and the current brush for filling the shape. Notice that unless the brush is transparent, the lines connecting the centre of the circle to the end points of the arc are drawn as well.

void wxDC::DrawArc (const wxPoint & *ptStart,* const wxPoint & *ptEnd,* const wxPoint & *centre*)

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.

void wxDC::DrawBitmap (const wxBitmap & *bitmap,* wxCoord *x,* wxCoord *y,* bool *useMask* = `false`)

Draw a bitmap on the device context at the specified point.

If *transparent* is true and the bitmap has a transparency mask, the bitmap will be drawn transparently.

When drawing a mono-bitmap, the current text foreground colour will be used to draw the foreground of the bitmap (all bits set to 1), and the current text background colour to draw the background (all bits set to 0).

See also

SetTextForeground(), SetTextBackground(), wxMemoryDC

void wxDC::DrawBitmap (const wxBitmap & *bmp,* const wxPoint & *pt,* bool *useMask* = `false`)

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.

void wxDC::DrawCheckMark (wxCoord *x,* wxCoord *y,* wxCoord *width,* wxCoord *height*)

Draws a check mark inside the given rectangle.

void wxDC::DrawCheckMark (const wxRect & *rect*)

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.

void wxDC::DrawCircle (wxCoord *x,* wxCoord *y,* wxCoord *radius*)

Draws a circle with the given centre and radius.

See also

DrawEllipse()

void wxDC::DrawCircle (const wxPoint & *pt,* wxCoord *radius*)

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.

void wxDC::DrawEllipse (wxCoord *x,* wxCoord *y,* wxCoord *width,* wxCoord *height*)

Draws an ellipse contained in the rectangle specified either with the given top left corner and the given size or directly.

The current pen is used for the outline and the current brush for filling the shape.

See also

DrawCircle()

void wxDC::DrawEllipse (const wxPoint & *pt,* const wxSize & *size*)

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.

void wxDC::DrawEllipse (const wxRect & *rect*)

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.

void wxDC::DrawEllipticArc (wxCoord *x,* wxCoord *y,* wxCoord *width,* wxCoord *height,* double *start,* double *end*)

Draws an arc of an ellipse.

The current pen is used for drawing the arc and the current brush is used for drawing the pie.

x and *y* specify the x and y coordinates of the upper-left corner of the rectangle that contains the ellipse.

width and *height* specify the width and height of the rectangle that contains the ellipse.

start and *end* specify the end points of the arc relative to the three-o'clock position from the center of the rectangle. Angles are specified in degrees with 0 degree angle corresponding to the positive horizontal axis (3 o'clock) direction.

Independently of whether *start* is greater than or less than *end*, the arc is drawn in the counter-clockwise direction. Also, if *start* is equal to *end*, a complete ellipse is drawn.

Notice that unlike DrawArc(), this function does not draw the lines to the arc ends, even when using non-transparent brush.

void wxDC::DrawEllipticArc (const wxPoint & *pt,* const wxSize & *sz,* double *sa,* double *ea*)

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.

void wxDC::DrawIcon (const wxIcon & *icon,* wxCoord *x,* wxCoord *y*)

Draw an icon on the display (does nothing if the device context is PostScript).

This can be the simplest way of drawing bitmaps on a window.

void wxDC::DrawIcon (const wxIcon & *icon,* const wxPoint & *pt*)

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.

void wxDC::DrawLabel (const wxString & *text,* const wxBitmap & *bitmap,* const wxRect & *rect,* int *alignment* = wxALIGN_LEFT|wxALIGN_TOP, int *indexAccel* = -1, wxRect * *rectBounding* = NULL)

Draw optional bitmap and the text into the given rectangle and aligns it as specified by alignment parameter; it also will emphasize the character with the given index if it is != -1 and return the bounding rectangle if required.

void wxDC::DrawLabel (const wxString & *text,* const wxRect & *rect,* int *alignment* = wxALIGN_LEFT|wxALIGN_TOP, int *indexAccel* = -1)

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.

void wxDC::DrawLine (wxCoord *x1,* wxCoord *y1,* wxCoord *x2,* wxCoord *y2*)

Draws a line from the first point to the second.

The current pen is used for drawing the line. Note that the point (*x2*, *y2*) is not part of the line and is not drawn by this function (this is consistent with the behaviour of many other toolkits).

void wxDC::DrawLine (const wxPoint & *pt1,* const wxPoint & *pt2*)

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.

void wxDC::DrawLines (int *n,* const wxPoint *points[],* wxCoord *xoffset* = 0, wxCoord *yoffset* = 0)

Draws lines using an array of points of size *n* adding the optional offset coordinate.

The current pen is used for drawing the lines.

wxPerl Note: Not supported by wxPerl.

void wxDC::DrawLines (const wxPointList * *points,* wxCoord *xoffset* = 0, wxCoord *yoffset* = 0)

This method uses a list of wxPoints, adding the optional offset coordinate.

The programmer is responsible for deleting the list of points.

wxPerl Note: The wxPerl version of this method accepts as its first parameter a reference to an array of wxPoint objects.

void wxDC::DrawPoint (wxCoord *x,* wxCoord *y*)

Draws a point using the color of the current pen.

Note that the other properties of the pen are not used, such as width.

void wxDC::DrawPoint (const wxPoint & *pt*)

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.

void wxDC::DrawPolygon (int *n*, const wxPoint *points[]*, wxCoord *xoffset* = 0, wxCoord *yoffset* = 0, wxPolygonFillMode *fill_style* = wxODDEVEN_RULE)

Draws a filled polygon using an array of points of size *n*, adding the optional offset coordinate.

The first and last points are automatically closed.

The last argument specifies the fill rule: **wxODDEVEN_RULE** (the default) or **wxWINDING_RULE**.

The current pen is used for drawing the outline, and the current brush for filling the shape. Using a transparent brush suppresses filling.

wxPerl Note: Not supported by wxPerl.

void wxDC::DrawPolygon (const wxPointList * *points*, wxCoord *xoffset* = 0, wxCoord *yoffset* = 0, wxPolygonFillMode *fill_style* = wxODDEVEN_RULE)

This method draws a filled polygon using a list of wxPoints, adding the optional offset coordinate.

The first and last points are automatically closed.

The last argument specifies the fill rule: **wxODDEVEN_RULE** (the default) or **wxWINDING_RULE**.

The current pen is used for drawing the outline, and the current brush for filling the shape. Using a transparent brush suppresses filling.

The programmer is responsible for deleting the list of points.

wxPerl Note: The wxPerl version of this method accepts as its first parameter a reference to an array of wxPoint objects.

void wxDC::DrawPolyPolygon (int *n*, const int *count[]*, const wxPoint *points[]*, wxCoord *xoffset* = 0, wxCoord *yoffset* = 0, wxPolygonFillMode *fill_style* = wxODDEVEN_RULE)

Draws two or more filled polygons using an array of *points*, adding the optional offset coordinates.

Notice that for the platforms providing a native implementation of this function (Windows and PostScript-based wxDC currently), this is more efficient than using DrawPolygon() in a loop.

n specifies the number of polygons to draw, the array *count* of size *n* specifies the number of points in each of the polygons in the *points* array.

The last argument specifies the fill rule: **wxODDEVEN_RULE** (the default) or **wxWINDING_RULE**.

The current pen is used for drawing the outline, and the current brush for filling the shape. Using a transparent brush suppresses filling.

The polygons maybe disjoint or overlapping. Each polygon specified in a call to DrawPolyPolygon() must be closed. Unlike polygons created by the DrawPolygon() member function, the polygons created by this method are not closed automatically.

void wxDC::DrawRectangle (wxCoord *x*, wxCoord *y*, wxCoord *width*, wxCoord *height*)

Draws a rectangle with the given top left corner, and with the given size.

The current pen is used for the outline and the current brush for filling the shape.

void wxDC::DrawRectangle (const wxPoint & *pt,* const wxSize & *sz*)

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.

void wxDC::DrawRectangle (const wxRect & *rect*)

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.

void wxDC::DrawRotatedText (const wxString & *text,* wxCoord *x,* wxCoord *y,* double *angle*)

Draws the text rotated by *angle* degrees (positive angles are counterclockwise; the full angle is 360 degrees).

Notice that, as with DrawText(), the *text* can contain multiple lines separated by the new line (`'\n'`) characters.

Note

Under Win9x only TrueType fonts can be drawn by this function. In particular, a font different from `wxNORMAL_FONT` should be used as the latter is not a TrueType font. `wxSWISS_FONT` is an example of a font which is.

See also

DrawText()

void wxDC::DrawRotatedText (const wxString & *text,* const wxPoint & *point,* double *angle*)

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.

void wxDC::DrawRoundedRectangle (wxCoord *x,* wxCoord *y,* wxCoord *width,* wxCoord *height,* double *radius*)

Draws a rectangle with the given top left corner, and with the given size.

The corners are quarter-circles using the given radius. The current pen is used for the outline and the current brush for filling the shape.

If *radius* is positive, the value is assumed to be the radius of the rounded corner. If *radius* is negative, the absolute value is assumed to be the *proportion* of the smallest dimension of the rectangle. This means that the corner can be a sensible size relative to the size of the rectangle, and also avoids the strange effects X produces when the corners are too big for the rectangle.

void wxDC::DrawRoundedRectangle (const wxPoint & *pt,* const wxSize & *sz,* double *radius*)

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.

void wxDC::DrawRoundedRectangle (const wxRect & *rect,* double *radius*)

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.

void wxDC::DrawSpline (int *n,* const wxPoint *points[]*)

Draws a spline between all given points using the current pen.

wxPerl Note: Not supported by wxPerl.

void wxDC::DrawSpline (const wxPointList * *points*)

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.

wxPerl Note: The wxPerl version of this method accepts as its first parameter a reference to an array of wxPoint objects.

void wxDC::DrawSpline (wxCoord *x1,* wxCoord *y1,* wxCoord *x2,* wxCoord *y2,* wxCoord *x3,* wxCoord *y3*)

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.

wxPerl Note: Not supported by wxPerl.

void wxDC::DrawText (const wxString & *text,* wxCoord *x,* wxCoord *y*)

Draws a text string at the specified point, using the current text font, and the current text foreground and background colours.

The coordinates refer to the top-left corner of the rectangle bounding the string. See GetTextExtent() for how to get the dimensions of a text string, which can be used to position the text more precisely and DrawLabel() if you need to align the string differently.

Starting from wxWidgets 2.9.2 *text* parameter can be a multi-line string, i.e. contain new line characters, and will be rendered correctly.

Note

The current logical function is ignored by this function.

void wxDC::DrawText (const wxString & *text,* const wxPoint & *pt*)

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.

void wxDC::EndDoc ( )

Ends a document (only relevant when outputting to a printer).

void wxDC::EndPage ( )

Ends a document page (only relevant when outputting to a printer).

bool wxDC::FloodFill (wxCoord *x,* wxCoord *y,* const wxColour & *colour,* wxFloodFillStyle *style* = wxFLOOD_SURFACE)

Flood fills the device context starting from the given point, using the current brush colour, and using a style:

- wxFLOOD_SURFACE: The flooding occurs until a colour other than the given colour is encountered.
- wxFLOOD_BORDER: The area to be flooded is bounded by the given colour.

Currently this method is not implemented in wxOSX and does nothing there.

Returns

false if the operation failed.

Note

The present implementation for non-Windows platforms may fail to find colour borders if the pixels do not match the colour exactly. However the function will still return true.
This method shouldn't be used with wxPaintDC under non-Windows platforms as it uses GetPixel() internally and this may give wrong results, notably in wxGTK. If you need to flood fill wxPaintDC, create a temporary wxMemoryDC, flood fill it and then blit it to, or draw as a bitmap on, wxPaintDC. See the example of doing this in the drawing sample and wxBufferedPaintDC class.

bool wxDC::FloodFill (const wxPoint & *pt,* const wxColour & *col,* wxFloodFillStyle *style* = wxFLOOD_SURFACE)

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.

wxBitmap wxDC::GetAsBitmap (const wxRect * *subrect* = NULL) const

If supported by the platform and the type of DC, fetch the contents of the DC, or a subset of it, as a bitmap.

const wxBrush& wxDC::GetBackground ( ) const

Gets the brush used for painting the background.

See also

wxDC::SetBackground()

int wxDC::GetBackgroundMode ( ) const

Returns the current background mode: wxPENSTYLE_SOLID or wxPENSTYLE_TRANSPARENT.

See also

SetBackgroundMode()

const wxBrush& wxDC::GetBrush ( ) const

Gets the current brush.

See also

wxDC::SetBrush()

wxCoord wxDC::GetCharHeight ( ) const

Gets the character height of the currently set font.

wxCoord wxDC::GetCharWidth ( ) const

Gets the average character width of the currently set font.

void wxDC::GetClippingBox (wxCoord * *x*, wxCoord * *y*, wxCoord * *width*, wxCoord * *height*) const

Gets the rectangle surrounding the current clipping region.

int wxDC::GetDepth ( ) const

Returns the depth (number of bits/pixel) of this DC.

See also

wxDisplayDepth()

wxPoint wxDC::GetDeviceOrigin ( ) const

Returns the current device origin.

See also

SetDeviceOrigin()

const wxFont& wxDC::GetFont ( ) const

Gets the current font.

Notice that even although each device context object has some default font after creation, this method would return a wxNullFont initially and only after calling SetFont() a valid font is returned.

wxFontMetrics wxDC::GetFontMetrics ( ) const

Returns the various font characteristics.

This method allows to retrieve some of the font characteristics not returned by GetTextExtent(), notably internal leading and average character width.

Currently this method returns correct results only under wxMSW, in the other ports the internal leading will always be 0 and the average character width will be computed as the width of the character 'x'.

Since

2.9.2

void* wxDC::GetHandle ( ) const

Returns a value that can be used as a handle to the native drawing context, if this wxDC has something that could be thought of in that way.

(Not all of them do.)

For example, on Windows the return value is an HDC, on OSX it is a CGContextRef and on wxGTK it will be a GdkDrawable. If the DC is a wxGCDC then the return value will be the value returned from wxGraphicsContext::GetNativeContext. A value of NULL is returned if the DC does not have anything that fits the handle concept.

Since

2.9.5

wxLayoutDirection wxDC::GetLayoutDirection ( ) const

Gets the current layout direction of the device context.

On platforms where RTL layout is supported, the return value will either be `wxLayout_LeftToRight` or `wxLayout_RightToLeft`. If RTL layout is not supported, the return value will be `wxLayout_Default`.

See also

SetLayoutDirection()

wxRasterOperationMode wxDC::GetLogicalFunction ( ) const

Gets the current logical function.

See also

SetLogicalFunction()

void wxDC::GetLogicalOrigin (wxCoord * *x*, wxCoord * *y*) const

wxPoint wxDC::GetLogicalOrigin ( ) const

void wxDC::GetLogicalScale (double * *x*, double * *y*) const

wxMappingMode wxDC::GetMapMode ( ) const

Gets the current mapping mode for the device context.

See also

SetMapMode()

void wxDC::GetMultiLineTextExtent (const wxString & *string*, wxCoord * *w*, wxCoord * *h*, wxCoord * *heightLine* = `NULL`, const wxFont * *font* = `NULL`) const

Gets the dimensions of the string using the currently selected font.

string is the text string to measure, *heightLine*, if non NULL, is where to store the height of a single line.

The text extent is set in the given *w* and *h* pointers.

If the optional parameter *font* is specified and valid, then it is used for the text extent calculation, otherwise the currently selected font is used.

Note

This function works with both single-line and multi-line strings.

wxPerl Note: In wxPerl this method is implemented as GetMultiLineTextExtent(string, font = undef) returning a 3-element list (width, height, line_height)

See also

wxFont, SetFont(), GetPartialTextExtents(), GetTextExtent()

wxSize wxDC::GetMultiLineTextExtent (const wxString & *string*) const

Gets the dimensions of the string using the currently selected font.

string is the text string to measure, *heightLine*, if non NULL, is where to store the height of a single line.

Returns

The text extent as a wxSize object.

Note

This function works with both single-line and multi-line strings.

wxPerl Note: Not supported by wxPerl.

See also

wxFont, SetFont(), GetPartialTextExtents(), GetTextExtent()

bool wxDC::GetPartialTextExtents (const wxString & *text,* wxArrayInt & *widths*) const

Fills the *widths* array with the widths from the beginning of *text* to the corresponding character of *text*.

The generic version simply builds a running total of the widths of each character using GetTextExtent(), however if the various platforms have a native API function that is faster or more accurate than the generic implementation then it should be used instead.

wxPerl Note: In wxPerl this method only takes the *text* parameter and returns the widths as a list of integers.

See also

GetMultiLineTextExtent(), GetTextExtent()

const wxPen& wxDC::GetPen ( ) const

Gets the current pen.

See also

SetPen()

bool wxDC::GetPixel (wxCoord *x*, wxCoord *y*, wxColour * *colour*) const

Gets in *colour* the colour at the specified location.

Not available for wxPostScriptDC or wxMetafileDC.

Note

Setting a pixel can be done using DrawPoint().
This method shouldn't be used with wxPaintDC as accessing the DC while drawing can result in unexpected results, notably in wxGTK.

wxSize wxDC::GetPPI ( ) const

Returns the resolution of the device in pixels per inch.

void wxDC::GetSize (wxCoord * *width*, wxCoord * *height*) const

Gets the horizontal and vertical extent of this device context in *device* units.

It can be used to scale graphics to fit the page.

For example, if *maxX* and *maxY* represent the maximum horizontal and vertical 'pixel' values used in your application, the following code will scale the graphic to fit on the printer page:

```
wxCoord w, h;
dc.GetSize(&w, &h);
double scaleX = (double)(maxX / w);
double scaleY = (double)(maxY / h);
dc.SetUserScale(min(scaleX, scaleY),min(scaleX, scaleY));
```

wxPerl Note: In wxPerl there are two methods instead of a single overloaded method:

- GetSize(): returns a Wx::Size object.
- GetSizeWH(): returns a 2-element list (width, height).

wxSize wxDC::GetSize ( ) const

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.

void wxDC::GetSizeMM (wxCoord * *width*, wxCoord * *height*) const

Returns the horizontal and vertical resolution in millimetres.

wxSize wxDC::GetSizeMM ( ) const

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.

const wxColour& wxDC::GetTextBackground ( ) const

Gets the current text background colour.

See also

SetTextBackground()

void wxDC::GetTextExtent (const wxString & *string*, wxCoord * *w*, wxCoord * *h*, wxCoord * *descent* = NULL, wxCoord * *externalLeading* = NULL, const wxFont * *font* = NULL) const

Gets the dimensions of the string using the currently selected font.

string is the text string to measure, *descent* is the dimension from the baseline of the font to the bottom of the descender, and *externalLeading* is any extra vertical space added to the font by the font designer (usually is zero).

The text extent is returned in *w* and *h* pointers or as a wxSize object depending on which version of this function is used.

If the optional parameter *font* is specified and valid, then it is used for the text extent calculation. Otherwise the currently selected font is.

Note

This function only works with single-line strings.

wxPerl Note: In wxPerl this method is implemented as GetTextExtent(string, font = undef) returning a 4-element list (width, height, descent, externalLeading)

See also

wxFont, SetFont(), GetPartialTextExtents(), GetMultiLineTextExtent()

wxSize wxDC::GetTextExtent (const wxString & *string*) const

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.

wxPerl Note: Not supported by wxPerl.

const wxColour& wxDC::GetTextForeground ( ) const

Gets the current text foreground colour.

See also

SetTextForeground()

wxAffineMatrix2D wxDC::GetTransformMatrix ( ) const

Return the transformation matrix used by this device context.

By default the transformation matrix is the identity matrix.

Since

2.9.2

void wxDC::GetUserScale (double * *x*, double * *y*) const

Gets the current user scale factor.

wxPerl Note: In wxPerl this method takes no arguments and return a two element array (x, y).

See also

SetUserScale()

void wxDC::GradientFillConcentric (const wxRect & *rect,* const wxColour & *initialColour,* const wxColour & *destColour*)

Fill the area specified by rect with a radial gradient, starting from *initialColour* at the centre of the circle and fading to *destColour* on the circle outside.

The circle is placed at the centre of *rect*.

Note

Currently this function is very slow, don't use it for real-time drawing.

void wxDC::GradientFillConcentric (const wxRect & *rect,* const wxColour & *initialColour,* const wxColour & *destColour,* const wxPoint & *circleCenter*)

Fill the area specified by rect with a radial gradient, starting from *initialColour* at the centre of the circle and fading to *destColour* on the circle outside.

circleCenter are the relative coordinates of centre of the circle in the specified *rect*.

Note

Currently this function is very slow, don't use it for real-time drawing.

void wxDC::GradientFillLinear (const wxRect & *rect,* const wxColour & *initialColour,* const wxColour & *destColour,* wxDirection *nDirection* = wxRIGHT)

Fill the area specified by *rect* with a linear gradient, starting from *initialColour* and eventually fading to *destColour*.

The *nDirection* specifies the direction of the colour change, default is to use *initialColour* on the left part of the rectangle and *destColour* on the right one.

bool wxDC::IsOk ( ) const

Returns true if the DC is ok to use.

wxCoord wxDC::LogicalToDeviceX (wxCoord *x*) const

Converts logical X coordinate to device coordinate, using the current mapping mode, user scale factor, device origin and axis orientation.

wxCoord wxDC::LogicalToDeviceXRel (wxCoord *x*) const

Converts logical X coordinate to relative device coordinate, using the current mapping mode and user scale factor but ignoring the axis orientation.

Use this for converting a width, for example.

wxCoord wxDC::LogicalToDeviceY (wxCoord *y*) const

Converts logical Y coordinate to device coordinate, using the current mapping mode, user scale factor, device origin and axis orientation.

wxCoord wxDC::LogicalToDeviceYRel (wxCoord *y*) const

Converts logical Y coordinate to relative device coordinate, using the current mapping mode and user scale factor but ignoring the axis orientation.

Use this for converting a height, for example.

wxCoord wxDC::MaxX ( ) const

Gets the maximum horizontal extent used in drawing commands so far.

wxCoord wxDC::MaxY ( ) const

Gets the maximum vertical extent used in drawing commands so far.

wxCoord wxDC::MinX ( ) const

Gets the minimum horizontal extent used in drawing commands so far.

wxCoord wxDC::MinY ( ) const

Gets the minimum vertical extent used in drawing commands so far.

void wxDC::ResetBoundingBox ( )

Resets the bounding box: after a call to this function, the bounding box doesn't contain anything.

See also

CalcBoundingBox()

void wxDC::ResetTransformMatrix ( )

Revert the transformation matrix to identity matrix.

Since

2.9.2

void wxDC::SetAxisOrientation (bool *xLeftRight*, bool *yBottomUp*)

Sets the x and y axis orientation (i.e. the direction from lowest to highest values on the axis).

The default orientation is x axis from left to right and y axis from top down.

Parameters

xLeftRight	True to set the x axis orientation to the natural left to right orientation, false to invert it.
yBottomUp	True to set the y axis orientation to the natural bottom up orientation, false to invert it.

void wxDC::SetBackground (const wxBrush & *brush*)

Sets the current background brush for the DC.

void wxDC::SetBackgroundMode (int *mode*)

mode may be one of `wxPENSTYLE_SOLID` and `wxPENSTYLE_TRANSPARENT`.

This setting determines whether text will be drawn with a background colour or not.

void wxDC::SetBrush (const wxBrush & *brush*)

Sets the current brush for the DC.

If the argument is wxNullBrush (or another invalid brush; see wxBrush::IsOk), the current brush is selected out of the device context (leaving wxDC without any valid brush), allowing the current brush to be destroyed safely.

See also

wxBrush, wxMemoryDC (for the interpretation of colours when drawing into a monochrome bitmap)

void wxDC::SetClippingRegion (wxCoord *x,* wxCoord *y,* wxCoord *width,* wxCoord *height*)

Sets the clipping region for this device context to the intersection of the given region described by the parameters of this method and the previously set clipping region.

The clipping region is an area to which drawing is restricted. Possible uses for the clipping region are for clipping text or for speeding up window redraws when only a known area of the screen is damaged.

Notice that you need to call DestroyClippingRegion() if you want to set the clipping region exactly to the region specified.

Also note that if the clipping region is empty, any previously set clipping region is destroyed, i.e. it is equivalent to calling DestroyClippingRegion(), and not to clipping out all drawing on the DC as might be expected.

See also

DestroyClippingRegion(), wxRegion

void wxDC::SetClippingRegion (const wxPoint & *pt,* const wxSize & *sz*)

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.

void wxDC::SetClippingRegion (const wxRect & *rect*)

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.

void wxDC::SetDeviceClippingRegion (const wxRegion & *region*)

Sets the clipping region for this device context.

Unlike SetClippingRegion(), this function works with physical coordinates and not with the logical ones.

void wxDC::SetDeviceOrigin (wxCoord *x,* wxCoord *y*)

Sets the device origin (i.e. the origin in pixels after scaling has been applied).

This function may be useful in Windows printing operations for placing a graphic on a page.

void wxDC::SetFont (const wxFont & *font*)

Sets the current font for the DC.

If the argument is wxNullFont (or another invalid font; see wxFont::IsOk), the current font is selected out of the device context (leaving wxDC without any valid font), allowing the current font to be destroyed safely.

See also

wxFont

void wxDC::SetLayoutDirection (wxLayoutDirection *dir*)

Sets the current layout direction for the device context.

Parameters

dir	May be either `wxLayout_Default`, `wxLayout_LeftToRight` or `wxLayout_RightToLeft`.

See also

GetLayoutDirection()

void wxDC::SetLogicalFunction (wxRasterOperationMode *function*)

Sets the current logical function for the device context.

It determines how a *source* pixel (from a pen or brush colour, or source device context if using Blit()) combines with a *destination* pixel in the current device context. Text drawing is not affected by this function.

See wxRasterOperationMode enumeration values for more info.

The default is `wxCOPY`, which simply draws with the current colour. The others combine the current colour and the background using a logical operation. `wxINVERT` is commonly used for drawing rubber bands or moving outlines, since drawing twice reverts to the original colour.

void wxDC::SetLogicalOrigin (wxCoord *x*, wxCoord *y*)

void wxDC::SetLogicalScale (double *x*, double *y*)

void wxDC::SetMapMode (wxMappingMode *mode*)

The mapping mode of the device context defines the unit of measurement used to convert *logical* units to *device* units.

Note that in X, text drawing isn't handled consistently with the mapping mode; a font is always specified in point size. However, setting the user scale (see SetUserScale()) scales the text appropriately. In Windows, scalable TrueType fonts are always used; in X, results depend on availability of fonts, but usually a reasonable match is found.

The coordinate origin is always at the top left of the screen/printer.

Drawing to a Windows printer device context uses the current mapping mode, but mapping mode is currently ignored for PostScript output.

void wxDC::SetPalette (const wxPalette & *palette*)

If this is a window DC or memory DC, assigns the given palette to the window or bitmap associated with the DC.

If the argument is wxNullPalette, the current palette is selected out of the device context, and the original palette restored.

See also

wxPalette

void wxDC::SetPen (const wxPen & *pen*)

Sets the current pen for the DC.

If the argument is wxNullPen (or another invalid pen; see wxPen::IsOk), the current pen is selected out of the device context (leaving wxDC without any valid pen), allowing the current pen to be destroyed safely.

See also

wxMemoryDC for the interpretation of colours when drawing into a monochrome bitmap.

void wxDC::SetTextBackground (const wxColour & *colour*)

Sets the current text background colour for the DC.

void wxDC::SetTextForeground (const wxColour & *colour*)

Sets the current text foreground colour for the DC.

See also

wxMemoryDC for the interpretation of colours when drawing into a monochrome bitmap.

bool wxDC::SetTransformMatrix (const wxAffineMatrix2D & *matrix*)

Set the transformation matrix.

If transformation matrix is supported on the current system, the specified *matrix* will be used to transform between wxDC and physical coordinates. Otherwise the function returns false and doesn't change the coordinate mapping.

Since

2.9.2

void wxDC::SetUserScale (double *xScale,* double *yScale*)

Sets the user scaling factor, useful for applications which require 'zooming'.

bool wxDC::StartDoc (const wxString & *message*)

Starts a document (only relevant when outputting to a printer).

message is a message to show while printing.

void wxDC::StartPage ( )

Starts a document page (only relevant when outputting to a printer).

bool wxDC::StretchBlit (wxCoord *xdest*, wxCoord *ydest*, wxCoord *dstWidth*, wxCoord *dstHeight*, wxDC * *source*, wxCoord *xsrc*, wxCoord *ysrc*, wxCoord *srcWidth*, wxCoord *srcHeight*, wxRasterOperationMode *logicalFunc* = wxCOPY, bool *useMask* = `false`, wxCoord *xsrcMask* = wxDefaultCoord, wxCoord *ysrcMask* = wxDefaultCoord)

Copy from a source DC to this DC possibly changing the scale.

Unlike Blit(), this method allows to specify different source and destination region sizes, meaning that it can stretch or shrink it while copying. The same can be achieved by changing the scale of the source or target DC but calling this method is simpler and can also be more efficient if the platform provides a native implementation of it.

The meaning of its other parameters is the same as with Blit(), in particular all source coordinates are interpreted using the source DC coordinate system, i.e. are affected by its scale, origin translation and axis direction.

Parameters

xdest	Destination device context x position.
ydest	Destination device context y position.
dstWidth	Width of destination area.
dstHeight	Height of destination area.
source	Source device context.
xsrc	Source device context x position.
ysrc	Source device context y position.
srcWidth	Width of source area to be copied.
srcHeight	Height of source area to be copied.
logicalFunc	Logical function to use, see SetLogicalFunction().
useMask	If true, Blit does a transparent blit using the mask that is associated with the bitmap selected into the source device context. The Windows implementation does the following if MaskBlt cannot be used: 1. Creates a temporary bitmap and copies the destination area into it. 2. Copies the source area into the temporary bitmap using the specified logical function. 3. Sets the masked area in the temporary bitmap to BLACK by ANDing the mask bitmap with the temp bitmap with the foreground colour set to WHITE and the bg colour set to BLACK. 4. Sets the unmasked area in the destination area to BLACK by ANDing the mask bitmap with the destination area with the foreground colour set to BLACK and the background colour set to WHITE. 5. ORs the temporary bitmap with the destination area. 6. Deletes the temporary bitmap. This sequence of operations ensures that the source's transparent area need not be black, and logical functions are supported. **Note:** on Windows, blitting with masks can be speeded up considerably by compiling wx↩ Widgets with the wxUSE_DC_CACHEING option enabled. You can also influence whether MaskBlt or the explicit mask blitting code above is used, by using wxSystemOptions and setting the `no-maskblt` option to 1.

xsrcMask	Source x position on the mask. If both xsrcMask and ysrcMask are wxDefaultCoord, *xsrc* and *ysrc* will be assumed for the mask source position. Currently only implemented on Windows.
ysrcMask	Source y position on the mask. If both xsrcMask and ysrcMask are wxDefaultCoord, *xsrc* and *ysrc* will be assumed for the mask source position. Currently only implemented on Windows.

There is partial support for Blit() in wxPostScriptDC, under X.

See wxMemoryDC for typical usage.

Since

2.9.0

See also

Blit(), wxMemoryDC, wxBitmap, wxMask

21.174 wxDCBrushChanger Class Reference

`#include <wx/dc.h>`

21.174.1 Detailed Description

wxDCBrushChanger is a small helper class for setting a brush on a wxDC and unsetting it automatically in the destructor, restoring the previous one.

Library: wxCore

Category: Graphics Device Interface (GDI)

See also

wxDC::SetBrush(), wxDCFontChanger, wxDCTextColourChanger, wxDCPenChanger, wxDCClipper

Public Member Functions

- wxDCBrushChanger (wxDC &dc, const wxBrush &brush)

  Sets brush on the given dc, storing the old one.
- ~wxDCBrushChanger ()

  Restores the brush originally selected in the DC passed to the ctor.

21.174.2 Constructor & Destructor Documentation

wxDCBrushChanger::wxDCBrushChanger (wxDC & *dc,* const wxBrush & *brush*)

Sets *brush* on the given *dc*, storing the old one.

Parameters

dc	The DC where the brush must be temporary set.
brush	The brush to set.

wxDCBrushChanger::~wxDCBrushChanger ( )

Restores the brush originally selected in the DC passed to the ctor.

21.175 wxDCClipper Class Reference

`#include <wx/dc.h>`

21.175.1 Detailed Description

wxDCClipper is a helper class for setting a clipping region on a wxDC during its lifetime.

An object of wxDCClipper class is typically created on the stack so that it is automatically destroyed when the object goes out of scope. A typical usage example:

```
void MyFunction(wxDC& dc)
{
    wxDCClipper clip(dc, rect);
    // ... drawing functions here are affected by clipping rect ...
}

void OtherFunction()
{
    wxDC dc;
    MyFunction(dc);
    // ... drawing functions here are not affected by clipping rect ...
}
```

Note

Unlike other similar classes such as wxDCFontChanger, wxDCClipper currently doesn't restore the previously active clipping region when it is destroyed but simply resets clipping on the associated wxDC. This may be changed in the future wxWidgets versions but has to be taken into account explicitly in the current one.

Library: wxCore

Category: Graphics Device Interface (GDI)

See also

wxDC::SetClippingRegion(), wxDCFontChanger, wxDCTextColourChanger, wxDCPenChanger, wxDCBrushChanger

Public Member Functions

- ~wxDCClipper ()

  Destroys the clipping region associated with the DC passed to the ctor.

- wxDCClipper (wxDC &dc, const wxRegion &region)

  Sets the clipping region to the specified region/coordinates.

- wxDCClipper (wxDC &dc, const wxRect &rect)

Sets the clipping region to the specified region/coordinates.

- wxDCClipper (wxDC &dc, wxCoord x, wxCoord y, wxCoord w, wxCoord h)

  Sets the clipping region to the specified region/coordinates.

21.175.2 Constructor & Destructor Documentation

wxDCClipper::wxDCClipper (wxDC & *dc,* const wxRegion & *region*)

Sets the clipping region to the specified region/coordinates.

The clipping region is automatically unset when this object is destroyed.

wxDCClipper::wxDCClipper (wxDC & *dc,* const wxRect & *rect*)

Sets the clipping region to the specified region/coordinates.

The clipping region is automatically unset when this object is destroyed.

wxDCClipper::wxDCClipper (wxDC & *dc,* wxCoord *x,* wxCoord *y,* wxCoord *w,* wxCoord *h*)

Sets the clipping region to the specified region/coordinates.

The clipping region is automatically unset when this object is destroyed.

wxDCClipper::~wxDCClipper ( )

Destroys the clipping region associated with the DC passed to the ctor.

21.176 wxDCFontChanger Class Reference

```
#include <wx/dc.h>
```

21.176.1 Detailed Description

wxDCFontChanger is a small helper class for setting a font on a wxDC and unsetting it automatically in the destructor, restoring the previous one.

Since

2.9.0

Library: wxCore

Category: Graphics Device Interface (GDI)

See also

wxDC::SetFont(), wxDCTextColourChanger, wxDCPenChanger, wxDCBrushChanger, wxDCClipper

Public Member Functions

- wxDCFontChanger (wxDC &dc)

  Trivial constructor not changing anything.
- wxDCFontChanger (wxDC &dc, const wxFont &font)

  Sets font on the given dc, storing the old one.
- void Set (const wxFont &font)

  Set the font to use.
- ~wxDCFontChanger ()

  Restores the font originally selected in the DC passed to the ctor.

21.176.2 Constructor & Destructor Documentation

wxDCFontChanger::wxDCFontChanger (wxDC & *dc*)

Trivial constructor not changing anything.

This constructor is useful if you don't know beforehand if the font needs to be changed or not. It simply creates the object which won't do anything in its destructor unless Set() is called – in which case it would reset the previous font.

Since

2.9.1

wxDCFontChanger::wxDCFontChanger (wxDC & *dc,* const wxFont & *font*)

Sets *font* on the given *dc*, storing the old one.

Parameters

dc	The DC where the font must be temporary set.
font	The font to set.

wxDCFontChanger::~wxDCFontChanger ( )

Restores the font originally selected in the DC passed to the ctor.

21.176.3 Member Function Documentation

void wxDCFontChanger::Set (const wxFont & *font*)

Set the font to use.

This method is meant to be called once only and only on the objects created with the constructor overload not taking wxColour argument and has the same effect as the other constructor, i.e. sets the font to the given *font* and ensures that the old value is restored when this object is destroyed.

21.177 wxDCOverlay Class Reference

`#include <wx/overlay.h>`

21.177.1 Detailed Description

Connects an overlay with a drawing DC.

Library: wxCore

See also

wxOverlay, wxDC

Public Member Functions

- wxDCOverlay (wxOverlay &overlay, wxDC *dc, int x, int y, int width, int height)
  Connects this overlay to the corresponding drawing dc, if the overlay is not initialized yet this call will do so.
- wxDCOverlay (wxOverlay &overlay, wxDC *dc)
  Convenience wrapper that behaves the same using the entire area of the dc.
- virtual ~wxDCOverlay ()
  Removes the connection between the overlay and the dc.
- void Clear ()
  Clears the layer, restoring the state at the last init.

21.177.2 Constructor & Destructor Documentation

wxDCOverlay::wxDCOverlay (wxOverlay & *overlay,* wxDC * *dc,* int *x,* int *y,* int *width,* int *height*)

Connects this overlay to the corresponding drawing dc, if the overlay is not initialized yet this call will do so.

wxDCOverlay::wxDCOverlay (wxOverlay & *overlay,* wxDC * *dc*)

Convenience wrapper that behaves the same using the entire area of the dc.

virtual wxDCOverlay::~wxDCOverlay ( ) [virtual]

Removes the connection between the overlay and the dc.

21.177.3 Member Function Documentation

void wxDCOverlay::Clear ( )

Clears the layer, restoring the state at the last init.

21.178 wxDCPenChanger Class Reference

```
#include <wx/dc.h>
```

21.178.1 Detailed Description

wxDCPenChanger is a small helper class for setting a pen on a wxDC and unsetting it automatically in the destructor, restoring the previous one.

Library: wxCore

Category: Graphics Device Interface (GDI)

See also

wxDC::SetPen(), wxDCFontChanger, wxDCTextColourChanger, wxDCBrushChanger, wxDCClipper

Public Member Functions

- wxDCPenChanger (wxDC &dc, const wxPen &pen)

  Sets pen on the given dc, storing the old one.
- ~wxDCPenChanger ()

  Restores the pen originally selected in the DC passed to the ctor.

21.178.2 Constructor & Destructor Documentation

wxDCPenChanger::wxDCPenChanger (wxDC & *dc,* const wxPen & *pen*)

Sets *pen* on the given *dc*, storing the old one.

Parameters

dc	The DC where the pen must be temporary set.
pen	The pen to set.

wxDCPenChanger::~wxDCPenChanger ( )

Restores the pen originally selected in the DC passed to the ctor.

21.179 wxDCTextColourChanger Class Reference

```
#include <wx/dc.h>
```

21.179.1 Detailed Description

wxDCTextColourChanger is a small helper class for setting a foreground text colour on a wxDC and unsetting it automatically in the destructor, restoring the previous one.

Library: wxCore

Category: Graphics Device Interface (GDI)

See also

wxDC::SetTextForeground(), wxDCFontChanger, wxDCPenChanger, wxDCBrushChanger, wxDCClipper

Public Member Functions

- wxDCTextColourChanger (wxDC &dc)

  Trivial constructor not changing anything.
- wxDCTextColourChanger (wxDC &dc, const wxColour &col)

  Sets col on the given dc, storing the old one.
- void Set (const wxColour &col)

  Set the colour to use.
- ~wxDCTextColourChanger ()

  Restores the colour originally selected in the DC passed to the ctor.

21.179.2 Constructor & Destructor Documentation

wxDCTextColourChanger::wxDCTextColourChanger (wxDC & *dc*)

Trivial constructor not changing anything.

This constructor is useful if you don't know beforehand if the colour needs to be changed or not. It simply creates the object which won't do anything in its destructor unless Set() is called – in which case it would reset the previous colour.

wxDCTextColourChanger::wxDCTextColourChanger (wxDC & *dc,* const wxColour & *col*)

Sets *col* on the given *dc*, storing the old one.

Parameters

dc	The DC where the colour must be temporary set.
col	The colour to set.

wxDCTextColourChanger::~wxDCTextColourChanger ( )

Restores the colour originally selected in the DC passed to the ctor.

21.179.3 Member Function Documentation

void wxDCTextColourChanger::Set (const wxColour & *col*)

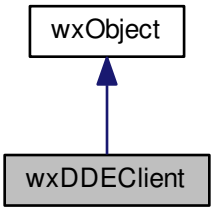
Set the colour to use.

This method is meant to be called once only and only on the objects created with the constructor overload not taking wxColour argument and has the same effect as the other constructor, i.e. sets the colour to the given *col* and ensures that the old value is restored when this object is destroyed.

21.180 wxDDEClient Class Reference

```
#include <wx/dde.h>
```

Inheritance diagram for wxDDEClient:



21.180.1 Detailed Description

A wxDDEClient object represents the client part of a client-server DDE (Dynamic Data Exchange) conversation.

To create a client which can communicate with a suitable server, you need to derive a class from wxDDEConnection and another from wxDDEClient. The custom wxDDEConnection class will intercept communications in a "conversation" with a server, and the custom wxDDEServer is required so that a user-overridden OnMakeConnection() member can return a wxDDEConnection of the required class, when a connection is made.

This DDE-based implementation is available on Windows only, but a platform-independent, socket-based version of this API is available using wxTCPClient.

Library: wxBase

Category: Interprocess Communication Availability: only available for the wxMSW port.

See also

wxDDEServer, wxDDEConnection, Interprocess Communication

Public Member Functions

- wxDDEClient ()

  Constructs a client object.
- wxConnectionBase * MakeConnection (const wxString &host, const wxString &service, const wxString &topic)

  Tries to make a connection with a server specified by the host (machine name under UNIX, ignored under Windows), service name (must contain an integer port number under UNIX), and topic string.
- wxConnectionBase * OnMakeConnection ()

  The type of wxDDEConnection returned from a MakeConnection() call can be altered by deriving the OnMake↩ Connection() member to return your own derived connection object.
- bool ValidHost (const wxString &host)

  Returns true if this is a valid host name, false otherwise.

Additional Inherited Members

21.180.2 Constructor & Destructor Documentation

wxDDEClient::wxDDEClient ( )

Constructs a client object.

21.180.3 Member Function Documentation

wxConnectionBase* wxDDEClient::MakeConnection (const wxString & *host,* const wxString & *service,* const wxString & *topic*)

Tries to make a connection with a server specified by the host (machine name under UNIX, ignored under Windows), service name (must contain an integer port number under UNIX), and topic string.

If the server allows a connection, a wxDDEConnection object will be returned.

The type of wxDDEConnection returned can be altered by overriding the OnMakeConnection() member to return your own derived connection object.

wxConnectionBase* wxDDEClient::OnMakeConnection ( )

The type of wxDDEConnection returned from a MakeConnection() call can be altered by deriving the OnMake↩Connection() member to return your own derived connection object.

By default, a wxDDEConnection object is returned.

The advantage of deriving your own connection class is that it will enable you to intercept messages initiated by the server, such as wxDDEConnection::OnAdvise(). You may also want to store application-specific data in instances of the new class.

bool wxDDEClient::ValidHost (const wxString & *host*)

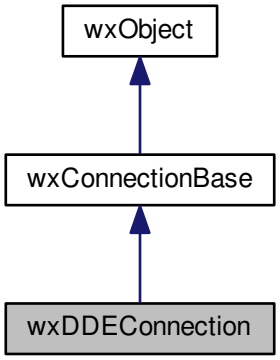
Returns true if this is a valid host name, false otherwise.

This always returns true under MS Windows.

21.181 wxDDEConnection Class Reference

```
#include <wx/dde.h>
```

Inheritance diagram for wxDDEConnection:



21.181.1 Detailed Description

A wxDDEConnection object represents the connection between a client and a server.

It can be created by making a connection using a wxDDEClient object, or by the acceptance of a connection by a wxDDEServer object. The bulk of a DDE (Dynamic Data Exchange) conversation is controlled by calling members in a wxDDEConnection object or by overriding its members.

An application should normally derive a new connection class from wxDDEConnection, in order to override the communication event handlers to do something interesting.

This DDE-based implementation is available on Windows only, but a platform-independent, socket-based version of this API is available using wxTCPConnection.

Library: wxBase

Category: Interprocess Communication Availability: only available for the wxMSW port.

See also

wxConnectionBase, wxDDEClient, wxDDEServer, Interprocess Communication

Public Member Functions

- wxDDEConnection ()

  Constructs a connection object.
- wxDDEConnection (void ∗buffer, size_t size)

  Constructs a connection object.
- bool Disconnect ()

  Called by the client or server application to disconnect from the other program; it causes the OnDisconnect() message to be sent to the corresponding connection object in the other program.
- virtual bool OnAdvise (const wxString &topic, const wxString &item, const void ∗data, size_t size, wxIPC↩ Format format)

Message sent to the client application when the server notifies it of a change in the data associated with the given item.

- virtual bool OnDisconnect ()

  Message sent to the client or server application when the other application notifies it to delete the connection.
- virtual bool OnExecute (const wxString &topic, const void *data, size_t size, wxIPCFormat format)

  Message sent to the server application when the client notifies it to execute the given data.
- virtual bool OnPoke (const wxString &topic, const wxString &item, const void *data, size_t size, wxIPCFormat format)

  Message sent to the server application when the client notifies it to accept the given data.
- virtual const void * OnRequest (const wxString &topic, const wxString &item, size_t *size, wxIPCFormat format)

  Message sent to the server application when the client calls Request().
- virtual bool OnStartAdvise (const wxString &topic, const wxString &item)

  Message sent to the server application by the client, when the client wishes to start an "advise loop" for the given topic and item.
- virtual bool OnStopAdvise (const wxString &topic, const wxString &item)

  Message sent to the server application by the client, when the client wishes to stop an "advise loop" for the given topic and item.
- const void * Request (const wxString &item, size_t *size, wxIPCFormat format=wxIPC_TEXT)

  Called by the client application to request data from the server.
- bool StartAdvise (const wxString &item)

  Called by the client application to ask if an advise loop can be started with the server.
- bool StopAdvise (const wxString &item)

  Called by the client application to ask if an advise loop can be stopped.

- bool Advise (const wxString &item, const void *data, size_t size, wxIPCFormat format=wxIPC_PRIVATE)

  Called by the server application to advise the client of a change in the data associated with the given item.
- bool Advise (const wxString &item, const char *data)

  Called by the server application to advise the client of a change in the data associated with the given item.
- bool Advise (const wxString &item, const wchar_t *data)

  Called by the server application to advise the client of a change in the data associated with the given item.
- bool Advise (const wxString &item, const wxString data)

  Called by the server application to advise the client of a change in the data associated with the given item.

- bool Execute (const void *data, size_t size, wxIPCFormat format=wxIPC_PRIVATE)

  Called by the client application to execute a command on the server.
- bool Execute (const char *data)

  Called by the client application to execute a command on the server.
- bool Execute (const wchar_t *data)

  Called by the client application to execute a command on the server.
- bool Execute (const wxString data)

  Called by the client application to execute a command on the server.

- bool Poke (const wxString &item, const void *data, size_t size, wxIPCFormat format=wxIPC_PRIVATE)

  Called by the client application to poke data into the server.
- bool Poke (const wxString &item, const char *data)

  Called by the client application to poke data into the server.
- bool Poke (const wxString &item, const wchar_t *data)

  Called by the client application to poke data into the server.
- bool Poke (const wxString &item, const wxString data)

  Called by the client application to poke data into the server.

Additional Inherited Members

21.181.2 Constructor & Destructor Documentation

wxDDEConnection::wxDDEConnection ( )

Constructs a connection object.

If no user-defined connection object is to be derived from wxDDEConnection, then the constructor should not be called directly, since the default connection object will be provided on requesting (or accepting) a connection. However, if the user defines his or her own derived connection object, the wxDDEServer::OnAcceptConnection() and/or wxDDEClient::OnMakeConnection() members should be replaced by functions which construct the new connection object.

A default buffer will be associated with this connection.

wxDDEConnection::wxDDEConnection (void * *buffer*, size_t *size*)

Constructs a connection object.

If no user-defined connection object is to be derived from wxDDEConnection, then the constructor should not be called directly, since the default connection object will be provided on requesting (or accepting) a connection. However, if the user defines his or her own derived connection object, the wxDDEServer::OnAcceptConnection() and/or wxDDEClient::OnMakeConnection() members should be replaced by functions which construct the new connection object.

Parameters

buffer	Buffer for this connection object to use in transactions.
size	Size of the buffer given.

21.181.3 Member Function Documentation

bool wxDDEConnection::Advise (const wxString & *item*, const void * *data*, size_t *size*, wxIPCFormat *format* = wxIPC_PRIVATE)

Called by the server application to advise the client of a change in the data associated with the given item.

Causes the client connection's OnAdvise() member to be called.

Returns

true if successful.

bool wxDDEConnection::Advise (const wxString & *item*, const char * *data*)

Called by the server application to advise the client of a change in the data associated with the given item.

Causes the client connection's OnAdvise() member to be called.

Returns

true if successful.

bool wxDDEConnection::Advise (const wxString & *item*, const wchar_t * *data*)

Called by the server application to advise the client of a change in the data associated with the given item.

Causes the client connection's OnAdvise() member to be called.

Returns

true if successful.

bool wxDDEConnection::Advise (const wxString & *item,* const wxString *data*)

Called by the server application to advise the client of a change in the data associated with the given item.

Causes the client connection's OnAdvise() member to be called.

Returns

true if successful.

bool wxDDEConnection::Disconnect ( )

Called by the client or server application to disconnect from the other program; it causes the OnDisconnect() message to be sent to the corresponding connection object in the other program.

The default behaviour of OnDisconnect() is to delete the connection, but the calling application must explicitly delete its side of the connection having called Disconnect().

Returns

true if successful.

bool wxDDEConnection::Execute (const void * *data,* size_t *size,* wxIPCFormat *format* = wxIPC_PRIVATE)

Called by the client application to execute a command on the server.

Can also be used to transfer arbitrary data to the server (similar to Poke() in that respect). Causes the server connection's OnExecute() member to be called.

Returns

true if successful.

bool wxDDEConnection::Execute (const char * *data*)

Called by the client application to execute a command on the server.

Can also be used to transfer arbitrary data to the server (similar to Poke() in that respect). Causes the server connection's OnExecute() member to be called.

Returns

true if successful.

bool wxDDEConnection::Execute (const wchar_t * *data*)

Called by the client application to execute a command on the server.

Can also be used to transfer arbitrary data to the server (similar to Poke() in that respect). Causes the server connection's OnExecute() member to be called.

Returns

true if successful.

bool wxDDEConnection::Execute (const wxString *data*)

Called by the client application to execute a command on the server.

Can also be used to transfer arbitrary data to the server (similar to Poke() in that respect). Causes the server connection's OnExecute() member to be called.

Returns

true if successful.

virtual bool wxDDEConnection::OnAdvise (const wxString & *topic,* const wxString & *item,* const void * *data,* size_t *size,* wxIPCFormat *format*) [virtual]

Message sent to the client application when the server notifies it of a change in the data associated with the given item.

virtual bool wxDDEConnection::OnDisconnect ( ) [virtual]

Message sent to the client or server application when the other application notifies it to delete the connection.

Default behaviour is to delete the connection object.

virtual bool wxDDEConnection::OnExecute (const wxString & *topic,* const void * *data,* size_t *size,* wxIPCFormat *format*) [virtual]

Message sent to the server application when the client notifies it to execute the given data.

Note that there is no item associated with this message.

virtual bool wxDDEConnection::OnPoke (const wxString & *topic,* const wxString & *item,* const void * *data,* size_t *size,* wxIPCFormat *format*) [virtual]

Message sent to the server application when the client notifies it to accept the given data.

virtual const void* wxDDEConnection::OnRequest (const wxString & *topic,* const wxString & *item,* size_t * *size,* wxIPCFormat *format*) [virtual]

Message sent to the server application when the client calls Request().

The server should respond by returning a character string from OnRequest(), or NULL to indicate no data.

virtual bool wxDDEConnection::OnStartAdvise (const wxString & *topic,* const wxString & *item*) [virtual]

Message sent to the server application by the client, when the client wishes to start an "advise loop" for the given topic and item.

The server can refuse to participate by returning false.

virtual bool wxDDEConnection::OnStopAdvise (const wxString & *topic,* const wxString & *item*) [virtual]

Message sent to the server application by the client, when the client wishes to stop an "advise loop" for the given topic and item.

The server can refuse to stop the advise loop by returning false, although this doesn't have much meaning in practice.

bool wxDDEConnection::Poke (const wxString & *item*, const void * *data*, size_t *size*, wxIPCFormat *format* = wxIPC_PRIVATE)

Called by the client application to poke data into the server.

Can be used to transfer arbitrary data to the server. Causes the server connection's OnPoke() member to be called.

Returns

true if successful.

bool wxDDEConnection::Poke (const wxString & *item*, const char * *data*)

Called by the client application to poke data into the server.

Can be used to transfer arbitrary data to the server. Causes the server connection's OnPoke() member to be called.

Returns

true if successful.

bool wxDDEConnection::Poke (const wxString & *item*, const wchar_t * *data*)

Called by the client application to poke data into the server.

Can be used to transfer arbitrary data to the server. Causes the server connection's OnPoke() member to be called.

Returns

true if successful.

bool wxDDEConnection::Poke (const wxString & *item*, const wxString *data*)

Called by the client application to poke data into the server.

Can be used to transfer arbitrary data to the server. Causes the server connection's OnPoke() member to be called.

Returns

true if successful.

const void* wxDDEConnection::Request (const wxString & *item*, size_t * *size*, wxIPCFormat *format* = wxIPC_TEXT)

Called by the client application to request data from the server.

Causes the server connection's OnRequest() member to be called.

Returns

A character string (actually a pointer to the connection's buffer) if successful, NULL otherwise.

bool wxDDEConnection::StartAdvise (const wxString & *item*)

Called by the client application to ask if an advise loop can be started with the server.

Causes the server connection's OnStartAdvise() member to be called.

Returns

true if the server okays it, false otherwise.

bool wxDDEConnection::StopAdvise (const wxString & *item*)

Called by the client application to ask if an advise loop can be stopped.

Causes the server connection's OnStopAdvise() member to be called.

Returns

true if the server okays it, false otherwise.

21.182 wxDDEServer Class Reference

`#include <wx/dde.h>`

21.182.1 Detailed Description

A wxDDEServer object represents the server part of a client-server DDE (Dynamic Data Exchange) conversation.

This DDE-based implementation is available on Windows only, but a platform-independent, socket-based version of this API is available using wxTCPServer.

Library: wxBase

Category: Interprocess Communication Availability: only available for the wxMSW port.

See also

wxDDEClient, wxDDEConnection, Interprocess Communication

Public Member Functions

- wxDDEServer ()

  Constructs a server object.
- bool Create (const wxString &service)

  Registers the server using the given service name.
- virtual wxConnectionBase * OnAcceptConnection (const wxString &topic)

  When a client calls wxDDEClient::MakeConnection(), the server receives the message and this member is called.

21.182.2 Constructor & Destructor Documentation

wxDDEServer::wxDDEServer ( )

Constructs a server object.

21.182.3 Member Function Documentation

bool wxDDEServer::Create (const wxString & *service*)

Registers the server using the given service name.

Under UNIX, the string must contain an integer id which is used as an Internet port number. false is returned if the call failed (for example, if the port number is already in use).

virtual wxConnectionBase* wxDDEServer::OnAcceptConnection (const wxString & *topic*) `[virtual]`

When a client calls wxDDEClient::MakeConnection(), the server receives the message and this member is called.

The application should derive a member to intercept this message and return a connection object of either the standard wxDDEConnection type, or of a user-derived type.

If the *topic* is "STDIO", the application may wish to refuse the connection. Under UNIX, when a server is created the OnAcceptConnection() message is always sent for standard input and output, but in the context of DDE messages it doesn't make a lot of sense.

21.183 wxDebugContext Class Reference

`#include <wx/memory.h>`

21.183.1 Detailed Description

A class for performing various debugging and memory tracing operations.

Full functionality (such as printing out objects currently allocated) is only present in a debugging build of wxWidgets, i.e. if the **WXDEBUG** symbol is defined. wxDebugContext and related functions and macros can be compiled out by setting wxUSE_DEBUG_CONTEXT to 0 is setup.h

Library: wxBase

Category: Debugging

See also

Debugging

Static Public Member Functions

- static int Check (bool checkAll=false)

  Checks the memory blocks for errors, starting from the currently set checkpoint.
- static bool Dump ()

  Performs a memory dump from the currently set checkpoint, writing to the current debug stream.
- static bool GetCheckPrevious ()

  Returns true if the memory allocator checks all previous memory blocks for errors.
- static bool GetDebugMode ()

  Returns true if debug mode is on.
- static int GetLevel ()

  Gets the debug level (default 1).
- static bool PrintClasses ()

  Prints a list of the classes declared in this application, giving derivation and whether instances of this class can be dynamically created.
- static bool PrintStatistics (bool detailed=true)

  Performs a statistics analysis from the currently set checkpoint, writing to the current debug stream.
- static void SetCheckPrevious (bool check)

  Tells the memory allocator to check all previous memory blocks for errors.
- static void SetCheckpoint (bool all=false)

  Sets the current checkpoint: Dump and PrintStatistics operations will be performed from this point on.

- static void SetDebugMode (bool debug)

  Sets the debug mode on or off.
- static void SetLevel (int level)

  Sets the debug level (default 1).
- static void SetShutdownNotifyFunction (wxShutdownNotifyFunction func)

  Installs a function to be called at the end of wxWidgets shutdown.

21.183.2 Member Function Documentation

static int wxDebugContext::Check (bool *checkAll* = `false`) `[static]`

Checks the memory blocks for errors, starting from the currently set checkpoint.

Returns

Returns the number of errors, so a value of zero represents success. Returns -1 if an error was detected that prevents further checking.

static bool wxDebugContext::Dump ( ) `[static]`

Performs a memory dump from the currently set checkpoint, writing to the current debug stream.

Calls the **Dump** member function for each wxObject derived instance.

Returns

true if the function succeeded, false otherwise.

static bool wxDebugContext::GetCheckPrevious ( ) `[static]`

Returns true if the memory allocator checks all previous memory blocks for errors.

By default, this is false since it slows down execution considerably.

See also

SetCheckPrevious()

static bool wxDebugContext::GetDebugMode ( ) `[static]`

Returns true if debug mode is on.

If debug mode is on, the wxObject new and delete operators store or use information about memory allocation. Otherwise, a straight malloc and free will be performed by these operators.

See also

SetDebugMode()

static int wxDebugContext::GetLevel ( ) [static]

Gets the debug level (default 1).

The debug level is used by the wxTraceLevel function and the WXTRACELEVEL macro to specify how detailed the trace information is; setting a different level will only have an effect if trace statements in the application specify a value other than one.

Deprecated This is obsolete, replaced by wxLog functionality.

See also

SetLevel()

static bool wxDebugContext::PrintClasses ( ) [static]

Prints a list of the classes declared in this application, giving derivation and whether instances of this class can be dynamically created.

See also

PrintStatistics()

static bool wxDebugContext::PrintStatistics (bool *detailed* = true) [static]

Performs a statistics analysis from the currently set checkpoint, writing to the current debug stream.

The number of object and non-object allocations is printed, together with the total size.

Parameters

detailed	If true, the function will also print how many objects of each class have been allocated, and the space taken by these class instances.

See also

PrintStatistics()

static void wxDebugContext::SetCheckpoint (bool *all* = false) [static]

Sets the current checkpoint: Dump and PrintStatistics operations will be performed from this point on.

This allows you to ignore allocations that have been performed up to this point.

Parameters

all	If true, the checkpoint is reset to include all memory allocations since the program started.

static void wxDebugContext::SetCheckPrevious (bool *check*) [static]

Tells the memory allocator to check all previous memory blocks for errors.

By default, this is false since it slows down execution considerably.

See also

GetCheckPrevious()

static void wxDebugContext::SetDebugMode (bool *debug*) `[static]`

Sets the debug mode on or off.

If debug mode is on, the wxObject new and delete operators store or use information about memory allocation. Otherwise, a straight malloc and free will be performed by these operators.

By default, debug mode is on if **WXDEBUG** is defined. If the application uses this function, it should make sure that all object memory allocated is deallocated with the same value of debug mode. Otherwise, the delete operator might try to look for memory information that does not exist.

See also

GetDebugMode()

static void wxDebugContext::SetLevel (int *level*) `[static]`

Sets the debug level (default 1).

The debug level is used by the wxTraceLevel function and the WXTRACELEVEL macro to specify how detailed the trace information is; setting a different level will only have an effect if trace statements in the application specify a value other than one.

Deprecated This is obsolete, replaced by wxLog functionality.

See also

GetLevel()

static void wxDebugContext::SetShutdownNotifyFunction (wxShutdownNotifyFunction *func*) `[static]`

Installs a function to be called at the end of wxWidgets shutdown.

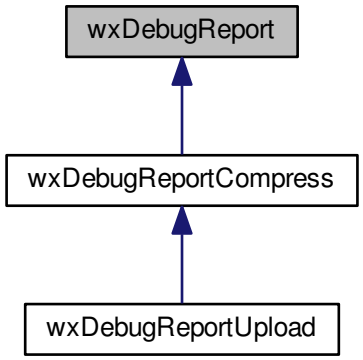
It will be called after all files with global instances of wxDebugContextDumpDelayCounter have run their destructors.

The shutdown function must be take no parameters and return nothing.

21.184 wxDebugReport Class Reference

`#include <wx/debugrpt.h>`

Inheritance diagram for wxDebugReport:



21.184.1 Detailed Description

wxDebugReport is used to generate a debug report, containing information about the program current state.

It is usually used from wxApp::OnFatalException() as shown in the Debug Reporter Sample.

A wxDebugReport object contains one or more files. A few of them can be created by the class itself but more can be created from the outside and then added to the report. Also note that several virtual functions may be overridden to further customize the class behaviour.

Once a report is fully assembled, it can simply be left in the temporary directory so that the user can email it to the developers (in which case you should still use wxDebugReportCompress to compress it in a single file) or uploaded to a Web server using wxDebugReportUpload (setting up the Web server to accept uploads is your responsibility, of course). Other handlers, for example for automatically emailing the report, can be defined as well but are not currently included in wxWidgets.

A typical usage example:

```
wxDebugReport report;
wxDebugReportPreviewStd preview;

report.AddCurrentContext();  // could also use AddAll()
report.AddCurrentDump();     // to do both at once

if ( preview.Show(report) )
    report.Process();
```

Library: wxQA

Category: Debugging

Public Types

- enum Context {
  Context_Current,
  Context_Exception }

  This enum is used for functions that report either the current state or the state during the last (fatal) exception.

Public Member Functions

- wxDebugReport ()

  The constructor creates a temporary directory where the files that will be included in the report are created.
- virtual ~wxDebugReport ()

  The destructor normally destroys the temporary directory created in the constructor with all the files it contains.
- void AddAll (Context context=Context_Exception)

  Adds all available information to the report.
- virtual bool AddContext (Context ctx)

  Add an XML file containing the current or exception context and the stack trace.
- bool AddCurrentContext ()

  The same as calling AddContext(Context_Current).
- bool AddCurrentDump ()

  The same as calling AddDump(Context_Current).
- virtual bool AddDump (Context ctx)

  Adds the minidump file to the debug report.
- bool AddExceptionContext ()

  The same as calling AddContext(Context_Exception).
- bool AddExceptionDump ()

  The same as calling AddDump(Context_Exception).
- virtual void AddFile (const wxString &filename, const wxString &description)

  Add another file to the report.
- bool AddText (const wxString &filename, const wxString &text, const wxString &description)

  This is a convenient wrapper around AddFile().
- const wxString & GetDirectory () const

  This method should be used to construct the full name of the files which you wish to add to the report using AddFile().
- bool GetFile (size_t n, wxString *name, wxString *desc) const

  Retrieves the name (relative to GetDirectory()) and the description of the file with the given index.
- size_t GetFilesCount () const

  Gets the current number files in this report.
- virtual wxString GetReportName () const

  Gets the name used as a base name for various files, by default wxApp::GetAppName() is used.
- bool IsOk () const

  Returns true if the object was successfully initialized.
- bool Process ()

  Processes this report: the base class simply notifies the user that the report has been generated.
- void RemoveFile (const wxString &name)

  Removes the file from report: this is used by wxDebugReportPreview to allow the user to remove files potentially containing private information from the report.
- void Reset ()

  Resets the directory name we use.

Protected Member Functions

- virtual void DoAddCustomContext (wxXmlNode *nodeRoot)

  This function may be overridden to add arbitrary custom context to the XML context file created by AddContext().
- virtual bool DoAddExceptionInfo (wxXmlNode *nodeContext)

  This function may be overridden to modify the contents of the exception tag in the XML context file.
- virtual bool DoAddLoadedModules (wxXmlNode *nodeModules)

  This function may be overridden to modify the contents of the modules tag in the XML context file.
- virtual bool DoAddSystemInfo (wxXmlNode *nodeSystemInfo)

  This function may be overridden to modify the contents of the system tag in the XML context file.

21.184.2 Member Enumeration Documentation

enum wxDebugReport::Context

This enum is used for functions that report either the current state or the state during the last (fatal) exception.

Enumerator

Context_Current

Context_Exception

21.184.3 Constructor & Destructor Documentation

wxDebugReport::wxDebugReport ( )

The constructor creates a temporary directory where the files that will be included in the report are created.

Use IsOk() to check for errors.

virtual wxDebugReport::~wxDebugReport ( ) [virtual]

The destructor normally destroys the temporary directory created in the constructor with all the files it contains.

Call Reset() to prevent this from happening.

21.184.4 Member Function Documentation

void wxDebugReport::AddAll (Context *context* = Context_Exception)

Adds all available information to the report.

Currently this includes a text (XML) file describing the process context and, under Win32, a minidump file.

virtual bool wxDebugReport::AddContext (Context *ctx*) [virtual]

Add an XML file containing the current or exception context and the stack trace.

bool wxDebugReport::AddCurrentContext ( )

The same as calling AddContext(Context_Current).

bool wxDebugReport::AddCurrentDump ( )

The same as calling AddDump(Context_Current).

virtual bool wxDebugReport::AddDump (Context *ctx*) [virtual]

Adds the minidump file to the debug report.

Minidumps are only available under recent Win32 versions (`dbghlp32.dll` can be installed under older systems to make minidumps available).

bool wxDebugReport::AddExceptionContext ( )

The same as calling AddContext(Context_Exception).

bool wxDebugReport::AddExceptionDump ( )

The same as calling AddDump(Context_Exception).

virtual void wxDebugReport::AddFile (const wxString & *filename,* const wxString & *description*) `[virtual]`

Add another file to the report.

If *filename* is an absolute path, it is copied to a file in the debug report directory with the same name. Otherwise the file will be searched in the temporary directory returned by GetDirectory().

The argument *description* only exists to be displayed to the user in the report summary shown by wxDebugReportPreview.

See also

GetDirectory(), AddText()

bool wxDebugReport::AddText (const wxString & *filename,* const wxString & *text,* const wxString & *description*)

This is a convenient wrapper around AddFile().

It creates the file with the given *name* and writes *text* to it, then adds the file to the report. The *filename* shouldn't contain the path.

Returns

true if file could be added successfully, false if an IO error occurred.

virtual void wxDebugReport::DoAddCustomContext (wxXmlNode * *nodeRoot*) `[protected], [virtual]`

This function may be overridden to add arbitrary custom context to the XML context file created by AddContext().

By default, it does nothing.

virtual bool wxDebugReport::DoAddExceptionInfo (wxXmlNode * *nodeContext*) `[protected], [virtual]`

This function may be overridden to modify the contents of the exception tag in the XML context file.

virtual bool wxDebugReport::DoAddLoadedModules (wxXmlNode * *nodeModules*) `[protected], [virtual]`

This function may be overridden to modify the contents of the modules tag in the XML context file.

virtual bool wxDebugReport::DoAddSystemInfo (wxXmlNode * *nodeSystemInfo*) `[protected], [virtual]`

This function may be overridden to modify the contents of the system tag in the XML context file.

const wxString& wxDebugReport::GetDirectory ( ) const

This method should be used to construct the full name of the files which you wish to add to the report using AddFile().

Returns

The name of the temporary directory used for the files in this report.

bool wxDebugReport::GetFile (size_t *n*, wxString * *name*, wxString * *desc*) const

Retrieves the name (relative to GetDirectory()) and the description of the file with the given index.

If *n* is greater than or equal to the number of files, then false is returned.

size_t wxDebugReport::GetFilesCount ( ) const

Gets the current number files in this report.

virtual wxString wxDebugReport::GetReportName ( ) const `[virtual]`

Gets the name used as a base name for various files, by default wxApp::GetAppName() is used.

bool wxDebugReport::IsOk ( ) const

Returns true if the object was successfully initialized.

If this method returns false the report can't be used.

bool wxDebugReport::Process ( )

Processes this report: the base class simply notifies the user that the report has been generated.

This is usually not enough – instead you should override this method to do something more useful to you.

void wxDebugReport::RemoveFile (const wxString & *name*)

Removes the file from report: this is used by wxDebugReportPreview to allow the user to remove files potentially containing private information from the report.

void wxDebugReport::Reset ( )

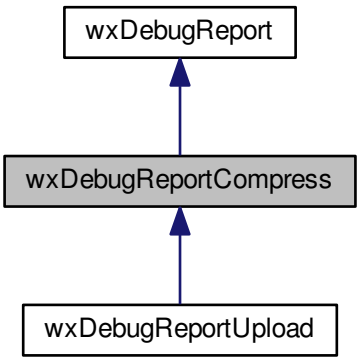
Resets the directory name we use.

The object can't be used any more after this as it becomes uninitialized and invalid.

21.185 wxDebugReportCompress Class Reference

`#include <wx/debugrpt.h>`

Inheritance diagram for wxDebugReportCompress:



21.185.1 Detailed Description

wxDebugReportCompress is a wxDebugReport which compresses all the files in this debug report into a single ZIP file in its wxDebugReport::Process() function.

Library: wxQA

Category: Debugging

Public Member Functions

- wxDebugReportCompress ()

  Default constructor does nothing special.
- void SetCompressedFileDirectory (const wxString &dir)

  Set the directory where the debug report should be generated.
- void SetCompressedFileBaseName (const wxString &name)

  Set the base name of the generated debug report file.
- const wxString & GetCompressedFileName () const

  Returns the full path of the compressed file (empty if creation failed).

Additional Inherited Members

21.185.2 Constructor & Destructor Documentation

wxDebugReportCompress::wxDebugReportCompress ( )

Default constructor does nothing special.

21.185.3 Member Function Documentation

const wxString& wxDebugReportCompress::GetCompressedFileName ( ) const

Returns the full path of the compressed file (empty if creation failed).

void wxDebugReportCompress::SetCompressedFileBaseName (const wxString & *name*)

Set the base name of the generated debug report file.

This function is similar to SetCompressedFileDirectory() but allows to change the base name of the file. Notice that the file extension will always be .zip.

By default, a unique name constructed from wxApp::GetAppName(), the current process id and the current date and time is used.

Parameters

name	The base name (i.e. without extension) of the file.

Since

2.9.1

void wxDebugReportCompress::SetCompressedFileDirectory (const wxString & *dir*)

Set the directory where the debug report should be generated.

By default, the debug report is generated under user temporary files directory. This is usually fine if it is meant to be processed in some way (e.g. automatically uploaded to a remote server) but if the user is asked to manually upload or send the report, it may be more convenient to generate it in e.g. the users home directory and this function allows to do this.

Notice that it should be called before wxDebugReport::Process() or it has no effect.

Parameters

dir	The full path to an existing directory where the debug report file should be generated.

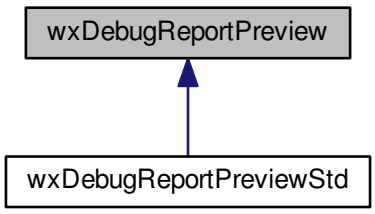
Since

2.9.1

21.186 wxDebugReportPreview Class Reference

`#include <wx/debugrpt.h>`

Inheritance diagram for wxDebugReportPreview:



21.186.1 Detailed Description

This class presents the debug report to the user and allows him to veto report entirely or remove some parts of it.

Although not mandatory, using this class is strongly recommended as data included in the debug report might contain sensitive private information and the user should be notified about it as well as having a possibility to examine the data which had been gathered to check whether this is effectively the case and discard the debug report if it is.

wxDebugReportPreview is an abstract base class, currently the only concrete class deriving from it is wxDebugReportPreviewStd.

Library: wxQA

Category: Debugging

Public Member Functions

- wxDebugReportPreview ()

  Default constructor.

- virtual ~wxDebugReportPreview ()

  Destructor is trivial as well but should be virtual for a base class.

- virtual bool Show (wxDebugReport &dbgrpt) const =0

  Present the report to the user and allow him to modify it by removing some or all of the files and, potentially, adding some notes.

21.186.2 Constructor & Destructor Documentation

wxDebugReportPreview::wxDebugReportPreview ( )

Default constructor.

virtual wxDebugReportPreview::~wxDebugReportPreview ( ) [virtual]

Destructor is trivial as well but should be virtual for a base class.

21.186.3 Member Function Documentation

virtual bool wxDebugReportPreview::Show (wxDebugReport & *dbgrpt*) const [pure virtual]

Present the report to the user and allow him to modify it by removing some or all of the files and, potentially, adding some notes.

Returns

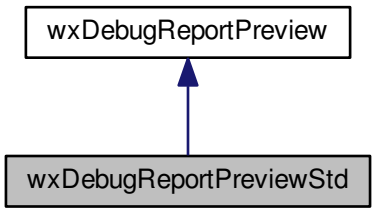
true if the report should be processed or false if the user chose to cancel report generation or removed all files from it.

Implemented in wxDebugReportPreviewStd.

21.187 wxDebugReportPreviewStd Class Reference

`#include <wx/debugrpt.h>`

Inheritance diagram for wxDebugReportPreviewStd:



21.187.1 Detailed Description

wxDebugReportPreviewStd is a standard debug report preview window.

It displays a dialog allowing the user to examine the contents of a debug report, remove files from and add notes to it.

Library: wxQA

Category: Debugging

Public Member Functions

- wxDebugReportPreviewStd ()

  Trivial default constructor.
- bool Show (wxDebugReport &dbgrpt) const

  Shows the dialog.

21.187.2 Constructor & Destructor Documentation

wxDebugReportPreviewStd::wxDebugReportPreviewStd ( )

Trivial default constructor.

21.187.3 Member Function Documentation

bool wxDebugReportPreviewStd::Show (wxDebugReport & *dbgrpt*) const `[virtual]`

Shows the dialog.

See also

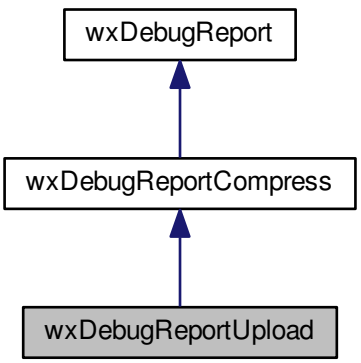
wxDebugReportPreview::Show()

Implements wxDebugReportPreview.

21.188 wxDebugReportUpload Class Reference

`#include <wx/debugrpt.h>`

Inheritance diagram for wxDebugReportUpload:



21.188.1 Detailed Description

This class is used to upload a compressed file using HTTP POST request.

As this class derives from wxDebugReportCompress, before upload the report is compressed in a single ZIP file.

Library: wxQA

Category: Debugging

Public Member Functions

- wxDebugReportUpload (const wxString &url, const wxString &input, const wxString &action, const wxString &curl="curl")

  This class will upload the compressed file created by its base class to an HTML multipart/form-data form at the specified address.

Protected Member Functions

- virtual bool OnServerReply (const wxArrayString &reply)

  This function may be overridden in a derived class to show the output from curl: this may be an HTML page or anything else that the server returned.

Additional Inherited Members

21.188.2 Constructor & Destructor Documentation

wxDebugReportUpload::wxDebugReportUpload (const wxString & *url,* const wxString & *input,* const wxString & *action,* const wxString & *curl* = `"curl"`)

This class will upload the compressed file created by its base class to an HTML multipart/form-data form at the specified address.

The *url* is the upload page address, *input* is the name of the `"type=file"` control on the form used for the file name and *action* is the value of the form action field. The report is uploaded using the *curl* program which should be available, the *curl* parameter may be used to specify the full path to it.

21.188.3 Member Function Documentation

virtual bool wxDebugReportUpload::OnServerReply (const wxArrayString & *reply*) `[protected], [virtual]`

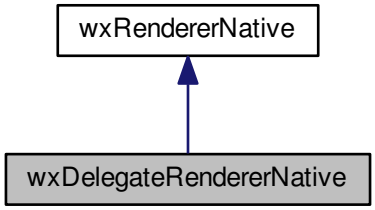
This function may be overridden in a derived class to show the output from curl: this may be an HTML page or anything else that the server returned.

Value returned by this function becomes the return value of wxDebugReport::Process().

21.189 wxDelegateRendererNative Class Reference

`#include <wx/renderer.h>`

Inheritance diagram for wxDelegateRendererNative:



21.189.1 Detailed Description

wxDelegateRendererNative allows reuse of renderers code by forwarding all the wxRendererNative methods to the given object and thus allowing you to only modify some of its methods – without having to reimplement all of them.

Note that the "normal", inheritance-based approach, doesn't work with the renderers as it is impossible to derive from a class unknown at compile-time and the renderer is only chosen at run-time. So suppose that you want to only add something to the drawing of the tree control buttons but leave all the other methods unchanged – the only way to do it, considering that the renderer class which you want to customize might not even be written yet when you write your code (it could be written later and loaded from a DLL during run-time), is by using this class.

Except for the constructor, it has exactly the same methods as wxRendererNative and their implementation is trivial: they are simply forwarded to the real renderer. Note that the "real" renderer may, in turn, be a wxDelegate↩ RendererNative as well and that there may be arbitrarily many levels like this – but at the end of the chain there must be a real renderer which does the drawing.

Library: wxCore

Category: Graphics Device Interface (GDI)

See also

wxRendererNative

Public Member Functions

- wxDelegateRendererNative ()

  The default constructor does the same thing as the other one except that it uses the generic renderer instead of the user-specified rendererNative.
- wxDelegateRendererNative (wxRendererNative &rendererNative)

  This constructor uses the user-specified rendererNative to set up the delegate renderer object to follow all calls to the specified real renderer.
- virtual int DrawHeaderButton (wxWindow ∗win, wxDC &dc, const wxRect &rect, int flags=0, wxHeaderSort↩ IconType sortArrow=wxHDR_SORT_ICON_NONE, wxHeaderButtonParams ∗params=NULL)

  Draw the header control button (used, for example, by wxListCtrl).
- virtual int DrawHeaderButtonContents (wxWindow ∗win, wxDC &dc, const wxRect &rect, int flags=0, wx↩ HeaderSortIconType sortArrow=wxHDR_SORT_ICON_NONE, wxHeaderButtonParams ∗params=NULL)

  Draw the contents of a header control button (label, sort arrows, etc.).

- virtual int GetHeaderButtonHeight (wxWindow *win)

  Returns the height of a header button, either a fixed platform height if available, or a generic height based on the win window's font.
- virtual int GetHeaderButtonMargin (wxWindow *win)

  Returns the horizontal margin on the left and right sides of header button's label.
- virtual void DrawTreeItemButton (wxWindow *win, wxDC &dc, const wxRect &rect, int flags=0)

  Draw the expanded/collapsed icon for a tree control item.
- virtual void DrawSplitterBorder (wxWindow *win, wxDC &dc, const wxRect &rect, int flags=0)

  Draw the border for sash window: this border must be such that the sash drawn by DrawSplitterSash() blends into it well.
- virtual void DrawSplitterSash (wxWindow *win, wxDC &dc, const wxSize &size, wxCoord position, wxOrientation orient, int flags=0)

  Draw a sash.
- virtual void DrawComboBoxDropButton (wxWindow *win, wxDC &dc, const wxRect &rect, int flags=0)

  Draw a button like the one used by wxComboBox to show a drop down window.
- virtual void DrawDropArrow (wxWindow *win, wxDC &dc, const wxRect &rect, int flags=0)

  Draw a drop down arrow that is suitable for use outside a combo box.
- virtual void DrawCheckBox (wxWindow *win, wxDC &dc, const wxRect &rect, int flags=0)

  Draw a check box.
- virtual wxSize GetCheckBoxSize (wxWindow *win)

  Returns the size of a check box.
- virtual void DrawPushButton (wxWindow *win, wxDC &dc, const wxRect &rect, int flags=0)

  Draw a blank push button that looks very similar to wxButton.
- virtual void DrawItemSelectionRect (wxWindow *win, wxDC &dc, const wxRect &rect, int flags=0)

  Draw a selection rectangle underneath the text as used e.g.
- virtual void DrawFocusRect (wxWindow *win, wxDC &dc, const wxRect &rect, int flags=0)

  Draw a focus rectangle using the specified rectangle.
- virtual wxSplitterRenderParams GetSplitterParams (const wxWindow *win)

  Get the splitter parameters, see wxSplitterRenderParams.
- virtual wxRendererVersion GetVersion () const

  This function is used for version checking: Load() refuses to load any shared libraries implementing an older or incompatible version.

Additional Inherited Members

21.189.2 Constructor & Destructor Documentation

wxDelegateRendererNative::wxDelegateRendererNative ( )

The default constructor does the same thing as the other one except that it uses the generic renderer instead of the user-specified *rendererNative*.

In any case, this sets up the delegate renderer object to follow all calls to the specified real renderer.

wxDelegateRendererNative::wxDelegateRendererNative (**wxRendererNative** & *rendererNative*)

This constructor uses the user-specified *rendererNative* to set up the delegate renderer object to follow all calls to the specified real renderer.

Note

This object does not take ownership of (i.e. won't delete) *rendererNative*.

21.189.3 Member Function Documentation

virtual void wxDelegateRendererNative::DrawCheckBox (wxWindow * *win*, wxDC & *dc*, const wxRect & *rect*, int *flags* = 0) [virtual]

Draw a check box.

flags may have the `wxCONTROL_CHECKED`, `wxCONTROL_CURRENT` or `wxCONTROL_UNDETERMINED` bit set, see wxCONTROL_FLAGS.

Implements wxRendererNative.

virtual void wxDelegateRendererNative::DrawComboBoxDropButton (wxWindow * *win*, wxDC & *dc*, const wxRect & *rect*, int *flags* = 0) [virtual]

Draw a button like the one used by wxComboBox to show a drop down window.

The usual appearance is a downwards pointing arrow.

flags may have the `wxCONTROL_PRESSED` or `wxCONTROL_CURRENT` bit set, see wxCONTROL_FLAGS.

Implements wxRendererNative.

virtual void wxDelegateRendererNative::DrawDropArrow (wxWindow * *win*, wxDC & *dc*, const wxRect & *rect*, int *flags* = 0) [virtual]

Draw a drop down arrow that is suitable for use outside a combo box.

Arrow will have transparent background.

rect is not entirely filled by the arrow. Instead, you should use bounding rectangle of a drop down button which arrow matches the size you need.

flags may have the `wxCONTROL_PRESSED` or `wxCONTROL_CURRENT` bit set, see wxCONTROL_FLAGS.

Implements wxRendererNative.

virtual void wxDelegateRendererNative::DrawFocusRect (wxWindow * *win*, wxDC & *dc*, const wxRect & *rect*, int *flags* = 0) [virtual]

Draw a focus rectangle using the specified rectangle.

wxListCtrl.

The only supported flags is `wxCONTROL_SELECTED` for items which are selected. see wxCONTROL_FLAGS.

Implements wxRendererNative.

virtual int wxDelegateRendererNative::DrawHeaderButton (wxWindow * *win*, wxDC & *dc*, const wxRect & *rect*, int *flags* = 0, wxHeaderSortIconType *sortArrow* = wxHDR_SORT_ICON_NONE, wxHeaderButtonParams * *params* = NULL) [virtual]

Draw the header control button (used, for example, by wxListCtrl).

Depending on platforms the *flags* parameter may support the `wxCONTROL_SELECTED` `wxCONTROL_DISABLED` and `wxCONTROL_CURRENT` bits, see wxCONTROL_FLAGS.

Returns

The optimal width to contain the unabbreviated label text or bitmap, the sort arrow if present, and internal margins.

Implements wxRendererNative.

virtual int wxDelegateRendererNative::DrawHeaderButtonContents (wxWindow * *win,* wxDC & *dc,* const wxRect & *rect,* int *flags* = 0, wxHeaderSortIconType *sortArrow* = wxHDR_SORT_ICON_NONE, wxHeaderButtonParams * *params* = NULL) [virtual]

Draw the contents of a header control button (label, sort arrows, etc.).

This function is normally only called by DrawHeaderButton().

Depending on platforms the *flags* parameter may support the wxCONTROL_SELECTED wxCONTROL_DISABLED and wxCONTROL_CURRENT bits, see wxCONTROL_FLAGS.

Returns

The optimal width to contain the unabbreviated label text or bitmap, the sort arrow if present, and internal margins.

Implements wxRendererNative.

virtual void wxDelegateRendererNative::DrawItemSelectionRect (wxWindow * *win,* wxDC & *dc,* const wxRect & *rect,* int *flags* = 0) [virtual]

Draw a selection rectangle underneath the text as used e.g.

in a wxListCtrl.

The supported *flags* are wxCONTROL_SELECTED for items which are selected (e.g. often a blue rectangle) and wxCONTROL_CURRENT for the item that has the focus (often a dotted line around the item's text). wxCONTROL_FOCUSED may be used to indicate if the control has the focus (otherwise the selection rectangle is e.g. often grey and not blue). This may be ignored by the renderer or deduced by the code directly from the *win*.

Implements wxRendererNative.

virtual void wxDelegateRendererNative::DrawPushButton (wxWindow * *win,* wxDC & *dc,* const wxRect & *rect,* int *flags* = 0) [virtual]

Draw a blank push button that looks very similar to wxButton.

flags may have the wxCONTROL_PRESSED, wxCONTROL_CURRENT or wxCONTROL_ISDEFAULT bit set, see wxCONTROL_FLAGS.

Implements wxRendererNative.

virtual void wxDelegateRendererNative::DrawSplitterBorder (wxWindow * *win,* wxDC & *dc,* const wxRect & *rect,* int *flags* = 0) [virtual]

Draw the border for sash window: this border must be such that the sash drawn by DrawSplitterSash() blends into it well.

Implements wxRendererNative.

virtual void wxDelegateRendererNative::DrawSplitterSash (wxWindow * *win,* wxDC & *dc,* const wxSize & *size,* wxCoord *position,* wxOrientation *orient,* int *flags* = 0) [virtual]

Draw a sash.

The *orient* parameter defines whether the sash should be vertical or horizontal and how the *position* should be interpreted.

Implements wxRendererNative.

virtual void wxDelegateRendererNative::DrawTreeItemButton (wxWindow * *win*, wxDC & *dc*, const wxRect & *rect*, int *flags* = 0) [virtual]

Draw the expanded/collapsed icon for a tree control item.

To draw an expanded button the *flags* parameter must contain `wxCONTROL_EXPANDED` bit, see wxCONTROL_FLAGS.

Implements wxRendererNative.

virtual wxSize wxDelegateRendererNative::GetCheckBoxSize (wxWindow * *win*) [virtual]

Returns the size of a check box.

The *win* parameter is not used currently and can be NULL.

Implements wxRendererNative.

virtual int wxDelegateRendererNative::GetHeaderButtonHeight (wxWindow * *win*) [virtual]

Returns the height of a header button, either a fixed platform height if available, or a generic height based on the *win* window's font.

Implements wxRendererNative.

virtual int wxDelegateRendererNative::GetHeaderButtonMargin (wxWindow * *win*) [virtual]

Returns the horizontal margin on the left and right sides of header button's label.

Since

2.9.2

Implements wxRendererNative.

virtual wxSplitterRenderParams wxDelegateRendererNative::GetSplitterParams (const wxWindow * *win*) [virtual]

Get the splitter parameters, see wxSplitterRenderParams.

The *win* parameter should be a wxSplitterWindow.

Implements wxRendererNative.

virtual wxRendererVersion wxDelegateRendererNative::GetVersion ( ) const [virtual]

This function is used for version checking: Load() refuses to load any shared libraries implementing an older or incompatible version.

Remarks

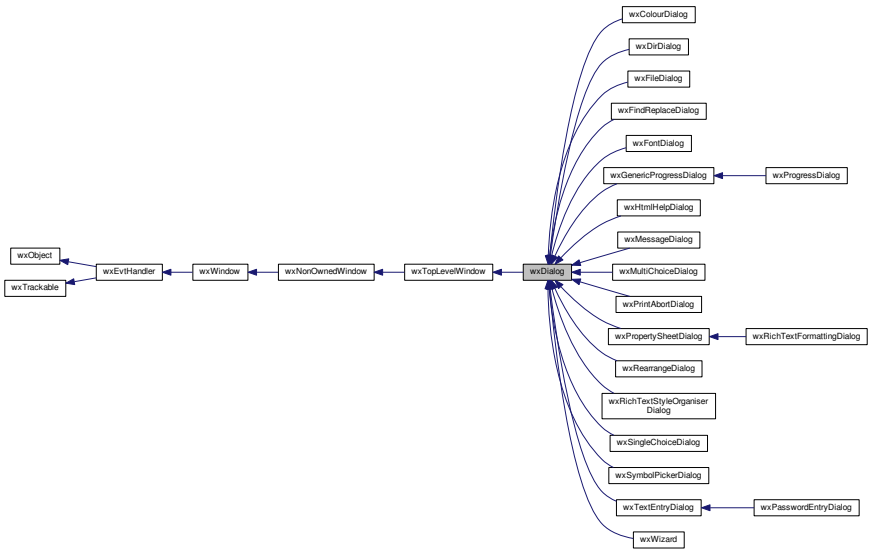
The implementation of this method is always the same in all renderers (simply construct wxRendererVersion using the `wxRendererVersion::Current_XXX` values), but it has to be in the derived, not base, class, to detect mismatches between the renderers versions and so you have to implement it anew in all renderers.

Implements wxRendererNative.

21.190 wxDialog Class Reference

`#include <wx/dialog.h>`

Inheritance diagram for wxDialog:



21.190.1 Detailed Description

A dialog box is a window with a title bar and sometimes a system menu, which can be moved around the screen.

It can contain controls and other windows and is often used to allow the user to make some choice or to answer a question.

Dialogs can be made scrollable, automatically, for computers with low resolution screens: please see Automatic Scrolled Dialogs for further details.

Dialogs usually contain either a single button allowing to close the dialog or two buttons, one accepting the changes and the other one discarding them (such button, if present, is automatically activated if the user presses the "Esc" key). By default, buttons with the standard wxID_OK and wxID_CANCEL identifiers behave as expected. Starting with wxWidgets 2.7 it is also possible to use a button with a different identifier instead, see SetAffirmativeId() and SetEscapeId().

Also notice that the CreateButtonSizer() should be used to create the buttons appropriate for the current platform and positioned correctly (including their order which is platform-dependent).

21.190.2 Modal and Modeless

There are two kinds of dialog, modal and modeless. A modal dialog blocks program flow and user input on other windows until it is dismissed, whereas a modeless dialog behaves more like a frame in that program flow continues, and input in other windows is still possible. To show a modal dialog you should use the ShowModal() method while to show a dialog modelessly you simply use Show(), just as with frames.

Note that the modal dialog is one of the very few examples of wxWindow-derived objects which may be created on the stack and not on the heap. In other words, while most windows would be created like this:

```
void AskUser()
{
    MyAskDialog *dlg = new MyAskDialog(...);
    if ( dlg->ShowModal() == wxID_OK )
```

```
        // ...
    //else: dialog was cancelled or some another button pressed

    dlg->Destroy();
}
```

You can achieve the same result with dialogs by using simpler code:

```
void AskUser()
{
    MyAskDialog dlg(...);
    if ( dlg.ShowModal() == wxID_OK )
        // ...

    // no need to call Destroy() here
}
```

An application can define a wxCloseEvent handler for the dialog to respond to system close events.

Styles

This class supports the following styles:

- wxCAPTION: Puts a caption on the dialog box.
- wxDEFAULT_DIALOG_STYLE: Equivalent to a combination of wxCAPTION, wxCLOSE_BOX and wxSYS↩TEM_MENU (the last one is not used under Unix).
- wxRESIZE_BORDER: Display a resizable frame around the window.
- wxSYSTEM_MENU: Display a system menu.
- wxCLOSE_BOX: Displays a close box on the frame.
- wxMAXIMIZE_BOX: Displays a maximize box on the dialog.
- wxMINIMIZE_BOX: Displays a minimize box on the dialog.
- wxTHICK_FRAME: Display a thick frame around the window.
- wxSTAY_ON_TOP: The dialog stays on top of all other windows.
- wxNO_3D: This style is obsolete and doesn't do anything any more, don't use it in any new code.
- wxDIALOG_NO_PARENT: By default, a dialog created with a NULL parent window will be given the application's top level window as parent. Use this style to prevent this from happening and create an orphan dialog. This is not recommended for modal dialogs.
- wxDIALOG_EX_CONTEXTHELP: Under Windows, puts a query button on the caption. When pressed, Windows will go into a context-sensitive help mode and wxWidgets will send a `wxEVT_HELP` event if the user clicked on an application window. Note that this is an extended style and must be set by calling SetExtraStyle() before Create is called (two-step construction).
- wxDIALOG_EX_METAL: On Mac OS X, frames with this style will be shown with a metallic look. This is an extra style.

Under Unix or Linux, MWM (the Motif Window Manager) or other window managers recognizing the MHM hints should be running for any of these styles to have an effect.

Events emitted by this class

The following event handler macros redirect the events to member function handlers '**func**' with prototypes like: void handlerFuncName(wxCloseEvent& event)

Event macros for events emitted by this class:

- EVT_CLOSE(func): The dialog is being closed by the user or programmatically (see wxWindow::Close). The user may generate this event clicking the close button (typically the 'X' on the top-right of the title bar) if it's present (see the `wxCLOSE_BOX` style) or by clicking a button with the `wxID_CANCEL` or `wxID_OK` ids.
- EVT_INIT_DIALOG(func): Process a `wxEVT_INIT_DIALOG` event. See wxInitDialogEvent.

Library: wxCore

Category: Common Dialogs

wxDialog Overview, wxFrame, wxValidator Overview

Public Member Functions

- wxDialog ()

  Default constructor.
- wxDialog (wxWindow *parent, wxWindowID id, const wxString &title, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, long style=wxDEFAULT_DIALOG_STYLE, const wxString &name=wxDialogNameStr)

  Constructor.
- virtual ~wxDialog ()

  Destructor.
- void AddMainButtonId (wxWindowID id)

  Adds an identifier to be regarded as a main button for the non-scrolling area of a dialog.
- virtual bool CanDoLayoutAdaptation ()

  Returns true if this dialog can and should perform layout adaptation using DoLayoutAdaptation(), usually if the dialog is too large to fit on the display.
- void Centre (int direction=wxBOTH)

  Centres the dialog box on the display.
- bool Create (wxWindow *parent, wxWindowID id, const wxString &title, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, long style=wxDEFAULT_DIALOG_STYLE, const wxString &name=wxDialogNameStr)

  Used for two-step dialog box construction.
- wxSizer * CreateButtonSizer (long flags)

  Creates a sizer with standard buttons.
- wxSizer * CreateSeparatedButtonSizer (long flags)

  Creates a sizer with standard buttons using CreateButtonSizer() separated from the rest of the dialog contents by a horizontal wxStaticLine.
- wxSizer * CreateSeparatedSizer (wxSizer *sizer)

  Returns the sizer containing the given one with a separating wxStaticLine if necessarily.
- wxStdDialogButtonSizer * CreateStdDialogButtonSizer (long flags)

  Creates a wxStdDialogButtonSizer with standard buttons.
- wxSizer * CreateTextSizer (const wxString &message)

  Splits text up at newlines and places the lines into wxStaticText objects in a vertical wxBoxSizer.

- virtual bool DoLayoutAdaptation ()

  Performs layout adaptation, usually if the dialog is too large to fit on the display.
- virtual bool DoOK ()

  This function is called when the titlebar OK button is pressed (PocketPC only).
- virtual void EndModal (int retCode)

  Ends a modal dialog, passing a value to be returned from the ShowModal() invocation.
- int GetAffirmativeId () const

  Gets the identifier of the button which works like standard OK button in this dialog.
- virtual wxWindow * GetContentWindow () const

  Override this to return a window containing the main content of the dialog.
- int GetEscapeId () const

  Gets the identifier of the button to map presses of `ESC` button to.
- bool GetLayoutAdaptationDone () const

  Returns true if the dialog has been adapted, usually by making it scrollable to work with a small display.
- int GetLayoutAdaptationLevel () const

  Gets a value representing the aggressiveness of search for buttons and sizers to be in the non-scrolling part of a layout-adapted dialog.
- wxDialogLayoutAdaptationMode GetLayoutAdaptationMode () const

  Gets the adaptation mode, overriding the global adaptation flag.
- wxArrayInt & GetMainButtonIds ()

  Returns an array of identifiers to be regarded as the main buttons for the non-scrolling area of a dialog.
- int GetReturnCode () const

  Gets the return code for this window.
- wxToolBar * GetToolBar () const

  On PocketPC, a dialog is automatically provided with an empty toolbar.
- virtual void Iconize (bool iconize=true)

  Iconizes or restores the dialog.
- virtual bool IsIconized () const

  Returns true if the dialog box is iconized.
- bool IsMainButtonId (wxWindowID id) const

  Returns true if id is in the array of identifiers to be regarded as the main buttons for the non-scrolling area of a dialog.
- virtual bool IsModal () const

  Returns true if the dialog box is modal, false otherwise.
- void SetAffirmativeId (int id)

  Sets the identifier to be used as OK button.
- void SetEscapeId (int id)

  Sets the identifier of the button which should work like the standard "Cancel" button in this dialog.
- void SetIcon (const wxIcon &icon)

  Sets the icon for this dialog.
- void SetIcons (const wxIconBundle &icons)

  Sets the icons for this dialog.
- void SetLayoutAdaptationDone (bool done)

  Marks the dialog as having been adapted, usually by making it scrollable to work with a small display.
- void SetLayoutAdaptationLevel (int level)

  Sets the aggressiveness of search for buttons and sizers to be in the non-scrolling part of a layout-adapted dialog.
- void SetLayoutAdaptationMode (wxDialogLayoutAdaptationMode mode)

  Sets the adaptation mode, overriding the global adaptation flag.
- void SetReturnCode (int retCode)

  Sets the return code for this window.
- virtual bool Show (bool show=1)

  Hides or shows the dialog.

- virtual int ShowModal ()

  Shows an application-modal dialog.
- void ShowWindowModal ()

  Shows a dialog modal to the parent top level window only.
- template<typename Functor >
  void ShowWindowModalThenDo (const Functor &onEndModal)

  Shows a dialog modal to the parent top level window only and call a functor after the dialog is closed.

Static Public Member Functions

- static void EnableLayoutAdaptation (bool enable)

  A static function enabling or disabling layout adaptation for all dialogs.
- static wxDialogLayoutAdapter * GetLayoutAdapter ()

  A static function getting the current layout adapter object.
- static bool IsLayoutAdaptationEnabled ()

  A static function returning true if layout adaptation is enabled for all dialogs.
- static wxDialogLayoutAdapter * SetLayoutAdapter (wxDialogLayoutAdapter *adapter)

  A static function for setting the current layout adapter object, returning the old adapter.

Additional Inherited Members

21.190.3 Constructor & Destructor Documentation

wxDialog::wxDialog ( )

Default constructor.

wxDialog::wxDialog (wxWindow * *parent*, wxWindowID *id*, const wxString & *title*, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, long *style* = wxDEFAULT_DIALOG_STYLE, const wxString & *name* = `wxDialogNameStr`)

Constructor.

Parameters

parent	Can be NULL, a frame or another dialog box.
id	An identifier for the dialog. A value of -1 is taken to mean a default.
title	The title of the dialog.
pos	The dialog position. The value wxDefaultPosition indicates a default position, chosen by either the windowing system or wxWidgets, depending on platform.
size	The dialog size. The value wxDefaultSize indicates a default size, chosen by either the windowing system or wxWidgets, depending on platform.
style	The window style.
name	Used to associate a name with the window, allowing the application user to set Motif resource values for individual dialog boxes.

See also

Create()

virtual wxDialog::~wxDialog ( ) [virtual]

Destructor.

Deletes any child windows before deleting the physical window.

See Window Deletion for more info.

21.190.4 Member Function Documentation

void wxDialog::AddMainButtonId (wxWindowID *id*)

Adds an identifier to be regarded as a main button for the non-scrolling area of a dialog.

See also

Automatic Scrolled Dialogs (for more on layout adaptation)

virtual bool wxDialog::CanDoLayoutAdaptation ( ) [virtual]

Returns true if this dialog can and should perform layout adaptation using DoLayoutAdaptation(), usually if the dialog is too large to fit on the display.

See also

Automatic Scrolled Dialogs (for more on layout adaptation)

void wxDialog::Centre (int *direction* = wxBOTH)

Centres the dialog box on the display.

Parameters

direction	May be wxHORIZONTAL, wxVERTICAL or wxBOTH.

bool wxDialog::Create (wxWindow * *parent*, wxWindowID *id*, const wxString & *title*, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, long *style* = wxDEFAULT_DIALOG_STYLE, const wxString & *name* = wxDialogNameStr)

Used for two-step dialog box construction.

See also

wxDialog()

wxSizer* wxDialog::CreateButtonSizer (long *flags*)

Creates a sizer with standard buttons.

flags is a bit list of the following flags: wxOK, wxCANCEL, wxYES, wxNO, wxAPPLY, wxCLOSE, wxHELP, wxNO↩_DEFAULT.

The sizer lays out the buttons in a manner appropriate to the platform.

This function uses CreateStdDialogButtonSizer() internally for most platforms but doesn't create the sizer at all for the platforms with hardware buttons (such as smartphones) for which it sets up the hardware buttons appropriately and returns NULL, so don't forget to test that the return value is valid before using it.

wxSizer* wxDialog::CreateSeparatedButtonSizer (long *flags*)

Creates a sizer with standard buttons using CreateButtonSizer() separated from the rest of the dialog contents by a horizontal wxStaticLine.

Note

Just like CreateButtonSizer(), this function may return NULL if no buttons were created.

This is a combination of CreateButtonSizer() and CreateSeparatedSizer().

wxSizer* wxDialog::CreateSeparatedSizer (wxSizer * *sizer*)

Returns the sizer containing the given one with a separating wxStaticLine if necessarily.

This function is useful for creating the sizer containing footer-like contents in dialog boxes. It will add a separating static line only if it conforms to the current platform convention (currently it is not added under Mac where the use of static lines for grouping is discouraged and is added elsewhere).

Since

2.9.2

Parameters

sizer	The sizer to wrap, must be non-NULL.

Returns

The sizer wrapping the input one or possibly the input sizer itself if no wrapping is necessary.

wxStdDialogButtonSizer* wxDialog::CreateStdDialogButtonSizer (long *flags*)

Creates a wxStdDialogButtonSizer with standard buttons.

flags is a bit list of the following flags: wxOK, wxCANCEL, wxYES, wxNO, wxAPPLY, wxCLOSE, wxHELP, wxNO↩ _DEFAULT.

The sizer lays out the buttons in a manner appropriate to the platform.

wxSizer* wxDialog::CreateTextSizer (const wxString & *message*)

Splits text up at newlines and places the lines into wxStaticText objects in a vertical wxBoxSizer.

virtual bool wxDialog::DoLayoutAdaptation ( ) [virtual]

Performs layout adaptation, usually if the dialog is too large to fit on the display.

See also

Automatic Scrolled Dialogs (for more on layout adaptation)

virtual bool wxDialog::DoOK ( ) [virtual]

This function is called when the titlebar OK button is pressed (PocketPC only).

A command event for the identifier returned by GetAffirmativeId() is sent by default. You can override this function. If the function returns false, wxWidgets will call Close() for the dialog.

Availability: only available for the wxMSW port.

static void wxDialog::EnableLayoutAdaptation (bool *enable*) `[static]`

A static function enabling or disabling layout adaptation for all dialogs.

See also

Automatic Scrolled Dialogs (for more on layout adaptation)

virtual void wxDialog::EndModal (int *retCode*) `[virtual]`

Ends a modal dialog, passing a value to be returned from the ShowModal() invocation.

Parameters

retCode	The value that should be returned by ShowModal.

See also

ShowModal(), GetReturnCode(), SetReturnCode()

int wxDialog::GetAffirmativeId ( ) const

Gets the identifier of the button which works like standard OK button in this dialog.

See also

SetAffirmativeId()

virtual wxWindow* wxDialog::GetContentWindow ( ) const `[virtual]`

Override this to return a window containing the main content of the dialog.

This is particularly useful when the dialog implements pages, such as wxPropertySheetDialog, and allows the layout adaptation code to know that only the pages need to be made scrollable.

int wxDialog::GetEscapeId ( ) const

Gets the identifier of the button to map presses of `ESC` button to.

See also

SetEscapeId()

bool wxDialog::GetLayoutAdaptationDone ( ) const

Returns true if the dialog has been adapted, usually by making it scrollable to work with a small display.

See also

Automatic Scrolled Dialogs (for more on layout adaptation)

int wxDialog::GetLayoutAdaptationLevel ( ) const

Gets a value representing the aggressiveness of search for buttons and sizers to be in the non-scrolling part of a layout-adapted dialog.

Zero switches off adaptation, and 3 allows search for standard buttons anywhere in the dialog.

See also

Automatic Scrolled Dialogs (for more on layout adaptation)

wxDialogLayoutAdaptationMode wxDialog::GetLayoutAdaptationMode ( ) const

Gets the adaptation mode, overriding the global adaptation flag.

See also

Automatic Scrolled Dialogs (for more on layout adaptation)

static wxDialogLayoutAdapter* wxDialog::GetLayoutAdapter ( ) [static]

A static function getting the current layout adapter object.

See also

Automatic Scrolled Dialogs (for more on layout adaptation)

wxArrayInt& wxDialog::GetMainButtonIds ( )

Returns an array of identifiers to be regarded as the main buttons for the non-scrolling area of a dialog.

See also

Automatic Scrolled Dialogs (for more on layout adaptation)

int wxDialog::GetReturnCode ( ) const

Gets the return code for this window.

Remarks

A return code is normally associated with a modal dialog, where ShowModal() returns a code to the application.

See also

SetReturnCode(), ShowModal(), EndModal()

wxToolBar* wxDialog::GetToolBar ( ) const

On PocketPC, a dialog is automatically provided with an empty toolbar.

This function allows you to access the toolbar and add tools to it. Removing tools and adding arbitrary controls are not currently supported.

This function is not available on any other platform.

Availability: only available for the wxMSW port.

virtual void wxDialog::Iconize (bool *iconize* = `true`) `[virtual]`

Iconizes or restores the dialog.

Windows only.

Parameters

iconize	If true, iconizes the dialog box; if false, shows and restores it.

Remarks

Note that in Windows, iconization has no effect since dialog boxes cannot be iconized. However, applications may need to explicitly restore dialog boxes under Motif which have user-iconizable frames, and under Windows calling Iconize(false) will bring the window to the front, as does Show(true).

Reimplemented from wxTopLevelWindow.

virtual bool wxDialog::IsIconized ( ) const `[virtual]`

Returns true if the dialog box is iconized.

Windows only.

Remarks

Always returns false under Windows since dialogs cannot be iconized.

Reimplemented from wxTopLevelWindow.

static bool wxDialog::IsLayoutAdaptationEnabled ( ) `[static]`

A static function returning true if layout adaptation is enabled for all dialogs.

See also

Automatic Scrolled Dialogs (for more on layout adaptation)

bool wxDialog::IsMainButtonId (wxWindowID *id*) const

Returns true if *id* is in the array of identifiers to be regarded as the main buttons for the non-scrolling area of a dialog.

Availability: only available for the wxMSW port.

See also

Automatic Scrolled Dialogs (for more on layout adaptation)

virtual bool wxDialog::IsModal ( ) const `[virtual]`

Returns true if the dialog box is modal, false otherwise.

void wxDialog::SetAffirmativeId (int *id*)

Sets the identifier to be used as OK button.

When the button with this identifier is pressed, the dialog calls wxWindow::Validate() and wxWindow::TransferDataFromWindow() and, if they both return true, closes the dialog with the affirmative id return code.

Also, when the user presses a hardware OK button on the devices having one or the special OK button in the PocketPC title bar, an event with this id is generated.

By default, the affirmative id is wxID_OK.

See also

GetAffirmativeId(), SetEscapeId()

void wxDialog::SetEscapeId (int *id*)

Sets the identifier of the button which should work like the standard "Cancel" button in this dialog.

When the button with this id is clicked, the dialog is closed. Also, when the user presses ESC key in the dialog or closes the dialog using the close button in the title bar, this is mapped to the click of the button with the specified id.

By default, the escape id is the special value wxID_ANY meaning that wxID_CANCEL button is used if it's present in the dialog and otherwise the button with GetAffirmativeId() is used. Another special value for *id* is wxID_NONE meaning that ESC presses should be ignored. If any other value is given, it is interpreted as the id of the button to map the escape key to.

Note

This method should be used for custom modal dialog implemented in wxWidgets itself, native dialogs such as wxMessageDialog or wxFileDialog, handle ESC presses in their own way which cannot be customized.

void wxDialog::SetIcon (const wxIcon & *icon*)

Sets the icon for this dialog.

Parameters

icon	The icon to associate with this dialog.

See also

wxIcon

void wxDialog::SetIcons (const wxIconBundle & *icons*) [virtual]

Sets the icons for this dialog.

Parameters

icons	The icons to associate with this dialog.

See also

wxIconBundle

Reimplemented from wxTopLevelWindow.

void wxDialog::SetLayoutAdaptationDone (bool *done*)

Marks the dialog as having been adapted, usually by making it scrollable to work with a small display.

See also

Automatic Scrolled Dialogs (for more on layout adaptation)

void wxDialog::SetLayoutAdaptationLevel (int *level*)

Sets the aggressiveness of search for buttons and sizers to be in the non-scrolling part of a layout-adapted dialog.

Zero switches off adaptation, and 3 allows search for standard buttons anywhere in the dialog.

See also

Automatic Scrolled Dialogs (for more on layout adaptation)

void wxDialog::SetLayoutAdaptationMode (wxDialogLayoutAdaptationMode *mode*)

Sets the adaptation mode, overriding the global adaptation flag.

See also

wxDialogLayoutAdaptationMode, Automatic Scrolled Dialogs (for more on layout adaptation)

static wxDialogLayoutAdapter* wxDialog::SetLayoutAdapter (wxDialogLayoutAdapter * *adapter*) `[static]`

A static function for setting the current layout adapter object, returning the old adapter.

If you call this, you should delete the old adapter object.

See also

wxDialogLayoutAdapter, Automatic Scrolled Dialogs

void wxDialog::SetReturnCode (int *retCode*)

Sets the return code for this window.

A return code is normally associated with a modal dialog, where ShowModal() returns a code to the application. The function EndModal() calls SetReturnCode().

Parameters

retCode	The integer return code, usually a control identifier.

See also

GetReturnCode(), ShowModal(), EndModal()

virtual bool wxDialog::Show (bool *show* = `1`) `[virtual]`

Hides or shows the dialog.

The preferred way of dismissing a modal dialog is to use EndModal().

Parameters

show	If true, the dialog box is shown and brought to the front, otherwise the box is hidden. If false and the dialog is modal, control is returned to the calling program.

Reimplemented from wxWindow.

virtual int wxDialog::ShowModal ( ) [virtual]

Shows an application-modal dialog.

Program flow does not return until the dialog has been dismissed with EndModal().

Notice that it is possible to call ShowModal() for a dialog which had been previously shown with Show(), this allows to make an existing modeless dialog modal. However ShowModal() can't be called twice without intervening EndModal() calls.

Note that this function creates a temporary event loop which takes precedence over the application's main event loop (see wxEventLoopBase) and which is destroyed when the dialog is dismissed. This also results in a call to wxApp::ProcessPendingEvents().

Returns

The value set with SetReturnCode().

See also

ShowWindowModal(), ShowWindowModalThenDo(), EndModal(), GetReturnCode(), SetReturnCode()

Reimplemented in wxFileDialog, wxMessageDialog, wxSingleChoiceDialog, wxTextEntryDialog, wxMultiChoiceDialog, wxDirDialog, wxFontDialog, and wxColourDialog.

void wxDialog::ShowWindowModal ( )

Shows a dialog modal to the parent top level window only.

Unlike ShowModal(), dialogs shown with this function only prevent the user from interacting with their parent frame only but not with the rest of the application. They also don't block the program execution but instead return immediately, as Show(), and generate a wxEVT_WINDOW_MODAL_DIALOG_CLOSED event (wxWindowModalDialogEvent) later when the dialog is closed.

Currently this function is only fully implemented in wxOSX ports, under the other platforms it behaves like ShowModal() (but also sends the above mentioned event).

See also

wxWindowModalDialogEvent, ShowWindowModalThenDo()

Since

2.9.0

template<typename Functor > void wxDialog::ShowWindowModalThenDo (const Functor & *onEndModal*)

Shows a dialog modal to the parent top level window only and call a functor after the dialog is closed.

Same as the other ShowWindowModal() overload, but calls the functor passed as the argument upon completion, instead of generating the wxEVT_WINDOW_MODAL_DIALOG_CLOSED event.

This form is particularly useful in combination with C++11 lambdas, when it allows writing window-modal very similarly to how ShowModal() is used (with the notable exception of not being able to create the dialog on stack):

```
wxWindowPtr<wxDialog> dlg(new wxMessageDialog(this, "Hello!"));

dlg->ShowWindowModalThenDo([this,dlg](int retcode){
    if ( retcode == wxID_OK )
        DoSomething();
    // dlg is implicitly destroyed here, because the pointer was
    // explicitly captured by the lambda
});
```

Parameters

onEndModal	Function object to call when the dialog is closed. The functor is called with a single integer argument, dialog's return code.

Note

The dialog instance must not be destroyed until *onEndModal* is called. The best way to ensure that is to use wxWindowPtr to hold a pointer and include it in the lambda's capture, by value (not reference!), as shown in the example above.

Since

3.0

See also

wxWindowPtr<T>

21.191 wxDialogLayoutAdapter Class Reference

`#include <wx/dialog.h>`

21.191.1 Detailed Description

This abstract class is the base for classes that help wxWidgets perform run-time layout adaptation of dialogs.

Principally, this is to cater for small displays by making part of the dialog scroll, but the application developer may find other uses for layout adaption.

By default, there is one instance of wxStandardDialogLayoutAdapter which can perform adaptation for most custom dialogs and dialogs with book controls such as wxPropertySheetDialog.

Library: wxCore

Category: Window Layout

Public Member Functions

- wxDialogLayoutAdapter ()

  Default constructor.
- virtual bool CanDoLayoutAdaptation (wxDialog *dialog)=0

  Override this to returns true if adaptation can and should be done.

- virtual bool DoLayoutAdaptation (wxDialog *dialog)=0

  Override this to perform layout adaptation, such as making parts of the dialog scroll and resizing the dialog to fit the display.

21.191.2 Constructor & Destructor Documentation

wxDialogLayoutAdapter::wxDialogLayoutAdapter ( )

Default constructor.

21.191.3 Member Function Documentation

virtual bool wxDialogLayoutAdapter::CanDoLayoutAdaptation (wxDialog * *dialog*) `[pure virtual]`

Override this to returns true if adaptation can and should be done.

virtual bool wxDialogLayoutAdapter::DoLayoutAdaptation (wxDialog * *dialog*) `[pure virtual]`

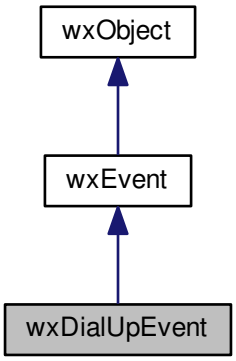
Override this to perform layout adaptation, such as making parts of the dialog scroll and resizing the dialog to fit the display.

Normally this function will be called just before the dialog is shown.

21.192 wxDialUpEvent Class Reference

`#include <wx/dialup.h>`

Inheritance diagram for wxDialUpEvent:



21.192.1 Detailed Description

This is the event class for the dialup events sent by wxDialUpManager.

Library: wxCore

Category: Events

Public Member Functions

- wxDialUpEvent (bool isConnected, bool isOwnEvent)

  Constructor is only used by wxDialUpManager.
- bool IsConnectedEvent () const

  Is this a `CONNECTED` *or* `DISCONNECTED` *event? In other words, does it notify about transition from offline to online state or vice versa?*
- bool IsOwnEvent () const

  Does this event come from wxDialUpManager::Dial() or from some external process (i.e.

Additional Inherited Members

21.192.2 Constructor & Destructor Documentation

wxDialUpEvent::wxDialUpEvent (bool *isConnected,* bool *isOwnEvent*)

Constructor is only used by wxDialUpManager.

21.192.3 Member Function Documentation

bool wxDialUpEvent::IsConnectedEvent ( ) const

Is this a `CONNECTED` or `DISCONNECTED` event? In other words, does it notify about transition from offline to online state or vice versa?

bool wxDialUpEvent::IsOwnEvent ( ) const

Does this event come from wxDialUpManager::Dial() or from some external process (i.e.

does it result from our own attempt to establish the connection)?

21.193 wxDialUpManager Class Reference

```
#include <wx/dialup.h>
```

21.193.1 Detailed Description

This class encapsulates functions dealing with verifying the connection status of the workstation (connected to the Internet via a direct connection, connected through a modem or not connected at all) and to establish this connection if possible/required (i.e.

in the case of the modem).

The program may also wish to be notified about the change in the connection status (for example, to perform some action when the user connects to the network the next time or, on the contrary, to stop receiving data from the net when the user hangs up the modem). For this, you need to use one of the event macros described below.

This class is different from other wxWidgets classes in that there is at most one instance of this class in the program accessed via Create() and you can't create the objects of this class directly.

Events emitted by this class

The following event handler macros redirect the events to member function handlers '**func**' with prototypes like: void handlerFuncName(wxDialUpEvent& event)

Event macros for events emitted by this class:

- EVT_DIALUP_CONNECTED(func): A connection with the network was established.
- EVT_DIALUP_DISCONNECTED(func): The connection with the network was lost.

Library: wxCore

Category: Networking

See also

Dialup Sample, wxDialUpEvent

Public Member Functions

- virtual ~wxDialUpManager ()

  Destructor.
- virtual bool CancelDialing ()=0

  Cancel dialing the number initiated with Dial() with async parameter equal to true.
- virtual bool Dial (const wxString &nameOfISP=wxEmptyString, const wxString &username=wxEmptyString, const wxString &password=wxEmptyString, bool async=true)=0

  Dial the given ISP, use username and password to authenticate.
- virtual void DisableAutoCheckOnlineStatus ()=0

  Disable automatic check for connection status change - notice that the `wxEVT_DIALUP_XXX` events won't be sent any more neither.
- virtual bool EnableAutoCheckOnlineStatus (size_t nSeconds=60)=0

  Enable automatic checks for the connection status and sending of `wxEVT_DIALUP_CONNECTED/wxEVT_DIALUP_DISCONNECTED` events.
- virtual size_t GetISPNames (wxArrayString &names) const =0

  This function is only implemented under Windows.
- virtual bool HangUp ()=0

  Hang up the currently active dial up connection.
- virtual bool IsAlwaysOnline () const =0

  Returns true if the computer has a permanent network connection (i.e.
- virtual bool IsDialing () const =0

  Returns true if (async) dialing is in progress.
- virtual bool IsOk () const =0

  Returns true if the dialup manager was initialized correctly.
- virtual bool IsOnline () const =0

  Returns true if the computer is connected to the network: under Windows, this just means that a RAS connection exists, under Unix we check that the "well-known host" (as specified by SetWellKnownHost()) is reachable.
- virtual void SetConnectCommand (const wxString &commandDial="/usr/bin/pon", const wxString &commandHangup="/usr/bin/poff")=0

This method is for Unix only.

- virtual void SetOnlineStatus (bool isOnline=true)=0

  Sometimes the built-in logic for determining the online status may fail, so, in general, the user should be allowed to override it.

- virtual void SetWellKnownHost (const wxString &hostname, int portno=80)=0

  This method is for Unix only.

Static Public Member Functions

- static wxDialUpManager * Create ()

  This function should create and return the object of the platform-specific class derived from wxDialUpManager.

21.193.2 Constructor & Destructor Documentation

virtual wxDialUpManager::~wxDialUpManager ( ) [virtual]

Destructor.

21.193.3 Member Function Documentation

virtual bool wxDialUpManager::CancelDialing ( ) [pure virtual]

Cancel dialing the number initiated with Dial() with async parameter equal to true.

Note

This won't result in a DISCONNECTED event being sent.

See also

IsDialing()

static wxDialUpManager* wxDialUpManager::Create ( ) [static]

This function should create and return the object of the platform-specific class derived from wxDialUpManager.

You should delete the pointer when you are done with it.

virtual bool wxDialUpManager::Dial (const wxString & *nameOfISP* = wxEmptyString, const wxString & *username* = wxEmptyString, const wxString & *password* = wxEmptyString, bool *async* = true) [pure virtual]

Dial the given ISP, use *username* and *password* to authenticate.

The parameters are only used under Windows currently, for Unix you should use SetConnectCommand() to customize this functions behaviour.

If no *nameOfISP* is given, the function will select the default one (proposing the user to choose among all connections defined on this machine) and if no username and/or password are given, the function will try to do without them, but will ask the user if really needed.

If *async* parameter is false, the function waits until the end of dialing and returns true upon successful completion.

If *async* is true, the function only initiates the connection and returns immediately - the result is reported via events (an event is sent anyhow, but if dialing failed it will be a DISCONNECTED one).

virtual void wxDialUpManager::DisableAutoCheckOnlineStatus ( ) [pure virtual]

Disable automatic check for connection status change - notice that the wxEVT_DIALUP_XXX events won't be sent any more neither.

virtual bool wxDialUpManager::EnableAutoCheckOnlineStatus (size_t *nSeconds* = 60) [pure virtual]

Enable automatic checks for the connection status and sending of wxEVT_DIALUP_CONNECTED/wxEVT_DIALUP_DISCONNECTED events.

The interval parameter is only for Unix where we do the check manually and specifies how often should we repeat the check (each minute by default). Under Windows, the notification about the change of connection status is sent by the system and so we don't do any polling and this parameter is ignored.

Returns

false if couldn't set up automatic check for online status.

virtual size_t wxDialUpManager::GetISPNames (wxArrayString & *names*) const [pure virtual]

This function is only implemented under Windows.

Fills the array with the names of all possible values for the first parameter to Dial() on this machine and returns their number (may be 0).

virtual bool wxDialUpManager::HangUp ( ) [pure virtual]

Hang up the currently active dial up connection.

virtual bool wxDialUpManager::IsAlwaysOnline ( ) const [pure virtual]

Returns true if the computer has a permanent network connection (i.e.

\ is on a LAN) and so there is no need to use Dial() function to go online.

Note

This function tries to guess the result and it is not always guaranteed to be correct, so it is better to ask user for confirmation or give him a possibility to override it.

virtual bool wxDialUpManager::IsDialing ( ) const [pure virtual]

Returns true if (async) dialing is in progress.

See also

Dial()

virtual bool wxDialUpManager::IsOk ( ) const [pure virtual]

Returns true if the dialup manager was initialized correctly.

If this function returns false, no other functions will work neither, so it is a good idea to call this function and check its result before calling any other wxDialUpManager methods.

virtual bool wxDialUpManager::IsOnline ( ) const `[pure virtual]`

Returns true if the computer is connected to the network: under Windows, this just means that a RAS connection exists, under Unix we check that the "well-known host" (as specified by SetWellKnownHost()) is reachable.

virtual void wxDialUpManager::SetConnectCommand (const wxString & *commandDial* = "/usr/bin/pon", const wxString & *commandHangup* = "/usr/bin/poff") `[pure virtual]`

This method is for Unix only.

Sets the commands to start up the network and to hang up again.

virtual void wxDialUpManager::SetOnlineStatus (bool *isOnline* = true) `[pure virtual]`

Sometimes the built-in logic for determining the online status may fail, so, in general, the user should be allowed to override it.

This function allows to forcefully set the online status - whatever our internal algorithm may think about it.

See also

IsOnline()

virtual void wxDialUpManager::SetWellKnownHost (const wxString & *hostname*, int *portno* = 80) `[pure virtual]`

This method is for Unix only.

Under Unix, the value of well-known host is used to check whether we're connected to the internet. It is unused under Windows, but this function is always safe to call. The default value is "www.yahoo.com:80".

21.194 wxDir Class Reference

`#include <wx/dir.h>`

21.194.1 Detailed Description

wxDir is a portable equivalent of Unix open/read/closedir functions which allow enumerating of the files in a directory.

wxDir allows to enumerate files as well as directories.

wxDir also provides a flexible way to enumerate files recursively using Traverse() or a simpler GetAllFiles() function.

Example of use:

```
wxDir dir(wxGetCwd());

if ( !dir.IsOpened() )
{
    // deal with the error here - wxDir would already log an error message
    // explaining the exact reason of the failure
    return;
}

puts("Enumerating object files in current directory:");

wxString filename;

bool cont = dir.GetFirst(&filename, filespec, flags);
while ( cont )
{
    printf("%s\n", filename.c_str());

    cont = dir.GetNext(&filename);
}
```

Library: wxBase

Category: File Handling

Public Member Functions

- wxDir ()

  Default constructor, use Open() afterwards.
- wxDir (const wxString &dir)

  Opens the directory for enumeration, use IsOpened() to test for errors.
- ~wxDir ()

  Destructor cleans up the associated resources by calling Close().
- void Close ()

  Close the directory.
- bool GetFirst (wxString *filename, const wxString &filespec=wxEmptyString, int flags=wxDIR_DEFAULT) const

  Start enumerating all files matching filespec (or all files if it is empty) and flags, return true on success.
- wxString GetName () const

  Returns the name of the directory itself.
- wxString GetNameWithSep () const

  Returns the name of the directory with the path separator appended.
- bool GetNext (wxString *filename) const

  Continue enumerating files which satisfy the criteria specified by the last call to GetFirst().
- bool HasFiles (const wxString &filespec=wxEmptyString) const

  Returns true if the directory contains any files matching the given filespec.
- bool HasSubDirs (const wxString &dirspec=wxEmptyString) const

  Returns true if the directory contains any subdirectories (if a non empty filespec is given, only check for directories matching it).
- bool IsOpened () const

  Returns true if the directory was successfully opened by a previous call to Open().
- bool Open (const wxString &dir)

  Open the directory for enumerating, returns true on success or false if an error occurred.
- size_t Traverse (wxDirTraverser &sink, const wxString &filespec=wxEmptyString, int flags=wxDIR_DEFAULT) const

  Enumerate all files and directories under the given directory.

Static Public Member Functions

- static bool Exists (const wxString &dir)

  Test for existence of a directory with the given name.
- static wxString FindFirst (const wxString &dirname, const wxString &filespec, int flags=wxDIR_DEFAULT)

  The function returns the path of the first file matching the given filespec or an empty string if there are no files matching it.
- static size_t GetAllFiles (const wxString &dirname, wxArrayString *files, const wxString &filespec=wxEmptyString, int flags=wxDIR_DEFAULT)

  The function appends the names of all the files under directory dirname to the array files (note that its old content is preserved).
- static wxULongLong GetTotalSize (const wxString &dir, wxArrayString *filesSkipped=NULL)

  Returns the size (in bytes) of all files recursively found in `dir` or `wxInvalidSize` in case of error.
- static bool Make (const wxString &dir, int perm=wxS_DIR_DEFAULT, int flags=0)

Creates a directory.

- static bool Remove (const wxString &dir, int flags=0)

  Removes a directory.

21.194.2 Constructor & Destructor Documentation

wxDir::wxDir ( )

Default constructor, use Open() afterwards.

wxDir::wxDir (const wxString & *dir*)

Opens the directory for enumeration, use IsOpened() to test for errors.

wxDir::~wxDir ( )

Destructor cleans up the associated resources by calling Close().

It is not virtual and so this class is not meant to be used polymorphically.

21.194.3 Member Function Documentation

void wxDir::Close ( )

Close the directory.

The object can't be used after closing it, but Open() may be called again to reopen it later.

Since

2.9.5

static bool wxDir::Exists (const wxString & *dir*) `[static]`

Test for existence of a directory with the given name.

static wxString wxDir::FindFirst (const wxString & *dirname*, const wxString & *filespec*, int *flags* = wxDIR_DEFAULT) `[static]`

The function returns the path of the first file matching the given *filespec* or an empty string if there are no files matching it.

The *flags* parameter may or may not include wxDIR_FILES, the function always behaves as if it were specified. By default, *flags* includes wxDIR_DIRS and so the function recurses into the subdirectories but if this flag is not specified, the function restricts the search only to the directory *dirname* itself. See wxDirFlags for the list of the possible flags.

See also

Traverse()

static size_t wxDir::GetAllFiles (const wxString & *dirname*, wxArrayString * *files*, const wxString & *filespec* = wxEmptyString, int *flags* = wxDIR_DEFAULT) [static]

The function appends the names of all the files under directory *dirname* to the array *files* (note that its old content is preserved).

Only files matching the *filespec* are taken, with empty spec matching all the files.

The *flags* parameter should always include wxDIR_FILES or the array would be unchanged and should include wxDIR_DIRS flag to recurse into subdirectories (both flags are included in the value by default). See wxDirFlags for the list of the possible flags.

Returns

Returns the total number of files found while traversing the directory *dirname* (i.e. the number of entries appended to the *files* array).

See also

Traverse()

bool wxDir::GetFirst (wxString * *filename*, const wxString & *filespec* = wxEmptyString, int *flags* = wxDIR_DEFAULT) const

Start enumerating all files matching *filespec* (or all files if it is empty) and *flags*, return true on success.

See wxDirFlags for the list of the possible flags.

wxString wxDir::GetName ( ) const

Returns the name of the directory itself.

The returned string does not have the trailing path separator (slash or backslash).

Notice that in spite of this the last character of the returned string can still be the path separator if this directory is the root one. Because of this, don't append `wxFILE_SEP_PATH` to the returned value if you do need a slash-terminated directory name but use GetNameWithSep() instead to avoid having duplicate consecutive slashes.

wxString wxDir::GetNameWithSep ( ) const

Returns the name of the directory with the path separator appended.

The last character of the returned string is always `wxFILE_SEP_PATH` unless the string is empty, indicating that this directory is invalid.

See also

GetName()

Since

2.9.4

bool wxDir::GetNext (wxString * *filename*) const

Continue enumerating files which satisfy the criteria specified by the last call to GetFirst().

static wxULongLong wxDir::GetTotalSize (const wxString & *dir,* wxArrayString * *filesSkipped* = NULL) [static]

Returns the size (in bytes) of all files recursively found in `dir` or `wxInvalidSize` in case of error.

In case it happens that while traversing folders a file's size cannot be read, that file is added to the *filesSkipped* array, if not NULL, and then skipped. This usually happens with some special folders which are locked by the operating system or by another process. Remember that when the size of *filesSkipped* is not zero, then the returned value is not 100% accurate and, if the skipped files were big, it could be far from real size of the directory.

See also

wxFileName::GetHumanReadableSize(), wxGetDiskSpace()

bool wxDir::HasFiles (const wxString & *filespec* = wxEmptyString) const

Returns true if the directory contains any files matching the given *filespec*.

If *filespec* is empty, look for any files at all. In any case, even hidden files are taken into account.

bool wxDir::HasSubDirs (const wxString & *dirspec* = wxEmptyString) const

Returns true if the directory contains any subdirectories (if a non empty *filespec* is given, only check for directories matching it).

The hidden subdirectories are taken into account as well.

bool wxDir::IsOpened ( ) const

Returns true if the directory was successfully opened by a previous call to Open().

static bool wxDir::Make (const wxString & *dir,* int *perm* = wxS_DIR_DEFAULT, int *flags* = 0) [static]

Creates a directory.

This is just an alias for wxFileName::Mkdir(); refer to that function for more info.

bool wxDir::Open (const wxString & *dir*)

Open the directory for enumerating, returns true on success or false if an error occurred.

static bool wxDir::Remove (const wxString & *dir,* int *flags* = 0) [static]

Removes a directory.

This is just an alias for wxFileName::Rmdir(); refer to that function for more info.

size_t wxDir::Traverse (wxDirTraverser & *sink,* const wxString & *filespec* = wxEmptyString, int *flags* = wxDIR_DEFAULT) const

Enumerate all files and directories under the given directory.

If *flags* contains wxDIR_DIRS this enumeration is recursive, i.e. all the subdirectories of the given one and the files inside them will be traversed. Otherwise only the files in this directory itself are.

If *flags* doesn't contain wxDIR_FILES then only subdirectories are examined but not normal files. It doesn't make sense to not specify either wxDIR_DIRS or wxDIR_FILES and usually both of them should be specified, as is the case by default.

For each directory found, sink.OnDir() is called and sink.OnFile() is called for every file. Depending on the return value, the enumeration may continue or stop. If entering a subdirectory fails, sink.OnOpenError() is called.

The function returns the total number of files found or "`(size_t)-1`" on error.

See wxDirFlags for the full list of the possible flags.

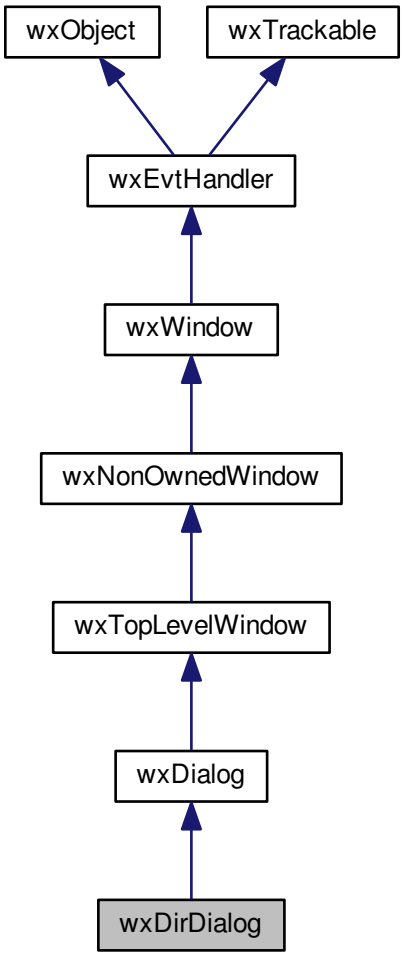
GetAllFiles()

21.195 wxDirDialog Class Reference

`#include <wx/dirdlg.h>`

Inheritance diagram for wxDirDialog:



21.195.1 Detailed Description

This class represents the directory chooser dialog.

Styles

This class supports the following styles:

- wxDD_DEFAULT_STYLE: Equivalent to a combination of wxDEFAULT_DIALOG_STYLE and wxRESIZE↩ _BORDER (the last one is not used under wxWinCE).
- wxDD_DIR_MUST_EXIST: The dialog will allow the user to choose only an existing folder. When this style is not given, a "Create new directory" button is added to the dialog (on Windows) or some other way is provided to the user to type the name of a new folder.
- wxDD_CHANGE_DIR: Change the current working directory to the directory chosen by the user.

Notice that `wxRESIZE_BORDER` has special side effect under recent (i.e. later than Win9x) Windows where two different directory selection dialogs are available and this style also implicitly selects the new version as the old one always has fixed size. As the new version is almost always preferable, it is recommended that `wxRESIZE_BO↩ RDER` style be always used. This is the case if the dialog is created with the default style value but if you need to use any additional styles you should still specify `wxDD_DEFAULT_STYLE` unless you explicitly need to use the old dialog version under Windows. E.g. do

```
wxDirDialog dlg(NULL, "Choose input directory", "",
                wxDD_DEFAULT_STYLE | wxDD_DIR_MUST_EXIST);
```

instead of just using `wxDD_DIR_MUST_EXIST` style alone.

- wxDirDialog (wxWindow *parent, const wxString &message=wxDirSelectorPromptStr, const wxString &defaultPath=wxEmptyString, long style=wxDD_DEFAULT_STYLE, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, const wxString &name=wxDirDialogNameStr)

  Constructor.
- virtual ~wxDirDialog ()

  Destructor.
- virtual wxString GetMessage () const

  Returns the message that will be displayed on the dialog.
- virtual wxString GetPath () const

  Returns the default or user-selected path.
- virtual void SetMessage (const wxString &message)

  Sets the message that will be displayed on the dialog.
- virtual void SetPath (const wxString &path)

  Sets the default path.
- int ShowModal ()

  Shows the dialog, returning wxID_OK if the user pressed OK, and wxID_CANCEL otherwise.

Additional Inherited Members

21.195.2 Constructor & Destructor Documentation

wxDirDialog::wxDirDialog (wxWindow * *parent*, const wxString & *message* = wxDirSelectorPromptStr, const wxString & *defaultPath* = wxEmptyString, long *style* = wxDD_DEFAULT_STYLE, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, const wxString & *name* = wxDirDialogNameStr)

Constructor.

Use ShowModal() to show the dialog.

Parameters

parent	Parent window.
message	Message to show on the dialog.
defaultPath	The default path, or the empty string.
style	The dialog style. See wxDirDialog
pos	Dialog position. Ignored under Windows.
size	Dialog size. Ignored under Windows.
name	The dialog name, not used.

virtual wxDirDialog::~wxDirDialog ( ) [virtual]

Destructor.

21.195.3 Member Function Documentation

virtual wxString wxDirDialog::GetMessage ( ) const [virtual]

Returns the message that will be displayed on the dialog.

virtual wxString wxDirDialog::GetPath ( ) const [virtual]

Returns the default or user-selected path.

virtual void wxDirDialog::SetMessage (const wxString & *message*) [virtual]

Sets the message that will be displayed on the dialog.

virtual void wxDirDialog::SetPath (const wxString & *path*) [virtual]

Sets the default path.

int wxDirDialog::ShowModal ( ) [virtual]

Shows the dialog, returning wxID_OK if the user pressed OK, and wxID_CANCEL otherwise.

Reimplemented from wxDialog.

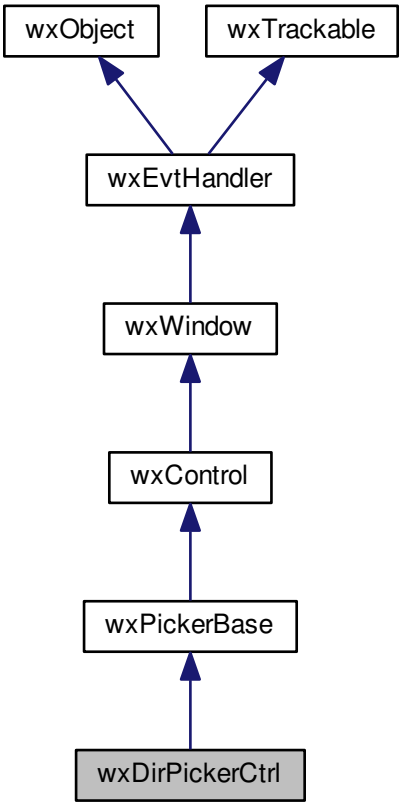
21.197 wxDirPickerCtrl Class Reference

#include <wx/filepicker.h>

Inheritance diagram for wxDirPickerCtrl:



21.197.1 Detailed Description

This control allows the user to select a directory.

The generic implementation is a button which brings up a wxDirDialog when clicked. Native implementation may differ but this is usually a (small) widget which give access to the dir-chooser dialog. It is only available if wxUSE↩

_DIRPICKERCTRL is set to 1 (the default).

Styles

This class supports the following styles:

- wxDIRP_DEFAULT_STYLE: The default style: includes wxDIRP_DIR_MUST_EXIST and, under wxMSW only, wxDIRP_USE_TEXTCTRL.
- wxDIRP_USE_TEXTCTRL: Creates a text control to the left of the picker button which is completely managed by the wxDirPickerCtrl and which can be used by the user to specify a path (see SetPath). The text control is automatically synchronized with button's value. Use functions defined in wxPickerBase to modify the text control.
- wxDIRP_DIR_MUST_EXIST: Creates a picker which allows to select only existing directories. wxGTK control always adds this flag internally as it does not support its absence.
- wxDIRP_CHANGE_DIR: Change current working directory on each user directory selection change.
- wxDIRP_SMALL: Use smaller version of the control with a small "..." button instead of the normal "Browse" one. This flag is new since wxWidgets 2.9.3.

Events emitted by this class

The following event handler macros redirect the events to member function handlers '**func**' with prototypes like: void handlerFuncName(wxFileDirPickerEvent& event)

Event macros for events emitted by this class:

- EVT_DIRPICKER_CHANGED(id, func): The user changed the directory selected in the control either using the button or using text control (see wxDIRP_USE_TEXTCTRL; note that in this case the event is fired only if the user's input is valid, e.g. an existing directory path).

Library: wxCore

Category: Picker Controls

Public Member Functions

- wxDirPickerCtrl ()
- wxDirPickerCtrl (wxWindow *parent, wxWindowID id, const wxString &path=wxEmptyString, const wxString &message=wxDirSelectorPromptStr, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, long style=wxDIRP_DEFAULT_STYLE, const wxValidator &validator=wxDefaultValidator, const wxString &name=wxDirPickerCtrlNameStr)

  Initializes the object and calls Create() with all the parameters.
- bool Create (wxWindow *parent, wxWindowID id, const wxString &path=wxEmptyString, const wxString &message=wxDirSelectorPromptStr, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, long style=wxDIRP_DEFAULT_STYLE, const wxValidator &validator=wxDefaultValidator, const wxString &name=wxDirPickerCtrlNameStr)

  Creates the widgets with the given parameters.
- wxFileName GetDirName () const

Returns the absolute path of the currently selected directory as a wxFileName object.

- wxString GetPath () const

  Returns the absolute path of the currently selected directory.

- void SetDirName (const wxFileName &dirname)

  Just like SetPath() but this function takes a wxFileName object.

- void SetInitialDirectory (const wxString &dir)

  Set the directory to show when starting to browse for directories.

- void SetPath (const wxString &dirname)

  Sets the absolute path of the currently selected directory (the default converter uses current locale's charset).

Additional Inherited Members

21.197.2 Constructor & Destructor Documentation

wxDirPickerCtrl::wxDirPickerCtrl ( )

wxDirPickerCtrl::wxDirPickerCtrl (wxWindow * *parent*, wxWindowID *id*, const wxString & *path* = wxEmptyString, const wxString & *message* = wxDirSelectorPromptStr, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, long *style* = wxDIRP_DEFAULT_STYLE, const wxValidator & *validator* = wxDefaultValidator, const wxString & *name* = `wxDirPickerCtrlNameStr`)

Initializes the object and calls Create() with all the parameters.

21.197.3 Member Function Documentation

bool wxDirPickerCtrl::Create (wxWindow * *parent*, wxWindowID *id*, const wxString & *path* = wxEmptyString, const wxString & *message* = wxDirSelectorPromptStr, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, long *style* = wxDIRP_DEFAULT_STYLE, const wxValidator & *validator* = wxDefaultValidator, const wxString & *name* = `wxDirPickerCtrlNameStr`)

Creates the widgets with the given parameters.

Parameters

parent	Parent window, must not be non-NULL.
id	The identifier for the control.
path	The initial directory shown in the control. Must be a valid path to a directory or the empty string.
message	The message shown to the user in the wxDirDialog shown by the control.
pos	Initial position.
size	Initial size.
style	The window style, see wxDIRP_* flags.
validator	Validator which can be used for additional date checks.
name	Control name.

Returns

true if the control was successfully created or false if creation failed.

wxFileName wxDirPickerCtrl::GetDirName ( ) const

Returns the absolute path of the currently selected directory as a wxFileName object.

This function is equivalent to GetPath().

wxString wxDirPickerCtrl::GetPath ( ) const

Returns the absolute path of the currently selected directory.

void wxDirPickerCtrl::SetDirName (const wxFileName & *dirname*)

Just like SetPath() but this function takes a wxFileName object.

void wxDirPickerCtrl::SetInitialDirectory (const wxString & *dir*)

Set the directory to show when starting to browse for directories.

This function is mostly useful for the directory picker controls which have no selection initially to configure the directory that should be shown if the user starts browsing for directories as otherwise the initially selected directory is used, which is usually the desired behaviour and so the directory specified by this function is ignored in this case.

Since

2.9.4

void wxDirPickerCtrl::SetPath (const wxString & *dirname*)

Sets the absolute path of the currently selected directory (the default converter uses current locale's charset).

This must be a valid directory if `wxDIRP_DIR_MUST_EXIST` style was given.

21.198 wxDirTraverser Class Reference

`#include <wx/dir.h>`

21.198.1 Detailed Description

wxDirTraverser is an abstract interface which must be implemented by objects passed to wxDir::Traverse() function.

Example of use (this works almost like wxDir::GetAllFiles()):

```
class wxDirTraverserSimple : public wxDirTraverser
{
public:
    wxDirTraverserSimple(wxArrayString& files) : m_files(files) { }

    virtual wxDirTraverseResult OnFile(const wxString& filename)
    {
        m_files.Add(filename);
        return wxDIR_CONTINUE;
    }

    virtual wxDirTraverseResult OnDir(const wxString& WXUNUSED(dirname))
    {
        return wxDIR_CONTINUE;
    }

private:
    wxArrayString& m_files;
};

// get the names of all files in the array
wxArrayString files;
wxDirTraverserSimple traverser(files);

wxDir dir(dirname);
dir.Traverse(traverser);
```

Library: wxBase

Category: File Handling

Public Member Functions

- virtual wxDirTraverseResult OnDir (const wxString &dirname)=0

  This function is called for each directory.
- virtual wxDirTraverseResult OnFile (const wxString &filename)=0

  This function is called for each file.
- virtual wxDirTraverseResult OnOpenError (const wxString &openerrorname)

  This function is called for each directory which we failed to open for enumerating.

21.198.2 Member Function Documentation

virtual wxDirTraverseResult wxDirTraverser::OnDir (const wxString & *dirname*) `[pure virtual]`

This function is called for each directory.

It may return wxDIR_STOP to abort traversing completely, wxDIR_IGNORE to skip this directory but continue with others or wxDIR_CONTINUE to enumerate all files and subdirectories in this directory.

This is a pure virtual function and must be implemented in the derived class.

virtual wxDirTraverseResult wxDirTraverser::OnFile (const wxString & *filename*) `[pure virtual]`

This function is called for each file.

It may return wxDIR_STOP to abort traversing (for example, if the file being searched is found) or wxDIR_CONTINUE to proceed.

This is a pure virtual function and must be implemented in the derived class.

virtual wxDirTraverseResult wxDirTraverser::OnOpenError (const wxString & *openerrorname*) `[virtual]`

This function is called for each directory which we failed to open for enumerating.

It may return wxDIR_STOP to abort traversing completely, wxDIR_IGNORE to skip this directory but continue with others or wxDIR_CONTINUE to retry opening this directory once again.

The base class version always returns wxDIR_IGNORE.

21.199 wxDisplay Class Reference

```
#include <wx/display.h>
```

21.199.1 Detailed Description

Determines the sizes and locations of displays connected to the system.

Library: wxCore

Category: Application and System configuration

See also

wxClientDisplayRect(), wxDisplaySize(), wxDisplaySizeMM()

Public Member Functions

- wxDisplay (unsigned int index=0)

  Constructor, setting up a wxDisplay instance with the specified display.
- ~wxDisplay ()

  Destructor.
- bool ChangeMode (const wxVideoMode &mode=wxDefaultVideoMode)

  Changes the video mode of this display to the mode specified in the mode parameter.
- wxRect GetClientArea () const

  Returns the client area of the display.
- wxVideoMode GetCurrentMode () const

  Returns the current video mode that this display is in.
- wxRect GetGeometry () const

  Returns the bounding rectangle of the display whose index was passed to the constructor.
- wxArrayVideoModes GetModes (const wxVideoMode &mode=wxDefaultVideoMode) const

  Fills and returns an array with all the video modes that are supported by this display, or video modes that are supported by this display and match the mode parameter (if mode is not wxDefaultVideoMode).
- wxString GetName () const

  Returns the display's name.
- bool IsPrimary () const

  Returns true if the display is the primary display.

Static Public Member Functions

- static unsigned int GetCount ()

  Returns the number of connected displays.
- static int GetFromPoint (const wxPoint &pt)

  Returns the index of the display on which the given point lies, or `wxNOT_FOUND` if the point is not on any connected display.
- static int GetFromWindow (const wxWindow *win)

  Returns the index of the display on which the given window lies.

21.199.2 Constructor & Destructor Documentation

wxDisplay::wxDisplay (unsigned int *index* = `0`)

Constructor, setting up a wxDisplay instance with the specified display.

Parameters

index	The index of the display to use. This must be non-negative and lower than the value returned by GetCount().

wxDisplay::~wxDisplay ( )

Destructor.

21.199.3 Member Function Documentation

bool wxDisplay::ChangeMode (const wxVideoMode & *mode* = wxDefaultVideoMode)

Changes the video mode of this display to the mode specified in the mode parameter.

If wxDefaultVideoMode is passed in as the mode parameter, the defined behaviour is that wxDisplay will reset the video mode to the default mode used by the display. On Windows, the behaviour is normal. However, there are differences on other platforms. On Unix variations using X11 extensions it should behave as defined, but some irregularities may occur.

wxRect wxDisplay::GetClientArea ( ) const

Returns the client area of the display.

The client area is the part of the display available for the normal (non full screen) windows, usually it is the same as GetGeometry() but it could be less if there is a taskbar (or equivalent) on this display.

static unsigned int wxDisplay::GetCount ( ) [static]

Returns the number of connected displays.

wxVideoMode wxDisplay::GetCurrentMode ( ) const

Returns the current video mode that this display is in.

static int wxDisplay::GetFromPoint (const wxPoint & *pt*) [static]

Returns the index of the display on which the given point lies, or `wxNOT_FOUND` if the point is not on any connected display.

Parameters

pt	The point to locate.

static int wxDisplay::GetFromWindow (const wxWindow * *win*) [static]

Returns the index of the display on which the given window lies.

If the window is on more than one display it gets the display that overlaps the window the most.

Returns `wxNOT_FOUND` if the window is not on any connected display.

Parameters

win	The window to locate.

wxRect wxDisplay::GetGeometry ( ) const

Returns the bounding rectangle of the display whose index was passed to the constructor.

See also

GetClientArea(), wxDisplaySize()

wxArrayVideoModes wxDisplay::GetModes (const wxVideoMode & *mode* = wxDefaultVideoMode) const

Fills and returns an array with all the video modes that are supported by this display, or video modes that are supported by this display and match the mode parameter (if mode is not wxDefaultVideoMode).

wxString wxDisplay::GetName ( ) const

Returns the display's name.

A name is not available on all platforms.

bool wxDisplay::IsPrimary ( ) const

Returns true if the display is the primary display.

The primary display is the one whose index is 0.

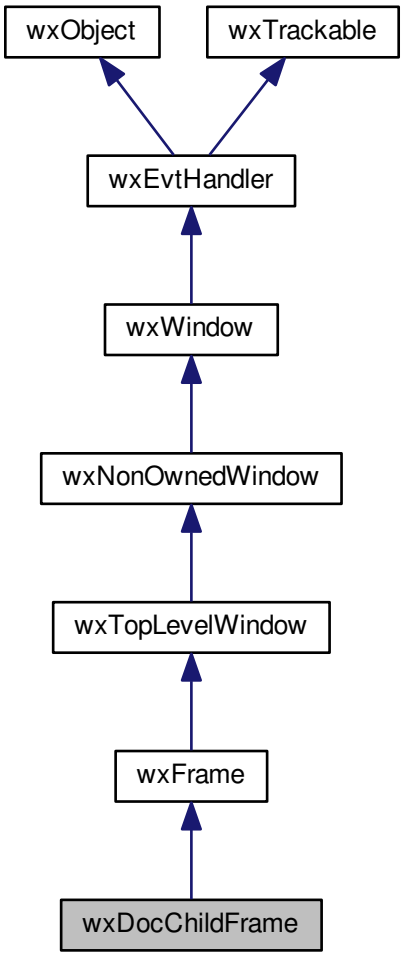
21.201 wxDocChildFrame Class Reference

`#include <wx/docview.h>`

Inheritance diagram for wxDocChildFrame:



21.201.1 Detailed Description

The wxDocChildFrame class provides a default frame for displaying documents on separate windows.

This class can only be used for SDI (not MDI) child frames.

The class is part of the document/view framework supported by wxWidgets, and cooperates with the wxView, wx↩Document, wxDocManager and wxDocTemplate classes.

Notice that this class handles wxEVT_ACTIVATE event and activates the child view on receiving it. Don't intercept this event unless you want to prevent from this happening.

The same remark applies to wxEVT_CLOSE_WINDOW, as wxDocParentFrame the frame handles this event by trying to close the associated view.

Library: wxCore

Category: Document/View Framework

wxDocument* wxDocChildFrame::GetDocument ( ) const

Returns the document associated with this frame.

wxView* wxDocChildFrame::GetView ( ) const

Returns the view associated with this frame.

void wxDocChildFrame::SetDocument (wxDocument * *doc*)

Sets the document for this frame.

void wxDocChildFrame::SetView (wxView * *view*)

Sets the view for this frame.

21.201.4 Member Data Documentation

wxDocument* wxDocChildFrame::m_childDocument

The document associated with the frame.

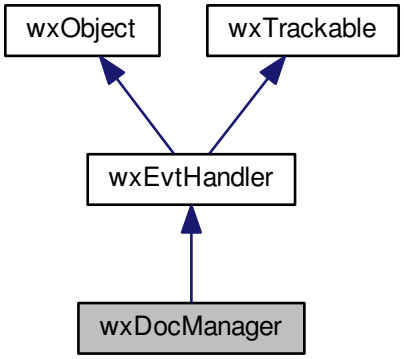
wxView* wxDocChildFrame::m_childView

The view associated with the frame.

21.202 wxDocManager Class Reference

`#include <wx/docview.h>`

Inheritance diagram for wxDocManager:



21.202.1 Detailed Description

The wxDocManager class is part of the document/view framework supported by wxWidgets, and cooperates with the wxView, wxDocument and wxDocTemplate classes.

Library: wxCore

Category: Document/View Framework

See also

wxDocManager Overview, wxDocument, wxView, wxDocTemplate, wxFileHistory

Public Member Functions

- wxDocManager (long flags=0, bool initialize=true)

  Constructor.
- virtual ~wxDocManager ()

  Destructor.
- virtual void ActivateView (wxView *doc, bool activate=true)

  Sets the current view.
- void AddDocument (wxDocument *doc)

  Adds the document to the list of documents.
- virtual void AddFileToHistory (const wxString &filename)

  Adds a file to the file history list, if we have a pointer to an appropriate file menu.
- void AssociateTemplate (wxDocTemplate *temp)

  Adds the template to the document manager's template list.
- wxDocTemplate * FindTemplate (const wxClassInfo *classinfo)

  Search for a particular document template.
- wxDocument * FindDocumentByPath (const wxString &path) const

  Search for the document corresponding to the given file.

- bool CloseDocument (wxDocument *doc, bool force=false)

  Closes the specified document.
- bool CloseDocuments (bool force=true)

  Closes all currently opened documents.
- virtual wxDocument * CreateDocument (const wxString &path, long flags=0)

  Creates a new document.
- wxDocument * CreateNewDocument ()

  Creates an empty new document.
- virtual wxView * CreateView (wxDocument *doc, long flags=0)

  Creates a new view for the given document.
- void DisassociateTemplate (wxDocTemplate *temp)

  Removes the template from the list of templates.
- virtual void FileHistoryAddFilesToMenu ()

  Appends the files in the history list to all menus managed by the file history object.
- virtual void FileHistoryAddFilesToMenu (wxMenu *menu)

  Appends the files in the history list to the given menu only.
- virtual void FileHistoryLoad (const wxConfigBase &config)

  Loads the file history from a config object.
- virtual void FileHistoryRemoveMenu (wxMenu *menu)

  Removes the given menu from the list of menus managed by the file history object.
- virtual void FileHistorySave (wxConfigBase &resourceFile)

  Saves the file history into a config object.
- virtual void FileHistoryUseMenu (wxMenu *menu)

  Use this menu for appending recently-visited document filenames, for convenient access.
- virtual wxDocTemplate * FindTemplateForPath (const wxString &path)

  Given a path, try to find template that matches the extension.
- wxView * GetAnyUsableView () const

  Returns the view to apply a user command to.
- wxDocument * GetCurrentDocument () const

  Returns the document associated with the currently active view (if any).
- virtual wxView * GetCurrentView () const

  Returns the currently active view.
- wxDocVector GetDocumentsVector () const

  Returns a vector of wxDocument pointers.
- wxDocTemplateVector GetTemplatesVector () const

  Returns a vector of wxDocTemplate pointers.
- wxList & GetDocuments ()

  Returns a reference to the list of documents.
- virtual wxFileHistory * GetFileHistory () const

  Returns a pointer to file history.
- virtual size_t GetHistoryFilesCount () const

  Returns the number of files currently stored in the file history.
- wxString GetLastDirectory () const

  Returns the directory last selected by the user when opening a file.
- int GetMaxDocsOpen () const

  Returns the number of documents that can be open simultaneously.
- wxList & GetTemplates ()

  Returns a reference to the list of associated templates.
- virtual bool Initialize ()

  Initializes data; currently just calls OnCreateFileHistory().
- virtual wxString MakeNewDocumentName ()

Return a string containing a suitable default name for a new document.

- virtual wxFileHistory * OnCreateFileHistory ()

  A hook to allow a derived class to create a different type of file history.
- void OnFileClose (wxCommandEvent &event)

  Closes and deletes the currently active document.
- void OnFileCloseAll (wxCommandEvent &event)

  Closes and deletes all the currently opened documents.
- void OnFileNew (wxCommandEvent &event)

  Creates a document from a list of templates (if more than one template).
- void OnFileOpen (wxCommandEvent &event)

  Creates a new document and reads in the selected file.
- void OnFileRevert (wxCommandEvent &event)

  Reverts the current document by calling wxDocument::Revert() for the current document.
- void OnFileSave (wxCommandEvent &event)

  Saves the current document by calling wxDocument::Save() for the current document.
- void OnFileSaveAs (wxCommandEvent &event)

  Calls wxDocument::SaveAs() for the current document.
- void RemoveDocument (wxDocument *doc)

  Removes the document from the list of documents.
- virtual wxDocTemplate * SelectDocumentPath (wxDocTemplate **templates, int noTemplates, wxString &path, long flags, bool save=false)

  Under Windows, pops up a file selector with a list of filters corresponding to document templates.
- virtual wxDocTemplate * SelectDocumentType (wxDocTemplate **templates, int noTemplates, bool sort=false)

  Returns a document template by asking the user (if there is more than one template).
- virtual wxDocTemplate * SelectViewType (wxDocTemplate **templates, int noTemplates, bool sort=false)

  Returns a document template by asking the user (if there is more than one template), displaying a list of valid views.
- void SetLastDirectory (const wxString &dir)

  Sets the directory to be displayed to the user when opening a file.
- void SetMaxDocsOpen (int n)

  Sets the maximum number of documents that can be open at a time.

Protected Member Functions

- virtual void OnMRUFileNotExist (unsigned n, const wxString &filename)

  Called when a file selected from the MRU list doesn't exist any more.
- virtual wxPreviewFrame * CreatePreviewFrame (wxPrintPreviewBase *preview, wxWindow *parent, const wxString &title)

  Create the frame used for print preview.

Protected Attributes

- wxView * m_currentView

  The currently active view.
- int m_defaultDocumentNameCounter

  Stores the integer to be used for the next default document name.
- wxList m_docs

  A list of all documents.
- wxFileHistory * m_fileHistory

  A pointer to an instance of wxFileHistory, which manages the history of recently-visited files on the File menu.
- wxString m_lastDirectory

The directory last selected by the user when opening a file.

- int m_maxDocsOpen

  Stores the maximum number of documents that can be opened before existing documents are closed.

Additional Inherited Members

21.202.2 Constructor & Destructor Documentation

wxDocManager::wxDocManager (long *flags* = `0`, bool *initialize* = `true`)

Constructor.

Create a document manager instance dynamically near the start of your application before doing any document or view operations.

If *initialize* is true, the Initialize() function will be called to create a default history list object. If you derive from wxDocManager, you may wish to call the base constructor with false, and then call Initialize() in your own constructor, to allow your own Initialize() or OnCreateFileHistory functions to be called.

Parameters

flags	Currently unused.
initialize	Indicates whether Initialize() should be called by this ctor.

virtual wxDocManager::~wxDocManager ( ) `[virtual]`

Destructor.

21.202.3 Member Function Documentation

virtual void wxDocManager::ActivateView (wxView * *doc*, bool *activate* = `true`) `[virtual]`

Sets the current view.

void wxDocManager::AddDocument (wxDocument * *doc*)

Adds the document to the list of documents.

virtual void wxDocManager::AddFileToHistory (const wxString & *filename*) `[virtual]`

Adds a file to the file history list, if we have a pointer to an appropriate file menu.

void wxDocManager::AssociateTemplate (wxDocTemplate * *temp*)

Adds the template to the document manager's template list.

bool wxDocManager::CloseDocument (wxDocument * *doc*, bool *force* = `false`)

Closes the specified document.

If *force* is true, the document is closed even if it has unsaved changes.

Parameters

doc	The document to close, must be non-NULL.
force	If true, close the document even if wxDocument::Close() returns false.

Returns

true if the document was closed or false if closing it was cancelled by user (only in *force* = false case).

bool wxDocManager::CloseDocuments (bool *force* = `true`)

Closes all currently opened documents.

See also

CloseDocument()

virtual wxDocument* wxDocManager::CreateDocument (const wxString & *path*, long *flags* = `0`) `[virtual]`

Creates a new document.

This function can either create a document corresponding to a new file or to an already existing one depending on whether `wxDOC_NEW` is specified in the *flags*.

By default, this function asks the user for the type of document to open and the path to its file if it's not specified, i.e. if *path* is empty. Specifying `wxDOC_SILENT` flag suppresses any prompts and means that the *path* must be non-empty and there must be a registered document template handling the extension of this file, otherwise a warning message is logged and the function returns NULL. Notice that `wxDOC_SILENT` can be combined with `wxDOC_NEW`, however in this case the *path* must still be specified, even if the file with this path typically won't exist.

Finally notice that if this document manager was configured to allow only a limited number of simultaneously opened documents using SetMaxDocsOpen(), this function will try to close the oldest existing document if this number was reached before creating a new document. And if closing the old document fails (e.g. because it was vetoed by user), this function fails as well.

Parameters

path	Path to a file or an empty string. If the path is empty, the user will be asked to select it (thus, this is incompatible with the use of `wxDOC_SILENT`). The file should exist unless *flags* includes `wxDOC_NEW`.
flags	By default, none. May include `wxDOC_NEW` to indicate that the new document corresponds to a new file and not an existing one and `wxDOC_SILENT` to suppress any dialogs asking the user about the file path and type.

Returns

a new document object or NULL on failure.

wxDocument* wxDocManager::CreateNewDocument ( )

Creates an empty new document.

This is equivalent to calling CreateDocument() with `wxDOC_NEW` flags and without the file name.

virtual wxPreviewFrame* wxDocManager::CreatePreviewFrame (wxPrintPreviewBase * *preview*, wxWindow * *parent*, const wxString & *title*) `[protected]`, `[virtual]`

Create the frame used for print preview.

This method can be overridden if you need to change the behaviour or appearance of the preview window. By default, a standard wxPreviewFrame is created.

Since

2.9.1

Parameters

preview	The associated preview object.
parent	The parent window for the frame.
title	The suggested title for the print preview frame.

Returns

A new print preview frame, must not return NULL.

virtual wxView* wxDocManager::CreateView (wxDocument * *doc*, long *flags* = 0) [virtual]

Creates a new view for the given document.

If more than one view is allowed for the document (by virtue of multiple templates mentioning the same document type), a choice of view is presented to the user.

void wxDocManager::DisassociateTemplate (wxDocTemplate * *temp*)

Removes the template from the list of templates.

virtual void wxDocManager::FileHistoryAddFilesToMenu ( ) [virtual]

Appends the files in the history list to all menus managed by the file history object.

virtual void wxDocManager::FileHistoryAddFilesToMenu (wxMenu * *menu*) [virtual]

Appends the files in the history list to the given *menu* only.

virtual void wxDocManager::FileHistoryLoad (const wxConfigBase & *config*) [virtual]

Loads the file history from a config object.

See also

wxConfigBase

virtual void wxDocManager::FileHistoryRemoveMenu (wxMenu * *menu*) [virtual]

Removes the given menu from the list of menus managed by the file history object.

virtual void wxDocManager::FileHistorySave (wxConfigBase & *resourceFile*) [virtual]

Saves the file history into a config object.

This must be called explicitly by the application.

See also

wxConfigBase

virtual void wxDocManager::FileHistoryUseMenu (wxMenu * *menu*) [virtual]

Use this menu for appending recently-visited document filenames, for convenient access.

Calling this function with a valid menu pointer enables the history list functionality.

Note

You can add multiple menus using this function, to be managed by the file history object.

wxDocument* wxDocManager::FindDocumentByPath (const wxString & *path*) const

Search for the document corresponding to the given file.

Parameters

path	Document file path.

Returns

Pointer to a wxDocument, or NULL if none found.

Since

2.9.5

wxDocTemplate* wxDocManager::FindTemplate (const wxClassInfo * *classinfo*)

Search for a particular document template.

Example:

```
// creating a document instance of the specified document type:
m_doc = (MyDoc*)docManager->FindTemplate(CLASSINFO(MyDoc))->
            CreateDocument(wxEmptyString, wxDOC_SILENT);
```

Parameters

classinfo	Class info of a document class for which a wxDocTemplate had been previously created.

Returns

Pointer to a wxDocTemplate, or NULL if none found.

Since

2.9.2

virtual wxDocTemplate* wxDocManager::FindTemplateForPath (const wxString & *path*) [virtual]

Given a path, try to find template that matches the extension.

This is only an approximate method of finding a template for creating a document.

wxView* wxDocManager::GetAnyUsableView ( ) const

Returns the view to apply a user command to.

This method tries to find the view that the user wants to interact with. It returns the same view as GetCurrentDocument() if there is any currently active view but falls back to the first view of the first document if there is no active view.

Since

2.9.5

wxDocument* wxDocManager::GetCurrentDocument ( ) const

Returns the document associated with the currently active view (if any).

virtual wxView* wxDocManager::GetCurrentView ( ) const `[virtual]`

Returns the currently active view.

This method can return NULL if no view is currently active.

See also

GetAnyUsableView()

wxList& wxDocManager::GetDocuments ( )

Returns a reference to the list of documents.

wxDocVector wxDocManager::GetDocumentsVector ( ) const

Returns a vector of wxDocument pointers.

Since

2.9.5

virtual wxFileHistory* wxDocManager::GetFileHistory ( ) const `[virtual]`

Returns a pointer to file history.

virtual size_t wxDocManager::GetHistoryFilesCount ( ) const `[virtual]`

Returns the number of files currently stored in the file history.

wxString wxDocManager::GetLastDirectory ( ) const

Returns the directory last selected by the user when opening a file.

Initially empty.

int wxDocManager::GetMaxDocsOpen ( ) const

Returns the number of documents that can be open simultaneously.

wxList& wxDocManager::GetTemplates ( )

Returns a reference to the list of associated templates.

wxDocTemplateVector wxDocManager::GetTemplatesVector ( ) const

Returns a vector of wxDocTemplate pointers.

Since

2.9.5

virtual bool wxDocManager::Initialize ( ) [virtual]

Initializes data; currently just calls OnCreateFileHistory().

Some data cannot always be initialized in the constructor because the programmer must be given the opportunity to override functionality. If OnCreateFileHistory() was called from the constructor, an overridden virtual OnCreate↩ FileHistory() would not be called due to C++'s 'interesting' constructor semantics. In fact Initialize() *is* called from the wxDocManager constructor, but this can be vetoed by passing false to the second argument, allowing the derived class's constructor to call Initialize(), possibly calling a different OnCreateFileHistory() from the default.

The bottom line: if you're not deriving from Initialize(), forget it and construct wxDocManager with no arguments.

virtual wxString wxDocManager::MakeNewDocumentName ( ) [virtual]

Return a string containing a suitable default name for a new document.

By default this is implemented by appending an integer counter to the string **unnamed** but can be overridden in the derived classes to do something more appropriate.

virtual wxFileHistory* wxDocManager::OnCreateFileHistory ( ) [virtual]

A hook to allow a derived class to create a different type of file history.

Called from Initialize().

void wxDocManager::OnFileClose (wxCommandEvent & *event*)

Closes and deletes the currently active document.

void wxDocManager::OnFileCloseAll (wxCommandEvent & *event*)

Closes and deletes all the currently opened documents.

void wxDocManager::OnFileNew (wxCommandEvent & *event*)

Creates a document from a list of templates (if more than one template).

void wxDocManager::OnFileOpen (wxCommandEvent & *event*)

Creates a new document and reads in the selected file.

void wxDocManager::OnFileRevert (wxCommandEvent & *event*)

Reverts the current document by calling wxDocument::Revert() for the current document.

void wxDocManager::OnFileSave (wxCommandEvent & *event*)

Saves the current document by calling wxDocument::Save() for the current document.

void wxDocManager::OnFileSaveAs (wxCommandEvent & *event*)

Calls wxDocument::SaveAs() for the current document.

virtual void wxDocManager::OnMRUFileNotExist (unsigned *n,* const wxString & *filename*) `[protected], [virtual]`

Called when a file selected from the MRU list doesn't exist any more.

The default behaviour is to remove the file from the MRU (most recently used) files list and the corresponding menu and notify the user about it but this method can be overridden to customize it.

For example, an application may want to just give an error about the missing file *filename* but not remove it from the file history. Or it could ask the user whether the file should be kept or removed.

Notice that this method is called only if the file selected by user from the MRU files in the menu doesn't exist, but not if opening it failed for any other reason because in the latter case the default behaviour of removing the file from the MRU list is inappropriate. If you still want to do it, you would need to do it by calling RemoveFileFromHistory() explicitly in the part of the file opening code that may fail.

Since

2.9.3

Parameters

n	The index of the file in the MRU list, it can be passed to RemoveFileFromHistory() to remove this file from the list.
filename	The full name of the file.

void wxDocManager::RemoveDocument (wxDocument * *doc*)

Removes the document from the list of documents.

virtual wxDocTemplate* wxDocManager::SelectDocumentPath (wxDocTemplate ** *templates,* int *noTemplates,* wxString & *path,* long *flags,* bool *save* = `false`) `[virtual]`

Under Windows, pops up a file selector with a list of filters corresponding to document templates.

The wxDocTemplate corresponding to the selected file's extension is returned.

On other platforms, if there is more than one document template a choice list is popped up, followed by a file selector.

This function is used in CreateDocument().

wxPerl Note: In wxPerl *templates* is a reference to a list of templates. If you override this method in your document manager it must return two values, eg:

```
(doctemplate, path) = My::DocManager->SelectDocumentPath(...);
```

virtual wxDocTemplate* wxDocManager::SelectDocumentType (wxDocTemplate ** *templates*, int *noTemplates*, bool *sort* = false) [virtual]

Returns a document template by asking the user (if there is more than one template).

This function is used in CreateDocument().

Parameters

templates	Pointer to an array of templates from which to choose a desired template.
noTemplates	Number of templates being pointed to by the templates pointer.
sort	If more than one template is passed into templates, then this parameter indicates whether the list of templates that the user will have to choose from is sorted or not when shown the choice box dialog. Default is false.

wxPerl Note: In wxPerl *templates* is a reference to a list of templates.

virtual wxDocTemplate* wxDocManager::SelectViewType (wxDocTemplate ** *templates*, int *noTemplates*, bool *sort* = false) [virtual]

Returns a document template by asking the user (if there is more than one template), displaying a list of valid views.

This function is used in CreateView(). The dialog normally will not appear because the array of templates only contains those relevant to the document in question, and often there will only be one such.

Parameters

templates	Pointer to an array of templates from which to choose a desired template.
noTemplates	Number of templates being pointed to by the templates pointer.
sort	If more than one template is passed into templates, then this parameter indicates whether the list of templates that the user will have to choose from is sorted or not when shown the choice box dialog. Default is false.

wxPerl Note: In wxPerl *templates* is a reference to a list of templates.

void wxDocManager::SetLastDirectory (const wxString & *dir*)

Sets the directory to be displayed to the user when opening a file.

Initially this is empty.

void wxDocManager::SetMaxDocsOpen (int *n*)

Sets the maximum number of documents that can be open at a time.

By default, this is INT_MAX, i.e. the number of documents is unlimited. If you set it to 1, existing documents will be saved and deleted when the user tries to open or create a new one (similar to the behaviour of Windows Write, for example). Allowing multiple documents gives behaviour more akin to MS Word and other Multiple Document Interface applications.

21.202.4 Member Data Documentation

wxView* wxDocManager::m_currentView [protected]

The currently active view.

int wxDocManager::m_defaultDocumentNameCounter [protected]

Stores the integer to be used for the next default document name.

wxList wxDocManager::m_docs [protected]

A list of all documents.

wxFileHistory* **wxDocManager::m_fileHistory** [protected]

A pointer to an instance of wxFileHistory, which manages the history of recently-visited files on the File menu.

wxString wxDocManager::m_lastDirectory [protected]

The directory last selected by the user when opening a file.

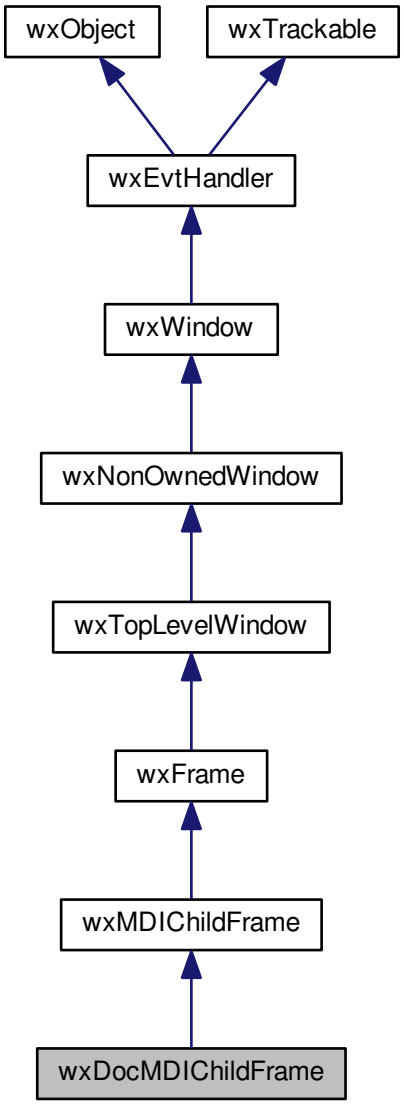
int wxDocManager::m_maxDocsOpen [protected]

Stores the maximum number of documents that can be opened before existing documents are closed.
By default, this is `INT_MAX` i.e. practically unlimited.

21.203 wxDocMDIChildFrame Class Reference

```
#include <wx/docmdi.h>
```

Inheritance diagram for wxDocMDIChildFrame:



21.203.1 Detailed Description

The wxDocMDIChildFrame class provides a default frame for displaying documents on separate windows.

This class can only be used for MDI child frames.

The class is part of the document/view framework supported by wxWidgets, and cooperates with the wxView, wx↩ Document, wxDocManager and wxDocTemplate classes.

Library: wxCore

Category: Document/View Framework

Creates the window.

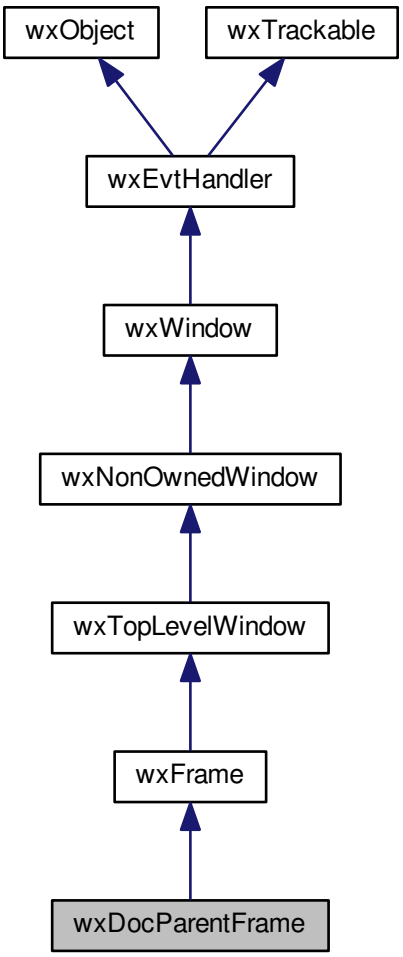
21.205 wxDocParentFrame Class Reference

`#include <wx/docview.h>`

Inheritance diagram for wxDocParentFrame:



21.205.1 Detailed Description

The wxDocParentFrame class provides a default top-level frame for applications using the document/view framework.

This class can only be used for SDI (not MDI) parent frames.

It cooperates with the wxView, wxDocument, wxDocManager and wxDocTemplate classes.

Notice that this class processes wxEVT_CLOSE_WINDOW event and tries to close all open views from its handler. If all the views can be closed, i.e. if none of them contains unsaved changes or the user decides to not save them, the window is destroyed. Don't intercept this event in your code unless you want to replace this logic.

wxDocTemplate Overview, wxDocument, wxView

Public Member Functions

- wxDocTemplate (wxDocManager *manager, const wxString &descr, const wxString &filter, const wxString &dir, const wxString &ext, const wxString &docTypeName, const wxString &viewTypeName, wxClassInfo *docClassInfo=0, wxClassInfo *viewClassInfo=0, long flags=wxTEMPLATE_VISIBLE)

  Constructor.
- virtual ~wxDocTemplate ()

Destructor.

- virtual wxDocument * CreateDocument (const wxString &path, long flags=0)

  Creates a new instance of the associated document class.
- virtual wxView * CreateView (wxDocument *doc, long flags=0)

  Creates a new instance of the associated view class.
- virtual bool FileMatchesTemplate (const wxString &path)

  This function implements the default (very primitive) format detection which checks if the extension is that of the template.
- wxString GetDefaultExtension () const

  Returns the default file extension for the document data, as passed to the document template constructor.
- wxString GetDescription () const

  Returns the text description of this template, as passed to the document template constructor.
- wxString GetDirectory () const

  Returns the default directory, as passed to the document template constructor.
- wxClassInfo * GetDocClassInfo () const

  Returns the run-time class information that allows document instances to be constructed dynamically, as passed to the document template constructor.
- wxDocManager * GetDocumentManager () const

  Returns a pointer to the document manager instance for which this template was created.
- virtual wxString GetDocumentName () const

  Returns the document type name, as passed to the document template constructor.
- wxString GetFileFilter () const

  Returns the file filter, as passed to the document template constructor.
- long GetFlags () const

  Returns the flags, as passed to the document template constructor.
- wxClassInfo * GetViewClassInfo () const

  Returns the run-time class information that allows view instances to be constructed dynamically, as passed to the document template constructor.
- virtual wxString GetViewName () const

  Returns the view type name, as passed to the document template constructor.
- virtual bool InitDocument (wxDocument *doc, const wxString &path, long flags=0)

  Initialises the document, calling wxDocument::OnCreate().
- bool IsVisible () const

  Returns true if the document template can be shown in user dialogs, false otherwise.
- void SetDefaultExtension (const wxString &ext)

  Sets the default file extension.
- void SetDescription (const wxString &descr)

  Sets the template description.
- void SetDirectory (const wxString &dir)

  Sets the default directory.
- void SetDocumentManager (wxDocManager *manager)

  Sets the pointer to the document manager instance for which this template was created.
- void SetFileFilter (const wxString &filter)

  Sets the file filter.
- void SetFlags (long flags)

  Sets the internal document template flags (see the constructor description for more details).

- wxPageSetupDialogData & GetPageSetupDialogData ()

  Returns a reference to the wxPageSetupDialogData associated with the printing operations of this document manager.
- const wxPageSetupDialogData & GetPageSetupDialogData () const

  Returns a reference to the wxPageSetupDialogData associated with the printing operations of this document manager.

Public Attributes

- wxString m_defaultExt

  The default extension for files of this type.
- wxString m_description

  A short description of this template.
- wxString m_directory

  The default directory for files of this type.
- wxClassInfo * m_docClassInfo

  Run-time class information that allows document instances to be constructed dynamically.
- wxString m_docTypeName

  The named type of the document associated with this template.
- wxDocTemplate * m_documentManager

  A pointer to the document manager for which this template was created.
- wxString m_fileFilter

  The file filter (such as ".txt") to be used in file selector dialogs.*
- long m_flags

  The flags passed to the constructor.
- wxClassInfo * m_viewClassInfo

  Run-time class information that allows view instances to be constructed dynamically.
- wxString m_viewTypeName

  The named type of the view associated with this template.

Additional Inherited Members

21.206.2 Constructor & Destructor Documentation

wxDocTemplate::wxDocTemplate (wxDocManager * *manager,* const wxString & *descr,* const wxString & *filter,* const wxString & *dir,* const wxString & *ext,* const wxString & *docTypeName,* const wxString & *viewTypeName,* wxClassInfo * *docClassInfo* = `0`, wxClassInfo * *viewClassInfo* = `0`, long *flags* = `wxTEMPLATE_VISIBLE`)

Constructor.

Create instances dynamically near the start of your application after creating a wxDocManager instance, and before doing any document or view operations.

Parameters

manager	The document manager object which manages this template.
descr	A short description of what the template is for. This string will be displayed in the file filter list of Windows file selectors.
filter	An appropriate file filter such as "*.txt".
dir	The default directory to use for file selectors.
ext	The default file extension (such as "txt").
docTypeName	A name that should be unique for a given type of document, used for gathering a list of views relevant to a particular document.
viewTypeName	A name that should be unique for a given view.
docClassInfo	A pointer to the run-time document class information as returned by the wxCLASSINFO() macro, e.g. wxCLASSINFO(MyDocumentClass). If this is not supplied, you will need to derive a new wxDocTemplate class and override the CreateDocument() member to return a new document instance on demand.

viewClassInfo	A pointer to the run-time view class information as returned by the wxCLASSINFO() macro, e.g. wxCLASSINFO(MyViewClass). If this is not supplied, you will need to derive a new wxDocTemplate class and override the CreateView() member to return a new view instance on demand.
flags	A bit list of the following: • wxTEMPLATE_VISIBLE - The template may be displayed to the user in dialogs. • wxTEMPLATE_INVISIBLE - The template may not be displayed to the user in dialogs. • wxDEFAULT_TEMPLATE_FLAGS - Defined as wxTEMPLATE_VISIBLE.

wxPerl Note:

In wxPerl *docClassInfo* and *viewClassInfo* can be either `Wx::ClassInfo` objects or strings containing the name of the perl packages which are to be used as `Wx::Document` and `Wx::View` classes (they must have a constructor named new); as an example:

- Wx::DocTemplate->new(docmgr, descr, filter, dir, ext, docTypeName, viewTypeName, docClassInfo, viewClassInfo, flags): will construct document and view objects from the class information.
- Wx::DocTemplate->new(docmgr, descr, filter, dir, ext, docTypeName, viewTypeName, docClassName, viewClassName, flags): will construct document and view objects from perl packages.
- Wx::DocTemplate->new(docmgr, descr, filter, dir, ext, docTypeName, viewTypeName): in this case `Wx::DocTemplate::CreateDocument()` and `Wx::DocTemplate::CreateView()` must be overridden

virtual wxDocTemplate::~wxDocTemplate ( ) [virtual]

Destructor.

21.206.3 Member Function Documentation

virtual wxDocument* wxDocTemplate::CreateDocument (const wxString & *path*, long *flags* = 0) [virtual]

Creates a new instance of the associated document class.

If you have not supplied a wxClassInfo parameter to the template constructor, you will need to override this function to return an appropriate document instance.

This function calls InitDocument() which in turns calls wxDocument::OnCreate().

virtual wxView* wxDocTemplate::CreateView (wxDocument * *doc*, long *flags* = 0) [virtual]

Creates a new instance of the associated view class.

If you have not supplied a wxClassInfo parameter to the template constructor, you will need to override this function to return an appropriate view instance.

If the new view initialization fails, it must call wxDocument::RemoveView() for consistency with the default behaviour of this function.

virtual bool wxDocTemplate::FileMatchesTemplate (const wxString & *path*) [virtual]

This function implements the default (very primitive) format detection which checks if the extension is that of the template.

Parameters

path	The path to be checked against the template.

wxString wxDocTemplate::GetDefaultExtension ( ) const

Returns the default file extension for the document data, as passed to the document template constructor.

wxString wxDocTemplate::GetDescription ( ) const

Returns the text description of this template, as passed to the document template constructor.

wxString wxDocTemplate::GetDirectory ( ) const

Returns the default directory, as passed to the document template constructor.

wxClassInfo* wxDocTemplate::GetDocClassInfo ( ) const

Returns the run-time class information that allows document instances to be constructed dynamically, as passed to the document template constructor.

wxDocManager* wxDocTemplate::GetDocumentManager ( ) const

Returns a pointer to the document manager instance for which this template was created.

virtual wxString wxDocTemplate::GetDocumentName ( ) const `[virtual]`

Returns the document type name, as passed to the document template constructor.

wxString wxDocTemplate::GetFileFilter ( ) const

Returns the file filter, as passed to the document template constructor.

long wxDocTemplate::GetFlags ( ) const

Returns the flags, as passed to the document template constructor.

wxPageSetupDialogData& wxDocTemplate::GetPageSetupDialogData ( )

Returns a reference to the wxPageSetupDialogData associated with the printing operations of this document manager.

const wxPageSetupDialogData& wxDocTemplate::GetPageSetupDialogData ( ) const

Returns a reference to the wxPageSetupDialogData associated with the printing operations of this document manager.

wxClassInfo* wxDocTemplate::GetViewClassInfo ( ) const

Returns the run-time class information that allows view instances to be constructed dynamically, as passed to the document template constructor.

virtual wxString wxDocTemplate::GetViewName ( ) const [virtual]

Returns the view type name, as passed to the document template constructor.

virtual bool wxDocTemplate::InitDocument (wxDocument * *doc,* const wxString & *path,* long *flags* = 0) [virtual]

Initialises the document, calling wxDocument::OnCreate().

This is called from CreateDocument().

If you override this method, notice that you must *delete* the *doc* if its initialization fails for consistency with the default behaviour.

Parameters

doc	The document to initialize.
path	The associated file path.
flags	Flags passed to CreateDocument().

Returns

true if the initialization was successful or false if it failed in which case *doc* should be deleted by this function.

bool wxDocTemplate::IsVisible ( ) const

Returns true if the document template can be shown in user dialogs, false otherwise.

void wxDocTemplate::SetDefaultExtension (const wxString & *ext*)

Sets the default file extension.

void wxDocTemplate::SetDescription (const wxString & *descr*)

Sets the template description.

void wxDocTemplate::SetDirectory (const wxString & *dir*)

Sets the default directory.

void wxDocTemplate::SetDocumentManager (wxDocManager * *manager*)

Sets the pointer to the document manager instance for which this template was created.

Should not be called by the application.

void wxDocTemplate::SetFileFilter (const wxString & *filter*)

Sets the file filter.

void wxDocTemplate::SetFlags (long *flags*)

Sets the internal document template flags (see the constructor description for more details).

21.206.4 Member Data Documentation

wxString wxDocTemplate::m_defaultExt

The default extension for files of this type.

wxString wxDocTemplate::m_description

A short description of this template.

wxString wxDocTemplate::m_directory

The default directory for files of this type.

wxClassInfo* wxDocTemplate::m_docClassInfo

Run-time class information that allows document instances to be constructed dynamically.

wxString wxDocTemplate::m_docTypeName

The named type of the document associated with this template.

wxDocTemplate* wxDocTemplate::m_documentManager

A pointer to the document manager for which this template was created.

wxString wxDocTemplate::m_fileFilter

The file filter (such as "*.txt") to be used in file selector dialogs.

long wxDocTemplate::m_flags

The flags passed to the constructor.

wxClassInfo* wxDocTemplate::m_viewClassInfo

Run-time class information that allows view instances to be constructed dynamically.

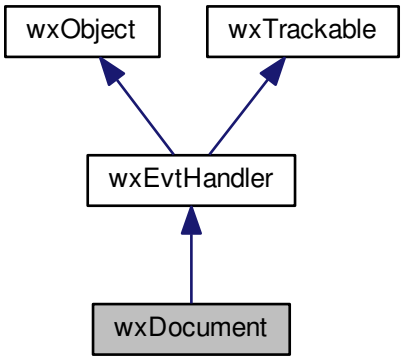
wxString wxDocTemplate::m_viewTypeName

The named type of the view associated with this template.

21.207 wxDocument Class Reference

`#include <wx/docview.h>`

Inheritance diagram for wxDocument:



21.207.1 Detailed Description

The document class can be used to model an application's file-based data.

It is part of the document/view framework supported by wxWidgets, and cooperates with the wxView, wxDocTemplate and wxDocManager classes.

A normal document is the one created without parent document and is associated with a disk file. Since version 2.9.2 wxWidgets also supports a special kind of documents called *child documents* which are virtual in the sense that they do not correspond to a file but rather to a part of their parent document. Because of this, the child documents can't be created directly by user but can only be created by the parent document (usually when it's being created itself). They also can't be independently saved. A child document has its own view with the corresponding window. This view can be closed by user but, importantly, is also automatically closed when its parent document is closed. Thus, child documents may be convenient for creating additional windows which need to be closed when the main document is. The docview sample demonstrates this use of child documents by creating a child document containing the information about the parameters of the image opened in the main document.

Library: wxCore

Category: Document/View Framework

See also

Document/View Framework, wxView, wxDocTemplate, wxDocManager

Public Member Functions

- wxDocument (wxDocument *parent=NULL)

  Constructor.
- virtual ~wxDocument ()

Destructor.

- virtual bool AddView (wxView ∗view)

  If the view is not already in the list of views, adds the view and calls OnChangedViewList().
- bool AlreadySaved () const

  Returns true if the document hasn't been modified since the last time it had been saved.
- void Activate () const

  Activate the first view of the document if any.
- virtual bool Close ()

  Closes the document, by calling OnSaveModified() and then (if this returned true) OnCloseDocument().
- virtual bool DeleteAllViews ()

  Calls wxView::Close() and deletes each view.
- virtual bool DeleteContents ()

  Virtual method called from OnCloseDocument().
- virtual wxCommandProcessor ∗ GetCommandProcessor () const

  Returns a pointer to the command processor associated with this document.
- virtual wxDocManager ∗ GetDocumentManager () const

  Gets a pointer to the associated document manager.
- wxString GetDocumentName () const

  Gets the document type name for this document.
- bool GetDocumentSaved () const

  Return true if this document had been already saved.
- virtual wxDocTemplate ∗ GetDocumentTemplate () const

  Gets a pointer to the template that created the document.
- virtual wxWindow ∗ GetDocumentWindow () const

  Intended to return a suitable window for using as a parent for document-related dialog boxes.
- wxString GetFilename () const

  Gets the filename associated with this document, or "" if none is associated.
- wxView ∗ GetFirstView () const

  A convenience function to get the first view for a document, because in many cases a document will only have a single view.
- wxString GetTitle () const

  Gets the title for this document.
- virtual wxString GetUserReadableName () const

  Return the document name suitable to be shown to the user.
- wxViewVector GetViewsVector () const

  Returns a vector of wxView pointers.
- bool IsChildDocument () const

  Returns true if this document is a child document corresponding to a part of the parent document and not a disk file as usual.
- virtual bool IsModified () const

  Returns true if the document has been modified since the last save, false otherwise.
- virtual void Modify (bool modify)

  Call with true to mark the document as modified since the last save, false otherwise.
- virtual void OnChangedViewList ()

  Called when a view is added to or deleted from this document.
- virtual bool OnCloseDocument ()

  This virtual function is called when the document is being closed.
- virtual bool OnCreate (const wxString &path, long flags)

  Called just after the document object is created to give it a chance to initialize itself.
- virtual wxCommandProcessor ∗ OnCreateCommandProcessor ()

  Override this function if you want a different (or no) command processor to be created when the document is created.

- virtual bool OnNewDocument ()

  The default implementation calls OnSaveModified() and DeleteContents(), makes a default title for the document, and notifies the views that the filename (in fact, the title) has changed.
- virtual bool OnOpenDocument (const wxString &filename)

  Constructs an input file stream for the given filename (which must not be empty), and calls LoadObject().
- virtual bool OnSaveDocument (const wxString &filename)

  Constructs an output file stream for the given filename (which must not be empty), and calls SaveObject().
- virtual bool OnSaveModified ()

  If the document has been modified, prompts the user to ask if the changes should be saved.
- virtual bool RemoveView (wxView ∗view)

  Removes the view from the document's list of views, and calls OnChangedViewList().
- virtual bool Save ()

  Saves the document by calling OnSaveDocument() if there is an associated filename, or SaveAs() if there is no filename.
- virtual bool SaveAs ()

  Prompts the user for a file to save to, and then calls OnSaveDocument().
- virtual bool Revert ()

  Discard changes and load last saved version.
- virtual void SetCommandProcessor (wxCommandProcessor ∗processor)

  Sets the command processor to be used for this document.
- void SetDocumentName (const wxString &name)

  Sets the document type name for this document.
- virtual void SetDocumentTemplate (wxDocTemplate ∗templ)

  Sets the pointer to the template that created the document.
- void SetDocumentSaved (bool saved=true)

  Sets if this document has been already saved or not.
- void SetFilename (const wxString &filename, bool notifyViews=false)

  Sets the filename for this document.
- virtual void OnChangeFilename (bool notifyViews)

  If notifyViews is true, wxView::OnChangeFilename() is called for all views.
- void SetTitle (const wxString &title)

  Sets the title for this document.
- virtual void UpdateAllViews (wxView ∗sender=NULL, wxObject ∗hint=NULL)

  Updates all views.

- wxList & GetViews ()

  Returns the list whose elements are the views on the document.
- const wxList & GetViews () const

  Returns the list whose elements are the views on the document.

- virtual istream & LoadObject (istream &stream)

  Override this function and call it from your own LoadObject() before streaming your own data.
- virtual wxInputStream & LoadObject (wxInputStream &stream)

  Override this function and call it from your own LoadObject() before streaming your own data.

- virtual ostream & SaveObject (ostream &stream)

  Override this function and call it from your own SaveObject() before streaming your own data.
- virtual wxOutputStream & SaveObject (wxOutputStream &stream)

  Override this function and call it from your own SaveObject() before streaming your own data.

Protected Member Functions

- virtual bool DoSaveDocument (const wxString &file)

  This method is called by OnSaveDocument() to really save the document contents to the specified file.
- virtual bool DoOpenDocument (const wxString &file)

  This method is called by OnOpenDocument() to really load the document contents from the specified file.

Protected Attributes

- wxCommandProcessor * m_commandProcessor

  A pointer to the command processor associated with this document.
- wxString m_documentFile

  Filename associated with this document ("" if none).
- bool m_documentModified

  true if the document has been modified, false otherwise.
- wxDocTemplate * m_documentTemplate

  A pointer to the template from which this document was created.
- wxString m_documentTitle

  Document title.
- wxString m_documentTypeName

  The document type name given to the wxDocTemplate constructor, copied to this variable when the document is created.
- wxList m_documentViews

  List of wxView instances associated with this document.

Additional Inherited Members

21.207.2 Constructor & Destructor Documentation

wxDocument::wxDocument (wxDocument * *parent* = NULL)

Constructor.

Define your own default constructor to initialize application-specific data.

Parameters

parent	Specifying a non-NULL parent document here makes this document a special *child document*, see their description in the class documentation. Notice that this parameter exists but is ignored in wxWidgets versions prior to 2.9.1.

virtual wxDocument::~wxDocument ( ) [virtual]

Destructor.

Removes itself from the document manager.

21.207.3 Member Function Documentation

void wxDocument::Activate ( ) const

Activate the first view of the document if any.

This function simply calls the Raise() method of the frame of the first view. You may need to override the Raise() method to get the desired effect if you are not using a standard wxFrame for your view. For instance, if your document is inside its own notebook tab you could implement Raise() like this:

```
void MyNotebookPage::Raise()
{
    wxNotebook* notebook = wxStaticCast(GetParent(),
      wxNotebook);
    notebook->SetSelection(notebook->FindPage(this));
}
```

See also

GetFirstView()

Since

2.9.5

virtual bool wxDocument::AddView (wxView * *view*) [virtual]

If the view is not already in the list of views, adds the view and calls OnChangedViewList().

bool wxDocument::AlreadySaved ( ) const

Returns true if the document hasn't been modified since the last time it had been saved.

Notice that this function returns false if the document had been never saved at all, so it may be also used to test whether it makes sense to save the document: if it returns true, there is nothing to save but if false is returned, it can be saved, even if it might be not modified (this can be used to create an empty document file by the user).

See also

IsModified(), GetDocumentSaved()

Since

2.9.0

virtual bool wxDocument::Close ( ) [virtual]

Closes the document, by calling OnSaveModified() and then (if this returned true) OnCloseDocument().

This does not normally delete the document object, use DeleteAllViews() to do this implicitly.

virtual bool wxDocument::DeleteAllViews ( ) [virtual]

Calls wxView::Close() and deletes each view.

Deleting the final view will implicitly delete the document itself, because the wxView destructor calls RemoveView(). This in turns calls OnChangedViewList(), whose default implemention is to save and delete the document if no views exist.

virtual bool wxDocument::DeleteContents ( ) [virtual]

Virtual method called from OnCloseDocument().

This method may be overridden to perform any additional cleanup which might be needed when the document is closed.

The return value of this method is currently ignored.

The default version does nothing and simply returns true.

virtual bool wxDocument::DoOpenDocument (const wxString & *file*) [protected], [virtual]

This method is called by OnOpenDocument() to really load the document contents from the specified file.

Base class version creates a file-based stream and calls LoadObject(). Override this if you need to do something else or prefer not to use LoadObject() at all.

virtual bool wxDocument::DoSaveDocument (const wxString & *file*) [protected], [virtual]

This method is called by OnSaveDocument() to really save the document contents to the specified file.

Base class version creates a file-based stream and calls SaveObject(). Override this if you need to do something else or prefer not to use SaveObject() at all.

virtual wxCommandProcessor* wxDocument::GetCommandProcessor ( ) const [virtual]

Returns a pointer to the command processor associated with this document.

See also

wxCommandProcessor

virtual wxDocManager* wxDocument::GetDocumentManager ( ) const [virtual]

Gets a pointer to the associated document manager.

wxString wxDocument::GetDocumentName ( ) const

Gets the document type name for this document.

See the comment for m_documentTypeName.

bool wxDocument::GetDocumentSaved ( ) const

Return true if this document had been already saved.

See also

IsModified()

virtual wxDocTemplate* wxDocument::GetDocumentTemplate ( ) const [virtual]

Gets a pointer to the template that created the document.

virtual wxWindow* wxDocument::GetDocumentWindow ( ) const `[virtual]`

Intended to return a suitable window for using as a parent for document-related dialog boxes.

By default, uses the frame associated with the first view.

wxString wxDocument::GetFilename ( ) const

Gets the filename associated with this document, or "" if none is associated.

wxView* wxDocument::GetFirstView ( ) const

A convenience function to get the first view for a document, because in many cases a document will only have a single view.

See also

GetViews()

wxString wxDocument::GetTitle ( ) const

Gets the title for this document.

The document title is used for an associated frame (if any), and is usually constructed by the framework from the filename.

virtual wxString wxDocument::GetUserReadableName ( ) const `[virtual]`

Return the document name suitable to be shown to the user.

The default implementation uses the document title, if any, of the name part of the document filename if it was set or, otherwise, the string **unnamed**.

wxList& wxDocument::GetViews ( )

Returns the list whose elements are the views on the document.

See also

GetFirstView()

const wxList& wxDocument::GetViews ( ) const

Returns the list whose elements are the views on the document.

See also

GetFirstView()

wxViewVector wxDocument::GetViewsVector ( ) const

Returns a vector of wxView pointers.

Since

2.9.5

bool wxDocument::IsChildDocument ( ) const

Returns true if this document is a child document corresponding to a part of the parent document and not a disk file as usual.

This method can be used to check whether file-related operations make sense for this document as they only apply to top-level documents and not child ones.

Since

2.9.2

virtual bool wxDocument::IsModified ( ) const [virtual]

Returns true if the document has been modified since the last save, false otherwise.

You may need to override this if your document view maintains its own record of being modified.

See also

Modify()

virtual istream& wxDocument::LoadObject (istream & *stream*) [virtual]

Override this function and call it from your own LoadObject() before streaming your own data.

LoadObject() is called by the framework automatically when the document contents need to be loaded.

Note

This version of LoadObject() may not exist depending on how wxWidgets was configured.

virtual wxInputStream& wxDocument::LoadObject (wxInputStream & *stream*) [virtual]

Override this function and call it from your own LoadObject() before streaming your own data.

LoadObject() is called by the framework automatically when the document contents need to be loaded.

Note

This version of LoadObject() may not exist depending on how wxWidgets was configured.

virtual void wxDocument::Modify (bool *modify*) [virtual]

Call with true to mark the document as modified since the last save, false otherwise.

You may need to override this if your document view maintains its own record of being modified.

See also

IsModified()

virtual void wxDocument::OnChangedViewList ( ) [virtual]

Called when a view is added to or deleted from this document.

The default implementation saves and deletes the document if no views exist (the last one has just been removed).

virtual void wxDocument::OnChangeFilename (bool *notifyViews*) `[virtual]`

If *notifyViews* is true, wxView::OnChangeFilename() is called for all views.

Since

2.9.0

virtual bool wxDocument::OnCloseDocument ( ) `[virtual]`

This virtual function is called when the document is being closed.

The default implementation calls DeleteContents() (which may be overridden to perform additional cleanup) and sets the modified flag to false. You can override it to supply additional behaviour when the document is closed with Close().

Notice that previous wxWidgets versions used to call this function also from OnNewDocument(), rather counter-intuitively. This is no longer the case since wxWidgets 2.9.0.

virtual bool wxDocument::OnCreate (const wxString & *path,* long *flags*) `[virtual]`

Called just after the document object is created to give it a chance to initialize itself.

The default implementation uses the template associated with the document to create an initial view.

For compatibility reasons, this method may either delete the document itself if its initialization fails or not do it in which case it is deleted by caller. It is recommended to delete the document explicitly in this function if it can't be initialized.

Parameters

path	The associated file path.
flags	Flags passed to CreateDocument().

Returns

true if the initialization was successful or false if it failed.

virtual wxCommandProcessor* wxDocument::OnCreateCommandProcessor ( ) `[virtual]`

Override this function if you want a different (or no) command processor to be created when the document is created.

By default, it returns an instance of wxCommandProcessor.

See also

wxCommandProcessor

virtual bool wxDocument::OnNewDocument ( ) `[virtual]`

The default implementation calls OnSaveModified() and DeleteContents(), makes a default title for the document, and notifies the views that the filename (in fact, the title) has changed.

virtual bool wxDocument::OnOpenDocument (const wxString & *filename*) `[virtual]`

Constructs an input file stream for the given filename (which must not be empty), and calls LoadObject().

If LoadObject() returns true, the document is set to unmodified; otherwise, an error message box is displayed. The document's views are notified that the filename has changed, to give windows an opportunity to update their titles. All of the document's views are then updated.

virtual bool wxDocument::OnSaveDocument (const wxString & *filename*) `[virtual]`

Constructs an output file stream for the given filename (which must not be empty), and calls SaveObject().

If SaveObject() returns true, the document is set to unmodified; otherwise, an error message box is displayed.

virtual bool wxDocument::OnSaveModified ( ) `[virtual]`

If the document has been modified, prompts the user to ask if the changes should be saved.

If the user replies Yes, the Save() function is called. If No, the document is marked as unmodified and the function succeeds. If Cancel, the function fails.

virtual bool wxDocument::RemoveView (wxView * *view*) `[virtual]`

Removes the view from the document's list of views, and calls OnChangedViewList().

virtual bool wxDocument::Revert ( ) `[virtual]`

Discard changes and load last saved version.

Prompts the user first, and then calls DoOpenDocument() to reload the current file.

virtual bool wxDocument::Save ( ) `[virtual]`

Saves the document by calling OnSaveDocument() if there is an associated filename, or SaveAs() if there is no filename.

virtual bool wxDocument::SaveAs ( ) `[virtual]`

Prompts the user for a file to save to, and then calls OnSaveDocument().

virtual ostream& wxDocument::SaveObject (ostream & *stream*) `[virtual]`

Override this function and call it from your own SaveObject() before streaming your own data.

SaveObject() is called by the framework automatically when the document contents need to be saved.

Note

This version of SaveObject() may not exist depending on how wxWidgets was configured.

virtual wxOutputStream& wxDocument::SaveObject (wxOutputStream & *stream*) `[virtual]`

Override this function and call it from your own SaveObject() before streaming your own data.

SaveObject() is called by the framework automatically when the document contents need to be saved.

Note

This version of SaveObject() may not exist depending on how wxWidgets was configured.

virtual void wxDocument::SetCommandProcessor (wxCommandProcessor * *processor*) [virtual]

Sets the command processor to be used for this document.

The document will then be responsible for its deletion. Normally you should not call this; override OnCreate↩ CommandProcessor() instead.

See also

wxCommandProcessor

void wxDocument::SetDocumentName (const wxString & *name*)

Sets the document type name for this document.

See the comment for m_documentTypeName.

void wxDocument::SetDocumentSaved (bool *saved* = true)

Sets if this document has been already saved or not.

Normally there is no need to call this function as the document-view framework does it itself as the documents are loaded from and saved to the files. However it may be useful in some particular cases, for example it may be called with false argument to prevent the user from saving the just opened document into the same file if this shouldn't be done for some reason (e.g. file format version changes and a new extension should be used for saving).

See also

GetDocumentSaved(), AlreadySaved()

virtual void wxDocument::SetDocumentTemplate (wxDocTemplate * *templ*) [virtual]

Sets the pointer to the template that created the document.

Should only be called by the framework.

void wxDocument::SetFilename (const wxString & *filename,* bool *notifyViews* = false)

Sets the filename for this document.

Usually called by the framework.

Calls OnChangeFilename() which in turn calls wxView::OnChangeFilename() for all views if *notifyViews* is true.

void wxDocument::SetTitle (const wxString & *title*)

Sets the title for this document.

The document title is used for an associated frame (if any), and is usually constructed by the framework from the filename.

virtual void wxDocument::UpdateAllViews (wxView * *sender* = NULL, wxObject * *hint* = NULL) [virtual]

Updates all views.

If *sender* is non-NULL, does not update this view. *hint* represents optional information to allow a view to optimize its update.

21.207.4 Member Data Documentation

wxCommandProcessor* **wxDocument::m_commandProcessor** [protected]

A pointer to the command processor associated with this document.

wxString wxDocument::m_documentFile [protected]

Filename associated with this document ("" if none).

bool wxDocument::m_documentModified [protected]

true if the document has been modified, false otherwise.

wxDocTemplate* **wxDocument::m_documentTemplate** [protected]

A pointer to the template from which this document was created.

wxString wxDocument::m_documentTitle [protected]

Document title.

The document title is used for an associated frame (if any), and is usually constructed by the framework from the filename.

wxString wxDocument::m_documentTypeName [protected]

The document type name given to the wxDocTemplate constructor, copied to this variable when the document is created.

If several document templates are created that use the same document type, this variable is used in wxDocManager::CreateView() to collate a list of alternative view types that can be used on this kind of document. Do not change the value of this variable.

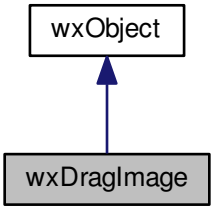
wxList wxDocument::m_documentViews [protected]

List of wxView instances associated with this document.

21.208 wxDragImage Class Reference

`#include <wx/dragimag.h>`

Inheritance diagram for wxDragImage:



21.208.1 Detailed Description

This class is used when you wish to drag an object on the screen, and a simple cursor is not enough.

On Windows, the Win32 API is used to achieve smooth dragging. On other platforms, wxGenericDragImage is used. Applications may also prefer to use wxGenericDragImage on Windows, too.

To use this class, when you wish to start dragging an image, create a wxDragImage object and store it somewhere you can access it as the drag progresses. Call BeginDrag() to start, and EndDrag() to stop the drag. To move the image, initially call Show() and then Move(). If you wish to update the screen contents during the drag (for example, highlight an item as in the dragimag sample), first call Hide(), update the screen, call Move(), and then call Show().

You can drag within one window, or you can use full-screen dragging either across the whole screen, or just restricted to one area of the screen to save resources. If you want the user to drag between two windows, then you will need to use full-screen dragging.

If you wish to draw the image yourself, use wxGenericDragImage and override DoDrawImage() and GetImage↩ Rect().

Library: wxCore

Category: Clipboard and Drag & Drop

See also

Drag Image Sample

Public Member Functions

- wxDragImage ()

  Default constructor.
- wxDragImage (const wxBitmap &image, const wxCursor &cursor=wxNullCursor)

  Constructs a drag image from a bitmap and optional cursor.
- wxDragImage (const wxIcon &image, const wxCursor &cursor=wxNullCursor)

  Constructs a drag image from an icon and optional cursor.
- wxDragImage (const wxString &text, const wxCursor &cursor=wxNullCursor)

  Constructs a drag image from a text string and optional cursor.
- wxDragImage (const wxTreeCtrl &treeCtrl, wxTreeItemId &id)

Constructs a drag image from the text in the given tree control item, and optional cursor.

- wxDragImage (const wxListCtrl &listCtrl, long id)

  Constructs a drag image from the text in the given list control item, and optional cursor.
- bool BeginDrag (const wxPoint &hotspot, wxWindow *window, bool fullScreen=false, wxRect *rect=NULL)

  Start dragging the image, in a window or full screen.
- bool BeginDrag (const wxPoint &hotspot, wxWindow *window, wxWindow *boundingWindow)

  Start dragging the image, using the first window to capture the mouse and the second to specify the bounding area.
- virtual bool DoDrawImage (wxDC &dc, const wxPoint &pos) const

  Draws the image on the device context with top-left corner at the given position.
- bool EndDrag ()

  Call this when the drag has finished.
- virtual wxRect GetImageRect (const wxPoint &pos) const

  Returns the rectangle enclosing the image, assuming that the image is drawn with its top-left corner at the given point.
- bool Hide ()

  Hides the image.
- bool Move (const wxPoint &pt)

  Call this to move the image to a new position.
- bool Show ()

  Shows the image.
- virtual bool UpdateBackingFromWindow (wxDC &windowDC, wxMemoryDC &destDC, const wxRect &sourceRect, const wxRect &destRect) const

  Override this if you wish to draw the window contents to the backing bitmap yourself.

Additional Inherited Members

21.208.2 Constructor & Destructor Documentation

wxDragImage::wxDragImage ( )

Default constructor.

wxDragImage::wxDragImage (const wxBitmap & *image*, const wxCursor & *cursor* = wxNullCursor)

Constructs a drag image from a bitmap and optional cursor.

Parameters

image	Bitmap to be used as the drag image. The bitmap can have a mask.
cursor	Optional cursor to combine with the image.

wxDragImage::wxDragImage (const wxIcon & *image*, const wxCursor & *cursor* = wxNullCursor)

Constructs a drag image from an icon and optional cursor.

Parameters

image	Icon to be used as the drag image.
cursor	Optional cursor to combine with the image.

wxDragImage::wxDragImage (const wxString & *text*, const wxCursor & *cursor* = wxNullCursor)

Constructs a drag image from a text string and optional cursor.

Parameters

text	Text used to construct a drag image.
cursor	Optional cursor to combine with the image.

wxDragImage::wxDragImage (const wxTreeCtrl & *treeCtrl*, wxTreeItemId & *id*)

Constructs a drag image from the text in the given tree control item, and optional cursor.

Parameters

treeCtrl	Tree control for constructing a tree drag image.
id	Tree control item id.

wxDragImage::wxDragImage (const wxListCtrl & *listCtrl*, long *id*)

Constructs a drag image from the text in the given list control item, and optional cursor.

Parameters

listCtrl	List control for constructing a list drag image.
id	List control item id.

21.208.3 Member Function Documentation

bool wxDragImage::BeginDrag (const wxPoint & *hotspot*, wxWindow * *window*, bool *fullScreen* = `false`, wxRect * *rect* = `NULL`)

Start dragging the image, in a window or full screen.

You need to then call Show() and Move() to show the image on the screen. Call EndDrag() when the drag has finished.

Note that this call automatically calls CaptureMouse().

Parameters

hotspot	The location of the drag position relative to the upper-left corner of the image.
window	The window that captures the mouse, and within which the dragging is limited unless fullScreen is true.
fullScreen	If true, specifies that the drag will be visible over the full screen, or over as much of the screen as is specified by rect. Note that the mouse will still be captured in window.
rect	If non-NULL, specifies the rectangle (in screen coordinates) that bounds the dragging operation. Specifying this can make the operation more efficient by cutting down on the area under consideration, and it can also make a visual difference since the drag is clipped to this area.

bool wxDragImage::BeginDrag (const wxPoint & *hotspot*, wxWindow * *window*, wxWindow * *boundingWindow*)

Start dragging the image, using the first window to capture the mouse and the second to specify the bounding area.

This form is equivalent to using the first form, but more convenient than working out the bounding rectangle explicitly.

You need to then call Show() and Move() to show the image on the screen. Call EndDrag() when the drag has finished.

Note that this call automatically calls CaptureMouse().

Parameters

hotspot	The location of the drag position relative to the upper-left corner of the image.
window	The window that captures the mouse, and within which the dragging is limited.
boundingWindow	Specifies the area within which the drag occurs.

virtual bool wxDragImage::DoDrawImage (wxDC & *dc,* const wxPoint & *pos*) const [virtual]

Draws the image on the device context with top-left corner at the given position.

This function is only available with wxGenericDragImage, to allow applications to draw their own image instead of using an actual bitmap. If you override this function, you must also override GetImageRect().

bool wxDragImage::EndDrag ( )

Call this when the drag has finished.

Note

This function automatically releases mouse capture.

virtual wxRect wxDragImage::GetImageRect (const wxPoint & *pos*) const [virtual]

Returns the rectangle enclosing the image, assuming that the image is drawn with its top-left corner at the given point.

This function is available in wxGenericDragImage only, and may be overridden (together with DoDrawImage()) to provide a virtual drawing capability.

bool wxDragImage::Hide ( )

Hides the image.

You may wish to call this before updating the window contents (perhaps highlighting an item). Then call Move() and Show().

bool wxDragImage::Move (const wxPoint & *pt*)

Call this to move the image to a new position.

The image will only be shown if Show() has been called previously (for example at the start of the drag).

Parameters

pt	The position in client coordinates (relative to the window specified in BeginDrag()).

You can move the image either when the image is hidden or shown, but in general dragging will be smoother if you move the image when it is shown.

bool wxDragImage::Show ( )

Shows the image.

Call this at least once when dragging.

virtual bool wxDragImage::UpdateBackingFromWindow (wxDC & *windowDC,* wxMemoryDC & *destDC,* const wxRect & *sourceRect,* const wxRect & *destRect*) const `[virtual]`

Override this if you wish to draw the window contents to the backing bitmap yourself.

This can be desirable if you wish to avoid flicker by not having to redraw the updated window itself just before dragging, which can cause a flicker just as the drag starts. Instead, paint the drag image's backing bitmap to show the appropriate graphic *minus* the objects to be dragged, and leave the window itself to be updated by the drag image. This can provide eerily smooth, flicker-free drag behaviour.

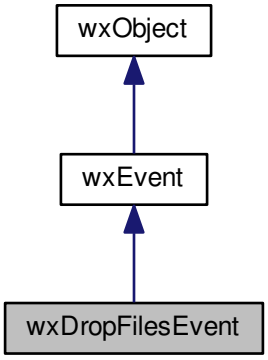
The default implementation copies the window contents to the backing bitmap. A new implementation will normally copy information from another source, such as from its own backing bitmap if it has one, or directly from internal data structures.

This function is available in wxGenericDragImage only.

21.209 wxDropFilesEvent Class Reference

`#include <wx/event.h>`

Inheritance diagram for wxDropFilesEvent:



21.209.1 Detailed Description

This class is used for drop files events, that is, when files have been dropped onto the window.

This functionality is currently only available under Windows.

The window must have previously been enabled for dropping by calling wxWindow::DragAcceptFiles().

Important note: this is a separate implementation to the more general drag and drop implementation documented in the Drag and Drop Overview. It uses the older, Windows message-based approach of dropping files.

Events using this class

The following event handler macros redirect the events to member function handlers '**func**' with prototypes like: void handlerFuncName(wxDropFilesEvent& event)

Event macros:

- EVT_DROP_FILES(func): Process a `wxEVT_DROP_FILES` event.

Availability: only available for the wxMSW port.

Library: wxCore

Category: Events

Events and Event Handling

Public Member Functions

- wxDropFilesEvent (wxEventType id=0, int noFiles=0, wxString *files=NULL)

  Constructor.
- wxString * GetFiles () const

  Returns an array of filenames.
- int GetNumberOfFiles () const

  Returns the number of files dropped.
- wxPoint GetPosition () const

  Returns the position at which the files were dropped.

Additional Inherited Members

21.209.2 Constructor & Destructor Documentation

wxDropFilesEvent::wxDropFilesEvent (wxEventType *id* = `0`, int *noFiles* = `0`, wxString * *files* = `NULL`)

Constructor.

21.209.3 Member Function Documentation

wxString* wxDropFilesEvent::GetFiles ( ) const

Returns an array of filenames.

int wxDropFilesEvent::GetNumberOfFiles ( ) const

Returns the number of files dropped.

wxPoint wxDropFilesEvent::GetPosition ( ) const

Returns the position at which the files were dropped.

Returns an array of filenames.

21.210 wxDropSource Class Reference

```
#include <wx/dnd.h>
```

21.210.1 Detailed Description

This class represents a source for a drag and drop operation.

Library: wxCore

Category: Clipboard and Drag & Drop

Drag and Drop Overview, wxDataObject Overview, wxDropTarget, wxTextDropTarget, wxFileDropTarget

Public Member Functions

- wxDropSource (wxWindow *win=NULL, const wxCursor &iconCopy=wxNullCursor, const wxCursor &iconMove=wxNullCursor, const wxCursor &iconNone=wxNullCursor)

  This constructor requires that you must call SetData() later.
- wxDropSource (wxDataObject &data, wxWindow *win=NULL, const wxCursor &iconCopy=wxNullCursor, const wxCursor &iconMove=wxNullCursor, const wxCursor &iconNone=wxNullCursor)

  The constructor taking a wxDataObject.
- wxDropSource (wxWindow *win=NULL, const wxIcon &iconCopy=wxNullIcon, const wxIcon &iconMove=wxNullIcon, const wxIcon &iconNone=wxNullIcon)

  This constructor requires that you must call SetData() later.
- wxDropSource (wxDataObject &data, wxWindow *win=NULL, const wxIcon &iconCopy=wxNullIcon, const wxIcon &iconMove=wxNullIcon, const wxIcon &iconNone=wxNullIcon)

  The constructor taking a wxDataObject.
- virtual wxDragResult DoDragDrop (int flags=wxDrag_CopyOnly)

  Starts the drag-and-drop operation which will terminate when the user releases the mouse.
- wxDataObject * GetDataObject ()

  Returns the wxDataObject object that has been assigned previously.
- virtual bool GiveFeedback (wxDragResult effect)

  You may give some custom UI feedback during the drag and drop operation by overriding this function.
- void SetCursor (wxDragResult res, const wxCursor &cursor)

  Set the icon to use for a certain drag result.
- void SetIcon (wxDragResult res, const wxIcon &icon)

  Set the icon to use for a certain drag result.
- void SetData (wxDataObject &data)

  Sets the data wxDataObject associated with the drop source.

21.210.2 Constructor & Destructor Documentation

wxDropSource::wxDropSource (wxWindow * *win* = NULL, const wxCursor & *iconCopy* = wxNullCursor, const wxCursor & *iconMove* = wxNullCursor, const wxCursor & *iconNone* = wxNullCursor)

This constructor requires that you must call SetData() later.

Note that the type of *iconCopy* and subsequent parameters differs between different ports: these are cursors under Windows and OS X but icons for GTK. You should use the macro wxDROP_ICON() in portable programs instead of directly using either of these types.

Availability: only available for the wxMSW, wxOSX ports.

Parameters

win	The window which initiates the drag and drop operation.
iconCopy	The icon or cursor used for feedback for copy operation.
iconMove	The icon or cursor used for feedback for move operation.
iconNone	The icon or cursor used for feedback when operation can't be done.

wxDropSource::wxDropSource (wxDataObject & *data*, wxWindow * *win* = NULL, const wxCursor & *iconCopy* = wxNullCursor, const wxCursor & *iconMove* = wxNullCursor, const wxCursor & *iconNone* = wxNullCursor)

The constructor taking a wxDataObject.

Note that the type of *iconCopy* and subsequent parameters differs between different ports: these are cursors under Windows and OS X but icons for GTK. You should use the macro wxDROP_ICON() in portable programs instead of directly using either of these types.

Availability: only available for the wxMSW, wxOSX ports.

Parameters

data	The data associated with the drop source.
win	The window which initiates the drag and drop operation.
iconCopy	The icon or cursor used for feedback for copy operation.
iconMove	The icon or cursor used for feedback for move operation.
iconNone	The icon or cursor used for feedback when operation can't be done.

wxDropSource::wxDropSource (wxWindow * *win* = NULL, const wxIcon & *iconCopy* = wxNullIcon, const wxIcon & *iconMove* = wxNullIcon, const wxIcon & *iconNone* = wxNullIcon)

This constructor requires that you must call SetData() later.

This is the wxGTK-specific version of the constructor taking wxIcon instead of wxCursor as the other ports.

Availability: only available for the wxGTK port.

Parameters

win	The window which initiates the drag and drop operation.
iconCopy	The icon or cursor used for feedback for copy operation.
iconMove	The icon or cursor used for feedback for move operation.
iconNone	The icon or cursor used for feedback when operation can't be done.

wxDropSource::wxDropSource (wxDataObject & *data*, wxWindow * *win* = NULL, const wxIcon & *iconCopy* = wxNullIcon, const wxIcon & *iconMove* = wxNullIcon, const wxIcon & *iconNone* = wxNullIcon)

The constructor taking a wxDataObject.

This is the wxGTK-specific version of the constructor taking wxIcon instead of wxCursor as the other ports.

Availability: only available for the wxGTK port.

Parameters

data	The data associated with the drop source.
win	The window which initiates the drag and drop operation.

iconCopy	The icon or cursor used for feedback for copy operation.
iconMove	The icon or cursor used for feedback for move operation.
iconNone	The icon or cursor used for feedback when operation can't be done.

21.210.3 Member Function Documentation

virtual wxDragResult wxDropSource::DoDragDrop (int *flags* = wxDrag_CopyOnly) [virtual]

Starts the drag-and-drop operation which will terminate when the user releases the mouse.

Call this in response to a mouse button press, for example.

Parameters

flags	If wxDrag_AllowMove is included in the flags, data may be moved and not only copied as is the case for the default wxDrag_CopyOnly. If wxDrag_DefaultMove is specified (which includes the previous flag), moving is not only possible but becomes the default operation.

Returns

The operation requested by the user, may be wxDragCopy, wxDragMove, wxDragLink, wxDragCancel or wxDragNone if an error occurred.

wxDataObject* wxDropSource::GetDataObject ( )

Returns the wxDataObject object that has been assigned previously.

virtual bool wxDropSource::GiveFeedback (wxDragResult *effect*) [virtual]

You may give some custom UI feedback during the drag and drop operation by overriding this function.

It is called on each mouse move, so your implementation must not be too slow.

Parameters

effect	The effect to implement. One of wxDragCopy, wxDragMove, wxDragLink and wxDragNone.

Returns

false if you want default feedback, or true if you implement your own feedback. The return value is ignored under GTK.

void wxDropSource::SetCursor (wxDragResult *res*, const wxCursor & *cursor*)

Set the icon to use for a certain drag result.

Parameters

res	The drag result to set the icon for.
cursor	The icon to show when this drag result occurs.

Availability: only available for the wxMSW, wxOSX ports.

void wxDropSource::SetData (wxDataObject & *data*)

Sets the data wxDataObject associated with the drop source.

This will not delete any previously associated data.

void wxDropSource::SetIcon (wxDragResult *res,* const wxIcon & *icon*)

Set the icon to use for a certain drag result.

Parameters

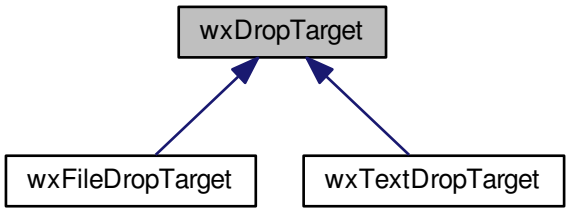
res	The drag result to set the icon for.
icon	The icon to show when this drag result occurs.

Availability: only available for the wxGTK port.

21.211 wxDropTarget Class Reference

`#include <wx/dnd.h>`

Inheritance diagram for wxDropTarget:



21.211.1 Detailed Description

This class represents a target for a drag and drop operation.

A wxDataObject can be associated with it and by default, this object will be filled with the data from the drag source, if the data formats supported by the data object match the drag source data format.

There are various virtual handler functions defined in this class which may be overridden to give visual feedback or react in a more fine-tuned way, e.g. by not accepting data on the whole window area, but only a small portion of it. The normal sequence of calls is OnEnter(), OnDragOver() possibly many times, OnDrop() and finally OnData().

Library: wxCore

Category: Clipboard and Drag & Drop

See also

Drag and Drop Overview, wxDataObject Overview, wxDropSource, wxTextDropTarget, wxFileDropTarget, wxDataFormat, wxDataObject

Public Member Functions

- wxDropTarget (wxDataObject *data=NULL)

  Constructor.

- virtual ~wxDropTarget ()

  Destructor.
- virtual bool GetData ()

  This method may only be called from within OnData().
- virtual wxDragResult OnData (wxCoord x, wxCoord y, wxDragResult defResult)=0

  Called after OnDrop() returns true.
- virtual wxDragResult OnDragOver (wxCoord x, wxCoord y, wxDragResult defResult)

  Called when the mouse is being dragged over the drop target.
- virtual bool OnDrop (wxCoord x, wxCoord y)

  Called when the user drops a data object on the target.
- virtual wxDragResult OnEnter (wxCoord x, wxCoord y, wxDragResult defResult)

  Called when the mouse enters the drop target.
- virtual void OnLeave ()

  Called when the mouse leaves the drop target.
- wxDataObject * GetDataObject () const

  Returns the data wxDataObject associated with the drop target.
- void SetDataObject (wxDataObject *data)

  Sets the data wxDataObject associated with the drop target and deletes any previously associated data object.
- void SetDefaultAction (wxDragResult action)

  Sets the default action for drag and drop.
- wxDragResult GetDefaultAction ()

  Returns default action for drag and drop or wxDragNone if this not specified.

21.211.2 Constructor & Destructor Documentation

wxDropTarget::wxDropTarget (wxDataObject * *data* = NULL)

Constructor.

data is the data to be associated with the drop target.

virtual wxDropTarget::~wxDropTarget ( ) [virtual]

Destructor.

Deletes the associated data object, if any.

21.211.3 Member Function Documentation

virtual bool wxDropTarget::GetData ( ) [virtual]

This method may only be called from within OnData().

By default, this method copies the data from the drop source to the wxDataObject associated with this drop target, calling its wxDataObject::SetData() method.

wxDataObject* wxDropTarget::GetDataObject ( ) const

Returns the data wxDataObject associated with the drop target.

wxDragResult wxDropTarget::GetDefaultAction ( )

Returns default action for drag and drop or wxDragNone if this not specified.

virtual wxDragResult wxDropTarget::OnData (wxCoord *x*, wxCoord *y*, wxDragResult *defResult*) `[pure virtual]`

Called after OnDrop() returns true.

By default this will usually GetData() and will return the suggested default value *defResult*.

virtual wxDragResult wxDropTarget::OnDragOver (wxCoord *x*, wxCoord *y*, wxDragResult *defResult*) `[virtual]`

Called when the mouse is being dragged over the drop target.

By default, this calls functions return the suggested return value *defResult*.

Parameters

x	The x coordinate of the mouse.
y	The y coordinate of the mouse.
defResult	Suggested value for return value. Determined by SHIFT or CONTROL key states.

Returns

The desired operation or wxDragNone. This is used for optical feedback from the side of the drop source, typically in form of changing the icon.

virtual bool wxDropTarget::OnDrop (wxCoord *x*, wxCoord *y*) `[virtual]`

Called when the user drops a data object on the target.

Return false to veto the operation.

Parameters

x	The x coordinate of the mouse.
y	The y coordinate of the mouse.

Returns

true to accept the data, or false to veto the operation.

Reimplemented in wxFileDropTarget, and wxTextDropTarget.

virtual wxDragResult wxDropTarget::OnEnter (wxCoord *x*, wxCoord *y*, wxDragResult *defResult*) `[virtual]`

Called when the mouse enters the drop target.

By default, this calls OnDragOver().

Parameters

x	The x coordinate of the mouse.
y	The y coordinate of the mouse.
defResult	Suggested default for return value. Determined by SHIFT or CONTROL key states.

Returns

The desired operation or wxDragNone. This is used for optical feedback from the side of the drop source, typically in form of changing the icon.

virtual void wxDropTarget::OnLeave ( ) [virtual]

Called when the mouse leaves the drop target.

void wxDropTarget::SetDataObject (wxDataObject * *data*)

Sets the data wxDataObject associated with the drop target and deletes any previously associated data object.

void wxDropTarget::SetDefaultAction (wxDragResult *action*)

Sets the default action for drag and drop.

Use wxDragMove or wxDragCopy to set default action to move or copy and use wxDragNone (default) to set default action specified by initialization of draging (see wxDropSource::DoDragDrop())

21.212 wxDynamicLibrary Class Reference

```
#include <wx/dynlib.h>
```

21.212.1 Detailed Description

wxDynamicLibrary is a class representing dynamically loadable library (Windows DLL, shared library under Unix etc).

Just create an object of this class to load a library and don't worry about unloading it – it will be done in the objects destructor automatically.

The following flags can be used with wxDynamicLibrary() or Load():

Styles

This class supports the following styles:

- wxDL_LAZY: Equivalent of RTLD_LAZY under Unix, ignored elsewhere.
- wxDL_NOW: Equivalent of RTLD_NOW under Unix, ignored elsewhere.
- wxDL_GLOBAL: Equivalent of RTLD_GLOBAL under Unix, ignored elsewhere.
- wxDL_VERBATIM: Don't try to append the appropriate extension to the library name (this is done by default).
- wxDL_DEFAULT: Default flags, same as wxDL_NOW currently.
- wxDL_QUIET: Don't log an error message if the library couldn't be loaded.

Library: wxBase

Category: Application and Process Management

Public Member Functions

- wxDynamicLibrary ()

  Default constructor.
- wxDynamicLibrary (const wxString &name, int flags=wxDL_DEFAULT)

  Constructor.
- wxDllType Detach ()

  Detaches this object from its library handle, i.e. the object will not unload the library any longer in its destructor but it is now the callers responsibility to do this using Unload().
- void * GetSymbol (const wxString &name, bool *success=0) const

  Returns pointer to symbol name in the library or NULL if the library contains no such symbol.
- void * GetSymbolAorW (const wxString &name) const

  This function is available only under Windows as it is only useful when dynamically loading symbols from standard Windows DLLs.
- bool HasSymbol (const wxString &name) const

  Returns true if the symbol with the given name is present in the dynamic library, false otherwise.
- bool IsLoaded () const

  Returns true if the library was successfully loaded, false otherwise.
- bool Load (const wxString &name, int flags=wxDL_DEFAULT)

  Loads DLL with the given name into memory.
- void Unload ()

  Unloads the library from memory.

Static Public Member Functions

- static wxString CanonicalizeName (const wxString &name, wxDynamicLibraryCategory cat=wxDL_LIBRARY)

  Returns the platform-specific full name for the library called name.
- static wxString CanonicalizePluginName (const wxString &name, wxPluginCategory cat=wxDL_PLUGIN_GUI)

  This function does the same thing as CanonicalizeName() but for wxWidgets plugins.
- static wxDllType GetProgramHandle ()

  Return a valid handle for the main program itself or NULL if symbols from the main program can't be loaded on this platform.
- static wxDynamicLibraryDetailsArray ListLoaded ()

  This static method returns a wxArray containing the details of all modules loaded into the address space of the current project.
- static void * GetModuleFromAddress (const void *addr, wxString *path=NULL)

  Returns the load address of the module containing the specified address or NULL if not found.
- static void Unload (wxDllType handle)

  Unloads the library from memory.

21.212.2 Constructor & Destructor Documentation

wxDynamicLibrary::wxDynamicLibrary ( )

Default constructor.

wxDynamicLibrary::wxDynamicLibrary (const wxString & *name*, int *flags* = `wxDL_DEFAULT`)

Constructor.

Calls Load() with the given *name*.

21.212.3 Member Function Documentation

static wxString wxDynamicLibrary::CanonicalizeName (const wxString & *name,* wxDynamicLibraryCategory *cat* = wxDL_LIBRARY) [static]

Returns the platform-specific full name for the library called *name*.

E.g. it adds a "`.dll`" extension under Windows and "`lib`" prefix and "`.so`", "`.sl`" or "`.dylib`" extension under Unix.

See also

CanonicalizePluginName()

static wxString wxDynamicLibrary::CanonicalizePluginName (const wxString & *name,* wxPluginCategory *cat* = wxDL_PLUGIN_GUI) [static]

This function does the same thing as CanonicalizeName() but for wxWidgets plugins.

The only difference is that compiler and version information are added to the name to ensure that the plugin which is going to be loaded will be compatible with the main program.

wxDllType wxDynamicLibrary::Detach ( )

Detaches this object from its library handle, i.e. the object will not unload the library any longer in its destructor but it is now the callers responsibility to do this using Unload().

static void* wxDynamicLibrary::GetModuleFromAddress (const void * *addr,* wxString * *path* = `NULL`) [static]

Returns the load address of the module containing the specified address or NULL if not found.

If the second argument *path* is not NULL, it is filled with the full path to the file the module was loaded from upon a successful return.

This method is implemented under MSW and Unix platforms providing `dladdr()` call (which include Linux and various BSD systems) and always returns NULL elsewhere.

Since

3.1.0

static wxDllType wxDynamicLibrary::GetProgramHandle ( ) [static]

Return a valid handle for the main program itself or NULL if symbols from the main program can't be loaded on this platform.

void* wxDynamicLibrary::GetSymbol (const wxString & *name,* bool * *success* = `0`) const

Returns pointer to symbol *name* in the library or NULL if the library contains no such symbol.

See also

wxDYNLIB_FUNCTION()

void* wxDynamicLibrary::GetSymbolAorW (const wxString & *name*) const

This function is available only under Windows as it is only useful when dynamically loading symbols from standard Windows DLLs.

Such functions have either `'A'` (in ANSI build) or `'W'` (in Unicode, or wide character build) suffix if they take string parameters. Using this function, you can use just the base name of the function and the correct suffix is appended automatically depending on the current build. Otherwise, this method is identical to GetSymbol().

Availability: only available for the wxMSW port.

bool wxDynamicLibrary::HasSymbol (const wxString & *name*) const

Returns true if the symbol with the given *name* is present in the dynamic library, false otherwise.

Unlike GetSymbol(), this function doesn't log an error message if the symbol is not found.

Since

2.5.4

bool wxDynamicLibrary::IsLoaded ( ) const

Returns true if the library was successfully loaded, false otherwise.

static wxDynamicLibraryDetailsArray wxDynamicLibrary::ListLoaded ( ) [static]

This static method returns a wxArray containing the details of all modules loaded into the address space of the current project.

The array elements are objects of the type: wxDynamicLibraryDetails. The array will be empty if an error occurred.

This method is currently implemented only under Win32 and Linux and is useful mostly for diagnostics purposes.

bool wxDynamicLibrary::Load (const wxString & *name*, int *flags* = `wxDL_DEFAULT`)

Loads DLL with the given *name* into memory.

The *flags* argument can be a combination of the styles outlined in the class description.

Returns true if the library was successfully loaded, false otherwise.

void wxDynamicLibrary::Unload ( )

Unloads the library from memory.

wxDynamicLibrary object automatically calls this method from its destructor if it had been successfully loaded.

static void wxDynamicLibrary::Unload (wxDllType *handle*) [static]

Unloads the library from memory.

wxDynamicLibrary object automatically calls this method from its destructor if it had been successfully loaded.

This version of Unload() is only used if you need to keep the library in memory during a longer period of time than the scope of the wxDynamicLibrary object. In this case you may call Detach() and store the handle somewhere and call this static method later to unload it.

21.213 wxDynamicLibraryDetails Class Reference

`#include <wx/dynlib.h>`

21.213.1 Detailed Description

This class is used for the objects returned by the wxDynamicLibrary::ListLoaded() method and contains the information about a single module loaded into the address space of the current process.

A module in this context may be either a dynamic library or the main program itself.

Library: wxBase

Category: Application and Process Management

Public Member Functions

- bool GetAddress (void *addr, size_t *len) const

  Retrieves the load address and the size of this module.
- wxString GetName () const

  Returns the base name of this module, e.g. "kernel32.dll" or "libc-2.3.2.so".
- wxString GetPath () const

  Returns the full path of this module if available, e.g. "c:\windows\system32\kernel32.dll" or "/lib/libc-2.3.2.so".
- wxString GetVersion () const

  Returns the version of this module, e.g. "5.2.3790.0" or "2.3.2".

21.213.2 Member Function Documentation

bool wxDynamicLibraryDetails::GetAddress (void * *addr*, size_t * *len*) const

Retrieves the load address and the size of this module.

Parameters

addr	The pointer to the location to return load address in, may be NULL.
len	Pointer to the location to return the size of this module in memory in, may be NULL.

Returns

true if the load address and module size were retrieved, false if this information is not available.

wxString wxDynamicLibraryDetails::GetName ( ) const

Returns the base name of this module, e.g. "kernel32.dll" or "libc-2.3.2.so".

wxString wxDynamicLibraryDetails::GetPath ( ) const

Returns the full path of this module if available, e.g. "c:\windows\system32\kernel32.dll" or "/lib/libc-2.3.2.so".

wxString wxDynamicLibraryDetails::GetVersion ( ) const

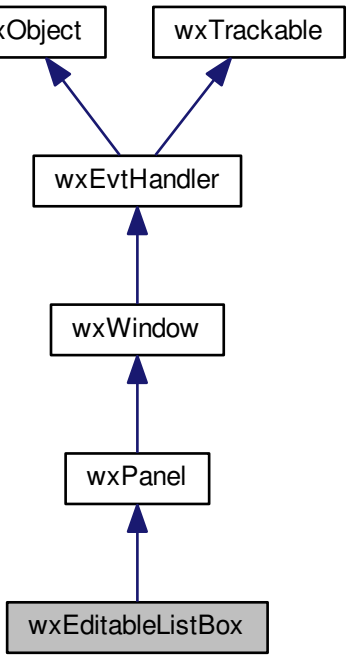
Returns the version of this module, e.g. `"5.2.3790.0"` or `"2.3.2"`.

The returned string is empty if the version information is not available.

21.214 wxEditableListBox Class Reference

`#include <wx/editlbox.h>`

Inheritance diagram for wxEditableListBox:



21.214.1 Detailed Description

An editable listbox is composite control that lets the user easily enter, delete and reorder a list of strings.

Styles

This class supports the following styles:

- wxEL_ALLOW_NEW: Allows the user to enter new strings.
- wxEL_ALLOW_EDIT: Allows the user to edit existing strings.
- wxEL_ALLOW_DELETE: Allows the user to delete existing strings.
- wxEL_NO_REORDER: Does not allow the user to reorder the strings.

- wxEL_DEFAULT_STYLE: Default style: wxEL_ALLOW_NEW|wxEL_ALLOW_EDIT|wxEL_ALLOW_DELETE.

The control uses a wxListCtrl internally and emit its events.

Library: wxAdvanced

Category: Controls

See also

wxListBox, wxListCtrl

Public Member Functions

- wxEditableListBox ()

  Default ctor.
- wxEditableListBox (wxWindow *parent, wxWindowID id, const wxString &label, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, long style=wxEL_DEFAULT_STYLE, const wxString &name=wxEditableListBoxNameStr)

  Constructor, creating and showing a list box.
- virtual ~wxEditableListBox ()

  Destructor, destroying the list box.
- bool Create (wxWindow *parent, wxWindowID id, const wxString &label, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, long style=wxEL_DEFAULT_STYLE, const wxString &name=wxEditableListBoxNameStr)

  Creates the editable listbox for two-step construction.
- void SetStrings (const wxArrayString &strings)

  Replaces current contents with given strings.
- void GetStrings (wxArrayString &strings) const

  Returns in the given array the current contents of the control (the array will be erased before control's contents are appended).

Additional Inherited Members

21.214.2 Constructor & Destructor Documentation

wxEditableListBox::wxEditableListBox ( )

Default ctor.

wxEditableListBox::wxEditableListBox (wxWindow * *parent,* wxWindowID *id,* const wxString & *label,* const wxPoint & *pos =* wxDefaultPosition, const wxSize & *size =* wxDefaultSize, long *style =* wxEL_DEFAULT_STYLE, const wxString & *name =* `wxEditableListBoxNameStr`)

Constructor, creating and showing a list box.

Parameters

parent	Parent window. Must not be NULL.
id	Window identifier. The value wxID_ANY indicates a default value.
label	The text shown just before the list control.
pos	Window position. If wxDefaultPosition is specified then a default position is chosen.
size	Window size. If wxDefaultSize is specified then the window is sized appropriately.
style	Window style. See wxEditableListBox.
name	Window name.

See also

Create()

virtual wxEditableListBox::~wxEditableListBox ( ) [virtual]

Destructor, destroying the list box.

21.214.3 Member Function Documentation

bool wxEditableListBox::Create (wxWindow * *parent*, wxWindowID *id*, const wxString & *label*, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, long *style* = wxEL_DEFAULT_STYLE, const wxString & *name* = wxEditableListBoxNameStr)

Creates the editable listbox for two-step construction.

See wxEditableListBox() for further details.

void wxEditableListBox::GetStrings (wxArrayString & *strings*) const

Returns in the given array the current contents of the control (the array will be erased before control's contents are appended).

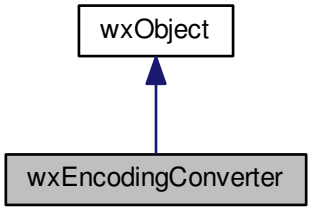
void wxEditableListBox::SetStrings (const wxArrayString & *strings*)

Replaces current contents with given strings.

21.215 wxEncodingConverter Class Reference

`#include <wx/encconv.h>`

Inheritance diagram for wxEncodingConverter:



21.215.1 Detailed Description

This class is capable of converting strings between two 8-bit encodings/charsets.

It can also convert from/to Unicode.

Only a limited subset of encodings is supported by wxEncodingConverter: `wxFONTENCODING_ISO8859_1`..15, `wxFONTENCODING_CP1250`..1257 and `wxFONTENCODING_KOI8`.

Note

Please use wxMBConv classes instead if possible. wxCSConv has much better support for various encodings than wxEncodingConverter. wxEncodingConverter is useful only if you rely on wxCONVERT_SUBSTITUTE mode of operation (see wxEncodingConverter::Init()).

Library: wxBase

Category: Text Conversion

See also

wxFontMapper, wxMBConv, Writing Non-English Applications

Public Member Functions

- wxEncodingConverter ()

  Constructor.
- bool Init (wxFontEncoding input_enc, wxFontEncoding output_enc, int method=wxCONVERT_STRICT)

  Initialize the conversion.

Conversion functions

- bool Convert (const char *input, char *output) const

  Convert input string according to settings passed to Init() and writes the result to output.
- bool Convert (const wchar_t *input, wchar_t *output) const

  Convert input string according to settings passed to Init() and writes the result to output.
- bool Convert (const char *input, wchar_t *output) const

  Convert input string according to settings passed to Init() and writes the result to output.
- bool Convert (const wchar_t *input, char *output) const

Convert input string according to settings passed to Init() and writes the result to output.

- bool Convert (char *str) const

  Convert input string according to settings passed to Init() in-place.

- bool Convert (wchar_t *str) const

  Convert input string according to settings passed to Init() in-place.

- wxString Convert (const wxString &input) const

  Convert a wxString and return a new wxString object.

Static Public Member Functions

- static bool CanConvert (wxFontEncoding encIn, wxFontEncoding encOut)

  Return true if (any text in) multibyte encoding encIn can be converted to another one (encOut) losslessly.

- static wxFontEncodingArray GetAllEquivalents (wxFontEncoding enc)

  Similar to GetPlatformEquivalents(), but this one will return ALL equivalent encodings, regardless of the platform, and including itself.

- static wxFontEncodingArray GetPlatformEquivalents (wxFontEncoding enc, int platform=wxPLATFORM_CURRENT)

  Return equivalents for given font that are used under given platform.

Additional Inherited Members

21.215.2 Constructor & Destructor Documentation

wxEncodingConverter::wxEncodingConverter ( )

Constructor.

21.215.3 Member Function Documentation

static bool wxEncodingConverter::CanConvert (wxFontEncoding *encIn*, wxFontEncoding *encOut*) [static]

Return true if (any text in) multibyte encoding *encIn* can be converted to another one (*encOut*) losslessly.

Do not call this method with `wxFONTENCODING_UNICODE` as either parameter, it doesn't make sense (always works in one sense and always depends on the text to convert in the other).

bool wxEncodingConverter::Convert (const char * *input*, char * *output*) const

Convert input string according to settings passed to Init() and writes the result to output.

All the Convert() function overloads return true if the conversion was lossless and false if at least one of the characters couldn't be converted was and replaced with '?' in the output.

Note that if `wxCONVERT_SUBSTITUTE` was passed to Init(), substitution is considered a lossless operation.

Note

You must call Init() before using this method!

bool wxEncodingConverter::Convert (const wchar_t * *input*, wchar_t * *output*) const

Convert input string according to settings passed to Init() and writes the result to output.

All the Convert() function overloads return true if the conversion was lossless and false if at least one of the characters couldn't be converted was and replaced with '?' in the output.

Note that if `wxCONVERT_SUBSTITUTE` was passed to Init(), substitution is considered a lossless operation.

Note

You must call Init() before using this method!

bool wxEncodingConverter::Convert (const char * *input*, wchar_t * *output*) const

Convert input string according to settings passed to Init() and writes the result to output.

All the Convert() function overloads return true if the conversion was lossless and false if at least one of the characters couldn't be converted was and replaced with '?' in the output.

Note that if `wxCONVERT_SUBSTITUTE` was passed to Init(), substitution is considered a lossless operation.

Note

You must call Init() before using this method!

bool wxEncodingConverter::Convert (const wchar_t * *input*, char * *output*) const

Convert input string according to settings passed to Init() and writes the result to output.

All the Convert() function overloads return true if the conversion was lossless and false if at least one of the characters couldn't be converted was and replaced with '?' in the output.

Note that if `wxCONVERT_SUBSTITUTE` was passed to Init(), substitution is considered a lossless operation.

Note

You must call Init() before using this method!

bool wxEncodingConverter::Convert (char * *str*) const

Convert input string according to settings passed to Init() in-place.

With this overload, the conversion result is written to the same memory area from which the input is read.

See the Convert(const char*,char*) const overload for more info.

bool wxEncodingConverter::Convert (wchar_t * *str*) const

Convert input string according to settings passed to Init() in-place.

With this overload, the conversion result is written to the same memory area from which the input is read.

See the Convert(const wchar_t*,wchar_t*) const overload for more info.

wxString wxEncodingConverter::Convert (const wxString & *input*) const

Convert a wxString and return a new wxString object.

See the Convert(const char*,char*) const overload for more info.

static wxFontEncodingArray wxEncodingConverter::GetAllEquivalents (wxFontEncoding *enc*) [static]

Similar to GetPlatformEquivalents(), but this one will return ALL equivalent encodings, regardless of the platform, and including itself.

This platform's encodings are before others in the array. And again, if *enc* is in the array, it is the very first item in it.

static wxFontEncodingArray wxEncodingConverter::GetPlatformEquivalents (wxFontEncoding *enc,* int *platform =* `wxPLATFORM_CURRENT`) [static]

Return equivalents for given font that are used under given platform.

Supported platforms:

- wxPLATFORM_UNIX
- wxPLATFORM_WINDOWS
- wxPLATFORM_MAC
- wxPLATFORM_CURRENT

wxPLATFORM_CURRENT means the platform this binary was compiled for.

Examples:

```
current platform   enc          returned value
-----------------------------------------------
unix            CP1250             {ISO8859_2}
unix         ISO8859_2             {ISO8859_2}
windows      ISO8859_2                {CP1250}
unix            CP1252  {ISO8859_1,ISO8859_15}
```

Equivalence is defined in terms of convertibility: two encodings are equivalent if you can convert text between then without losing information (it may - and will - happen that you lose special chars like quotation marks or em-dashes but you shouldn't lose any diacritics and language-specific characters when converting between equivalent encodings).

Remember that this function does **NOT** check for presence of fonts in system. It only tells you what are most suitable encodings. (It usually returns only one encoding.)

Note

Note that argument enc itself may be present in the returned array, so that you can, as a side-effect, detect whether the encoding is native for this platform or not.
Convert() is not limited to converting between equivalent encodings, it can convert between two arbitrary encodings.
If *enc* is present in the returned array, then it is always the first item of it.
Please note that the returned array may contain no items at all.

bool wxEncodingConverter::Init (wxFontEncoding *input_enc,* wxFontEncoding *output_enc,* int *method =* `wxCONVERT_STRICT`)

Initialize the conversion.

Both output or input encoding may be wxFONTENCODING_UNICODE, but only if wxUSE_ENCODING is set to 1.

All subsequent calls to Convert() will interpret its argument as a string in *input_enc* encoding and will output string in *output_enc* encoding.

You must call this method before calling Convert. You may call it more than once in order to switch to another conversion.

method affects behaviour of Convert() in case input character cannot be converted because it does not exist in output encoding:

- **wxCONVERT_STRICT:** follow behaviour of GNU Recode - just copy unconvertible characters to output and don't change them (its integer value will stay the same)

- **wxCONVERT_SUBSTITUTE:** try some (lossy) substitutions - e.g. replace unconvertible latin capitals with acute by ordinary capitals, replace en-dash or em-dash by '-' etc.

Both modes guarantee that output string will have same length as input string.

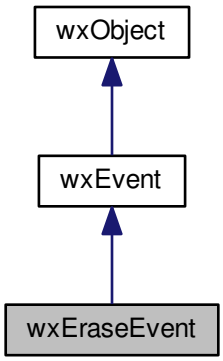
Returns

false if given conversion is impossible, true otherwise (conversion may be impossible either if you try to convert to Unicode with non-Unicode build of wxWidgets or if input or output encoding is not supported).

21.216 wxEraseEvent Class Reference

`#include <wx/event.h>`

Inheritance diagram for wxEraseEvent:



21.216.1 Detailed Description

An erase event is sent when a window's background needs to be repainted.

On some platforms, such as GTK+, this event is simulated (simply generated just before the paint event) and may cause flicker. It is therefore recommended that you set the text background colour explicitly in order to prevent flicker. The default background colour under GTK+ is grey.

To intercept this event, use the EVT_ERASE_BACKGROUND macro in an event table definition.

You must use the device context returned by GetDC() to draw on, don't create a wxPaintDC in the event handler.

Events using this class

The following event handler macros redirect the events to member function handlers '**func**' with prototypes like: void handlerFuncName(wxEraseEvent& event)

Event macros:

- EVT_ERASE_BACKGROUND(func): Process a `wxEVT_ERASE_BACKGROUND` event.

Library: wxCore

Category: Events

See also

Events and Event Handling

Public Member Functions

- wxEraseEvent (int id=0, wxDC *dc=NULL)

  Constructor.

- wxDC * GetDC () const

  Returns the device context associated with the erase event to draw on.

Additional Inherited Members

21.216.2 Constructor & Destructor Documentation

wxEraseEvent::wxEraseEvent (int *id* = `0`, wxDC * *dc* = `NULL`)

Constructor.

21.216.3 Member Function Documentation

wxDC* wxEraseEvent::GetDC ( ) const

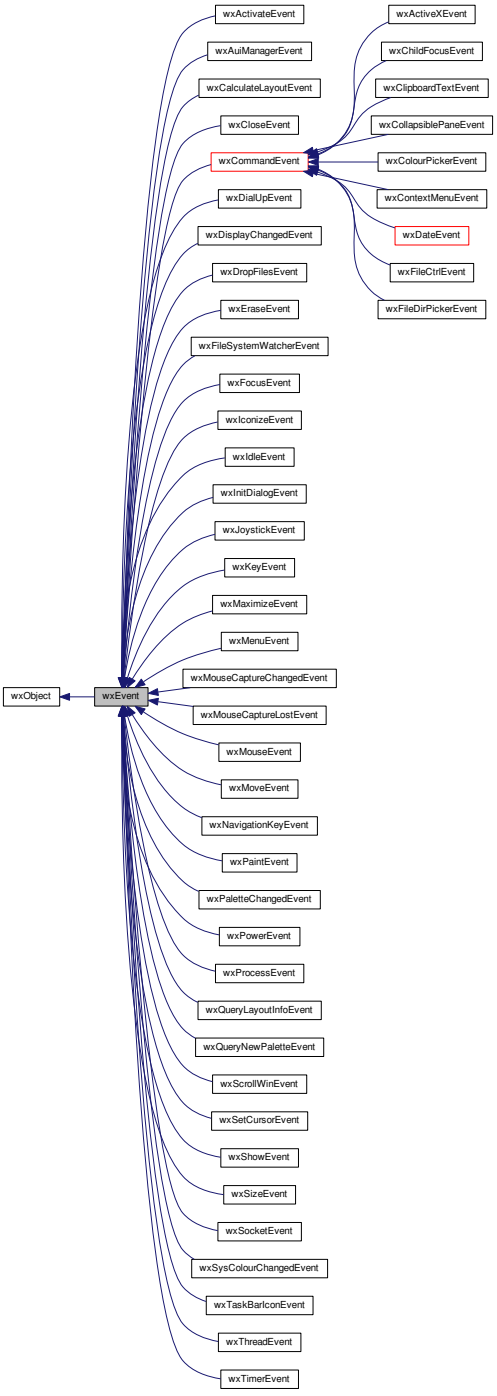
Returns the device context associated with the erase event to draw on.

The returned pointer is never NULL.

21.217 wxEvent Class Reference

```
#include <wx/event.h>
```

Inheritance diagram for wxEvent:



21.217.1 Detailed Description

An event is a structure holding information about an event passed to a callback or member function.

wxEvent used to be a multipurpose event object, and is an abstract base class for other event classes (see below).

For more information about events, see the Events and Event Handling overview.

wxPerl Note: In wxPerl custom event classes should be derived from `Wx::PlEvent` and `Wx::PlCommand`↩

`Event`.

Library: wxBase

Category: Events

See also

wxCommandEvent, wxMouseEvent

Public Member Functions

- wxEvent (int id=0, wxEventType eventType=wxEVT_NULL)

  Constructor.
- virtual wxEvent * Clone () const =0

  Returns a copy of the event.
- wxObject * GetEventObject () const

  Returns the object (usually a window) associated with the event, if any.
- wxEventType GetEventType () const

  Returns the identifier of the given event type, such as `wxEVT_BUTTON`.
- virtual wxEventCategory GetEventCategory () const

  Returns a generic category for this event.
- int GetId () const

  Returns the identifier associated with this event, such as a button command id.
- wxObject * GetEventUserData () const

  Return the user data associated with a dynamically connected event handler.
- bool GetSkipped () const

  Returns true if the event handler should be skipped, false otherwise.
- long GetTimestamp () const

  Gets the timestamp for the event.
- bool IsCommandEvent () const

  Returns true if the event is or is derived from wxCommandEvent else it returns false.
- void ResumePropagation (int propagationLevel)

  Sets the propagation level to the given value (for example returned from an earlier call to wxEvent::StopPropagation).
- void SetEventObject (wxObject *object)

  Sets the originating object.
- void SetEventType (wxEventType type)

  Sets the event type.
- void SetId (int id)

  Sets the identifier associated with this event, such as a button command id.
- void SetTimestamp (long timeStamp=0)

  Sets the timestamp for the event.
- bool ShouldPropagate () const

  Test if this event should be propagated or not, i.e. if the propagation level is currently greater than 0.
- void Skip (bool skip=true)

  This method can be used inside an event handler to control whether further event handlers bound to this event will be called after the current one returns.
- int StopPropagation ()

  Stop the event from propagating to its parent window.

Protected Attributes

- int m_propagationLevel

  Indicates how many levels the event can propagate.

Additional Inherited Members

21.217.2 Constructor & Destructor Documentation

wxEvent::wxEvent (int *id* = 0, wxEventType *eventType* = wxEVT_NULL)

Constructor.

Notice that events are usually created by wxWidgets itself and creating e.g. a wxPaintEvent in your code and sending it to e.g. a wxTextCtrl will not usually affect it at all as native controls have no specific knowledge about wxWidgets events. However you may construct objects of specific types and pass them to wxEvtHandler::ProcessEvent() if you want to create your own custom control and want to process its events in the same manner as the standard ones.

Also please notice that the order of parameters in this constructor is different from almost all the derived classes which specify the event type as the first argument.

Parameters

id	The identifier of the object (window, timer, ...) which generated this event.
eventType	The unique type of event, e.g. `wxEVT_PAINT`, `wxEVT_SIZE` or `wxEVT_BUTTON`.

21.217.3 Member Function Documentation

virtual wxEvent* wxEvent::Clone ( ) const `[pure virtual]`

Returns a copy of the event.

Any event that is posted to the wxWidgets event system for later action (via wxEvtHandler::AddPendingEvent, wxEvtHandler::QueueEvent or wxPostEvent()) must implement this method.

All wxWidgets events fully implement this method, but any derived events implemented by the user should also implement this method just in case they (or some event derived from them) are ever posted.

All wxWidgets events implement a copy constructor, so the easiest way of implementing the Clone function is to implement a copy constructor for a new event (call it MyEvent) and then define the Clone function like this:

```
wxEvent *Clone() const { return new MyEvent(*this); }
```

Implemented in wxThreadEvent, wxRichTextEvent, wxTextUrlEvent, and wxWindowModalDialogEvent.

virtual wxEventCategory wxEvent::GetEventCategory ( ) const `[virtual]`

Returns a generic category for this event.

wxEvent implementation returns `wxEVT_CATEGORY_UI` by default.

This function is used to selectively process events in wxEventLoopBase::YieldFor.

Reimplemented in wxThreadEvent.

wxObject* wxEvent::GetEventObject ( ) const

Returns the object (usually a window) associated with the event, if any.

wxEventType wxEvent::GetEventType ( ) const

Returns the identifier of the given event type, such as `wxEVT_BUTTON`.

wxObject* wxEvent::GetEventUserData ( ) const

Return the user data associated with a dynamically connected event handler.

wxEvtHandler::Connect() and wxEvtHandler::Bind() allow associating optional `userData` pointer with the handler and this method returns the value of this pointer.

The returned pointer is owned by wxWidgets and must not be deleted.

Since

2.9.5

int wxEvent::GetId ( ) const

Returns the identifier associated with this event, such as a button command id.

bool wxEvent::GetSkipped ( ) const

Returns true if the event handler should be skipped, false otherwise.

long wxEvent::GetTimestamp ( ) const

Gets the timestamp for the event.

The timestamp is the time in milliseconds since some fixed moment (not necessarily the standard Unix Epoch, so only differences between the timestamps and not their absolute values usually make sense).

Warning

wxWidgets returns a non-NULL timestamp only for mouse and key events (see wxMouseEvent and wxKeyEvent).

bool wxEvent::IsCommandEvent ( ) const

Returns true if the event is or is derived from wxCommandEvent else it returns false.

Note

exists only for optimization purposes.

void wxEvent::ResumePropagation (int *propagationLevel*)

Sets the propagation level to the given value (for example returned from an earlier call to wxEvent::StopPropagation).

void wxEvent::SetEventObject (wxObject * *object*)

Sets the originating object.

void wxEvent::SetEventType (wxEventType *type*)

Sets the event type.

void wxEvent::SetId (int *id*)

Sets the identifier associated with this event, such as a button command id.

void wxEvent::SetTimestamp (long *timeStamp* = `0`)

Sets the timestamp for the event.

bool wxEvent::ShouldPropagate ( ) const

Test if this event should be propagated or not, i.e. if the propagation level is currently greater than 0.

void wxEvent::Skip (bool *skip* = `true`)

This method can be used inside an event handler to control whether further event handlers bound to this event will be called after the current one returns.

Without Skip() (or equivalently if Skip(false) is used), the event will not be processed any more. If Skip(true) is called, the event processing system continues searching for a further handler function for this event, even though it has been processed already in the current handler.

In general, it is recommended to skip all non-command events to allow the default handling to take place. The command events are, however, normally not skipped as usually a single command such as a button click or menu item selection must only be processed by one handler.

int wxEvent::StopPropagation ( )

Stop the event from propagating to its parent window.

Returns the old propagation level value which may be later passed to ResumePropagation() to allow propagating the event again.

21.217.4 Member Data Documentation

int wxEvent::m_propagationLevel `[protected]`

Indicates how many levels the event can propagate.

This member is protected and should typically only be set in the constructors of the derived classes. It may be temporarily changed by StopPropagation() and ResumePropagation() and tested with ShouldPropagate().

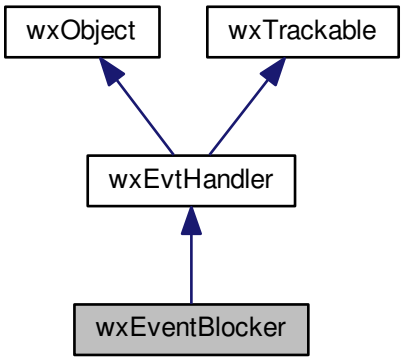
The initial value is set to either `wxEVENT_PROPAGATE_NONE` (by default) meaning that the event shouldn't be propagated at all or to `wxEVENT_PROPAGATE_MAX` (for command events) meaning that it should be propagated as much as necessary.

Any positive number means that the event should be propagated but no more than the given number of times. E.g. the propagation level may be set to 1 to propagate the event to its parent only, but not to its grandparent.

21.218 wxEventBlocker Class Reference

```
#include <wx/event.h>
```

Inheritance diagram for wxEventBlocker:



21.218.1 Detailed Description

This class is a special event handler which allows to discard any event (or a set of event types) directed to a specific window.

Example:

```
void MyWindow::DoSomething()
{
    {
        // block all events directed to this window while
        // we do the 1000 FunctionWhichSendsEvents() calls
        wxEventBlocker blocker(this);

        for ( int i = 0; i  1000; i++ )
            FunctionWhichSendsEvents(i);

    } // ~wxEventBlocker called, old event handler is restored

    // the event generated by this call will be processed:
    FunctionWhichSendsEvents(0)
}
```

Library: wxCore

Category: Events

See also

How Events are Processed, wxEvtHandler

Public Member Functions

- wxEventBlocker (wxWindow *win, wxEventType type=-1)

  Constructs the blocker for the given window and for the given event type.
- virtual ~wxEventBlocker ()

  Destructor.
- void Block (wxEventType eventType)

  Adds to the list of event types which should be blocked the given eventType.

Additional Inherited Members

21.218.2 Constructor & Destructor Documentation

wxEventBlocker::wxEventBlocker (wxWindow * *win,* wxEventType *type* = -1)

Constructs the blocker for the given window and for the given event type.

If *type* is `wxEVT_ANY`, then all events for that window are blocked. You can call Block() after creation to add other event types to the list of events to block.

Note that the *win* window **must** remain alive until the wxEventBlocker object destruction.

virtual wxEventBlocker::~wxEventBlocker ( ) [virtual]

Destructor.

The blocker will remove itself from the chain of event handlers for the window provided in the constructor, thus restoring normal processing of events.

21.218.3 Member Function Documentation

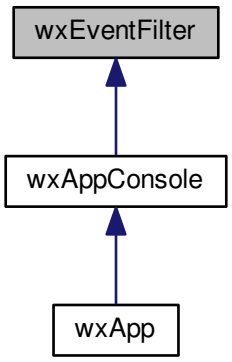
void wxEventBlocker::Block (wxEventType *eventType*)

Adds to the list of event types which should be blocked the given *eventType*.

21.219 wxEventFilter Class Reference

`#include <wx/eventfilter.h>`

Inheritance diagram for wxEventFilter:



21.219.1 Detailed Description

A global event filter for pre-processing all the events generated in the program.

This is a very simple class which just provides FilterEvent() virtual method to be called by wxEvtHandler before starting process of any event. Thus, inheriting from this class and overriding FilterEvent() allows to capture and possibly handle or ignore all the events happening in the program. Of course, having event filters adds additional overhead to every event processing and so should not be used lightly and your FilterEvent() code should try to return as quickly as possible, especially for the events it is not interested in.

An example of using this class:

```
// This class allows to determine the last time the user has worked with
// this application:
class LastActivityTimeDetector : public wxEventFilter
{
public:
    LastActivityTimeDetector()
    {
        wxEvtHandler::AddFilter(this);

        m_last = wxDateTime::Now();
    }

    virtual ~LastActivityTimeDetector()
    {
        wxEvtHandler::RemoveFilter(this);
    }

    virtual int FilterEvent(wxEvent& event)
    {
        // Update the last user activity
        const wxEventType t = event.GetEventType();
        if ( t == wxEVT_KEY_DOWN || t == wxEVT_MOTION ||
                t == wxEVT_LEFT_DOWN ||
                    t == wxEVT_RIGHT_DOWN ||
                        t == wxEVT_MIDDLE_DOWN )
        {
            m_last = wxDateTime::Now();
        }

        // Continue processing the event normally as well.
        return Event_Skip;
    }

    // This function could be called periodically from some timer to
    // do something (e.g. hide sensitive data or log out from remote
    // server) if the user has been inactive for some time period.
    bool IsInactiveFor(const wxTimeSpan& diff) const
    {
        return wxDateTime::Now() - diff > m_last;
    }

private:
    wxDateTime m_last;
};
```

Notice that wxApp derives from wxEventFilter and is registered as an event filter during its creation so you may also override FilterEvent() method in your wxApp-derived class and, in fact, this is often the most convenient way to do it. However creating a new class deriving directly from wxEventFilter allows to isolate the event filtering code in its own separate class and also to have several independent filters, if necessary.

Category: Events

Since

2.9.3

Public Types

- enum {
  Event_Skip = -1,
  Event_Ignore = 0,
  Event_Processed = 1 }

  Possible return values for FilterEvent().

Public Member Functions

- wxEventFilter ()

  Default constructor.

- virtual ~wxEventFilter ()

  Destructor.

- virtual int FilterEvent (wxEvent &event)=0

  Override this method to implement event pre-processing.

21.219.2 Constructor & Destructor Documentation

wxEventFilter::wxEventFilter ( )

Default constructor.

Constructor does not register this filter using wxEvtHandler::AddFilter(), it's your responsibility to do it when necessary.

Notice that the objects of this class can't be copied.

virtual wxEventFilter::~wxEventFilter ( ) `[virtual]`

Destructor.

You must call wxEvtHandler::RemoveFilter() before destroying this object (possibly from the derived class destructor), failure to do this is indicated by an assert unless assertions are disabled.

21.219.3 Member Function Documentation

virtual int wxEventFilter::FilterEvent (wxEvent & *event*) `[pure virtual]`

Override this method to implement event pre-processing.

This method allows to filter all the events processed by the program, so you should try to return quickly from it to avoid slowing down the program to a crawl.

Although the return type of this method is `int`, this is only due to backwards compatibility concerns and the actual return value must be one of the `Event_XXX` constants defined above:

- Event_Skip to continue processing the event normally (this should be used in most cases).
- Event_Ignore to not process this event at all (this can be used to suppress some events).
- Event_Processed to not process this event normally but indicate that it was already processed by the event filter and so no default processing should take place neither (this should only be used if the filter really did process the event).

Implemented in wxAppConsole.

21.220 wxEventLoopActivator Class Reference

```
#include <wx/evtloop.h>
```

21.220.1 Detailed Description

Makes an event loop temporarily active.

This class is used to make the event loop active during its life-time, e.g.:

```
class MyEventLoop : public wxEventLoopBase { ... };

void RunMyLoop()
{
    MyEventLoop loop;
    wxEventLoopActivator activate(&loop);

    ...
} // the previously active event loop restored here
```

Library: wxBase

Category: Application and Process Management

See also

wxEventLoopBase

Public Member Functions

- wxEventLoopActivator (wxEventLoopBase *loop)

  Makes the loop passed as the parameter currently active.

- ~wxEventLoopActivator ()

  Restores the previously active event loop stored by the constructor.

21.220.2 Constructor & Destructor Documentation

wxEventLoopActivator::wxEventLoopActivator (wxEventLoopBase * *loop*)

Makes the loop passed as the parameter currently active.

This saves the current return value of wxEventLoopBase::GetActive() and then calls wxEventLoopBase::SetActive() with the given *loop*.

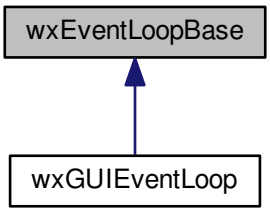
wxEventLoopActivator::~wxEventLoopActivator ( )

Restores the previously active event loop stored by the constructor.

21.221 wxEventLoopBase Class Reference

`#include <wx/evtloop.h>`

Inheritance diagram for wxEventLoopBase:



21.221.1 Detailed Description

Base class for all event loop implementations.

An event loop is a class which queries the queue of native events sent to the wxWidgets application and dispatches them to the appropriate wxEvtHandlers.

An object of this class is created by wxAppTraits::CreateEventLoop() and used by wxApp to run the main application event loop. Temporary event loops are usually created by wxDialog::ShowModal().

You can create your own event loop if you need, provided that you restore the main event loop once yours is destroyed (see wxEventLoopActivator).

Notice that there can be more than one event loop at any given moment, e.g. an event handler called from the main loop can show a modal dialog, which starts its own loop resulting in two nested loops, with the modal dialog being the active one (its IsRunning() returns true). And a handler for a button inside the modal dialog can, of course, create another modal dialog with its own event loop and so on. So in general event loops form a stack and only the event loop at the top of the stack is considered to be active. It is also the only loop that can be directly asked to terminate by calling Exit() (which is done by wxDialog::EndModal()), an outer event loop can't be stopped while an inner one is still running. It is however possible to ask an outer event loop to terminate as soon as all its nested loops exit and the control returns back to it by using ScheduleExit().

Library: wxBase

Category: Application and Process Management

See also

wxApp, wxEventLoopActivator

Public Member Functions

- bool IsMain () const

  Returns true if this is the main loop executed by wxApp::OnRun().

Dispatch and processing

- virtual int Run ()=0

  Start the event loop, return the exit code when it is finished.

- bool IsRunning () const

  Return true if this event loop is currently running.
- virtual bool IsOk () const

  Use this to check whether the event loop was successfully created before using it.
- virtual void Exit (int rc=0)

  Exit the currently running loop with the given exit code.
- virtual void ScheduleExit (int rc=0)=0

  Schedule an exit from the loop with the given exit code.
- virtual bool Pending () const =0

  Return true if any events are available.
- virtual bool Dispatch ()=0

  Dispatches the next event in the windowing system event queue.
- virtual int DispatchTimeout (unsigned long timeout)=0

  Dispatch an event but not wait longer than the specified timeout for it.
- virtual void WakeUp ()=0

  Called by wxWidgets to wake up the event loop even if it is currently blocked inside Dispatch().

Idle handling

- virtual void WakeUpIdle ()

  Makes sure that idle events are sent again.
- virtual bool ProcessIdle ()

  This virtual function is called when the application becomes idle and normally just sends wxIdleEvent to all interested parties.

Yield-related hooks

- virtual bool IsYielding () const

  Returns true if called from inside Yield() or from inside YieldFor().
- bool Yield (bool onlyIfNeeded=false)

  Yields control to pending messages in the windowing system.
- bool YieldFor (long eventsToProcess)

  Works like Yield() with onlyIfNeeded == true, except that it allows the caller to specify a mask of the wxEvent↩ Category values which indicates which events should be processed and which should instead be "delayed" (i.e.
- virtual bool IsEventAllowedInsideYield (wxEventCategory cat) const

  Returns true if the given event category is allowed inside a YieldFor() call (i.e.

Static Public Member Functions

- static wxEventLoopBase * GetActive ()

  Return the currently active (running) event loop.
- static void SetActive (wxEventLoopBase *loop)

  Set currently active (running) event loop.

Protected Member Functions

- virtual void OnExit ()

  This function is called before the event loop terminates, whether this happens normally (because of Exit() call) or abnormally (because of an exception thrown from inside the loop).

21.221.2 Member Function Documentation

virtual bool wxEventLoopBase::Dispatch ( ) [pure virtual]

Dispatches the next event in the windowing system event queue.

Blocks until an event appears if there are none currently (use Pending() if this is not wanted).

This can be used for programming event loops, e.g.

```
while (evtloop->Pending())
    evtloop->Dispatch();
```

Returns

false if the event loop should stop and true otherwise.

See also

Pending(), wxEventLoopBase

virtual int wxEventLoopBase::DispatchTimeout (unsigned long *timeout*) [pure virtual]

Dispatch an event but not wait longer than the specified timeout for it.

If an event is received before the specified *timeout* expires, it is processed and the function returns 1 normally or 0 if the event loop should quite. Otherwise, i.e. if the timeout expires, the functions returns -1 without processing any events.

Parameters

timeout	The maximal time to wait for the events in milliseconds.

Returns

1 if an event was processed, 0 if the event loop should quit or -1 if the timeout expired.

virtual void wxEventLoopBase::Exit (int *rc* = 0) [virtual]

Exit the currently running loop with the given exit code.

The loop will exit, i.e. its Run() method will return, during the next event loop iteration.

Notice that this method can only be used if this event loop is the currently running one, i.e. its IsRunning() returns true. If this is not the case, an assert failure is triggered and nothing is done as outer event loops can't be exited from immediately. Use ScheduleExit() if you'd like to exit this loop even if it doesn't run currently.

static wxEventLoopBase* wxEventLoopBase::GetActive ( ) [static]

Return the currently active (running) event loop.

May return NULL if there is no active event loop (e.g. during application startup or shutdown).

virtual bool wxEventLoopBase::IsEventAllowedInsideYield (wxEventCategory *cat*) const [virtual]

Returns true if the given event category is allowed inside a YieldFor() call (i.e.

compares the given category against the last mask passed to YieldFor()).

See also

wxEvent::GetEventCategory

bool wxEventLoopBase::IsMain ( ) const

Returns true if this is the main loop executed by wxApp::OnRun().

virtual bool wxEventLoopBase::IsOk ( ) const `[virtual]`

Use this to check whether the event loop was successfully created before using it.

bool wxEventLoopBase::IsRunning ( ) const

Return true if this event loop is currently running.

Notice that even if this event loop hasn't terminated yet but has just spawned a nested (e.g. modal) event loop, this method would return false.

virtual bool wxEventLoopBase::IsYielding ( ) const `[virtual]`

Returns true if called from inside Yield() or from inside YieldFor().

virtual void wxEventLoopBase::OnExit ( ) `[protected], [virtual]`

This function is called before the event loop terminates, whether this happens normally (because of Exit() call) or abnormally (because of an exception thrown from inside the loop).

The default implementation calls wxAppConsole::OnEventLoopExit.

virtual bool wxEventLoopBase::Pending ( ) const `[pure virtual]`

Return true if any events are available.

If this method returns true, calling Dispatch() will not block.

virtual bool wxEventLoopBase::ProcessIdle ( ) `[virtual]`

This virtual function is called when the application becomes idle and normally just sends wxIdleEvent to all interested parties.

It should return true if more idle events are needed, false if not.

virtual int wxEventLoopBase::Run ( ) `[pure virtual]`

Start the event loop, return the exit code when it is finished.

Logically, this method calls Dispatch() in a loop until it returns false and also takes care of generating idle events during each loop iteration. However not all implementations of this class really implement it like this (e.g. wxGTK does not) so you shouldn't rely on Dispatch() being called from inside this function.

Returns

The argument passed to Exit() which terminated this event loop.

virtual void wxEventLoopBase::ScheduleExit (int *rc* = 0) [pure virtual]

Schedule an exit from the loop with the given exit code.

This method is similar to Exit() but can be called even if this event loop is not the currently running one – and if it is the active loop, then it works in exactly the same way as Exit().

The loop will exit as soon as the control flow returns to it, i.e. after any nested loops terminate.

Since

2.9.5

static void wxEventLoopBase::SetActive (wxEventLoopBase * *loop*) [static]

Set currently active (running) event loop.

Called by wxEventLoopActivator, use an instance of this class instead of calling this method directly to ensure that the previously active event loop is restored.

Results in a call to wxAppConsole::OnEventLoopEnter.

virtual void wxEventLoopBase::WakeUp ( ) [pure virtual]

Called by wxWidgets to wake up the event loop even if it is currently blocked inside Dispatch().

virtual void wxEventLoopBase::WakeUpIdle ( ) [virtual]

Makes sure that idle events are sent again.

bool wxEventLoopBase::Yield (bool *onlyIfNeeded* = false)

Yields control to pending messages in the windowing system.

This can be useful, for example, when a time-consuming process writes to a text window. Without an occasional yield, the text window will not be updated properly, and on systems with cooperative multitasking, such as Windows 3.1 other processes will not respond.

Caution should be exercised, however, since yielding may allow the user to perform actions which are not compatible with the current task. Disabling menu items or whole menus during processing can avoid unwanted reentrance of code: see wxSafeYield for a better function.

Note that Yield() will not flush the message logs. This is intentional as calling Yield() is usually done to quickly update the screen and popping up a message box dialog may be undesirable. If you do wish to flush the log messages immediately (otherwise it will be done during the next idle loop iteration), call wxLog::FlushActive.

If *onlyIfNeeded* parameter is true and the flow control is already inside Yield(), i.e. IsYielding() returns true, the method just silently returns false and doesn't do anything.

bool wxEventLoopBase::YieldFor (long *eventsToProcess*)

Works like Yield() with *onlyIfNeeded* == true, except that it allows the caller to specify a mask of the wxEvent↩ Category values which indicates which events should be processed and which should instead be "delayed" (i.e.

processed by the main loop later).

Note that this is a safer alternative to Yield() since it ensures that only the events you're interested to will be processed; i.e. this method helps to avoid unwanted reentrancies.

Note that currently only wxMSW and wxGTK do support selective yield of native events coming from the underlying GUI toolkit. wxWidgets events posted using wxEvtHandler::AddPendingEvent or wxEvtHandler::QueueEvent are instead selectively processed by all ports.

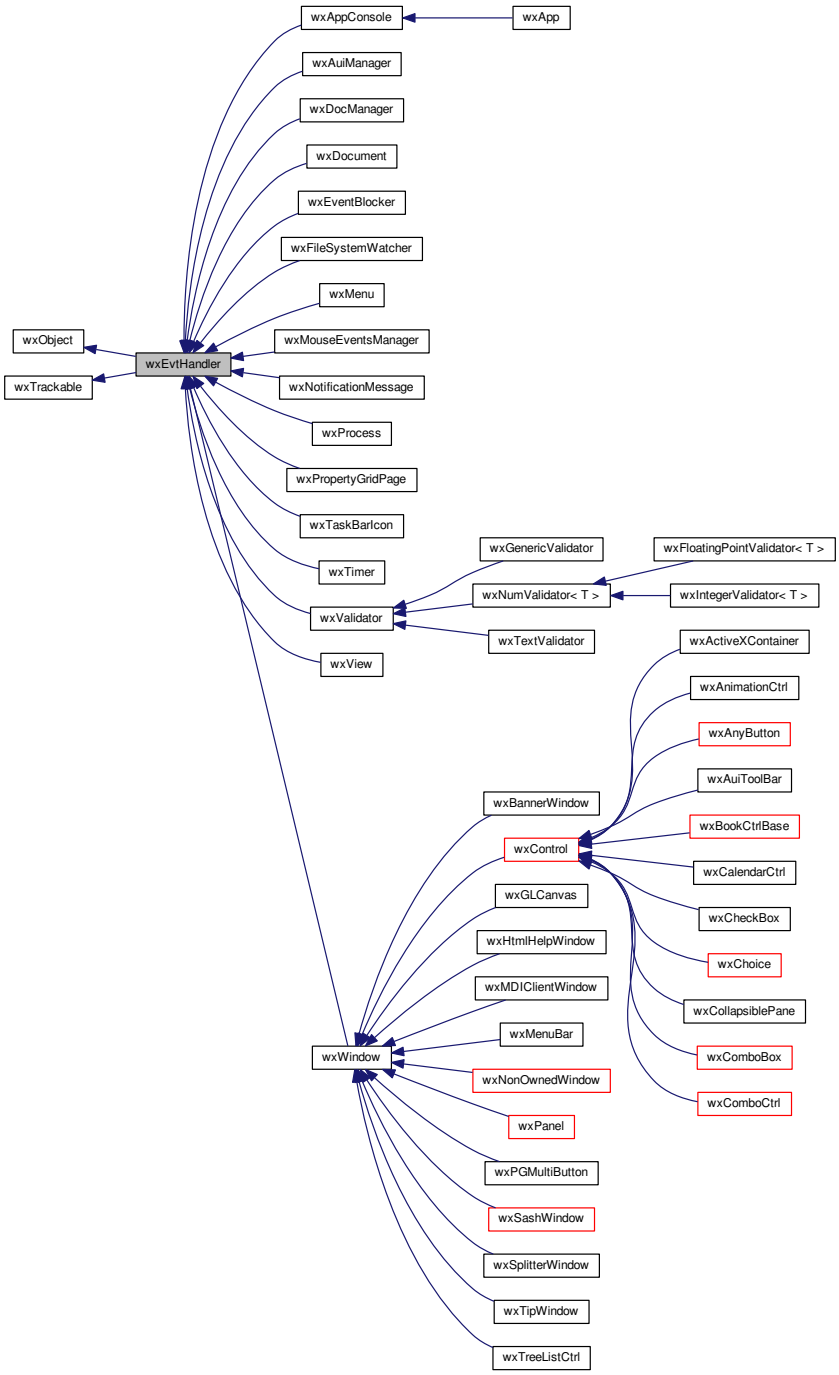
wxEvent::GetEventCategory

21.222 wxEvtHandler Class Reference

```
#include <wx/event.h>
```

Inheritance diagram for wxEvtHandler:



21.222.1 Detailed Description

A class that can handle events from the windowing system.

wxWindow is (and therefore all window classes are) derived from this class.

When events are received, wxEvtHandler invokes the method listed in the event table using itself as the object. When using multiple inheritance **it is imperative that the wxEvtHandler(-derived) class is the first class inherited** such that the `this` pointer for the overall object will be identical to the `this` pointer of the wxEvtHandler

portion.

Library: wxBase

Category: Events

See also

How Events are Processed, wxEventBlocker, wxEventLoopBase

Public Member Functions

- wxEvtHandler ()

  Constructor.
- virtual ~wxEvtHandler ()

  Destructor.

Event queuing and processing

- virtual void QueueEvent (wxEvent *event)

  Queue event for a later processing.
- virtual void AddPendingEvent (const wxEvent &event)

  Post an event to be processed later.
- template<typename T , typename T1 , ... >
  void CallAfter (void(T::*method)(T1,...), T1 x1,...)

  Asynchronously call the given method.
- template<typename T >
  void CallAfter (const T &functor)

  Asynchronously call the given functor.
- virtual bool ProcessEvent (wxEvent &event)

  Processes an event, searching event tables and calling zero or more suitable event handler function(s).
- bool ProcessEventLocally (wxEvent &event)

  Try to process the event in this handler and all those chained to it.
- bool SafelyProcessEvent (wxEvent &event)

  Processes an event by calling ProcessEvent() and handles any exceptions that occur in the process.
- void ProcessPendingEvents ()

  Processes the pending events previously queued using QueueEvent() or AddPendingEvent(); you must call this function only if you are sure there are pending events for this handler, otherwise a `wxCHECK` will fail.
- void DeletePendingEvents ()

  Deletes all events queued on this event handler using QueueEvent() or AddPendingEvent().
- virtual bool SearchEventTable (wxEventTable &table, wxEvent &event)

  Searches the event table, executing an event handler function if an appropriate one is found.

Connecting and disconnecting

- void Connect (int id, int lastId, wxEventType eventType, wxObjectEventFunction function, wxObject *userData=NULL, wxEvtHandler *eventSink=NULL)

  Connects the given function dynamically with the event handler, id and event type.
- void Connect (int id, wxEventType eventType, wxObjectEventFunction function, wxObject *userData=NULL, wxEvtHandler *eventSink=NULL)

  See the Connect(int, int, wxEventType, wxObjectEventFunction, wxObject, wxEvtHandler*) overload for more info.*
- void Connect (wxEventType eventType, wxObjectEventFunction function, wxObject *userData=NULL, wxEvtHandler *eventSink=NULL)

  See the Connect(int, int, wxEventType, wxObjectEventFunction, wxObject, wxEvtHandler*) overload for more info.*

- bool Disconnect (wxEventType eventType, wxObjectEventFunction function, wxObject *userData=NULL, wxEvtHandler *eventSink=NULL)

  Disconnects the given function dynamically from the event handler, using the specified parameters as search criteria and returning true if a matching function has been found and removed.
- bool Disconnect (int id=wxID_ANY, wxEventType eventType=wxEVT_NULL, wxObjectEventFunction function=NULL, wxObject *userData=NULL, wxEvtHandler *eventSink=NULL)

  See the Disconnect(wxEventType, wxObjectEventFunction, wxObject, wxEvtHandler*) overload for more info.*
- bool Disconnect (int id, int lastId, wxEventType eventType, wxObjectEventFunction function=NULL, wxObject *userData=NULL, wxEvtHandler *eventSink=NULL)

  See the Disconnect(wxEventType, wxObjectEventFunction, wxObject, wxEvtHandler*) overload for more info.*

Binding and Unbinding

- template<typename EventTag , typename Functor >
  void Bind (const EventTag &eventType, Functor functor, int id=wxID_ANY, int lastId=wxID_ANY, wxObject *userData=NULL)

  Binds the given function, functor or method dynamically with the event.
- template<typename EventTag , typename Class , typename EventArg , typename EventHandler >
  void Bind (const EventTag &eventType, void(Class::*method)(EventArg &), EventHandler *handler, int id=wxID_ANY, int lastId=wxID_ANY, wxObject *userData=NULL)

  See the Bind<>(const EventTag&, Functor, int, int, wxObject) overload for more info.*
- template<typename EventTag , typename Functor >
  bool Unbind (const EventTag &eventType, Functor functor, int id=wxID_ANY, int lastId=wxID_ANY, wxObject *userData=NULL)

  Unbinds the given function, functor or method dynamically from the event handler, using the specified parameters as search criteria and returning true if a matching function has been found and removed.
- template<typename EventTag , typename Class , typename EventArg , typename EventHandler >
  bool Unbind (const EventTag &eventType, void(Class::*method)(EventArg &), EventHandler *handler, int id=wxID_ANY, int lastId=wxID_ANY, wxObject *userData=NULL)

  See the Unbind<>(const EventTag&, Functor, int, int, wxObject) overload for more info.*

User-supplied data

- void * GetClientData () const

  Returns user-supplied client data.
- wxClientData * GetClientObject () const

  Returns a pointer to the user-supplied client data object.
- void SetClientData (void *data)

  Sets user-supplied client data.
- void SetClientObject (wxClientData *data)

  Set the client data object.

Event handler chaining

wxEvtHandler can be arranged in a double-linked list of handlers which is automatically iterated by ProcessEvent() if needed.

- bool GetEvtHandlerEnabled () const

  Returns true if the event handler is enabled, false otherwise.
- wxEvtHandler * GetNextHandler () const

  Returns the pointer to the next handler in the chain.
- wxEvtHandler * GetPreviousHandler () const

  Returns the pointer to the previous handler in the chain.
- void SetEvtHandlerEnabled (bool enabled)

  Enables or disables the event handler.
- virtual void SetNextHandler (wxEvtHandler *handler)

  Sets the pointer to the next handler.
- virtual void SetPreviousHandler (wxEvtHandler *handler)

  Sets the pointer to the previous handler.

- void Unlink ()

  Unlinks this event handler from the chain it's part of (if any); then links the "previous" event handler to the "next" one (so that the chain won't be interrupted).
- bool IsUnlinked () const

  Returns true if the next and the previous handler pointers of this event handler instance are NULL.

Static Public Member Functions

Global event filters.

Methods for working with the global list of event filters.

Event filters can be defined to pre-process all the events that happen in an application, see wxEventFilter documentation for more information.

- static void AddFilter (wxEventFilter *filter)

  Add an event filter whose FilterEvent() method will be called for each and every event processed by wxWidgets.
- static void RemoveFilter (wxEventFilter *filter)

  Remove a filter previously installed with AddFilter().

Protected Member Functions

- virtual bool TryBefore (wxEvent &event)

  Method called by ProcessEvent() before examining this object event tables.
- virtual bool TryAfter (wxEvent &event)

  Method called by ProcessEvent() as last resort.

Additional Inherited Members

21.222.2 Constructor & Destructor Documentation

wxEvtHandler::wxEvtHandler ( )

Constructor.

virtual wxEvtHandler::~wxEvtHandler ( ) [virtual]

Destructor.

If the handler is part of a chain, the destructor will unlink itself (see Unlink()).

21.222.3 Member Function Documentation

static void wxEvtHandler::AddFilter (wxEventFilter * *filter*) [static]

Add an event filter whose FilterEvent() method will be called for each and every event processed by wxWidgets.

The filters are called in LIFO order and wxApp is registered as an event filter by default. The pointer must remain valid until it's removed with RemoveFilter() and is not deleted by wxEvtHandler.

Since

2.9.3

virtual void wxEvtHandler::AddPendingEvent (const wxEvent & *event*) `[virtual]`

Post an event to be processed later.

This function is similar to QueueEvent() but can't be used to post events from worker threads for the event objects with wxString fields (i.e. in practice most of them) because of an unsafe use of the same wxString object which happens because the wxString field in the original *event* object and its copy made internally by this function share the same string buffer internally. Use QueueEvent() to avoid this.

A copy of *event* is made by the function, so the original can be deleted as soon as function returns (it is common that the original is created on the stack). This requires that the wxEvent::Clone() method be implemented by event so that it can be duplicated and stored until it gets processed.

Parameters

event	Event to add to the pending events queue.

Reimplemented in wxWindow.

template<typename EventTag , typename Functor > void wxEvtHandler::Bind (const EventTag & *eventType*, Functor *functor*, int *id* = wxID_ANY, int *lastId* = wxID_ANY, wxObject * *userData* = NULL)

Binds the given function, functor or method dynamically with the event.

This offers basically the same functionality as Connect(), but it is more flexible as it also allows you to use ordinary functions and arbitrary functors as event handlers. It is also less restrictive then Connect() because you can use an arbitrary method as an event handler, whereas Connect() requires a wxEvtHandler derived handler.

See Dynamic Event Handling for more detailed explanation of this function and the Event Sample sample for usage examples.

Parameters

eventType	The event type to be associated with this event handler.
functor	The event handler functor. This can be an ordinary function but also an arbitrary functor like boost::function<>.
id	The first ID of the identifier range to be associated with the event handler.
lastId	The last ID of the identifier range to be associated with the event handler.
userData	Optional data to be associated with the event table entry. wxWidgets will take ownership of this pointer, i.e. it will be destroyed when the event handler is disconnected or at the program termination. This pointer can be retrieved using wxEvent::GetEventUserData() later.

See also

Caveats When Not Using C++ RTTI

Since

2.9.0

template<typename EventTag , typename Class , typename EventArg , typename EventHandler > void wxEvtHandler::Bind (const EventTag & *eventType*, void(Class::*)(EventArg &) *method*, EventHandler * *handler*, int *id* = wxID_ANY, int *lastId* = wxID_ANY, wxObject * *userData* = NULL)

See the Bind<>(const EventTag&, Functor, int, int, wxObject*) overload for more info.

This overload will bind the given method as the event handler.

Parameters

eventType	The event type to be associated with this event handler.
method	The event handler method. This can be an arbitrary method (doesn't need to be from a wxEvtHandler derived class).
handler	Object whose method should be called. It must always be specified so it can be checked at compile time whether the given method is an actual member of the given handler.
id	The first ID of the identifier range to be associated with the event handler.
lastId	The last ID of the identifier range to be associated with the event handler.
userData	Optional data to be associated with the event table entry. wxWidgets will take ownership of this pointer, i.e. it will be destroyed when the event handler is disconnected or at the program termination. This pointer can be retrieved using wxEvent::GetEventUserData() later.

See also

Caveats When Not Using C++ RTTI

Since

2.9.0

template<typename T , typename T1 , ... > void wxEvtHandler::CallAfter (void(T::*)(T1,...) *method,* T1 *x1,* ...)

Asynchronously call the given method.

Calling this function on an object schedules an asynchronous call to the method specified as CallAfter() argument at a (slightly) later time. This is useful when processing some events as certain actions typically can't be performed inside their handlers, e.g. you shouldn't show a modal dialog from a mouse click event handler as this would break the mouse capture state – but you can call a method showing this message dialog after the current event handler completes.

The method being called must be the method of the object on which CallAfter() itself is called.

Notice that it is safe to use CallAfter() from other, non-GUI, threads, but that the method will be always called in the main, GUI, thread context.

Example of use:

```
class MyFrame : public wxFrame {
   void OnClick(wxMouseEvent& event) {
       CallAfter(&MyFrame::ShowPosition, event.GetPosition());
   }

   void ShowPosition(const wxPoint& pos) {
       if ( wxMessageBox(
               wxString::Format("Perform click at (%d, %d)?",
                                pos.x, pos.y), "", wxYES_NO) == wxYES )
       {
           ... do take this click into account ...
       }
   }
};
```

Parameters

method	The method to call.
x1	The (optional) first parameter to pass to the method. Currently, 0, 1 or 2 parameters can be passed. If you need to pass more than 2 arguments, you can use the CallAfter<T>(const T& fn) overload that can call any functor.

Note

This method is not available with Visual C++ before version 8 (Visual Studio 2005) as earlier versions of the compiler don't have the required support for C++ templates to implement it.

Since

2.9.5

template<typename T > void wxEvtHandler::CallAfter (const T & *functor*)

Asynchronously call the given functor.

Calling this function on an object schedules an asynchronous call to the functor specified as CallAfter() argument at a (slightly) later time. This is useful when processing some events as certain actions typically can't be performed inside their handlers, e.g. you shouldn't show a modal dialog from a mouse click event handler as this would break the mouse capture state – but you can call a function showing this message dialog after the current event handler completes.

Notice that it is safe to use CallAfter() from other, non-GUI, threads, but that the method will be always called in the main, GUI, thread context.

This overload is particularly useful in combination with C++11 lambdas:

```
wxGetApp().CallAfter([]{
    wxBell();
});
```

Parameters

functor	The functor to call.

Note

This method is not available with Visual C++ before version 8 (Visual Studio 2005) as earlier versions of the compiler don't have the required support for C++ templates to implement it.

Since

3.0

void wxEvtHandler::Connect (int *id,* int *lastId,* wxEventType *eventType,* wxObjectEventFunction *function,* wxObject * *userData* = NULL, wxEvtHandler * *eventSink* = NULL)

Connects the given function dynamically with the event handler, id and event type.

Notice that Bind() provides a more flexible and safer way to do the same thing as Connect(), please use it in any new code – while Connect() is not formally deprecated due to its existing widespread usage, it has no advantages compared to Bind().

This is an alternative to the use of static event tables. It is more flexible as it allows to connect events generated by some object to an event handler defined in a different object of a different class (which is impossible to do directly with the event tables – the events can be only handled in another object if they are propagated upwards to it). Do make sure to specify the correct *eventSink* when connecting to an event of a different object.

See Dynamic Event Handling for more detailed explanation of this function and the Event Sample sample for usage examples.

This specific overload allows you to connect an event handler to a *range* of *source* IDs. Do not confuse *source* IDs with event *types:* source IDs identify the event generator objects (typically wxMenuItem or wxWindow objects) while the event *type* identify which type of events should be handled by the given *function* (an event generator object may generate many different types of events!).

Parameters

id	The first ID of the identifier range to be associated with the event handler function.
lastId	The last ID of the identifier range to be associated with the event handler function.
eventType	The event type to be associated with this event handler.
function	The event handler function. Note that this function should be explicitly converted to the correct type which can be done using a macro called `wxFooEventHandler` for the handler for any `wxFooEvent`.
userData	Optional data to be associated with the event table entry. wxWidgets will take ownership of this pointer, i.e. it will be destroyed when the event handler is disconnected or at the program termination. This pointer can be retrieved using wxEvent::GetEventUserData() later.
eventSink	Object whose member function should be called. It must be specified when connecting an event generated by one object to a member function of a different object. If it is omitted, `this` is used.

wxPerl Note: In wxPerl this function takes 4 arguments: *id*, *lastid*, *type*, *method*; if *method* is undef, the handler is disconnected.}

See also

Bind<>()

void wxEvtHandler::Connect (int *id*, wxEventType *eventType*, wxObjectEventFunction *function*, wxObject * *userData* = NULL, wxEvtHandler * *eventSink* = NULL)

See the Connect(int, int, wxEventType, wxObjectEventFunction, wxObject*, wxEvtHandler*) overload for more info.

This overload can be used to attach an event handler to a single source ID:

Example:

```
frame->Connect( wxID_EXIT,
                wxEVT_MENU,
                wxCommandEventHandler(MyFrame::OnQuit) );
```

wxPerl Note: Not supported by wxPerl.

void wxEvtHandler::Connect (wxEventType *eventType*, wxObjectEventFunction *function*, wxObject * *userData* = NULL, wxEvtHandler * *eventSink* = NULL)

See the Connect(int, int, wxEventType, wxObjectEventFunction, wxObject*, wxEvtHandler*) overload for more info.

This overload will connect the given event handler so that regardless of the ID of the event source, the handler will be called.

wxPerl Note: Not supported by wxPerl.

void wxEvtHandler::DeletePendingEvents ( )

Deletes all events queued on this event handler using QueueEvent() or AddPendingEvent().

Use with care because the events which are deleted are (obviously) not processed and this may have unwanted consequences (e.g. user actions events will be lost).

bool wxEvtHandler::Disconnect (wxEventType *eventType*, wxObjectEventFunction *function*, wxObject * *userData* = NULL, wxEvtHandler * *eventSink* = NULL)

Disconnects the given function dynamically from the event handler, using the specified parameters as search criteria and returning true if a matching function has been found and removed.

This method can only disconnect functions which have been added using the Connect() method. There is no way to disconnect functions connected using the (static) event tables.

Parameters

eventType	The event type associated with this event handler.
function	The event handler function.
userData	Data associated with the event table entry.
eventSink	Object whose member function should be called.

wxPerl Note: Not supported by wxPerl.

bool wxEvtHandler::Disconnect (int *id* = wxID_ANY, wxEventType *eventType* = wxEVT_NULL, wxObjectEventFunction *function* = NULL, wxObject * *userData* = NULL, wxEvtHandler * *eventSink* = NULL)

See the Disconnect(wxEventType, wxObjectEventFunction, wxObject*, wxEvtHandler*) overload for more info.

This overload takes the additional *id* parameter.

wxPerl Note: Not supported by wxPerl.

bool wxEvtHandler::Disconnect (int *id*, int *lastId*, wxEventType *eventType*, wxObjectEventFunction *function* = NULL, wxObject * *userData* = NULL, wxEvtHandler * *eventSink* = NULL)

See the Disconnect(wxEventType, wxObjectEventFunction, wxObject*, wxEvtHandler*) overload for more info.

This overload takes an additional range of source IDs.

wxPerl Note: In wxPerl this function takes 3 arguments: *id*, *lastid*, *type*.

void* wxEvtHandler::GetClientData ( ) const

Returns user-supplied client data.

Remarks

Normally, any extra data the programmer wishes to associate with the object should be made available by deriving a new class with new data members.

See also

SetClientData()

wxClientData* wxEvtHandler::GetClientObject ( ) const

Returns a pointer to the user-supplied client data object.

See also

SetClientObject(), wxClientData

bool wxEvtHandler::GetEvtHandlerEnabled ( ) const

Returns true if the event handler is enabled, false otherwise.

See also

SetEvtHandlerEnabled()

wxEvtHandler* wxEvtHandler::GetNextHandler ( ) const

Returns the pointer to the next handler in the chain.

See also

SetNextHandler(), GetPreviousHandler(), SetPreviousHandler(), wxWindow::PushEventHandler, wxWindow::PopEventHandler

wxEvtHandler* wxEvtHandler::GetPreviousHandler ( ) const

Returns the pointer to the previous handler in the chain.

See also

SetPreviousHandler(), GetNextHandler(), SetNextHandler(), wxWindow::PushEventHandler, wxWindow::PopEventHandler

bool wxEvtHandler::IsUnlinked ( ) const

Returns true if the next and the previous handler pointers of this event handler instance are NULL.

Since

2.9.0

See also

SetPreviousHandler(), SetNextHandler()

virtual bool wxEvtHandler::ProcessEvent (wxEvent & *event*) [virtual]

Processes an event, searching event tables and calling zero or more suitable event handler function(s).

Normally, your application would not call this function: it is called in the wxWidgets implementation to dispatch incoming user interface events to the framework (and application).

However, you might need to call it if implementing new functionality (such as a new control) where you define new event types, as opposed to allowing the user to override virtual functions.

Notice that you don't usually need to override ProcessEvent() to customize the event handling, overriding the specially provided TryBefore() and TryAfter() functions is usually enough. For example, wxMDIParentFrame may override TryBefore() to ensure that the menu events are processed in the active child frame before being processed in the parent frame itself.

The normal order of event table searching is as follows:

1. wxApp::FilterEvent() is called. If it returns anything but `-1` (default) the processing stops here.
2. TryBefore() is called (this is where wxValidator are taken into account for wxWindow objects). If this returns true, the function exits.
3. If the object is disabled (via a call to wxEvtHandler::SetEvtHandlerEnabled) the function skips to step (7).
4. Dynamic event table of the handlers bound using Bind<>() is searched in the most-recently-bound to the most-early-bound order. If a handler is found, it is executed and the function returns true unless the handler used wxEvent::Skip() to indicate that it didn't handle the event in which case the search continues.

5. Static events table of the handlers bound using event table macros is searched for this event handler in the order of appearance of event table macros in the source code. If this fails, the base class event table is tried, and so on until no more tables exist or an appropriate function was found. If a handler is found, the same logic as in the previous step applies.
6. The search is applied down the entire chain of event handlers (usually the chain has a length of one). This chain can be formed using wxEvtHandler::SetNextHandler(): (referring to the image, if `A->ProcessEvent` is called and it doesn't handle the event, `B->ProcessEvent` will be called and so on...). Note that in the case of wxWindow you can build a stack of event handlers (see wxWindow::PushEventHandler() for more info). If any of the handlers of the chain return true, the function exits.
7. TryAfter() is called: for the wxWindow object this may propagate the event to the window parent (recursively). If the event is still not processed, ProcessEvent() on wxTheApp object is called as the last step.

Notice that steps (2)-(6) are performed in ProcessEventLocally() which is called by this function.

Parameters

event	Event to process.

Returns

true if a suitable event handler function was found and executed, and the function did not call wxEvent::Skip.

See also

SearchEventTable()

Reimplemented in wxWindow.

bool wxEvtHandler::ProcessEventLocally (wxEvent & *event*)

Try to process the event in this handler and all those chained to it.

As explained in ProcessEvent() documentation, the event handlers may be chained in a doubly-linked list. This function tries to process the event in this handler (including performing any pre-processing done in TryBefore(), e.g. applying validators) and all those following it in the chain until the event is processed or the chain is exhausted.

This function is called from ProcessEvent() and, in turn, calls TryBefore() and TryAfter(). It is not virtual and so cannot be overridden but can, and should, be called to forward an event to another handler instead of ProcessEvent() which would result in a duplicate call to TryAfter(), e.g. resulting in all unprocessed events being sent to the application object multiple times.

Since

2.9.1

Parameters

event	Event to process.

Returns

true if this handler of one of those chained to it processed the event.

void wxEvtHandler::ProcessPendingEvents ( )

Processes the pending events previously queued using QueueEvent() or AddPendingEvent(); you must call this function only if you are sure there are pending events for this handler, otherwise a `wxCHECK` will fail.

The real processing still happens in ProcessEvent() which is called by this function.

Note that this function needs a valid application object (see wxAppConsole::GetInstance()) because wxApp holds the list of the event handlers with pending events and this function manipulates that list.

virtual void wxEvtHandler::QueueEvent (wxEvent * *event*) [virtual]

Queue event for a later processing.

This method is similar to ProcessEvent() but while the latter is synchronous, i.e. the event is processed immediately, before the function returns, this one is asynchronous and returns immediately while the event will be processed at some later time (usually during the next event loop iteration).

Another important difference is that this method takes ownership of the *event* parameter, i.e. it will delete it itself. This implies that the event should be allocated on the heap and that the pointer can't be used any more after the function returns (as it can be deleted at any moment).

QueueEvent() can be used for inter-thread communication from the worker threads to the main thread, it is safe in the sense that it uses locking internally and avoids the problem mentioned in AddPendingEvent() documentation by ensuring that the *event* object is not used by the calling thread any more. Care should still be taken to avoid that some fields of this object are used by it, notably any wxString members of the event object must not be shallow copies of another wxString object as this would result in them still using the same string buffer behind the scenes. For example:

```
void FunctionInAWorkerThread(const wxString& str)
{
    wxCommandEvent* evt = new wxCommandEvent;

    // NOT evt->SetString(str) as this would be a shallow copy
    evt->SetString(str.c_str()); // make a deep copy

    wxTheApp->QueueEvent( evt );
}
```

Note that you can use wxThreadEvent instead of wxCommandEvent to avoid this problem:

```
void FunctionInAWorkerThread(const wxString& str)
{
    wxThreadEvent evt;
    evt.SetString(str);

    // wxThreadEvent::Clone() makes sure that the internal wxString
    // member is not shared by other wxString instances:
    wxTheApp->QueueEvent( evt.Clone() );
}
```

Finally notice that this method automatically wakes up the event loop if it is currently idle by calling wxWakeUpIdle() so there is no need to do it manually when using it.

Since

2.9.0

Parameters

event	A heap-allocated event to be queued, QueueEvent() takes ownership of it. This parameter shouldn't be NULL.

Reimplemented in wxWindow.

static void wxEvtHandler::RemoveFilter (wxEventFilter * *filter*) [static]

Remove a filter previously installed with AddFilter().

It's an error to remove a filter that hadn't been previously added or was already removed.

Since

2.9.3

bool wxEvtHandler::SafelyProcessEvent (wxEvent & *event*)

Processes an event by calling ProcessEvent() and handles any exceptions that occur in the process.

If an exception is thrown in event handler, wxApp::OnExceptionInMainLoop is called.

Parameters

event	Event to process.

Returns

true if the event was processed, false if no handler was found or an exception was thrown.

See also

wxWindow::HandleWindowEvent

virtual bool wxEvtHandler::SearchEventTable (wxEventTable & *table,* wxEvent & *event*) [virtual]

Searches the event table, executing an event handler function if an appropriate one is found.

Parameters

table	Event table to be searched.
event	Event to be matched against an event table entry.

Returns

true if a suitable event handler function was found and executed, and the function did not call wxEvent::Skip.

Remarks

This function looks through the object's event table and tries to find an entry that will match the event. An entry will match if:

- The event type matches, and
- the identifier or identifier range matches, or the event table entry's identifier is zero.

If a suitable function is called but calls wxEvent::Skip, this function will fail, and searching will continue.

Todo this function in the header is listed as an "implementation only" function; are we sure we want to document it?

See also

ProcessEvent()

void wxEvtHandler::SetClientData (void * *data*)

Sets user-supplied client data.

Parameters

data	Data to be associated with the event handler.

Remarks

Normally, any extra data the programmer wishes to associate with the object should be made available by deriving a new class with new data members. You must not call this method and SetClientObject on the same class - only one of them.

See also

GetClientData()

void wxEvtHandler::SetClientObject (wxClientData * *data*)

Set the client data object.

Any previous object will be deleted.

See also

GetClientObject(), wxClientData

void wxEvtHandler::SetEvtHandlerEnabled (bool *enabled*)

Enables or disables the event handler.

Parameters

enabled	true if the event handler is to be enabled, false if it is to be disabled.

Remarks

You can use this function to avoid having to remove the event handler from the chain, for example when implementing a dialog editor and changing from edit to test mode.

See also

GetEvtHandlerEnabled()

virtual void wxEvtHandler::SetNextHandler (wxEvtHandler * *handler*) [virtual]

Sets the pointer to the next handler.

Remarks

See ProcessEvent() for more info about how the chains of event handlers are internally used. Also remember that wxEvtHandler uses double-linked lists and thus if you use this function, you should also call SetPrevious↩ Handler() on the argument passed to this function:

```
handlerA->SetNextHandler(handlerB);
handlerB->SetPreviousHandler(handlerA);
```

Parameters

handler	The event handler to be set as the next handler. Cannot be NULL.

See also

How Events are Processed

Reimplemented in wxWindow.

virtual void wxEvtHandler::SetPreviousHandler (wxEvtHandler * *handler*) [virtual]

Sets the pointer to the previous handler.

All remarks about SetNextHandler() apply to this function as well.

Parameters

handler	The event handler to be set as the previous handler. Cannot be NULL.

See also

How Events are Processed

Reimplemented in wxWindow.

virtual bool wxEvtHandler::TryAfter (wxEvent & *event*) [protected], [virtual]

Method called by ProcessEvent() as last resort.

This method can be overridden to implement post-processing for the events which were not processed anywhere else.

The base class version handles forwarding the unprocessed events to wxApp at wxEvtHandler level and propagating them upwards the window child-parent chain at wxWindow level and so should usually be called when overriding this method:

```
class MyClass : public BaseClass // inheriting from wxEvtHandler
{
...
protected:
    virtual bool TryAfter(wxEvent& event)
    {
        if ( BaseClass::TryAfter(event) )
            return true;

        return MyPostProcess(event);
    }
};
```

See also

ProcessEvent()

virtual bool wxEvtHandler::TryBefore (wxEvent & *event*) [protected], [virtual]

Method called by ProcessEvent() before examining this object event tables.

This method can be overridden to hook into the event processing logic as early as possible. You should usually call the base class version when overriding this method, even if wxEvtHandler itself does nothing here, some derived classes do use this method, e.g. wxWindow implements support for wxValidator in it.

Example:

```
class MyClass : public BaseClass // inheriting from wxEvtHandler
{
...
protected:
    virtual bool TryBefore(wxEvent& event)
    {
        if ( MyPreProcess(event) )
            return true;

        return BaseClass::TryBefore(event);
    }
};
```

See also

ProcessEvent()

template<typename EventTag , typename Functor > bool wxEvtHandler::Unbind (const EventTag & *eventType*, Functor *functor*, int *id* = wxID_ANY, int *lastId* = wxID_ANY, wxObject * *userData* = NULL)

Unbinds the given function, functor or method dynamically from the event handler, using the specified parameters as search criteria and returning true if a matching function has been found and removed.

This method can only unbind functions, functors or methods which have been added using the Bind<>() method. There is no way to unbind functions bound using the (static) event tables.

Note

Currently functors are compared by their address which, unfortunately, doesn't work correctly if the same address is reused for two different functor objects. Because of this, using Unbind() is not recommended if there are multiple functors using the same *eventType* and *id* and *lastId* as a wrong one could be unbound.

Parameters

eventType	The event type associated with this event handler.
functor	The event handler functor. This can be an ordinary function but also an arbitrary functor like boost::function<>.
id	The first ID of the identifier range associated with the event handler.
lastId	The last ID of the identifier range associated with the event handler.
userData	Data associated with the event table entry.

See also

Caveats When Not Using C++ RTTI

Since

2.9.0

template<typename EventTag , typename Class , typename EventArg , typename EventHandler > bool wxEvtHandler::Unbind (const EventTag & *eventType*, void(Class::*)(EventArg &) *method*, EventHandler * *handler*, int *id* = wxID_ANY, int *lastId* = wxID_ANY, wxObject * *userData* = NULL)

See the Unbind<>(const EventTag&, Functor, int, int, wxObject*) overload for more info.

This overload unbinds the given method from the event..

Parameters

eventType	The event type associated with this event handler.
method	The event handler method associated with this event.
handler	Object whose method was called.
id	The first ID of the identifier range associated with the event handler.
lastId	The last ID of the identifier range associated with the event handler.
userData	Data associated with the event table entry.

See also

Caveats When Not Using C++ RTTI

Since

2.9.0

void wxEvtHandler::Unlink ( )

Unlinks this event handler from the chain it's part of (if any); then links the "previous" event handler to the "next" one (so that the chain won't be interrupted).

E.g. if before calling Unlink() you have the following chain: then after calling `B->Unlink()` you'll have:

Since

2.9.0

21.223 wxExecuteEnv Struct Reference

```
#include <wx/utils.h>
```

21.223.1 Detailed Description

This structure can optionally be passed to wxExecute() to specify additional options to use for the child process.

Since

2.9.2

Include file:

```
#include <wx/utils.h>
```

Public Attributes

- wxString cwd

  The initial working directory for the new process.

- wxEnvVariableHashMap env

  The environment variable map.

21.223.2 Member Data Documentation

wxString wxExecuteEnv::cwd

The initial working directory for the new process.

If this field is empty, the current working directory of this process is used.

wxEnvVariableHashMap wxExecuteEnv::env

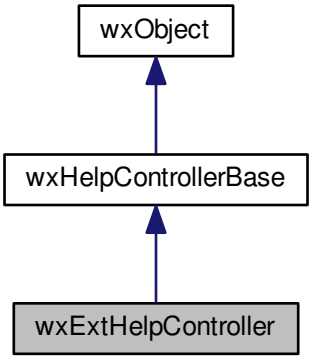
The environment variable map.

If the map is empty, the environment variables of the current process are also used for the child one, otherwise only the variables defined in this map are used.

21.224 wxExtHelpController Class Reference

`#include <wx/generic/helpext.h>`

Inheritance diagram for wxExtHelpController:



21.224.1 Detailed Description

This class implements help via an external browser.

It requires the name of a directory containing the documentation and a file mapping numerical Section numbers to relative URLS.

The map file contains two or three fields per line: numeric_id relative_URL [; comment/documentation]

The numeric_id is the id used to look up the entry in DisplaySection()/DisplayBlock(). The relative_URL is a filename of an html file, relative to the help directory. The optional comment/documentation field (after a ';') is used for keyword searches, so some meaningful text here does not hurt. If the documentation itself contains a ';', only the part before that will be displayed in the listbox, but all of it used for search.

Lines starting with ';' will be ignored.

Library: wxAdvanced

Category: Help

wxHelpController

Public Member Functions

- wxExtHelpController (wxWindow *parentWindow=NULL)
- virtual ~wxExtHelpController ()
- virtual void SetViewer (const wxString &viewer=wxEmptyString, long flags=wxHELP_NETSCAPE)

  Tell it which browser to use.
- virtual bool Initialize (const wxString &dir)

  This must be called to tell the controller where to find the documentation.
- virtual bool LoadFile (const wxString &file=wxEmptyString)

  If file is "", reloads file given in Initialize.
- virtual bool DisplayContents ()

  Display list of all help entries.
- virtual bool DisplaySection (int sectionNo)

  Display help for id sectionNo.
- virtual bool DisplaySection (const wxString &section)

  Display help for id sectionNo – identical with DisplaySection().
- virtual bool DisplayBlock (long blockNo)

  Display help for URL (using DisplayHelp) or keyword (using KeywordSearch)
- virtual bool KeywordSearch (const wxString &k, wxHelpSearchMode mode=wxHELP_SEARCH_ALL)

  Search comment/documentation fields in map file and present a list to chose from.
- virtual bool Quit ()

  Does nothing.
- virtual void OnQuit ()

  Does nothing.
- virtual bool DisplayHelp (const wxString &relativeURL)

  Call the browser using a relative URL.
- virtual void SetFrameParameters (const wxString &titleFormat, const wxSize &size, const wxPoint &pos=wxDefaultPosition, bool newFrameEachTime=false)

  Allows one to override the default settings for the help frame.
- virtual wxFrame * GetFrameParameters (wxSize *size=NULL, wxPoint *pos=NULL, bool *newFrameEachTime=NULL)

  Obtains the latest settings used by the help frame and the help frame.

Additional Inherited Members

21.224.2 Constructor & Destructor Documentation

wxExtHelpController::wxExtHelpController (wxWindow * *parentWindow* = `NULL`)

virtual wxExtHelpController::~wxExtHelpController ( ) `[virtual]`

21.224.3 Member Function Documentation

virtual bool wxExtHelpController::DisplayBlock (long *blockNo*) `[virtual]`

Display help for URL (using DisplayHelp) or keyword (using KeywordSearch)

Returns

true on success

Implements wxHelpControllerBase.

virtual bool wxExtHelpController::DisplayContents ( ) `[virtual]`

Display list of all help entries.

Returns

true on success

Implements wxHelpControllerBase.

virtual bool wxExtHelpController::DisplayHelp (const wxString & *relativeURL*) `[virtual]`

Call the browser using a relative URL.

virtual bool wxExtHelpController::DisplaySection (int *sectionNo*) `[virtual]`

Display help for id sectionNo.

Returns

true on success

Implements wxHelpControllerBase.

virtual bool wxExtHelpController::DisplaySection (const wxString & *section*) `[virtual]`

Display help for id sectionNo – identical with DisplaySection().

Returns

true on success

Reimplemented from wxHelpControllerBase.

virtual wxFrame* wxExtHelpController::GetFrameParameters (wxSize * *size* = NULL, wxPoint * *pos* = NULL, bool * *newFrameEachTime* = NULL) `[virtual]`

Obtains the latest settings used by the help frame and the help frame.

Reimplemented from wxHelpControllerBase.

virtual bool wxExtHelpController::Initialize (const wxString & *dir*) `[virtual]`

This must be called to tell the controller where to find the documentation.

If a locale is set, look in file/localename, i.e. If passed "/usr/local/myapp/help" and the current wxLocale is set to be "de", then look in "/usr/local/myapp/help/de/" first and fall back to "/usr/local/myapp/help" if that doesn't exist.

Parameters

dir	directory name where to fine the help files

Returns

true on success

Reimplemented from wxHelpControllerBase.

virtual bool wxExtHelpController::KeywordSearch (const wxString & *k*, wxHelpSearchMode *mode* = wxHELP_SEARCH_ALL) [virtual]

Search comment/documentation fields in map file and present a list to chose from.

Parameters

k	string to search for, empty string will list all entries
mode	optional parameter allows the search the index (wxHELP_SEARCH_INDEX) but this currently only supported by the wxHtmlHelpController.

Returns

true on success

Implements wxHelpControllerBase.

virtual bool wxExtHelpController::LoadFile (const wxString & *file* = wxEmptyString) [virtual]

If file is "", reloads file given in Initialize.

Parameters

file	Name of help directory.

Returns

true on success

Implements wxHelpControllerBase.

virtual void wxExtHelpController::OnQuit ( ) [virtual]

Does nothing.

Reimplemented from wxHelpControllerBase.

virtual bool wxExtHelpController::Quit ( ) [virtual]

Does nothing.

Implements wxHelpControllerBase.

virtual void wxExtHelpController::SetFrameParameters (const wxString & *titleFormat*, const wxSize & *size*, const wxPoint & *pos* = wxDefaultPosition, bool *newFrameEachTime* = false) [virtual]

Allows one to override the default settings for the help frame.

Reimplemented from wxHelpControllerBase.

virtual void wxExtHelpController::SetViewer (const wxString & *viewer* = wxEmptyString, long *flags* = wxHELP_NETSCAPE) [virtual]

Tell it which browser to use.

The Netscape support will check whether Netscape is already running (by looking at the .netscape/lock file in the user's home directory) and tell it to load the page into the existing window.

Parameters

viewer	The command to call a browser/html viewer.
flags	Set this to wxHELP_NETSCAPE if the browser is some variant of Netscape.

Reimplemented from wxHelpControllerBase.

21.225 wxFFile Class Reference

`#include <wx/ffile.h>`

21.225.1 Detailed Description

wxFFile implements buffered file I/O.

This is a very small class designed to minimize the overhead of using it - in fact, there is hardly any overhead at all, but using it brings you automatic error checking and hides differences between platforms and compilers.

It wraps inside it a `FILE *` handle used by standard C IO library (also known as `stdio`).

Library: wxBase

Category: File Handling

wxFFile::IsOpened

Public Member Functions

- wxFFile ()
- wxFFile (FILE *fp)

  Opens a file with the given file pointer, which has already been opened.
- wxFFile (const wxString &filename, const wxString &mode="r")

  Opens a file with the given mode.
- ~wxFFile ()

  Destructor will close the file.
- void Attach (FILE *fp, const wxString &name=wxEmptyString)

  Attaches an existing file pointer to the wxFFile object.
- bool Close ()

  Closes the file and returns true on success.
- FILE * Detach ()

  Get back a file pointer from wxFFile object – the caller is responsible for closing the file if this descriptor is opened.
- bool Eof () const

  Returns true if an attempt has been made to read past the end of the file.

- bool Error () const

  Returns true if an error has occurred on this file, similar to the standard `ferror()` function.
- bool Flush ()

  Flushes the file and returns true on success.
- wxFileKind GetKind () const

  Returns the type of the file.
- const wxString & GetName () const

  Returns the file name.
- bool IsOpened () const

  Returns true if the file is opened.
- wxFileOffset Length () const

  Returns the length of the file.
- bool Open (const wxString &filename, const wxString &mode="r")

  Opens the file, returning true if successful.
- size_t Read (void ∗buffer, size_t count)

  Reads the specified number of bytes into a buffer, returning the actual number read.
- bool ReadAll (wxString ∗str, const wxMBConv &conv=wxConvAuto())

  Reads the entire contents of the file into a string.
- bool Seek (wxFileOffset ofs, wxSeekMode mode=wxFromStart)

  Seeks to the specified position and returns true on success.
- bool SeekEnd (wxFileOffset ofs=0)

  Moves the file pointer to the specified number of bytes before the end of the file and returns true on success.
- wxFileOffset Tell () const

  Returns the current position.
- bool Write (const wxString &str, const wxMBConv &conv=wxConvAuto())

  Writes the contents of the string to the file, returns true on success.
- size_t Write (const void ∗buffer, size_t count)

  Writes the specified number of bytes from a buffer.
- FILE ∗ fp () const

  Returns the file pointer associated with the file.

21.225.2 Constructor & Destructor Documentation

wxFFile::wxFFile ( )

wxFFile::wxFFile (FILE ∗ *fp*)

Opens a file with the given file pointer, which has already been opened.

Parameters

fp	An existing file descriptor, such as stderr.

wxFFile::wxFFile (const wxString & *filename*, const wxString & *mode* = "r")

Opens a file with the given mode.

As there is no way to return whether the operation was successful or not from the constructor you should test the return value of IsOpened() to check that it didn't fail.

Parameters

filename	The filename.
mode	The mode in which to open the file using standard C strings. Note that you should use "b" flag if you use binary files under Windows or the results might be unexpected due to automatic newline conversion done for the text files.

wxFFile::~wxFFile ( )

Destructor will close the file.

Note

it is not virtual so you should *not* derive from wxFFile!

21.225.3 Member Function Documentation

void wxFFile::Attach (FILE * *fp*, const wxString & *name* = wxEmptyString)

Attaches an existing file pointer to the wxFFile object.

The descriptor should be already opened and it will be closed by wxFFile object.

bool wxFFile::Close ( )

Closes the file and returns true on success.

FILE* wxFFile::Detach ( )

Get back a file pointer from wxFFile object – the caller is responsible for closing the file if this descriptor is opened.

IsOpened() will return false after call to Detach().

Returns

The FILE pointer (this is new since wxWidgets 3.0.0, in the previous versions this method didn't return anything).

bool wxFFile::Eof ( ) const

Returns true if an attempt has been made to read *past* the end of the file.

Note that the behaviour of the file descriptor based class wxFile is different as wxFile::Eof() will return true here as soon as the last byte of the file has been read.

Also note that this method may only be called for opened files and may crash if the file is not opened.

Todo THIS METHOD MAY CRASH? DOESN'T SOUND GOOD

See also

IsOpened()

bool wxFFile::Error ( ) const

Returns true if an error has occurred on this file, similar to the standard `ferror()` function.

Please note that this method may only be called for opened files and may crash if the file is not opened.

Todo THIS METHOD MAY CRASH? DOESN'T SOUND GOOD

See also

IsOpened()

bool wxFFile::Flush ( )

Flushes the file and returns true on success.

FILE* wxFFile::fp ( ) const

Returns the file pointer associated with the file.

wxFileKind wxFFile::GetKind ( ) const

Returns the type of the file.

See also

wxFileKind

const wxString& wxFFile::GetName ( ) const

Returns the file name.

This is the name that was specified when the object was constructed or to the last call to Open(). Notice that it may be empty if Attach() was called without specifying the name.

bool wxFFile::IsOpened ( ) const

Returns true if the file is opened.

Most of the methods of this class may only be used for an opened file.

wxFileOffset wxFFile::Length ( ) const

Returns the length of the file.

bool wxFFile::Open (const wxString & *filename*, const wxString & *mode* = "r")

Opens the file, returning true if successful.

Parameters

filename	The filename.
mode	The mode in which to open the file.

size_t wxFFile::Read (void * *buffer,* size_t *count*)

Reads the specified number of bytes into a buffer, returning the actual number read.

Parameters

buffer	A buffer to receive the data.
count	The number of bytes to read.

Returns

The number of bytes read.

bool wxFFile::ReadAll (wxString * *str,* const wxMBConv & *conv* = wxConvAuto ())

Reads the entire contents of the file into a string.

Parameters

str	String to read data into.
conv	Conversion object to use in Unicode build; by default supposes that file contents is encoded in UTF-8.

Returns

true if file was read successfully, false otherwise.

bool wxFFile::Seek (wxFileOffset *ofs,* wxSeekMode *mode* = wxFromStart)

Seeks to the specified position and returns true on success.

Parameters

ofs	Offset to seek to.
mode	One of wxFromStart, wxFromEnd, wxFromCurrent.

bool wxFFile::SeekEnd (wxFileOffset *ofs* = 0)

Moves the file pointer to the specified number of bytes before the end of the file and returns true on success.

Parameters

ofs	Number of bytes before the end of the file.

wxFileOffset wxFFile::Tell ( ) const

Returns the current position.

bool wxFFile::Write (const wxString & *str,* const wxMBConv & *conv* = wxConvAuto())

Writes the contents of the string to the file, returns true on success.

The second argument is only meaningful in Unicode build of wxWidgets when *conv* is used to convert *str* to multibyte representation.

size_t wxFFile::Write (const void * *buffer,* size_t *count*)

Writes the specified number of bytes from a buffer.

Parameters

buffer	A buffer containing the data.
count	The number of bytes to write.

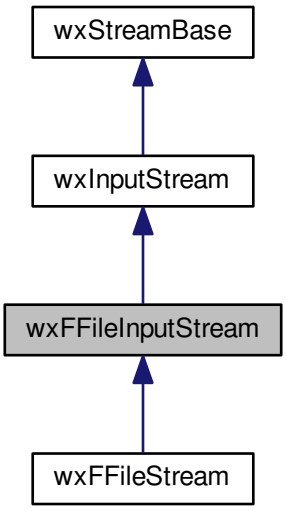
Returns

The number of bytes written.

21.226 wxFFileInputStream Class Reference

`#include <wx/wfstream.h>`

Inheritance diagram for wxFFileInputStream:



21.226.1 Detailed Description

This class represents data read in from a file.

There are actually two such groups of classes: this one is based on wxFFile whereas wxFileInputStream is based in the wxFile class.

Note that wxInputStream::SeekI() can seek beyond the end of the stream (file) and will thus not return wxInvalidOffset for that.

Library: wxBase

wxFFileInputStream, wxFFileOutputStream, wxFileStream

Public Member Functions

- wxFFileStream (const wxString &iofileName, const wxString &mode="w+b")

  Initializes a new file stream in the given mode using the specified iofileName name.
- bool IsOk () const

  Returns true if the stream is initialized and ready.

Additional Inherited Members

21.228.2 Constructor & Destructor Documentation

wxFFileStream::wxFFileStream (const wxString & *iofileName,* const wxString & *mode* = "w+b")

Initializes a new file stream in the given *mode* using the specified *iofileName* name.

Warning

You should use wxStreamBase::IsOk() to verify if the constructor succeeded.

21.228.3 Member Function Documentation

bool wxFFileStream::IsOk ( ) const [virtual]

Returns true if the stream is initialized and ready.

This method returns true if the stream can be both read from and written to.

Reimplemented from wxFFileOutputStream.

21.229 wxFile Class Reference

`#include <wx/file.h>`

21.229.1 Detailed Description

A wxFile performs raw file I/O.

This is a very small class designed to minimize the overhead of using it - in fact, there is hardly any overhead at all, but using it brings you automatic error checking and hides differences between platforms and compilers. wxFile also automatically closes the file in its destructor so you won't forget to do so. wxFile is a wrapper around `file` descriptor. - see also wxFFile for a wrapper around `FILE` structure.

wxFileOffset is used by the wxFile functions which require offsets as parameter or return them. If the platform supports it, wxFileOffset is a typedef for a native 64 bit integer, otherwise a 32 bit integer is used for wxFileOffset.

Library: wxBase

Category: File Handling

Public Types

- enum OpenMode {
  read,
  write,
  read_write,
  write_append,
  write_excl }

  The OpenMode enumeration defines the different modes for opening a file with wxFile.
- enum {
  fd_invalid = -1,
  fd_stdin,
  fd_stdout,
  fd_stderr }

  Standard file descriptors.

Public Member Functions

- wxFile ()

  Default constructor.
- wxFile (const wxString &filename, wxFile::OpenMode mode=wxFile::read)

  Opens a file with a filename.
- wxFile (int fd)

  Associates the file with the given file descriptor, which has already been opened.
- ~wxFile ()

  Destructor will close the file.
- int GetLastError () const

  Returns the error code for the last unsuccessful operation.
- void ClearLastError ()

  Resets the error code.
- void Attach (int fd)

  Attaches an existing file descriptor to the wxFile object.
- bool Close ()

  Closes the file.
- bool Create (const wxString &filename, bool overwrite=false, int access=wxS_DEFAULT)

  Creates a file for writing.
- int Detach ()

  Get back a file descriptor from wxFile object - the caller is responsible for closing the file if this descriptor is opened.
- bool Eof () const

  Returns true if the end of the file has been reached.
- bool Flush ()

  Flushes the file descriptor.
- wxFileKind GetKind () const

  Returns the type of the file.
- bool IsOpened () const

  Returns true if the file has been opened.
- wxFileOffset Length () const

  Returns the length of the file.
- bool Open (const wxString &filename, wxFile::OpenMode mode=wxFile::read, int access=wxS_DEFAULT)

  Opens the file, returning true if successful.
- ssize_t Read (void *buffer, size_t count)

  Reads from the file into a memory buffer.

- bool ReadAll (wxString *str, const wxMBConv &conv=wxConvAuto())

  Reads the entire contents of the file into a string.
- wxFileOffset Seek (wxFileOffset ofs, wxSeekMode mode=wxFromStart)

  Seeks to the specified position.
- wxFileOffset SeekEnd (wxFileOffset ofs=0)

  Moves the file pointer to the specified number of bytes relative to the end of the file.
- wxFileOffset Tell () const

  Returns the current position or wxInvalidOffset if file is not opened or if another error occurred.
- size_t Write (const void *buffer, size_t count)

  Write data to the file (descriptor).
- bool Write (const wxString &s, const wxMBConv &conv=wxConvUTF8)

  Writes the contents of the string to the file, returns true on success.
- int fd () const

  Returns the file descriptor associated with the file.

Static Public Member Functions

- static bool Access (const wxString &name, wxFile::OpenMode mode)

  This function verifies if we may access the given file in specified mode.
- static bool Exists (const wxString &filename)

  Returns true if the given name specifies an existing regular file (not a directory or a link).

21.229.2 Member Enumeration Documentation

anonymous enum

Standard file descriptors.

Enumerator

fd_invalid

fd_stdin

fd_stdout

fd_stderr

enum wxFile::OpenMode

The OpenMode enumeration defines the different modes for opening a file with wxFile.

It is also used with wxFile::Access function.

Enumerator

read Open file for reading or test if it can be opened for reading with Access()

write Open file for writing deleting the contents of the file if it already exists or test if it can be opened for writing with Access().

read_write Open file for reading and writing; cannot be used with Access()

write_append Open file for appending: the file is opened for writing, but the old contents of the file are not erased and the file pointer is initially placed at the end of the file; cannot be used with Access(). This is the same as OpenMode::write if the file doesn't exist.

write_excl Open the file securely for writing (Uses O_EXCL | O_CREAT). Will fail if the file already exists, else create and open it atomically. Useful for opening temporary files without being vulnerable to race exploits.

21.229.3 Constructor & Destructor Documentation

wxFile::wxFile ( )

Default constructor.

wxFile::wxFile (const wxString & *filename,* wxFile::OpenMode *mode* = wxFile::read)

Opens a file with a filename.

Parameters

filename	The filename.
mode	The mode in which to open the file.

Warning

You should use IsOpened() to verify that the constructor succeeded.

wxFile::wxFile (int *fd*)

Associates the file with the given file descriptor, which has already been opened.

See Attach() for the list of predefined descriptors.

Parameters

fd	An existing file descriptor.

wxFile::~wxFile ( )

Destructor will close the file.

Note

This destructor is not virtual so you should not use wxFile polymorphically.

21.229.4 Member Function Documentation

static bool wxFile::Access (const wxString & *name,* wxFile::OpenMode *mode*) [static]

This function verifies if we may access the given file in specified mode.

Only values of `wxFile::read` or `wxFile::write` really make sense here.

void wxFile::Attach (int *fd*)

Attaches an existing file descriptor to the wxFile object.

Examples of predefined file descriptors are 0, 1 and 2 which correspond to stdin, stdout and stderr (and have symbolic names of `wxFile::fd_stdin`, `wxFile::fd_stdout` and `wxFile::fd_stderr`).

The descriptor should be already opened and it will be closed by wxFile object.

void wxFile::ClearLastError ( )

Resets the error code.

GetLastError() will return 0 until the next error occurs.

Since

2.9.2

bool wxFile::Close ( )

Closes the file.

bool wxFile::Create (const wxString & *filename*, bool *overwrite* = `false`, int *access* = wxS_DEFAULT)

Creates a file for writing.

If the file already exists, setting **overwrite** to true will ensure it is overwritten.

access may be an OR combination of the wxPosixPermissions enumeration values.

int wxFile::Detach ( )

Get back a file descriptor from wxFile object - the caller is responsible for closing the file if this descriptor is opened.

IsOpened() will return false after call to Detach().

Returns

The file descriptor (this is new since wxWidgets 3.0.0, in the previous versions this method didn't return anything).

bool wxFile::Eof ( ) const

Returns true if the end of the file has been reached.

Note that the behaviour of the file pointer-based class wxFFile is different as wxFFile::Eof() will return true here only if an attempt has been made to read **past** the last byte of the file, while wxFile::Eof() will return true even before such attempt is made if the file pointer is at the last position in the file.

Note also that this function doesn't work on unseekable file descriptors (examples include pipes, terminals and sockets under Unix) and an attempt to use it will result in an error message.

So, to read the entire file into memory, you should write a loop which uses Read() repeatedly and tests its return condition instead of using Eof() as this will not work for special files under Unix.

static bool wxFile::Exists (const wxString & *filename*) `[static]`

Returns true if the given name specifies an existing regular file (not a directory or a link).

int wxFile::fd ( ) const

Returns the file descriptor associated with the file.

bool wxFile::Flush ( )

Flushes the file descriptor.

Note that Flush() is not implemented on some Windows compilers due to a missing fsync function, which reduces the usefulness of this function (it can still be called but it will do nothing on unsupported compilers).

wxFileKind wxFile::GetKind ( ) const

Returns the type of the file.

int wxFile::GetLastError ( ) const

Returns the error code for the last unsuccessful operation.

The error code is system-dependent and corresponds to the value of the standard `errno` variable when the last error occurred.

Notice that only simple accessors such as IsOpened() and Eof() (and this method itself) don't modify the last error value, all other methods can potentially change it if an error occurs, including the const ones such as Tell() or Length().

Since

2.9.2

See also

ClearLastError()

bool wxFile::IsOpened ( ) const

Returns true if the file has been opened.

wxFileOffset wxFile::Length ( ) const

Returns the length of the file.

bool wxFile::Open (const wxString & *filename*, wxFile::OpenMode *mode* = wxFile::read, int *access* = wxS_DEFAULT)

Opens the file, returning true if successful.

Parameters

filename	The filename.
mode	The mode in which to open the file.
access	An OR-combination of wxPosixPermissions enumeration values.

ssize_t wxFile::Read (void * *buffer*, size_t *count*)

Reads from the file into a memory buffer.

Parameters

buffer	Buffer to write in
count	Bytes to read

Returns

The number of bytes read, or the symbol wxInvalidOffset.

bool wxFile::ReadAll (wxString * *str*, const wxMBConv & *conv* = wxConvAuto())

Reads the entire contents of the file into a string.

Parameters

str	Non-NULL pointer to a string to read data into.
conv	Conversion object to use in Unicode build; by default supposes that file contents is encoded in UTF-8 but falls back to the current locale encoding (or Latin-1 if it is UTF-8 too) if it is not.

Returns

true if file was read successfully, false otherwise.

Since

2.9.5

wxFileOffset wxFile::Seek (wxFileOffset *ofs*, wxSeekMode *mode* = wxFromStart)

Seeks to the specified position.

Parameters

ofs	Offset to seek to.
mode	One of wxFromStart, wxFromEnd, wxFromCurrent.

Returns

The actual offset position achieved, or wxInvalidOffset on failure.

wxFileOffset wxFile::SeekEnd (wxFileOffset *ofs* = 0)

Moves the file pointer to the specified number of bytes relative to the end of the file.

For example, `SeekEnd`(-5) would position the pointer 5 bytes before the end.

Parameters

ofs	Number of bytes before the end of the file.

Returns

The actual offset position achieved, or wxInvalidOffset on failure.

wxFileOffset wxFile::Tell ( ) const

Returns the current position or wxInvalidOffset if file is not opened or if another error occurred.

size_t wxFile::Write (const void * *buffer*, size_t *count*)

Write data to the file (descriptor).

Parameters

buffer	Buffer from which to read data
count	Number of bytes to write

Returns

The number of bytes written.

bool wxFile::Write (const wxString & *s*, const wxMBConv & *conv* = `wxConvUTF8`)

Writes the contents of the string to the file, returns true on success.

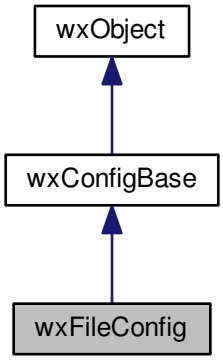
The second argument is only meaningful in Unicode build of wxWidgets when *conv* is used to convert *s* to a multibyte representation.

Note that this method only works with `NUL-terminated` strings, if you want to write data with embedded `NULs` to the file you should use the other Write() overload.

21.230 wxFileConfig Class Reference

`#include <wx/fileconf.h>`

Inheritance diagram for wxFileConfig:



21.230.1 Detailed Description

wxFileConfig implements wxConfigBase interface for storing and retrieving configuration information using plain text files.

The files have a simple format reminiscent of Windows INI files with lines of the form `"key = value"` defining the keys and lines of special form `"[group]"` indicating the start of each group.

This class is used by default for wxConfig on Unix platforms but may also be used explicitly if you want to use files and not the registry even under Windows.

Library: wxBase

Category: Application and System configuration

See also

wxFileConfig::Save

Public Member Functions

- wxFileConfig (const wxString &appName=wxEmptyString, const wxString &vendorName=wxEmptyString, const wxString &localFilename=wxEmptyString, const wxString &globalFilename=wxEmptyString, long style=wxCONFIG_USE_LOCAL_FILE|wxCONFIG_USE_GLOBAL_FILE, const wxMBConv &conv=wxConvAuto())

  Constructor allowing to choose the file names to use.
- wxFileConfig (wxInputStream &is, const wxMBConv &conv=wxConvAuto())

  Read the config data from the specified stream instead of the associated file, as usual.
- virtual bool Save (wxOutputStream &os, const wxMBConv &conv=wxConvAuto())

  Saves all config data to the given stream, returns true if data was saved successfully or false on error.
- void SetUmask (int mode)

  Allows to set the mode to be used for the config file creation.
- virtual void SetPath (const wxString &strPath)

  Set current path: if the first character is '/', it is the absolute path, otherwise it is a relative path.
- virtual const wxString & GetPath () const

  Retrieve the current path (always as absolute path).
- virtual bool GetFirstGroup (wxString &str, long &lIndex) const

  Gets the first group.
- virtual bool GetNextGroup (wxString &str, long &lIndex) const

  Gets the next group.
- virtual bool GetFirstEntry (wxString &str, long &lIndex) const

  Gets the first entry.
- virtual bool GetNextEntry (wxString &str, long &lIndex) const

  Gets the next entry.
- virtual size_t GetNumberOfEntries (bool bRecursive=false) const

  Get number of entries in the current group.
- virtual size_t GetNumberOfGroups (bool bRecursive=false) const

  Get number of entries/subgroups in the current group, with or without its subgroups.
- virtual bool HasGroup (const wxString &strName) const
- virtual bool HasEntry (const wxString &strName) const
- virtual bool Flush (bool bCurrentOnly=false)

  Permanently writes all changes (otherwise, they're only written from object's destructor).
- virtual bool RenameEntry (const wxString &oldName, const wxString &newName)

  Renames an entry in the current group.
- virtual bool RenameGroup (const wxString &oldName, const wxString &newName)

  Renames a subgroup of the current group.
- virtual bool DeleteEntry (const wxString &key, bool bGroupIfEmptyAlso=true)

  Deletes the specified entry and the group it belongs to if it was the last key in it and the second parameter is true.
- virtual bool DeleteGroup (const wxString &szKey)

  Delete the group (with all subgroups).
- virtual bool DeleteAll ()

  Delete the whole underlying object (disk file, registry key, ...).

Static Public Member Functions

- static wxFileName GetGlobalFile (const wxString &basename)

  Return the full path to the file which would be used by wxFileConfig as global, system-wide, file if it were constructed with basename as "global filename" parameter in the constructor.

- static wxFileName GetLocalFile (const wxString &basename, int style=0)

  Return the full path to the file which would be used by wxFileConfig as local, user-specific, file if it were constructed with basename as "local filename" parameter in the constructor.

- static wxString GetGlobalFileName (const wxString &szFile)
- static wxString GetLocalFileName (const wxString &szFile, int style=0)

Additional Inherited Members

21.230.2 Constructor & Destructor Documentation

wxFileConfig::wxFileConfig (const wxString & *appName* = wxEmptyString, const wxString & *vendorName* = wxEmptyString, const wxString & *localFilename* = wxEmptyString, const wxString & *globalFilename* = wxEmptyString, long *style* = wxCONFIG_USE_LOCAL_FILE|wxCONFIG_USE_GLOBAL_FILE, const wxMBConv & *conv* = wxConvAuto())

Constructor allowing to choose the file names to use.

If *localFilename* and/or *globalFilename* are explicitly specified, they are used as the names of the user and system-wide configuration files (the latter is only read by the program while the former is read from and written to). Otherwise the behaviour depends on *style* parameter. If it includes wxCONFIG_USE_LOCAL_FILE, then the local file name is constructed from the information in *appName* and *vendorName* arguments in a system-dependent way. If wxCONFIG_USE_GLOBAL_FILE is not specified at all (and *globalFilename* is empty) then the system-wide file is not used at all. Otherwise its name and path are also constructed in the way appropriate for the current platform from the application and vendor names.

wxFileConfig::wxFileConfig (wxInputStream & *is*, const wxMBConv & *conv* = wxConvAuto())

Read the config data from the specified stream instead of the associated file, as usual.

See also

Save()

21.230.3 Member Function Documentation

virtual bool wxFileConfig::DeleteAll ( ) [virtual]

Delete the whole underlying object (disk file, registry key, ...).

Primarily for use by uninstallation routine.

Implements wxConfigBase.

virtual bool wxFileConfig::DeleteEntry (const wxString & *key*, bool *bDeleteGroupIfEmpty* = true) [virtual]

Deletes the specified entry and the group it belongs to if it was the last key in it and the second parameter is true.

Implements wxConfigBase.

virtual bool wxFileConfig::DeleteGroup (const wxString & *key*) `[virtual]`

Delete the group (with all subgroups).

If the current path is under the group being deleted it is changed to its deepest still existing component. E.g. if the current path is `"/A/B/C/D"` and the group `C` is deleted, the path becomes `"/A/B"`.

Implements wxConfigBase.

virtual bool wxFileConfig::Flush (bool *bCurrentOnly* = `false`) `[virtual]`

Permanently writes all changes (otherwise, they're only written from object's destructor).

Implements wxConfigBase.

virtual bool wxFileConfig::GetFirstEntry (wxString & *str,* long & *index*) const `[virtual]`

Gets the first entry.

wxPerl Note: In wxPerl this method takes no parameters and returns a 3-element list (continue_flag, string, index↩ _for_getnextentry).

Implements wxConfigBase.

virtual bool wxFileConfig::GetFirstGroup (wxString & *str,* long & *index*) const `[virtual]`

Gets the first group.

wxPerl Note: In wxPerl this method takes no parameters and returns a 3-element list (continue_flag, string, index↩ _for_getnextentry).

Implements wxConfigBase.

static wxFileName wxFileConfig::GetGlobalFile (const wxString & *basename*) `[static]`

Return the full path to the file which would be used by wxFileConfig as global, system-wide, file if it were constructed with *basename* as "global filename" parameter in the constructor.

Notice that this function cannot be used if *basename* is already a full path name.

static wxString wxFileConfig::GetGlobalFileName (const wxString & *szFile*) `[static]`

static wxFileName wxFileConfig::GetLocalFile (const wxString & *basename,* int *style* = `0`) `[static]`

Return the full path to the file which would be used by wxFileConfig as local, user-specific, file if it were constructed with *basename* as "local filename" parameter in the constructor.

style has the same meaning as in wxConfig constructor and can contain any combination of styles but only wxC↩ ONFIG_USE_SUBDIR bit is examined by this function.

Notice that this function cannot be used if *basename* is already a full path name.

static wxString wxFileConfig::GetLocalFileName (const wxString & *szFile,* int *style* = `0`) `[static]`

virtual bool wxFileConfig::GetNextEntry (wxString & *str,* long & *index*) const `[virtual]`

Gets the next entry.

wxPerl Note: In wxPerl this method only takes the *index* parameter and returns a 3-element list (continue_flag, string, index_for_getnextentry).

Implements wxConfigBase.

virtual bool wxFileConfig::GetNextGroup (wxString & *str,* long & *index*) const `[virtual]`

Gets the next group.

wxPerl Note: In wxPerl this method only takes the *index* parameter and returns a 3-element list (continue_flag, string, index_for_getnextentry).

Implements wxConfigBase.

virtual size_t wxFileConfig::GetNumberOfEntries (bool *bRecursive* = `false`) const `[virtual]`

Get number of entries in the current group.

Implements wxConfigBase.

virtual size_t wxFileConfig::GetNumberOfGroups (bool *bRecursive* = `false`) const `[virtual]`

Get number of entries/subgroups in the current group, with or without its subgroups.

Implements wxConfigBase.

virtual const wxString& wxFileConfig::GetPath ( ) const `[virtual]`

Retrieve the current path (always as absolute path).

Implements wxConfigBase.

virtual bool wxFileConfig::HasEntry (const wxString & *strName*) const `[virtual]`

Returns

true if the entry by this name exists.

Implements wxConfigBase.

virtual bool wxFileConfig::HasGroup (const wxString & *strName*) const `[virtual]`

Returns

true if the group by this name exists.

Implements wxConfigBase.

virtual bool wxFileConfig::RenameEntry (const wxString & *oldName,* const wxString & *newName*) `[virtual]`

Renames an entry in the current group.

The entries names (both the old and the new one) shouldn't contain backslashes, i.e. only simple names and not arbitrary paths are accepted by this function.

Returns

false if *oldName* doesn't exist or if *newName* already exists.

Implements wxConfigBase.

virtual bool wxFileConfig::RenameGroup (const wxString & *oldName,* const wxString & *newName*) [virtual]

Renames a subgroup of the current group.

The subgroup names (both the old and the new one) shouldn't contain backslashes, i.e. only simple names and not arbitrary paths are accepted by this function.

Returns

false if *oldName* doesn't exist or if *newName* already exists.

Implements wxConfigBase.

virtual bool wxFileConfig::Save (wxOutputStream & *os,* const wxMBConv & *conv* = wxConvAuto()) [virtual]

Saves all config data to the given stream, returns true if data was saved successfully or false on error.

Note the interaction of this function with the internal "dirty flag": the data is saved unconditionally, i.e. even if the object is not dirty. However after saving it successfully, the dirty flag is reset so no changes will be written back to the file this object is associated with until you change its contents again.

See also

wxConfigBase::Flush

virtual void wxFileConfig::SetPath (const wxString & *strPath*) [virtual]

Set current path: if the first character is '/', it is the absolute path, otherwise it is a relative path.

'..' is supported. If *strPath* doesn't exist, it is created.

See also

wxConfigPathChanger

Implements wxConfigBase.

void wxFileConfig::SetUmask (int *mode*)

Allows to set the mode to be used for the config file creation.

For example, to create a config file which is not readable by other users (useful if it stores some sensitive information, such as passwords), you could use `SetUmask(0077)`.

This function doesn't do anything on non-Unix platforms.

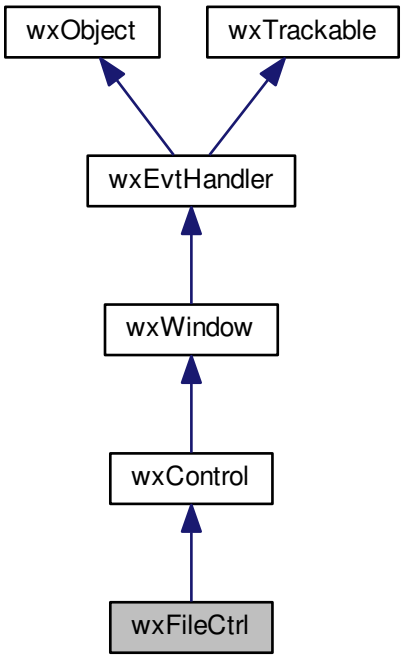
See also

wxCHANGE_UMASK()

21.231 wxFileCtrl Class Reference

`#include <wx/filectrl.h>`

Inheritance diagram for wxFileCtrl:



21.231.1 Detailed Description

This control allows the user to select a file.

Two implementations of this class exist, one for Gtk and another generic one for all the other ports.

This class is only available if `wxUSE_FILECTRL` is set to 1.

Styles

This class supports the following styles:

- wxFC_DEFAULT_STYLE: The default style: wxFC_OPEN
- wxFC_OPEN: Creates an file control suitable for opening files. Cannot be combined with wxFC_SAVE.
- wxFC_SAVE: Creates an file control suitable for saving files. Cannot be combined with wxFC_OPEN.
- wxFC_MULTIPLE: For open control only, Allows selecting multiple files. Cannot be combined with wxFC_↩ SAVE
- wxFC_NOSHOWHIDDEN: Hides the "Show Hidden Files" checkbox (Generic only)

Events emitted by this class

The following event handler macros redirect the events to member function handlers '**func**' with prototypes like: void handlerFuncName(wxFileCtrlEvent& event)

Event macros for events emitted by this class:

- EVT_FILECTRL_FILEACTIVATED(id, func): The user activated a file(by double-clicking or pressing Enter)
- EVT_FILECTRL_SELECTIONCHANGED(id, func): The user changed the current selection(by selecting or deselecting a file)
- EVT_FILECTRL_FOLDERCHANGED(id, func): The current folder of the file control has been changed
- EVT_FILECTRL_FILTERCHANGED(id, func): The current file filter of the file control has been changed.

  Since

  2.9.1.

Library: wxCore

Category: Controls

Implementations: native under wxGTK port; a generic implementation is used elsewhere.

wxGenericDirCtrl

Public Member Functions

- wxFileCtrl ()
- wxFileCtrl (wxWindow *parent, wxWindowID id, const wxString &defaultDirectory=wxEmptyString, const wxString &defaultFilename=wxEmptyString, const wxString &wildCard=wxFileSelectorDefaultWildcardStr, long style=wxFC_DEFAULT_STYLE, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, const wxString &name=wxFileCtrlNameStr)

  Constructs the window.
- bool Create (wxWindow *parent, wxWindowID id, const wxString &defaultDirectory=wxEmptyString, const wxString &defaultFilename=wxEmptyString, const wxString &wildCard=wxFileSelectorDefaultWildcardStr, long style=wxFC_DEFAULT_STYLE, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, const wxString &name=wxFileCtrlNameStr)

  Create function for two-step construction.
- virtual wxString GetDirectory () const

  Returns the current directory of the file control (i.e. the directory shown by it).
- virtual wxString GetFilename () const

  Returns the currently selected filename.
- virtual void GetFilenames (wxArrayString &filenames) const

  Fills the array filenames with the filenames only of selected items.
- virtual int GetFilterIndex () const

  Returns the zero-based index of the currently selected filter.
- virtual wxString GetPath () const

  Returns the full path (directory and filename) of the currently selected file.
- virtual void GetPaths (wxArrayString &paths) const

  Fills the array paths with the full paths of the files chosen.
- virtual wxString GetWildcard () const

Returns the current wildcard.

- virtual bool SetDirectory (const wxString &directory)

  Sets(changes) the current directory displayed in the control.
- virtual bool SetFilename (const wxString &filename)

  Selects a certain file.
- virtual bool SetPath (const wxString &path)

  Changes to a certain directory and selects a certain file.
- virtual void SetFilterIndex (int filterIndex)

  Sets the current filter index, starting from zero.
- virtual void SetWildcard (const wxString &wildCard)

  Sets the wildcard, which can contain multiple file types, for example: "BMP files (∗.bmp)|∗.bmp|GIF files (∗.gif)|∗.gif".
- virtual void ShowHidden (bool show)

  Sets whether hidden files and folders are shown or not.

Additional Inherited Members

21.231.2 Constructor & Destructor Documentation

wxFileCtrl::wxFileCtrl ( )

wxFileCtrl::wxFileCtrl (wxWindow ∗ *parent*, wxWindowID *id*, const wxString & *defaultDirectory* = wxEmptyString, const wxString & *defaultFilename* = wxEmptyString, const wxString & *wildCard* = wxFileSelectorDefaultWildcardStr, long *style* = wxFC_DEFAULT_STYLE, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, const wxString & *name* = `wxFileCtrlNameStr`)

Constructs the window.

Parameters

parent	Parent window, must not be non-NULL.
id	The identifier for the control.
defaultDirectory	The initial directory shown in the control. Must be a valid path to a directory or the empty string. In case it is the empty string, the current working directory is used.
defaultFilename	The default filename, or the empty string.
wildCard	A wildcard specifying which files can be selected, such as "∗.∗" or "BMP files (∗.bmp)|∗.bmp|GIF files (∗.gif)|∗.gif".
style	The window style, see wxFC_∗ flags.
pos	Initial position.
size	Initial size.
name	Control name.

Returns

true if the control was successfully created or false if creation failed.

21.231.3 Member Function Documentation

bool wxFileCtrl::Create (wxWindow ∗ *parent*, wxWindowID *id*, const wxString & *defaultDirectory* = wxEmptyString, const wxString & *defaultFilename* = wxEmptyString, const wxString & *wildCard* = wxFileSelectorDefaultWildcardStr, long *style* = wxFC_DEFAULT_STYLE, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, const wxString & *name* = `wxFileCtrlNameStr`)

Create function for two-step construction.

See wxFileCtrl() for details.

virtual wxString wxFileCtrl::GetDirectory ( ) const `[virtual]`

Returns the current directory of the file control (i.e. the directory shown by it).

virtual wxString wxFileCtrl::GetFilename ( ) const `[virtual]`

Returns the currently selected filename.

For the controls having the `wxFC_MULTIPLE` style, use GetFilenames() instead.

virtual void wxFileCtrl::GetFilenames (wxArrayString & *filenames*) const `[virtual]`

Fills the array *filenames* with the filenames only of selected items.

This function should only be used with the controls having the `wxFC_MULTIPLE` style, use GetFilename() for the others.

Remarks

filenames is emptied first.

virtual int wxFileCtrl::GetFilterIndex ( ) const `[virtual]`

Returns the zero-based index of the currently selected filter.

virtual wxString wxFileCtrl::GetPath ( ) const `[virtual]`

Returns the full path (directory and filename) of the currently selected file.

For the controls having the `wxFC_MULTIPLE` style, use GetPaths() instead.

virtual void wxFileCtrl::GetPaths (wxArrayString & *paths*) const `[virtual]`

Fills the array *paths* with the full paths of the files chosen.

This function should be used with the controls having the `wxFC_MULTIPLE` style, use GetPath() otherwise.

Remarks

paths is emptied first.

virtual wxString wxFileCtrl::GetWildcard ( ) const `[virtual]`

Returns the current wildcard.

virtual bool wxFileCtrl::SetDirectory (const wxString & *directory*) `[virtual]`

Sets(changes) the current directory displayed in the control.

Returns

Returns true on success, false otherwise.

virtual bool wxFileCtrl::SetFilename (const wxString & *filename*) `[virtual]`

Selects a certain file.

Returns

Returns true on success, false otherwise

virtual void wxFileCtrl::SetFilterIndex (int *filterIndex*) `[virtual]`

Sets the current filter index, starting from zero.

virtual bool wxFileCtrl::SetPath (const wxString & *path*) `[virtual]`

Changes to a certain directory and selects a certain file.

In case the filename specified isn't found/couldn't be shown with currently selected filter, false is returned.

Returns

Returns true on success, false otherwise

virtual void wxFileCtrl::SetWildcard (const wxString & *wildCard*) `[virtual]`

Sets the wildcard, which can contain multiple file types, for example: "BMP files (∗.bmp)|∗.bmp|GIF files (∗.gif)|∗.↩ gif".

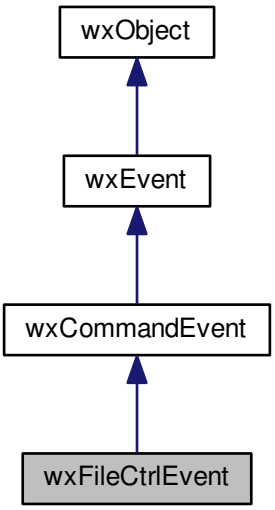
virtual void wxFileCtrl::ShowHidden (bool *show*) `[virtual]`

Sets whether hidden files and folders are shown or not.

21.232 wxFileCtrlEvent Class Reference

`#include <wx/filectrl.h>`

Inheritance diagram for wxFileCtrlEvent:



21.232.1 Detailed Description

A file control event holds information about events associated with wxFileCtrl objects.

Events using this class

The following event handler macros redirect the events to member function handlers '**func**' with prototypes like: void handlerFuncName(wxFileCtrlEvent& event)

Event macros:

- EVT_FILECTRL_FILEACTIVATED(id, func): The user activated a file(by double-clicking or pressing Enter)
- EVT_FILECTRL_SELECTIONCHANGED(id, func): The user changed the current selection(by selecting or deselecting a file)
- EVT_FILECTRL_FOLDERCHANGED(id, func): The current folder of the file control has been changed
- EVT_FILECTRL_FILTERCHANGED(id, func): The current file filter of the file control has been changed

Library: wxCore

Category: Events

Public Member Functions

- wxFileCtrlEvent (wxEventType type, wxObject *evtObject, int id)

  Constructor.

- wxString GetDirectory () const

  Returns the current directory.
- wxString GetFile () const

  Returns the file selected (assuming it is only one file).
- wxArrayString GetFiles () const

  Returns the files selected.
- int GetFilterIndex () const

  Returns the current file filter index.
- void SetFiles (const wxArrayString &files)

  Sets the files changed by this event.
- void SetDirectory (const wxString &directory)

  Sets the directory of this event.
- void SetFilterIndex (int index)

  Sets the filter index changed by this event.

Additional Inherited Members

21.232.2 Constructor & Destructor Documentation

wxFileCtrlEvent::wxFileCtrlEvent (wxEventType *type,* wxObject * *evtObject,* int *id*)

Constructor.

21.232.3 Member Function Documentation

wxString wxFileCtrlEvent::GetDirectory ( ) const

Returns the current directory.

In case of a **EVT_FILECTRL_FOLDERCHANGED**, this method returns the new directory.

wxString wxFileCtrlEvent::GetFile ( ) const

Returns the file selected (assuming it is only one file).

wxArrayString wxFileCtrlEvent::GetFiles ( ) const

Returns the files selected.

In case of a **EVT_FILECTRL_SELECTIONCHANGED**, this method returns the files selected after the event.

int wxFileCtrlEvent::GetFilterIndex ( ) const

Returns the current file filter index.

For a **EVT_FILECTRL_FILTERCHANGED** event, this method returns the new file filter index.

Since

2.9.1

void wxFileCtrlEvent::SetDirectory (const wxString & *directory*)

Sets the directory of this event.

void wxFileCtrlEvent::SetFiles (const wxArrayString & *files*)

Sets the files changed by this event.

void wxFileCtrlEvent::SetFilterIndex (int *index*)

Sets the filter index changed by this event.

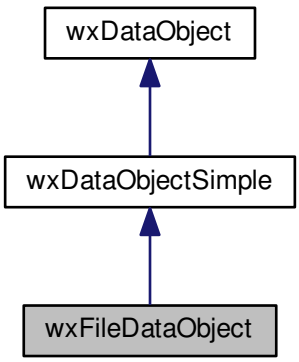
Since

2.9.1

21.233 wxFileDataObject Class Reference

`#include <wx/dataobj.h>`

Inheritance diagram for wxFileDataObject:



21.233.1 Detailed Description

wxFileDataObject is a specialization of wxDataObject for file names.

The program works with it just as if it were a list of absolute file names, but internally it uses the same format as Explorer and other compatible programs under Windows or GNOME/KDE filemanager under Unix which makes it possible to receive files from them using this class.

Warning

Under all non-Windows platforms this class is currently "input-only", i.e. you can receive the files from another application, but copying (or dragging) file(s) from a wxWidgets application is not currently supported. PS: GTK2 should work as well.

Library: wxCore

Category: Clipboard and Drag & Drop

See also

wxDataObject, wxDataObjectSimple, wxTextDataObject, wxBitmapDataObject, wxDataObject

Public Member Functions

- wxFileDataObject ()

  Constructor.

- void AddFile (const wxString &file)

  Adds a file to the file list represented by this data object (Windows only).

- const wxArrayString & GetFilenames () const

  Returns the array of file names.

Additional Inherited Members

21.233.2 Constructor & Destructor Documentation

wxFileDataObject::wxFileDataObject ( )

Constructor.

21.233.3 Member Function Documentation

void wxFileDataObject::AddFile (const wxString & *file*)

Adds a file to the file list represented by this data object (Windows only).

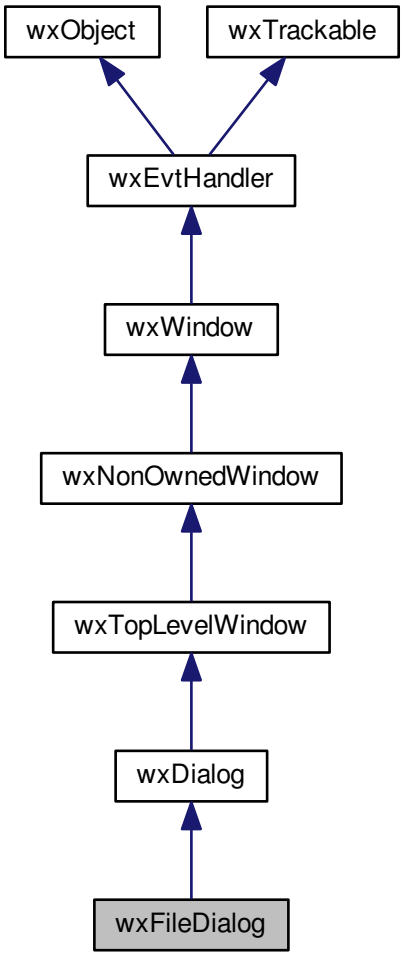
const wxArrayString& wxFileDataObject::GetFilenames ( ) const

Returns the array of file names.

21.234 wxFileDialog Class Reference

```
#include <wx/filedlg.h>
```

Inheritance diagram for wxFileDialog:



21.234.1 Detailed Description

This class represents the file chooser dialog.

The path and filename are distinct elements of a full file pathname. If path is wxEmptyString, the current directory will be used. If filename is wxEmptyString, no default filename will be supplied. The wildcard determines what files are displayed in the file selector, and file extension supplies a type extension for the required filename.

The typical usage for the open file dialog is:

```
void MyFrame::OnOpen(wxCommandEvent& WXUNUSED(event))
{
    if (...current content has not been saved...)
    {
        if (wxMessageBox(_("Current content has not been saved! Proceed?"),
      _("Please confirm"),
                         wxICON_QUESTION | wxYES_NO, this) ==
      wxNO )
            return;
        //else: proceed asking to the user the new file to open
    }
```

```
    wxFileDialog
        openFileDialog(this, _("Open XYZ file"), "", "",
                       "XYZ files (*.xyz)|*.xyz", wxFD_OPEN|
      wxFD_FILE_MUST_EXIST);

    if (openFileDialog.ShowModal() == wxID_CANCEL)
        return;     // the user changed idea...

    // proceed loading the file chosen by the user;
    // this can be done with e.g. wxWidgets input streams:
    wxFileInputStream input_stream(openFileDialog.GetPath());
    if (!input_stream.IsOk())
    {
        wxLogError("Cannot open file '%s'.", openFileDialog.GetPath());
        return;
    }

    ...
}
```

The typical usage for the save file dialog is instead somewhat simpler:

```
void MyFrame::OnSaveAs(wxCommandEvent& WXUNUSED(event))
{
    wxFileDialog
        saveFileDialog(this, _("Save XYZ file"), "", "",
                       "XYZ files (*.xyz)|*.xyz", wxFD_SAVE|
      wxFD_OVERWRITE_PROMPT);

    if (saveFileDialog.ShowModal() == wxID_CANCEL)
        return;     // the user changed idea...

    // save the current contents in the file;
    // this can be done with e.g. wxWidgets output streams:
    wxFileOutputStream output_stream(saveFileDialog.GetPath());
    if (!output_stream.IsOk())
    {
        wxLogError("Cannot save current contents in file '%s'.", saveFileDialog.GetPath());
        return;
    }

    ...
}
```

Remarks

All implementations of the wxFileDialog provide a wildcard filter. Typing a filename containing wildcards (*, ?) in the filename text item, and clicking on Ok, will result in only those files matching the pattern being displayed. The wildcard may be a specification for multiple types of file with a description for each, such as:

```
"BMP and GIF files (*.bmp;*.gif)|*.bmp;*.gif|PNG files (*.png)|*.png"
```

It must be noted that wildcard support in the native Motif file dialog is quite limited: only one file type is supported, and it is displayed without the descriptive test; "BMP files (*.bmp)|*.bmp" is displayed as "*.bmp", and both "BMP files (*.bmp)|*.bmp|GIF files (*.gif)|*.gif" and "Image files|*.bmp;*.gif" are errors.

Styles

This class supports the following styles:

- wxFD_DEFAULT_STYLE: Equivalent to `wxFD_OPEN`.
- wxFD_OPEN: This is an open dialog; usually this means that the default button's label of the dialog is "Open". Cannot be combined with `wxFD_SAVE`.
- wxFD_SAVE: This is a save dialog; usually this means that the default button's label of the dialog is "Save". Cannot be combined with `wxFD_OPEN`.
- wxFD_OVERWRITE_PROMPT: For save dialog only: prompt for a confirmation if a file will be overwritten.
- wxFD_NO_FOLLOW: Directs the dialog to return the path and file name of the selected shortcut file, not its target as it does by default. Currently this flag is only implemented in wxMSW and the non-dereferenced link path is always returned, even without this flag, under Unix and so using it there doesn't do anything. This flag was added in wxWidgets 3.1.0.

- wxFD_FILE_MUST_EXIST: For open dialog only: the user may only select files that actually exist. Notice that under OS X the file dialog with `wxFD_OPEN` style always behaves as if this style was specified, because it is impossible to choose a file that doesn't exist from a standard OS X file dialog.
- wxFD_MULTIPLE: For open dialog only: allows selecting multiple files.
- wxFD_CHANGE_DIR: Change the current working directory (when the dialog is dismissed) to the directory where the file(s) chosen by the user are.
- wxFD_PREVIEW: Show the preview of the selected files (currently only supported by wxGTK).

Library: wxCore

Category: Common Dialogs

wxFileDialog Overview, wxFileSelector()

Public Types

- typedef wxWindow *(* ExtraControlCreatorFunction)(wxWindow *)

  The type of function used as an argument for SetExtraControlCreator().

Public Member Functions

- wxFileDialog (wxWindow *parent, const wxString &message=wxFileSelectorPromptStr, const wxString &defaultDir=wxEmptyString, const wxString &defaultFile=wxEmptyString, const wxString &wildcard=wxFileSelectorDefaultWildcardStr, long style=wxFD_DEFAULT_STYLE, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, const wxString &name=wxFileDialogNameStr)

  Constructor.
- virtual ~wxFileDialog ()

  Destructor.
- virtual wxString GetCurrentlySelectedFilename () const

  Returns the path of the file currently selected in dialog.
- virtual wxString GetDirectory () const

  Returns the default directory.
- wxWindow * GetExtraControl () const

  If functions SetExtraControlCreator() and ShowModal() were called, returns the extra window.
- virtual wxString GetFilename () const

  Returns the default filename.
- virtual void GetFilenames (wxArrayString &filenames) const

  Fills the array filenames with the names of the files chosen.
- virtual int GetFilterIndex () const

  Returns the index into the list of filters supplied, optionally, in the wildcard parameter.
- virtual wxString GetMessage () const

  Returns the message that will be displayed on the dialog.
- virtual wxString GetPath () const

  Returns the full path (directory and filename) of the selected file.
- virtual void GetPaths (wxArrayString &paths) const

  Fills the array paths with the full paths of the files chosen.
- virtual wxString GetWildcard () const

Returns the file dialog wildcard.

- virtual void SetDirectory (const wxString &directory)

  Sets the default directory.
- bool SetExtraControlCreator (ExtraControlCreatorFunction creator)

  Customize file dialog by adding extra window, which is typically placed below the list of files and above the buttons.
- virtual void SetFilename (const wxString &setfilename)

  Sets the default filename.
- virtual void SetFilterIndex (int filterIndex)

  Sets the default filter index, starting from zero.
- virtual void SetMessage (const wxString &message)

  Sets the message that will be displayed on the dialog.
- virtual void SetPath (const wxString &path)

  Sets the path (the combined directory and filename that will be returned when the dialog is dismissed).
- virtual void SetWildcard (const wxString &wildCard)

  Sets the wildcard, which can contain multiple file types, for example: "BMP files (∗.bmp)|∗.bmp|GIF files (∗.gif)|∗.gif".
- virtual int ShowModal ()

  Shows the dialog, returning `wxID_OK` if the user pressed OK, and `wxID_CANCEL` otherwise.

Additional Inherited Members

21.234.2 Member Typedef Documentation

typedef wxWindow∗(∗ wxFileDialog::ExtraControlCreatorFunction)(wxWindow ∗)

The type of function used as an argument for SetExtraControlCreator().

Since

2.9.0

21.234.3 Constructor & Destructor Documentation

wxFileDialog::wxFileDialog (wxWindow ∗ *parent*, const wxString & *message* = `wxFileSelectorPromptStr`, const wxString & *defaultDir* = wxEmptyString, const wxString & *defaultFile* = wxEmptyString, const wxString & *wildcard* = wxFileSelectorDefaultWildcardStr, long *style* = wxFD_DEFAULT_STYLE, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, const wxString & *name* = `wxFileDialogNameStr`)

Constructor.

Use ShowModal() to show the dialog.

Parameters

parent	Parent window.
message	Message to show on the dialog.
defaultDir	The default directory, or the empty string.
defaultFile	The default filename, or the empty string.
wildcard	A wildcard, such as "∗.∗" or "BMP files (∗.bmp)|∗.bmp|GIF files (∗.gif)|∗.gif". Note that the native Motif dialog has some limitations with respect to wildcards; see the Remarks section above.

style	A dialog style. See `wxFD_*` styles for more info.
pos	Dialog position. Not implemented.
size	Dialog size. Not implemented.
name	Dialog name. Not implemented.

virtual wxFileDialog::~wxFileDialog ( ) [virtual]

Destructor.

21.234.4 Member Function Documentation

virtual wxString wxFileDialog::GetCurrentlySelectedFilename ( ) const [virtual]

Returns the path of the file currently selected in dialog.

Notice that this file is not necessarily going to be accepted by the user, so calling this function mostly makes sense from an update UI event handler of a custom file dialog extra control to update its state depending on the currently selected file.

Currently this function is fully implemented under GTK and MSW and always returns an empty string elsewhere.

Since

2.9.5

Returns

The path of the currently selected file or an empty string if nothing is selected.

See also

SetExtraControlCreator()

virtual wxString wxFileDialog::GetDirectory ( ) const [virtual]

Returns the default directory.

wxWindow* wxFileDialog::GetExtraControl ( ) const

If functions SetExtraControlCreator() and ShowModal() were called, returns the extra window.

Otherwise returns NULL.

Since

2.9.0

virtual wxString wxFileDialog::GetFilename ( ) const [virtual]

Returns the default filename.

virtual void wxFileDialog::GetFilenames (wxArrayString & *filenames*) const `[virtual]`

Fills the array *filenames* with the names of the files chosen.

This function should only be used with the dialogs which have `wxFD_MULTIPLE` style, use GetFilename() for the others.

Note that under Windows, if the user selects shortcuts, the filenames include paths, since the application cannot determine the full path of each referenced file by appending the directory containing the shortcuts to the filename.

virtual int wxFileDialog::GetFilterIndex ( ) const `[virtual]`

Returns the index into the list of filters supplied, optionally, in the wildcard parameter.

Before the dialog is shown, this is the index which will be used when the dialog is first displayed.

After the dialog is shown, this is the index selected by the user.

virtual wxString wxFileDialog::GetMessage ( ) const `[virtual]`

Returns the message that will be displayed on the dialog.

virtual wxString wxFileDialog::GetPath ( ) const `[virtual]`

Returns the full path (directory and filename) of the selected file.

virtual void wxFileDialog::GetPaths (wxArrayString & *paths*) const `[virtual]`

Fills the array *paths* with the full paths of the files chosen.

This function should only be used with the dialogs which have `wxFD_MULTIPLE` style, use GetPath() for the others.

virtual wxString wxFileDialog::GetWildcard ( ) const `[virtual]`

Returns the file dialog wildcard.

virtual void wxFileDialog::SetDirectory (const wxString & *directory*) `[virtual]`

Sets the default directory.

bool wxFileDialog::SetExtraControlCreator (ExtraControlCreatorFunction *creator*)

Customize file dialog by adding extra window, which is typically placed below the list of files and above the buttons.

SetExtraControlCreator() can be called only once, before calling ShowModal().

The `creator` function should take pointer to parent window (file dialog) and should return a window allocated with operator new.

Supported platforms: wxGTK, wxMSW, wxUniv.

Since

2.9.0

virtual void wxFileDialog::SetFilename (const wxString & *setfilename*) `[virtual]`

Sets the default filename.

In wxGTK this will have little effect unless a default directory has previously been set.

virtual void wxFileDialog::SetFilterIndex (int *filterIndex*) `[virtual]`

Sets the default filter index, starting from zero.

virtual void wxFileDialog::SetMessage (const wxString & *message*) `[virtual]`

Sets the message that will be displayed on the dialog.

virtual void wxFileDialog::SetPath (const wxString & *path*) `[virtual]`

Sets the path (the combined directory and filename that will be returned when the dialog is dismissed).

virtual void wxFileDialog::SetWildcard (const wxString & *wildCard*) `[virtual]`

Sets the wildcard, which can contain multiple file types, for example: "BMP files (∗.bmp)|∗.bmp|GIF files (∗.gif)|∗.↩ gif".

Note that the native Motif dialog has some limitations with respect to wildcards; see the Remarks section above.

virtual int wxFileDialog::ShowModal ( ) `[virtual]`

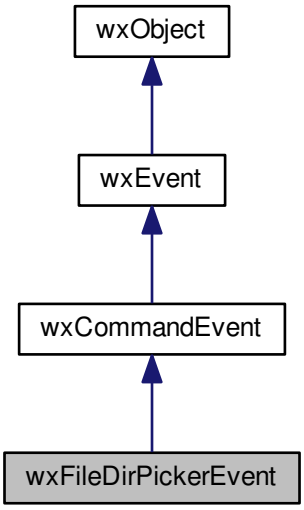
Shows the dialog, returning `wxID_OK` if the user pressed OK, and `wxID_CANCEL` otherwise.

Reimplemented from wxDialog.

21.235 wxFileDirPickerEvent Class Reference

`#include <wx/filepicker.h>`

Inheritance diagram for wxFileDirPickerEvent:



21.235.1 Detailed Description

This event class is used for the events generated by wxFilePickerCtrl and by wxDirPickerCtrl.

Events using this class

The following event handler macros redirect the events to member function handlers '**func**' with prototypes like: void handlerFuncName(wxFileDirPickerEvent& event)

Event macros:

- EVT_FILEPICKER_CHANGED(id, func): Generated whenever the selected file changes.
- EVT_DIRPICKER_CHANGED(id, func): Generated whenever the selected directory changes.

Library: wxCore

Category: Events

See also

wxFilePickerCtrl, wxDirPickerCtrl

Public Member Functions

- wxFileDirPickerEvent ()
- wxFileDirPickerEvent (wxEventType type, wxObject *generator, int id, const wxString &path)

  The constructor is not normally used by the user code.

- wxString GetPath () const

  Retrieve the absolute path of the file/directory the user has just selected.

- void SetPath (const wxString &path)

  Set the absolute path of the file/directory associated with the event.

Additional Inherited Members

21.235.2 Constructor & Destructor Documentation

wxFileDirPickerEvent::wxFileDirPickerEvent ( )

wxFileDirPickerEvent::wxFileDirPickerEvent (wxEventType *type*, wxObject * *generator*, int *id*, const wxString & *path*)

The constructor is not normally used by the user code.

21.235.3 Member Function Documentation

wxString wxFileDirPickerEvent::GetPath ( ) const

Retrieve the absolute path of the file/directory the user has just selected.

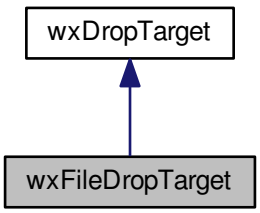
void wxFileDirPickerEvent::SetPath (const wxString & *path*)

Set the absolute path of the file/directory associated with the event.

21.236 wxFileDropTarget Class Reference

`#include <wx/dnd.h>`

Inheritance diagram for wxFileDropTarget:



21.236.1 Detailed Description

This is a drop target which accepts files (dragged from File Manager or Explorer).

Library: wxCore

Category: Clipboard and Drag & Drop

See also

Drag and Drop Overview, wxDropSource, wxDropTarget, wxTextDropTarget

Public Member Functions

- wxFileDropTarget ()

  Constructor.
- virtual bool OnDrop (wxCoord x, wxCoord y)

  See wxDropTarget::OnDrop().
- virtual bool OnDropFiles (wxCoord x, wxCoord y, const wxArrayString &filenames)=0

  Override this function to receive dropped files.

21.236.2 Constructor & Destructor Documentation

wxFileDropTarget::wxFileDropTarget ( )

Constructor.

21.236.3 Member Function Documentation

virtual bool wxFileDropTarget::OnDrop (wxCoord *x*, wxCoord *y*) `[virtual]`

See wxDropTarget::OnDrop().

This function is implemented appropriately for files, and calls OnDropFiles().

Reimplemented from wxDropTarget.

virtual bool wxFileDropTarget::OnDropFiles (wxCoord *x*, wxCoord *y*, const wxArrayString & *filenames*) `[pure virtual]`

Override this function to receive dropped files.

Parameters

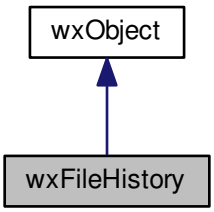
x	The x coordinate of the mouse.
y	The y coordinate of the mouse.
filenames	An array of filenames.

Return true to accept the data, or false to veto the operation.

21.237 wxFileHistory Class Reference

`#include <wx/filehistory.h>`

Inheritance diagram for wxFileHistory:



21.237.1 Detailed Description

The wxFileHistory encapsulates a user interface convenience, the list of most recently visited files as shown on a menu (usually the File menu).

wxFileHistory can manage one or more file menus. More than one menu may be required in an MDI application, where the file history should appear on each MDI child menu as well as the MDI parent frame.

Library: wxCore

Category: Document/View Framework

See also

Document/View Framework, wxDocManager

Public Member Functions

- wxFileHistory (size_t maxFiles=9, wxWindowID idBase=wxID_FILE1)

  Constructor.
- virtual ~wxFileHistory ()

  Destructor.
- virtual void AddFileToHistory (const wxString &filename)

  Adds a file to the file history list, if the object has a pointer to an appropriate file menu.
- virtual void AddFilesToMenu ()

  Appends the files in the history list, to all menus managed by the file history object.
- virtual void AddFilesToMenu (wxMenu *menu)

  Appends the files in the history list, to the given menu only.
- wxWindowID GetBaseId () const

  Returns the base identifier for the range used for appending items.
- virtual size_t GetCount () const

  Returns the number of files currently stored in the file history.
- virtual wxString GetHistoryFile (size_t index) const

  Returns the file at this index (zero-based).
- virtual int GetMaxFiles () const

Returns the maximum number of files that can be stored.

- const wxList & GetMenus () const

  Returns the list of menus that are managed by this file history object.

- virtual void Load (const wxConfigBase &config)

  Loads the file history from the given config object.

- virtual void RemoveFileFromHistory (size_t i)

  Removes the specified file from the history.

- virtual void RemoveMenu (wxMenu *menu)

  Removes this menu from the list of those managed by this object.

- virtual void Save (wxConfigBase &config)

  Saves the file history into the given config object.

- void SetBaseId (wxWindowID baseId)

  Sets the base identifier for the range used for appending items.

- virtual void UseMenu (wxMenu *menu)

  Adds this menu to the list of those menus that are managed by this file history object.

Additional Inherited Members

21.237.2 Constructor & Destructor Documentation

wxFileHistory::wxFileHistory (size_t *maxFiles* = 9, wxWindowID *idBase* = wxID_FILE1)

Constructor.

Pass the maximum number of files that should be stored and displayed.

idBase defaults to wxID_FILE1 and represents the id given to the first history menu item. Since menu items can't share the same ID you should change *idBase* (to one of your own defined IDs) when using more than one wxFileHistory in your application.

virtual wxFileHistory::~wxFileHistory ( ) [virtual]

Destructor.

21.237.3 Member Function Documentation

virtual void wxFileHistory::AddFilesToMenu ( ) [virtual]

Appends the files in the history list, to all menus managed by the file history object.

virtual void wxFileHistory::AddFilesToMenu (wxMenu * *menu*) [virtual]

Appends the files in the history list, to the given menu only.

virtual void wxFileHistory::AddFileToHistory (const wxString & *filename*) [virtual]

Adds a file to the file history list, if the object has a pointer to an appropriate file menu.

wxWindowID wxFileHistory::GetBaseId ( ) const

Returns the base identifier for the range used for appending items.

virtual size_t wxFileHistory::GetCount ( ) const `[virtual]`

Returns the number of files currently stored in the file history.

virtual wxString wxFileHistory::GetHistoryFile (size_t *index*) const `[virtual]`

Returns the file at this index (zero-based).

virtual int wxFileHistory::GetMaxFiles ( ) const `[virtual]`

Returns the maximum number of files that can be stored.

const wxList& wxFileHistory::GetMenus ( ) const

Returns the list of menus that are managed by this file history object.

See also

UseMenu()

virtual void wxFileHistory::Load (const wxConfigBase & *config*) `[virtual]`

Loads the file history from the given config object.

This function should be called explicitly by the application.

See also

wxConfigBase

virtual void wxFileHistory::RemoveFileFromHistory (size_t *i*) `[virtual]`

Removes the specified file from the history.

virtual void wxFileHistory::RemoveMenu (wxMenu * *menu*) `[virtual]`

Removes this menu from the list of those managed by this object.

virtual void wxFileHistory::Save (wxConfigBase & *config*) `[virtual]`

Saves the file history into the given config object.

This must be called explicitly by the application.

See also

wxConfigBase

void wxFileHistory::SetBaseId (wxWindowID *baseId*)

Sets the base identifier for the range used for appending items.

virtual void wxFileHistory::UseMenu (wxMenu * *menu*) [virtual]

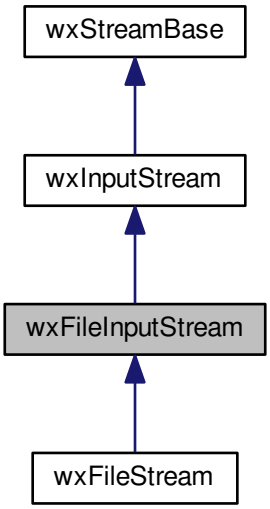
Adds this menu to the list of those menus that are managed by this file history object.

Also see AddFilesToMenu() for initializing the menu with filenames that are already in the history when this function is called, as this is not done automatically.

21.238 wxFileInputStream Class Reference

`#include <wx/wfstream.h>`

Inheritance diagram for wxFileInputStream:



21.238.1 Detailed Description

This class represents data read in from a file.

There are actually two such groups of classes: this one is based on wxFile whereas wxFFileInputStream is based in the wxFFile class.

Note that wxInputStream::SeekI() can seek beyond the end of the stream (file) and will thus not return wxInvalidOffset for that.

Library: wxBase

Category: Streams

See also

wxBufferedInputStream, wxFileOutputStream, wxFFileOutputStream

Public Member Functions

- wxFileInputStream (const wxString &ifileName)

  Opens the specified file using its ifileName name in read-only mode.
- wxFileInputStream (wxFile &file)

  Initializes a file stream in read-only mode using the file I/O object file.
- wxFileInputStream (int fd)

  Initializes a file stream in read-only mode using the specified file descriptor.
- virtual ~wxFileInputStream ()

  Destructor.
- bool IsOk () const

  Returns true if the stream is initialized and ready.
- wxFile * GetFile () const

  Returns the underlying file object.

Additional Inherited Members

21.238.2 Constructor & Destructor Documentation

wxFileInputStream::wxFileInputStream (const wxString & *ifileName*)

Opens the specified file using its *ifileName* name in read-only mode.

Warning

You should use wxStreamBase::IsOk() to verify if the constructor succeeded.

wxFileInputStream::wxFileInputStream (wxFile & *file*)

Initializes a file stream in read-only mode using the file I/O object file.

wxFileInputStream::wxFileInputStream (int *fd*)

Initializes a file stream in read-only mode using the specified file descriptor.

virtual wxFileInputStream::~wxFileInputStream ( ) [virtual]

Destructor.

21.238.3 Member Function Documentation

wxFile* wxFileInputStream::GetFile ( ) const

Returns the underlying file object.

Since

2.9.5

bool wxFileInputStream::IsOk ( ) const `[virtual]`

Returns true if the stream is initialized and ready.

Reimplemented from wxStreamBase.

Reimplemented in wxFileStream.

21.239 wxFileName Class Reference

`#include <wx/filename.h>`

21.239.1 Detailed Description

wxFileName encapsulates a file name.

This class serves two purposes: first, it provides the functions to split the file names into components and to recombine these components in the full file name which can then be passed to the OS file functions (and wxWidgets functions wrapping them). Second, it includes the functions for working with the files itself. Note that to change the file data you should use wxFile class instead. wxFileName provides functions for working with the file attributes.

When working with directory names (i.e. without filename and extension) make sure not to misuse the file name part of this class with the last directory. Instead initialize the wxFileName instance like this:

```
wxFileName dirname( "C:\mydir", "" );
MyMethod( dirname.GetPath() );
```

The same can be done using the static method wxFileName::DirName():

```
wxFileName dirname = wxFileName::DirName( "C:\mydir" );
MyMethod( dirname.GetPath() );
```

Accordingly, methods dealing with directories or directory names like wxFileName::IsDirReadable() use wxFileName::GetPath() whereas methods dealing with file names like wxFileName::IsFileReadable() use wxFileName::GetFullPath().

If it is not known whether a string contains a directory name or a complete file name (such as when interpreting user input) you need to use the static function wxFileName::DirExists() (or its identical variants wxDir::Exists() and wxDirExists()) and construct the wxFileName instance accordingly. This will only work if the directory actually exists, of course:

```
wxString user_input;
// get input from user

wxFileName fname;
if (wxDirExists(user_input))
    fname.AssignDir( user_input );
else
    fname.Assign( user_input );
```

Please note that many wxFileName methods accept the path format argument which is by `wxPATH_NATIVE` by default meaning to use the path format native for the current platform. The path format affects the operation of wxFileName functions in several ways: first and foremost, it defines the path separator character to use, but it also affects other things such as whether the path has the drive part or not. See wxPathFormat for more info.

21.239.2 File name format

wxFileName currently supports the file names in the Unix, DOS/Windows, Mac OS and VMS formats. Although these formats are quite different, wxFileName tries to treat them all in the same generic way. It supposes that all file

names consist of the following parts: the volume (also known as drive under Windows or device under VMS), the path which is a sequence of directory names separated by the path separators and the full filename itself which, in turn, is composed from the base file name and the extension. All of the individual components of the file name may be empty and, for example, the volume name is always empty under Unix, but if they are all empty simultaneously, the filename object is considered to be in an invalid state and wxFileName::IsOk() returns false for it.

File names can be case-sensitive or not, the function wxFileName::IsCaseSensitive() allows to determine this. The rules for determining whether the file name is absolute or relative also depend on the file name format and the only portable way to answer this question is to use wxFileName::IsAbsolute() or wxFileName::IsRelative() method.

Note that on Windows,"X:" refers to the current working directory on drive X. Therefore, a wxFileName instance constructed from for example "X:dir/file.ext" treats the portion beyond drive separator as being relative to that directory. To ensure that the filename is absolute, you may use wxFileName::MakeAbsolute(). There is also an inverse function wxFileName::MakeRelativeTo() which undoes what wxFileName::Normalize(wxPATH_NORM_DOTS) does. Other functions returning information about the file format provided by this class are wxFileName::GetVolumeSeparator(), wxFileName::IsPathSeparator().

21.239.3 File name construction

You can initialize a wxFileName instance using one of the following functions:

- wxFileName::wxFileName()
- wxFileName::Assign()
- wxFileName::AssignCwd()
- wxFileName::AssignDir()
- wxFileName::AssignHomeDir()
- wxFileName::AssignTempFileName()
- wxFileName::DirName()
- wxFileName::FileName()
- wxFileName::operator=()

21.239.4 File name tests

Before doing other tests, you should use wxFileName::IsOk() to verify that the filename is well defined. If it is, FileExists() can be used to test whether a file with such name exists and wxFileName::DirExists() can be used to test for directory existence. File names should be compared using the wxFileName::SameAs() method or wxFileName::operator==(). For testing basic access modes, you can use:

- wxFileName::IsDirWritable()
- wxFileName::IsDirReadable()
- wxFileName::IsFileWritable()
- wxFileName::IsFileReadable()
- wxFileName::IsFileExecutable()

21.239.5 File name components

These functions allow to examine and modify the individual directories of the path:

- wxFileName::AppendDir()
- wxFileName::InsertDir()
- wxFileName::GetDirCount()
- wxFileName::PrependDir()
- wxFileName::RemoveDir()
- wxFileName::RemoveLastDir()

To change the components of the file name individually you can use the following functions:

- wxFileName::GetExt()
- wxFileName::GetName()
- wxFileName::GetVolume()
- wxFileName::HasExt()
- wxFileName::HasName()
- wxFileName::HasVolume()
- wxFileName::SetExt()
- wxFileName::ClearExt()
- wxFileName::SetEmptyExt()
- wxFileName::SetName()
- wxFileName::SetVolume()

You can initialize a wxFileName instance using one of the following functions:

21.239.6 File name operations

These methods allow to work with the file creation, access and modification times. Note that not all filesystems under all platforms implement these times in the same way. For example, the access time under Windows has a resolution of one day (so it is really the access date and not time). The access time may be updated when the file is executed or not depending on the platform.

- wxFileName::GetModificationTime()
- wxFileName::GetTimes()
- wxFileName::SetTimes()
- wxFileName::Touch()

Other file system operations functions are:

- wxFileName::Mkdir()
- wxFileName::Rmdir()

Library: wxBase

Category: File Handling

- wxString GetHumanReadableSize (const wxString &failmsg=_("Not available"), int precision=1, wxSizeConvention conv=wxSIZE_CONV_TRADITIONAL) const

  Returns the representation of the file size in a human-readable form.
- static wxString GetHumanReadableSize (const wxULongLong &bytes, const wxString &nullsize=_("Not available"), int precision=1, wxSizeConvention conv=wxSIZE_CONV_TRADITIONAL)

  Returns the representation of the file size in a human-readable form.

Public Member Functions

- wxFileName ()

  Default constructor.
- wxFileName (const wxFileName &filename)

  Copy constructor.
- wxFileName (const wxString &fullpath, wxPathFormat format=wxPATH_NATIVE)

  Constructor taking a full filename.
- wxFileName (const wxString &path, const wxString &name, wxPathFormat format=wxPATH_NATIVE)

  Constructor a directory name and file name.
- wxFileName (const wxString &path, const wxString &name, const wxString &ext, wxPathFormat format=wxPATH_NATIVE)

  Constructor from a directory name, base file name and extension.
- wxFileName (const wxString &volume, const wxString &path, const wxString &name, const wxString &ext, wxPathFormat format=wxPATH_NATIVE)

  Constructor from a volume name, a directory name, base file name and extension.
- bool AppendDir (const wxString &dir)

  Appends a directory component to the path.
- void Assign (const wxFileName &filepath)

  Creates the file name from another filename object.
- void Assign (const wxString &fullpath, wxPathFormat format=wxPATH_NATIVE)

  Creates the file name from a full file name with a path.
- void Assign (const wxString &volume, const wxString &path, const wxString &name, const wxString &ext, bool hasExt, wxPathFormat format=wxPATH_NATIVE)

  Creates the file name from volume, path, name and extension.
- void Assign (const wxString &volume, const wxString &path, const wxString &name, const wxString &ext, wxPathFormat format=wxPATH_NATIVE)

  Creates the file name from volume, path, name and extension.
- void Assign (const wxString &path, const wxString &name, wxPathFormat format=wxPATH_NATIVE)

  Creates the file name from file path and file name.
- void Assign (const wxString &path, const wxString &name, const wxString &ext, wxPathFormat format=wxPATH_NATIVE)

  Creates the file name from path, name and extension.
- void AssignCwd (const wxString &volume=wxEmptyString)

  Makes this object refer to the current working directory on the specified volume (or current volume if volume is empty).
- void AssignDir (const wxString &dir, wxPathFormat format=wxPATH_NATIVE)

  Sets this file name object to the given directory name.
- void AssignHomeDir ()

  Sets this file name object to the home directory.

- void AssignTempFileName (const wxString &prefix)

  The function calls CreateTempFileName() to create a temporary file and sets this object to the name of the file.
- void AssignTempFileName (const wxString &prefix, wxFile *fileTemp)

  The function calls CreateTempFileName() to create a temporary file name and open fileTemp with it.
- void AssignTempFileName (const wxString &prefix, wxFFile *fileTemp)

  The function calls CreateTempFileName() to create a temporary file name and open fileTemp with it.
- void Clear ()

  Reset all components to default, uninitialized state.
- void ClearExt ()

  Removes the extension from the file name resulting in a file name with no trailing dot.
- bool DirExists () const

  Returns true if the directory with this name exists.
- void DontFollowLink ()

  Turns off symlink dereferencing.
- bool Exists (int flags=wxFILE_EXISTS_ANY) const

  Calls the static overload of this function with the full path of this object.
- bool FileExists () const

  Returns true if the file with this name exists.
- size_t GetDirCount () const

  Returns the number of directories in the file name.
- const wxArrayString & GetDirs () const

  Returns the directories in string array form.
- wxString GetExt () const

  Returns the file name extension.
- wxString GetFullName () const

  Returns the full name (including extension but excluding directories).
- wxString GetFullPath (wxPathFormat format=wxPATH_NATIVE) const

  Returns the full path with name and extension.
- wxString GetLongPath () const

  Return the long form of the path (returns identity on non-Windows platforms).
- wxDateTime GetModificationTime () const

  Returns the last time the file was last modified.
- wxString GetName () const

  Returns the name part of the filename (without extension).
- wxString GetPath (int flags=wxPATH_GET_VOLUME, wxPathFormat format=wxPATH_NATIVE) const

  Returns the path part of the filename (without the name or extension).
- wxString GetPathWithSep (wxPathFormat format=wxPATH_NATIVE) const

  Returns the path with the trailing separator, useful for appending the name to the given path.
- wxString GetShortPath () const

  Return the short form of the path (returns identity on non-Windows platforms).
- wxULongLong GetSize () const

  Returns the size of the file If the file does not exist or its size could not be read (because e.g.
- bool GetTimes (wxDateTime *dtAccess, wxDateTime *dtMod, wxDateTime *dtCreate) const

  Returns the last access, last modification and creation times.
- wxString GetVolume () const

  Returns the string containing the volume for this file name, empty if it doesn't have one or if the file system doesn't support volumes at all (for example, Unix).
- bool HasExt () const

  Returns true if an extension is present.
- bool HasName () const

  Returns true if a name is present.

- bool HasVolume () const

  Returns true if a volume specifier is present.
- bool InsertDir (size_t before, const wxString &dir)

  Inserts a directory component before the zero-based position in the directory list.
- bool IsAbsolute (wxPathFormat format=wxPATH_NATIVE) const

  Returns true if this filename is absolute.
- bool IsDir () const

  Returns true if this object represents a directory, false otherwise (i.e.
- bool IsDirReadable () const

  Returns true if the directory component of this instance is an existing directory and this process has read permissions on it.
- bool IsDirWritable () const

  Returns true if the directory component of this instance is an existing directory and this process has write permissions on it.
- bool IsFileExecutable () const

  Returns true if a file with this name exists and if this process has execute permissions on it.
- bool IsFileReadable () const

  Returns true if a file with this name exists and if this process has read permissions on it.
- bool IsFileWritable () const

  Returns true if a file with this name exists and if this process has write permissions on it.
- bool IsOk () const

  Returns true if the filename is valid, false if it is not initialized yet.
- bool IsRelative (wxPathFormat format=wxPATH_NATIVE) const

  Returns true if this filename is not absolute.
- bool MacSetDefaultTypeAndCreator ()

  On Mac OS, looks up the appropriate type and creator from the registration and then sets it.
- bool MakeAbsolute (const wxString &cwd=wxEmptyString, wxPathFormat format=wxPATH_NATIVE)

  Make the file name absolute.
- bool MakeRelativeTo (const wxString &pathBase=wxEmptyString, wxPathFormat format=wxPATH_NATIVE)

  This function tries to put this file name in a form relative to pathBase.
- bool Mkdir (int perm=wxS_DIR_DEFAULT, int flags=0) const

  Creates a directory.
- bool Normalize (int flags=wxPATH_NORM_ALL, const wxString &cwd=wxEmptyString, wxPathFormat format=wxPATH_NATIVE)

  Normalize the path.
- void PrependDir (const wxString &dir)

  Prepends a directory to the file path.
- void RemoveDir (size_t pos)

  Removes the specified directory component from the path.
- void RemoveLastDir ()

  Removes last directory component from the path.
- bool ReplaceEnvVariable (const wxString &envname, const wxString &replacementFmtString="$%s", wxPathFormat format=wxPATH_NATIVE)

  If the path contains the value of the environment variable named envname then this function replaces it with the string obtained from wxString::Format(replacementFmtString, value_of_envname_variable).
- bool ReplaceHomeDir (wxPathFormat format=wxPATH_NATIVE)

  Replaces, if present in the path, the home directory for the given user (see wxGetHomeDir) with a tilde (~).
- bool Rmdir (int flags=0) const

  Deletes the specified directory from the file system.
- bool SameAs (const wxFileName &filepath, wxPathFormat format=wxPATH_NATIVE) const

  Compares the filename using the rules of this platform.

- bool SetCwd () const

  Changes the current working directory.
- void SetEmptyExt ()

  Sets the extension of the file name to be an empty extension.
- void SetExt (const wxString &ext)

  Sets the extension of the file name.
- void SetFullName (const wxString &fullname)

  The full name is the file name and extension (but without the path).
- void SetName (const wxString &name)

  Sets the name part (without extension).
- void SetPath (const wxString &path, wxPathFormat format=wxPATH_NATIVE)

  Sets the path.
- bool SetPermissions (int permissions)

  Sets permissions for this file or directory.
- bool SetTimes (const wxDateTime *dtAccess, const wxDateTime *dtMod, const wxDateTime *dtCreate) const

  Sets the file creation and last access/modification times (any of the pointers may be NULL).
- void SetVolume (const wxString &volume)

  Sets the volume specifier.
- bool ShouldFollowLink () const

  Return whether some operations will follow symlink.
- bool Touch () const

  Sets the access and modification times to the current moment.
- bool operator!= (const wxFileName &filename) const

  Returns true if the filenames are different.
- bool operator!= (const wxString &filename) const

  Returns true if the filenames are different.
- bool operator== (const wxFileName &filename) const

  Returns true if the filenames are equal.
- bool operator== (const wxString &filename) const

  Returns true if the filenames are equal.
- wxFileName & operator= (const wxFileName &filename)

  Assigns the new value to this filename object.
- wxFileName & operator= (const wxString &filename)

  Assigns the new value to this filename object.

Static Public Member Functions

- static wxString CreateTempFileName (const wxString &prefix, wxFile *fileTemp=NULL)

  Returns a temporary file name starting with the given prefix.
- static wxString CreateTempFileName (const wxString &prefix, wxFFile *fileTemp=NULL)

  *This is the same as CreateTempFileName(const wxString &prefix, wxFile *fileTemp) but takes a wxFFile parameter instead of wxFile.*
- static bool DirExists (const wxString &dir)

  Returns true if the directory with name dir exists.
- static wxFileName DirName (const wxString &dir, wxPathFormat format=wxPATH_NATIVE)

  Returns the object corresponding to the directory with the given name.
- static bool Exists (const wxString &path, int flags=wxFILE_EXISTS_ANY)

  Returns true if either a file or a directory or something else with this name exists in the file system.
- static bool FileExists (const wxString &file)

  Returns true if the file with name file exists.

- static wxFileName FileName (const wxString &file, wxPathFormat format=wxPATH_NATIVE)

  Returns the file name object corresponding to the given file.
- static wxString GetCwd (const wxString &volume=wxEmptyString)

  Retrieves the value of the current working directory on the specified volume.
- static wxString GetForbiddenChars (wxPathFormat format=wxPATH_NATIVE)

  Returns the characters that can't be used in filenames and directory names for the specified format.
- static wxPathFormat GetFormat (wxPathFormat format=wxPATH_NATIVE)

  Returns the canonical path format for this platform.
- static wxString GetHomeDir ()

  Returns the home directory.
- static wxUniChar GetPathSeparator (wxPathFormat format=wxPATH_NATIVE)

  Returns the usually used path separator for this format.
- static wxString GetPathSeparators (wxPathFormat format=wxPATH_NATIVE)

  Returns the string containing all the path separators for this format.
- static wxString GetPathTerminators (wxPathFormat format=wxPATH_NATIVE)

  Returns the string of characters which may terminate the path part.
- static wxULongLong GetSize (const wxString &filename)

  Returns the size of the file If the file does not exist or its size could not be read (because e.g.
- static wxString GetTempDir ()

  Returns the directory used for temporary files.
- static wxString GetVolumeSeparator (wxPathFormat format=wxPATH_NATIVE)

  Returns the string separating the volume from the path for this format.
- static wxString GetVolumeString (char drive, int flags=wxPATH_GET_SEPARATOR)

  This function builds a volume path string, for example "C:\\".
- static bool IsCaseSensitive (wxPathFormat format=wxPATH_NATIVE)

  Returns true if the file names of this type are case-sensitive.
- static bool IsDirReadable (const wxString &dir)

  Returns true if the given dir is an existing directory and this process has read permissions on it.
- static bool IsDirWritable (const wxString &dir)

  Returns true if the given dir is an existing directory and this process has write permissions on it.
- static bool IsFileExecutable (const wxString &file)

  Returns true if a file with this name exists and if this process has execute permissions on it.
- static bool IsFileReadable (const wxString &file)

  Returns true if a file with this name exists and if this process has read permissions on it.
- static bool IsFileWritable (const wxString &file)

  Returns true if a file with this name exists and if this process has write permissions on it.
- static bool IsPathSeparator (wxChar ch, wxPathFormat format=wxPATH_NATIVE)

  Returns true if the char is a path separator for this format.
- static bool IsMSWUniqueVolumeNamePath (const wxString &path, wxPathFormat format=wxPATH_NATIVE)

  Returns true if the volume part of the path is a unique volume name.
- static bool MacFindDefaultTypeAndCreator (const wxString &ext, wxUint32 *type, wxUint32 *creator)

  On Mac OS, gets the common type and creator for the given extension.
- static void MacRegisterDefaultTypeAndCreator (const wxString &ext, wxUint32 type, wxUint32 creator)

  On Mac OS, registers application defined extensions and their default type and creator.
- static bool Mkdir (const wxString &dir, int perm=wxS_DIR_DEFAULT, int flags=0)

  Creates a directory.
- static bool Rmdir (const wxString &dir, int flags=0)

  Deletes the specified directory from the file system.
- static bool SetCwd (const wxString &cwd)

  Changes the current working directory.

- static void SplitVolume (const wxString &fullpath, wxString ∗volume, wxString ∗path, wxPathFormat format=wxPATH_NATIVE)

  Splits the given fullpath into the volume part (which may be empty) and the pure path part, not containing any volume.
- static wxString StripExtension (const wxString &fullname)

  Strip the file extension.

- static void SplitPath (const wxString &fullpath, wxString ∗volume, wxString ∗path, wxString ∗name, wxString ∗ext, bool ∗hasExt=NULL, wxPathFormat format=wxPATH_NATIVE)

  This function splits a full file name into components: the volume (with the first version) path (including the volume in the second version), the base name and the extension.
- static void SplitPath (const wxString &fullpath, wxString ∗volume, wxString ∗path, wxString ∗name, wxString ∗ext, wxPathFormat format)

  This function splits a full file name into components: the volume (with the first version) path (including the volume in the second version), the base name and the extension.
- static void SplitPath (const wxString &fullpath, wxString ∗path, wxString ∗name, wxString ∗ext, wxPathFormat format=wxPATH_NATIVE)

  This function splits a full file name into components: the volume (with the first version) path (including the volume in the second version), the base name and the extension.

21.239.7 Constructor & Destructor Documentation

wxFileName::wxFileName ( )

Default constructor.

wxFileName::wxFileName (const wxFileName & *filename*)

Copy constructor.

wxFileName::wxFileName (const wxString & *fullpath,* wxPathFormat *format* = wxPATH_NATIVE)

Constructor taking a full filename.

If it terminates with a '/', a directory path is constructed (the name will be empty), otherwise a file name and extension are extracted from it.

wxFileName::wxFileName (const wxString & *path,* const wxString & *name,* wxPathFormat *format* = wxPATH_NATIVE)

Constructor a directory name and file name.

wxFileName::wxFileName (const wxString & *path,* const wxString & *name,* const wxString & *ext,* wxPathFormat *format* = wxPATH_NATIVE)

Constructor from a directory name, base file name and extension.

wxFileName::wxFileName (const wxString & *volume,* const wxString & *path,* const wxString & *name,* const wxString & *ext,* wxPathFormat *format* = wxPATH_NATIVE)

Constructor from a volume name, a directory name, base file name and extension.

21.239.8 Member Function Documentation

bool wxFileName::AppendDir (const wxString & *dir*)

Appends a directory component to the path.

This component should contain a single directory name level, i.e. not contain any path or volume separators nor should it be empty, otherwise the function does nothing and returns false (and generates an assert failure in debug build).

Notice that the return value is only available in wxWidgets 2.9.5 or later.

void wxFileName::Assign (const wxFileName & *filepath*)

Creates the file name from another filename object.

void wxFileName::Assign (const wxString & *fullpath,* wxPathFormat *format* = wxPATH_NATIVE)

Creates the file name from a full file name with a path.

void wxFileName::Assign (const wxString & *volume,* const wxString & *path,* const wxString & *name,* const wxString & *ext,* bool *hasExt,* wxPathFormat *format* = wxPATH_NATIVE)

Creates the file name from volume, path, name and extension.

void wxFileName::Assign (const wxString & *volume,* const wxString & *path,* const wxString & *name,* const wxString & *ext,* wxPathFormat *format* = wxPATH_NATIVE)

Creates the file name from volume, path, name and extension.

void wxFileName::Assign (const wxString & *path,* const wxString & *name,* wxPathFormat *format* = wxPATH_NATIVE)

Creates the file name from file path and file name.

void wxFileName::Assign (const wxString & *path,* const wxString & *name,* const wxString & *ext,* wxPathFormat *format* = wxPATH_NATIVE)

Creates the file name from path, name and extension.

void wxFileName::AssignCwd (const wxString & *volume* = wxEmptyString)

Makes this object refer to the current working directory on the specified volume (or current volume if *volume* is empty).

See also

GetCwd()

void wxFileName::AssignDir (const wxString & *dir,* wxPathFormat *format* = wxPATH_NATIVE)

Sets this file name object to the given directory name.

The name and extension will be empty.

void wxFileName::AssignHomeDir ( )

Sets this file name object to the home directory.

void wxFileName::AssignTempFileName (const wxString & *prefix*)

The function calls CreateTempFileName() to create a temporary file and sets this object to the name of the file.

If a temporary file couldn't be created, the object is put into an invalid state (see IsOk()).

void wxFileName::AssignTempFileName (const wxString & *prefix,* wxFile * *fileTemp*)

The function calls CreateTempFileName() to create a temporary file name and open *fileTemp* with it.

If the file couldn't be opened, the object is put into an invalid state (see IsOk()).

void wxFileName::AssignTempFileName (const wxString & *prefix,* wxFFile * *fileTemp*)

The function calls CreateTempFileName() to create a temporary file name and open *fileTemp* with it.

If the file couldn't be opened, the object is put into an invalid state (see IsOk()).

void wxFileName::Clear ( )

Reset all components to default, uninitialized state.

void wxFileName::ClearExt ( )

Removes the extension from the file name resulting in a file name with no trailing dot.

See also

SetExt(), SetEmptyExt()

static wxString wxFileName::CreateTempFileName (const wxString & *prefix,* wxFile * *fileTemp* = NULL) [static]

Returns a temporary file name starting with the given *prefix*.

If *prefix* is an absolute path and ends in a separator, the temporary file is created in this directory; if it is an absolute filepath or there is no separator, the temporary file is created in its path, with the 'name' segment prepended to the temporary filename; otherwise it is created in the default system directory for temporary files or in the current directory.

If the function succeeds, the temporary file is actually created. If *fileTemp* is not NULL, this wxFile will be opened using the name of the temporary file. Where possible this is done in an atomic way to ensure that no race condition occurs between creating the temporary file name and opening it, which might lead to a security compromise on multiuser systems. If *fileTemp* is NULL, the file is created but not opened. Under Unix, the temporary file will have read and write permissions for the owner only, to minimize security problems.

Parameters

prefix	Location to use for the temporary file name construction. If *prefix* is a directory it must have a terminal separator

fileTemp	The file to open, or NULL just to get the name

Returns

The full temporary filepath, or an empty string on error.

static wxString wxFileName::CreateTempFileName (const wxString & *prefix,* wxFFile * *fileTemp* = NULL) [static]

This is the same as CreateTempFileName(const wxString &prefix, wxFile *fileTemp) but takes a wxFFile parameter instead of wxFile.

bool wxFileName::DirExists ( ) const

Returns true if the directory with this name exists.

Notice that this function tests the directory part of this object, i.e. the string returned by GetPath(), and not the full path returned by GetFullPath().

See also

FileExists(), Exists()

static bool wxFileName::DirExists (const wxString & *dir*) [static]

Returns true if the directory with name *dir* exists.

See also

FileExists(), Exists()

static wxFileName wxFileName::DirName (const wxString & *dir,* wxPathFormat *format* = wxPATH_NATIVE) [static]

Returns the object corresponding to the directory with the given name.

The *dir* parameter may have trailing path separator or not.

void wxFileName::DontFollowLink ( )

Turns off symlink dereferencing.

By default, all operations in this class work on the target of a symbolic link (symlink) if the path of the file is actually a symlink. Using this method allows to turn off this "symlink following" behaviour and apply the operations to this path itself, even if it is a symlink.

The following methods are currently affected by this option:

- GetTimes() (but not SetTimes() as there is no portable way to change the time of symlink itself).
- Existence checks: FileExists(), DirExists() and Exists() (notice that static versions of these methods always follow symlinks).
- IsSameAs().

See also

ShouldFollowLink()

Since

2.9.5

bool wxFileName::Exists (int *flags* = `wxFILE_EXISTS_ANY`) const

Calls the static overload of this function with the full path of this object.

Since

2.9.4 (*flags* is new since 2.9.5)

static bool wxFileName::Exists (const wxString & *path*, int *flags* = `wxFILE_EXISTS_ANY`) [static]

Returns true if either a file or a directory or something else with this name exists in the file system.

Don't dereference *path* if it is a symbolic link and *flags* argument contains wxFILE_EXISTS_NO_FOLLOW.

This method is equivalent to

```
FileExists() || DirExists()
```

under Windows, but under Unix it also returns true if the file identifies a special file system object such as a device, a socket or a FIFO.

Alternatively you may check for the existence of a file system entry of a specific type by passing the appropriate *flags* (this parameter is new since wxWidgets 2.9.5). E.g. to test for a symbolic link existence you could use wxFILE_EXISTS_SYMLINK.

Since

2.9.4

See also

FileExists(), DirExists()

bool wxFileName::FileExists ( ) const

Returns true if the file with this name exists.

See also

DirExists(), Exists()

static bool wxFileName::FileExists (const wxString & *file*) [static]

Returns true if the file with name *file* exists.

See also

DirExists(), Exists()

static wxFileName wxFileName::FileName (const wxString & *file,* wxPathFormat *format* = wxPATH_NATIVE) [static]

Returns the file name object corresponding to the given *file*.

This function exists mainly for symmetry with DirName().

static wxString wxFileName::GetCwd (const wxString & *volume* = wxEmptyString) [static]

Retrieves the value of the current working directory on the specified volume.

If the volume is empty, the program's current working directory is returned for the current volume.

Returns

The string containing the current working directory or an empty string on error.

See also

AssignCwd()

size_t wxFileName::GetDirCount ( ) const

Returns the number of directories in the file name.

const wxArrayString& wxFileName::GetDirs ( ) const

Returns the directories in string array form.

wxString wxFileName::GetExt ( ) const

Returns the file name extension.

static wxString wxFileName::GetForbiddenChars (wxPathFormat *format* = wxPATH_NATIVE) [static]

Returns the characters that can't be used in filenames and directory names for the specified format.

static wxPathFormat wxFileName::GetFormat (wxPathFormat *format* = wxPATH_NATIVE) [static]

Returns the canonical path format for this platform.

wxString wxFileName::GetFullName ( ) const

Returns the full name (including extension but excluding directories).

wxString wxFileName::GetFullPath (wxPathFormat *format* = wxPATH_NATIVE) const

Returns the full path with name and extension.

static wxString wxFileName::GetHomeDir ( ) [static]

Returns the home directory.

wxString wxFileName::GetHumanReadableSize (const wxString & *failmsg* = _("Not available"), int *precision* = 1, wxSizeConvention *conv* = wxSIZE_CONV_TRADITIONAL) const

Returns the representation of the file size in a human-readable form.

In the first version, the size of this file is used. In the second one, the specified size *bytes* is used.

If the file size could not be retrieved or *bytes* is wxInvalidSize or zero, the `failmsg` string is returned.

Otherwise the returned string is a floating-point number with `precision` decimal digits followed by the abbreviation of the unit used. By default the traditional, although incorrect, convention of using SI units for multiples of 1024 is used, i.e. returned string will use suffixes of B, KB, MB, GB, TB for bytes, kilobytes, megabytes, gigabytes and terabytes respectively. With the IEC convention the names of the units are changed to B, KiB, MiB, GiB and TiB for bytes, kibibytes, mebibytes, gibibytes and tebibytes. Finally, with SI convention the same B, KB, MB, GB and TB suffixes are used but in their correct SI meaning, i.e. as multiples of 1000 and not 1024.

Support for the different size conventions is new in wxWidgets 2.9.1, in previous versions only the traditional convention was implemented.

static wxString wxFileName::GetHumanReadableSize (const wxULongLong & *bytes*, const wxString & *nullsize* = _("Not available"), int *precision* = 1, wxSizeConvention *conv* = wxSIZE_CONV_TRADITIONAL) [static]

Returns the representation of the file size in a human-readable form.

In the first version, the size of this file is used. In the second one, the specified size *bytes* is used.

If the file size could not be retrieved or *bytes* is wxInvalidSize or zero, the `failmsg` string is returned.

Otherwise the returned string is a floating-point number with `precision` decimal digits followed by the abbreviation of the unit used. By default the traditional, although incorrect, convention of using SI units for multiples of 1024 is used, i.e. returned string will use suffixes of B, KB, MB, GB, TB for bytes, kilobytes, megabytes, gigabytes and terabytes respectively. With the IEC convention the names of the units are changed to B, KiB, MiB, GiB and TiB for bytes, kibibytes, mebibytes, gibibytes and tebibytes. Finally, with SI convention the same B, KB, MB, GB and TB suffixes are used but in their correct SI meaning, i.e. as multiples of 1000 and not 1024.

Support for the different size conventions is new in wxWidgets 2.9.1, in previous versions only the traditional convention was implemented.

wxString wxFileName::GetLongPath ( ) const

Return the long form of the path (returns identity on non-Windows platforms).

wxDateTime wxFileName::GetModificationTime ( ) const

Returns the last time the file was last modified.

wxString wxFileName::GetName ( ) const

Returns the name part of the filename (without extension).

See also

GetFullName()

wxString wxFileName::GetPath (int *flags* = wxPATH_GET_VOLUME, wxPathFormat *format* = wxPATH_NATIVE) const

Returns the path part of the filename (without the name or extension).

The possible flags values are:

- **wxPATH_GET_VOLUME:** Return the path with the volume (does nothing for the filename formats without volumes), otherwise the path without volume part is returned.
- **wxPATH_GET_SEPARATOR:** Return the path with the trailing separator, if this flag is not given there will be no separator at the end of the path.
- **wxPATH_NO_SEPARATOR:** Don't include the trailing separator in the returned string. This is the default (the value of this flag is 0) and exists only for symmetry with wxPATH_GET_SEPARATOR.

Note

If the path is a toplevel one (e.g. `"/"` on Unix or `"C:\"` on Windows), then the returned path will contain trailing separator even with `wxPATH_NO_SEPARATOR`.

static wxUniChar wxFileName::GetPathSeparator (wxPathFormat *format* = wxPATH_NATIVE) [static]

Returns the usually used path separator for this format.

For all formats but `wxPATH_DOS` there is only one path separator anyhow, but for DOS there are two of them and the native one, i.e. the backslash is returned by this method.

See also

GetPathSeparators()

static wxString wxFileName::GetPathSeparators (wxPathFormat *format* = wxPATH_NATIVE) [static]

Returns the string containing all the path separators for this format.

For all formats but `wxPATH_DOS` this string contains only one character but for DOS and Windows both `'/'` and `'\'` may be used as separators.

See also

GetPathSeparator()

static wxString wxFileName::GetPathTerminators (wxPathFormat *format* = wxPATH_NATIVE) [static]

Returns the string of characters which may terminate the path part.

This is the same as GetPathSeparators() except for VMS path format where] is used at the end of the path part.

wxString wxFileName::GetPathWithSep (wxPathFormat *format* = wxPATH_NATIVE) const

Returns the path with the trailing separator, useful for appending the name to the given path.

This is the same as calling

```
GetPath(wxPATH_GET_VOLUME | wxPATH_GET_SEPARATOR, format)
```

wxString wxFileName::GetShortPath ( ) const

Return the short form of the path (returns identity on non-Windows platforms).

wxULongLong wxFileName::GetSize ( ) const

Returns the size of the file If the file does not exist or its size could not be read (because e.g.

the file is locked by another process) the returned value is wxInvalidSize.

static wxULongLong wxFileName::GetSize (const wxString & *filename*) [static]

Returns the size of the file If the file does not exist or its size could not be read (because e.g.

the file is locked by another process) the returned value is wxInvalidSize.

static wxString wxFileName::GetTempDir ( ) [static]

Returns the directory used for temporary files.

bool wxFileName::GetTimes (wxDateTime * *dtAccess,* wxDateTime * *dtMod,* wxDateTime * *dtCreate*) const

Returns the last access, last modification and creation times.

The last access time is updated whenever the file is read or written (or executed in the case of Windows), last modification time is only changed when the file is written to. Finally, the creation time is indeed the time when the file was created under Windows and the inode change time under Unix (as it is impossible to retrieve the real file creation time there anyhow) which can also be changed by many operations after the file creation.

If no filename or extension is specified in this instance of wxFileName (and therefore IsDir() returns true) then this function will return the directory times of the path specified by GetPath(), otherwise the file times of the file specified by GetFullPath(). Any of the pointers may be NULL if the corresponding time is not needed.

Returns

true on success, false if we failed to retrieve the times.

wxString wxFileName::GetVolume ( ) const

Returns the string containing the volume for this file name, empty if it doesn't have one or if the file system doesn't support volumes at all (for example, Unix).

static wxString wxFileName::GetVolumeSeparator (wxPathFormat *format* = wxPATH_NATIVE) [static]

Returns the string separating the volume from the path for this format.

static wxString wxFileName::GetVolumeString (char *drive,* int *flags* = wxPATH_GET_SEPARATOR) [static]

This function builds a volume path string, for example "C:\\".

Implemented for the platforms which use drive letters, i.e. DOS, MSW and OS/2 only.

Since

2.9.0

Parameters

drive	The drive letter, 'A' through 'Z' or 'a' through 'z'.
flags	`wxPATH_NO_SEPARATOR` or `wxPATH_GET_SEPARATOR` to omit or include the trailing path separator, the default is to include it.

Returns

Volume path string.

bool wxFileName::HasExt ( ) const

Returns true if an extension is present.

bool wxFileName::HasName ( ) const

Returns true if a name is present.

bool wxFileName::HasVolume ( ) const

Returns true if a volume specifier is present.

bool wxFileName::InsertDir (size_t *before,* const wxString & *dir*)

Inserts a directory component before the zero-based position in the directory list.

As with AppendDir(), *dir* must be a single directory name and the function returns false and does nothing else if it isn't.

Notice that the return value is only available in wxWidgets 2.9.5 or later.

bool wxFileName::IsAbsolute (wxPathFormat *format* = wxPATH_NATIVE) const

Returns true if this filename is absolute.

static bool wxFileName::IsCaseSensitive (wxPathFormat *format* = wxPATH_NATIVE) [static]

Returns true if the file names of this type are case-sensitive.

bool wxFileName::IsDir ( ) const

Returns true if this object represents a directory, false otherwise (i.e.

if it is a file).

Note that this method doesn't test whether the directory or file really exists, you should use DirExists() or FileExists() for this.

bool wxFileName::IsDirReadable ( ) const

Returns true if the directory component of this instance is an existing directory and this process has read permissions on it.

Read permissions on a directory mean that you can list the directory contents but it doesn't imply that you have read permissions on the files contained.

static bool wxFileName::IsDirReadable (const wxString & *dir*) [static]

Returns true if the given *dir* is an existing directory and this process has read permissions on it.

Read permissions on a directory mean that you can list the directory contents but it doesn't imply that you have read permissions on the files contained.

bool wxFileName::IsDirWritable ( ) const

Returns true if the directory component of this instance is an existing directory and this process has write permissions on it.

Write permissions on a directory mean that you can create new files in the directory.

static bool wxFileName::IsDirWritable (const wxString & *dir*) [static]

Returns true if the given *dir* is an existing directory and this process has write permissions on it.

Write permissions on a directory mean that you can create new files in the directory.

bool wxFileName::IsFileExecutable ( ) const

Returns true if a file with this name exists and if this process has execute permissions on it.

static bool wxFileName::IsFileExecutable (const wxString & *file*) [static]

Returns true if a file with this name exists and if this process has execute permissions on it.

bool wxFileName::IsFileReadable ( ) const

Returns true if a file with this name exists and if this process has read permissions on it.

static bool wxFileName::IsFileReadable (const wxString & *file*) [static]

Returns true if a file with this name exists and if this process has read permissions on it.

bool wxFileName::IsFileWritable ( ) const

Returns true if a file with this name exists and if this process has write permissions on it.

static bool wxFileName::IsFileWritable (const wxString & *file*) [static]

Returns true if a file with this name exists and if this process has write permissions on it.

static bool wxFileName::IsMSWUniqueVolumeNamePath (const wxString & *path,* wxPathFormat *format =* wxPATH_NATIVE) [static]

Returns true if the volume part of the path is a unique volume name.

This function will always return false if the path format is not wxPATH_DOS.

Unique volume names are Windows volume identifiers which remain the same regardless of where the volume is actually mounted. Example of a path using a volume name could be

```
\\?\Volume{8089d7d7-d0ac-11db-9dd0-806d6172696f}\Program Files\setup.exe
```

Since

2.9.1

bool wxFileName::IsOk ( ) const

Returns true if the filename is valid, false if it is not initialized yet.

The assignment functions and Clear() may reset the object to the uninitialized, invalid state (the former only do it on failure).

static bool wxFileName::IsPathSeparator (wxChar *ch,* wxPathFormat *format* = wxPATH_NATIVE) [static]

Returns true if the char is a path separator for this format.

bool wxFileName::IsRelative (wxPathFormat *format* = wxPATH_NATIVE) const

Returns true if this filename is not absolute.

static bool wxFileName::MacFindDefaultTypeAndCreator (const wxString & *ext,* wxUint32 * *type,* wxUint32 * *creator*) [static]

On Mac OS, gets the common type and creator for the given extension.

Availability: only available for the wxOSX port.

static void wxFileName::MacRegisterDefaultTypeAndCreator (const wxString & *ext,* wxUint32 *type,* wxUint32 *creator*) [static]

On Mac OS, registers application defined extensions and their default type and creator.

Availability: only available for the wxOSX port.

bool wxFileName::MacSetDefaultTypeAndCreator ( )

On Mac OS, looks up the appropriate type and creator from the registration and then sets it.

Availability: only available for the wxOSX port.

bool wxFileName::MakeAbsolute (const wxString & *cwd* = wxEmptyString, wxPathFormat *format* = wxPATH_NATIVE)

Make the file name absolute.

This is a shortcut for

```
wxFileName::Normalize(wxPATH_NORM_DOTS |
      wxPATH_NORM_ABSOLUTE |
                    wxPATH_NORM_TILDE, cwd, format)
```

See also

MakeRelativeTo(), Normalize(), IsAbsolute()

bool wxFileName::MakeRelativeTo (const wxString & *pathBase* = wxEmptyString, wxPathFormat *format* = wxPATH_NATIVE)

This function tries to put this file name in a form relative to *pathBase*.

In other words, it returns the file name which should be used to access this file if the current directory were pathBase.

Parameters

pathBase	The directory to use as root, current directory is used by default
format	The file name format, native by default

Returns

true if the file name has been changed, false if we failed to do anything with it (currently this only happens if the file name is on a volume different from the volume specified by *pathBase*).

See also

Normalize()

bool wxFileName::Mkdir (int *perm* = wxS_DIR_DEFAULT, int *flags* = 0) const

Creates a directory.

Parameters

perm	The permissions for the newly created directory. See the wxPosixPermissions enumeration for more info.
flags	If the flags contain `wxPATH_MKDIR_FULL` flag, try to create each directory in the path and also don't return an error if the target directory already exists.

Returns

Returns true if the directory was successfully created, false otherwise.

static bool wxFileName::Mkdir (const wxString & *dir*, int *perm* = wxS_DIR_DEFAULT, int *flags* = 0) [static]

Creates a directory.

Parameters

dir	The directory to create
perm	The permissions for the newly created directory. See the wxPosixPermissions enumeration for more info.
flags	If the flags contain `wxPATH_MKDIR_FULL` flag, try to create each directory in the path and also don't return an error if the target directory already exists.

Returns

Returns true if the directory was successfully created, false otherwise.

bool wxFileName::Normalize (int *flags* = wxPATH_NORM_ALL, const wxString & *cwd* = wxEmptyString, wxPathFormat *format* = wxPATH_NATIVE)

Normalize the path.

With the default flags value, the path will be made absolute, without any ".." and "." and all environment variables will be expanded in it.

Notice that in some rare cases normalizing a valid path may result in an invalid wxFileName object. E.g. normalizing "./" path using wxPATH_NORM_DOTS but not wxPATH_NORM_ABSOLUTE will result in a completely empty and thus invalid object. As long as there is a non empty file name the result of normalization will be valid however.

Parameters

flags	The kind of normalization to do with the file name. It can be any or-combination of the wxPathNormalize enumeration values.
cwd	If not empty, this directory will be used instead of current working directory in normalization (see `wxPATH_NORM_ABSOLUTE`).
format	The file name format to use when processing the paths, native by default.

Returns

true if normalization was successfully or false otherwise.

bool wxFileName::operator!= (const wxFileName & *filename*) const

Returns true if the filenames are different.

The string *filenames* is interpreted as a path in the native filename format.

bool wxFileName::operator!= (const wxString & *filename*) const

Returns true if the filenames are different.

The string *filenames* is interpreted as a path in the native filename format.

wxFileName& wxFileName::operator= (const wxFileName & *filename*)

Assigns the new value to this filename object.

wxFileName& wxFileName::operator= (const wxString & *filename*)

Assigns the new value to this filename object.

bool wxFileName::operator== (const wxFileName & *filename*) const

Returns true if the filenames are equal.

The string *filenames* is interpreted as a path in the native filename format.

bool wxFileName::operator== (const wxString & *filename*) const

Returns true if the filenames are equal.

The string *filenames* is interpreted as a path in the native filename format.

void wxFileName::PrependDir (const wxString & *dir*)

Prepends a directory to the file path.

Please see AppendDir() for important notes.

void wxFileName::RemoveDir (size_t *pos*)

Removes the specified directory component from the path.

See also

GetDirCount()

void wxFileName::RemoveLastDir ( )

Removes last directory component from the path.

bool wxFileName::ReplaceEnvVariable (const wxString & *envname*, const wxString & *replacementFmtString* = "$%s", wxPathFormat *format* = wxPATH_NATIVE)

If the path contains the value of the environment variable named *envname* then this function replaces it with the string obtained from wxString::Format(replacementFmtString, value_of_envname_variable).

This function is useful to make the path shorter or to make it dependent from a certain environment variable. Normalize() with `wxPATH_NORM_ENV_VARS` can perform the opposite of this function (depending on the value of *replacementFmtString*).

The name and extension of this filename are not modified.

Example:

```
wxFileName fn("/usr/openwin/lib/someFile");
fn.ReplaceEnvVariable("OPENWINHOME");
        // now fn.GetFullPath() == "$OPENWINHOME/lib/someFile"
```

Since

2.9.0

Returns

true if the operation was successful (which doesn't mean that something was actually replaced, just that wxGetEnv didn't fail).

bool wxFileName::ReplaceHomeDir (wxPathFormat *format* = wxPATH_NATIVE)

Replaces, if present in the path, the home directory for the given user (see wxGetHomeDir) with a tilde (~).

Normalize() with `wxPATH_NORM_TILDE` performs the opposite of this function.

The name and extension of this filename are not modified.

Since

2.9.0

Returns

true if the operation was successful (which doesn't mean that something was actually replaced, just that wxGetHomeDir didn't fail).

bool wxFileName::Rmdir (int *flags* = 0) const

Deletes the specified directory from the file system.

Parameters

flags	Can contain one of wxPATH_RMDIR_FULL or wxPATH_RMDIR_RECURSIVE. By default contains neither so the directory will not be removed unless it is empty.

Returns

Returns true if the directory was successfully deleted, false otherwise.

static bool wxFileName::Rmdir (const wxString & *dir,* int *flags* = 0) [static]

Deletes the specified directory from the file system.

Parameters

dir	The directory to delete
flags	Can contain one of wxPATH_RMDIR_FULL or wxPATH_RMDIR_RECURSIVE. By default contains neither so the directory will not be removed unless it is empty.

Returns

Returns true if the directory was successfully deleted, false otherwise.

bool wxFileName::SameAs (const wxFileName & *filepath,* wxPathFormat *format* = wxPATH_NATIVE) const

Compares the filename using the rules of this platform.

bool wxFileName::SetCwd ( ) const

Changes the current working directory.

static bool wxFileName::SetCwd (const wxString & *cwd*) [static]

Changes the current working directory.

void wxFileName::SetEmptyExt ( )

Sets the extension of the file name to be an empty extension.

This is different from having no extension at all as the file name will have a trailing dot after a call to this method.

See also

SetExt(), ClearExt()

void wxFileName::SetExt (const wxString & *ext*)

Sets the extension of the file name.

Setting an empty string as the extension will remove the extension resulting in a file name without a trailing dot, unlike a call to SetEmptyExt().

See also

SetEmptyExt(), ClearExt()

void wxFileName::SetFullName (const wxString & *fullname*)

The full name is the file name and extension (but without the path).

void wxFileName::SetName (const wxString & *name*)

Sets the name part (without extension).

See also

SetFullName()

void wxFileName::SetPath (const wxString & *path,* wxPathFormat *format* = wxPATH_NATIVE)

Sets the path.

The *path* argument includes both the path and the volume, if supported by *format*.

Calling this function doesn't affect the name and extension components, to change them as well you can use Assign() or just an assignment operator.

See also

GetPath()

bool wxFileName::SetPermissions (int *permissions*)

Sets permissions for this file or directory.

Parameters

permissions	The new permissions: this should be a combination of wxPosixPermissions enum elements.

Since

3.0

Note

If this is a symbolic link and it should not be followed this call will fail.

Returns

true on success, false if an error occurred (for example, the file doesn't exist).

bool wxFileName::SetTimes (const wxDateTime * *dtAccess,* const wxDateTime * *dtMod,* const wxDateTime * *dtCreate*) const

Sets the file creation and last access/modification times (any of the pointers may be NULL).

Notice that the file creation time can't be changed under Unix, so *dtCreate* is ignored there (but true is still returned). Under Windows all three times can be set.

void wxFileName::SetVolume (const wxString & *volume*)

Sets the volume specifier.

bool wxFileName::ShouldFollowLink ( ) const

Return whether some operations will follow symlink.

By default, file operations "follow symlink", i.e. operate on its target and not on the symlink itself. See DontFollowLink() for more information.

Since

2.9.5

static void wxFileName::SplitPath (const wxString & *fullpath*, wxString * *volume*, wxString * *path*, wxString * *name*, wxString * *ext*, bool * *hasExt* = NULL, wxPathFormat *format* = wxPATH_NATIVE) [static]

This function splits a full file name into components: the volume (with the first version) path (including the volume in the second version), the base name and the extension.

Any of the output parameters (*volume*, *path*, *name* or *ext*) may be NULL if you are not interested in the value of a particular component. Also, *fullpath* may be empty on entry. On return, *path* contains the file path (without the trailing separator), *name* contains the file name and *ext* contains the file extension without leading dot. All three of them may be empty if the corresponding component is. The old contents of the strings pointed to by these parameters will be overwritten in any case (if the pointers are not NULL).

Note that for a filename "foo." the extension is present, as indicated by the trailing dot, but empty. If you need to cope with such cases, you should use *hasExt* instead of relying on testing whether *ext* is empty or not.

static void wxFileName::SplitPath (const wxString & *fullpath*, wxString * *volume*, wxString * *path*, wxString * *name*, wxString * *ext*, wxPathFormat *format*) [static]

This function splits a full file name into components: the volume (with the first version) path (including the volume in the second version), the base name and the extension.

Any of the output parameters (*volume*, *path*, *name* or *ext*) may be NULL if you are not interested in the value of a particular component. Also, *fullpath* may be empty on entry. On return, *path* contains the file path (without the trailing separator), *name* contains the file name and *ext* contains the file extension without leading dot. All three of them may be empty if the corresponding component is. The old contents of the strings pointed to by these parameters will be overwritten in any case (if the pointers are not NULL).

Note that for a filename "foo." the extension is present, as indicated by the trailing dot, but empty. If you need to cope with such cases, you should use *hasExt* instead of relying on testing whether *ext* is empty or not.

static void wxFileName::SplitPath (const wxString & *fullpath*, wxString * *path*, wxString * *name*, wxString * *ext*, wxPathFormat *format* = wxPATH_NATIVE) [static]

This function splits a full file name into components: the volume (with the first version) path (including the volume in the second version), the base name and the extension.

Any of the output parameters (*volume*, *path*, *name* or *ext*) may be NULL if you are not interested in the value of a particular component. Also, *fullpath* may be empty on entry. On return, *path* contains the file path (without the trailing separator), *name* contains the file name and *ext* contains the file extension without leading dot. All three of them may be empty if the corresponding component is. The old contents of the strings pointed to by these parameters will be overwritten in any case (if the pointers are not NULL).

Note that for a filename "foo." the extension is present, as indicated by the trailing dot, but empty. If you need to cope with such cases, you should use *hasExt* instead of relying on testing whether *ext* is empty or not.

static void wxFileName::SplitVolume (const wxString & *fullpath,* wxString * *volume,* wxString * *path,* wxPathFormat *format* = wxPATH_NATIVE) [static]

Splits the given *fullpath* into the volume part (which may be empty) and the pure path part, not containing any volume.

See also

SplitPath()

static wxString wxFileName::StripExtension (const wxString & *fullname*) [static]

Strip the file extension.

This function does more than just removing everything after the last period from the string, for example it will return the string ".vimrc" unchanged because the part after the period is not an extension but the file name in this case. You can use wxString::BeforeLast() to really get just the part before the last period (but notice that that function returns empty string if period is not present at all unlike this function which returns the *fullname* unchanged in this case).

Parameters

fullname	File path including name and, optionally, extension.

Returns

File path without extension

Since

2.9.0

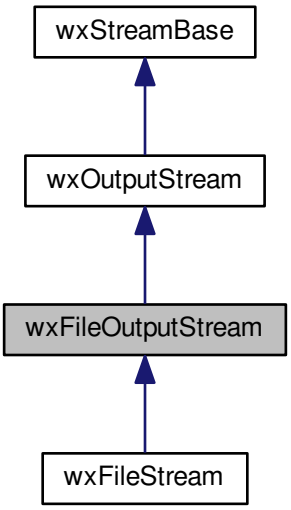
bool wxFileName::Touch ( ) const

Sets the access and modification times to the current moment.

21.240 wxFileOutputStream Class Reference

```
#include <wx/wfstream.h>
```

Inheritance diagram for wxFileOutputStream:



21.240.1 Detailed Description

This class represents data written to a file.

There are actually two such groups of classes: this one is based on wxFile whereas wxFFileOutputStream is based in the wxFFile class.

Note that wxOutputStream::SeekO() can seek beyond the end of the stream (file) and will thus not return wxInvalid↩ Offset for that.

Library: wxBase

Category: Streams

See also

wxBufferedOutputStream, wxFileInputStream, wxFFileOutputStream, wxFFileInputStream

Public Member Functions

- wxFileOutputStream (const wxString &ofileName)

  Creates a new file with ofileName name and initializes the stream in write-only mode.
- wxFileOutputStream (wxFile &file)

  Initializes a file stream in write-only mode using the file I/O object file.
- wxFileOutputStream (int fd)

  Initializes a file stream in write-only mode using the file descriptor fd.
- virtual ~wxFileOutputStream ()

  Destructor.

- bool IsOk () const

  Returns true if the stream is initialized and ready.
- wxFile * GetFile () const

  Returns the underlying file object.

Additional Inherited Members

21.240.2 Constructor & Destructor Documentation

wxFileOutputStream::wxFileOutputStream (const wxString & *ofileName*)

Creates a new file with *ofileName* name and initializes the stream in write-only mode.

Warning

You should use wxStreamBase::IsOk() to verify if the constructor succeeded.

wxFileOutputStream::wxFileOutputStream (wxFile & *file*)

Initializes a file stream in write-only mode using the file I/O object file.

wxFileOutputStream::wxFileOutputStream (int *fd*)

Initializes a file stream in write-only mode using the file descriptor *fd*.

virtual wxFileOutputStream::~wxFileOutputStream ( ) [virtual]

Destructor.

21.240.3 Member Function Documentation

wxFile* wxFileOutputStream::GetFile ( ) const

Returns the underlying file object.

Since

2.9.5

bool wxFileOutputStream::IsOk ( ) const [virtual]

Returns true if the stream is initialized and ready.

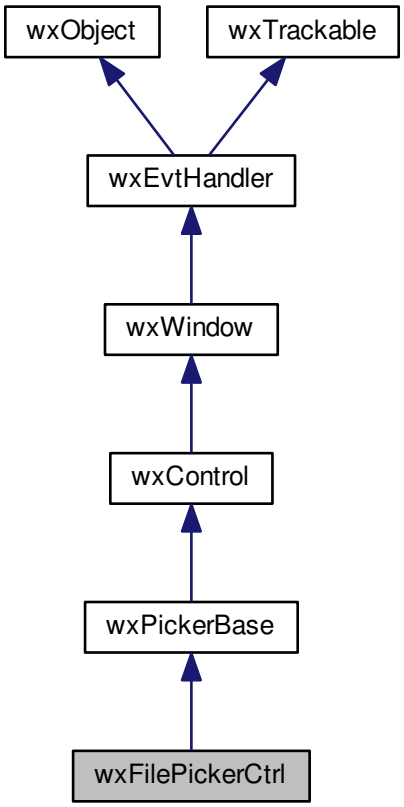
Reimplemented from wxStreamBase.

Reimplemented in wxFileStream.

21.241 wxFilePickerCtrl Class Reference

```
#include <wx/filepicker.h>
```

Inheritance diagram for wxFilePickerCtrl:



21.241.1 Detailed Description

This control allows the user to select a file.

The generic implementation is a button which brings up a wxFileDialog when clicked. Native implementation may differ but this is usually a (small) widget which give access to the file-chooser dialog. It is only available if `wxUSE_FILEPICKERCTRL` is set to 1 (the default).

Styles

This class supports the following styles:

- wxFLP_DEFAULT_STYLE: The default style: includes wxFLP_OPEN | wxFLP_FILE_MUST_EXIST and, under wxMSW only, wxFLP_USE_TEXTCTRL.
- wxFLP_USE_TEXTCTRL: Creates a text control to the left of the picker button which is completely managed by the wxFilePickerCtrl and which can be used by the user to specify a path (see SetPath). The text control is automatically synchronized with button's value. Use functions defined in wxPickerBase to modify the text control.
- wxFLP_OPEN: Creates a picker which allows the user to select a file to open.
- wxFLP_SAVE: Creates a picker which allows the user to select a file to save.

- wxFLP_OVERWRITE_PROMPT: Can be combined with wxFLP_SAVE only: ask confirmation to the user before selecting a file.
- wxFLP_FILE_MUST_EXIST: Can be combined with wxFLP_OPEN only: the selected file must be an existing file.
- wxFLP_CHANGE_DIR: Change current working directory on each user file selection change.
- wxFLP_SMALL: Use smaller version of the control with a small "..." button instead of the normal "Browse" one. This flag is new since wxWidgets 2.9.3.

Events emitted by this class

The following event handler macros redirect the events to member function handlers '**func**' with prototypes like: void handlerFuncName(wxFileDirPickerEvent& event)

Event macros for events emitted by this class:

- EVT_FILEPICKER_CHANGED(id, func): The user changed the file selected in the control either using the button or using text control (see wxFLP_USE_TEXTCTRL; note that in this case the event is fired only if the user's input is valid, e.g. an existing file path if wxFLP_FILE_MUST_EXIST was given).

Library: wxCore

Category: Picker Controls

wxFileDialog, wxFileDirPickerEvent

Public Member Functions

- wxFilePickerCtrl ()
- wxFilePickerCtrl (wxWindow *parent, wxWindowID id, const wxString &path=wxEmptyString, const wxString &message=wxFileSelectorPromptStr, const wxString &wildcard=wxFileSelectorDefaultWildcardStr, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, long style=wxFLP_DEFAULT_STYLE, const wxValidator &validator=wxDefaultValidator, const wxString &name=wxFilePickerCtrlNameStr)

  Initializes the object and calls Create() with all the parameters.
- bool Create (wxWindow *parent, wxWindowID id, const wxString &path=wxEmptyString, const wxString &message=wxFileSelectorPromptStr, const wxString &wildcard=wxFileSelectorDefaultWildcardStr, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, long style=wxFLP_DEFAULT_STYLE, const wxValidator &validator=wxDefaultValidator, const wxString &name=wxFilePickerCtrlNameStr)

  Creates this widget with the given parameters.
- wxFileName GetFileName () const

  Similar to GetPath() but returns the path of the currently selected file as a wxFileName object.
- wxString GetPath () const

  Returns the absolute path of the currently selected file.
- void SetFileName (const wxFileName &filename)

  This method does the same thing as SetPath() but takes a wxFileName object instead of a string.
- void SetInitialDirectory (const wxString &dir)

  Set the directory to show when starting to browse for files.
- void SetPath (const wxString &filename)

  Sets the absolute path of the currently selected file.

Additional Inherited Members

21.241.2 Constructor & Destructor Documentation

wxFilePickerCtrl::wxFilePickerCtrl ( )

wxFilePickerCtrl::wxFilePickerCtrl (wxWindow * *parent*, wxWindowID *id*, const wxString & *path* = wxEmptyString, const wxString & *message* = `wxFileSelectorPromptStr`, const wxString & *wildcard* = wxFileSelectorDefaultWildcardStr, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, long *style* = wxFLP_DEFAULT_STYLE, const wxValidator & *validator* = wxDefaultValidator, const wxString & *name* = `wxFilePickerCtrlNameStr`)

Initializes the object and calls Create() with all the parameters.

21.241.3 Member Function Documentation

bool wxFilePickerCtrl::Create (wxWindow * *parent*, wxWindowID *id*, const wxString & *path* = wxEmptyString, const wxString & *message* = `wxFileSelectorPromptStr`, const wxString & *wildcard* = wxFileSelectorDefaultWildcardStr, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, long *style* = wxFLP_DEFAULT_STYLE, const wxValidator & *validator* = wxDefaultValidator, const wxString & *name* = `wxFilePickerCtrlNameStr`)

Creates this widget with the given parameters.

Parameters

parent	Parent window, must not be non-NULL.
id	The identifier for the control.
path	The initial file shown in the control. Must be a valid path to a file or the empty string.
message	The message shown to the user in the wxFileDialog shown by the control.
wildcard	A wildcard which defines user-selectable files (use the same syntax as for wxFileDialog's wildcards).
pos	Initial position.
size	Initial size.
style	The window style, see wxFLP_* flags.
validator	Validator which can be used for additional data checks.
name	Control name.

Returns

true if the control was successfully created or false if creation failed.

wxFileName wxFilePickerCtrl::GetFileName ( ) const

Similar to GetPath() but returns the path of the currently selected file as a wxFileName object.

wxString wxFilePickerCtrl::GetPath ( ) const

Returns the absolute path of the currently selected file.

void wxFilePickerCtrl::SetFileName (const wxFileName & *filename*)

This method does the same thing as SetPath() but takes a wxFileName object instead of a string.

void wxFilePickerCtrl::SetInitialDirectory (const wxString & *dir*)

Set the directory to show when starting to browse for files.

This function is mostly useful for the file picker controls which have no selection initially to configure the directory that should be shown if the user starts browsing for files as otherwise the directory of initially selected file is used, which is usually the desired behaviour and so the directory specified by this function is ignored in this case.

Since

2.9.4

void wxFilePickerCtrl::SetPath (const wxString & *filename*)

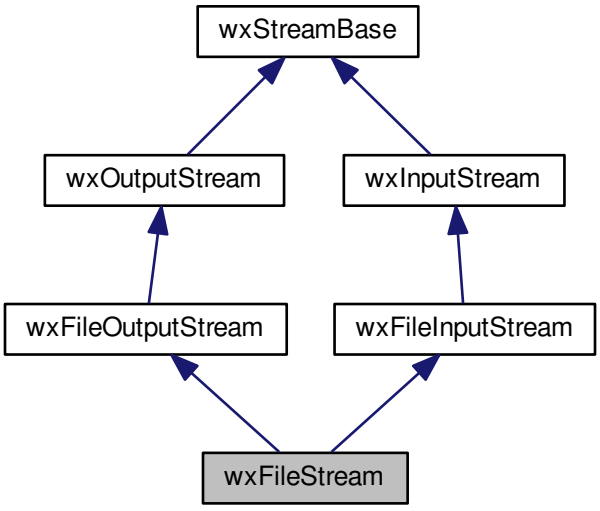
Sets the absolute path of the currently selected file.

This must be a valid file if the `wxFLP_FILE_MUST_EXIST` style was given.

21.242 wxFileStream Class Reference

`#include <wx/wfstream.h>`

Inheritance diagram for wxFileStream:



21.242.1 Detailed Description

This class represents data that can be both read from and written to a file.

There are actually two such groups of classes: this one is based on wxFile whereas wxFFileStream is based in the wxFFile class.

Library: wxBase

Category: Streams

See also

wxFileInputStream, wxFileOutputStream, wxFFileStream

Public Member Functions

- wxFileStream (const wxString &iofileName)

  Initializes a new file stream in read-write mode using the specified iofileName name.

- bool IsOk () const

  Returns true if the stream is initialized and ready.

Additional Inherited Members

21.242.2 Constructor & Destructor Documentation

wxFileStream::wxFileStream (const wxString & *iofileName*)

Initializes a new file stream in read-write mode using the specified *iofileName* name.

Warning

You should use IsOk() to verify if the constructor succeeded.

21.242.3 Member Function Documentation

bool wxFileStream::IsOk ( ) const `[virtual]`

Returns true if the stream is initialized and ready.

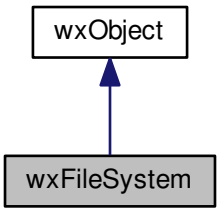
This method returns true if the stream can be both read from and written to.

Reimplemented from wxFileOutputStream.

21.243 wxFileSystem Class Reference

```
#include <wx/filesys.h>
```

Inheritance diagram for wxFileSystem:



21.243.1 Detailed Description

This class provides an interface for opening files on different file systems.

It can handle absolute and/or local filenames.

It uses a system of handlers (see wxFileSystemHandler) to provide access to user-defined virtual file systems.

Library: wxBase

Category: Virtual File System

See also

wxFileSystemHandler, wxFSFile, wxFileSystem Overview

Public Member Functions

- wxFileSystem ()

  Constructor.
- void ChangePathTo (const wxString &location, bool is_dir=false)

  Sets the current location.
- bool FindFileInPath (wxString *pStr, const wxString &path, const wxString &file)

  Looks for the file with the given name file in a colon or semi-colon (depending on the current platform) separated list of directories in path.
- wxString FindFirst (const wxString &wildcard, int flags=0)

  Works like wxFindFirstFile().
- wxString FindNext ()

  Returns the next filename that matches the parameters passed to FindFirst().
- wxString GetPath () const

  Returns the actual path (set by wxFileSystem::ChangePathTo).
- wxFSFile * OpenFile (const wxString &location, int flags=wxFS_READ)

  Opens the file and returns a pointer to a wxFSFile object or NULL if failed.

Static Public Member Functions

- static void AddHandler (wxFileSystemHandler *handler)

  This static function adds new handler into the list of handlers (see wxFileSystemHandler) which provide access to virtual FS.
- static wxFileSystemHandler * RemoveHandler (wxFileSystemHandler *handler)

  Remove a filesystem handler from the list of handlers.
- static wxString FileNameToURL (const wxFileName &filename)

  Converts a wxFileName into an URL.
- static bool HasHandlerForPath (const wxString &location)

  This static function returns true if there is a registered handler which can open the given location.
- static wxFileName URLToFileName (const wxString &url)

  Converts URL into a well-formed filename.

Additional Inherited Members

21.243.2 Constructor & Destructor Documentation

wxFileSystem::wxFileSystem ( )

Constructor.

The initial current path of this object will be empty (i.e. GetPath() == wxEmptyString) which means that e.g. OpenFile() or FindFirst() functions will use current working directory as current path (see also wxGetCwd).

21.243.3 Member Function Documentation

static void wxFileSystem::AddHandler (wxFileSystemHandler * *handler*) [static]

This static function adds new handler into the list of handlers (see wxFileSystemHandler) which provide access to virtual FS.

Note that if two handlers for the same protocol are added, the last added one takes precedence.

Note

You can call:

```
wxFileSystem::AddHandler(new My_FS_Handler);
```

This is because (a) AddHandler is a static method, and (b) the handlers are deleted in wxFileSystem's destructor so that you don't have to care about it.

void wxFileSystem::ChangePathTo (const wxString & *location*, bool *is_dir* = false)

Sets the current location.

location parameter passed to OpenFile() is relative to this path.

Remarks

Unless *is_dir* is true the *location* parameter is not the directory name but the name of the file in this directory.

All these commands change the path to "dir/subdir/":

```
ChangePathTo("dir/subdir/xh.htm");
ChangePathTo("dir/subdir", true);
ChangePathTo("dir/subdir/", true);
```

Example:

```
f = fs->OpenFile("hello.htm"); // opens file 'hello.htm'
fs->ChangePathTo("subdir/folder", true);
f = fs->OpenFile("hello.htm"); // opens file 'subdir/folder/hello.htm' !!
```

Parameters

location	the new location. Its meaning depends on the value of is_dir
is_dir	if true location is new directory. If false (the default) location is file in the new directory.

static wxString wxFileSystem::FileNameToURL (const wxFileName & *filename*) [static]

Converts a wxFileName into an URL.

See also

URLToFileName(), wxFileName

bool wxFileSystem::FindFileInPath (wxString * *pStr*, const wxString & *path*, const wxString & *file*)

Looks for the file with the given name *file* in a colon or semi-colon (depending on the current platform) separated list of directories in *path*.

If the file is found in any directory, returns true and the full path of the file in *str*, otherwise returns false and doesn't modify *str*.

Parameters

pStr	Receives the full path of the file, must not be NULL
path	wxPATH_SEP-separated list of directories
file	the name of the file to look for

wxString wxFileSystem::FindFirst (const wxString & *wildcard*, int *flags* = 0)

Works like wxFindFirstFile().

Returns the name of the first filename (within filesystem's current path) that matches *wildcard*.

Parameters

wildcard	The wildcard that the filename must match
flags	One of wxFILE (only files), wxDIR (only directories) or 0 (both).

wxString wxFileSystem::FindNext ( )

Returns the next filename that matches the parameters passed to FindFirst().

wxString wxFileSystem::GetPath ( ) const

Returns the actual path (set by wxFileSystem::ChangePathTo).

static bool wxFileSystem::HasHandlerForPath (const wxString & *location*) [static]

This static function returns true if there is a registered handler which can open the given location.

wxFSFile* wxFileSystem::OpenFile (const wxString & *location*, int *flags* = wxFS_READ)

Opens the file and returns a pointer to a wxFSFile object or NULL if failed.

It first tries to open the file in relative scope (based on value passed to ChangePathTo() method) and then as an absolute path.

Note that the user is responsible for deleting the returned wxFSFile. *flags* can be one or more of the wxFileSystem↩ OpenFlags values combined together.

A stream opened with just the default *wxFS_READ* flag may or may not be seekable depending on the underlying source.

Passing *"wxFS_READ | wxFS_SEEKABLE"* for *flags* will back a stream that is not natively seekable with memory or a file and return a stream that is always seekable.

Note

The *location* argument is, despite this method's name *not* a filename. It is a "location", aka wxFileSystem URL (see wxFileSystem Overview).

static wxFileSystemHandler* wxFileSystem::RemoveHandler (wxFileSystemHandler * *handler*) [static]

Remove a filesystem handler from the list of handlers.

static wxFileName wxFileSystem::URLToFileName (const wxString & *url*) [static]

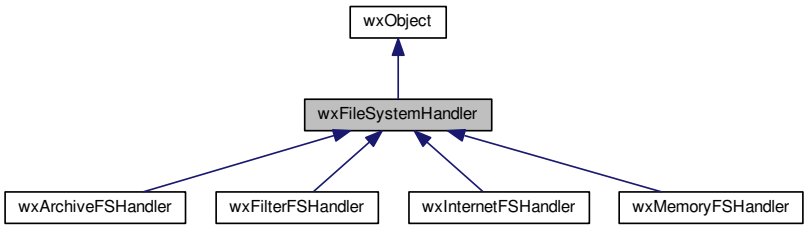
Converts URL into a well-formed filename.

The URL must use the `file` protocol.

21.244 wxFileSystemHandler Class Reference

`#include <wx/filesys.h>`

Inheritance diagram for wxFileSystemHandler:



21.244.1 Detailed Description

Classes derived from wxFileSystemHandler are used to access virtual file systems.

Its public interface consists of two methods: wxFileSystemHandler::CanOpen and wxFileSystemHandler::OpenFile.

It provides additional protected methods to simplify the process of opening the file: GetProtocol(), GetLeftLocation(), GetRightLocation(), GetAnchor(), GetMimeTypeFromExt().

Please have a look at overview (see wxFileSystem) if you don't know how locations are constructed.

Also consult the list of available handlers.

Note that the handlers are shared by all instances of wxFileSystem.

Remarks

wxHTML library provides handlers for local files and HTTP or FTP protocol.

Note

The location parameter passed to OpenFile() or CanOpen() methods is always an absolute path. You don't need to check the FS's current path.

wxPerl Note: In wxPerl, you need to derive your file system handler class from `Wx::PlFileSystemHandler`.

Library: wxBase

Category: Virtual File System

wxFileSystem, wxFSFile, wxFileSystem Overview

Public Member Functions

- wxFileSystemHandler ()

  Constructor.
- virtual bool CanOpen (const wxString &location)=0

  Returns true if the handler is able to open this file.
- virtual wxString FindFirst (const wxString &wildcard, int flags=0)

  Works like wxFindFirstFile().
- virtual wxString FindNext ()

  Returns next filename that matches parameters passed to wxFileSystem::FindFirst.
- virtual wxFSFile * OpenFile (wxFileSystem &fs, const wxString &location)=0

  Opens the file and returns wxFSFile pointer or NULL if failed.

Static Public Member Functions

- static wxString GetMimeTypeFromExt (const wxString &location)

  *Returns the MIME type based on **extension** of location.*

Static Protected Member Functions

- static wxString GetAnchor (const wxString &location)

  Returns the anchor if present in the location.
- static wxString GetLeftLocation (const wxString &location)

  Returns the left location string extracted from location.
- static wxString GetProtocol (const wxString &location)

  Returns the protocol string extracted from location.
- static wxString GetRightLocation (const wxString &location)

  Returns the right location string extracted from location.

Additional Inherited Members

21.244.2 Constructor & Destructor Documentation

wxFileSystemHandler::wxFileSystemHandler ( )

Constructor.

21.244.3 Member Function Documentation

virtual bool wxFileSystemHandler::CanOpen (const wxString & *location*) `[pure virtual]`

Returns true if the handler is able to open this file.

This function doesn't check whether the file exists or not, it only checks if it knows the protocol. Example:

```
bool MyHand::CanOpen(const wxString& location)
{
    return (GetProtocol(location) == "http");
}
```

Must be overridden in derived handlers.

virtual wxString wxFileSystemHandler::FindFirst (const wxString & *wildcard*, int *flags* = 0) `[virtual]`

Works like wxFindFirstFile().

Returns the name of the first filename (within filesystem's current path) that matches *wildcard*. *flags* may be one of wxFILE (only files), wxDIR (only directories) or 0 (both).

This method is only called if CanOpen() returns true.

virtual wxString wxFileSystemHandler::FindNext ( ) `[virtual]`

Returns next filename that matches parameters passed to wxFileSystem::FindFirst.

This method is only called if CanOpen() returns true and FindFirst() returned a non-empty string.

static wxString wxFileSystemHandler::GetAnchor (const wxString & *location*) `[static], [protected]`

Returns the anchor if present in the location.

See wxFSFile::GetAnchor for details.

Example:

```
GetAnchor("index.htm#chapter2") == "chapter2"
```

Note

the anchor is NOT part of the left location.

static wxString wxFileSystemHandler::GetLeftLocation (const wxString & *location*) `[static], [protected]`

Returns the left location string extracted from *location*.

Example:

```
GetLeftLocation("file:myzipfile.zip#zip:index.htm") == "file:myzipfile.zip"
```

static wxString wxFileSystemHandler::GetMimeTypeFromExt (const wxString & *location*) `[static]`

Returns the MIME type based on **extension** of *location*.

(While wxFSFile::GetMimeType() returns real MIME type - either extension-based or queried from HTTP.)

Example:

```
GetMimeTypeFromExt("index.htm") == "text/html"
```

static wxString wxFileSystemHandler::GetProtocol (const wxString & *location*) `[static], [protected]`

Returns the protocol string extracted from *location*.

Example:

```
GetProtocol("file:myzipfile.zip#zip:index.htm") == "zip"
```

static wxString wxFileSystemHandler::GetRightLocation (const wxString & *location*) `[static], [protected]`

Returns the right location string extracted from *location*.

Example:

```
GetRightLocation("file:myzipfile.zip#zip:index.htm") == "index.htm"
```

virtual wxFSFile* wxFileSystemHandler::OpenFile (wxFileSystem & *fs*, const wxString & *location*) `[pure virtual]`

Opens the file and returns wxFSFile pointer or NULL if failed.

Must be overridden in derived handlers.

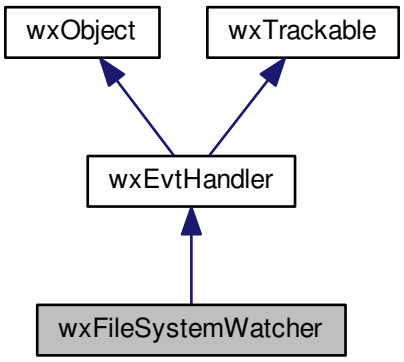
Parameters

fs	Parent FS (the FS from that OpenFile was called). See the ZIP handler for details of how to use it.
location	The absolute location of file.

21.245 wxFileSystemWatcher Class Reference

```
#include <wx/fswatcher.h>
```

Inheritance diagram for wxFileSystemWatcher:



21.245.1 Detailed Description

The wxFileSystemWatcher class allows to receive notifications of file system changes.

Note

Implementation limitations: this class is currently implemented for MSW, OS X and GTK ports but doesn't detect all changes correctly everywhere: under MSW accessing the file is not detected (only modifying it is) and under OS X neither accessing nor modifying is detected (only creating and deleting files is). Moreover, OS X version doesn't currently collapse pairs of create/delete events in a rename event, unlike the other ones.

For the full list of change types that are reported see wxFSWFlags.

This class notifies the application about the file system changes by sending events of wxFileSystemWatcherEvent class. By default these events are sent to the wxFileSystemWatcher object itself so you can derive from it and use the event table `EVT_FSWATCHER` macro to handle these events in a derived class method. Alternatively, you can use wxFileSystemWatcher::SetOwner() to send the events to another object. Or you could use wxEvtHandler::Connect() with `wxEVT_FSWATCHER` to handle these events in any other object. See the fswatcher sample for an example of the latter approach.

Library: wxBase

Category: File Handling

Since

2.9.1

Public Member Functions

- wxFileSystemWatcher ()

  Default constructor.
- virtual ~wxFileSystemWatcher ()

Destructor.

- virtual bool Add (const wxFileName &path, int events=wxFSW_EVENT_ALL)

  Adds path to currently watched files.

- virtual bool AddTree (const wxFileName &path, int events=wxFSW_EVENT_ALL, const wxString &filter=wxEmptyString)

  This is the same as Add(), but also recursively adds every file/directory in the tree rooted at path.

- virtual bool Remove (const wxFileName &path)

  Removes path from the list of watched paths.

- virtual bool RemoveTree (const wxFileName &path)

  This is the same as Remove(), but also removes every file/directory belonging to the tree rooted at path.

- virtual bool RemoveAll ()

  Clears the list of currently watched paths.

- int GetWatchedPathsCount () const

  Returns the number of currently watched paths.

- int GetWatchedPaths (wxArrayString *paths) const

  Retrieves all watched paths and places them in paths.

- void SetOwner (wxEvtHandler *handler)

  Associates the file system watcher with the given handler object.

Additional Inherited Members

21.245.2 Constructor & Destructor Documentation

wxFileSystemWatcher::wxFileSystemWatcher ( )

Default constructor.

virtual wxFileSystemWatcher::~wxFileSystemWatcher ( ) [virtual]

Destructor.

Stops all paths from being watched and frees any system resources used by this file system watcher object.

21.245.3 Member Function Documentation

virtual bool wxFileSystemWatcher::Add (const wxFileName & *path*, int *events* = wxFSW_EVENT_ALL) [virtual]

Adds *path* to currently watched files.

The *path* argument can currently only be a directory and any changes to this directory itself or its immediate children will generate the events. Use AddTree() to monitor the directory recursively.

Note that on platforms that use symbolic links, you should consider the possibility that *path* is a symlink. To watch the symlink itself and not its target you may call wxFileName::DontFollowLink() on *path*.

Parameters

path	The name of the path to watch.
events	An optional filter to receive only events of particular types. This is currently implemented only for GTK.

virtual bool wxFileSystemWatcher::AddTree (const wxFileName & *path*, int *events* = wxFSW_EVENT_ALL, const wxString & *filter* = wxEmptyString) [virtual]

This is the same as Add(), but also recursively adds every file/directory in the tree rooted at *path*.

Additionally a file mask can be specified to include only files matching that particular mask.

This method is implemented efficiently on MSW, but should be used with care on other platforms for directories with lots of children (e.g. the root directory) as it calls Add() for each subdirectory, potentially creating a lot of watches and taking a long time to execute.

Note that on platforms that use symbolic links, you will probably want to have called wxFileName::DontFollowLink on *path*. This is especially important if the symlink targets may themselves be watched.

int wxFileSystemWatcher::GetWatchedPaths (wxArrayString * *paths*) const

Retrieves all watched paths and places them in *paths*.

Returns the number of watched paths, which is also the number of entries added to *paths*.

int wxFileSystemWatcher::GetWatchedPathsCount ( ) const

Returns the number of currently watched paths.

See also

GetWatchedPaths()

virtual bool wxFileSystemWatcher::Remove (const wxFileName & *path*) [virtual]

Removes *path* from the list of watched paths.

See the comment in Add() about symbolic links. *path* should treat symbolic links in the same way as in the original Add() call.

virtual bool wxFileSystemWatcher::RemoveAll ( ) [virtual]

Clears the list of currently watched paths.

virtual bool wxFileSystemWatcher::RemoveTree (const wxFileName & *path*) [virtual]

This is the same as Remove(), but also removes every file/directory belonging to the tree rooted at *path*.

See the comment in AddTree() about symbolic links. *path* should treat symbolic links in the same way as in the original AddTree() call.

void wxFileSystemWatcher::SetOwner (wxEvtHandler * *handler*)

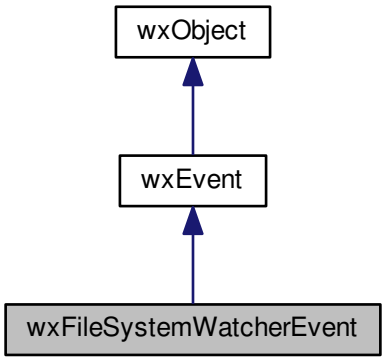
Associates the file system watcher with the given *handler* object.

All the events generated by this object will be passed to the specified owner.

21.246 wxFileSystemWatcherEvent Class Reference

`#include <wx/fswatcher.h>`

Inheritance diagram for wxFileSystemWatcherEvent:



21.246.1 Detailed Description

A class of events sent when a file system event occurs.

Types of events reported may vary depending on a platform, however all platforms report at least creation of new file/directory and access, modification, move (rename) or deletion of an existing one.

Library: wxBase

Category: Events

See also

wxFileSystemWatcher
Events and Event Handling

Since

2.9.1

Public Member Functions

- wxFileSystemWatcherEvent (int changeType=0, int watchid=wxID_ANY)
- wxFileSystemWatcherEvent (int changeType, wxFSWWarningType warningType, const wxString &errorMsg, int watchid=wxID_ANY)
- wxFileSystemWatcherEvent (int changeType, const wxFileName &path, const wxFileName &newPath, int watchid=wxID_ANY)
- const wxFileName & GetPath () const

  Returns the path at which the event occurred.
- const wxFileName & GetNewPath () const

  Returns the new path of the renamed file/directory if this is a rename event.
- int GetChangeType () const

Returns the type of file system change that occurred.

- bool IsError () const

  Returns `true` *if this error is an error event.*

- wxString GetErrorDescription () const

  Return a description of the warning or error if this is an error event.

- wxFSWWarningType GetWarningType () const

  Return the type of the warning if this event is a warning one.

- wxString ToString () const

  Returns a wxString describing an event, useful for logging, debugging or testing.

Additional Inherited Members

21.246.2 Constructor & Destructor Documentation

wxFileSystemWatcherEvent::wxFileSystemWatcherEvent (int *changeType* = `0`, int *watchid* = wxID_ANY)

wxFileSystemWatcherEvent::wxFileSystemWatcherEvent (int *changeType*, wxFSWWarningType *warningType*, const wxString & *errorMsg*, int *watchid* = wxID_ANY)

wxFileSystemWatcherEvent::wxFileSystemWatcherEvent (int *changeType*, const wxFileName & *path*, const wxFileName & *newPath*, int *watchid* = wxID_ANY)

21.246.3 Member Function Documentation

int wxFileSystemWatcherEvent::GetChangeType ( ) const

Returns the type of file system change that occurred.

See wxFSWFlags for the list of possible file system change types.

wxString wxFileSystemWatcherEvent::GetErrorDescription ( ) const

Return a description of the warning or error if this is an error event.

This string may be empty if the exact reason for the error or the warning is not known.

const wxFileName& wxFileSystemWatcherEvent::GetNewPath ( ) const

Returns the new path of the renamed file/directory if this is a rename event.

Otherwise it returns the same path as GetPath().

const wxFileName& wxFileSystemWatcherEvent::GetPath ( ) const

Returns the path at which the event occurred.

wxFSWWarningType wxFileSystemWatcherEvent::GetWarningType ( ) const

Return the type of the warning if this event is a warning one.

If this is not a warning event, i.e. if GetChangeType() doesn't include wxFSW_EVENT_WARNING, returns wxFS↩W_WARNING_NONE.

Since

3.0

bool wxFileSystemWatcherEvent::IsError ( ) const

Returns `true` if this error is an error event.

Error event is an event generated when a warning or error condition arises.

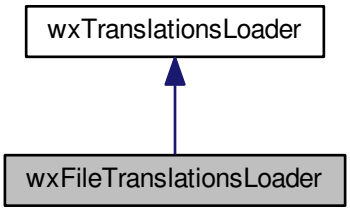
wxString wxFileSystemWatcherEvent::ToString ( ) const

Returns a wxString describing an event, useful for logging, debugging or testing.

21.247 wxFileTranslationsLoader Class Reference

`#include <wx/translation.h>`

Inheritance diagram for wxFileTranslationsLoader:



21.247.1 Detailed Description

Standard wxTranslationsLoader implementation.

This finds catalogs in the filesystem, using the standard Unix layout. This is the default unless you change the loader with wxTranslations::SetLoader().

Catalogs are searched for in standard places (system locales directory, `LC_PATH` on Unix systems, Resources subdirectory of the application bundle on OS X, executable's directory on Windows), but you may also prepend additional directories to the search path with AddCatalogLookupPathPrefix().

Since

2.9.1

Static Public Member Functions

- static void AddCatalogLookupPathPrefix (const wxString &prefix)

  Add a prefix to the catalog lookup path: the message catalog files will be looked up under prefix/lang/LC_MESSAGES and prefix/lang directories (in this order).

Additional Inherited Members

21.247.2 Member Function Documentation

static void wxFileTranslationsLoader::AddCatalogLookupPathPrefix (const wxString & *prefix*) `[static]`

Add a prefix to the catalog lookup path: the message catalog files will be looked up under prefix/lang/LC_MESSAGES and prefix/lang directories (in this order).

This only applies to subsequent invocations of wxTranslations::AddCatalog().

21.248 wxFileType Class Reference

`#include <wx/mimetype.h>`

21.248.1 Detailed Description

This class holds information about a given *file* type.

File type is the same as MIME type under Unix, but under Windows it corresponds more to an extension than to MIME type (in fact, several extensions may correspond to a file type).

This object may be created in several different ways: the program might know the file extension and wish to find out the corresponding MIME type or, conversely, it might want to find the right extension for the file to which it writes the contents of given MIME type. Depending on how it was created some fields may be unknown so the return value of all the accessors **must** be checked: false will be returned if the corresponding information couldn't be found.

The objects of this class are never created by the application code but are returned by wxMimeTypesManager::GetFileTypeFromMimeType and wxMimeTypesManager::GetFileTypeFromExtension methods. But it is your responsibility to delete the returned pointer when you're done with it!

A brief reminder about what the MIME types are (see the RFC 1341 for more information): basically, it is just a pair category/type (for example, "text/plain") where the category is a basic indication of what a file is. Examples of categories are "application", "image", "text", "binary", and type is a precise definition of the document format: "plain" in the example above means just ASCII text without any formatting, while "text/html" is the HTML document source.

A MIME type may have one or more associated extensions: "text/plain" will typically correspond to the extension ".txt", but may as well be associated with ".ini" or ".conf".

21.248.2 MessageParameters class

One of the most common usages of MIME is to encode an e-mail message. The MIME type of the encoded message is an example of a message parameter. These parameters are found in the message headers ("Content-XXX").

At the very least, they must specify the MIME type and the version of MIME used, but almost always they provide additional information about the message such as the original file name or the charset (for the text documents). These parameters may be useful to the program used to open, edit, view or print the message, so, for example, an e-mail client program will have to pass them to this program. Because wxFileType itself cannot know about these parameters, it uses MessageParameters class to query them.

The default implementation only requires the caller to provide the file name (always used by the program to be called - it must know which file to open) and the MIME type and supposes that there are no other parameters.

If you wish to supply additional parameters, you must derive your own class from MessageParameters and override GetParamValue() function, for example:

```
// provide the message parameters for the MIME type manager
class MailMessageParameters : public wxFileType::MessageParameters
{
public:
```

```
    MailMessageParameters(const wxString& filename,
                          const wxString& mimetype)
        : wxFileType::MessageParameters(filename, mimetype)
    {
    }

    virtual wxString GetParamValue(const wxString& name) const
    {
        // parameter names are not case-sensitive
        if ( name.CmpNoCase("charset") == 0 )
            return "US-ASCII";
        else
            return wxFileType::MessageParameters::GetParamValue
      (name);
    }
};
```

Now you only need to create an object of this class and pass it to, for example, GetOpenCommand like this:

```
wxString command;
if ( filetype->GetOpenCommand(&command,
                              MailMessageParameters("foo.txt", "text/plain")) )
{
    // the full command for opening the text documents is in 'command'
    // (it might be "notepad foo.txt" under Windows or "cat foo.txt" under Unix)
}
else
{
    // we don't know how to handle such files...
}
```

Windows: As only the file name is used by the program associated with the given extension anyhow (but no other message parameters), there is no need to ever derive from MessageParameters class for a Windows-only program.

Library: wxBase

Category: Data Structures

See also

wxMimeTypesManager

Classes

- class MessageParameters

  Class representing message parameters.

Public Member Functions

- wxFileType (const wxFileTypeInfo &ftInfo)

  Copy ctor.
- ~wxFileType ()

  The destructor of this class is not virtual, so it should not be derived from.
- bool GetDescription (wxString *desc) const

  If the function returns true, the string pointed to by desc is filled with a brief description for this file type: for example, "text document" for the "text/plain" MIME type.
- bool GetExtensions (wxArrayString &extensions)

  If the function returns true, the array extensions is filled with all extensions associated with this file type: for example, it may contain the following two elements for the MIME type "text/html" (notice the absence of the leading dot): "html" and "htm".
- bool GetIcon (wxIconLocation *iconLoc) const

If the function returns true, the `iconLoc` is filled with the location of the icon for this MIME type.

- bool GetMimeType (wxString *mimeType) const

  If the function returns true, the string pointed to by mimeType is filled with full MIME type specification for this file type: for example, "text/plain".

- bool GetMimeTypes (wxArrayString &mimeTypes) const

  Same as GetMimeType() but returns array of MIME types.

- bool GetPrintCommand (wxString *command, const MessageParameters &params) const

  If the function returns true, the string pointed to by command is filled with the command which must be executed (see wxExecute()) in order to print the file of the given type.

- size_t GetAllCommands (wxArrayString *verbs, wxArrayString *commands, const wxFileType::MessageParameters &params) const

  Returns the number of commands for this mime type, and fills the verbs and commands arrays with the command information.

- bool GetOpenCommand (wxString *command, const MessageParameters &params)

  With the first version of this method, if the true is returned, the string pointed to by command is filled with the command which must be executed (see wxExecute()) in order to open the file of the given type.

- wxString GetOpenCommand (const wxString &filename) const

  With the first version of this method, if the true is returned, the string pointed to by command is filled with the command which must be executed (see wxExecute()) in order to open the file of the given type.

Static Public Member Functions

- static wxString ExpandCommand (const wxString &command, const MessageParameters &params)

  This function is primarily intended for GetOpenCommand and GetPrintCommand usage but may be also used by the application directly if, for example, you want to use some non-default command to open the file.

Private Member Functions

- wxFileType ()

  The default constructor is private because you should never create objects of this type: they are only returned by wxMimeTypesManager methods.

21.248.3 Constructor & Destructor Documentation

wxFileType::wxFileType ( ) [private]

The default constructor is private because you should never create objects of this type: they are only returned by wxMimeTypesManager methods.

wxFileType::wxFileType (const wxFileTypeInfo & *ftInfo*)

Copy ctor.

wxFileType::~wxFileType ( )

The destructor of this class is not virtual, so it should not be derived from.

21.248.4 Member Function Documentation

static wxString wxFileType::ExpandCommand (const wxString & *command,* const MessageParameters & *params*) [static]

This function is primarily intended for GetOpenCommand and GetPrintCommand usage but may be also used by the application directly if, for example, you want to use some non-default command to open the file.

The function replaces all occurrences of:

- s with the full file name
- t with the MIME type
- %{param} with the value of the parameter *param* using the MessageParameters object you pass to it.

If there is no 's' in the command string (and the string is not empty), it is assumed that the command reads the data on stdin and so the effect is the same as " %s" were appended to the string.

Unlike all other functions of this class, there is no error return for this function.

size_t wxFileType::GetAllCommands (wxArrayString * *verbs,* wxArrayString * *commands,* const wxFileType::MessageParameters & *params*) const

Returns the number of commands for this mime type, and fills the verbs and commands arrays with the command information.

bool wxFileType::GetDescription (wxString * *desc*) const

If the function returns true, the string pointed to by *desc* is filled with a brief description for this file type: for example, "text document" for the "text/plain" MIME type.

bool wxFileType::GetExtensions (wxArrayString & *extensions*)

If the function returns true, the array *extensions* is filled with all extensions associated with this file type: for example, it may contain the following two elements for the MIME type "text/html" (notice the absence of the leading dot): "html" and "htm".

Windows: This function is currently not implemented: there is no (efficient) way to retrieve associated extensions from the given MIME type on this platform, so it will only return true if the wxFileType object was created by wxMimeTypesManager::GetFileTypeFromExtension function in the first place.

bool wxFileType::GetIcon (wxIconLocation * *iconLoc*) const

If the function returns true, the `iconLoc` is filled with the location of the icon for this MIME type.

A wxIcon may be created from *iconLoc* later.

Note

Under Unix MIME manager gathers information about icons from GNOME and KDE settings and thus GetIcon's success depends on availability of these desktop environments.

bool wxFileType::GetMimeType (wxString * *mimeType*) const

If the function returns true, the string pointed to by *mimeType* is filled with full MIME type specification for this file type: for example, "text/plain".

bool wxFileType::GetMimeTypes (wxArrayString & *mimeTypes*) const

Same as GetMimeType() but returns array of MIME types.

This array will contain only one item in most cases but sometimes, notably under Unix with KDE, may contain more MIME types. This happens when one file extension is mapped to different MIME types by KDE, mailcap and mime.types.

bool wxFileType::GetOpenCommand (wxString * *command,* const MessageParameters & *params*)

With the first version of this method, if the true is returned, the string pointed to by *command* is filled with the command which must be executed (see wxExecute()) in order to open the file of the given type.

In this case, the name of the file as well as any other parameters is retrieved from MessageParameters() class.

In the second case, only the filename is specified and the command to be used to open this kind of file is returned directly. An empty string is returned to indicate that an error occurred (typically meaning that there is no standard way to open this kind of files).

wxString wxFileType::GetOpenCommand (const wxString & *filename*) const

With the first version of this method, if the true is returned, the string pointed to by *command* is filled with the command which must be executed (see wxExecute()) in order to open the file of the given type.

In this case, the name of the file as well as any other parameters is retrieved from MessageParameters() class.

In the second case, only the filename is specified and the command to be used to open this kind of file is returned directly. An empty string is returned to indicate that an error occurred (typically meaning that there is no standard way to open this kind of files).

bool wxFileType::GetPrintCommand (wxString * *command,* const MessageParameters & *params*) const

If the function returns true, the string pointed to by *command* is filled with the command which must be executed (see wxExecute()) in order to print the file of the given type.

The name of the file is retrieved from the MessageParameters class.

21.249 wxFileTypeInfo Class Reference

`#include <wx/mimetype.h>`

21.249.1 Detailed Description

Container of information about wxFileType.

This class simply stores information associated with the file type. It doesn't do anything on its own and is used only to allow constructing wxFileType from it (instead of specifying all the constituent pieces separately) and also with wxMimeTypesManager::AddFallbacks().

Public Member Functions

- wxFileTypeInfo ()

  Default constructor creates an invalid file type info object.
- wxFileTypeInfo (const wxString &mimeType)

  Constructor specifying just the MIME type name.

- wxFileTypeInfo (const wxString &mimeType, const wxString &openCmd, const wxString &printCmd, const wxString &description, const wxString &extension,...)

  Constructor allowing to specify all the fields at once.
- wxFileTypeInfo (const wxArrayString &sArray)

  Constuctor using an array of string elements corresponding to the parameters of the ctor above in the same order.
- void AddExtension (const wxString &ext)

  Add another extension associated with this file type.
- void SetDescription (const wxString &description)

  Set the file type description.
- void SetOpenCommand (const wxString &command)

  Set the command to be used for opening files of this type.
- void SetPrintCommand (const wxString &command)

  Set the command to be used for printing files of this type.
- void SetShortDesc (const wxString &shortDesc)

  Set the short description for the files of this type.
- void SetIcon (const wxString &iconFile, int iconIndex=0)

  Set the icon information.
- const wxString & GetMimeType () const

  Get the MIME type.
- const wxString & GetOpenCommand () const

  Get the open command.
- const wxString & GetPrintCommand () const

  Get the print command.
- const wxString & GetShortDesc () const

  Get the short description (only used under Win32 so far)
- const wxString & GetDescription () const

  Get the long, user visible description.
- const wxArrayString & GetExtensions () const

  Get the array of all extensions.
- size_t GetExtensionsCount () const

  Get the number of extensions.
- const wxString & GetIconFile () const

  Get the icon filename.
- int GetIconIndex () const

  Get the index of the icon within the icon file.

21.249.2 Constructor & Destructor Documentation

wxFileTypeInfo::wxFileTypeInfo ( )

Default constructor creates an invalid file type info object.

Such invalid/empty object should be used to terminate the list of file types passed to wxMimeTypesManager::AddFallbacks().

wxFileTypeInfo::wxFileTypeInfo (const wxString & *mimeType*)

Constructor specifying just the MIME type name.

Use the various setter methods below to fully initialize the object.

Since

2.9.2

wxFileTypeInfo::wxFileTypeInfo (const wxString & *mimeType,* const wxString & *openCmd,* const wxString & *printCmd,* const wxString & *description,* const wxString & *extension,* ...)

Constructor allowing to specify all the fields at once.

This is a vararg constructor taking an arbitrary number of extensions after the first four required parameters. The list must be terminated by `wxNullPtr`, notice that `NULL` can't be used here in portable code (C++0x `nullptr` can be used as well if your compiler supports it).

wxFileTypeInfo::wxFileTypeInfo (const wxArrayString & *sArray*)

Constuctor using an array of string elements corresponding to the parameters of the ctor above in the same order.

21.249.3 Member Function Documentation

void wxFileTypeInfo::AddExtension (const wxString & *ext*)

Add another extension associated with this file type.

Since

2.9.2

const wxString& wxFileTypeInfo::GetDescription ( ) const

Get the long, user visible description.

const wxArrayString& wxFileTypeInfo::GetExtensions ( ) const

Get the array of all extensions.

size_t wxFileTypeInfo::GetExtensionsCount ( ) const

Get the number of extensions.

const wxString& wxFileTypeInfo::GetIconFile ( ) const

Get the icon filename.

int wxFileTypeInfo::GetIconIndex ( ) const

Get the index of the icon within the icon file.

const wxString& wxFileTypeInfo::GetMimeType ( ) const

Get the MIME type.

const wxString& wxFileTypeInfo::GetOpenCommand ( ) const

Get the open command.

const wxString& wxFileTypeInfo::GetPrintCommand ( ) const

Get the print command.

const wxString& wxFileTypeInfo::GetShortDesc ( ) const

Get the short description (only used under Win32 so far)

void wxFileTypeInfo::SetDescription (const wxString & *description*)

Set the file type description.

Since

2.9.2

void wxFileTypeInfo::SetIcon (const wxString & *iconFile,* int *iconIndex* = 0)

Set the icon information.

void wxFileTypeInfo::SetOpenCommand (const wxString & *command*)

Set the command to be used for opening files of this type.

Since

2.9.2

void wxFileTypeInfo::SetPrintCommand (const wxString & *command*)

Set the command to be used for printing files of this type.

Since

2.9.2

void wxFileTypeInfo::SetShortDesc (const wxString & *shortDesc*)

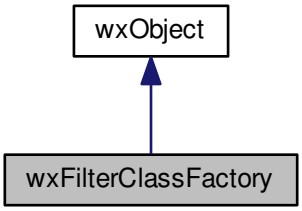
Set the short description for the files of this type.

This is only used under MSW for some of the registry keys used for the file type registration.

21.250 wxFilterClassFactory Class Reference

`#include <wx/stream.h>`

Inheritance diagram for wxFilterClassFactory:



21.250.1 Detailed Description

Allows the creation of filter streams to handle compression formats such as gzip and bzip2.

For example, given a filename you can search for a factory that will handle it and create a stream to decompress it:

```
factory = wxFilterClassFactory::Find(filename,
      wxSTREAM_FILEEXT);
if (factory)
    stream = factory->NewStream(new wxFFileInputStream(filename));
```

wxFilterClassFactory::Find can also search for a factory by MIME type, HTTP encoding or by wxFileSystem protocol. The available factories can be enumerated using wxFilterClassFactory::GetFirst() and wxFilterClassFactory::GetNext().

Library: wxBase

Category: Streams

See also

wxFilterInputStream, wxFilterOutputStream, wxArchiveClassFactory, Archive Formats

- const wxFilterClassFactory * GetNext () const

  GetFirst and GetNext can be used to enumerate the available factories.
- static const wxFilterClassFactory * GetFirst ()

  GetFirst and GetNext can be used to enumerate the available factories.

Public Member Functions

- bool CanHandle (const wxString &protocol, wxStreamProtocolType type=wxSTREAM_PROTOCOL) const

  Returns true if this factory can handle the given protocol, MIME type, HTTP encoding or file extension.
- wxString GetProtocol () const

  Returns the wxFileSystem protocol supported by this factory.
- virtual const wxChar *const * GetProtocols (wxStreamProtocolType type=wxSTREAM_PROTOCOL) const =0

  Returns the protocols, MIME types, HTTP encodings or file extensions supported by this factory, as an array of null terminated strings.

- wxString PopExtension (const wxString &location) const

  Remove the file extension of location if it is one of the file extensions handled by this factory.
- void PushFront ()

  Adds this class factory to the list returned by GetFirst()/GetNext().
- void Remove ()

  Removes this class factory from the list returned by GetFirst()/GetNext().

- virtual wxFilterInputStream * NewStream (wxInputStream &stream) const =0

  Create a new input or output stream to decompress or compress a given stream.
- virtual wxFilterOutputStream * NewStream (wxOutputStream &stream) const =0

  Create a new input or output stream to decompress or compress a given stream.
- virtual wxFilterInputStream * NewStream (wxInputStream *stream) const =0

  Create a new input or output stream to decompress or compress a given stream.
- virtual wxFilterOutputStream * NewStream (wxOutputStream *stream) const =0

  Create a new input or output stream to decompress or compress a given stream.

Static Public Member Functions

- static const wxFilterClassFactory * Find (const wxString &protocol, wxStreamProtocolType type=wxSTREAM_PROTOCOL)

  A static member that finds a factory that can handle a given protocol, MIME type, HTTP encoding or file extension.

Additional Inherited Members

21.250.2 Member Function Documentation

bool wxFilterClassFactory::CanHandle (const wxString & *protocol,* wxStreamProtocolType *type* = wxSTREAM_PROTOCOL) const

Returns true if this factory can handle the given protocol, MIME type, HTTP encoding or file extension.

When using `wxSTREAM_FILEEXT` for the second parameter, the first parameter can be a complete filename rather than just an extension.

static const wxFilterClassFactory* wxFilterClassFactory::Find (const wxString & *protocol,* wxStreamProtocolType *type* = wxSTREAM_PROTOCOL) [static]

A static member that finds a factory that can handle a given protocol, MIME type, HTTP encoding or file extension.

Returns a pointer to the class factory if found, or NULL otherwise. It does not give away ownership of the factory.

When using `wxSTREAM_FILEEXT` for the second parameter, the first parameter can be a complete filename rather than just an extension.

static const wxFilterClassFactory* wxFilterClassFactory::GetFirst ( ) [static]

GetFirst and GetNext can be used to enumerate the available factories.

For example, to list them:

```
wxString list;
const wxFilterClassFactory *factory =
      wxFilterClassFactory::GetFirst();

while (factory) {
    list << factory->GetProtocol() << wxT("\n");
    factory = factory->GetNext();
}
```

GetFirst()/GetNext() return a pointer to a factory or NULL if no more are available. They do not give away ownership of the factory.

const wxFilterClassFactory* wxFilterClassFactory::GetNext ( ) const

GetFirst and GetNext can be used to enumerate the available factories.

For example, to list them:

```
wxString list;
const wxFilterClassFactory *factory =
      wxFilterClassFactory::GetFirst();

while (factory) {
    list << factory->GetProtocol() << wxT("\n");
    factory = factory->GetNext();
}
```

GetFirst()/GetNext() return a pointer to a factory or NULL if no more are available. They do not give away ownership of the factory.

wxString wxFilterClassFactory::GetProtocol ( ) const

Returns the wxFileSystem protocol supported by this factory.

Equivalent to

```
wxString(*GetProtocols())
```

.

virtual const wxChar* const* wxFilterClassFactory::GetProtocols (wxStreamProtocolType *type* = wxSTREAM_PROTOCOL) const [pure virtual]

Returns the protocols, MIME types, HTTP encodings or file extensions supported by this factory, as an array of null terminated strings.

It does not give away ownership of the array or strings.

For example, to list the file extensions a factory supports:

```
wxString list;
const wxChar *const *p;

for (p = factory->GetProtocols(wxSTREAM_FILEEXT); *p; p++)
    list << *p << wxT("\n");
```

virtual wxFilterInputStream* wxFilterClassFactory::NewStream (wxInputStream & *stream*) const [pure virtual]

Create a new input or output stream to decompress or compress a given stream.

If the parent stream is passed as a pointer then the new filter stream takes ownership of it. If it is passed by reference then it does not.

virtual wxFilterOutputStream* wxFilterClassFactory::NewStream (wxOutputStream & *stream*) const [pure virtual]

Create a new input or output stream to decompress or compress a given stream.

If the parent stream is passed as a pointer then the new filter stream takes ownership of it. If it is passed by reference then it does not.

virtual wxFilterInputStream* wxFilterClassFactory::NewStream (wxInputStream * *stream*) const [pure virtual]

Create a new input or output stream to decompress or compress a given stream.

If the parent stream is passed as a pointer then the new filter stream takes ownership of it. If it is passed by reference then it does not.

virtual wxFilterOutputStream* wxFilterClassFactory::NewStream (wxOutputStream * *stream*) const [pure virtual]

Create a new input or output stream to decompress or compress a given stream.

If the parent stream is passed as a pointer then the new filter stream takes ownership of it. If it is passed by reference then it does not.

wxString wxFilterClassFactory::PopExtension (const wxString & *location*) const

Remove the file extension of *location* if it is one of the file extensions handled by this factory.

void wxFilterClassFactory::PushFront ( )

Adds this class factory to the list returned by GetFirst()/GetNext().

It is not necessary to do this to use the filter streams. It is usually used when implementing streams, typically the implementation will add a static instance of its factory class.

It can also be used to change the order of a factory already in the list, bringing it to the front. This isn't a thread safe operation so can't be done when other threads are running that will be using the list.

The list does not take ownership of the factory.

void wxFilterClassFactory::Remove ( )

Removes this class factory from the list returned by GetFirst()/GetNext().

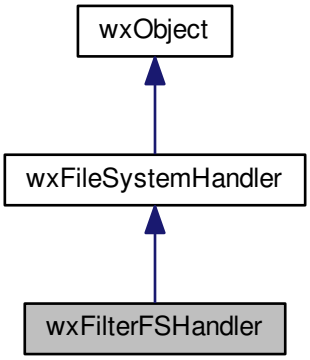
Removing from the list isn't a thread safe operation so can't be done when other threads are running that will be using the list.

The list does not own the factories, so removing a factory does not delete it.

21.251 wxFilterFSHandler Class Reference

`#include <wx/fs_filter.h>`

Inheritance diagram for wxFilterFSHandler:



21.251.1 Detailed Description

Filter file system handler.

Public Member Functions

- wxFilterFSHandler ()
- virtual ~wxFilterFSHandler ()

Additional Inherited Members

21.251.2 Constructor & Destructor Documentation

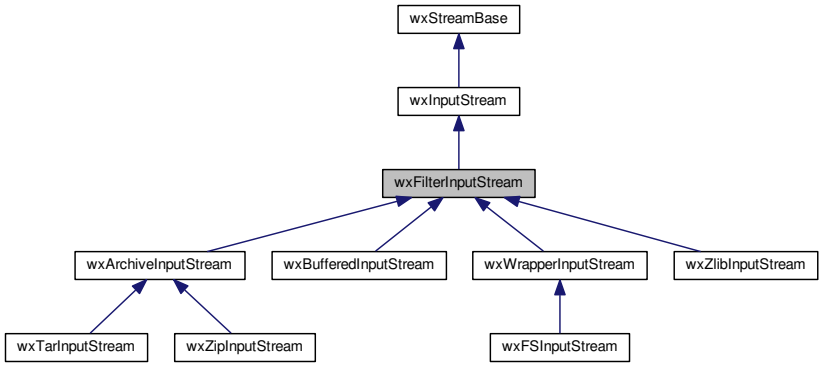
wxFilterFSHandler::wxFilterFSHandler ( )

virtual wxFilterFSHandler::~wxFilterFSHandler ( ) [virtual]

21.252 wxFilterInputStream Class Reference

`#include <wx/stream.h>`

Inheritance diagram for wxFilterInputStream:



21.252.1 Detailed Description

A filter stream has the capability of a normal stream but it can be placed on top of another stream.

So, for example, it can uncompress or decrypt the data which are read from another stream and pass it to the requester.

Note

The interface of this class is the same as that of wxInputStream. Only a constructor differs and it is documented below.

Library: wxBase

Category: Streams

See also

wxFilterClassFactory, wxFilterOutputStream

Public Member Functions

- wxFilterInputStream (wxInputStream &stream)
  Initializes a "filter" stream.
- wxFilterInputStream (wxInputStream *stream)
  Initializes a "filter" stream.

Additional Inherited Members

21.252.2 Constructor & Destructor Documentation

wxFilterInputStream::wxFilterInputStream (wxInputStream & *stream*)

Initializes a "filter" stream.

If the parent stream is passed as a pointer then the new filter stream takes ownership of it. If it is passed by reference then it does not.

wxFilterInputStream::wxFilterInputStream (wxInputStream * *stream*)

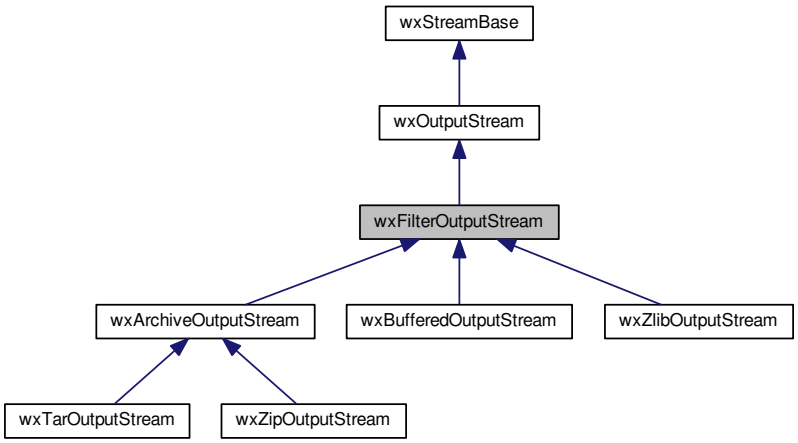
Initializes a "filter" stream.

If the parent stream is passed as a pointer then the new filter stream takes ownership of it. If it is passed by reference then it does not.

21.253 wxFilterOutputStream Class Reference

`#include <wx/stream.h>`

Inheritance diagram for wxFilterOutputStream:



21.253.1 Detailed Description

A filter stream has the capability of a normal stream but it can be placed on top of another stream.

So, for example, it can compress, encrypt the data which are passed to it and write them to another stream.

Note

The use of this class is exactly the same as of wxOutputStream. Only a constructor differs and it is documented below.

Library: wxBase

Category: Streams

See also

wxFilterClassFactory, wxFilterInputStream

Public Member Functions

- wxFilterOutputStream (wxOutputStream &stream)

Initializes a "filter" stream.

- wxFilterOutputStream (wxOutputStream ∗stream)

  Initializes a "filter" stream.

Additional Inherited Members

21.253.2 Constructor & Destructor Documentation

wxFilterOutputStream::wxFilterOutputStream (wxOutputStream & *stream*)

Initializes a "filter" stream.

If the parent stream is passed as a pointer then the new filter stream takes ownership of it. If it is passed by reference then it does not.

wxFilterOutputStream::wxFilterOutputStream (wxOutputStream ∗ *stream*)

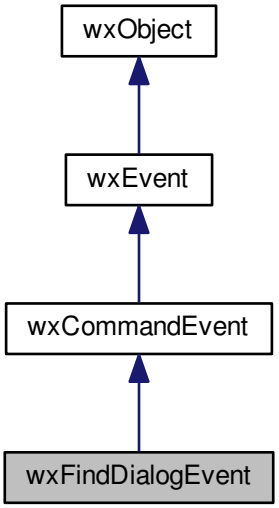
Initializes a "filter" stream.

If the parent stream is passed as a pointer then the new filter stream takes ownership of it. If it is passed by reference then it does not.

21.254 wxFindDialogEvent Class Reference

`#include <wx/fdrepdlg.h>`

Inheritance diagram for wxFindDialogEvent:



21.254.1 Detailed Description

wxFindReplaceDialog events.

Events using this class

The following event handler macros redirect the events to member function handlers '**func**' with prototypes like: void handlerFuncName(wxFindDialogEvent& event)

Event macros:

- EVT_FIND(id, func): Find button was pressed in the dialog.
- EVT_FIND_NEXT(id, func): Find next button was pressed in the dialog.
- EVT_FIND_REPLACE(id, func): Replace button was pressed in the dialog.
- EVT_FIND_REPLACE_ALL(id, func): Replace all button was pressed in the dialog.
- EVT_FIND_CLOSE(id, func): The dialog is being destroyed, any pointers to it cannot be used any longer.

Library: wxCore

Category: Events

Public Member Functions

- wxFindDialogEvent (wxEventType commandType=wxEVT_NULL, int id=0)

  Constructor used by wxWidgets only.
- wxFindReplaceDialog * GetDialog () const

  Return the pointer to the dialog which generated this event.
- wxString GetFindString () const

  Return the string to find (never empty).
- int GetFlags () const

  Get the currently selected flags: this is the combination of the wxFindReplaceFlags enumeration values.
- const wxString & GetReplaceString () const

  Return the string to replace the search string with (only for replace and replace all events).

Additional Inherited Members

21.254.2 Constructor & Destructor Documentation

wxFindDialogEvent::wxFindDialogEvent (wxEventType *commandType* = wxEVT_NULL, int *id* = 0)

Constructor used by wxWidgets only.

21.254.3 Member Function Documentation

wxFindReplaceDialog* wxFindDialogEvent::GetDialog ( ) const

Return the pointer to the dialog which generated this event.

wxString wxFindDialogEvent::GetFindString ( ) const

Return the string to find (never empty).

int wxFindDialogEvent::GetFlags ( ) const

Get the currently selected flags: this is the combination of the wxFindReplaceFlags enumeration values.

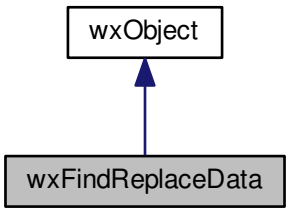
const wxString& wxFindDialogEvent::GetReplaceString ( ) const

Return the string to replace the search string with (only for replace and replace all events).

21.255 wxFindReplaceData Class Reference

`#include <wx/fdrepdlg.h>`

Inheritance diagram for wxFindReplaceData:



21.255.1 Detailed Description

wxFindReplaceData holds the data for wxFindReplaceDialog.

It is used to initialize the dialog with the default values and will keep the last values from the dialog when it is closed. It is also updated each time a wxFindDialogEvent is generated so instead of using the wxFindDialogEvent methods you can also directly query this object.

Note that all `SetXXX()` methods may only be called before showing the dialog and calling them has no effect later.

Library: wxCore

Category: Common Dialogs, Data Structures

Public Member Functions

- wxFindReplaceData (wxUint32 flags=0)

  Constructor initializes the flags to default value (0).
- const wxString & GetFindString () const

  Get the string to find.
- int GetFlags () const

  Get the combination of `wxFindReplaceFlags` values.
- const wxString & GetReplaceString () const

Get the replacement string.

- void SetFindString (const wxString &str)

  Set the string to find (used as initial value by the dialog).

- void SetFlags (wxUint32 flags)

  Set the flags to use to initialize the controls of the dialog.

- void SetReplaceString (const wxString &str)

  Set the replacement string (used as initial value by the dialog).

Additional Inherited Members

21.255.2 Constructor & Destructor Documentation

wxFindReplaceData::wxFindReplaceData (wxUint32 *flags* = `0`)

Constructor initializes the flags to default value (0).

21.255.3 Member Function Documentation

const wxString& wxFindReplaceData::GetFindString ( ) const

Get the string to find.

int wxFindReplaceData::GetFlags ( ) const

Get the combination of `wxFindReplaceFlags` values.

const wxString& wxFindReplaceData::GetReplaceString ( ) const

Get the replacement string.

void wxFindReplaceData::SetFindString (const wxString & *str*)

Set the string to find (used as initial value by the dialog).

void wxFindReplaceData::SetFlags (wxUint32 *flags*)

Set the flags to use to initialize the controls of the dialog.

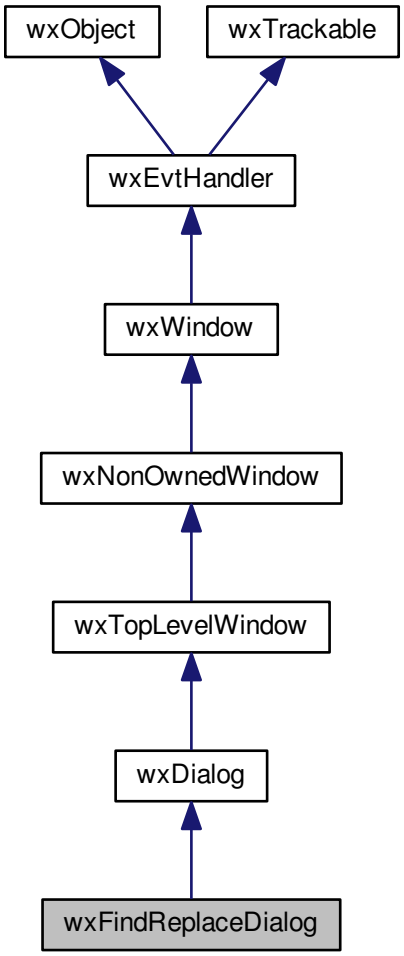
void wxFindReplaceData::SetReplaceString (const wxString & *str*)

Set the replacement string (used as initial value by the dialog).

21.256 wxFindReplaceDialog Class Reference

`#include <wx/fdrepdlg.h>`

Inheritance diagram for wxFindReplaceDialog:



21.256.1 Detailed Description

wxFindReplaceDialog is a standard modeless dialog which is used to allow the user to search for some text (and possibly replace it with something else).

The actual searching is supposed to be done in the owner window which is the parent of this dialog. Note that it means that unlike for the other standard dialogs this one **must** have a parent window. Also note that there is no way to use this dialog in a modal way; it is always, by design and implementation, modeless.

Please see the Dialogs Sample sample for an example of using it.

Library: wxCore

Category: Common Dialogs

Public Member Functions

- wxFindReplaceDialog ()
- wxFindReplaceDialog (wxWindow *parent, wxFindReplaceData *data, const wxString &title, int style=0)

  After using default constructor Create() must be called.
- virtual ~wxFindReplaceDialog ()

  Destructor.
- bool Create (wxWindow *parent, wxFindReplaceData *data, const wxString &title, int style=0)

  Creates the dialog; use wxWindow::Show to show it on screen.
- const wxFindReplaceData * GetData () const

  Get the wxFindReplaceData object used by this dialog.

Additional Inherited Members

21.256.2 Constructor & Destructor Documentation

wxFindReplaceDialog::wxFindReplaceDialog ( )

wxFindReplaceDialog::wxFindReplaceDialog (wxWindow * *parent*, wxFindReplaceData * *data*, const wxString & *title*, int *style* = `0`)

After using default constructor Create() must be called.

The *parent* and *data* parameters must be non-NULL.

virtual wxFindReplaceDialog::~wxFindReplaceDialog ( ) `[virtual]`

Destructor.

21.256.3 Member Function Documentation

bool wxFindReplaceDialog::Create (wxWindow * *parent*, wxFindReplaceData * *data*, const wxString & *title*, int *style* = `0`)

Creates the dialog; use wxWindow::Show to show it on screen.

The *parent* and *data* parameters must be non-NULL.

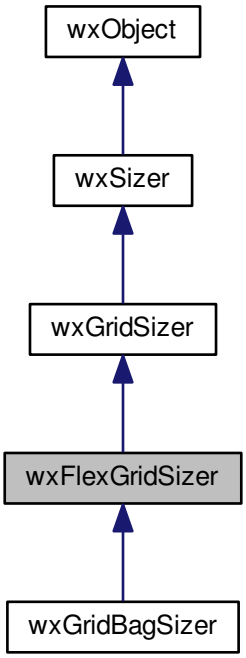
const wxFindReplaceData* wxFindReplaceDialog::GetData ( ) const

Get the wxFindReplaceData object used by this dialog.

21.257 wxFlexGridSizer Class Reference

`#include <wx/sizer.h>`

Inheritance diagram for wxFlexGridSizer:



21.257.1 Detailed Description

A flex grid sizer is a sizer which lays out its children in a two-dimensional table with all table fields in one row having the same height and all fields in one column having the same width, but all rows or all columns are not necessarily the same height or width as in the wxGridSizer.

Since wxWidgets 2.5.0, wxFlexGridSizer can also size items equally in one direction but unequally ("flexibly") in the other. If the sizer is only flexible in one direction (this can be changed using wxFlexGridSizer::SetFlexibleDirection), it needs to be decided how the sizer should grow in the other ("non-flexible") direction in order to fill the available space. The wxFlexGridSizer::SetNonFlexibleGrowMode() method serves this purpose.

Library: wxCore

Category: Window Layout

wxSizer, Sizers Overview

Public Member Functions

- void AddGrowableCol (size_t idx, int proportion=0)

  Specifies that column idx (starting from zero) should be grown if there is extra space available to the sizer.
- void AddGrowableRow (size_t idx, int proportion=0)

Specifies that row idx (starting from zero) should be grown if there is extra space available to the sizer.

- int GetFlexibleDirection () const

  Returns a wxOrientation value that specifies whether the sizer flexibly resizes its columns, rows, or both (default).

- wxFlexSizerGrowMode GetNonFlexibleGrowMode () const

  Returns the value that specifies how the sizer grows in the "non-flexible" direction if there is one.

- bool IsColGrowable (size_t idx)

  Returns true if column idx is growable.

- bool IsRowGrowable (size_t idx)

  Returns true if row idx is growable.

- void RemoveGrowableCol (size_t idx)

  Specifies that the idx column index is no longer growable.

- void RemoveGrowableRow (size_t idx)

  Specifies that the idx row index is no longer growable.

- void SetFlexibleDirection (int direction)

  Specifies whether the sizer should flexibly resize its columns, rows, or both.

- void SetNonFlexibleGrowMode (wxFlexSizerGrowMode mode)

  Specifies how the sizer should grow in the non-flexible direction if there is one (so SetFlexibleDirection() must have been called previously).

- const wxArrayInt & GetRowHeights () const

  Returns a read-only array containing the heights of the rows in the sizer.

- const wxArrayInt & GetColWidths () const

  Returns a read-only array containing the widths of the columns in the sizer.

- virtual void RecalcSizes ()

  This method is abstract and has to be overwritten by any derived class.

- virtual wxSize CalcMin ()

  This method is abstract and has to be overwritten by any derived class.

- wxFlexGridSizer (int cols, int vgap, int hgap)

  wxFlexGridSizer constructors.

- wxFlexGridSizer (int cols, const wxSize &gap=wxSize(0, 0))

  wxFlexGridSizer constructors.

- wxFlexGridSizer (int rows, int cols, int vgap, int hgap)

  wxFlexGridSizer constructors.

- wxFlexGridSizer (int rows, int cols, const wxSize &gap)

  wxFlexGridSizer constructors.

21.257.2 Constructor & Destructor Documentation

wxFlexGridSizer::wxFlexGridSizer (int *cols,* int *vgap,* int *hgap*)

wxFlexGridSizer constructors.

Please see wxGridSizer::wxGridSizer documentation.

Since

2.9.1 (except for the four argument overload)

wxFlexGridSizer::wxFlexGridSizer (int *cols*, const wxSize & *gap* = wxSize(0, 0))

wxFlexGridSizer constructors.

Please see wxGridSizer::wxGridSizer documentation.

Since

2.9.1 (except for the four argument overload)

wxFlexGridSizer::wxFlexGridSizer (int *rows*, int *cols*, int *vgap*, int *hgap*)

wxFlexGridSizer constructors.

Please see wxGridSizer::wxGridSizer documentation.

Since

2.9.1 (except for the four argument overload)

wxFlexGridSizer::wxFlexGridSizer (int *rows*, int *cols*, const wxSize & *gap*)

wxFlexGridSizer constructors.

Please see wxGridSizer::wxGridSizer documentation.

Since

2.9.1 (except for the four argument overload)

21.257.3 Member Function Documentation

void wxFlexGridSizer::AddGrowableCol (size_t *idx*, int *proportion* = 0)

Specifies that column *idx* (starting from zero) should be grown if there is extra space available to the sizer.

The *proportion* parameter has the same meaning as the stretch factor for the sizers (see wxBoxSizer) except that if all proportions are 0, then all columns are resized equally (instead of not being resized at all).

Notice that the column must not be already growable, if you need to change the proportion you must call RemoveGrowableCol() first and then make it growable (with a different proportion) again. You can use IsColGrowable() to check whether a column is already growable.

void wxFlexGridSizer::AddGrowableRow (size_t *idx*, int *proportion* = 0)

Specifies that row idx (starting from zero) should be grown if there is extra space available to the sizer.

This is identical to AddGrowableCol() except that it works with rows and not columns.

virtual wxSize wxFlexGridSizer::CalcMin ( ) [virtual]

This method is abstract and has to be overwritten by any derived class.

Here, the sizer will do the actual calculation of its children's minimal sizes.

Reimplemented from wxGridSizer.

Reimplemented in wxGridBagSizer.

const wxArrayInt& wxFlexGridSizer::GetColWidths ( ) const

Returns a read-only array containing the widths of the columns in the sizer.

int wxFlexGridSizer::GetFlexibleDirection ( ) const

Returns a wxOrientation value that specifies whether the sizer flexibly resizes its columns, rows, or both (default).

Returns

One of the following values:

- wxVERTICAL: Rows are flexibly sized.
- wxHORIZONTAL: Columns are flexibly sized.
- wxBOTH: Both rows and columns are flexibly sized (this is the default value).

See also

SetFlexibleDirection()

wxFlexSizerGrowMode wxFlexGridSizer::GetNonFlexibleGrowMode ( ) const

Returns the value that specifies how the sizer grows in the "non-flexible" direction if there is one.

The behaviour of the elements in the flexible direction (i.e. both rows and columns by default, or rows only if GetFlexibleDirection() is `wxVERTICAL` or columns only if it is `wxHORIZONTAL`) is always governed by their proportion as specified in the call to AddGrowableRow() or AddGrowableCol(). What happens in the other direction depends on the value of returned by this function as described below.

Returns

One of the following values:

- wxFLEX_GROWMODE_NONE: Sizer doesn't grow its elements at all in the non-flexible direction.
- wxFLEX_GROWMODE_SPECIFIED: Sizer honors growable columns/rows set with AddGrowableCol() and AddGrowableRow() in the non-flexible direction as well. In this case equal sizing applies to minimum sizes of columns or rows (this is the default value).
- wxFLEX_GROWMODE_ALL: Sizer equally stretches all columns or rows in the non-flexible direction, independently of the proportions applied in the flexible direction.

See also

SetFlexibleDirection(), SetNonFlexibleGrowMode()

const wxArrayInt& wxFlexGridSizer::GetRowHeights ( ) const

Returns a read-only array containing the heights of the rows in the sizer.

bool wxFlexGridSizer::IsColGrowable (size_t *idx*)

Returns true if column *idx* is growable.

Since

2.9.0

bool wxFlexGridSizer::IsRowGrowable (size_t *idx*)

Returns true if row *idx* is growable.

Since

2.9.0

virtual void wxFlexGridSizer::RecalcSizes ( ) [virtual]

This method is abstract and has to be overwritten by any derived class.

Here, the sizer will do the actual calculation of its children's positions and sizes.

Reimplemented from wxGridSizer.

Reimplemented in wxGridBagSizer.

void wxFlexGridSizer::RemoveGrowableCol (size_t *idx*)

Specifies that the *idx* column index is no longer growable.

void wxFlexGridSizer::RemoveGrowableRow (size_t *idx*)

Specifies that the *idx* row index is no longer growable.

void wxFlexGridSizer::SetFlexibleDirection (int *direction*)

Specifies whether the sizer should flexibly resize its columns, rows, or both.

Argument *direction* can be `wxVERTICAL`, `wxHORIZONTAL` or `wxBOTH` (which is the default value). Any other value is ignored.

See GetFlexibleDirection() for the explanation of these values. Note that this method does not trigger relayout.

void wxFlexGridSizer::SetNonFlexibleGrowMode (wxFlexSizerGrowMode *mode*)

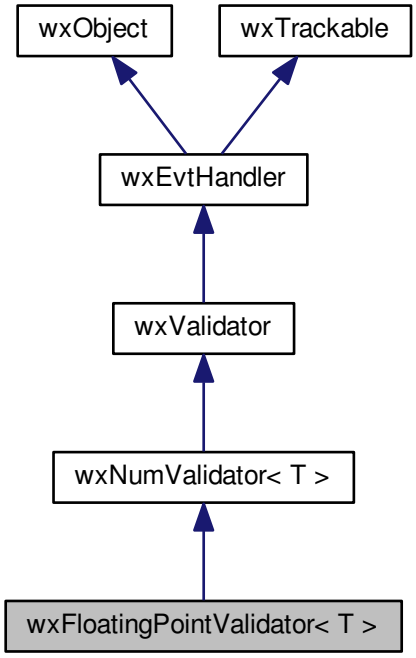
Specifies how the sizer should grow in the non-flexible direction if there is one (so SetFlexibleDirection() must have been called previously).

Argument *mode* can be one of those documented in GetNonFlexibleGrowMode(), please see there for their explanation. Note that this method does not trigger relayout.

21.258 wxFloatingPointValidator< T > Class Template Reference

`#include <wx/valnum.h>`

Inheritance diagram for wxFloatingPointValidator< T >:



21.258.1 Detailed Description

template<typename T>class wxFloatingPointValidator< T >

Validator for text entries used for floating point numbers entry.

This validator can be used with wxTextCtrl or wxComboBox (and potentially any other class implementing wxTextEntry interface) to check that only valid floating point values can be entered into them. Currently only fixed format is supported on input, i.e. scientific format with mantissa and exponent is not supported.

This template class can be instantiated for either `float` or `double`, `long double` values are not currently supported.

Similarly to wxIntegerValidator<>, the range for the accepted values is by default set appropriately for the type. Additionally, this validator allows to specify the maximum number of digits that can be entered after the decimal separator. By default this is also set appropriately for the type used, e.g. 6 for `float` and 15 for `double` on a typical IEEE-754-based implementation. As with the range, the precision can be restricted after the validator creation if necessary.

When the validator displays numbers with decimal or thousands separators, the characters used for the separators (usually "." or ",") depend on the locale set with wxLocale (note that you shouldn't change locale with setlocale() as this can result in a mismatch between the separators used by wxLocale and the one used by the run-time library).

A simple example of using this class:

```
class MyDialog : public wxDialog
{
public:
    MyDialog()
    {
        ...
```

```
        // Allow floating point numbers from 0 to 100 with 2 decimal
        // digits only and handle empty string as 0 by default.
        wxFloatingPointValidator<float>
            val(2, &m_value, wxNUM_VAL_ZERO_AS_BLANK);
        val.SetRange(0, 100);

        // Associate it with the text control:
        new wxTextCtrl(this, ..., val);
    }

private:
    float m_value;
};
```

For more information, please see wxValidator Overview.

wxValidator Overview, wxValidator, wxGenericValidator, wxTextValidator, wxMakeIntegerValidator()

Since

2.9.2

Public Types

- typedef T ValueType

  Type of the values this validator is used with.

Public Member Functions

- wxFloatingPointValidator (ValueType *value=NULL, int style=wxNUM_VAL_DEFAULT)

  Constructor for validator using the default precision.
- wxFloatingPointValidator (int precision, ValueType *value=NULL, int style=wxNUM_VAL_DEFAULT)

  Constructor for validator specifying the precision.
- void SetPrecision (unsigned precision)

  Set precision.

Additional Inherited Members

21.258.2 Member Typedef Documentation

template<typename T> typedef T wxFloatingPointValidator< T >::ValueType

Type of the values this validator is used with.

21.258.3 Constructor & Destructor Documentation

template<typename T> wxFloatingPointValidator< T >::wxFloatingPointValidator (ValueType * *value* = NULL, int *style* = wxNUM_VAL_DEFAULT)

Constructor for validator using the default precision.

Parameters

value	A pointer to the variable associated with the validator. If non NULL, this variable should have a lifetime equal to or longer than the validator lifetime (which is usually determined by the lifetime of the window).
style	A combination of wxNumValidatorStyle enum values.

template<typename T> wxFloatingPointValidator< T >::wxFloatingPointValidator (int *precision,* ValueType * *value* = NULL, int *style* = wxNUM_VAL_DEFAULT)

Constructor for validator specifying the precision.

Parameters

value	A pointer to the variable associated with the validator. If non NULL, this variable should have a lifetime equal to or longer than the validator lifetime (which is usually determined by the lifetime of the window).
style	A combination of wxNumValidatorStyle enum values.
precision	The number of decimal digits after the decimal separator to show and accept.

21.258.4 Member Function Documentation

template<typename T> void wxFloatingPointValidator< T >::SetPrecision (unsigned *precision*)

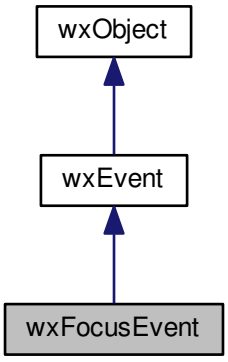
Set precision.

Precision is the number of digits shown (and accepted on input) after the decimal point. By default this is set to the maximal precision supported by the type handled by the validator in its constructor.

21.259 wxFocusEvent Class Reference

`#include <wx/event.h>`

Inheritance diagram for wxFocusEvent:



21.259.1 Detailed Description

A focus event is sent when a window's focus changes.

The window losing focus receives a "kill focus" event while the window gaining it gets a "set focus" one.

Notice that the set focus event happens both when the user gives focus to the window (whether using the mouse or keyboard) and when it is done from the program itself using wxWindow::SetFocus.

The focus event handlers should almost invariably call wxEvent::Skip() on their event argument to allow the default handling to take place. Failure to do this may result in incorrect behaviour of the native controls. Also note that wxE↩ VT_KILL_FOCUS handler must not call wxWindow::SetFocus() as this, again, is not supported by all native controls. If you need to do this, consider using the Delayed Action Mechanism described in wxIdleEvent documentation.

Events using this class

The following event handler macros redirect the events to member function handlers '**func**' with prototypes like: void handlerFuncName(wxFocusEvent& event)

Event macros:

- EVT_SET_FOCUS(func): Process a `wxEVT_SET_FOCUS` event.
- EVT_KILL_FOCUS(func): Process a `wxEVT_KILL_FOCUS` event.

Library: wxCore

Category: Events

See also

Events and Event Handling

Public Member Functions

- wxFocusEvent (wxEventType eventType=wxEVT_NULL, int id=0)

  Constructor.
- wxWindow * GetWindow () const

  Returns the window associated with this event, that is the window which had the focus before for the `wxEVT_SET↩ _FOCUS` event and the window which is going to receive focus for the `wxEVT_KILL_FOCUS` one.
- void SetWindow (wxWindow *win)

Additional Inherited Members

21.259.2 Constructor & Destructor Documentation

wxFocusEvent::wxFocusEvent (wxEventType *eventType* = wxEVT_NULL, int *id* = 0)

Constructor.

21.259.3 Member Function Documentation

wxWindow* wxFocusEvent::GetWindow ( ) const

Returns the window associated with this event, that is the window which had the focus before for the `wxEVT_SE↩T_FOCUS` event and the window which is going to receive focus for the `wxEVT_KILL_FOCUS` one.

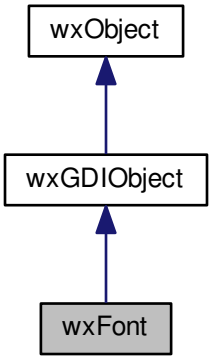
Warning: the window pointer may be NULL!

void wxFocusEvent::SetWindow (wxWindow * *win*)

21.260 wxFont Class Reference

`#include <wx/font.h>`

Inheritance diagram for wxFont:



21.260.1 Detailed Description

A font is an object which determines the appearance of text.

Fonts are used for drawing text to a device context, and setting the appearance of a window's text, see wxDC::Set↩Font() and wxWindow::SetFont().

The easiest way to create a custom font is to use wxFontInfo object to specify the font attributes and then use wxFont::wxFont(const wxFontInfo&) constructor. Alternatively, you could start with one of the pre-defined fonts or use wxWindow::GetFont() and modify the font, e.g. by increasing its size using MakeLarger() or changing its weight using MakeBold().

This class uses reference counting and copy-on-write internally so that assignments between two instances of this class are very cheap. You can therefore use actual objects instead of pointers without efficiency problems. If an instance of this class is changed it will create its own data internally so that other instances, which previously shared the data using the reference counting, are not affected.

You can retrieve the current system font settings with wxSystemSettings.

Library: wxCore

Category: Graphics Device Interface (GDI)

Predefined objects/pointers: wxNullFont, wxNORMAL_FONT, wxSMALL_FONT, wxITALIC_FONT, wxSWISS_F↩ ONT

See also

wxFont Overview, wxDC::SetFont, wxDC::DrawText, wxDC::GetTextExtent, wxFontDialog, wxSystemSettings

Public Member Functions

- wxFont ()

  Default ctor.
- wxFont (const wxFont &font)

  Copy constructor, uses reference counting.
- wxFont (const wxFontInfo &font)

  Creates a font object using the specified font description.
- wxFont (int pointSize, wxFontFamily family, wxFontStyle style, wxFontWeight weight, bool underline=false, const wxString &faceName=wxEmptyString, wxFontEncoding encoding=wxFONTENCODING_DEFAULT)

  Creates a font object with the specified attributes and size in points.
- wxFont (const wxSize &pixelSize, wxFontFamily family, wxFontStyle style, wxFontWeight weight, bool underline=false, const wxString &faceName=wxEmptyString, wxFontEncoding encoding=wxFONTENCODING_↩ DEFAULT)

  Creates a font object with the specified attributes and size in pixels.
- wxFont (const wxString &nativeInfoString)

  Constructor from font description string.
- wxFont (const wxNativeFontInfo &nativeInfo)

  Construct font from a native font info structure.
- virtual ∼wxFont ()

  Destructor.
- bool operator!= (const wxFont &font) const

  Inequality operator.
- bool operator== (const wxFont &font) const

  Equality operator.
- wxFont & operator= (const wxFont &font)

  Assignment operator, using reference counting.

Getters

- wxFont GetBaseFont () const

  Returns a font with the same face/size as the given one but with normal weight and style and not underlined nor stricken through.
- virtual wxFontEncoding GetEncoding () const

  Returns the encoding of this font.
- virtual wxString GetFaceName () const

  Returns the face name associated with the font, or the empty string if there is no face information.
- virtual wxFontFamily GetFamily () const

  Gets the font family if possible.
- wxString GetNativeFontInfoDesc () const

  Returns the platform-dependent string completely describing this font.
- wxString GetNativeFontInfoUserDesc () const

  Returns a user-friendly string for this font object.
- const wxNativeFontInfo ∗ GetNativeFontInfo () const

  Returns a font with the same face/size as the given one but with normal weight and style and not underlined nor stricken through.
- virtual int GetPointSize () const

  Gets the point size.

- virtual wxSize GetPixelSize () const
  Gets the pixel size.
- virtual wxFontStyle GetStyle () const
  Gets the font style.
- virtual bool GetUnderlined () const
  Returns true if the font is underlined, false otherwise.
- virtual bool GetStrikethrough () const
  Returns true if the font is stricken-through, false otherwise.
- virtual wxFontWeight GetWeight () const
  Gets the font weight.
- virtual bool IsFixedWidth () const
  Returns true if the font is a fixed width (or monospaced) font, false if it is a proportional one or font is invalid.
- virtual bool IsOk () const
  Returns true if this object is a valid font, false otherwise.

Similar fonts creation

The functions in this section either modify the font in place or create a new font similar to the given one but with its weight, style or size changed.

- wxFont Bold () const
  Returns a bold version of this font.
- wxFont Italic () const
  Returns an italic version of this font.
- wxFont Larger () const
  Returns a larger version of this font.
- wxFont Smaller () const
  Returns a smaller version of this font.
- wxFont Underlined () const
  Returns underlined version of this font.
- wxFont Strikethrough () const
  Returns stricken-through version of this font.
- wxFont & MakeBold ()
  Changes this font to be bold.
- wxFont & MakeItalic ()
  Changes this font to be italic.
- wxFont & MakeLarger ()
  Changes this font to be larger.
- wxFont & MakeSmaller ()
  Changes this font to be smaller.
- wxFont & MakeUnderlined ()
  Changes this font to be underlined.
- wxFont & MakeStrikethrough ()
  Changes this font to be stricken-through.
- wxFont & Scale (float x)
  Changes the size of this font.
- wxFont Scaled (float x) const
  Returns a scaled version of this font.

Setters

These functions internally recreate the native font object with the new specified property.

- virtual void SetEncoding (wxFontEncoding encoding)
  Sets the encoding for this font.
- virtual bool SetFaceName (const wxString &faceName)
  Sets the facename for the font.
- virtual void SetFamily (wxFontFamily family)
  Sets the font family.
- bool SetNativeFontInfo (const wxString &info)

Creates the font corresponding to the given native font description string which must have been previously returned by GetNativeFontInfoDesc().

- bool SetNativeFontInfoUserDesc (const wxString &info)

  Creates the font corresponding to the given native font description string and returns true if the creation was successful.
- void SetNativeFontInfo (const wxNativeFontInfo &info)

  Sets the encoding for this font.
- virtual void SetPointSize (int pointSize)

  Sets the point size.
- virtual void SetPixelSize (const wxSize &pixelSize)

  Sets the pixel size.
- virtual void SetStyle (wxFontStyle style)

  Sets the font style.
- void SetSymbolicSize (wxFontSymbolicSize size)

  Sets the font size using a predefined symbolic size name.
- void SetSymbolicSizeRelativeTo (wxFontSymbolicSize size, int base)

  Sets the font size compared to the base font size.
- virtual void SetUnderlined (bool underlined)

  Sets underlining.
- virtual void SetStrikethrough (bool strikethrough)

  Sets strike-through attribute of the font.
- virtual void SetWeight (wxFontWeight weight)

  Sets the font weight.

Static Public Member Functions

- static wxFontEncoding GetDefaultEncoding ()

  Returns the current application's default encoding.
- static void SetDefaultEncoding (wxFontEncoding encoding)

  Sets the default font encoding.

- static wxFont * New (int pointSize, wxFontFamily family, wxFontStyle style, wxFontWeight weight, bool underline=false, const wxString &faceName=wxEmptyString, wxFontEncoding encoding=wxFONTENCODING_DEFAULT)

  This function takes the same parameters as the relative wxFont constructor and returns a new font object allocated on the heap.
- static wxFont * New (int pointSize, wxFontFamily family, int flags=wxFONTFLAG_DEFAULT, const wxString &faceName=wxEmptyString, wxFontEncoding encoding=wxFONTENCODING_DEFAULT)

  This function takes the same parameters as the relative wxFont constructor and returns a new font object allocated on the heap.
- static wxFont * New (const wxSize &pixelSize, wxFontFamily family, wxFontStyle style, wxFontWeight weight, bool underline=false, const wxString &faceName=wxEmptyString, wxFontEncoding encoding=wxFONTENCODING_DEFAULT)

  This function takes the same parameters as the relative wxFont constructor and returns a new font object allocated on the heap.
- static wxFont * New (const wxSize &pixelSize, wxFontFamily family, int flags=wxFONTFLAG_DEFAULT, const wxString &faceName=wxEmptyString, wxFontEncoding encoding=wxFONTENCODING_DEFAULT)

  This function takes the same parameters as the relative wxFont constructor and returns a new font object allocated on the heap.
- static wxFont * New (const wxNativeFontInfo &nativeInfo)

  This function takes the same parameters as the relative wxFont constructor and returns a new font object allocated on the heap.
- static wxFont * New (const wxString &nativeInfoString)

  This function takes the same parameters as the relative wxFont constructor and returns a new font object allocated on the heap.

Additional Inherited Members

21.260.2 Constructor & Destructor Documentation

wxFont::wxFont ( )

Default ctor.

wxFont::wxFont (const wxFont & *font*)

Copy constructor, uses reference counting.

wxFont::wxFont (const wxFontInfo & *font*)

Creates a font object using the specified font description.

This is the preferred way to create font objects as using this ctor results in more readable code and it is also extensible, e.g. it could continue to be used if support for more font attributes is added in the future. For example, this constructor provides the only way of creating fonts with strike-through style.

Example of creating a font using this ctor:

```
wxFont font(wxFontInfo(10).Bold().Underlined());
```

Since

2.9.5

wxFont::wxFont (int *pointSize*, wxFontFamily *family*, wxFontStyle *style*, wxFontWeight *weight*, bool *underline* = `false`, const wxString & *faceName* = wxEmptyString, wxFontEncoding *encoding* = wxFONTENCODING_DEFAULT)

Creates a font object with the specified attributes and size in points.

Notice that the use of this constructor is often more verbose and less readable than using wxFont(const wxFontInfo& font), e.g. the example in that constructor documentation would need to be written as:

```
wxFont font(10, wxFONTFAMILY_DEFAULT,
      wxFONTSTYLE_NORMAL,
            wxFONTWEIGHT_BOLD, true);
```

Parameters

pointSize	Size in points. See SetPointSize() for more info.
family	The font family: a generic portable way of referring to fonts without specifying a facename. This parameter must be one of the wxFontFamily enumeration values. If the *faceName* argument is provided, then it overrides the font family.
style	One of `wxFONTSTYLE_NORMAL`, `wxFONTSTYLE_SLANT` and `wxFONTSTYLE_ITALIC`.
weight	Font weight, sometimes also referred to as font boldness. One of the wxFontWeight enumeration values.

underline	The value can be true or false. At present this has an effect on Windows and Motif 2.x only.
faceName	An optional string specifying the face name to be used. If it is an empty string, a default face name will be chosen based on the family.
encoding	An encoding which may be one of the enumeration values of wxFontEncoding. If the specified encoding isn't available, no font is created (see also Font Encodings).

Remarks

If the desired font does not exist, the closest match will be chosen. Under Windows, only scalable TrueType fonts are used.

wxFont::wxFont (const wxSize & *pixelSize*, wxFontFamily *family*, wxFontStyle *style*, wxFontWeight *weight*, bool *underline* = `false`, const wxString & *faceName* = wxEmptyString, wxFontEncoding *encoding* = wxFONTENCODING_DEFAULT)

Creates a font object with the specified attributes and size in pixels.

Notice that the use of this constructor is often more verbose and less readable than the use of constructor from wxFontInfo, consider using that constructor instead.

Parameters

pixelSize	Size in pixels. See SetPixelSize() for more info.
family	The font family: a generic portable way of referring to fonts without specifying a facename. This parameter must be one of the wxFontFamily enumeration values. If the *faceName* argument is provided, then it overrides the font family.
style	One of `wxFONTSTYLE_NORMAL`, `wxFONTSTYLE_SLANT` and `wxFONTSTYLE_ITALIC`.
weight	Font weight, sometimes also referred to as font boldness. One of the wxFontWeight enumeration values.
underline	The value can be true or false. At present this has an effect on Windows and Motif 2.x only.
faceName	An optional string specifying the face name to be used. If it is an empty string, a default face name will be chosen based on the family.
encoding	An encoding which may be one of the enumeration values of wxFontEncoding. If the specified encoding isn't available, no font is created (see also Font Encodings).

Remarks

If the desired font does not exist, the closest match will be chosen. Under Windows, only scalable TrueType fonts are used.

wxFont::wxFont (const wxString & *nativeInfoString*)

Constructor from font description string.

This constructor uses SetNativeFontInfo() to initialize the font. If *fontdesc* is invalid the font remains uninitialized, i.e. its IsOk() method will return false.

wxFont::wxFont (const wxNativeFontInfo & *nativeInfo*)

Construct font from a native font info structure.

virtual wxFont::~wxFont ( ) [virtual]

Destructor.

See reference-counted object destruction for more info.

Remarks

Although all remaining fonts are deleted when the application exits, the application should try to clean up all fonts itself. This is because wxWidgets cannot know if a pointer to the font object is stored in an application data structure, and there is a risk of double deletion.

21.260.3 Member Function Documentation

wxFont wxFont::Bold ( ) const

Returns a bold version of this font.

See also

MakeBold()

Since

2.9.1

wxFont wxFont::GetBaseFont ( ) const

Returns a font with the same face/size as the given one but with normal weight and style and not underlined nor stricken through.

Since

3.1.0

static wxFontEncoding wxFont::GetDefaultEncoding ( ) [static]

Returns the current application's default encoding.

See also

Font Encodings, SetDefaultEncoding()

virtual wxFontEncoding wxFont::GetEncoding ( ) const [virtual]

Returns the encoding of this font.

Note that under wxGTK the returned value is always `wxFONTENCODING_UTF8`.

See also

SetEncoding()

virtual wxString wxFont::GetFaceName ( ) const [virtual]

Returns the face name associated with the font, or the empty string if there is no face information.

See also

SetFaceName()

virtual wxFontFamily wxFont::GetFamily ( ) const `[virtual]`

Gets the font family if possible.

As described in wxFontFamily docs the returned value acts as a rough, basic classification of the main font properties (look, spacing).

If the current font face name is not recognized by wxFont or by the underlying system, `wxFONTFAMILY_DEFAULT` is returned.

Note that currently this function is not very precise and so not particularly useful. Font families mostly make sense only for font creation, see SetFamily().

See also

SetFamily()

const wxNativeFontInfo* wxFont::GetNativeFontInfo ( ) const

Returns a font with the same face/size as the given one but with normal weight and style and not underlined nor stricken through.

Since

3.1.0

wxString wxFont::GetNativeFontInfoDesc ( ) const

Returns the platform-dependent string completely describing this font.

Returned string is always non-empty unless the font is invalid (in which case an assert is triggered).

Note that the returned string is not meant to be shown or edited by the user: a typical use of this function is for serializing in string-form a wxFont object.

See also

SetNativeFontInfo(), GetNativeFontInfoUserDesc()

wxString wxFont::GetNativeFontInfoUserDesc ( ) const

Returns a user-friendly string for this font object.

Returned string is always non-empty unless the font is invalid (in which case an assert is triggered).

The string does not encode all wxFont infos under all platforms; e.g. under wxMSW the font family is not present in the returned string.

Some examples of the formats of returned strings (which are platform-dependent) are in SetNativeFontInfoUserDesc().

See also

SetNativeFontInfoUserDesc(), GetNativeFontInfoDesc()

virtual wxSize wxFont::GetPixelSize ( ) const [virtual]

Gets the pixel size.

Note that under wxMSW if you passed to SetPixelSize() (or to the ctor) a wxSize object with a null width value, you'll get a null width in the returned object.

See also

SetPixelSize()

virtual int wxFont::GetPointSize ( ) const [virtual]

Gets the point size.

See also

SetPointSize()

virtual bool wxFont::GetStrikethrough ( ) const [virtual]

Returns true if the font is stricken-through, false otherwise.

See also

SetStrikethrough()

Since

2.9.4

virtual wxFontStyle wxFont::GetStyle ( ) const [virtual]

Gets the font style.

See wxFontStyle for a list of valid styles.

See also

SetStyle()

virtual bool wxFont::GetUnderlined ( ) const [virtual]

Returns true if the font is underlined, false otherwise.

See also

SetUnderlined()

virtual wxFontWeight wxFont::GetWeight ( ) const [virtual]

Gets the font weight.

See wxFontWeight for a list of valid weight identifiers.

See also

SetWeight()

virtual bool wxFont::IsFixedWidth ( ) const `[virtual]`

Returns true if the font is a fixed width (or monospaced) font, false if it is a proportional one or font is invalid.

Note that this function under some platforms is different than just testing for the font family being equal to `wxFONTFAMILY_TELETYPE` because native platform-specific functions are used for the check (resulting in a more accurate return value).

virtual bool wxFont::IsOk ( ) const `[virtual]`

Returns true if this object is a valid font, false otherwise.

wxFont wxFont::Italic ( ) const

Returns an italic version of this font.

See also

MakeItalic()

Since

2.9.1

wxFont wxFont::Larger ( ) const

Returns a larger version of this font.

The font size is multiplied by `1.2`, the factor of `1.2` being inspired by the W3C CSS specification.

See also

MakeLarger(), Smaller(), Scaled()

Since

2.9.1

wxFont& wxFont::MakeBold ( )

Changes this font to be bold.

See also

Bold()

Since

2.9.1

wxFont& wxFont::MakeItalic ( )

Changes this font to be italic.

See also

Italic()

Since

2.9.1

wxFont& wxFont::MakeLarger ( )

Changes this font to be larger.

The font size is multiplied by `1.2`, the factor of `1.2` being inspired by the W3C CSS specification.

See also

Larger(), MakeSmaller(), Scale()

Since

2.9.1

wxFont& wxFont::MakeSmaller ( )

Changes this font to be smaller.

The font size is divided by `1.2`, the factor of `1.2` being inspired by the W3C CSS specification.

See also

Smaller(), MakeLarger(), Scale()

Since

2.9.1

wxFont& wxFont::MakeStrikethrough ( )

Changes this font to be stricken-through.

Currently stricken-through fonts are only supported in wxMSW, wxGTK and OSX.

See also

Strikethrough()

Since

2.9.4

wxFont& wxFont::MakeUnderlined ( )

Changes this font to be underlined.

See also

Underlined()

Since

2.9.2

static wxFont* wxFont::New (int *pointSize*, wxFontFamily *family*, wxFontStyle *style*, wxFontWeight *weight*, bool *underline* = `false`, const wxString & *faceName* = wxEmptyString, wxFontEncoding *encoding* = wxFONTENCODING_DEFAULT) `[static]`

This function takes the same parameters as the relative wxFont constructor and returns a new font object allocated on the heap.

Their use is discouraged, use wxFont constructor from wxFontInfo instead.

static wxFont* wxFont::New (int *pointSize*, wxFontFamily *family*, int *flags* = wxFONTFLAG_DEFAULT, const wxString & *faceName* = wxEmptyString, wxFontEncoding *encoding* = wxFONTENCODING_DEFAULT) `[static]`

This function takes the same parameters as the relative wxFont constructor and returns a new font object allocated on the heap.

Their use is discouraged, use wxFont constructor from wxFontInfo instead.

static wxFont* wxFont::New (const wxSize & *pixelSize*, wxFontFamily *family*, wxFontStyle *style*, wxFontWeight *weight*, bool *underline* = `false`, const wxString & *faceName* = wxEmptyString, wxFontEncoding *encoding* = wxFONTENCODING_DEFAULT) `[static]`

This function takes the same parameters as the relative wxFont constructor and returns a new font object allocated on the heap.

Their use is discouraged, use wxFont constructor from wxFontInfo instead.

static wxFont* wxFont::New (const wxSize & *pixelSize*, wxFontFamily *family*, int *flags* = wxFONTFLAG_DEFAULT, const wxString & *faceName* = wxEmptyString, wxFontEncoding *encoding* = wxFONTENCODING_DEFAULT) `[static]`

This function takes the same parameters as the relative wxFont constructor and returns a new font object allocated on the heap.

Their use is discouraged, use wxFont constructor from wxFontInfo instead.

static wxFont* wxFont::New (const wxNativeFontInfo & *nativeInfo*) `[static]`

This function takes the same parameters as the relative wxFont constructor and returns a new font object allocated on the heap.

Their use is discouraged, use wxFont constructor from wxFontInfo instead.

static wxFont* wxFont::New (const wxString & *nativeInfoString*) `[static]`

This function takes the same parameters as the relative wxFont constructor and returns a new font object allocated on the heap.

Their use is discouraged, use wxFont constructor from wxFontInfo instead.

bool wxFont::operator!= (const wxFont & *font*) const

Inequality operator.

See reference-counted object comparison for more info.

wxFont& wxFont::operator= (const wxFont & *font*)

Assignment operator, using reference counting.

bool wxFont::operator== (const wxFont & *font*) const

Equality operator.

See reference-counted object comparison for more info.

wxFont& wxFont::Scale (float *x*)

Changes the size of this font.

The font size is multiplied by the given factor (which may be less than 1 to create a smaller version of the font).

See also

Scaled(), MakeLarger(), MakeSmaller()

Since

2.9.1

wxFont wxFont::Scaled (float *x*) const

Returns a scaled version of this font.

The font size is multiplied by the given factor (which may be less than 1 to create a smaller version of the font).

See also

Scale(), Larger(), Smaller()

Since

2.9.1

static void wxFont::SetDefaultEncoding (wxFontEncoding *encoding*) `[static]`

Sets the default font encoding.

See also

Font Encodings, GetDefaultEncoding()

virtual void wxFont::SetEncoding (wxFontEncoding *encoding*) [virtual]

Sets the encoding for this font.

Note that under wxGTK this function has no effect (because the underlying Pango library always uses wxFONTENCODING_UTF8).

See also

GetEncoding()

virtual bool wxFont::SetFaceName (const wxString & *faceName*) [virtual]

Sets the facename for the font.

Parameters

faceName	A valid facename, which should be on the end-user's system.

Remarks

To avoid portability problems, don't rely on a specific face, but specify the font family instead (see wxFontFamily and SetFamily()).

Returns

true if the given face name exists; if the face name doesn't exist in the user's system then the font is invalidated (so that IsOk() will return false) and false is returned.

See also

GetFaceName(), SetFamily()

virtual void wxFont::SetFamily (wxFontFamily *family*) [virtual]

Sets the font family.

As described in wxFontFamily docs the given *family* value acts as a rough, basic indication of the main font properties (look, spacing).

Note that changing the font family results in changing the font face name.

Parameters

family	One of the wxFontFamily values.

See also

GetFamily(), SetFaceName()

bool wxFont::SetNativeFontInfo (const wxString & *info*)

Creates the font corresponding to the given native font description string which must have been previously returned by GetNativeFontInfoDesc().

If the string is invalid, font is unchanged. This function is typically used for de-serializing a wxFont object previously saved in a string-form.

Returns

true if the creation was successful.

See also

SetNativeFontInfoUserDesc()

void wxFont::SetNativeFontInfo (const wxNativeFontInfo & *info*)

Sets the encoding for this font.

Note that under wxGTK this function has no effect (because the underlying Pango library always uses `wxFONTENCODING_UTF8`).

See also

GetEncoding()

bool wxFont::SetNativeFontInfoUserDesc (const wxString & *info*)

Creates the font corresponding to the given native font description string and returns true if the creation was successful.

Unlike SetNativeFontInfo(), this function accepts strings which are user-friendly. Examples of accepted string formats are:

platform	generic syntax	example
wxGTK2	`[underlined] [strikethrough] [FACE-NAME] [bold] [oblique|italic] [POINTSIZE]`	Monospace bold 10
wxMSW	`[light|bold] [italic] [FACE-NAME] [POINTSIZE] [ENCODING]`	Tahoma 10 WINDOWS-1252

Todo add an example for wxMac

For more detailed information about the allowed syntaxes you can look at the documentation of the native API used for font-rendering (e.g. `pango_font_description_from_string` under GTK, although notice that it doesn't support the "underlined" and "strikethrough" attributes and so those are handled by wxWidgets itself).

Note that unlike SetNativeFontInfo(), this function doesn't always restore all attributes of the wxFont object under all platforms; e.g. on wxMSW the font family is not restored (because GetNativeFontInfoUserDesc doesn't return it on wxMSW). If you want to serialize/deserialize a font in string form, you should use GetNativeFontInfoDesc() and SetNativeFontInfo() instead.

See also

SetNativeFontInfo()

virtual void wxFont::SetPixelSize (const wxSize & *pixelSize*) [virtual]

Sets the pixel size.

The height parameter of *pixelSize* must be positive while the width parameter may also be zero (to indicate that you're not interested in the width of the characters: a suitable width will be chosen for best rendering).

This feature (specifying the font pixel size) is directly supported only under wxMSW and wxGTK currently; under other platforms a font with the closest size to the given one is found using binary search (this maybe slower).

See also

GetPixelSize()

virtual void wxFont::SetPointSize (int *pointSize*) [virtual]

Sets the point size.

The *point size* is defined as 1/72 of the Anglo-Saxon inch (25.4 mm): it is approximately 0.0139 inch or 352.8 um.

Parameters

pointSize	Size in points.

See also

GetPointSize()

virtual void wxFont::SetStrikethrough (bool *strikethrough*) [virtual]

Sets strike-through attribute of the font.

Currently stricken-through fonts are only supported in wxMSW, wxGTK and OSX.

Parameters

strikethrough	true to add strike-through style, false to remove it.

See also

GetStrikethrough()

Since

2.9.4

virtual void wxFont::SetStyle (wxFontStyle *style*) [virtual]

Sets the font style.

Parameters

style	One of the wxFontStyle enumeration values.

See also

GetStyle()

void wxFont::SetSymbolicSize (wxFontSymbolicSize *size*)

Sets the font size using a predefined symbolic size name.

This function allows to change font size to be (very) large or small compared to the standard font size.

See also

SetSymbolicSizeRelativeTo().

Since

2.9.2

void wxFont::SetSymbolicSizeRelativeTo (wxFontSymbolicSize *size*, int *base*)

Sets the font size compared to the base font size.

This is the same as SetSymbolicSize() except that it uses the given font size as the normal font size instead of the standard font size.

Since

2.9.2

virtual void wxFont::SetUnderlined (bool *underlined*) [virtual]

Sets underlining.

Parameters

underlined	true to underline, false otherwise.

See also

GetUnderlined()

virtual void wxFont::SetWeight (wxFontWeight *weight*) [virtual]

Sets the font weight.

Parameters

weight	One of the wxFontWeight values.

See also

GetWeight()

wxFont wxFont::Smaller ( ) const

Returns a smaller version of this font.

The font size is divided by `1.2`, the factor of `1.2` being inspired by the W3C CSS specification.

See also

MakeSmaller(), Larger(), Scaled()

Since

2.9.1

wxFont wxFont::Strikethrough ( ) const

Returns stricken-through version of this font.

Currently stricken-through fonts are only supported in wxMSW, wxGTK and OSX.

See also

MakeStrikethrough()

Since

2.9.4

wxFont wxFont::Underlined ( ) const

Returns underlined version of this font.

See also

MakeUnderlined()

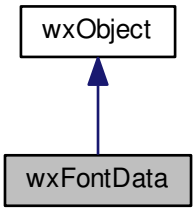
Since

2.9.2

21.261 wxFontData Class Reference

`#include <wx/fontdata.h>`

Inheritance diagram for wxFontData:



21.261.1 Detailed Description

This class holds a variety of information related to font dialogs.

Library: wxCore

Category: Common Dialogs, Data Structures

See also

wxFontDialog Overview, wxFont, wxFontDialog

Public Member Functions

- wxFontData ()

  Constructor.
- void EnableEffects (bool enable)

  Enables or disables "effects" under Windows or generic only.
- bool GetAllowSymbols () const

  Under Windows, returns a flag determining whether symbol fonts can be selected.
- wxFont GetChosenFont () const

  Gets the font chosen by the user if the user pressed OK (wxFontDialog::ShowModal() returned wxID_OK).
- const wxColour & GetColour () const

  Gets the colour associated with the font dialog.
- bool GetEnableEffects () const

  Determines whether "effects" are enabled under Windows.
- wxFont GetInitialFont () const

  Gets the font that will be initially used by the font dialog.
- bool GetShowHelp () const

  Returns true if the Help button will be shown (Windows only).
- void SetAllowSymbols (bool allowSymbols)

  Under Windows, determines whether symbol fonts can be selected.
- void SetChosenFont (const wxFont &font)

  Sets the font that will be returned to the user (for internal use only).
- void SetColour (const wxColour &colour)

  Sets the colour that will be used for the font foreground colour.
- void SetInitialFont (const wxFont &font)

  Sets the font that will be initially used by the font dialog.
- void SetRange (int min, int max)

  Sets the valid range for the font point size (Windows only).
- void SetShowHelp (bool showHelp)

  Determines whether the Help button will be displayed in the font dialog (Windows only).
- wxFontData & operator= (const wxFontData &data)

  Assignment operator for the font data.

Additional Inherited Members

21.261.2 Constructor & Destructor Documentation

wxFontData::wxFontData ( )

Constructor.

Initializes *fontColour* to black, *showHelp* to false, *allowSymbols* to true, *enableEffects* to true, *minSize* to 0 and *maxSize* to 0.

21.261.3 Member Function Documentation

void wxFontData::EnableEffects (bool *enable*)

Enables or disables "effects" under Windows or generic only.

This refers to the controls for manipulating colour, strikeout and underline properties.

The default value is true.

bool wxFontData::GetAllowSymbols ( ) const

Under Windows, returns a flag determining whether symbol fonts can be selected.

Has no effect on other platforms.

The default value is true.

wxFont wxFontData::GetChosenFont ( ) const

Gets the font chosen by the user if the user pressed OK (wxFontDialog::ShowModal() returned wxID_OK).

const wxColour& wxFontData::GetColour ( ) const

Gets the colour associated with the font dialog.

The default value is black.

bool wxFontData::GetEnableEffects ( ) const

Determines whether "effects" are enabled under Windows.

This refers to the controls for manipulating colour, strikeout and underline properties.

The default value is true.

wxFont wxFontData::GetInitialFont ( ) const

Gets the font that will be initially used by the font dialog.

This should have previously been set by the application.

bool wxFontData::GetShowHelp ( ) const

Returns true if the Help button will be shown (Windows only).

The default value is false.

wxFontData& wxFontData::operator= (const wxFontData & *data*)

Assignment operator for the font data.

void wxFontData::SetAllowSymbols (bool *allowSymbols*)

Under Windows, determines whether symbol fonts can be selected.

Has no effect on other platforms.

The default value is true.

void wxFontData::SetChosenFont (const wxFont & *font*)

Sets the font that will be returned to the user (for internal use only).

void wxFontData::SetColour (const wxColour & *colour*)

Sets the colour that will be used for the font foreground colour.
The default colour is black.

void wxFontData::SetInitialFont (const wxFont & *font*)

Sets the font that will be initially used by the font dialog.

void wxFontData::SetRange (int *min,* int *max*)

Sets the valid range for the font point size (Windows only).
The default is 0, 0 (unrestricted range).

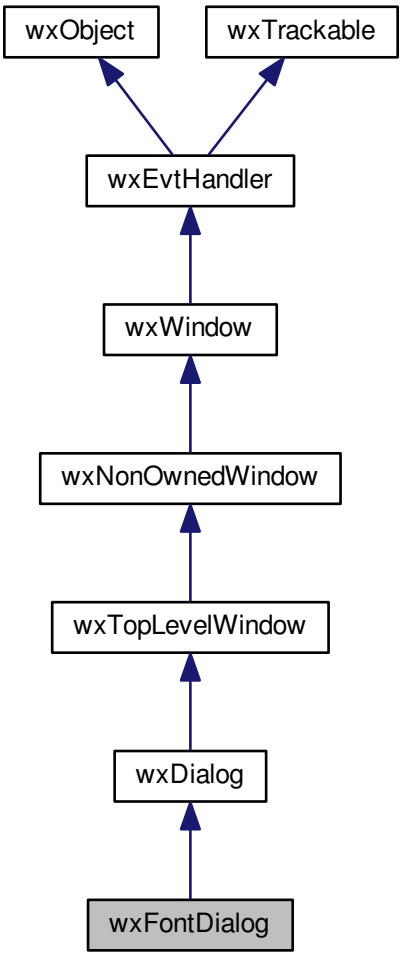
void wxFontData::SetShowHelp (bool *showHelp*)

Determines whether the Help button will be displayed in the font dialog (Windows only).
The default value is false.

21.262 wxFontDialog Class Reference

`#include <wx/fontdlg.h>`

Inheritance diagram for wxFontDialog:



21.262.1 Detailed Description

This class represents the font chooser dialog.

Library: wxCore

Category: Common Dialogs

See also

wxFontDialog Overview, wxFontData, wxGetFontFromUser()

Public Member Functions

- wxFontDialog ()

Default ctor.

- wxFontDialog (wxWindow *parent)

  Constructor with parent window.
- wxFontDialog (wxWindow *parent, const wxFontData &data)

  Constructor.
- bool Create (wxWindow *parent)

  Creates the dialog if the wxFontDialog object had been initialized using the default constructor.
- bool Create (wxWindow *parent, const wxFontData &data)

  Creates the dialog if the wxFontDialog object had been initialized using the default constructor.
- int ShowModal ()

  Shows the dialog, returning `wxID_OK` if the user pressed Ok, and `wxID_CANCEL` otherwise.
- const wxFontData & GetFontData () const

  Returns the font data associated with the font dialog.
- wxFontData & GetFontData ()

  Returns the font data associated with the font dialog.

Additional Inherited Members

21.262.2 Constructor & Destructor Documentation

wxFontDialog::wxFontDialog ( )

Default ctor.

Create() must be called before the dialog can be shown.

wxFontDialog::wxFontDialog (wxWindow * *parent*)

Constructor with parent window.

wxFontDialog::wxFontDialog (wxWindow * *parent,* const wxFontData & *data*)

Constructor.

Pass a parent window, and the font data object to be used to initialize the dialog controls.

21.262.3 Member Function Documentation

bool wxFontDialog::Create (wxWindow * *parent*)

Creates the dialog if the wxFontDialog object had been initialized using the default constructor.

Returns

true on success and false if an error occurred.

bool wxFontDialog::Create (wxWindow * *parent,* const wxFontData & *data*)

Creates the dialog if the wxFontDialog object had been initialized using the default constructor.

Returns

true on success and false if an error occurred.

const wxFontData& wxFontDialog::GetFontData ( ) const

Returns the font data associated with the font dialog.

wxFontData& wxFontDialog::GetFontData ( )

Returns the font data associated with the font dialog.

int wxFontDialog::ShowModal ( ) [virtual]

Shows the dialog, returning `wxID_OK` if the user pressed Ok, and `wxID_CANCEL` otherwise.

If the user cancels the dialog (ShowModal returns `wxID_CANCEL`), no font will be created. If the user presses OK, a new wxFont will be created and stored in the font dialog's wxFontData structure.

See also

GetFontData()

Reimplemented from wxDialog.

21.263 wxFontEnumerator Class Reference

`#include <wx/fontenum.h>`

21.263.1 Detailed Description

wxFontEnumerator enumerates either all available fonts on the system or only the ones with given attributes - either only fixed-width (suited for use in programs such as terminal emulators and the like) or the fonts available in the given encoding).

To do this, you just have to call one of EnumerateXXX() functions - either wxFontEnumerator::EnumerateFacenames() or wxFontEnumerator::EnumerateEncodings() and the corresponding callback (wxFontEnumerator::OnFacename() or wxFontEnumerator::OnFontEncoding()) will be called repeatedly until either all fonts satisfying the specified criteria are exhausted or the callback returns false.

21.263.2 Virtual functions to override

Either OnFacename or OnFontEncoding should be overridden depending on whether you plan to call EnumerateFacenames or EnumerateEncodings. Of course, if you call both of them, you should override both functions.

Library: wxCore

Category: Graphics Device Interface (GDI)

See also

Font Encodings, Font Sample, wxFont, wxFontMapper

Public Member Functions

- wxFontEnumerator ()
- virtual ~wxFontEnumerator ()
- virtual bool EnumerateEncodings (const wxString &font=wxEmptyString)

  Call OnFontEncoding() for each encoding supported by the given font - or for each encoding supported by at least some font if font is not specified.
- virtual bool EnumerateFacenames (wxFontEncoding encoding=wxFONTENCODING_SYSTEM, bool fixedWidthOnly=false)

  Call OnFacename() for each font which supports given encoding (only if it is not `wxFONTENCODING_SYSTEM`) and is of fixed width (if fixedWidthOnly is true).
- virtual bool OnFacename (const wxString &font)

  Called by EnumerateFacenames() for each match.
- virtual bool OnFontEncoding (const wxString &font, const wxString &encoding)

  Called by EnumerateEncodings() for each match.

Static Public Member Functions

- static wxArrayString GetEncodings (const wxString &facename=wxEmptyString)

  Return array of strings containing all encodings found by EnumerateEncodings().
- static wxArrayString GetFacenames (wxFontEncoding encoding=wxFONTENCODING_SYSTEM, bool fixedWidthOnly=false)

  Return array of strings containing all facenames found by EnumerateFacenames().
- static bool IsValidFacename (const wxString &facename)

  Returns true if the given string is valid face name, i.e.

21.263.3 Constructor & Destructor Documentation

wxFontEnumerator::wxFontEnumerator ( )

virtual wxFontEnumerator::~wxFontEnumerator ( ) `[virtual]`

21.263.4 Member Function Documentation

virtual bool wxFontEnumerator::EnumerateEncodings (const wxString & *font* = wxEmptyString) `[virtual]`

Call OnFontEncoding() for each encoding supported by the given font - or for each encoding supported by at least some font if *font* is not specified.

virtual bool wxFontEnumerator::EnumerateFacenames (wxFontEncoding *encoding* = wxFONTENCODING_SYSTEM, bool *fixedWidthOnly* = `false`) `[virtual]`

Call OnFacename() for each font which supports given encoding (only if it is not `wxFONTENCODING_SYSTEM`) and is of fixed width (if *fixedWidthOnly* is true).

Calling this function with default arguments will result in enumerating all fonts available on the system.

static wxArrayString wxFontEnumerator::GetEncodings (const wxString & *facename* = wxEmptyString) `[static]`

Return array of strings containing all encodings found by EnumerateEncodings().

static wxArrayString wxFontEnumerator::GetFacenames (wxFontEncoding *encoding* = wxFONTENCODING_SYSTEM, bool *fixedWidthOnly* = `false`) [static]

Return array of strings containing all facenames found by EnumerateFacenames().

static bool wxFontEnumerator::IsValidFacename (const wxString & *facename*) [static]

Returns true if the given string is valid face name, i.e.

it's the face name of an installed font and it can safely be used with wxFont::SetFaceName.

virtual bool wxFontEnumerator::OnFacename (const wxString & *font*) [virtual]

Called by EnumerateFacenames() for each match.

Return true to continue enumeration or false to stop it.

virtual bool wxFontEnumerator::OnFontEncoding (const wxString & *font*, const wxString & *encoding*) [virtual]

Called by EnumerateEncodings() for each match.

Return true to continue enumeration or false to stop it.

21.264 wxFontInfo Class Reference

`#include <wx/font.h>`

21.264.1 Detailed Description

This class is a helper used for wxFont creation using named parameter idiom: it allows to specify various wxFont attributes using the chained calls to its clearly named methods instead of passing them in the fixed order to wxFont constructors.

For example, to create an italic font with the given face name and size you could use:

```
wxFont font(wxFontInfo(12).FaceName("Helvetica").Italic());
```

Notice that all of the methods of this object return a reference to the object itself, allowing the calls to them to be chained as in the example above.

All methods taking boolean parameters can be used to turn the specified font attribute on or off and turn it on by default.

Since

2.9.5

Public Member Functions

- wxFontInfo ()

  Default constructor uses the default font size for the current platform.
- wxFontInfo (int pointSize)

  Constructor setting the font size in points to use.
- wxFontInfo (const wxSize &pixelSize)

  Constructor setting the font size in pixels to use.

- wxFontInfo & Family (wxFontFamily family)

  Set the font family.
- wxFontInfo & FaceName (const wxString &faceName)

  Set the font face name to use.
- wxFontInfo & Bold (bool bold=true)

  Use a bold version of the font.
- wxFontInfo & Light (bool light=true)

  Use a lighter version of the font.
- wxFontInfo & Italic (bool italic=true)

  Use an italic version of the font.
- wxFontInfo & Slant (bool slant=true)

  Use a slanted version of the font.
- wxFontInfo & AntiAliased (bool antiAliased=true)

  Set anti-aliasing flag.
- wxFontInfo & Underlined (bool underlined=true)

  Use an underlined version of the font.
- wxFontInfo & Strikethrough (bool strikethrough=true)

  Use a strike-through version of the font.
- wxFontInfo & Encoding (wxFontEncoding encoding)

  Set the font encoding to use.
- wxFontInfo & AllFlags (int flags)

  Set all the font attributes at once.

21.264.2 Constructor & Destructor Documentation

wxFontInfo::wxFontInfo ( )

Default constructor uses the default font size for the current platform.

wxFontInfo::wxFontInfo (int *pointSize*) `[explicit]`

Constructor setting the font size in points to use.

See also

wxFont::SetPointSize()

wxFontInfo::wxFontInfo (const wxSize & *pixelSize*) `[explicit]`

Constructor setting the font size in pixels to use.

See also

wxFont::SetPixelSize()

21.264.3 Member Function Documentation

wxFontInfo& wxFontInfo::AllFlags (int *flags*)

Set all the font attributes at once.

See wxFontFlag for the various flags that can be used.

wxFontInfo& wxFontInfo::AntiAliased (bool *antiAliased* = `true`)

Set anti-aliasing flag.

Force the use of anti-aliasing on or off.

Currently this is not implemented, i.e. using this method doesn't do anything.

wxFontInfo& wxFontInfo::Bold (bool *bold* = `true`)

Use a bold version of the font.

See also

wxFontWeight, wxFont::SetWeight()

wxFontInfo& wxFontInfo::Encoding (wxFontEncoding *encoding*)

Set the font encoding to use.

This is mostly unneeded in Unicode builds of wxWidgets.

See also

wxFontEncoding, wxFont::SetEncoding()

wxFontInfo& wxFontInfo::FaceName (const wxString & *faceName*)

Set the font face name to use.

Face names are not portable, so prefer to use Family() in portable code.

See also

wxFont::SetFaceName()

wxFontInfo& wxFontInfo::Family (wxFontFamily *family*)

Set the font family.

The family is a generic portable way of referring to fonts without specifying a precise face name. This parameter must be one of the wxFontFamily enumeration values.

If the FaceName() is used, then it overrides the font family.

See also

wxFont::SetFamily()

wxFontInfo& wxFontInfo::Italic (bool *italic* = `true`)

Use an italic version of the font.

See also

wxFontStyle, wxFont::SetStyle()

wxFontInfo& wxFontInfo::Light (bool *light* = `true`)

Use a lighter version of the font.

See also

wxFontWeight, wxFont::SetWeight()

wxFontInfo& wxFontInfo::Slant (bool *slant* = `true`)

Use a slanted version of the font.

See also

wxFontStyle, wxFont::SetStyle()

wxFontInfo& wxFontInfo::Strikethrough (bool *strikethrough* = `true`)

Use a strike-through version of the font.

Currently this is only implemented in wxMSW, wxGTK and OSX.

wxFontInfo& wxFontInfo::Underlined (bool *underlined* = `true`)

Use an underlined version of the font.

21.265 wxFontList Class Reference

`#include <wx/font.h>`

21.265.1 Detailed Description

A font list is a list containing all fonts which have been created.

There is only one instance of this class: wxTheFontList.

Use this object to search for a previously created font of the desired type and create it if not already found.

In some windowing systems, the font may be a scarce resource, so it is best to reuse old resources if possible. When an application finishes, all fonts will be deleted and their resources freed, eliminating the possibility of 'memory leaks'.

Library: wxCore

Category: Graphics Device Interface (GDI)

See also

wxFont

Public Member Functions

- wxFontList ()

  Constructor.
- wxFont * FindOrCreateFont (int point_size, wxFontFamily family, wxFontStyle style, wxFontWeight weight, bool underline=false, const wxString &facename=wxEmptyString, wxFontEncoding encoding=wxFONTENCODING_DEFAULT)

  Finds a font of the given specification, or creates one and adds it to the list.

21.265.2 Constructor & Destructor Documentation

wxFontList::wxFontList ( )

Constructor.

The application should not construct its own font list: use the object pointer wxTheFontList.

21.265.3 Member Function Documentation

wxFont* wxFontList::FindOrCreateFont (int *point_size,* wxFontFamily *family,* wxFontStyle *style,* wxFontWeight *weight,* bool *underline* = `false`, const wxString & *facename* = wxEmptyString, wxFontEncoding *encoding* = wxFONTENCODING_DEFAULT)

Finds a font of the given specification, or creates one and adds it to the list.

See the wxFont constructor for details of the arguments.

21.266 wxFontMapper Class Reference

```
#include <wx/fontmap.h>
```

21.266.1 Detailed Description

wxFontMapper manages user-definable correspondence between logical font names and the fonts present on the machine.

The default implementations of all functions will ask the user if they are not capable of finding the answer themselves and store the answer in a config file (configurable via SetConfigXXX functions). This behaviour may be disabled by giving the value of false to "interactive" parameter.

However, the functions will always consult the config file to allow the user-defined values override the default logic and there is no way to disable this - which shouldn't be ever needed because if "interactive" was never true, the config file is never created anyhow.

In case everything else fails (i.e. there is no record in config file and "interactive" is false or user denied to choose any replacement), the class queries wxEncodingConverter for "equivalent" encodings (e.g. iso8859-2 and cp1250) and tries them.

21.266.2 Using wxFontMapper in conjunction with wxMBConv classes

If you need to display text in encoding which is not available at host system (see wxFontMapper::IsEncodingAvailable), you may use these two classes to find font in some similar encoding (see wxFontMapper::GetAltForEncoding) and convert the text to this encoding (wxMBConv classes). Following code snippet demonstrates it:

```
if (!wxFontMapper::Get()->IsEncodingAvailable(enc, facename))
{
    wxFontEncoding alternative;
    if (wxFontMapper::Get()->GetAltForEncoding(enc, &alternative,
                                               facename, false))
    {
        wxCSConv convFrom(wxFontMapper::Get()->
      GetEncodingName(enc));
        wxCSConv convTo(wxFontMapper::Get()->
      GetEncodingName(alternative));
        text = wxString(text.mb_str(convFrom), convTo);
    }
    else
        ...failure (or we may try iso8859-1/7bit ASCII)...
}
...display text...
```

Library: wxCore

Public Member Functions

- wxFontMapper ()

  Default ctor.
- virtual ~wxFontMapper ()

  Virtual dtor.
- virtual wxFontEncoding CharsetToEncoding (const wxString &charset, bool interactive=true)

  Returns the encoding for the given charset (in the form of RFC 2046) or `wxFONTENCODING_SYSTEM` *if couldn't decode it.*
- virtual bool IsEncodingAvailable (wxFontEncoding encoding, const wxString &facename=wxEmptyString)

  Check whether given encoding is available in given face or not.
- void SetConfigPath (const wxString &prefix)

  Set the root config path to use (should be an absolute path).
- void SetDialogParent (wxWindow *parent)

  The parent window for modal dialogs.
- void SetDialogTitle (const wxString &title)

  The title for the dialogs (note that default is quite reasonable).

- bool GetAltForEncoding (wxFontEncoding encoding, wxNativeEncodingInfo *info, const wxString &facename=wxEmptyString, bool interactive=true)

  Find an alternative for the given encoding (which is supposed to not be available on this system).
- bool GetAltForEncoding (wxFontEncoding encoding, wxFontEncoding *alt_encoding, const wxString &facename=wxEmptyString, bool interactive=true)

  Find an alternative for the given encoding (which is supposed to not be available on this system).

Static Public Member Functions

- static wxFontMapper * Get ()

  Get the current font mapper object.
- static const wxChar ** GetAllEncodingNames (wxFontEncoding encoding)

  Returns the array of all possible names for the given encoding.

- static wxFontEncoding GetEncoding (size_t n)

  Returns the n-th supported encoding.
- static wxString GetEncodingDescription (wxFontEncoding encoding)

  Return user-readable string describing the given encoding.
- static wxFontEncoding GetEncodingFromName (const wxString &encoding)

  Return the encoding corresponding to the given internal name.
- static wxString GetEncodingName (wxFontEncoding encoding)

  Return internal string identifier for the encoding (see also wxFontMapper::GetEncodingDescription).
- static size_t GetSupportedEncodingsCount ()

  Returns the number of the font encodings supported by this class.
- static wxFontMapper * Set (wxFontMapper *mapper)

  Set the current font mapper object and return previous one (may be NULL).

21.266.3 Constructor & Destructor Documentation

wxFontMapper::wxFontMapper ( )

Default ctor.

Note

The preferred way of creating a wxFontMapper instance is to call wxFontMapper::Get().

virtual wxFontMapper::~wxFontMapper ( ) [virtual]

Virtual dtor.

21.266.4 Member Function Documentation

virtual wxFontEncoding wxFontMapper::CharsetToEncoding (const wxString & *charset*, bool *interactive* = true) [virtual]

Returns the encoding for the given charset (in the form of RFC 2046) or wxFONTENCODING_SYSTEM if couldn't decode it.

Be careful when using this function with *interactive* set to true (default value) as the function then may show a dialog box to the user which may lead to unexpected reentrancies and may also take a significantly longer time than a simple function call. For these reasons, it is almost always a bad idea to call this function from the event handlers for repeatedly generated events such as EVT_PAINT.

static wxFontMapper* wxFontMapper::Get ( ) [static]

Get the current font mapper object.

If there is no current object, creates one.

See also

Set()

static const wxChar wxFontMapper::GetAllEncodingNames (wxFontEncoding *encoding*) [static]**

Returns the array of all possible names for the given encoding.

The array is NULL-terminated. IF it isn't empty, the first name in it is the canonical encoding name, i.e. the same string as returned by GetEncodingName().

bool wxFontMapper::GetAltForEncoding (wxFontEncoding *encoding*, wxNativeEncodingInfo * *info*, const wxString & *facename* = wxEmptyString, bool *interactive* = true)

Find an alternative for the given encoding (which is supposed to not be available on this system).

If successful, return true and fill info structure with the parameters required to create the font, otherwise return false.

The first form is for wxWidgets' internal use while the second one is better suitable for general use – it returns wxFontEncoding which can consequently be passed to wxFont constructor.

bool wxFontMapper::GetAltForEncoding (wxFontEncoding *encoding*, wxFontEncoding * *alt_encoding*, const wxString & *facename* = wxEmptyString, bool *interactive* = true)

Find an alternative for the given encoding (which is supposed to not be available on this system).

If successful, return true and fill info structure with the parameters required to create the font, otherwise return false.

The first form is for wxWidgets' internal use while the second one is better suitable for general use – it returns wxFontEncoding which can consequently be passed to wxFont constructor.

static wxFontEncoding wxFontMapper::GetEncoding (size_t *n*) [static]

Returns the *n-th* supported encoding.

Together with GetSupportedEncodingsCount() this method may be used to get all supported encodings.

static wxString wxFontMapper::GetEncodingDescription (wxFontEncoding *encoding*) [static]

Return user-readable string describing the given encoding.

static wxFontEncoding wxFontMapper::GetEncodingFromName (const wxString & *encoding*) [static]

Return the encoding corresponding to the given internal name.

This function is the inverse of GetEncodingName() and is intentionally less general than CharsetToEncoding(), i.e. it doesn't try to make any guesses nor ever asks the user. It is meant just as a way of restoring objects previously serialized using GetEncodingName().

static wxString wxFontMapper::GetEncodingName (wxFontEncoding *encoding*) [static]

Return internal string identifier for the encoding (see also wxFontMapper::GetEncodingDescription).

See also

GetEncodingFromName()

static size_t wxFontMapper::GetSupportedEncodingsCount ( ) [static]

Returns the number of the font encodings supported by this class.

Together with GetEncoding() this method may be used to get all supported encodings.

virtual bool wxFontMapper::IsEncodingAvailable (wxFontEncoding *encoding*, const wxString & *facename* = wxEmptyString) [virtual]

Check whether given encoding is available in given face or not.

If no facename is given, find *any* font in this encoding.

static wxFontMapper* wxFontMapper::Set (wxFontMapper * *mapper*) [static]

Set the current font mapper object and return previous one (may be NULL).

This method is only useful if you want to plug-in an alternative font mapper into wxWidgets.

See also

Get()

void wxFontMapper::SetConfigPath (const wxString & *prefix*)

Set the root config path to use (should be an absolute path).

void wxFontMapper::SetDialogParent (wxWindow * *parent*)

The parent window for modal dialogs.

void wxFontMapper::SetDialogTitle (const wxString & *title*)

The title for the dialogs (note that default is quite reasonable).

21.267 wxFontMetrics Struct Reference

`#include <wx/dc.h>`

21.267.1 Detailed Description

Simple collection of various font metrics.

This object is returned by wxDC::GetFontMetrics().

Since

2.9.2

Library: wxCore

Category: Device Contexts, Graphics Device Interface (GDI)

Public Member Functions

- wxFontMetrics ()

  Constructor initializes all fields to 0.

Public Attributes

- int height

  Total character height.
- int ascent

  Part of the height above the baseline.
- int descent

  Part of the height below the baseline.
- int internalLeading

  Intra-line spacing.
- int externalLeading

  Inter-line spacing.
- int averageWidth

  Average font width, a.k.a. "x-width".

21.267.2 Constructor & Destructor Documentation

wxFontMetrics::wxFontMetrics ( )

Constructor initializes all fields to 0.

21.267.3 Member Data Documentation

int wxFontMetrics::ascent

Part of the height above the baseline.

int wxFontMetrics::averageWidth

Average font width, a.k.a. "x-width".

int wxFontMetrics::descent

Part of the height below the baseline.

int wxFontMetrics::externalLeading

Inter-line spacing.

int wxFontMetrics::height

Total character height.

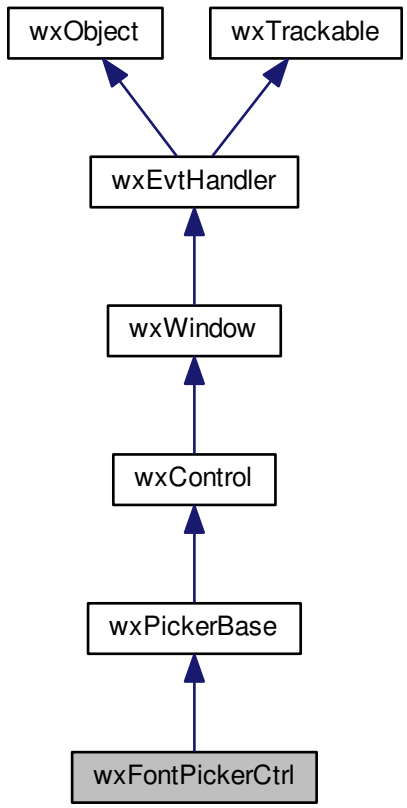
int wxFontMetrics::internalLeading

Intra-line spacing.

21.268 wxFontPickerCtrl Class Reference

`#include <wx/fontpicker.h>`

Inheritance diagram for wxFontPickerCtrl:



21.268.1 Detailed Description

This control allows the user to select a font.

The generic implementation is a button which brings up a wxFontDialog when clicked. Native implementation may differ but this is usually a (small) widget which give access to the font-chooser dialog. It is only available if `wxUSE_FONTPICKERCTRL` is set to 1 (the default).

Styles

This class supports the following styles:

- wxFNTP_DEFAULT_STYLE: The default style: wxFNTP_FONTDESC_AS_LABEL | wxFNTP_USEFONT_FOR_LABEL.
- wxFNTP_USE_TEXTCTRL: Creates a text control to the left of the picker button which is completely managed by the wxFontPickerCtrl and which can be used by the user to specify a font (see SetSelectedFont). The text

control is automatically synchronized with button's value. Use functions defined in wxPickerBase to modify the text control.

- wxFNTP_FONTDESC_AS_LABEL: Keeps the label of the button updated with the fontface name and the font size. E.g. choosing "Times New Roman bold, italic with size 10" from the fontdialog, will update the label (overwriting any previous label) with the "Times New Roman, 10" text.
- wxFNTP_USEFONT_FOR_LABEL: Uses the currently selected font to draw the label of the button.

Events emitted by this class

The following event handler macros redirect the events to member function handlers '**func**' with prototypes like: void handlerFuncName(wxFontPickerEvent& event)

Event macros for events emitted by this class:

- EVT_FONTPICKER_CHANGED(id, func): The user changed the font selected in the control either using the button or using text control (see wxFNTP_USE_TEXTCTRL; note that in this case the event is fired only if the user's input is valid, i.e. recognizable).

Library: wxCore

Category: Picker Controls

- wxFontPickerCtrl (wxWindow *parent, wxWindowID id, const wxFont &font=wxNullFont, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, long style=wxFNTP_DEFAULT_STYLE, const wxValidator &validator=wxDefaultValidator, const wxString &name=wxFontPickerCtrlNameStr)

  Initializes the object and calls Create() with all the parameters.
- bool Create (wxWindow *parent, wxWindowID id, const wxFont &font=wxNullFont, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, long style=wxFNTP_DEFAULT_STYLE, const wxValidator &validator=wxDefaultValidator, const wxString &name=wxFontPickerCtrlNameStr)

  Creates this widget with given parameters.
- unsigned int GetMaxPointSize () const

  Returns the maximum point size value allowed for the user-chosen font.
- wxColour GetSelectedColour () const

  Returns the currently selected colour.
- wxFont GetSelectedFont () const

  Returns the currently selected font.
- void SetMaxPointSize (unsigned int max)

  Sets the maximum point size value allowed for the user-chosen font.
- void SetSelectedColour (const wxColour &colour)

  Sets the font colour.
- void SetSelectedFont (const wxFont &font)

  Sets the currently selected font.

Additional Inherited Members

21.268.2 Constructor & Destructor Documentation

wxFontPickerCtrl::wxFontPickerCtrl ( )

wxFontPickerCtrl::wxFontPickerCtrl (wxWindow * *parent*, wxWindowID *id*, const wxFont & *font* = wxNullFont, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, long *style* = wxFNTP_DEFAULT_STYLE, const wxValidator & *validator* = wxDefaultValidator, const wxString & *name* = `wxFontPickerCtrlNameStr`)

Initializes the object and calls Create() with all the parameters.

21.268.3 Member Function Documentation

bool wxFontPickerCtrl::Create (wxWindow * *parent*, wxWindowID *id*, const wxFont & *font* = wxNullFont, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, long *style* = wxFNTP_DEFAULT_STYLE, const wxValidator & *validator* = wxDefaultValidator, const wxString & *name* = `wxFontPickerCtrlNameStr`)

Creates this widget with given parameters.

Parameters

parent	Parent window, must not be non-NULL.
id	The identifier for the control.
font	The initial font shown in the control. If wxNullFont is given, the default font is used.
pos	Initial position.
size	Initial size.
style	The window style, see wxFNTP_* flags.
validator	Validator which can be used for additional date checks.
name	Control name.

Returns

true if the control was successfully created or false if creation failed.

unsigned int wxFontPickerCtrl::GetMaxPointSize ( ) const

Returns the maximum point size value allowed for the user-chosen font.

wxColour wxFontPickerCtrl::GetSelectedColour ( ) const

Returns the currently selected colour.

Note that the colour of the font can only be set by the user under Windows currently, elsewhere this method simply returns the colour previously set by SetSelectedColour() or black if it hadn't been called.

Since

3.1.0

wxFont wxFontPickerCtrl::GetSelectedFont ( ) const

Returns the currently selected font.

Note that this function is completely different from wxWindow::GetFont.

void wxFontPickerCtrl::SetMaxPointSize (unsigned int *max*)

Sets the maximum point size value allowed for the user-chosen font.

The default value is 100. Note that big fonts can require a lot of memory and CPU time both for creation and for rendering; thus, specially because the user has the option to specify the fontsize through a text control (see wxF↩NTP_USE_TEXTCTRL), it's a good idea to put a limit to the maximum font size when huge fonts do not make much sense.

void wxFontPickerCtrl::SetSelectedColour (const wxColour & *colour*)

Sets the font colour.

The font colour is actually only used under Windows currently, but this function is available under all platforms for consistency.

Since

3.1.0

void wxFontPickerCtrl::SetSelectedFont (const wxFont & *font*)

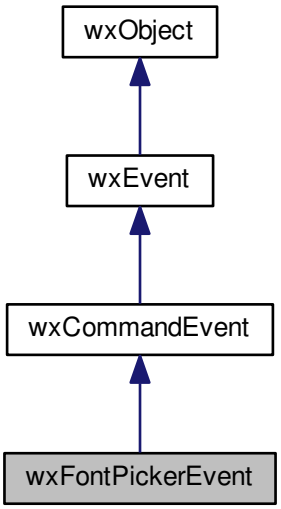
Sets the currently selected font.

Note that this function is completely different from wxWindow::SetFont.

21.269 wxFontPickerEvent Class Reference

`#include <wx/fontpicker.h>`

Inheritance diagram for wxFontPickerEvent:



21.269.1 Detailed Description

This event class is used for the events generated by wxFontPickerCtrl.

Events using this class

The following event handler macros redirect the events to member function handlers '**func**' with prototypes like: void handlerFuncName(wxFontPickerEvent& event)

Event macros:

- EVT_FONTPICKER_CHANGED(id, func): Generated whenever the selected font changes.

Library: wxCore

Category: Events

21.269.3 Member Function Documentation

wxFont wxFontPickerEvent::GetFont ( ) const

Retrieve the font the user has just selected.

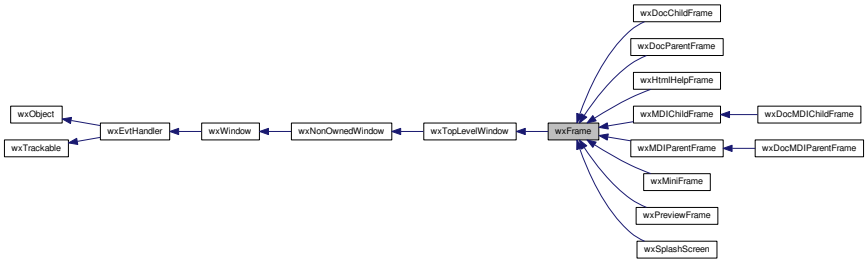
void wxFontPickerEvent::SetFont (const wxFont & *f*)

Set the font associated with the event.

21.270 wxFrame Class Reference

`#include <wx/frame.h>`

Inheritance diagram for wxFrame:



21.270.1 Detailed Description

A frame is a window whose size and position can (usually) be changed by the user.

It usually has thick borders and a title bar, and can optionally contain a menu bar, toolbar and status bar. A frame can contain any window that is not a frame or dialog.

A frame that has a status bar and toolbar, created via the CreateStatusBar() and CreateToolBar() functions, manages these windows and adjusts the value returned by GetClientSize() to reflect the remaining size available to application windows.

Remarks

An application should normally define an wxCloseEvent handler for the frame to respond to system close events, for example so that related data and subwindows can be cleaned up.

21.270.2 Default event processing

wxFrame processes the following events:

- `wxEVT_SIZE`: if the frame has exactly one child window, not counting the status and toolbar, this child is resized to take the entire frame client area. If two or more windows are present, they should be laid out explicitly either by manually handling `wxEVT_SIZE` or using sizers;
- `wxEVT_MENU_HIGHLIGHT`: the default implementation displays the help string associated with the selected item in the first pane of the status bar, if there is one.

Styles

This class supports the following styles:

- wxDEFAULT_FRAME_STYLE: Defined as wxMINIMIZE_BOX | wxMAXIMIZE_BOX | wxRESIZE_BORDER | wxSYSTEM_MENU | wxCAPTION | wxCLOSE_BOX | wxCLIP_CHILDREN.
- wxICONIZE: Display the frame iconized (minimized). Windows only.
- wxCAPTION: Puts a caption on the frame. Notice that this flag is required by wxMINIMIZE_BOX, wxMA↩ XIMIZE_BOX and wxCLOSE_BOX on most systems as the corresponding buttons cannot be shown if the window has no title bar at all. I.e. if wxCAPTION is not specified those styles would be simply ignored.

- wxMINIMIZE: Identical to wxICONIZE. Windows only.
- wxMINIMIZE_BOX: Displays a minimize box on the frame.
- wxMAXIMIZE: Displays the frame maximized. Windows and GTK+ only.
- wxMAXIMIZE_BOX: Displays a maximize box on the frame. Notice that under wxGTK wxRESIZE_BORDER must be used as well or this style is ignored.
- wxCLOSE_BOX: Displays a close box on the frame.
- wxSTAY_ON_TOP: Stay on top of all other windows, see also wxFRAME_FLOAT_ON_PARENT.
- wxSYSTEM_MENU: Displays a system menu containing the list of various windows commands in the window title bar. Unlike wxMINIMIZE_BOX, wxMAXIMIZE_BOX and wxCLOSE_BOX styles this style can be used without wxCAPTION, at least under Windows, and makes the system menu available without showing it on screen in this case. However it is recommended to only use it together with wxCAPTION for consistent behaviour under all platforms.
- wxRESIZE_BORDER: Displays a resizable border around the window.
- wxFRAME_TOOL_WINDOW: Causes a frame with a small title bar to be created; the frame does not appear in the taskbar under Windows or GTK+.
- wxFRAME_NO_TASKBAR: Creates an otherwise normal frame but it does not appear in the taskbar under Windows or GTK+ (note that it will minimize to the desktop window under Windows which may seem strange to the users and thus it might be better to use this style only without wxMINIMIZE_BOX style). In wxGTK, the flag is respected only if the window manager supports _NET_WM_STATE_SKIP_TASKBAR hint.
- wxFRAME_FLOAT_ON_PARENT: The frame will always be on top of its parent (unlike wxSTAY_ON_TOP). A frame created with this style must have a non-NULL parent.
- wxFRAME_SHAPED: Windows with this style are allowed to have their shape changed with the SetShape() method.

The default frame style is for normal, resizable frames. To create a frame which cannot be resized by user, you may use the following combination of styles:

```
wxDEFAULT_FRAME_STYLE & ~(wxRESIZE_BORDER |
      wxMAXIMIZE_BOX)
```

See also the Window Styles.

Extra Styles

This class supports the following extra styles:

- wxFRAME_EX_CONTEXTHELP: Under Windows, puts a query button on the caption. When pressed, Windows will go into a context-sensitive help mode and wxWidgets will send a `wxEVT_HELP` event if the user clicked on an application window. Note that this is an extended style and must be set by calling SetExtraStyle before Create is called (two-step construction). You cannot use this style together with wxMAXIMIZE_BOX or wxMINIMIZE_BOX, so you should use wxDEFAULT_FRAME_STYLE ~ (wxMINIMIZE_BOX | wxMAXI↩ MIZE_BOX) for the frames having this style (the dialogs don't have a minimize or a maximize box by default)
- wxFRAME_EX_METAL: On Mac OS X, frames with this style will be shown with a metallic look. This is an extra style.

Events emitted by this class

Event macros for events emitted by this class:

- EVT_CLOSE(func): Process a `wxEVT_CLOSE_WINDOW` event when the frame is being closed by the user or programmatically (see wxWindow::Close). The user may generate this event clicking the close button (typically the 'X' on the top-right of the title bar) if it's present (see the `wxCLOSE_BOX` style). See wxCloseEvent.
- EVT_ICONIZE(func): Process a `wxEVT_ICONIZE` event. See wxIconizeEvent.
- EVT_MENU_OPEN(func): A menu is about to be opened. See wxMenuEvent.
- EVT_MENU_CLOSE(func): A menu has been just closed. See wxMenuEvent.
- EVT_MENU_HIGHLIGHT(id, func): The menu item with the specified id has been highlighted: used to show help prompts in the status bar by wxFrame. See wxMenuEvent.
- EVT_MENU_HIGHLIGHT_ALL(func): A menu item has been highlighted, i.e. the currently selected menu item has changed. See wxMenuEvent.

Public Member Functions

- wxFrame ()

  Default constructor.
- wxFrame (wxWindow *parent, wxWindowID id, const wxString &title, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, long style=wxDEFAULT_FRAME_STYLE, const wxString &name=wxFrameNameStr)

  Constructor, creating the window.
- virtual ~wxFrame ()

  Destructor.
- void Centre (int direction=wxBOTH)

  Centres the frame on the display.
- bool Create (wxWindow *parent, wxWindowID id, const wxString &title, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, long style=wxDEFAULT_FRAME_STYLE, const wxString &name=wxFrameNameStr)

  Used in two-step frame construction.
- virtual wxStatusBar * CreateStatusBar (int number=1, long style=wxSTB_DEFAULT_STYLE, wxWindowID id=0, const wxString &name=wxStatusBarNameStr)

  Creates a status bar at the bottom of the frame.
- virtual wxToolBar * CreateToolBar (long style=wxTB_DEFAULT_STYLE, wxWindowID id=wxID_ANY, const wxString &name=wxToolBarNameStr)

  Creates a toolbar at the top or left of the frame.
- virtual void DoGiveHelp (const wxString &text, bool show)

  Method used to show help string of the selected menu toolbar item.
- virtual wxPoint GetClientAreaOrigin () const

Returns the origin of the frame client area (in client coordinates).

- virtual wxMenuBar * GetMenuBar () const

  Returns a pointer to the menubar currently associated with the frame (if any).
- virtual wxStatusBar * GetStatusBar () const

  Returns a pointer to the status bar currently associated with the frame (if any).
- int GetStatusBarPane () const

  Returns the status bar pane used to display menu and toolbar help.
- virtual wxToolBar * GetToolBar () const

  Returns a pointer to the toolbar currently associated with the frame (if any).
- virtual wxStatusBar * OnCreateStatusBar (int number, long style, wxWindowID id, const wxString &name)

  Virtual function called when a status bar is requested by CreateStatusBar().
- virtual wxToolBar * OnCreateToolBar (long style, wxWindowID id, const wxString &name)

  Virtual function called when a toolbar is requested by CreateToolBar().
- bool ProcessCommand (int id)

  Simulate a menu command.
- virtual void SetMenuBar (wxMenuBar *menuBar)

  Tells the frame to show the given menu bar.
- virtual void SetStatusBar (wxStatusBar *statusBar)

  Associates a status bar with the frame.
- void SetStatusBarPane (int n)

  Set the status bar pane used to display menu and toolbar help.
- virtual void SetStatusText (const wxString &text, int number=0)

  Sets the status bar text and redraws the status bar.
- virtual void SetStatusWidths (int n, const int *widths_field)

  Sets the widths of the fields in the status bar.
- virtual void SetToolBar (wxToolBar *toolBar)

  Associates a toolbar with the frame.
- wxTaskBarButton * MSWGetTaskBarButton ()

  MSW-specific function for accessing the taskbar button under Windows 7 or later.
- void PushStatusText (const wxString &text, int number=0)
- void PopStatusText (int number=0)

Additional Inherited Members

21.270.3 Constructor & Destructor Documentation

wxFrame::wxFrame ( )

Default constructor.

wxFrame::wxFrame (wxWindow * *parent*, wxWindowID *id*, const wxString & *title*, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, long *style* = wxDEFAULT_FRAME_STYLE, const wxString & *name* = `wxFrameNameStr`)

Constructor, creating the window.

Parameters

parent	The window parent. This may be NULL. If it is non-NULL, the frame will always be displayed on top of the parent window on Windows.
id	The window identifier. It may take a value of -1 to indicate a default value.
title	The caption to be displayed on the frame's title bar.
pos	The window position. The value wxDefaultPosition indicates a default position, chosen by either the windowing system or wxWidgets, depending on platform.
size	The window size. The value wxDefaultSize indicates a default size, chosen by either the windowing system or wxWidgets, depending on platform.
style	The window style. See wxFrame class description.
name	The name of the window. This parameter is used to associate a name with the item, allowing the application user to set Motif resource values for individual windows.

Remarks

For Motif, MWM (the Motif Window Manager) should be running for any window styles to work (otherwise all styles take effect).

See also

Create()

virtual wxFrame::~wxFrame ( ) [virtual]

Destructor.

Destroys all child windows and menu bar if present.

See Window Deletion for more info.

21.270.4 Member Function Documentation

void wxFrame::Centre (int *direction* = wxBOTH)

Centres the frame on the display.

Parameters

direction	The parameter may be wxHORIZONTAL, wxVERTICAL or wxBOTH.

bool wxFrame::Create (wxWindow * *parent*, wxWindowID *id*, const wxString & *title*, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, long *style* = wxDEFAULT_FRAME_STYLE, const wxString & *name* = wxFrameNameStr)

Used in two-step frame construction.

See wxFrame() for further details.

virtual wxStatusBar* wxFrame::CreateStatusBar (int *number* = 1, long *style* = wxSTB_DEFAULT_STYLE, wxWindowID *id* = 0, const wxString & *name* = wxStatusBarNameStr) [virtual]

Creates a status bar at the bottom of the frame.

Parameters

number	The number of fields to create. Specify a value greater than 1 to create a multi-field status bar.
style	The status bar style. See wxStatusBar for a list of valid styles.
id	The status bar window identifier. If -1, an identifier will be chosen by wxWidgets.
name	The status bar window name.

Returns

A pointer to the status bar if it was created successfully, NULL otherwise.

Remarks

The width of the status bar is the whole width of the frame (adjusted automatically when resizing), and the height and text size are chosen by the host windowing system.

See also

SetStatusText(), OnCreateStatusBar(), GetStatusBar()

virtual wxToolBar* wxFrame::CreateToolBar (long *style* = wxTB_DEFAULT_STYLE, wxWindowID *id* = wxID_ANY, const wxString & *name* = wxToolBarNameStr) [virtual]

Creates a toolbar at the top or left of the frame.

Parameters

style	The toolbar style. See wxToolBar for a list of valid styles.
id	The toolbar window identifier. If -1, an identifier will be chosen by wxWidgets.
name	The toolbar window name.

Returns

A pointer to the toolbar if it was created successfully, NULL otherwise.

Remarks

By default, the toolbar is an instance of wxToolBar. To use a different class, override OnCreateToolBar(). When a toolbar has been created with this function, or made known to the frame with wxFrame::SetToolBar(), the frame will manage the toolbar position and adjust the return value from wxWindow::GetClientSize() to reflect the available space for application windows. Under Pocket PC, you should always use this function for creating the toolbar to be managed by the frame, so that wxWidgets can use a combined menubar and toolbar. Where you manage your own toolbars, create a wxToolBar as usual.

See also

CreateStatusBar(), OnCreateToolBar(), SetToolBar(), GetToolBar()

virtual void wxFrame::DoGiveHelp (const wxString & *text*, bool *show*) [virtual]

Method used to show help string of the selected menu toolbar item.

This method is called by the default wxEVT_MENU_HIGHLIGHT event handler and also by wxToolBar to show the optional help string associated with the selected menu or toolbar item. It can be overridden if the default behaviour of showing this string in the frame status bar is not appropriate.

Parameters

text	The help string to show, may be empty. The default implementation simply shows this string in the frame status bar (after remembering its previous text to restore it later).
show	Whether the help should be shown or hidden. The default implementation restores the previously saved status bar text when it is false.

See also

SetStatusBarPane()

virtual wxPoint wxFrame::GetClientAreaOrigin ( ) const `[virtual]`

Returns the origin of the frame client area (in client coordinates).

It may be different from (0, 0) if the frame has a toolbar.

Reimplemented from wxWindow.

virtual wxMenuBar* wxFrame::GetMenuBar ( ) const `[virtual]`

Returns a pointer to the menubar currently associated with the frame (if any).

See also

SetMenuBar(), wxMenuBar, wxMenu

virtual wxStatusBar* wxFrame::GetStatusBar ( ) const `[virtual]`

Returns a pointer to the status bar currently associated with the frame (if any).

See also

CreateStatusBar(), wxStatusBar

int wxFrame::GetStatusBarPane ( ) const

Returns the status bar pane used to display menu and toolbar help.

See also

SetStatusBarPane()

virtual wxToolBar* wxFrame::GetToolBar ( ) const `[virtual]`

Returns a pointer to the toolbar currently associated with the frame (if any).

See also

CreateToolBar(), wxToolBar, SetToolBar()

wxTaskBarButton* wxFrame::MSWGetTaskBarButton ( )

MSW-specific function for accessing the taskbar button under Windows 7 or later.

Returns a wxTaskBarButton pointer representing the taskbar button of the window under Windows 7 or later. The returned wxTaskBarButton may be used, if non-NULL, to access the functionality including thumbnail representations, thumbnail toolbars, notification and status overlays, and progress indicators.

The returned pointer must *not* be deleted, it is owned by the frame and will be only deleted when the frame itself is destroyed.

This function is not available in the other ports by design, any occurrences of it in the portable code must be guarded by

```
#ifdef __WXMSW__
```

preprocessor guards.

Since

3.1.0

virtual wxStatusBar* wxFrame::OnCreateStatusBar (int *number,* long *style,* wxWindowID *id,* const wxString & *name*) [virtual]

Virtual function called when a status bar is requested by CreateStatusBar().

Parameters

number	The number of fields to create.
style	The window style. See wxStatusBar for a list of valid styles.
id	The window identifier. If -1, an identifier will be chosen by wxWidgets.
name	The window name.

Returns

A status bar object.

Remarks

An application can override this function to return a different kind of status bar. The default implementation returns an instance of wxStatusBar.

See also

CreateStatusBar(), wxStatusBar.

virtual wxToolBar* wxFrame::OnCreateToolBar (long *style,* wxWindowID *id,* const wxString & *name*) [virtual]

Virtual function called when a toolbar is requested by CreateToolBar().

Parameters

style	The toolbar style. See wxToolBar for a list of valid styles.

id	The toolbar window identifier. If -1, an identifier will be chosen by wxWidgets.
name	The toolbar window name.

Returns

A toolbar object.

Remarks

An application can override this function to return a different kind of toolbar. The default implementation returns an instance of wxToolBar.

See also

CreateToolBar(), wxToolBar.

void wxFrame::PopStatusText (int *number* = 0)

bool wxFrame::ProcessCommand (int *id*)

Simulate a menu command.

Parameters

id	The identifier for a menu item.

void wxFrame::PushStatusText (const wxString & *text*, int *number* = 0)

virtual void wxFrame::SetMenuBar (wxMenuBar * *menuBar*) [virtual]

Tells the frame to show the given menu bar.

Parameters

menuBar	The menu bar to associate with the frame.

Remarks

If the frame is destroyed, the menu bar and its menus will be destroyed also, so do not delete the menu bar explicitly (except by resetting the frame's menu bar to another frame or NULL). Under Windows, a size event is generated, so be sure to initialize data members properly before calling SetMenuBar(). Note that on some platforms, it is not possible to call this function twice for the same frame object.

See also

GetMenuBar(), wxMenuBar, wxMenu.

virtual void wxFrame::SetStatusBar (wxStatusBar * *statusBar*) [virtual]

Associates a status bar with the frame.

If *statusBar* is NULL, then the status bar, if present, is detached from the frame, but *not* deleted.

See also

CreateStatusBar(), wxStatusBar, GetStatusBar()

void wxFrame::SetStatusBarPane (int *n*)

Set the status bar pane used to display menu and toolbar help.

Using -1 disables help display.

virtual void wxFrame::SetStatusText (const wxString & *text*, int *number* = 0) [virtual]

Sets the status bar text and redraws the status bar.

Parameters

text	The text for the status field.
number	The status field (starting from zero).

Remarks

Use an empty string to clear the status bar.

See also

CreateStatusBar(), wxStatusBar

virtual void wxFrame::SetStatusWidths (int *n*, const int * *widths_field*) [virtual]

Sets the widths of the fields in the status bar.

Parameters

n	The number of fields in the status bar. It must be the same used in CreateStatusBar.
widths_field	Must contain an array of n integers, each of which is a status field width in pixels. A value of -1 indicates that the field is variable width; at least one field must be -1. You should delete this array after calling SetStatusWidths().

Remarks

The widths of the variable fields are calculated from the total width of all fields, minus the sum of widths of the non-variable fields, divided by the number of variable fields.

wxPerl Note: In wxPerl this method takes the field widths as parameters.

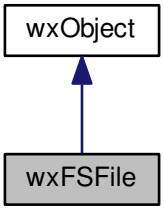
virtual void wxFrame::SetToolBar (wxToolBar * *toolBar*) [virtual]

Associates a toolbar with the frame.

21.271 wxFSFile Class Reference

`#include <wx/filesys.h>`

Inheritance diagram for wxFSFile:



21.271.1 Detailed Description

This class represents a single file opened by wxFileSystem.

It provides more information than wxWidgets' input streams (stream, filename, mime type, anchor).

Note

Any pointer returned by a method of wxFSFile is valid only as long as the wxFSFile object exists. For example a call to GetStream() doesn't *create* the stream but only returns the pointer to it. In other words after 10 calls to GetStream() you will have obtained ten identical pointers.

Library: wxBase

Category: Virtual File System, File Handling

wxFileSystemHandler, wxFileSystem, wxFileSystem Overview

Public Member Functions

- wxFSFile (wxInputStream *stream, const wxString &location, const wxString &mimetype, const wxString &anchor, wxDateTime modif)

  Constructor.
- wxInputStream * DetachStream ()

  Detaches the stream from the wxFSFile object.
- const wxString & GetAnchor () const

  Returns anchor (if present).
- const wxString & GetLocation () const

  Returns full location of the file, including path and protocol.
- const wxString & GetMimeType () const

  Returns the MIME type of the content of this file.
- wxDateTime GetModificationTime () const

  Returns time when this file was modified.
- wxInputStream * GetStream () const

  Returns pointer to the stream.

Additional Inherited Members

21.271.2 Constructor & Destructor Documentation

wxFSFile::wxFSFile (wxInputStream * *stream,* const wxString & *location,* const wxString & *mimetype,* const wxString & *anchor,* wxDateTime *modif*)

Constructor.

You probably won't use it. See the Note for details.

It is seldom used by the application programmer but you will need it if you are writing your own virtual FS. For example you may need something similar to wxMemoryInputStream, but because wxMemoryInputStream doesn't free the memory when destroyed and thus passing a memory stream pointer into wxFSFile constructor would lead to memory leaks, you can write your own class derived from wxFSFile:

```
class wxMyFSFile : public wxFSFile
{
    private:
        void *m_Mem;
    public:
        wxMyFSFile(.....)
        ~wxMyFSFile() {free(m_Mem);}
            // of course dtor is virtual ;-)
};
```

If you are not sure of the meaning of these params, see the description of the GetXXXX() functions.

Parameters

stream	The input stream that will be used to access data
location	The full location (aka filename) of the file
mimetype	MIME type of this file. It may be left empty, in which case the type will be determined from file's extension (location must not be empty in this case).
anchor	Anchor. See GetAnchor() for details.
modif	Modification date and time for this file.

21.271.3 Member Function Documentation

wxInputStream* wxFSFile::DetachStream ( )

Detaches the stream from the wxFSFile object.

That is, the stream obtained with GetStream() will continue its existence after the wxFSFile object is deleted.

You will have to delete the stream yourself.

const wxString& wxFSFile::GetAnchor ( ) const

Returns anchor (if present).

The term of **anchor** can be easily explained using few examples:

```
index.htm#anchor                      // 'anchor' is anchor
index/wx001.htm                       // NO anchor here!
archive/main.zip#zip:index.htm#global // 'global'
archive/main.zip#zip:index.htm        // NO anchor here!
```

Usually an anchor is presented only if the MIME type is 'text/html'. But it may have some meaning with other files; for example myanim.avi#200 may refer to position in animation or reality.wrl::MyView may refer to a predefined view in VRML.

const wxString& wxFSFile::GetLocation ( ) const

Returns full location of the file, including path and protocol.

Examples:

```
http://www.wxwidgets.org
http://www.ms.mff.cuni.cz/~vsla8348/wxhtml/archive.zip#zip:info.txt
file:/home/vasek/index.htm
relative-file.htm
```

const wxString& wxFSFile::GetMimeType ( ) const

Returns the MIME type of the content of this file.

It is either extension-based (see wxMimeTypesManager) or extracted from HTTP protocol Content-Type header.

wxDateTime wxFSFile::GetModificationTime ( ) const

Returns time when this file was modified.

wxInputStream* wxFSFile::GetStream ( ) const

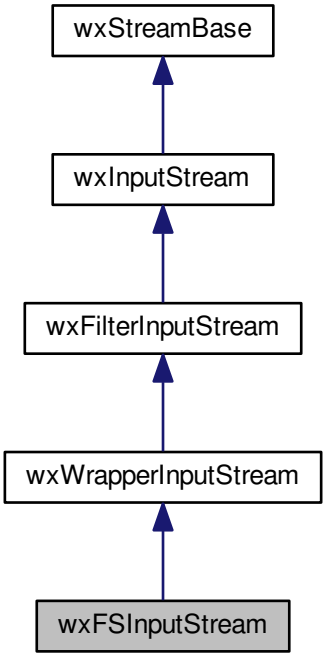
Returns pointer to the stream.

You can use the returned stream to directly access data. You may suppose that the stream provide Seek and GetSize functionality (even in the case of the HTTP protocol which doesn't provide this by default. wxHtml uses local cache to work around this and to speed up the connection).

21.272 wxFSInputStream Class Reference

```
#include <wx/filesys.h>
```

Inheritance diagram for wxFSInputStream:



21.272.1 Detailed Description

Input stream for virtual file stream files.

The stream reads data from wxFSFile obtained from wxFileSystem. It is especially useful to allow using virtual files with other wxWidgets functions and classes working with streams, e.g. for loading images or animations from virtual files and not only physical ones.

Library: wxBase

Category: Streams

See also

wxWrapperInputStream, wxFSFile

Since

2.9.4

Public Member Functions

- wxFileInputStream (const wxString &filename, int flags=0)

  Create a stream associated with the data of the given virtual file system file.

- bool IsOk () const

  Returns true if the stream is initialized and ready.

Additional Inherited Members

21.272.2 Member Function Documentation

bool wxFSInputStream::IsOk ( ) const `[virtual]`

Returns true if the stream is initialized and ready.

Reimplemented from wxStreamBase.

wxFSInputStream::wxFileInputStream (const wxString & *filename*, int *flags* = `0`)

Create a stream associated with the data of the given virtual file system file.

Parameters

filename	The name of the input file passed to wxFileSystem::OpenFile().
flags	Combination of flags from wxFileSystemOpenFlags. wxFS_READ is implied, i.e. it is always added to the flags value.

Use wxStreamBase::IsOk() to verify if the constructor succeeded.

21.273 wxFSVolume Class Reference

`#include <wx/volume.h>`

21.273.1 Detailed Description

wxFSVolume represents a volume (also known as 'drive') in a file system under wxMSW.

Unix ports of wxWidgets do not have the concept of volumes and thus do not implement wxFSVolume.

Availability: only available for the wxMSW port.

Library: wxBase

Category: Miscellaneous

Public Member Functions

- wxFSVolume ()

  Default ctor.
- wxFSVolume (const wxString &name)

  Create the volume object with the given name (which should be one of those returned by GetVolumes()).
- bool Create (const wxString &name)

  Create the volume object with the given name (which should be one of those returned by GetVolumes()).
- bool IsOk () const

  Is this a valid volume?
- wxFSVolumeKind GetKind () const

Returns the kind of this volume.

- int GetFlags () const

  Returns the flags of this volume.

- bool IsWritable () const

  Returns true if this volume is writable.

- wxString GetName () const

  Returns the name of the volume; this is the internal name for the volume used by the operating system.

- wxString GetDisplayName () const

  Returns the name of the volume meant to be shown to the user.

- wxIcon GetIcon (wxFSIconType type) const

  This function is available only when `wxUSE_GUI` is `1`.

Static Public Member Functions

- static wxArrayString GetVolumes (int flagsSet=wxFS_VOL_MOUNTED, int flagsUnset=0)

  Returns an array containing the names of the volumes of this system.

- static void CancelSearch ()

  Stops execution of GetVolumes() called previously (should be called from another thread, of course).

21.273.2 Constructor & Destructor Documentation

wxFSVolume::wxFSVolume ( )

Default ctor.

Use Create() later.

wxFSVolume::wxFSVolume (const wxString & *name*)

Create the volume object with the given *name* (which should be one of those returned by GetVolumes()).

21.273.3 Member Function Documentation

static void wxFSVolume::CancelSearch ( ) [static]

Stops execution of GetVolumes() called previously (should be called from another thread, of course).

bool wxFSVolume::Create (const wxString & *name*)

Create the volume object with the given *name* (which should be one of those returned by GetVolumes()).

wxString wxFSVolume::GetDisplayName ( ) const

Returns the name of the volume meant to be shown to the user.

int wxFSVolume::GetFlags ( ) const

Returns the flags of this volume.

See wxFSVolumeFlags enumeration values.

wxIcon wxFSVolume::GetIcon (wxFSIconType *type*) const

This function is available only when `wxUSE_GUI` is `1`.

Returns the icon used by the native toolkit for the given file system type.

wxFSVolumeKind wxFSVolume::GetKind ( ) const

Returns the kind of this volume.

wxString wxFSVolume::GetName ( ) const

Returns the name of the volume; this is the internal name for the volume used by the operating system.

static wxArrayString wxFSVolume::GetVolumes (int *flagsSet* = wxFS_VOL_MOUNTED, int *flagsUnset* = `0`) `[static]`

Returns an array containing the names of the volumes of this system.

Only the volumes with *flags* such that the expression

```
(flags & flagsSet) == flagsSet && !(flags & flagsUnset)
```

is true, are returned. By default, all mounted ones are returned. See wxFSVolumeFlags enumeration values for a list of valid flags.

This operation may take a while and, even if this function is synchronous, it can be stopped using CancelSearch().

bool wxFSVolume::IsOk ( ) const

Is this a valid volume?

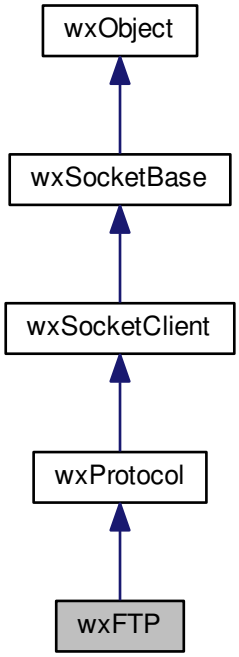
bool wxFSVolume::IsWritable ( ) const

Returns true if this volume is writable.

21.274 wxFTP Class Reference

`#include <wx/protocol/ftp.h>`

Inheritance diagram for wxFTP:



21.274.1 Detailed Description

wxFTP can be used to establish a connection to an FTP server and perform all the usual operations.

Please consult the RFC 959 (http://www.w3.org/Protocols/rfc959/) for more details about the FTP protocol.

wxFTP can thus be used to create a (basic) FTP **client**.

To use a command which doesn't involve file transfer (i.e. directory oriented commands) you just need to call a corresponding member function or use the generic wxFTP::SendCommand() method. However to actually transfer files you just get or give a stream to or from this class and the actual data are read or written using the usual stream methods.

Example of using wxFTP for file downloading:

```
wxFTP ftp;

// if you don't use these lines anonymous login will be used
ftp.SetUser("user");
ftp.SetPassword("password");

if ( !ftp.Connect("ftp.wxwidgets.org") )
{
    wxLogError("Couldn't connect");
    return;
}

ftp.ChDir("/pub/2.8.9");
const char *filename = "wxWidgets-2.8.9.tar.bz2";
int size = ftp.GetFileSize(filename);
if ( size == -1 )
{
    wxLogError("Couldn't get the file size for \"%s\"", filename);
}
```

```
wxInputStream *in = ftp.GetInputStream(filename);
if ( !in )
{
    wxLogError("Couldn't get the file");
}
else
{
    char *data = new char[size];
    if ( !in->Read(data, size) )
    {
        wxLogError("Read error: %d", ftp.GetError());
    }
    else
    {
        // file data is in the buffer
        ...
    }

    delete [] data;
    delete in;
}

// gracefully close the connection to the server
ftp.Close();
```

To upload a file you would do (assuming the connection to the server was opened successfully):

```
wxOutputStream *out = ftp.GetOutputStream("filename");
if ( out )
{
    out->Write(...); // your data
    delete out;
}
```

Library: wxNet

Category: Networking

See also

wxSocketBase

Public Types

- enum TransferMode {
  NONE,
  ASCII,
  BINARY }

  Transfer modes used by wxFTP.

Public Member Functions

- wxFTP ()

  Default constructor.
- virtual ~wxFTP ()

  Destructor will close the connection if connected.

- virtual bool Connect (const wxString &host)

  Connect to the FTP server to default port (21) of the specified host.
- virtual bool Connect (const wxString &host, unsigned short port)

  Connect to the FTP server to any port of the specified host.

Functions for managing the FTP connection

- virtual bool Abort ()

  Aborts the download currently in process, returns true if ok, false if an error occurred.
- virtual bool Close ()

  Gracefully closes the connection with the server.
- bool CheckCommand (const wxString &command, char ret)

  Send the specified command to the FTP server.
- const wxString & GetLastResult ()

  Returns the last command result, i.e.
- char SendCommand (const wxString &command)

  Send the specified command to the FTP server and return the first character of the return code.
- bool SetAscii ()

  Sets the transfer mode to ASCII.
- bool SetBinary ()

  Sets the transfer mode to binary.
- void SetPassive (bool pasv)

  If pasv is true, passive connection to the FTP server is used.
- virtual void SetPassword (const wxString &passwd)

  Sets the password to be sent to the FTP server to be allowed to log in.
- bool SetTransferMode (TransferMode mode)

  Sets the transfer mode to the specified one.
- virtual void SetUser (const wxString &user)

  Sets the user name to be sent to the FTP server to be allowed to log in.

Filesystem commands

- bool ChDir (const wxString &dir)

  Change the current FTP working directory.
- bool MkDir (const wxString &dir)

  Create the specified directory in the current FTP working directory.
- wxString Pwd ()

  Returns the current FTP working directory.
- bool Rename (const wxString &src, const wxString &dst)

  Rename the specified src element to dst.
- bool RmDir (const wxString &dir)

  Remove the specified directory from the current FTP working directory.
- bool RmFile (const wxString &path)

  Delete the file specified by path.
- bool FileExists (const wxString &filename)

  Returns true if the given remote file exists, false otherwise.
- bool GetDirList (wxArrayString &files, const wxString &wildcard=wxEmptyString)

  The GetList() function is quite low-level.
- int GetFileSize (const wxString &filename)

  Returns the file size in bytes or -1 if the file doesn't exist or the size couldn't be determined.
- bool GetFilesList (wxArrayString &files, const wxString &wildcard=wxEmptyString)

  This function returns the computer-parsable list of the files in the current directory (optionally only of the files matching the wildcard, all files by default).

Download and upload functions

- virtual wxInputStream * GetInputStream (const wxString &path)

  Creates a new input stream on the specified path.
- virtual wxOutputStream * GetOutputStream (const wxString &file)

  Initializes an output stream to the specified file.

Additional Inherited Members

21.274.2 Member Enumeration Documentation

enum wxFTP::TransferMode

Transfer modes used by wxFTP.

Enumerator

NONE not set by user explicitly.

ASCII

BINARY

21.274.3 Constructor & Destructor Documentation

wxFTP::wxFTP ( )

Default constructor.

virtual wxFTP::~wxFTP ( ) [virtual]

Destructor will close the connection if connected.

21.274.4 Member Function Documentation

virtual bool wxFTP::Abort ( ) [virtual]

Aborts the download currently in process, returns true if ok, false if an error occurred.

Implements wxProtocol.

bool wxFTP::ChDir (const wxString & *dir*)

Change the current FTP working directory.

Returns true if successful.

bool wxFTP::CheckCommand (const wxString & *command*, char *ret*)

Send the specified *command* to the FTP server.

ret specifies the expected result.

Returns

true if the command has been sent successfully, else false.

virtual bool wxFTP::Close ( ) [virtual]

Gracefully closes the connection with the server.

Reimplemented from wxSocketBase.

virtual bool wxFTP::Connect (const wxString & *host*) [virtual]

Connect to the FTP server to default port (21) of the specified *host*.

virtual bool wxFTP::Connect (const wxString & *host,* unsigned short *port*) [virtual]

Connect to the FTP server to any port of the specified *host*.

By default (*port* = 0), connection is made to default FTP port (21) of the specified *host*.

Since

2.9.1

bool wxFTP::FileExists (const wxString & *filename*)

Returns true if the given remote file exists, false otherwise.

bool wxFTP::GetDirList (wxArrayString & *files,* const wxString & *wildcard* = wxEmptyString)

The GetList() function is quite low-level.

It returns the list of the files in the current directory. The list can be filtered using the *wildcard* string.

If *wildcard* is empty (default), it will return all files in directory. The form of the list can change from one peer system to another. For example, for a UNIX peer system, it will look like this:

```
-r--r--r--   1 guilhem  lavaux      12738 Jan 16 20:17 cmndata.cpp
-r--r--r--   1 guilhem  lavaux      10866 Jan 24 16:41 config.cpp
-rw-rw-rw-   1 guilhem  lavaux      29967 Dec 21 19:17 cwlex_yy.c
-rw-rw-rw-   1 guilhem  lavaux      14342 Jan 22 19:51 cwy_tab.c
-r--r--r--   1 guilhem  lavaux      13890 Jan 29 19:18 date.cpp
-r--r--r--   1 guilhem  lavaux       3989 Feb  8 19:18 datstrm.cpp
```

But on Windows system, it will look like this:

```
winamp~1 exe    520196 02-25-1999  19:28  winamp204.exe
    1 file(s)           520 196 bytes
```

Returns

true if the file list was successfully retrieved, false otherwise.

See also

GetFilesList()

int wxFTP::GetFileSize (const wxString & *filename*)

Returns the file size in bytes or -1 if the file doesn't exist or the size couldn't be determined.

Notice that this size can be approximative size only and shouldn't be used for allocating the buffer in which the remote file is copied, for example.

bool wxFTP::GetFilesList (wxArrayString & *files*, const wxString & *wildcard* = wxEmptyString)

This function returns the computer-parsable list of the files in the current directory (optionally only of the files matching the *wildcard*, all files by default).

This list always has the same format and contains one full (including the directory path) file name per line.

Returns

true if the file list was successfully retrieved, false otherwise.

See also

GetDirList()

virtual wxInputStream* wxFTP::GetInputStream (const wxString & *path*) [virtual]

Creates a new input stream on the specified path.

You can use all but the seek functionality of wxStreamBase. wxStreamBase::Seek() isn't available on all streams. For example, HTTP or FTP streams do not deal with it. Other functions like wxStreamBase::Tell() are not available for this sort of stream, at present.

You will be notified when the EOF is reached by an error.

Returns

Returns NULL if an error occurred (it could be a network failure or the fact that the file doesn't exist).

Implements wxProtocol.

const wxString& wxFTP::GetLastResult ( )

Returns the last command result, i.e.

the full server reply for the last command.

virtual wxOutputStream* wxFTP::GetOutputStream (const wxString & *file*) [virtual]

Initializes an output stream to the specified *file*.

The returned stream has all but the seek functionality of wxStreams. When the user finishes writing data, he has to delete the stream to close it.

Returns

An initialized write-only stream. Returns NULL if an error occurred (it could be a network failure or the fact that the file doesn't exist).

bool wxFTP::MkDir (const wxString & *dir*)

Create the specified directory in the current FTP working directory.

Returns true if successful.

wxString wxFTP::Pwd ( )

Returns the current FTP working directory.

bool wxFTP::Rename (const wxString & *src,* const wxString & *dst*)

Rename the specified *src* element to *dst*.

Returns true if successful.

bool wxFTP::RmDir (const wxString & *dir*)

Remove the specified directory from the current FTP working directory.

Returns true if successful.

bool wxFTP::RmFile (const wxString & *path*)

Delete the file specified by *path*.

Returns true if successful.

char wxFTP::SendCommand (const wxString & *command*)

Send the specified *command* to the FTP server and return the first character of the return code.

bool wxFTP::SetAscii ( )

Sets the transfer mode to ASCII.

It will be used for the next transfer.

bool wxFTP::SetBinary ( )

Sets the transfer mode to binary.

It will be used for the next transfer.

void wxFTP::SetPassive (bool *pasv*)

If *pasv* is true, passive connection to the FTP server is used.

This is the default as it works with practically all firewalls. If the server doesn't support passive mode, you may call this function with false as argument to use an active connection.

virtual void wxFTP::SetPassword (const wxString & *passwd*) `[virtual]`

Sets the password to be sent to the FTP server to be allowed to log in.

Reimplemented from wxProtocol.

bool wxFTP::SetTransferMode (TransferMode *mode*)

Sets the transfer mode to the specified one.

It will be used for the next transfer.

If this function is never called, binary transfer mode is used by default.

virtual void wxFTP::SetUser (const wxString & *user*) `[virtual]`

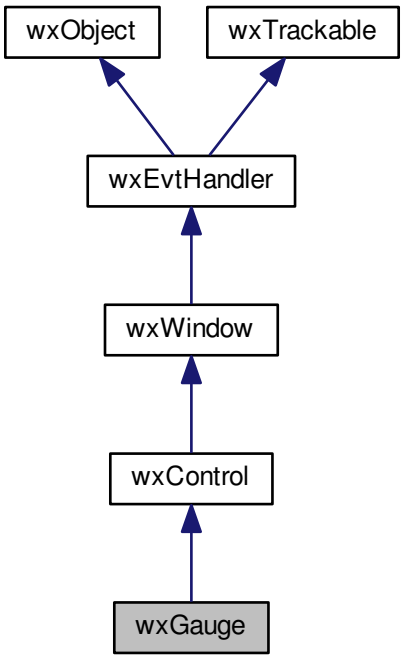
Sets the user name to be sent to the FTP server to be allowed to log in.

Reimplemented from wxProtocol.

21.275 wxGauge Class Reference

`#include <wx/gauge.h>`

Inheritance diagram for wxGauge:



21.275.1 Detailed Description

A gauge is a horizontal or vertical bar which shows a quantity (often time).

wxGauge supports two working modes: determinate and indeterminate progress.

The first is the usual working mode (see SetValue() and SetRange()) while the second can be used when the program is doing some processing but you don't know how much progress is being done. In this case, you can periodically call the Pulse() function to make the progress bar switch to indeterminate mode (graphically it's usually a set of blocks which move or bounce in the bar control).

wxGauge supports dynamic switch between these two work modes.

There are no user commands for the gauge.

Styles

This class supports the following styles:

- wxGA_HORIZONTAL: Creates a horizontal gauge.
- wxGA_VERTICAL: Creates a vertical gauge.
- wxGA_SMOOTH: Creates smooth progress bar with one pixel wide update step (not supported by all platforms).
- wxGA_TEXT: Display the current value in percents in the gauge itself. This style is only supported in wxQt and ignored under the other platforms.

  Since

  3.1.0
- wxGA_PROGRESS: Reflect the value of gauge in the application taskbar button under Windows 7 and later, ignored under the other platforms.

  Since

  3.1.0

Library: wxCore

Category: Controls

wxSlider, wxScrollBar

Public Member Functions

- wxGauge ()

  Default constructor.
- wxGauge (wxWindow *parent, wxWindowID id, int range, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, long style=wxGA_HORIZONTAL, const wxValidator &validator=wxDefaultValidator, const wxString &name=wxGaugeNameStr)

  Constructor, creating and showing a gauge.
- virtual ~wxGauge ()

  Destructor, destroying the gauge.
- bool Create (wxWindow *parent, wxWindowID id, int range, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, long style=wxGA_HORIZONTAL, const wxValidator &validator=wxDefaultValidator, const wxString &name=wxGaugeNameStr)

  Creates the gauge for two-step construction.
- int GetBezelFace () const

  Returns the width of the 3D bezel face.
- int GetRange () const

  Returns the maximum position of the gauge.
- int GetShadowWidth () const

  Returns the 3D shadow margin width.
- int GetValue () const

  Returns the current position of the gauge.
- bool IsVertical () const

Returns true if the gauge is vertical (has `wxGA_VERTICAL` style) and false otherwise.

- virtual void Pulse ()

  Switch the gauge to indeterminate mode (if required) and makes the gauge move a bit to indicate the user that some progress has been made.

- void SetBezelFace (int width)

  Sets the 3D bezel face width.

- void SetRange (int range)

  Sets the range (maximum value) of the gauge.

- void SetShadowWidth (int width)

  Sets the 3D shadow width.

- void SetValue (int pos)

  Sets the position of the gauge.

Additional Inherited Members

21.275.2 Constructor & Destructor Documentation

wxGauge::wxGauge ( )

Default constructor.

wxGauge::wxGauge (wxWindow * *parent*, wxWindowID *id*, int *range*, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, long *style* = wxGA_HORIZONTAL, const wxValidator & *validator* = wxDefaultValidator, const wxString & *name* = `wxGaugeNameStr`)

Constructor, creating and showing a gauge.

Parameters

parent	Window parent.
id	Window identifier.
range	Integer range (maximum value) of the gauge. See SetRange() for more details about the meaning of this value when using the gauge in indeterminate mode.
pos	Window position.
size	Window size.
style	Gauge style.
validator	Window validator.
name	Window name.

See also

Create()

virtual wxGauge::~wxGauge ( ) `[virtual]`

Destructor, destroying the gauge.

21.275.3 Member Function Documentation

bool wxGauge::Create (wxWindow * *parent*, wxWindowID *id*, int *range*, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, long *style* = wxGA_HORIZONTAL, const wxValidator & *validator* = wxDefaultValidator, const wxString & *name* = `wxGaugeNameStr`)

Creates the gauge for two-step construction.

See wxGauge() for further details.

int wxGauge::GetBezelFace ( ) const

Returns the width of the 3D bezel face.

Remarks

This method is not implemented (returns 0) for most platforms.

See also

SetBezelFace()

int wxGauge::GetRange ( ) const

Returns the maximum position of the gauge.

See also

SetRange()

int wxGauge::GetShadowWidth ( ) const

Returns the 3D shadow margin width.

Remarks

This method is not implemented (returns 0) for most platforms.

See also

SetShadowWidth()

int wxGauge::GetValue ( ) const

Returns the current position of the gauge.

See also

SetValue()

bool wxGauge::IsVertical ( ) const

Returns true if the gauge is vertical (has `wxGA_VERTICAL` style) and false otherwise.

virtual void wxGauge::Pulse ( ) [virtual]

Switch the gauge to indeterminate mode (if required) and makes the gauge move a bit to indicate the user that some progress has been made.

Note

After calling this function the value returned by GetValue() is undefined and thus you need to explicitly call SetValue() if you want to restore the determinate mode.

void wxGauge::SetBezelFace (int *width*)

Sets the 3D bezel face width.

Remarks

This method is not implemented (doesn't do anything) for most platforms.

See also

GetBezelFace()

void wxGauge::SetRange (int *range*)

Sets the range (maximum value) of the gauge.

This function makes the gauge switch to determinate mode, if it's not already.

When the gauge is in indeterminate mode, under wxMSW the gauge repeatedly goes from zero to *range* and back; under other ports when in indeterminate mode, the *range* setting is ignored.

See also

GetRange()

void wxGauge::SetShadowWidth (int *width*)

Sets the 3D shadow width.

Remarks

This method is not implemented (doesn't do anything) for most platforms.

void wxGauge::SetValue (int *pos*)

Sets the position of the gauge.

The *pos* must be between 0 and the gauge range as returned by GetRange(), inclusive.

This function makes the gauge switch to determinate mode, if it was in indeterminate mode before.

Parameters

pos	Position for the gauge level.

GetValue()

21.276 wxGBPosition Class Reference

`#include <wx/gbsizer.h>`

21.276.1 Detailed Description

This class represents the position of an item in a virtual grid of rows and columns managed by a wxGridBagSizer.

Library: wxCore

Category: Window Layout

Public Member Functions

- wxGBPosition ()

  Default constructor, setting the row and column to (0,0).
- wxGBPosition (int row, int col)

  Construct a new wxGBPosition, setting the row and column.
- int GetCol () const

  Get the current column value.
- int GetRow () const

  Get the current row value.
- void SetCol (int col)

  Set a new column value.
- void SetRow (int row)

  Set a new row value.
- bool operator!= (const wxGBPosition &p) const

  Compare inequality of two wxGBPositions.
- bool operator== (const wxGBPosition &p) const

  Compare equality of two wxGBPositions.

21.276.2 Constructor & Destructor Documentation

wxGBPosition::wxGBPosition ( )

Default constructor, setting the row and column to (0,0).

wxGBPosition::wxGBPosition (int *row,* int *col*)

Construct a new wxGBPosition, setting the row and column.

21.276.3 Member Function Documentation

int wxGBPosition::GetCol ( ) const

Get the current column value.

int wxGBPosition::GetRow ( ) const

Get the current row value.

bool wxGBPosition::operator!= (const wxGBPosition & *p*) const

Compare inequality of two wxGBPositions.

bool wxGBPosition::operator== (const wxGBPosition & *p*) const

Compare equality of two wxGBPositions.

void wxGBPosition::SetCol (int *col*)

Set a new column value.

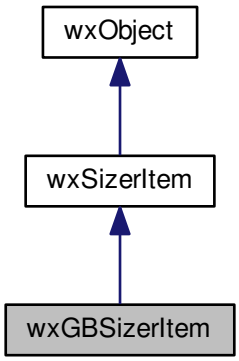
void wxGBPosition::SetRow (int *row*)

Set a new row value.

21.277 wxGBSizerItem Class Reference

`#include <wx/gbsizer.h>`

Inheritance diagram for wxGBSizerItem:



21.277.1 Detailed Description

The wxGBSizerItem class is used by the wxGridBagSizer for tracking the items in the sizer.

It adds grid position and spanning information to the normal wxSizerItem by adding wxGBPosition and wxGBSpan attributes. Most of the time you will not need to use a wxGBSizerItem directly in your code, but there are a couple of cases where it is handy.

Library: wxCore

Category: Window Layout

Public Member Functions

- wxGBSizerItem (int width, int height, const wxGBPosition &pos, const wxGBSpan &span=wxDefaultSpan, int flag=0, int border=0, wxObject ∗userData=NULL)

  Construct a sizer item for tracking a spacer.
- wxGBSizerItem (wxWindow ∗window, const wxGBPosition &pos, const wxGBSpan &span=wxDefaultSpan, int flag=0, int border=0, wxObject ∗userData=NULL)

  Construct a sizer item for tracking a window.
- wxGBSizerItem (wxSizer ∗sizer, const wxGBPosition &pos, const wxGBSpan &span=wxDefaultSpan, int flag=0, int border=0, wxObject ∗userData=NULL)

  Construct a sizer item for tracking a subsizer.
- void GetEndPos (int &row, int &col)

  Get the row and column of the endpoint of this item.
- bool Intersects (const wxGBSizerItem &other)

  Returns true if this item and the other item intersect.
- bool Intersects (const wxGBPosition &pos, const wxGBSpan &span)

  Returns true if the given pos/span would intersect with this item.
- bool SetPos (const wxGBPosition &pos)

  If the item is already a member of a sizer then first ensure that there is no other item that would intersect with this one at the new position, then set the new position.
- bool SetSpan (const wxGBSpan &span)

  If the item is already a member of a sizer then first ensure that there is no other item that would intersect with this one with its new spanning size, then set the new spanning.
- wxGridBagSizer ∗ GetGBSizer () const
- void SetGBSizer (wxGridBagSizer ∗sizer)

- wxGBPosition GetPos () const

  Get the grid position of the item.
- void GetPos (int &row, int &col) const

  Get the grid position of the item.

- wxGBSpan GetSpan () const

  Get the row and column spanning of the item.
- void GetSpan (int &rowspan, int &colspan) const

  Get the row and column spanning of the item.

Additional Inherited Members

21.277.2 Constructor & Destructor Documentation

wxGBSizerItem::wxGBSizerItem (int *width*, int *height*, const wxGBPosition & *pos*, const wxGBSpan & *span* = wxDefaultSpan, int *flag* = 0, int *border* = 0, wxObject ∗ *userData* = NULL)

Construct a sizer item for tracking a spacer.

wxGBSizerItem::wxGBSizerItem (wxWindow ∗ *window*, const wxGBPosition & *pos*, const wxGBSpan & *span* = wxDefaultSpan, int *flag* = 0, int *border* = 0, wxObject ∗ *userData* = NULL)

Construct a sizer item for tracking a window.

wxGBSizerItem::wxGBSizerItem (wxSizer * *sizer,* const wxGBPosition & *pos,* const wxGBSpan & *span =* wxDefaultSpan, int *flag =* 0, int *border =* 0, wxObject * *userData =* NULL)

Construct a sizer item for tracking a subsizer.

21.277.3 Member Function Documentation

void wxGBSizerItem::GetEndPos (int & *row,* int & *col*)

Get the row and column of the endpoint of this item.

wxGridBagSizer* wxGBSizerItem::GetGBSizer ( ) const

wxGBPosition wxGBSizerItem::GetPos ( ) const

Get the grid position of the item.

void wxGBSizerItem::GetPos (int & *row,* int & *col*) const

Get the grid position of the item.

wxGBSpan wxGBSizerItem::GetSpan ( ) const

Get the row and column spanning of the item.

void wxGBSizerItem::GetSpan (int & *rowspan,* int & *colspan*) const

Get the row and column spanning of the item.

bool wxGBSizerItem::Intersects (const wxGBSizerItem & *other*)

Returns true if this item and the *other* item intersect.

bool wxGBSizerItem::Intersects (const wxGBPosition & *pos,* const wxGBSpan & *span*)

Returns true if the given pos/span would intersect with this item.

void wxGBSizerItem::SetGBSizer (wxGridBagSizer * *sizer*)

bool wxGBSizerItem::SetPos (const wxGBPosition & *pos*)

If the item is already a member of a sizer then first ensure that there is no other item that would intersect with this one at the new position, then set the new position.

Returns true if the change is successful and after the next Layout the item will be moved.

bool wxGBSizerItem::SetSpan (const wxGBSpan & *span*)

If the item is already a member of a sizer then first ensure that there is no other item that would intersect with this one with its new spanning size, then set the new spanning.

Returns true if the change is successful and after the next Layout the item will be resized.

21.278 wxGBSpan Class Reference

```
#include <wx/gbsizer.h>
```

21.278.1 Detailed Description

This class is used to hold the row and column spanning attributes of items in a wxGridBagSizer.

Library: wxCore

Category: Window Layout

Public Member Functions

- wxGBSpan ()

  Default constructor, setting the rowspan and colspan to (1,1) meaning that the item occupies one cell in each direction.
- wxGBSpan (int rowspan, int colspan)

  Construct a new wxGBSpan, setting the rowspan and colspan.
- int GetColspan () const

  Get the current colspan value.
- int GetRowspan () const

  Get the current rowspan value.
- void SetColspan (int colspan)

  Set a new colspan value.
- void SetRowspan (int rowspan)

  Set a new rowspan value.
- bool operator!= (const wxGBSpan &o) const

  Compare inequality of two wxGBSpans.
- bool operator== (const wxGBSpan &o) const

  Compare equality of two wxGBSpans.

21.278.2 Constructor & Destructor Documentation

wxGBSpan::wxGBSpan ( )

Default constructor, setting the rowspan and colspan to (1,1) meaning that the item occupies one cell in each direction.

wxGBSpan::wxGBSpan (int *rowspan*, int *colspan*)

Construct a new wxGBSpan, setting the *rowspan* and *colspan*.

21.278.3 Member Function Documentation

int wxGBSpan::GetColspan ( ) const

Get the current colspan value.

int wxGBSpan::GetRowspan ( ) const

Get the current rowspan value.

bool wxGBSpan::operator!= (const wxGBSpan & *o*) const

Compare inequality of two wxGBSpans.

bool wxGBSpan::operator== (const wxGBSpan & *o*) const

Compare equality of two wxGBSpans.

void wxGBSpan::SetColspan (int *colspan*)

Set a new colspan value.

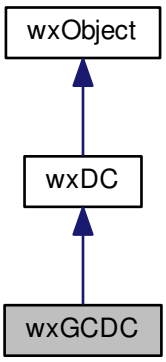
void wxGBSpan::SetRowspan (int *rowspan*)

Set a new rowspan value.

21.279 wxGCDC Class Reference

`#include <wx/dcgraph.h>`

Inheritance diagram for wxGCDC:



21.279.1 Detailed Description

wxGCDC is a device context that draws on a wxGraphicsContext.

Library: wxCore

Category: Device Contexts

See also

wxDC, wxGraphicsContext

Public Member Functions

- wxGCDC (const wxWindowDC &windowDC)

  Constructs a wxGCDC from a wxWindowDC.
- wxGCDC (const wxMemoryDC &memoryDC)

  Constructs a wxGCDC from a wxMemoryDC.
- wxGCDC (const wxPrinterDC &printerDC)

  Constructs a wxGCDC from a wxPrinterDC.
- wxGCDC (wxGraphicsContext *context)

  Construct a wxGCDC from an existing graphics context.
- wxGCDC (const wxEnhMetaFileDC &emfDC)

  Constructs a wxGCDC from a wxEnhMetaFileDC.
- wxGCDC ()
- virtual ~wxGCDC ()
- wxGraphicsContext * GetGraphicsContext () const

  Retrieves associated wxGraphicsContext.
- void SetGraphicsContext (wxGraphicsContext *ctx)

  Set the graphics context to be used for this wxGCDC.

Additional Inherited Members

21.279.2 Constructor & Destructor Documentation

wxGCDC::wxGCDC (const wxWindowDC & *windowDC*)

Constructs a wxGCDC from a wxWindowDC.

wxGCDC::wxGCDC (const wxMemoryDC & *memoryDC*)

Constructs a wxGCDC from a wxMemoryDC.

wxGCDC::wxGCDC (const wxPrinterDC & *printerDC*)

Constructs a wxGCDC from a wxPrinterDC.

wxGCDC::wxGCDC (wxGraphicsContext * *context*)

Construct a wxGCDC from an existing graphics context.

wxGCDC::wxGCDC (const wxEnhMetaFileDC & *emfDC*)

Constructs a wxGCDC from a wxEnhMetaFileDC.

This constructor is only available in wxMSW port and when `wxUSE_ENH_METAFILE` build option is enabled, i.e. when wxEnhMetaFileDC class itself is available.

Since

2.9.3

wxGCDC::wxGCDC ( )

virtual wxGCDC::~wxGCDC ( ) [virtual]

21.279.3 Member Function Documentation

wxGraphicsContext* wxGCDC::GetGraphicsContext ( ) const

Retrieves associated wxGraphicsContext.

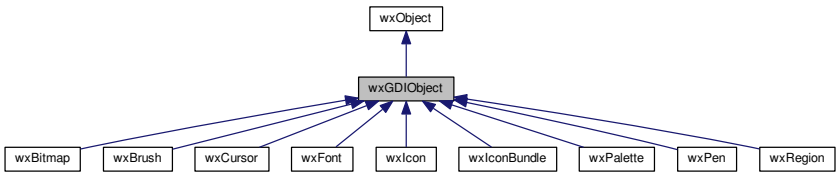
void wxGCDC::SetGraphicsContext (wxGraphicsContext * *ctx*)

Set the graphics context to be used for this wxGCDC.

21.280 wxGDIObject Class Reference

`#include <wx/gdiobj.h>`

Inheritance diagram for wxGDIObject:



21.280.1 Detailed Description

This class allows platforms to implement functionality to optimise GDI objects, such as wxPen, wxBrush and wxFont.

On Windows, the underling GDI objects are a scarce resource and are cleaned up when a usage count goes to zero. On some platforms this class may not have any special functionality.

Since the functionality of this class is platform-specific, it is not documented here in detail.

Library: wxCore

Category: Graphics Device Interface (GDI)

See also

wxPen, wxBrush, wxFont

Public Member Functions

- wxGDIObject ()

  Default constructor.

Additional Inherited Members

21.280.2 Constructor & Destructor Documentation

wxGDIObject::wxGDIObject ( )

Default constructor.

21.281 wxGenericAboutDialog Class Reference

`#include <wx/generic/aboutdlgg.h>`

21.281.1 Detailed Description

This class defines a customizable *About* dialog.

Note that if you don't need customization, you should use the global wxAboutBox() function that is both easier to use and shows the native dialog if available.

To use this class, you need to derive your own class from it and override the virtual method DoAddCustomControls().

To instantiate an object from your wxGenericAboutDialog-based class, you can use either the default constructor followed by a call to Create(), or directly using the alternate constructor. In either case, you have to prepare a wxAboutDialogInfo containing standard informations to display in an about-box.

Example of usage, MyAboutDlg being a class derived from wxGenericAboutDialog:

```
void MyFrame::OnAbout(wxCommandEvent& WXUNUSED(event))
{
    wxAboutDialogInfo aboutInfo;

    aboutInfo.SetName("MyApp");
    aboutInfo.SetVersion(MY_APP_VERSION_STRING);
    aboutInfo.SetDescription(_("My wxWidgets-based application!"));
    aboutInfo.SetCopyright("(C) 1992-2012");
    aboutInfo.SetWebSite("http://myapp.org");
    aboutInfo.AddDeveloper("My Self");

    MyAboutDlg dlgAbout(aboutInfo, this);
    dlgAbout.ShowModal();
}
```

Library: wxAdvanced

Category: Common Dialogs

See also

wxAboutDialogInfo

Public Member Functions

- wxGenericAboutDialog ()

Default constructor, Create() must be called later.

- wxGenericAboutDialog (const wxAboutDialogInfo &info, wxWindow *parent=NULL)

  Creates the dialog and initializes it with the given information.

- bool Create (const wxAboutDialogInfo &info, wxWindow *parent=NULL)

  Initializes the dialog created using the default constructor.

Protected Member Functions

- virtual void DoAddCustomControls ()

  This virtual method may be overridden to add more controls to the dialog.

- void AddControl (wxWindow *win, const wxSizerFlags &flags)

  Add arbitrary control to the sizer content with the specified flags.

- void AddControl (wxWindow *win)

  Add arbitrary control to the sizer content and centre it.

- void AddText (const wxString &text)

  Add the given (not empty) text to the sizer content.

- void AddCollapsiblePane (const wxString &title, const wxString &text)

  Add a wxCollapsiblePane containing the given text.

21.281.2 Constructor & Destructor Documentation

wxGenericAboutDialog::wxGenericAboutDialog ( )

Default constructor, Create() must be called later.

wxGenericAboutDialog::wxGenericAboutDialog (const wxAboutDialogInfo & *info*, wxWindow * *parent* = NULL)

Creates the dialog and initializes it with the given information.

21.281.3 Member Function Documentation

void wxGenericAboutDialog::AddCollapsiblePane (const wxString & *title*, const wxString & *text*) [protected]

Add a wxCollapsiblePane containing the given text.

void wxGenericAboutDialog::AddControl (wxWindow * *win*, const wxSizerFlags & *flags*) [protected]

Add arbitrary control to the sizer content with the specified flags.

For example, here is how to add an expandable line with a border of 3 pixels, then a line of text:

```
AddControl(new wxStaticLine(this), wxSizerFlags().Expand().Border(
      wxALL, 3));

AddText(_("This line is just an example of custom text."));
```

void wxGenericAboutDialog::AddControl (wxWindow * *win*) [protected]

Add arbitrary control to the sizer content and centre it.

void wxGenericAboutDialog::AddText (const wxString & *text*) `[protected]`

Add the given (not empty) text to the sizer content.

bool wxGenericAboutDialog::Create (const wxAboutDialogInfo & *info*, wxWindow * *parent* = NULL)

Initializes the dialog created using the default constructor.

virtual void wxGenericAboutDialog::DoAddCustomControls ( ) `[inline], [protected], [virtual]`

This virtual method may be overridden to add more controls to the dialog.

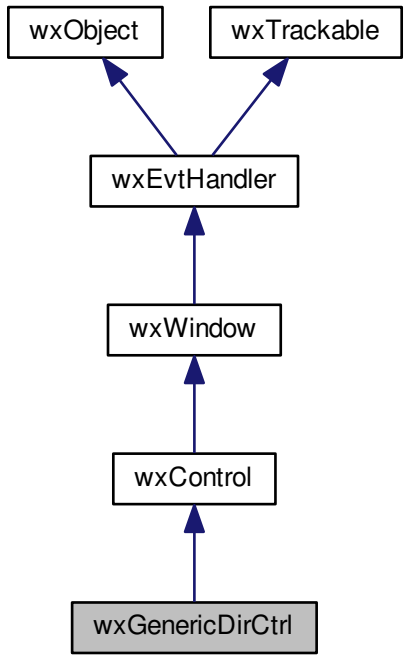
Use the protected AddControl(), AddText() and AddCollapsiblePane() methods to add custom controls.

This method is called during the dialog creation and you don't need to call it, only to override it.

21.282 wxGenericDirCtrl Class Reference

`#include <wx/dirctrl.h>`

Inheritance diagram for wxGenericDirCtrl:



21.282.1 Detailed Description

This control can be used to place a directory listing (with optional files) on an arbitrary window.

The control contains a wxTreeCtrl window representing the directory hierarchy, and optionally, a wxChoice window containing a list of filters.

Styles

This class supports the following styles:

- wxDIRCTRL_DIR_ONLY: Only show directories, and not files.
- wxDIRCTRL_3D_INTERNAL: Use 3D borders for internal controls. This is the default.
- wxDIRCTRL_SELECT_FIRST: When setting the default path, select the first file in the directory.
- wxDIRCTRL_SHOW_FILTERS: Show the drop-down filter list.
- wxDIRCTRL_EDIT_LABELS: Allow the folder and file labels to be editable.
- wxDIRCTRL_MULTIPLE: Allows multiple files and folders to be selected.

Library: wxCore

Category: Controls

Events emitted by this class

Event macros for events emitted by this class:

- EVT_DIRCTRL_SELECTIONCHANGED(id, func): Selected directory has changed. Processes a `wxEVT_DIRCTRL_SELECTIONCHANGED` event type. Notice that this event is generated even for the changes done by the program itself and not only those done by the user. Available since wxWidgets 2.9.5.
- EVT_DIRCTRL_FILEACTIVATED(id, func): The user activated a file by double-clicking or pressing Enter. Available since wxWidgets 2.9.5.

Public Member Functions

- wxGenericDirCtrl ()

  Default constructor.
- wxGenericDirCtrl (wxWindow *parent, const wxWindowID id=wxID_ANY, const wxString &dir=wxDirDialogDefaultFolderStr, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, long style=wxDIRCTRL_DEFAULT_STYLE, const wxString &filter=wxEmptyString, int defaultFilter=0, const wxString &name=wxTreeCtrlNameStr)

  Main constructor.
- virtual ~wxGenericDirCtrl ()

  Destructor.
- virtual bool CollapsePath (const wxString &path)

  Collapse the given path.
- virtual void CollapseTree ()

  Collapses the entire tree.
- bool Create (wxWindow *parent, const wxWindowID id=wxID_ANY, const wxString &dir=wxDirDialogDefaultFolderStr, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, long style=wxDIRCTRL_DEFAULT_STYLE, const wxString &filter=wxEmptyString, int defaultFilter=0, const wxString &name=wxTreeCtrlNameStr)

Create function for two-step construction.

- virtual bool ExpandPath (const wxString &path)

  Tries to expand as much of the given path as possible, so that the filename or directory is visible in the tree control.
- virtual wxString GetDefaultPath () const

  Gets the default path.
- virtual wxString GetFilePath () const

  Gets selected filename path only (else empty string).
- virtual void GetFilePaths (wxArrayString &paths) const

  Fills the array paths with the currently selected filepaths.
- virtual wxString GetFilter () const

  Returns the filter string.
- virtual int GetFilterIndex () const

  Returns the current filter index (zero-based).
- virtual wxDirFilterListCtrl * GetFilterListCtrl () const

  Returns a pointer to the filter list control (if present).
- virtual wxString GetPath () const

  Gets the currently-selected directory or filename.
- wxString GetPath (wxTreeItemId itemId) const

  Gets the path corresponding to the given tree control item.
- virtual void GetPaths (wxArrayString &paths) const

  Fills the array paths with the selected directories and filenames.
- virtual wxTreeItemId GetRootId ()

  Returns the root id for the tree control.
- virtual wxTreeCtrl * GetTreeCtrl () const

  Returns a pointer to the tree control.
- virtual void Init ()

  Initializes variables.
- virtual void ReCreateTree ()

  Collapse and expand the tree, thus re-creating it from scratch.
- virtual void SetDefaultPath (const wxString &path)

  Sets the default path.
- virtual void SetFilter (const wxString &filter)

  Sets the filter string.
- virtual void SetFilterIndex (int n)

  Sets the current filter index (zero-based).
- virtual void SetPath (const wxString &path)

  Sets the current path.
- virtual void ShowHidden (bool show)
- virtual void SelectPath (const wxString &path, bool select=true)

  Selects the given item.
- virtual void SelectPaths (const wxArrayString &paths)

  Selects only the specified paths, clearing any previous selection.
- virtual void UnselectAll ()

  Removes the selection from all currently selected items.

Additional Inherited Members

21.282.2 Constructor & Destructor Documentation

wxGenericDirCtrl::wxGenericDirCtrl ( )

Default constructor.

wxGenericDirCtrl::wxGenericDirCtrl (wxWindow * *parent*, const wxWindowID *id* = wxID_ANY, const wxString & *dir* = wxDirDialogDefaultFolderStr, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, long *style* = wxDIRCTRL_DEFAULT_STYLE, const wxString & *filter* = wxEmptyString, int *defaultFilter* = 0, const wxString & *name* = wxTreeCtrlNameStr)

Main constructor.

Parameters

parent	Parent window.
id	Window identifier.
dir	Initial folder.
pos	Position.
size	Size.
style	Window style. Please see wxGenericDirCtrl for a list of possible styles.
filter	A filter string, using the same syntax as that for wxFileDialog. This may be empty if filters are not being used. Example: `"All files (*.*)|*.*|JPEG files (*.jpg)|*.jpg"`
defaultFilter	The zero-indexed default filter setting.
name	The window name.

virtual wxGenericDirCtrl::~wxGenericDirCtrl ( ) [virtual]

Destructor.

21.282.3 Member Function Documentation

virtual bool wxGenericDirCtrl::CollapsePath (const wxString & *path*) [virtual]

Collapse the given *path*.

virtual void wxGenericDirCtrl::CollapseTree ( ) [virtual]

Collapses the entire tree.

bool wxGenericDirCtrl::Create (wxWindow * *parent*, const wxWindowID *id* = wxID_ANY, const wxString & *dir* = wxDirDialogDefaultFolderStr, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, long *style* = wxDIRCTRL_DEFAULT_STYLE, const wxString & *filter* = wxEmptyString, int *defaultFilter* = 0, const wxString & *name* = wxTreeCtrlNameStr)

Create function for two-step construction.

See wxGenericDirCtrl() for details.

virtual bool wxGenericDirCtrl::ExpandPath (const wxString & *path*) [virtual]

Tries to expand as much of the given *path* as possible, so that the filename or directory is visible in the tree control.

virtual wxString wxGenericDirCtrl::GetDefaultPath ( ) const [virtual]

Gets the default path.

virtual wxString wxGenericDirCtrl::GetFilePath ( ) const [virtual]

Gets selected filename path only (else empty string).

This function doesn't count a directory as a selection.

virtual void wxGenericDirCtrl::GetFilePaths (wxArrayString & *paths*) const [virtual]

Fills the array *paths* with the currently selected filepaths.

This function doesn't count a directory as a selection.

virtual wxString wxGenericDirCtrl::GetFilter ( ) const [virtual]

Returns the filter string.

virtual int wxGenericDirCtrl::GetFilterIndex ( ) const [virtual]

Returns the current filter index (zero-based).

virtual wxDirFilterListCtrl* wxGenericDirCtrl::GetFilterListCtrl ( ) const [virtual]

Returns a pointer to the filter list control (if present).

virtual wxString wxGenericDirCtrl::GetPath ( ) const [virtual]

Gets the currently-selected directory or filename.

wxString wxGenericDirCtrl::GetPath (wxTreeItemId *itemId*) const

Gets the path corresponding to the given tree control item.

Since

2.9.5

virtual void wxGenericDirCtrl::GetPaths (wxArrayString & *paths*) const [virtual]

Fills the array *paths* with the selected directories and filenames.

virtual wxTreeItemId wxGenericDirCtrl::GetRootId ( ) [virtual]

Returns the root id for the tree control.

virtual wxTreeCtrl* wxGenericDirCtrl::GetTreeCtrl ( ) const [virtual]

Returns a pointer to the tree control.

virtual void wxGenericDirCtrl::Init ( ) [virtual]

Initializes variables.

virtual void wxGenericDirCtrl::ReCreateTree ( ) [virtual]

Collapse and expand the tree, thus re-creating it from scratch.

May be used to update the displayed directory content.

virtual void wxGenericDirCtrl::SelectPath (const wxString & *path,* bool *select* = true) [virtual]

Selects the given item.

In multiple selection controls, can be also used to deselect a currently selected item if the value of *select* is false. Existing selections are not changed. Only visible items can be (de)selected, otherwise use ExpandPath().

virtual void wxGenericDirCtrl::SelectPaths (const wxArrayString & *paths*) [virtual]

Selects only the specified paths, clearing any previous selection.

Only supported when wxDIRCTRL_MULTIPLE is set.

virtual void wxGenericDirCtrl::SetDefaultPath (const wxString & *path*) [virtual]

Sets the default path.

virtual void wxGenericDirCtrl::SetFilter (const wxString & *filter*) [virtual]

Sets the filter string.

virtual void wxGenericDirCtrl::SetFilterIndex (int *n*) [virtual]

Sets the current filter index (zero-based).

virtual void wxGenericDirCtrl::SetPath (const wxString & *path*) [virtual]

Sets the current path.

virtual void wxGenericDirCtrl::ShowHidden (bool *show*) [virtual]

Parameters

show	If true, hidden folders and files will be displayed by the control. If false, they will not be displayed.

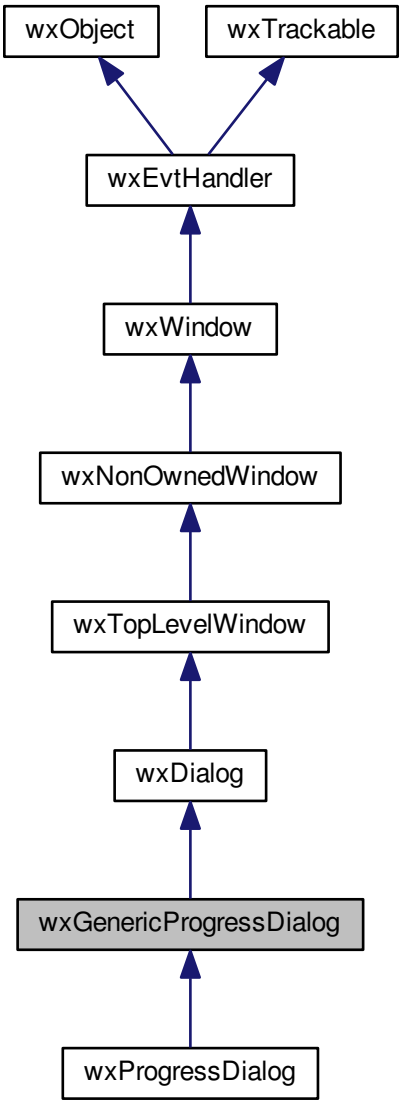
virtual void wxGenericDirCtrl::UnselectAll ( ) [virtual]

Removes the selection from all currently selected items.

21.283 wxGenericProgressDialog Class Reference

```
#include <wx/progdlg.h>
```

Inheritance diagram for wxGenericProgressDialog:



21.283.1 Detailed Description

This class represents a dialog that shows a short message and a progress bar.

Optionally, it can display ABORT and SKIP buttons, and the elapsed, remaining and estimated time for the end of the progress.

This class provides a generic implementation of the progress dialog. If the platform has a native progress dialog available then it will be accessible using the *wxProgressDialog* class, otherwise it will essentially be the same as this class.

Note that you must be aware that wxProgressDialog internally calls wxEventLoopBase::YieldFor with `wxEVT_CATEGORY_UI` and `wxEVT_CATEGORY_USER_INPUT` and this may cause unwanted re-entrancies or the out-of-order processing of pending events (to help preventing the last problem if you're using wxProgressDialog in

a multi-threaded application you should be sure to use wxThreadEvent for your inter-threads communications).

Styles

This class supports the following styles:

- wxPD_APP_MODAL: Make the progress dialog modal. If this flag is not given, it is only "locally" modal - that is the input to the parent window is disabled, but not to the other ones.
- wxPD_AUTO_HIDE: Causes the progress dialog to disappear from screen as soon as the maximum value of the progress meter has been reached. If this style is not present, the dialog will become a modal dialog (see wxDialog::ShowModal) once the maximum value has been reached and wait for the user to dismiss it.
- wxPD_SMOOTH: Causes smooth progress of the gauge control (uses a wxGauge with the `wxGA_SMOOTH` style).
- wxPD_CAN_ABORT: This flag tells the dialog that it should have a "Cancel" button which the user may press. If this happens, the next call to Update() will return false.
- wxPD_CAN_SKIP: This flag tells the dialog that it should have a "Skip" button which the user may press. If this happens, the next call to Update() will return true in its skip parameter.
- wxPD_ELAPSED_TIME: This flag tells the dialog that it should show elapsed time (since creating the dialog).
- wxPD_ESTIMATED_TIME: This flag tells the dialog that it should show estimated time.
- wxPD_REMAINING_TIME: This flag tells the dialog that it should show remaining time.

Library: wxCore

Category: Common Dialogs

Public Member Functions

- wxGenericProgressDialog (const wxString &title, const wxString &message, int maximum=100, wxWindow *parent=NULL, int style=wxPD_AUTO_HIDE|wxPD_APP_MODAL)

  Constructor.
- virtual ~wxGenericProgressDialog ()

  Destructor.
- int GetValue () const

  Returns the last value passed to the Update() function or `wxNOT_FOUND` if the dialog has no progress bar.
- int GetRange () const

  Returns the maximum value of the progress meter, as passed to the constructor or `wxNOT_FOUND` if the dialog has no progress bar.
- wxString GetMessage () const

  Returns the last message passed to the Update() function; if you always passed wxEmptyString to Update() then the message set through the constructor is returned.
- virtual bool Pulse (const wxString &newmsg=wxEmptyString, bool *skip=NULL)

  Like Update() but makes the gauge control run in indeterminate mode.
- void Resume ()

  Can be used to continue with the dialog, after the user had clicked the "Abort" button.
- void SetRange (int maximum)

  Changes the maximum value of the progress meter given in the constructor.
- bool WasCancelled () const

Returns true if the "Cancel" button was pressed.

- bool WasSkipped () const

  Returns true if the "Skip" button was pressed.

- virtual bool Update (int value, const wxString &newmsg=wxEmptyString, bool *skip=NULL)

  Updates the dialog, setting the progress bar to the new value and updating the message if new one is specified.

Additional Inherited Members

21.283.2 Constructor & Destructor Documentation

wxGenericProgressDialog::wxGenericProgressDialog (const wxString & *title*, const wxString & *message*, int *maximum* = 100, wxWindow * *parent* = NULL, int *style* = wxPD_AUTO_HIDE|wxPD_APP_MODAL)

Constructor.

Creates the dialog, displays it and disables user input for other windows, or, if wxPD_APP_MODAL flag is not given, for its parent window only.

Parameters

title	Dialog title to show in titlebar.
message	Message displayed above the progress bar.
maximum	Maximum value for the progress bar. In the generic implementation the progress bar is constructed only if this value is greater than zero.
parent	Parent window.
style	The dialog style. See wxProgressDialog.

virtual wxGenericProgressDialog::~wxGenericProgressDialog ( ) [virtual]

Destructor.

Deletes the dialog and enables all top level windows.

21.283.3 Member Function Documentation

wxString wxGenericProgressDialog::GetMessage ( ) const

Returns the last message passed to the Update() function; if you always passed wxEmptyString to Update() then the message set through the constructor is returned.

Since

2.9.0

int wxGenericProgressDialog::GetRange ( ) const

Returns the maximum value of the progress meter, as passed to the constructor or wxNOT_FOUND if the dialog has no progress bar.

Since

2.9.0

int wxGenericProgressDialog::GetValue ( ) const

Returns the last value passed to the Update() function or `wxNOT_FOUND` if the dialog has no progress bar.

Since

2.9.0

virtual bool wxGenericProgressDialog::Pulse (const wxString & *newmsg* = wxEmptyString, bool * *skip* = `NULL`) `[virtual]`

Like Update() but makes the gauge control run in indeterminate mode.

In indeterminate mode the remaining and the estimated time labels (if present) are set to "Unknown" or to *newmsg* (if it's non-empty). Each call to this function moves the progress bar a bit to indicate that some progress was done.

See also

wxGauge::Pulse(), Update()

void wxGenericProgressDialog::Resume ( )

Can be used to continue with the dialog, after the user had clicked the "Abort" button.

void wxGenericProgressDialog::SetRange (int *maximum*)

Changes the maximum value of the progress meter given in the constructor.

This function can only be called (with a positive value) if the value passed in the constructor was positive.

Since

2.9.1

virtual bool wxGenericProgressDialog::Update (int *value*, const wxString & *newmsg* = wxEmptyString, bool * *skip* = `NULL`) `[virtual]`

Updates the dialog, setting the progress bar to the new value and updating the message if new one is specified.

Returns true unless the "Cancel" button has been pressed.

If false is returned, the application can either immediately destroy the dialog or ask the user for the confirmation and if the abort is not confirmed the dialog may be resumed with Resume() function.

If *value* is the maximum value for the dialog, the behaviour of the function depends on whether `wxPD_AUTO_HIDE` was used when the dialog was created. If it was, the dialog is hidden and the function returns immediately. If it was not, the dialog becomes a modal dialog and waits for the user to dismiss it, meaning that this function does not return until this happens.

Notice that you may want to call Fit() to change the dialog size to conform to the length of the new message if desired. The dialog does not do this automatically.

Parameters

value	The new value of the progress meter. It should be less than or equal to the maximum value given to the constructor.
newmsg	The new messages for the progress dialog text, if it is empty (which is the default) the message is not changed.
skip	If "Skip" button was pressed since last Update() call, this is set to true.

bool wxGenericProgressDialog::WasCancelled ( ) const

Returns true if the "Cancel" button was pressed.

Normally a Cancel button press is indicated by Update() returning false but sometimes it may be more convenient to check if the dialog was cancelled from elsewhere in the code and this function allows to do it.

It always returns false if the Cancel button is not shown at all.

Since

2.9.1

bool wxGenericProgressDialog::WasSkipped ( ) const

Returns true if the "Skip" button was pressed.

This is similar to WasCancelled() but returns true if the "Skip" button was pressed, not the "Cancel" one.

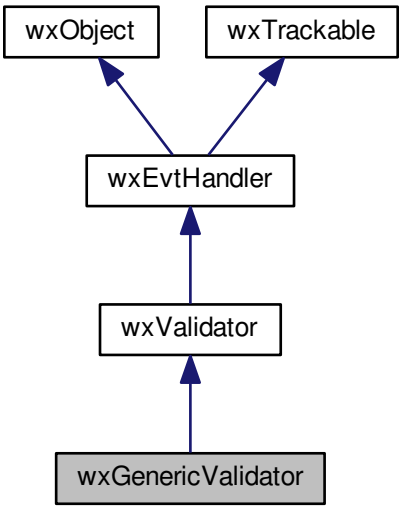
Since

2.9.1

21.284 wxGenericValidator Class Reference

`#include <wx/valgen.h>`

Inheritance diagram for wxGenericValidator:



21.284.1 Detailed Description

wxGenericValidator performs data transfer (but not validation or filtering) for many type of controls.

wxGenericValidator supports:

- wxButton, wxRadioButton, wxToggleButton, wxBitmapToggleButton, wxSpinButton
- wxCheckBox, wxRadioBox, wxComboBox, wxListBox, wxCheckListBox
- wxGauge, wxSlider, wxScrollBar, wxChoice, wxStaticText
- wxSpinCtrl, wxTextCtrl

It checks the type of the window and uses an appropriate type for it. For example, wxButton and wxTextCtrl transfer data to and from a wxString variable; wxListBox uses a wxArrayInt; wxCheckBox uses a boolean.

For more information, please see wxValidator Overview.

Library: wxCore

Category: Validators

See also

wxValidator Overview, wxValidator, wxTextValidator, wxIntegerValidator, wxFloatingPointValidator

Public Member Functions

- wxGenericValidator (const wxGenericValidator &validator)

Copy constructor.

- wxGenericValidator (bool ∗valPtr)

  Constructor taking a bool pointer.
- wxGenericValidator (wxString ∗valPtr)

  Constructor taking a wxString pointer.
- wxGenericValidator (int ∗valPtr)

  Constructor taking an integer pointer.
- wxGenericValidator (wxArrayInt ∗valPtr)

  Constructor taking a wxArrayInt pointer.
- wxGenericValidator (wxDateTime ∗valPtr)

  Constructor taking a wxDateTime pointer.
- wxGenericValidator (wxFileName ∗valPtr)

  Constructor taking a wxFileName pointer.
- wxGenericValidator (float ∗valPtr)

  Constructor taking a float pointer.
- wxGenericValidator (double ∗valPtr)

  Constructor taking a double pointer.
- virtual ∼wxGenericValidator ()

  Destructor.
- virtual wxObject ∗ Clone () const

  Clones the generic validator using the copy constructor.
- virtual bool TransferFromWindow ()

  Transfers the value from the window to the appropriate data type.
- virtual bool TransferToWindow ()

  Transfers the value to the window.

Additional Inherited Members

21.284.2 Constructor & Destructor Documentation

wxGenericValidator::wxGenericValidator (const wxGenericValidator & *validator*)

Copy constructor.

Parameters

validator	Validator to copy.

wxGenericValidator::wxGenericValidator (bool ∗ *valPtr*)

Constructor taking a bool pointer.

This will be used for wxCheckBox, wxRadioButton, wxToggleButton and wxBitmapToggleButton.

Parameters

valPtr	A pointer to a variable that contains the value. This variable should have a lifetime equal to or longer than the validator lifetime (which is usually determined by the lifetime of the window).

wxGenericValidator::wxGenericValidator (wxString ∗ *valPtr*)

Constructor taking a wxString pointer.

This will be used for wxButton, wxComboBox, wxStaticText, wxTextCtrl.

Parameters

valPtr	A pointer to a variable that contains the value. This variable should have a lifetime equal to or longer than the validator lifetime (which is usually determined by the lifetime of the window).

wxGenericValidator::wxGenericValidator (int * *valPtr*)

Constructor taking an integer pointer.

This will be used for wxChoice, wxGauge, wxScrollBar, wxRadioBox, wxSlider, wxSpinButton and wxSpinCtrl.

Parameters

valPtr	A pointer to a variable that contains the value. This variable should have a lifetime equal to or longer than the validator lifetime (which is usually determined by the lifetime of the window).

wxGenericValidator::wxGenericValidator (wxArrayInt * *valPtr*)

Constructor taking a wxArrayInt pointer.

This will be used for wxListBox, wxCheckListBox.

Parameters

valPtr	A pointer to a variable that contains the value. This variable should have a lifetime equal to or longer than the validator lifetime (which is usually determined by the lifetime of the window).

wxGenericValidator::wxGenericValidator (wxDateTime * *valPtr*)

Constructor taking a wxDateTime pointer.

This will be used for wxDatePickerCtrl.

Parameters

valPtr	A pointer to a variable that contains the value. This variable should have a lifetime equal to or longer than the validator lifetime (which is usually determined by the lifetime of the window).

wxGenericValidator::wxGenericValidator (wxFileName * *valPtr*)

Constructor taking a wxFileName pointer.

This will be used for wxTextCtrl.

Parameters

valPtr	A pointer to a variable that contains the value. This variable should have a lifetime equal to or longer than the validator lifetime (which is usually determined by the lifetime of the window).

Since

2.9.3

wxGenericValidator::wxGenericValidator (float * *valPtr*)

Constructor taking a float pointer.

This will be used for wxTextCtrl.

Parameters

valPtr	A pointer to a variable that contains the value. This variable should have a lifetime equal to or longer than the validator lifetime (which is usually determined by the lifetime of the window).

Since

2.9.3

wxGenericValidator::wxGenericValidator (double * *valPtr*)

Constructor taking a double pointer.

This will be used for wxTextCtrl.

Parameters

valPtr	A pointer to a variable that contains the value. This variable should have a lifetime equal to or longer than the validator lifetime (which is usually determined by the lifetime of the window).

Since

2.9.3

virtual wxGenericValidator::~wxGenericValidator ( ) [virtual]

Destructor.

21.284.3 Member Function Documentation

virtual wxObject* wxGenericValidator::Clone ( ) const [virtual]

Clones the generic validator using the copy constructor.

Reimplemented from wxValidator.

virtual bool wxGenericValidator::TransferFromWindow ( ) [virtual]

Transfers the value from the window to the appropriate data type.

Reimplemented from wxValidator.

virtual bool wxGenericValidator::TransferToWindow ( ) [virtual]

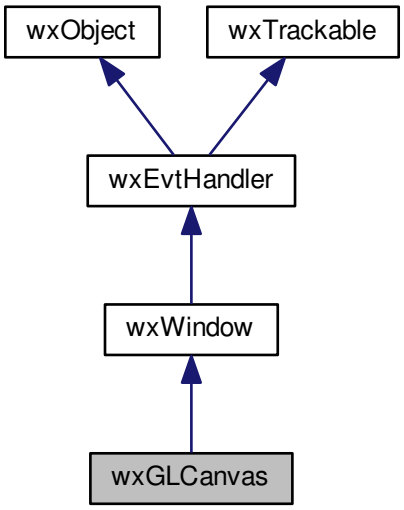
Transfers the value to the window.

Reimplemented from wxValidator.

21.285 wxGLCanvas Class Reference

```
#include <wx/glcanvas.h>
```

Inheritance diagram for wxGLCanvas:



21.285.1 Detailed Description

wxGLCanvas is a class for displaying OpenGL graphics.

It is always used in conjunction with wxGLContext as the context can only be made current (i.e. active for the OpenGL commands) when it is associated to a wxGLCanvas.

More precisely, you first need to create a wxGLCanvas window and then create an instance of a wxGLContext that is initialized with this wxGLCanvas and then later use either SetCurrent() with the instance of the wxGLContext or wxGLContext::SetCurrent() with the instance of the wxGLCanvas (which might be not the same as was used for the creation of the context) to bind the OpenGL state that is represented by the rendering context to the canvas, and then finally call SwapBuffers() to swap the buffers of the OpenGL canvas and thus show your current output.

Notice that versions of wxWidgets previous to 2.9 used to implicitly create a wxGLContext inside wxGLCanvas itself. This is still supported in the current version but is deprecated now and will be removed in the future, please update your code to create the rendering contexts explicitly.

To set up the attributes for the canvas (number of bits for the depth buffer, number of bits for the stencil buffer and so on) you should set up the correct values of the *attribList* parameter. The values that should be set up and their meanings will be described below.

Note

On those platforms which use a configure script (e.g. Linux and Mac OS) OpenGL support is automatically enabled if the relative headers and libraries are found. To switch it on under the other platforms (e.g. Windows), you need to edit the `setup.h` file and set `wxUSE_GLCANVAS` to `1` and then also pass `USE_OPENGL=1` to the make utility. You may also need to add `opengl32.lib` and `glu32.lib` to the list of the libraries your program is linked with.

Library: wxGL

Category: OpenGL

See also

wxGLContext

Public Member Functions

- wxGLCanvas (wxWindow *parent, wxWindowID id=wxID_ANY, const int *attribList=NULL, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, long style=0, const wxString &name="GL↩ Canvas", const wxPalette &palette=wxNullPalette)

  Creates a window with the given parameters.
- bool SetColour (const wxString &colour)

  Sets the current colour for this window (using `glcolor3f()`), using the wxWidgets colour database to find a named colour.
- bool SetCurrent (const wxGLContext &context) const

  Makes the OpenGL state that is represented by the OpenGL rendering context context current, i.e.
- virtual bool SwapBuffers ()

  Swaps the double-buffer of this window, making the back-buffer the front-buffer and vice versa, so that the output of the previous OpenGL commands is displayed on the window.

Static Public Member Functions

- static bool IsDisplaySupported (const int *attribList)

  Determines if a canvas having the specified attributes is available.
- static bool IsExtensionSupported (const char *extension)

  Returns true if the extension with given name is supported.

Additional Inherited Members

21.285.2 Constructor & Destructor Documentation

wxGLCanvas::wxGLCanvas (wxWindow * *parent*, wxWindowID *id* = wxID_ANY, const int * *attribList* = `NULL`, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, long *style* = `0`, const wxString & *name* = `"GLCanvas"`, const wxPalette & *palette* = wxNullPalette)

Creates a window with the given parameters.

Notice that you need to create and use a wxGLContext to output to this window.

If *attribList* is not specified, double buffered RGBA mode is used.

Parameters

parent	Pointer to a parent window.
id	Window identifier. If -1, will automatically create an identifier.
pos	Window position. wxDefaultPosition is (-1, -1) which indicates that wxWidgets should generate a default position for the window.
size	Window size. wxDefaultSize is (-1, -1) which indicates that wxWidgets should generate a default size for the window. If no suitable size can be found, the window will be sized to 20x20 pixels so that the window is visible but obviously not correctly sized.
style	Window style.
name	Window name.

attribList	Array of integers. With this parameter you can set the device context attributes associated to this window. This array is zero-terminated: it should be set up using wxGL_FLAGS constants. If a constant should be followed by a value, put it in the next array position. For example, WX_GL_DEPTH_SIZE should be followed by the value that indicates the number of bits for the depth buffer, e.g.:
	`attribList[n++] = WX_GL_DEPTH_SIZE;`
	`attribList[n++] = 32;`
	`attribList[n] = 0; // terminate the list`
	If the attribute list is not specified at all, i.e. if this parameter is NULL, the default attributes including WX_GL_RGBA and WX_GL_DOUBLEBUFFER are used. But notice that if you do specify some attributes you also need to explicitly include these two default attributes in the list if you need them.

palette	Palette for indexed colour (i.e. non WX_GL_RGBA) mode. Ignored under most platforms.

21.285.3 Member Function Documentation

static bool wxGLCanvas::IsDisplaySupported (const int * *attribList*) [static]

Determines if a canvas having the specified attributes is available.

Parameters

attribList	See *attribList* for wxGLCanvas().

Returns

true if attributes are supported.

static bool wxGLCanvas::IsExtensionSupported (const char * *extension*) [static]

Returns true if the extension with given name is supported.

Notice that while this function is implemented for all of GLX, WGL and AGL the extensions names are usually not the same for different platforms and so the code using it still usually uses conditional compilation.

bool wxGLCanvas::SetColour (const wxString & *colour*)

Sets the current colour for this window (using `glcolor3f()`), using the wxWidgets colour database to find a named colour.

bool wxGLCanvas::SetCurrent (const wxGLContext & *context*) const

Makes the OpenGL state that is represented by the OpenGL rendering context *context* current, i.e.

it will be used by all subsequent OpenGL calls.

This is equivalent to wxGLContext::SetCurrent() called with this window as parameter.

Note

This function may only be called when the window is shown on screen, in particular it can't usually be called from the constructor as the window isn't yet shown at this moment.

Returns

false if an error occurred.

virtual bool wxGLCanvas::SwapBuffers ( ) [virtual]

Swaps the double-buffer of this window, making the back-buffer the front-buffer and vice versa, so that the output of the previous OpenGL commands is displayed on the window.

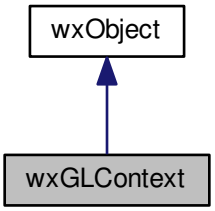
Returns

false if an error occurred.

21.286 wxGLContext Class Reference

`#include <wx/glcanvas.h>`

Inheritance diagram for wxGLContext:



21.286.1 Detailed Description

An instance of a wxGLContext represents the state of an OpenGL state machine and the connection between OpenGL and the system.

The OpenGL state includes everything that can be set with the OpenGL API: colors, rendering variables, display lists, texture objects, etc. Although it is possible to have multiple rendering contexts share display lists in order to save resources, this method is hardly used today any more, because display lists are only a tiny fraction of the overall state.

Therefore, one rendering context is usually used with or bound to multiple output windows in turn, so that the application has access to the complete and identical state while rendering into each window.

Binding (making current) a rendering context with another instance of a wxGLCanvas however works only if the other wxGLCanvas was created with the same attributes as the wxGLCanvas from which the wxGLContext was initialized. (This applies to sharing display lists among contexts analogously.)

Note that some wxGLContext features are extremely platform-specific - its best to check your native platform's glcanvas header (on windows include/wx/msw/glcanvas.h) to see what features your native platform provides.

wxHAS_OPENGL_ES is defined on platforms that only have this implementation available (eg the iPhone) und don't support the full specification.

Library: wxGL

Category: OpenGL

wxGLCanvas

Public Member Functions

- wxGLContext (wxGLCanvas *win, const wxGLContext *other=NULL)

  Constructor.

- virtual bool SetCurrent (const wxGLCanvas &win) const

  Makes the OpenGL state that is represented by this rendering context current with the wxGLCanvas win.

Additional Inherited Members

21.286.2 Constructor & Destructor Documentation

wxGLContext::wxGLContext (wxGLCanvas * *win,* const wxGLContext * *other* = NULL)

Constructor.

Parameters

win	The canvas that is used to initialize this context. This parameter is needed only temporarily, and the caller may do anything with it (e.g. destroy the window) after the constructor returned. It will be possible to bind (make current) this context to any other wxGLCanvas that has been created with equivalent attributes as win.
other	Context to share display lists with or NULL (the default) for no sharing.

21.286.3 Member Function Documentation

virtual bool wxGLContext::SetCurrent (const wxGLCanvas & *win*) const [virtual]

Makes the OpenGL state that is represented by this rendering context current with the wxGLCanvas *win*.

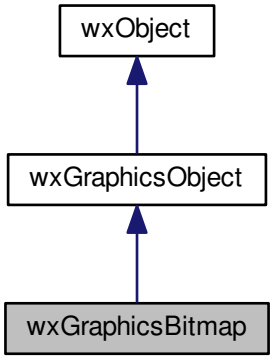
Note

win can be a different wxGLCanvas window than the one that was passed to the constructor of this rendering context. If *RC* is an object of type wxGLContext, the statements *"RC.SetCurrent(win);"* and *"win.SetCurrent(RC);"* are equivalent, see wxGLCanvas::SetCurrent().

21.287 wxGraphicsBitmap Class Reference

`#include <wx/graphics.h>`

Inheritance diagram for wxGraphicsBitmap:



21.287.1 Detailed Description

Represents a bitmap.

The objects of this class are not created directly but only via wxGraphicsContext or wxGraphicsRenderer CreateBitmap(), CreateBitmapFromImage() or CreateSubBitmap() methods. They can subsequently be used with wxGraphicsContext::DrawBitmap(). The only other operation is testing for the bitmap validity which can be performed using IsNull() method inherited from the base class.

Public Member Functions

- wxGraphicsBitmap ()

  Default constructor creates an invalid bitmap.
- wxImage ConvertToImage () const

  Return the contents of this bitmap as wxImage.
- void * GetNativeBitmap () const

  Return the pointer to the native bitmap data.

Additional Inherited Members

21.287.2 Constructor & Destructor Documentation

wxGraphicsBitmap::wxGraphicsBitmap ( ) [inline]

Default constructor creates an invalid bitmap.

21.287.3 Member Function Documentation

wxImage wxGraphicsBitmap::ConvertToImage ( ) const

Return the contents of this bitmap as wxImage.

Using this method is more efficient than converting wxGraphicsBitmap to wxBitmap first and then to wxImage and can be useful if, for example, you want to save wxGraphicsBitmap as a disk file in a format not directly supported by wxBitmap.

Invalid image is returned if the bitmap is invalid.

Since

2.9.3

void* wxGraphicsBitmap::GetNativeBitmap ( ) const

Return the pointer to the native bitmap data.

(CGImageRef for Core Graphics, cairo_surface_t for Cairo, Bitmap* for GDI+.)

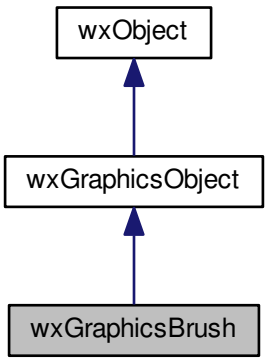
Since

2.9.4

21.288 wxGraphicsBrush Class Reference

`#include <wx/graphics.h>`

Inheritance diagram for wxGraphicsBrush:



21.288.1 Detailed Description

A wxGraphicsBrush is a native representation of a brush.

The contents are specific and private to the respective renderer. Instances are ref counted and can therefore be assigned as usual. The only way to get a valid instance is via wxGraphicsContext::CreateBrush() or wxGraphicsRenderer::CreateBrush().

Library: wxCore

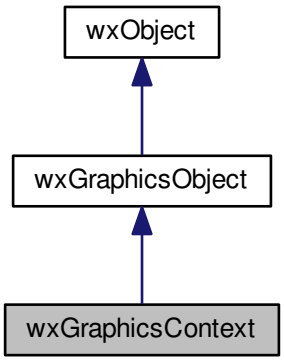
Category: Graphics Device Interface (GDI)

Additional Inherited Members

21.289 wxGraphicsContext Class Reference

`#include <wx/graphics.h>`

Inheritance diagram for wxGraphicsContext:



21.289.1 Detailed Description

A wxGraphicsContext instance is the object that is drawn upon.

It is created by a renderer using wxGraphicsRenderer::CreateContext(). This can be either directly using a renderer instance, or indirectly using the static convenience Create() functions of wxGraphicsContext that always delegate the task to the default renderer.

```
void MyCanvas::OnPaint(wxPaintEvent &event)
{
    // Create paint DC
    wxPaintDC dc(this);

    // Create graphics context from it
    wxGraphicsContext *gc = wxGraphicsContext::Create( dc );

    if (gc)
    {
```

```
        // make a path that contains a circle and some lines
        gc->SetPen( *wxRED_PEN );
        wxGraphicsPath path = gc->CreatePath();
        path.AddCircle( 50.0, 50.0, 50.0 );
        path.MoveToPoint(0.0, 50.0);
        path.AddLineToPoint(100.0, 50.0);
        path.MoveToPoint(50.0, 0.0);
        path.AddLineToPoint(50.0, 100.0 );
        path.CloseSubpath();
        path.AddRectangle(25.0, 25.0, 50.0, 50.0);

        gc->StrokePath(path);

        delete gc;
    }
}
```

Public Member Functions

- virtual void Clip (const wxRegion &region)=0

  Clips drawings to the specified region.
- virtual void Clip (wxDouble x, wxDouble y, wxDouble w, wxDouble h)=0

  Clips drawings to the specified rectangle.
- virtual void ConcatTransform (const wxGraphicsMatrix &matrix)=0

  Concatenates the passed in transform with the current transform of this context.
- virtual wxGraphicsBitmap CreateBitmap (const wxBitmap &bitmap)=0

  Creates wxGraphicsBitmap from an existing wxBitmap.
- virtual wxGraphicsBitmap CreateBitmapFromImage (const wxImage &image)

  Creates wxGraphicsBitmap from an existing wxImage.
- virtual wxGraphicsBitmap CreateSubBitmap (const wxGraphicsBitmap &bitmap, wxDouble x, wxDouble y, wxDouble w, wxDouble h)=0

  Extracts a sub-bitmap from an existing bitmap.
- virtual wxGraphicsBrush CreateBrush (const wxBrush &brush) const

  Creates a native brush from a wxBrush.
- virtual wxGraphicsFont CreateFont (const wxFont &font, const wxColour &col=∗wxBLACK) const

  Creates a native graphics font from a wxFont and a text colour.
- virtual wxGraphicsFont CreateFont (double sizeInPixels, const wxString &facename, int flags=wxFONTFL↩AG_DEFAULT, const wxColour &col=∗wxBLACK) const

  Creates a font object with the specified attributes.
- virtual wxGraphicsMatrix CreateMatrix (wxDouble a=1.0, wxDouble b=0.0, wxDouble c=0.0, wxDouble d=1.0, wxDouble tx=0.0, wxDouble ty=0.0) const

  Creates a native affine transformation matrix from the passed in values.
- wxGraphicsMatrix CreateMatrix (const wxAffineMatrix2DBase &mat) const

  Creates a native affine transformation matrix from the passed generic one.
- wxGraphicsPath CreatePath () const

  Creates a native graphics path which is initially empty.
- virtual wxGraphicsPen CreatePen (const wxPen &pen) const

  Creates a native pen from a wxPen.
- virtual void DrawEllipse (wxDouble x, wxDouble y, wxDouble w, wxDouble h)

Draws an ellipse.

- virtual void DrawIcon (const wxIcon &icon, wxDouble x, wxDouble y, wxDouble w, wxDouble h)=0

  Draws the icon.

- virtual void DrawLines (size_t n, const wxPoint2DDouble *points, wxPolygonFillMode fillStyle=wxODDEVEN_RULE)

  Draws a polygon.

- virtual void DrawPath (const wxGraphicsPath &path, wxPolygonFillMode fillStyle=wxODDEVEN_RULE)

  Draws the path by first filling and then stroking.

- virtual void DrawRectangle (wxDouble x, wxDouble y, wxDouble w, wxDouble h)

  Draws a rectangle.

- virtual void DrawRoundedRectangle (wxDouble x, wxDouble y, wxDouble w, wxDouble h, wxDouble radius)

  Draws a rounded rectangle.

- void DrawText (const wxString &str, wxDouble x, wxDouble y)

  Draws text at the defined position.

- void DrawText (const wxString &str, wxDouble x, wxDouble y, wxDouble angle)

  Draws text at the defined position.

- void DrawText (const wxString &str, wxDouble x, wxDouble y, const wxGraphicsBrush &backgroundBrush)

  Draws text at the defined position.

- void DrawText (const wxString &str, wxDouble x, wxDouble y, wxDouble angle, const wxGraphicsBrush &backgroundBrush)

  Draws text at the defined position.

- virtual void FillPath (const wxGraphicsPath &path, wxPolygonFillMode fillStyle=wxODDEVEN_RULE)=0

  Fills the path with the current brush.

- virtual void * GetNativeContext ()=0

  Returns the native context (CGContextRef for Core Graphics, Graphics pointer for GDIPlus and cairo_t pointer for cairo).

- virtual void GetPartialTextExtents (const wxString &text, wxArrayDouble &widths) const =0

  Fills the widths array with the widths from the beginning of text to the corresponding character of text.

- virtual void GetTextExtent (const wxString &text, wxDouble *width, wxDouble *height, wxDouble *descent, wxDouble *externalLeading) const =0

  Gets the dimensions of the string using the currently selected font.

- virtual wxGraphicsMatrix GetTransform () const =0

  Gets the current transformation matrix of this context.

- virtual void ResetClip ()=0

  Resets the clipping to original shape.

- virtual void Rotate (wxDouble angle)=0

  Rotates the current transformation matrix (in radians).

- virtual void Scale (wxDouble xScale, wxDouble yScale)=0

  Scales the current transformation matrix.

- void SetBrush (const wxBrush &brush)

  Sets the brush for filling paths.

- virtual void SetBrush (const wxGraphicsBrush &brush)

  Sets the brush for filling paths.

- void SetFont (const wxFont &font, const wxColour &colour)

  Sets the font for drawing text.

- virtual void SetFont (const wxGraphicsFont &font)

  Sets the font for drawing text.

- void SetPen (const wxPen &pen)

  Sets the pen used for stroking.

- virtual void SetPen (const wxGraphicsPen &pen)

  Sets the pen used for stroking.

- virtual void SetTransform (const wxGraphicsMatrix &matrix)=0

  Sets the current transformation matrix of this context.
- virtual void StrokeLine (wxDouble x1, wxDouble y1, wxDouble x2, wxDouble y2)

  Strokes a single line.
- virtual void StrokeLines (size_t n, const wxPoint2DDouble *beginPoints, const wxPoint2DDouble *endPoints)

  Stroke disconnected lines from begin to end points, fastest method available for this purpose.
- virtual void StrokeLines (size_t n, const wxPoint2DDouble *points)

  Stroke lines connecting all the points.
- virtual void StrokePath (const wxGraphicsPath &path)=0

  Strokes along a path with the current pen.
- virtual void Translate (wxDouble dx, wxDouble dy)=0

  Translates the current transformation matrix.
- virtual void BeginLayer (wxDouble opacity)=0

  Redirects all rendering is done into a fully transparent temporary context.
- virtual void EndLayer ()=0

  Composites back the drawings into the context with the opacity given at the BeginLayer call.
- virtual bool SetAntialiasMode (wxAntialiasMode antialias)=0

  Sets the antialiasing mode, returns true if it supported.
- virtual wxAntialiasMode GetAntialiasMode () const

  Returns the current shape antialiasing mode.
- virtual bool SetInterpolationQuality (wxInterpolationQuality interpolation)=0

  Sets the interpolation quality, returns true if it is supported.
- virtual wxInterpolationQuality GetInterpolationQuality () const

  Returns the current interpolation quality.
- virtual bool SetCompositionMode (wxCompositionMode op)=0

  Sets the compositing operator, returns true if it supported.
- virtual wxCompositionMode GetCompositionMode () const

  Returns the current compositing operator.
- virtual void PushState ()=0

  Push the current state of the context's transformation matrix on a stack.
- virtual void PopState ()=0

  Pops a stored state from the stack and sets the current transformation matrix to that state.
- virtual bool ShouldOffset () const
- virtual void EnableOffset (bool enable=true)
- void DisableOffset ()
- bool OffsetEnabled ()
- virtual bool StartDoc (const wxString &message)

  Begin a new document (relevant only for printing / pdf etc.) If there is a progress dialog, message will be shown.
- virtual void EndDoc ()

  Done with that document (relevant only for printing / pdf etc.)
- virtual void StartPage (wxDouble width=0, wxDouble height=0)

  Opens a new page (relevant only for printing / pdf etc.) with the given size in points.
- virtual void EndPage ()

  Ends the current page (relevant only for printing / pdf etc.)
- virtual void Flush ()

  Make sure that the current content of this context is immediately visible.
- void GetSize (wxDouble *width, wxDouble *height) const

  Returns the size of the graphics context in device coordinates.
- virtual void GetDPI (wxDouble *dpiX, wxDouble *dpiY)

  Returns the resolution of the graphics context in device points per inch.

- wxGraphicsBrush CreateLinearGradientBrush (wxDouble x1, wxDouble y1, wxDouble x2, wxDouble y2, const wxColour &c1, const wxColour &c2) const

  Creates a native brush with a linear gradient.
- wxGraphicsBrush CreateLinearGradientBrush (wxDouble x1, wxDouble y1, wxDouble x2, wxDouble y2, const wxGraphicsGradientStops &stops) const

  Creates a native brush with a linear gradient.

- virtual wxGraphicsBrush CreateRadialGradientBrush (wxDouble xo, wxDouble yo, wxDouble xc, wxDouble yc, wxDouble radius, const wxColour &oColor, const wxColour &cColor) const

  Creates a native brush with a radial gradient.
- virtual wxGraphicsBrush CreateRadialGradientBrush (wxDouble xo, wxDouble yo, wxDouble xc, wxDouble yc, wxDouble radius, const wxGraphicsGradientStops &stops)=0

  Creates a native brush with a radial gradient.

- virtual void DrawBitmap (const wxGraphicsBitmap &bmp, wxDouble x, wxDouble y, wxDouble w, wxDouble h)=0

  Draws the bitmap.
- virtual void DrawBitmap (const wxBitmap &bmp, wxDouble x, wxDouble y, wxDouble w, wxDouble h)=0

  Draws the bitmap.

Static Public Member Functions

- static wxGraphicsContext * Create (wxWindow *window)

  Creates a wxGraphicsContext from a wxWindow.
- static wxGraphicsContext * Create (const wxWindowDC &windowDC)

  Creates a wxGraphicsContext from a wxWindowDC.
- static wxGraphicsContext * Create (const wxMemoryDC &memoryDC)

  Creates a wxGraphicsContext from a wxMemoryDC.
- static wxGraphicsContext * Create (const wxPrinterDC &printerDC)

  Creates a wxGraphicsContext from a wxPrinterDC.
- static wxGraphicsContext * Create (const wxEnhMetaFileDC &metaFileDC)

  Creates a wxGraphicsContext from a wxEnhMetaFileDC.
- static wxGraphicsContext * Create (wxImage &image)

  Creates a wxGraphicsContext associated with a wxImage.
- static wxGraphicsContext * Create ()

  Create a lightweight context that can be used only for measuring text.
- static wxGraphicsContext * CreateFromNative (void *context)

  Creates a wxGraphicsContext from a native context.
- static wxGraphicsContext * CreateFromNativeWindow (void *window)

  Creates a wxGraphicsContext from a native window.

Additional Inherited Members

21.289.2 Member Function Documentation

virtual void wxGraphicsContext::BeginLayer (wxDouble *opacity*) `[pure virtual]`

Redirects all rendering is done into a fully transparent temporary context.

virtual void wxGraphicsContext::Clip (const wxRegion & *region*) `[pure virtual]`

Clips drawings to the specified region.

virtual void wxGraphicsContext::Clip (wxDouble *x,* wxDouble *y,* wxDouble *w,* wxDouble *h*) `[pure virtual]`

Clips drawings to the specified rectangle.

virtual void wxGraphicsContext::ConcatTransform (const wxGraphicsMatrix & *matrix*) `[pure virtual]`

Concatenates the passed in transform with the current transform of this context.

static wxGraphicsContext* wxGraphicsContext::Create (wxWindow * *window*) `[static]`

Creates a wxGraphicsContext from a wxWindow.

See also

wxGraphicsRenderer::CreateContext()

static wxGraphicsContext* wxGraphicsContext::Create (const wxWindowDC & *windowDC*) `[static]`

Creates a wxGraphicsContext from a wxWindowDC.

See also

wxGraphicsRenderer::CreateContext()

static wxGraphicsContext* wxGraphicsContext::Create (const wxMemoryDC & *memoryDC*) `[static]`

Creates a wxGraphicsContext from a wxMemoryDC.

See also

wxGraphicsRenderer::CreateContext()

static wxGraphicsContext* wxGraphicsContext::Create (const wxPrinterDC & *printerDC*) `[static]`

Creates a wxGraphicsContext from a wxPrinterDC.

Under GTK+, this will only work when using the GtkPrint printing backend which is available since GTK+ 2.10.

See also

wxGraphicsRenderer::CreateContext(), Printing Under Unix (GTK+)

static wxGraphicsContext* wxGraphicsContext::Create (const wxEnhMetaFileDC & *metaFileDC*) `[static]`

Creates a wxGraphicsContext from a wxEnhMetaFileDC.

This function, as wxEnhMetaFileDC class itself, is only available only under MSW.

See also

wxGraphicsRenderer::CreateContext()

static wxGraphicsContext* wxGraphicsContext::Create (wxImage & *image*) `[static]`

Creates a wxGraphicsContext associated with a wxImage.

The image specifies the size of the context as well as whether alpha is supported (if wxImage::HasAlpha()) or not and the initial contents of the context. The *image* object must have a life time greater than that of the new context as the context copies its contents back to the image when it is destroyed.

Since

2.9.3

static wxGraphicsContext* wxGraphicsContext::Create ( ) `[static]`

Create a lightweight context that can be used only for measuring text.

virtual wxGraphicsBitmap wxGraphicsContext::CreateBitmap (const wxBitmap & *bitmap*) `[pure virtual]`

Creates wxGraphicsBitmap from an existing wxBitmap.

Returns an invalid wxNullGraphicsBitmap on failure.

virtual wxGraphicsBitmap wxGraphicsContext::CreateBitmapFromImage (const wxImage & *image*) `[virtual]`

Creates wxGraphicsBitmap from an existing wxImage.

This method is more efficient than converting wxImage to wxBitmap first and then calling CreateBitmap() but otherwise has the same effect.

Returns an invalid wxNullGraphicsBitmap on failure.

Since

2.9.3

virtual wxGraphicsBrush wxGraphicsContext::CreateBrush (const wxBrush & *brush*) const `[virtual]`

Creates a native brush from a wxBrush.

virtual wxGraphicsFont wxGraphicsContext::CreateFont (const wxFont & *font,* const wxColour & *col* = *wxBLACK) const `[virtual]`

Creates a native graphics font from a wxFont and a text colour.

virtual wxGraphicsFont wxGraphicsContext::CreateFont (double *sizeInPixels,* const wxString & *facename,* int *flags* = wxFONTFLAG_DEFAULT, const wxColour & *col* = *wxBLACK) const `[virtual]`

Creates a font object with the specified attributes.

The use of overload taking wxFont is preferred, see wxGraphicsRenderer::CreateFont() for more details.

Since

2.9.3

static wxGraphicsContext* wxGraphicsContext::CreateFromNative (void * *context*) [static]

Creates a wxGraphicsContext from a native context.

This native context must be a CGContextRef for Core Graphics, a Graphics pointer for GDIPlus, or a cairo_t pointer for cairo.

See also

wxGraphicsRenderer::CreateContextFromNativeContext()

static wxGraphicsContext* wxGraphicsContext::CreateFromNativeWindow (void * *window*) [static]

Creates a wxGraphicsContext from a native window.

See also

wxGraphicsRenderer::CreateContextFromNativeWindow()

wxGraphicsBrush wxGraphicsContext::CreateLinearGradientBrush (wxDouble *x1*, wxDouble *y1*, wxDouble *x2*, wxDouble *y2*, const wxColour & *c1*, const wxColour & *c2*) const

Creates a native brush with a linear gradient.

The brush starts at (*x1*, *y1*) and ends at (*x2*, *y2*). Either just the start and end gradient colours (*c1* and *c2*) or full set of gradient *stops* can be specified.

The version taking wxGraphicsGradientStops is new in wxWidgets 2.9.1.

wxGraphicsBrush wxGraphicsContext::CreateLinearGradientBrush (wxDouble *x1*, wxDouble *y1*, wxDouble *x2*, wxDouble *y2*, const wxGraphicsGradientStops & *stops*) const

Creates a native brush with a linear gradient.

The brush starts at (*x1*, *y1*) and ends at (*x2*, *y2*). Either just the start and end gradient colours (*c1* and *c2*) or full set of gradient *stops* can be specified.

The version taking wxGraphicsGradientStops is new in wxWidgets 2.9.1.

virtual wxGraphicsMatrix wxGraphicsContext::CreateMatrix (wxDouble *a* = 1.0, wxDouble *b* = 0.0, wxDouble *c* = 0.0, wxDouble *d* = 1.0, wxDouble *tx* = 0.0, wxDouble *ty* = 0.0) const [virtual]

Creates a native affine transformation matrix from the passed in values.

The default parameters result in an identity matrix.

wxGraphicsMatrix wxGraphicsContext::CreateMatrix (const wxAffineMatrix2DBase & *mat*) const

Creates a native affine transformation matrix from the passed generic one.

Since

2.9.4

wxGraphicsPath wxGraphicsContext::CreatePath ( ) const

Creates a native graphics path which is initially empty.

virtual wxGraphicsPen wxGraphicsContext::CreatePen (const wxPen & *pen*) const [virtual]

Creates a native pen from a wxPen.

virtual wxGraphicsBrush wxGraphicsContext::CreateRadialGradientBrush (wxDouble *xo*, wxDouble *yo*, wxDouble *xc*, wxDouble *yc*, wxDouble *radius*, const wxColour & *oColor*, const wxColour & *cColor*) const [virtual]

Creates a native brush with a radial gradient.

The brush originates at (*xo*, *yc*) and ends on a circle around (*xc*, *yc*) with the given *radius*.

The gradient may be specified either by its start and end colours *oColor* and *cColor* or by a full set of gradient *stops*.

The version taking wxGraphicsGradientStops is new in wxWidgets 2.9.1.

virtual wxGraphicsBrush wxGraphicsContext::CreateRadialGradientBrush (wxDouble *xo*, wxDouble *yo*, wxDouble *xc*, wxDouble *yc*, wxDouble *radius*, const wxGraphicsGradientStops & *stops*) [pure virtual]

Creates a native brush with a radial gradient.

The brush originates at (*xo*, *yc*) and ends on a circle around (*xc*, *yc*) with the given *radius*.

The gradient may be specified either by its start and end colours *oColor* and *cColor* or by a full set of gradient *stops*.

The version taking wxGraphicsGradientStops is new in wxWidgets 2.9.1.

virtual wxGraphicsBitmap wxGraphicsContext::CreateSubBitmap (const wxGraphicsBitmap & *bitmap*, wxDouble *x*, wxDouble *y*, wxDouble *w*, wxDouble *h*) [pure virtual]

Extracts a sub-bitmap from an existing bitmap.

Currently this function is implemented in the native MSW and OS X versions but not when using Cairo.

void wxGraphicsContext::DisableOffset ( )

virtual void wxGraphicsContext::DrawBitmap (const wxGraphicsBitmap & *bmp*, wxDouble *x*, wxDouble *y*, wxDouble *w*, wxDouble *h*) [pure virtual]

Draws the bitmap.

In case of a mono bitmap, this is treated as a mask and the current brushed is used for filling.

virtual void wxGraphicsContext::DrawBitmap (const wxBitmap & *bmp*, wxDouble *x*, wxDouble *y*, wxDouble *w*, wxDouble *h*) [pure virtual]

Draws the bitmap.

In case of a mono bitmap, this is treated as a mask and the current brushed is used for filling.

virtual void wxGraphicsContext::DrawEllipse (wxDouble *x*, wxDouble *y*, wxDouble *w*, wxDouble *h*) [virtual]

Draws an ellipse.

virtual void wxGraphicsContext::DrawIcon (const wxIcon & *icon*, wxDouble *x*, wxDouble *y*, wxDouble *w*, wxDouble *h*) [pure virtual]

Draws the icon.

virtual void wxGraphicsContext::DrawLines (size_t *n,* const wxPoint2DDouble * *points,* wxPolygonFillMode *fillStyle =* wxODDEVEN_RULE) [virtual]

Draws a polygon.

virtual void wxGraphicsContext::DrawPath (const wxGraphicsPath & *path,* wxPolygonFillMode *fillStyle =* wxODDEVEN_RULE) [virtual]

Draws the path by first filling and then stroking.

virtual void wxGraphicsContext::DrawRectangle (wxDouble *x,* wxDouble *y,* wxDouble *w,* wxDouble *h*) [virtual]

Draws a rectangle.

virtual void wxGraphicsContext::DrawRoundedRectangle (wxDouble *x,* wxDouble *y,* wxDouble *w,* wxDouble *h,* wxDouble *radius*) [virtual]

Draws a rounded rectangle.

void wxGraphicsContext::DrawText (const wxString & *str,* wxDouble *x,* wxDouble *y*)

Draws text at the defined position.

void wxGraphicsContext::DrawText (const wxString & *str,* wxDouble *x,* wxDouble *y,* wxDouble *angle*)

Draws text at the defined position.

Parameters

str	The text to draw.
x	The x coordinate position to draw the text at.
y	The y coordinate position to draw the text at.
angle	The angle relative to the (default) horizontal direction to draw the string.

void wxGraphicsContext::DrawText (const wxString & *str,* wxDouble *x,* wxDouble *y,* const wxGraphicsBrush & *backgroundBrush*)

Draws text at the defined position.

Parameters

str	The text to draw.
x	The x coordinate position to draw the text at.
y	The y coordinate position to draw the text at.
backgroundBrush	Brush to fill the text with.

void wxGraphicsContext::DrawText (const wxString & *str,* wxDouble *x,* wxDouble *y,* wxDouble *angle,* const wxGraphicsBrush & *backgroundBrush*)

Draws text at the defined position.

Parameters

str	The text to draw.
x	The x coordinate position to draw the text at.
y	The y coordinate position to draw the text at.
angle	The angle relative to the (default) horizontal direction to draw the string.
background↩ Brush	Brush to fill the text with.

virtual void wxGraphicsContext::EnableOffset (bool *enable* = `true`) [virtual]

virtual void wxGraphicsContext::EndDoc ( ) [virtual]

Done with that document (relevant only for printing / pdf etc.)

virtual void wxGraphicsContext::EndLayer ( ) [pure virtual]

Composites back the drawings into the context with the opacity given at the BeginLayer call.

virtual void wxGraphicsContext::EndPage ( ) [virtual]

Ends the current page (relevant only for printing / pdf etc.)

virtual void wxGraphicsContext::FillPath (const wxGraphicsPath & *path*, wxPolygonFillMode *fillStyle* = wxODDEVEN_RULE) [pure virtual]

Fills the path with the current brush.

virtual void wxGraphicsContext::Flush ( ) [virtual]

Make sure that the current content of this context is immediately visible.

virtual wxAntialiasMode wxGraphicsContext::GetAntialiasMode ( ) const [virtual]

Returns the current shape antialiasing mode.

virtual wxCompositionMode wxGraphicsContext::GetCompositionMode ( ) const [virtual]

Returns the current compositing operator.

virtual void wxGraphicsContext::GetDPI (wxDouble * *dpiX*, wxDouble * *dpiY*) [virtual]

Returns the resolution of the graphics context in device points per inch.

virtual wxInterpolationQuality wxGraphicsContext::GetInterpolationQuality ( ) const [virtual]

Returns the current interpolation quality.

virtual void* wxGraphicsContext::GetNativeContext ( ) [pure virtual]

Returns the native context (CGContextRef for Core Graphics, Graphics pointer for GDIPlus and cairo_t pointer for cairo).

virtual void wxGraphicsContext::GetPartialTextExtents (const wxString & *text*, wxArrayDouble & *widths*) const [pure virtual]

Fills the *widths* array with the widths from the beginning of *text* to the corresponding character of *text*.

void wxGraphicsContext::GetSize (wxDouble * *width*, wxDouble * *height*) const

Returns the size of the graphics context in device coordinates.

virtual void wxGraphicsContext::GetTextExtent (const wxString & *text*, wxDouble * *width*, wxDouble * *height*, wxDouble * *descent*, wxDouble * *externalLeading*) const [pure virtual]

Gets the dimensions of the string using the currently selected font.

Parameters

text	The text string to measure.
width	Variable to store the total calculated width of the text.
height	Variable to store the total calculated height of the text.
descent	Variable to store the dimension from the baseline of the font to the bottom of the descender.
externalLeading	Any extra vertical space added to the font by the font designer (usually is zero).

virtual wxGraphicsMatrix wxGraphicsContext::GetTransform ( ) const [pure virtual]

Gets the current transformation matrix of this context.

bool wxGraphicsContext::OffsetEnabled ( )

virtual void wxGraphicsContext::PopState ( ) [pure virtual]

Pops a stored state from the stack and sets the current transformation matrix to that state.

See also

wxGraphicsContext::PopState

virtual void wxGraphicsContext::PushState ( ) [pure virtual]

Push the current state of the context's transformation matrix on a stack.

See also

wxGraphicsContext::PopState

virtual void wxGraphicsContext::ResetClip ( ) [pure virtual]

Resets the clipping to original shape.

virtual void wxGraphicsContext::Rotate (wxDouble *angle*) `[pure virtual]`

Rotates the current transformation matrix (in radians).

virtual void wxGraphicsContext::Scale (wxDouble *xScale,* wxDouble *yScale*) `[pure virtual]`

Scales the current transformation matrix.

virtual bool wxGraphicsContext::SetAntialiasMode (wxAntialiasMode *antialias*) `[pure virtual]`

Sets the antialiasing mode, returns true if it supported.

void wxGraphicsContext::SetBrush (const wxBrush & *brush*)

Sets the brush for filling paths.

virtual void wxGraphicsContext::SetBrush (const wxGraphicsBrush & *brush*) `[virtual]`

Sets the brush for filling paths.

virtual bool wxGraphicsContext::SetCompositionMode (wxCompositionMode *op*) `[pure virtual]`

Sets the compositing operator, returns true if it supported.

void wxGraphicsContext::SetFont (const wxFont & *font,* const wxColour & *colour*)

Sets the font for drawing text.

virtual void wxGraphicsContext::SetFont (const wxGraphicsFont & *font*) `[virtual]`

Sets the font for drawing text.

virtual bool wxGraphicsContext::SetInterpolationQuality (wxInterpolationQuality *interpolation*) `[pure virtual]`

Sets the interpolation quality, returns true if it is supported.
Not implemented in Cairo backend currently.

void wxGraphicsContext::SetPen (const wxPen & *pen*)

Sets the pen used for stroking.

virtual void wxGraphicsContext::SetPen (const wxGraphicsPen & *pen*) `[virtual]`

Sets the pen used for stroking.

virtual void wxGraphicsContext::SetTransform (const wxGraphicsMatrix & *matrix*) `[pure virtual]`

Sets the current transformation matrix of this context.

virtual bool wxGraphicsContext::ShouldOffset ( ) const [virtual]

virtual bool wxGraphicsContext::StartDoc (const wxString & *message*) [virtual]

Begin a new document (relevant only for printing / pdf etc.) If there is a progress dialog, message will be shown.

virtual void wxGraphicsContext::StartPage (wxDouble *width* = 0, wxDouble *height* = 0) [virtual]

Opens a new page (relevant only for printing / pdf etc.) with the given size in points.

(If both are null the default page size will be used.)

virtual void wxGraphicsContext::StrokeLine (wxDouble *x1*, wxDouble *y1*, wxDouble *x2*, wxDouble *y2*) [virtual]

Strokes a single line.

virtual void wxGraphicsContext::StrokeLines (size_t *n*, const wxPoint2DDouble * *beginPoints*, const wxPoint2DDouble * *endPoints*) [virtual]

Stroke disconnected lines from begin to end points, fastest method available for this purpose.

virtual void wxGraphicsContext::StrokeLines (size_t *n*, const wxPoint2DDouble * *points*) [virtual]

Stroke lines connecting all the points.

Unlike the other overload of this function, this method draws a single polyline and not a number of disconnected lines.

virtual void wxGraphicsContext::StrokePath (const wxGraphicsPath & *path*) [pure virtual]

Strokes along a path with the current pen.

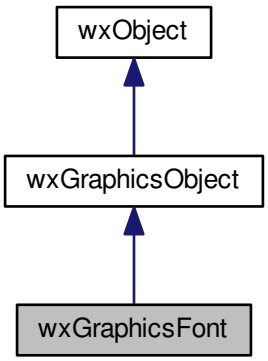
virtual void wxGraphicsContext::Translate (wxDouble *dx*, wxDouble *dy*) [pure virtual]

Translates the current transformation matrix.

21.290 wxGraphicsFont Class Reference

```
#include <wx/graphics.h>
```

Inheritance diagram for wxGraphicsFont:



21.290.1 Detailed Description

A wxGraphicsFont is a native representation of a font.

The contents are specific and private to the respective renderer. Instances are ref counted and can therefore be assigned as usual. The only way to get a valid instance is via wxGraphicsContext::CreateFont() or wxGraphicsRenderer::CreateFont().

Library: wxCore

Category: Graphics Device Interface (GDI)

Additional Inherited Members

21.291 wxGraphicsGradientStop Class Reference

```
#include <wx/graphics.h>
```

21.291.1 Detailed Description

Represents a single gradient stop in a collection of gradient stops as represented by wxGraphicsGradientStops.

Library: wxCore

Category: Graphics Device Interface (GDI)

Since

2.9.1

Public Member Functions

- wxGraphicsGradientStop (wxColour col=wxTransparentColour, float pos=0.)

  Creates a stop with the given colour and position.
- const wxColour & GetColour () const

  Return the stop colour.
- void SetColour (const wxColour &col)

  Change the stop colour.
- float GetPosition () const

  Return the stop position.
- void SetPosition (float pos)

  Change the stop position.

21.291.2 Constructor & Destructor Documentation

wxGraphicsGradientStop::wxGraphicsGradientStop (wxColour *col* = wxTransparentColour, float *pos* = 0.)

Creates a stop with the given colour and position.

Parameters

col	The colour of this stop. Note that the alpha component of the colour is honoured thus allowing the background colours to partially show through the gradient.
pos	The stop position, must be in [0, 1] range with 0 being the beginning and 1 the end of the gradient.

21.291.3 Member Function Documentation

const wxColour& wxGraphicsGradientStop::GetColour ( ) const

Return the stop colour.

float wxGraphicsGradientStop::GetPosition ( ) const

Return the stop position.

void wxGraphicsGradientStop::SetColour (const wxColour & *col*)

Change the stop colour.

Parameters

col	The new colour.

void wxGraphicsGradientStop::SetPosition (float *pos*)

Change the stop position.

Parameters

pos	The new position, must always be in [0, 1] range.

21.292 wxGraphicsGradientStops Class Reference

`#include <wx/graphics.h>`

21.292.1 Detailed Description

Represents a collection of wxGraphicGradientStop values for use with CreateLinearGradientBrush and CreateRadialGradientBrush.

The stops are maintained in order of position. If two or more stops are added with the same position then the one(s) added later come later. This can be useful for producing discontinuities in the colour gradient.

Notice that this class is write-once, you can't modify the stops once they had been added.

Library: wxCore

Category: Graphics Device Interface (GDI)

Since

2.9.1

Public Member Functions

- wxGraphicsGradientStops (wxColour startCol=wxTransparentColour, wxColour endCol=wxTransparentColour)

  Initializes the gradient stops with the given boundary colours.
- wxGraphicsGradientStop Item (unsigned n) const

  Returns the stop at the given index.
- size_t GetCount () const

  Returns the number of stops.
- void SetStartColour (wxColour col)

  Set the start colour to col.
- wxColour GetStartColour () const

  Returns the start colour.
- void SetEndColour (wxColour col)

  Set the end colour to col.
- wxColour GetEndColour () const

  Returns the end colour.

- void Add (const wxGraphicsGradientStop &stop)

  Add a new stop.
- void Add (wxColour col, float pos)

  Add a new stop.

21.292.2 Constructor & Destructor Documentation

wxGraphicsGradientStops::wxGraphicsGradientStops (wxColour *startCol* = wxTransparentColour, wxColour *endCol* = wxTransparentColour)

Initializes the gradient stops with the given boundary colours.

Creates a wxGraphicsGradientStops instance with start colour given by *startCol* and end colour given by *endCol*.

21.292.3 Member Function Documentation

void wxGraphicsGradientStops::Add (const wxGraphicsGradientStop & *stop*)

Add a new stop.

void wxGraphicsGradientStops::Add (wxColour *col*, float *pos*)

Add a new stop.

size_t wxGraphicsGradientStops::GetCount ( ) const

Returns the number of stops.

wxColour wxGraphicsGradientStops::GetEndColour ( ) const

Returns the end colour.

wxColour wxGraphicsGradientStops::GetStartColour ( ) const

Returns the start colour.

wxGraphicsGradientStop wxGraphicsGradientStops::Item (unsigned *n*) const

Returns the stop at the given index.

Parameters

n	The index, must be in [0, GetCount()) range.

void wxGraphicsGradientStops::SetEndColour (wxColour *col*)

Set the end colour to *col*.

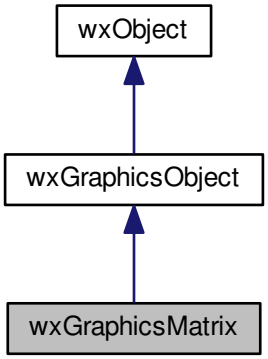
void wxGraphicsGradientStops::SetStartColour (wxColour *col*)

Set the start colour to *col*.

21.293 wxGraphicsMatrix Class Reference

```
#include <wx/graphics.h>
```

Inheritance diagram for wxGraphicsMatrix:



21.293.1 Detailed Description

A wxGraphicsMatrix is a native representation of an affine matrix.

The contents are specific and private to the respective renderer. Instances are ref counted and can therefore be assigned as usual. The only way to get a valid instance is via wxGraphicsContext::CreateMatrix() or wxGraphicsRenderer::CreateMatrix().

Library: wxCore

Category: Graphics Device Interface (GDI)

Public Member Functions

- virtual void Concat (const wxGraphicsMatrix *t)

  Concatenates the matrix passed with the current matrix.
- void Concat (const wxGraphicsMatrix &t)

  Concatenates the matrix passed with the current matrix.
- virtual void Get (wxDouble *a=NULL, wxDouble *b=NULL, wxDouble *c=NULL, wxDouble *d=NULL, wxDouble *tx=NULL, wxDouble *ty=NULL) const

  Returns the component values of the matrix via the argument pointers.
- virtual void * GetNativeMatrix () const

  Returns the native representation of the matrix.
- virtual void Invert ()

  Inverts the matrix.
- virtual bool IsEqual (const wxGraphicsMatrix *t) const

  Returns true if the elements of the transformation matrix are equal.
- bool IsEqual (const wxGraphicsMatrix &t) const

  Returns true if the elements of the transformation matrix are equal.
- virtual bool IsIdentity () const

  Return true if this is the identity matrix.

- virtual void Rotate (wxDouble angle)

  Rotates this matrix clockwise (in radians).
- virtual void Scale (wxDouble xScale, wxDouble yScale)

  Scales this matrix.
- virtual void Set (wxDouble a=1.0, wxDouble b=0.0, wxDouble c=0.0, wxDouble d=1.0, wxDouble tx=0.0, wxDouble ty=0.0)

  Sets the matrix to the respective values (default values are the identity matrix).
- virtual void TransformDistance (wxDouble *dx, wxDouble *dy) const

  Applies this matrix to a distance (ie.
- virtual void TransformPoint (wxDouble *x, wxDouble *y) const

  Applies this matrix to a point.
- virtual void Translate (wxDouble dx, wxDouble dy)

  Translates this matrix.

Additional Inherited Members

21.293.2 Member Function Documentation

virtual void wxGraphicsMatrix::Concat (const wxGraphicsMatrix * *t*) [virtual]

Concatenates the matrix passed with the current matrix.

void wxGraphicsMatrix::Concat (const wxGraphicsMatrix & *t*)

Concatenates the matrix passed with the current matrix.

virtual void wxGraphicsMatrix::Get (wxDouble * *a* = NULL, wxDouble * *b* = NULL, wxDouble * *c* = NULL, wxDouble * *d* = NULL, wxDouble * *tx* = NULL, wxDouble * *ty* = NULL) const [virtual]

Returns the component values of the matrix via the argument pointers.

virtual void* wxGraphicsMatrix::GetNativeMatrix ( ) const [virtual]

Returns the native representation of the matrix.

For CoreGraphics this is a CFAffineMatrix pointer, for GDIPlus a Matrix Pointer, and for Cairo a cairo_matrix_t pointer.

virtual void wxGraphicsMatrix::Invert ( ) [virtual]

Inverts the matrix.

virtual bool wxGraphicsMatrix::IsEqual (const wxGraphicsMatrix * *t*) const [virtual]

Returns true if the elements of the transformation matrix are equal.

bool wxGraphicsMatrix::IsEqual (const wxGraphicsMatrix & *t*) const

Returns true if the elements of the transformation matrix are equal.

virtual bool wxGraphicsMatrix::IsIdentity ( ) const [virtual]

Return true if this is the identity matrix.

virtual void wxGraphicsMatrix::Rotate (wxDouble *angle*) [virtual]

Rotates this matrix clockwise (in radians).

Parameters

angle	Rotation angle in radians, clockwise.

virtual void wxGraphicsMatrix::Scale (wxDouble *xScale,* wxDouble *yScale*) [virtual]

Scales this matrix.

virtual void wxGraphicsMatrix::Set (wxDouble *a* = 1.0, wxDouble *b* = 0.0, wxDouble *c* = 0.0, wxDouble *d* = 1.0, wxDouble *tx* = 0.0, wxDouble *ty* = 0.0) [virtual]

Sets the matrix to the respective values (default values are the identity matrix).

virtual void wxGraphicsMatrix::TransformDistance (wxDouble * *dx,* wxDouble * *dy*) const [virtual]

Applies this matrix to a distance (ie.

performs all transforms except translations).

virtual void wxGraphicsMatrix::TransformPoint (wxDouble * *x,* wxDouble * *y*) const [virtual]

Applies this matrix to a point.

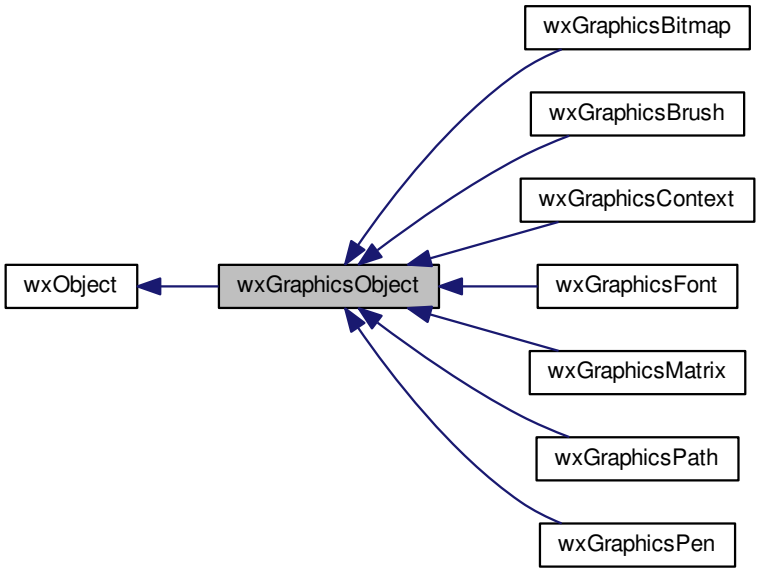
virtual void wxGraphicsMatrix::Translate (wxDouble *dx,* wxDouble *dy*) [virtual]

Translates this matrix.

21.294 wxGraphicsObject Class Reference

`#include <wx/graphics.h>`

Inheritance diagram for wxGraphicsObject:



21.294.1 Detailed Description

This class is the superclass of native graphics objects like pens etc.

It allows reference counting. Not instantiated by user code.

Library: wxCore

Category: Graphics Device Interface (GDI)

See also

wxGraphicsBrush, wxGraphicsPen, wxGraphicsMatrix, wxGraphicsPath

Public Member Functions

- wxGraphicsRenderer * GetRenderer () const

  Returns the renderer that was used to create this instance, or NULL if it has not been initialized yet.
- bool IsNull () const

Additional Inherited Members

21.294.2 Member Function Documentation

wxGraphicsRenderer* wxGraphicsObject::GetRenderer ( ) const

Returns the renderer that was used to create this instance, or NULL if it has not been initialized yet.

bool wxGraphicsObject::IsNull ( ) const

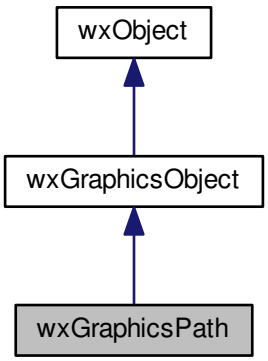
Returns

false if this object is valid, otherwise returns true.

21.295 wxGraphicsPath Class Reference

`#include <wx/graphics.h>`

Inheritance diagram for wxGraphicsPath:



21.295.1 Detailed Description

A wxGraphicsPath is a native representation of a geometric path.

The contents are specific and private to the respective renderer. Instances are reference counted and can therefore be assigned as usual. The only way to get a valid instance is by using wxGraphicsContext::CreatePath() or wxGraphicsRenderer::CreatePath().

Library: wxCore

Category: Graphics Device Interface (GDI)

Public Member Functions

- virtual void AddArcToPoint (wxDouble x1, wxDouble y1, wxDouble x2, wxDouble y2, wxDouble r)

  Appends a an arc to two tangents connecting (current) to (x1,y1) and (x1,y1) to (x2,y2), also a straight line from (current) to (x1,y1).
- virtual void AddCircle (wxDouble x, wxDouble y, wxDouble r)

  Appends a circle around (x,y) with radius r as a new closed subpath.
- virtual void AddCurveToPoint (wxDouble cx1, wxDouble cy1, wxDouble cx2, wxDouble cy2, wxDouble x, wxDouble y)

  Adds a cubic bezier curve from the current point, using two control points and an end point.

- void AddCurveToPoint (const wxPoint2DDouble &c1, const wxPoint2DDouble &c2, const wxPoint2DDouble &e)

  Adds a cubic bezier curve from the current point, using two control points and an end point.
- virtual void AddEllipse (wxDouble x, wxDouble y, wxDouble w, wxDouble h)

  Appends an ellipse fitting into the passed in rectangle.
- virtual void AddLineToPoint (wxDouble x, wxDouble y)

  Adds a straight line from the current point to (x,y).
- void AddLineToPoint (const wxPoint2DDouble &p)

  Adds a straight line from the current point to p.
- virtual void AddPath (const wxGraphicsPath &path)

  Adds another path.
- virtual void AddQuadCurveToPoint (wxDouble cx, wxDouble cy, wxDouble x, wxDouble y)

  Adds a quadratic bezier curve from the current point, using a control point and an end point.
- virtual void AddRectangle (wxDouble x, wxDouble y, wxDouble w, wxDouble h)

  Appends a rectangle as a new closed subpath.
- virtual void AddRoundedRectangle (wxDouble x, wxDouble y, wxDouble w, wxDouble h, wxDouble radius)

  Appends a rounded rectangle as a new closed subpath.
- virtual void CloseSubpath ()

  Closes the current sub-path.
- bool Contains (const wxPoint2DDouble &c, wxPolygonFillMode fillStyle=wxODDEVEN_RULE) const
- virtual bool Contains (wxDouble x, wxDouble y, wxPolygonFillMode fillStyle=wxODDEVEN_RULE) const
- wxRect2DDouble GetBox () const

  Gets the bounding box enclosing all points (possibly including control points).
- virtual void GetBox (wxDouble *x, wxDouble *y, wxDouble *w, wxDouble *h) const

  Gets the bounding box enclosing all points (possibly including control points).
- virtual void GetCurrentPoint (wxDouble *x, wxDouble *y) const

  Gets the last point of the current path, (0,0) if not yet set.
- wxPoint2DDouble GetCurrentPoint () const

  Gets the last point of the current path, (0,0) if not yet set.
- virtual void * GetNativePath () const

  Returns the native path (CGPathRef for Core Graphics, Path pointer for GDIPlus and a cairo_path_t pointer for cairo).
- virtual void MoveToPoint (wxDouble x, wxDouble y)

  Begins a new subpath at (x,y).
- void MoveToPoint (const wxPoint2DDouble &p)

  Begins a new subpath at p.
- virtual void Transform (const wxGraphicsMatrix &matrix)

  Transforms each point of this path by the matrix.
- virtual void UnGetNativePath (void *p) const

  Gives back the native path returned by GetNativePath() because there might be some deallocations necessary (e.g.

- virtual void AddArc (wxDouble x, wxDouble y, wxDouble r, wxDouble startAngle, wxDouble endAngle, bool clockwise)

  Adds an arc of a circle.
- void AddArc (const wxPoint2DDouble &c, wxDouble r, wxDouble startAngle, wxDouble endAngle, bool clockwise)

  Adds an arc of a circle.

Additional Inherited Members

21.295.2 Member Function Documentation

virtual void wxGraphicsPath::AddArc (wxDouble *x,* wxDouble *y,* wxDouble *r,* wxDouble *startAngle,* wxDouble *endAngle,* bool *clockwise*) [virtual]

Adds an arc of a circle.

The circle is defined by the coordinates of its centre (*x*, *y*) or *c* and its radius *r*. The arc goes from the starting angle *startAngle* to *endAngle* either clockwise or counter-clockwise depending on the value of *clockwise* argument.

The angles are measured in radians but, contrary to the usual mathematical convention, are always *clockwise* from the horizontal axis.

void wxGraphicsPath::AddArc (const wxPoint2DDouble & *c,* wxDouble *r,* wxDouble *startAngle,* wxDouble *endAngle,* bool *clockwise*)

Adds an arc of a circle.

The circle is defined by the coordinates of its centre (*x*, *y*) or *c* and its radius *r*. The arc goes from the starting angle *startAngle* to *endAngle* either clockwise or counter-clockwise depending on the value of *clockwise* argument.

The angles are measured in radians but, contrary to the usual mathematical convention, are always *clockwise* from the horizontal axis.

virtual void wxGraphicsPath::AddArcToPoint (wxDouble *x1,* wxDouble *y1,* wxDouble *x2,* wxDouble *y2,* wxDouble *r*) [virtual]

Appends a an arc to two tangents connecting (current) to (*x1*,*y1*) and (*x1*,*y1*) to (*x2*,*y2*), also a straight line from (current) to (*x1*,*y1*).

virtual void wxGraphicsPath::AddCircle (wxDouble *x,* wxDouble *y,* wxDouble *r*) [virtual]

Appends a circle around (*x*,*y*) with radius *r* as a new closed subpath.

virtual void wxGraphicsPath::AddCurveToPoint (wxDouble *cx1,* wxDouble *cy1,* wxDouble *cx2,* wxDouble *cy2,* wxDouble *x,* wxDouble *y*) [virtual]

Adds a cubic bezier curve from the current point, using two control points and an end point.

void wxGraphicsPath::AddCurveToPoint (const wxPoint2DDouble & *c1,* const wxPoint2DDouble & *c2,* const wxPoint2DDouble & *e*)

Adds a cubic bezier curve from the current point, using two control points and an end point.

virtual void wxGraphicsPath::AddEllipse (wxDouble *x,* wxDouble *y,* wxDouble *w,* wxDouble *h*) [virtual]

Appends an ellipse fitting into the passed in rectangle.

virtual void wxGraphicsPath::AddLineToPoint (wxDouble *x,* wxDouble *y*) [virtual]

Adds a straight line from the current point to (*x*,*y*).

void wxGraphicsPath::AddLineToPoint (const wxPoint2DDouble & *p*)

Adds a straight line from the current point to *p*.

virtual void wxGraphicsPath::AddPath (const wxGraphicsPath & *path*) `[virtual]`

Adds another path.

virtual void wxGraphicsPath::AddQuadCurveToPoint (wxDouble *cx,* wxDouble *cy,* wxDouble *x,* wxDouble *y*) `[virtual]`

Adds a quadratic bezier curve from the current point, using a control point and an end point.

virtual void wxGraphicsPath::AddRectangle (wxDouble *x,* wxDouble *y,* wxDouble *w,* wxDouble *h*) `[virtual]`

Appends a rectangle as a new closed subpath.

virtual void wxGraphicsPath::AddRoundedRectangle (wxDouble *x,* wxDouble *y,* wxDouble *w,* wxDouble *h,* wxDouble *radius*) `[virtual]`

Appends a rounded rectangle as a new closed subpath.

virtual void wxGraphicsPath::CloseSubpath ( ) `[virtual]`

Closes the current sub-path.

bool wxGraphicsPath::Contains (const wxPoint2DDouble & *c,* wxPolygonFillMode *fillStyle* = wxODDEVEN_RULE) const

Returns

true if the point is within the path.

virtual bool wxGraphicsPath::Contains (wxDouble *x,* wxDouble *y,* wxPolygonFillMode *fillStyle* = wxODDEVEN_RULE) const `[virtual]`

Returns

true if the point is within the path.

wxRect2DDouble wxGraphicsPath::GetBox ( ) const

Gets the bounding box enclosing all points (possibly including control points).

virtual void wxGraphicsPath::GetBox (wxDouble * *x,* wxDouble * *y,* wxDouble * *w,* wxDouble * *h*) const `[virtual]`

Gets the bounding box enclosing all points (possibly including control points).

virtual void wxGraphicsPath::GetCurrentPoint (wxDouble * *x*, wxDouble * *y*) const [virtual]

Gets the last point of the current path, (0,0) if not yet set.

wxPoint2DDouble wxGraphicsPath::GetCurrentPoint ( ) const

Gets the last point of the current path, (0,0) if not yet set.

virtual void* wxGraphicsPath::GetNativePath ( ) const [virtual]

Returns the native path (CGPathRef for Core Graphics, Path pointer for GDIPlus and a cairo_path_t pointer for cairo).

virtual void wxGraphicsPath::MoveToPoint (wxDouble *x*, wxDouble *y*) [virtual]

Begins a new subpath at (*x*,*y*).

void wxGraphicsPath::MoveToPoint (const wxPoint2DDouble & *p*)

Begins a new subpath at *p*.

virtual void wxGraphicsPath::Transform (const wxGraphicsMatrix & *matrix*) [virtual]

Transforms each point of this path by the matrix.

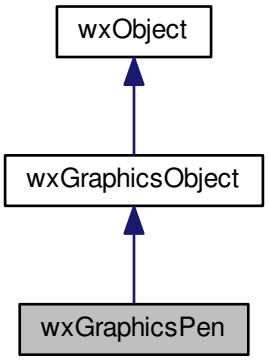
virtual void wxGraphicsPath::UnGetNativePath (void * *p*) const [virtual]

Gives back the native path returned by GetNativePath() because there might be some deallocations necessary (e.g. on cairo the native path returned by GetNativePath() is newly allocated each time).

21.296 wxGraphicsPen Class Reference

`#include <wx/graphics.h>`

Inheritance diagram for wxGraphicsPen:



21.296.1 Detailed Description

A wxGraphicsPen is a native representation of a pen.

The contents are specific and private to the respective renderer. Instances are ref counted and can therefore be assigned as usual. The only way to get a valid instance is via wxGraphicsContext::CreatePen() or wxGraphics↩ Renderer::CreatePen().

Library: wxCore

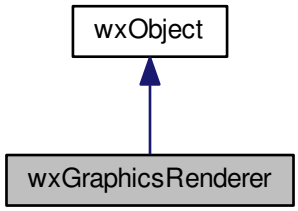
Category: Graphics Device Interface (GDI)

Additional Inherited Members

21.297 wxGraphicsRenderer Class Reference

```
#include <wx/graphics.h>
```

Inheritance diagram for wxGraphicsRenderer:



21.297.1 Detailed Description

A wxGraphicsRenderer is the instance corresponding to the rendering engine used.

There may be multiple instances on a system, if there are different rendering engines present, but there is always only one instance per engine. This instance is pointed back to by all objects created by it (wxGraphicsContext, wxGraphicsPath etc) and can be retrieved through their wxGraphicsObject::GetRenderer() method. Therefore you can create an additional instance of a path etc. by calling wxGraphicsObject::GetRenderer() and then using the appropriate CreateXXX() function of that renderer.

```
wxGraphicsPath *path = // from somewhere
wxGraphicsBrush *brush = path->GetRenderer()->
      CreateBrush( *wxBLACK_BRUSH );
```

Library: wxCore

Category: Graphics Device Interface (GDI)

Public Member Functions

- virtual wxGraphicsBitmap CreateBitmap (const wxBitmap &bitmap)=0

  Creates wxGraphicsBitmap from an existing wxBitmap.
- virtual wxGraphicsBitmap CreateBitmapFromImage (const wxImage &image)=0

  Creates wxGraphicsBitmap from an existing wxImage.
- virtual wxImage CreateImageFromBitmap (const wxGraphicsBitmap &bmp)=0

  Creates a wxImage from a wxGraphicsBitmap.
- virtual wxGraphicsBitmap CreateBitmapFromNativeBitmap (void *bitmap)=0

  Creates wxGraphicsBitmap from a native bitmap handle.
- virtual wxGraphicsContext * CreateContext (wxWindow *window)=0

  Creates a wxGraphicsContext from a wxWindow.
- virtual wxGraphicsContext * CreateContext (const wxWindowDC &windowDC)=0

  Creates a wxGraphicsContext from a wxWindowDC.
- virtual wxGraphicsContext * CreateContext (const wxMemoryDC &memoryDC)=0

  Creates a wxGraphicsContext from a wxMemoryDC.
- virtual wxGraphicsContext * CreateContext (const wxPrinterDC &printerDC)=0

  Creates a wxGraphicsContext from a wxPrinterDC.

- virtual wxGraphicsContext * CreateContext (const wxEnhMetaFileDC &metaFileDC)=0

  Creates a wxGraphicsContext from a wxEnhMetaFileDC.
- wxGraphicsContext * CreateContextFromImage (wxImage &image)

  Creates a wxGraphicsContext associated with a wxImage.
- virtual wxGraphicsBrush CreateBrush (const wxBrush &brush)=0

  Creates a native brush from a wxBrush.
- virtual wxGraphicsContext * CreateContextFromNativeContext (void *context)=0

  Creates a wxGraphicsContext from a native context.
- virtual wxGraphicsContext * CreateContextFromNativeWindow (void *window)=0

  Creates a wxGraphicsContext from a native window.
- virtual wxGraphicsContext * CreateMeasuringContext ()=0

  Creates a wxGraphicsContext that can be used for measuring texts only.
- virtual wxGraphicsFont CreateFont (const wxFont &font, const wxColour &col=*wxBLACK)=0

  Creates a native graphics font from a wxFont and a text colour.
- virtual wxGraphicsFont CreateFont (double sizeInPixels, const wxString &facename, int flags=wxFONTFLAG_DEFAULT, const wxColour &col=*wxBLACK)=0

  Creates a graphics font with the given characteristics.
- virtual wxGraphicsBrush CreateLinearGradientBrush (wxDouble x1, wxDouble y1, wxDouble x2, wxDouble y2, const wxGraphicsGradientStops &stops)=0

  Creates a native brush with a linear gradient.
- virtual wxGraphicsMatrix CreateMatrix (wxDouble a=1.0, wxDouble b=0.0, wxDouble c=0.0, wxDouble d=1.0, wxDouble tx=0.0, wxDouble ty=0.0)=0

  Creates a native affine transformation matrix from the passed in values.
- virtual wxGraphicsPath CreatePath ()=0

  Creates a native graphics path which is initially empty.
- virtual wxGraphicsPen CreatePen (const wxPen &pen)=0

  Creates a native pen from a wxPen.
- virtual wxGraphicsBrush CreateRadialGradientBrush (wxDouble xo, wxDouble yo, wxDouble xc, wxDouble yc, wxDouble radius, const wxGraphicsGradientStops &stops)=0

  Creates a native brush with a radial gradient.
- virtual wxGraphicsBitmap CreateSubBitmap (const wxGraphicsBitmap &bitmap, wxDouble x, wxDouble y, wxDouble w, wxDouble h)=0

  Extracts a sub-bitmap from an existing bitmap.
- virtual wxString GetName () const =0

  Returns the name of the technology used by the renderer.
- virtual void GetVersion (int *major, int *minor=NULL, int *micro=NULL) const =0

  Returns the version major, minor and micro/build of the technology used by the renderer.

Static Public Member Functions

- static wxGraphicsRenderer * GetDefaultRenderer ()

  Returns the default renderer on this platform.
- static wxGraphicsRenderer * GetCairoRenderer ()

Additional Inherited Members

21.297.2 Member Function Documentation

virtual wxGraphicsBitmap wxGraphicsRenderer::CreateBitmap (const wxBitmap & *bitmap*) `[pure virtual]`

Creates wxGraphicsBitmap from an existing wxBitmap.

Returns an invalid wxNullGraphicsBitmap on failure.

virtual wxGraphicsBitmap wxGraphicsRenderer::CreateBitmapFromImage (const wxImage & *image*) `[pure virtual]`

Creates wxGraphicsBitmap from an existing wxImage.

This method is more efficient than converting wxImage to wxBitmap first and then calling CreateBitmap() but otherwise has the same effect.

Returns an invalid wxNullGraphicsBitmap on failure.

Since

2.9.3

virtual wxGraphicsBitmap wxGraphicsRenderer::CreateBitmapFromNativeBitmap (void * *bitmap*) `[pure virtual]`

Creates wxGraphicsBitmap from a native bitmap handle.

bitmap meaning is platform-dependent. Currently it's a GDI+ `Bitmap` pointer under MSW, `CGImage` pointer under OS X or a `cairo_surface_t` pointer when using Cairo under any platform.

Notice that this method takes ownership of *bitmap*, i.e. it will be destroyed when the returned wxGraphicsBitmap is.

virtual wxGraphicsBrush wxGraphicsRenderer::CreateBrush (const wxBrush & *brush*) `[pure virtual]`

Creates a native brush from a wxBrush.

virtual wxGraphicsContext* wxGraphicsRenderer::CreateContext (wxWindow * *window*) `[pure virtual]`

Creates a wxGraphicsContext from a wxWindow.

virtual wxGraphicsContext* wxGraphicsRenderer::CreateContext (const wxWindowDC & *windowDC*) `[pure virtual]`

Creates a wxGraphicsContext from a wxWindowDC.

virtual wxGraphicsContext* wxGraphicsRenderer::CreateContext (const wxMemoryDC & *memoryDC*) `[pure virtual]`

Creates a wxGraphicsContext from a wxMemoryDC.

virtual wxGraphicsContext* wxGraphicsRenderer::CreateContext (const wxPrinterDC & *printerDC*) `[pure virtual]`

Creates a wxGraphicsContext from a wxPrinterDC.

virtual wxGraphicsContext* wxGraphicsRenderer::CreateContext (const wxEnhMetaFileDC & *metaFileDC*) `[pure virtual]`

Creates a wxGraphicsContext from a wxEnhMetaFileDC.

This function, as wxEnhMetaFileDC class itself, is only available only under MSW.

wxGraphicsContext* wxGraphicsRenderer::CreateContextFromImage (wxImage & *image*)

Creates a wxGraphicsContext associated with a wxImage.

This function is used by wxContext::CreateFromImage() and is not normally called directly.

Since

2.9.3

virtual wxGraphicsContext* wxGraphicsRenderer::CreateContextFromNativeContext (void * *context*) [pure virtual]

Creates a wxGraphicsContext from a native context.

This native context must be a CGContextRef for Core Graphics, a Graphics pointer for GDIPlus, or a cairo_t pointer for cairo.

virtual wxGraphicsContext* wxGraphicsRenderer::CreateContextFromNativeWindow (void * *window*) [pure virtual]

Creates a wxGraphicsContext from a native window.

virtual wxGraphicsFont wxGraphicsRenderer::CreateFont (const wxFont & *font,* const wxColour & *col* = *wxBLACK) [pure virtual]

Creates a native graphics font from a wxFont and a text colour.

virtual wxGraphicsFont wxGraphicsRenderer::CreateFont (double *sizeInPixels,* const wxString & *facename,* int *flags* = wxFONTFLAG_DEFAULT, const wxColour & *col* = *wxBLACK) [pure virtual]

Creates a graphics font with the given characteristics.

If possible, the CreateFont() overload taking wxFont should be used instead. The main advantage of this overload is that it can be used without X server connection under Unix when using Cairo.

Parameters

sizeInPixels	Height of the font in user space units, i.e. normally pixels. Notice that this is different from the overload taking wxFont as wxFont size is specified in points.
facename	The name of the font. The same font name might not be available under all platforms so the font name can also be empty to use the default platform font.
flags	Combination of wxFontFlag enum elements. Currently only `wxFONTFLAG_ITALIC` and `wxFONTFLAG_BOLD` are supported. By default the normal font version is used.
col	The font colour, black by default.

Since

2.9.3

virtual wxImage wxGraphicsRenderer::CreateImageFromBitmap (const wxGraphicsBitmap & *bmp*) [pure virtual]

Creates a wxImage from a wxGraphicsBitmap.

This method is used by the more convenient wxGraphicsBitmap::ConvertToImage.

virtual **wxGraphicsBrush** wxGraphicsRenderer::CreateLinearGradientBrush (**wxDouble** *x1,* **wxDouble** *y1,* **wxDouble** *x2,* **wxDouble** *y2,* const **wxGraphicsGradientStops** & *stops*) [pure virtual]

Creates a native brush with a linear gradient.

Stops support is new since wxWidgets 2.9.1, previously only the start and end colours could be specified.

virtual **wxGraphicsMatrix** wxGraphicsRenderer::CreateMatrix (**wxDouble** *a* = 1.0, **wxDouble** *b* = 0.0, **wxDouble** *c* = 0.0, **wxDouble** *d* = 1.0, **wxDouble** *tx* = 0.0, **wxDouble** *ty* = 0.0) [pure virtual]

Creates a native affine transformation matrix from the passed in values.

The defaults result in an identity matrix.

virtual **wxGraphicsContext**∗ wxGraphicsRenderer::CreateMeasuringContext ( ) [pure virtual]

Creates a wxGraphicsContext that can be used for measuring texts only.

No drawing commands are allowed.

virtual **wxGraphicsPath** wxGraphicsRenderer::CreatePath ( ) [pure virtual]

Creates a native graphics path which is initially empty.

virtual **wxGraphicsPen** wxGraphicsRenderer::CreatePen (const **wxPen** & *pen*) [pure virtual]

Creates a native pen from a wxPen.

virtual **wxGraphicsBrush** wxGraphicsRenderer::CreateRadialGradientBrush (**wxDouble** *xo,* **wxDouble** *yo,* **wxDouble** *xc,* **wxDouble** *yc,* **wxDouble** *radius,* const **wxGraphicsGradientStops** & *stops*) [pure virtual]

Creates a native brush with a radial gradient.

Stops support is new since wxWidgets 2.9.1, previously only the start and end colours could be specified.

virtual **wxGraphicsBitmap** wxGraphicsRenderer::CreateSubBitmap (const **wxGraphicsBitmap** & *bitmap,* **wxDouble** *x,* **wxDouble** *y,* **wxDouble** *w,* **wxDouble** *h*) [pure virtual]

Extracts a sub-bitmap from an existing bitmap.

Currently this function is implemented in the native MSW and OS X versions but not when using Cairo.

static **wxGraphicsRenderer**∗ wxGraphicsRenderer::GetCairoRenderer ( ) [static]

static **wxGraphicsRenderer**∗ wxGraphicsRenderer::GetDefaultRenderer ( ) [static]

Returns the default renderer on this platform.

On OS X this is the Core Graphics (a.k.a. Quartz 2D) renderer, on MSW the GDIPlus renderer, and on GTK we currently default to the cairo renderer.

virtual **wxString** wxGraphicsRenderer::GetName ( ) const [pure virtual]

Returns the name of the technology used by the renderer.

Currently this function returns "gdiplus" for Windows GDI+ implementation, "cairo" for Cairo implementation and "cg" for OS X CoreGraphics implementation.

Note: the string returned by this method is not user-readable and is expected to be used internally by the program only.

Since

3.1.0

virtual void wxGraphicsRenderer::GetVersion (int * *major*, int * *minor* = NULL, int * *micro* = NULL) const [pure virtual]

Returns the version major, minor and micro/build of the technology used by the renderer.

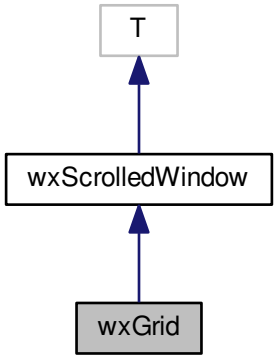
Currently this function returns the OS major and minor versions in the parameters with the matching names and sets *micro* to 0 for the GDI+ and CoreGraphics engines which are considered to be parts of their respective OS.

For Cairo, this is the major,minor,micro version of the Cairo library which is returned.

21.298 wxGrid Class Reference

`#include <wx/grid.h>`

Inheritance diagram for wxGrid:



21.298.1 Detailed Description

wxGrid and its related classes are used for displaying and editing tabular data.

They provide a rich set of features for display, editing, and interacting with a variety of data sources. For simple applications, and to help you get started, wxGrid is the only class you need to refer to directly. It will set up default instances of the other classes and manage them for you. For more complex applications you can derive your own classes for custom grid views, grid data tables, cell editors and renderers. The wxGrid Overview has examples of simple and more complex applications, explains the relationship between the various grid classes and has a summary of the keyboard shortcuts and mouse functions provided by wxGrid.

A wxGridTableBase class holds the actual data to be displayed by a wxGrid class. One or more wxGrid classes may act as a view for one table class. The default table class is called wxGridStringTable and holds an array of strings. An instance of such a class is created by CreateGrid().

wxGridCellRenderer is the abstract base class for rendering contents in a cell. The following renderers are predefined:

- wxGridCellBoolRenderer
- wxGridCellFloatRenderer
- wxGridCellNumberRenderer
- wxGridCellStringRenderer

The look of a cell can be further defined using wxGridCellAttr. An object of this type may be returned by wxGrid↩ TableBase::GetAttr().

wxGridCellEditor is the abstract base class for editing the value of a cell. The following editors are predefined:

- wxGridCellBoolEditor
- wxGridCellChoiceEditor
- wxGridCellFloatEditor
- wxGridCellNumberEditor
- wxGridCellTextEditor

Please see wxGridEvent, wxGridSizeEvent, wxGridRangeSelectEvent, and wxGridEditorCreatedEvent for the documentation of all event types you can use with wxGrid.

Library: wxAdvanced

Category: Grid Related Classes

See also

wxGrid Overview, wxGridUpdateLocker

Public Types

- enum wxGridSelectionModes {
  wxGridSelectCells,
  wxGridSelectRows,
  wxGridSelectColumns,
  wxGridSelectRowsOrColumns }

  Different selection modes supported by the grid.
- enum CellSpan {
  CellSpan_Inside = -1,
  CellSpan_None = 0,
  CellSpan_Main }

  Return values for GetCellSize().
- enum TabBehaviour {
  Tab_Stop,
  Tab_Wrap,
  Tab_Leave }

  Constants defining different support built-in TAB handling behaviours.

Public Member Functions

- virtual void DrawCellHighlight (wxDC &dc, const wxGridCellAttr *attr)
- virtual void DrawRowLabels (wxDC &dc, const wxArrayInt &rows)
- virtual void DrawRowLabel (wxDC &dc, int row)
- virtual void DrawColLabels (wxDC &dc, const wxArrayInt &cols)
- virtual void DrawColLabel (wxDC &dc, int col)
- virtual void DrawCornerLabel (wxDC &dc)
- void DrawTextRectangle (wxDC &dc, const wxString &text, const wxRect &rect, int horizontalAlignment=wxALIGN_LEFT, int verticalAlignment=wxALIGN_TOP, int textOrientation=wxHORIZONTAL) const
- void DrawTextRectangle (wxDC &dc, const wxArrayString &lines, const wxRect &rect, int horizontalAlignment=wxALIGN_LEFT, int verticalAlignment=wxALIGN_TOP, int textOrientation=wxHORIZONTAL) const
- wxColour GetCellHighlightColour () const
- int GetCellHighlightPenWidth () const
- int GetCellHighlightROPenWidth () const
- void SetCellHighlightColour (const wxColour &)
- void SetCellHighlightPenWidth (int width)
- void SetCellHighlightROPenWidth (int width)

Constructors and Initialization

- wxGrid ()
  Default constructor.
- wxGrid (wxWindow *parent, wxWindowID id, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, long style=wxWANTS_CHARS, const wxString &name=wxGridNameStr)
  Constructor creating the grid window.
- virtual ~wxGrid ()
  Destructor.
- bool Create (wxWindow *parent, wxWindowID id, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, long style=wxWANTS_CHARS, const wxString &name=wxGridNameStr)
  Creates the grid window for an object initialized using the default constructor.
- bool CreateGrid (int numRows, int numCols, wxGridSelectionModes selmode=wxGridSelectCells)
  Creates a grid with the specified initial number of rows and columns.
- bool SetTable (wxGridTableBase *table, bool takeOwnership=false, wxGridSelectionModes selmode=wxGridSelectCells)
  Passes a pointer to a custom grid table to be used by the grid.
- bool ProcessTableMessage (wxGridTableMessage &msg)
  Receive and handle a message from the table.

Grid Line Formatting

- void EnableGridLines (bool enable=true)
  Turns the drawing of grid lines on or off.
- virtual wxPen GetColGridLinePen (int col)
  Returns the pen used for vertical grid lines.
- virtual wxPen GetDefaultGridLinePen ()
  Returns the pen used for grid lines.
- wxColour GetGridLineColour () const
  Returns the colour used for grid lines.
- virtual wxPen GetRowGridLinePen (int row)
  Returns the pen used for horizontal grid lines.
- bool GridLinesEnabled () const
  Returns true if drawing of grid lines is turned on, false otherwise.
- void SetGridLineColour (const wxColour &colour)
  Sets the colour used to draw grid lines.

Label Values and Formatting

- void GetColLabelAlignment (int *horiz, int *vert) const
  Sets the arguments to the current column label alignment values.
- int GetColLabelTextOrientation () const
  Returns the orientation of the column labels (either `wxHORIZONTAL` or `wxVERTICAL`).
- wxString GetColLabelValue (int col) const
  Returns the specified column label.
- wxColour GetLabelBackgroundColour () const
  Returns the colour used for the background of row and column labels.
- wxFont GetLabelFont () const
  Returns the font used for row and column labels.
- wxColour GetLabelTextColour () const
  Returns the colour used for row and column label text.
- void GetRowLabelAlignment (int *horiz, int *vert) const
  Returns the alignment used for row labels.
- wxString GetRowLabelValue (int row) const
  Returns the specified row label.
- void HideColLabels ()
  Hides the column labels by calling SetColLabelSize() with a size of 0.
- void HideRowLabels ()
  Hides the row labels by calling SetRowLabelSize() with a size of 0.
- void SetColLabelAlignment (int horiz, int vert)
  Sets the horizontal and vertical alignment of column label text.
- void SetColLabelTextOrientation (int textOrientation)
  Sets the orientation of the column labels (either `wxHORIZONTAL` or `wxVERTICAL`).
- void SetColLabelValue (int col, const wxString &value)
  Set the value for the given column label.
- void SetLabelBackgroundColour (const wxColour &colour)
  Sets the background colour for row and column labels.
- void SetLabelFont (const wxFont &font)
  Sets the font for row and column labels.
- void SetLabelTextColour (const wxColour &colour)
  Sets the colour for row and column label text.
- void SetRowLabelAlignment (int horiz, int vert)
  Sets the horizontal and vertical alignment of row label text.
- void SetRowLabelValue (int row, const wxString &value)
  Sets the value for the given row label.
- void SetUseNativeColLabels (bool native=true)
  Call this in order to make the column labels use a native look by using wxRendererNative::DrawHeaderButton() internally.
- void UseNativeColHeader (bool native=true)
  Enable the use of native header window for column labels.

Cell Formatting

Note that wxGridCellAttr can be used alternatively to most of these methods.

See the "Attributes Management" of wxGridTableBase.

- void GetCellAlignment (int row, int col, int *horiz, int *vert) const
  Sets the arguments to the horizontal and vertical text alignment values for the grid cell at the specified location.
- wxColour GetCellBackgroundColour (int row, int col) const
  Returns the background colour of the cell at the specified location.
- wxFont GetCellFont (int row, int col) const
  Returns the font for text in the grid cell at the specified location.
- wxColour GetCellTextColour (int row, int col) const
  Returns the text colour for the grid cell at the specified location.
- void GetDefaultCellAlignment (int *horiz, int *vert) const
  Returns the default cell alignment.
- wxColour GetDefaultCellBackgroundColour () const
  Returns the current default background colour for grid cells.

- wxFont GetDefaultCellFont () const
  Returns the current default font for grid cell text.
- wxColour GetDefaultCellTextColour () const
  Returns the current default colour for grid cell text.
- void SetCellAlignment (int row, int col, int horiz, int vert)
  Sets the horizontal and vertical alignment for grid cell text at the specified location.
- void SetCellAlignment (int align, int row, int col)
  Sets the horizontal and vertical alignment for grid cell text at the specified location.
- void SetCellBackgroundColour (int row, int col, const wxColour &colour)
  Set the background colour for the given cell or all cells by default.
- void SetCellFont (int row, int col, const wxFont &font)
  Sets the font for text in the grid cell at the specified location.
- void SetCellTextColour (int row, int col, const wxColour &colour)
  Sets the text colour for the given cell.
- void SetCellTextColour (const wxColour &val, int row, int col)
  Sets the text colour for the given cell.
- void SetCellTextColour (const wxColour &colour)
  Sets the text colour for all cells by default.
- void SetDefaultCellAlignment (int horiz, int vert)
  Sets the default horizontal and vertical alignment for grid cell text.
- void SetDefaultCellBackgroundColour (const wxColour &colour)
  Sets the default background colour for grid cells.
- void SetDefaultCellFont (const wxFont &font)
  Sets the default font to be used for grid cell text.
- void SetDefaultCellTextColour (const wxColour &colour)
  Sets the current default colour for grid cell text.

Cell Values, Editors, and Renderers

Note that wxGridCellAttr can be used alternatively to most of these methods.

See the "Attributes Management" of wxGridTableBase.

- bool CanEnableCellControl () const
  Returns true if the in-place edit control for the current grid cell can be used and false otherwise.
- void DisableCellEditControl ()
  Disables in-place editing of grid cells.
- void EnableCellEditControl (bool enable=true)
  Enables or disables in-place editing of grid cell data.
- void EnableEditing (bool edit)
  Makes the grid globally editable or read-only.
- wxGridCellEditor * GetCellEditor (int row, int col) const
  Returns a pointer to the editor for the cell at the specified location.
- wxGridCellRenderer * GetCellRenderer (int row, int col) const
  Returns a pointer to the renderer for the grid cell at the specified location.
- wxString GetCellValue (int row, int col) const
  Returns the string contained in the cell at the specified location.
- wxString GetCellValue (const wxGridCellCoords &coords) const
  Returns the string contained in the cell at the specified location.
- wxGridCellEditor * GetDefaultEditor () const
  Returns a pointer to the current default grid cell editor.
- virtual wxGridCellEditor * GetDefaultEditorForCell (int row, int col) const
  Returns the default editor for the specified cell.
- wxGridCellEditor * GetDefaultEditorForCell (const wxGridCellCoords &c) const
  Returns the default editor for the specified cell.
- virtual wxGridCellEditor * GetDefaultEditorForType (const wxString &typeName) const
  Returns the default editor for the cells containing values of the given type.
- wxGridCellRenderer * GetDefaultRenderer () const
  Returns a pointer to the current default grid cell renderer.
- virtual wxGridCellRenderer * GetDefaultRendererForCell (int row, int col) const

Returns the default renderer for the given cell.

- virtual wxGridCellRenderer * GetDefaultRendererForType (const wxString &typeName) const

  Returns the default renderer for the cell containing values of the given type.
- void HideCellEditControl ()

  Hides the in-place cell edit control.
- bool IsCellEditControlEnabled () const

  Returns true if the in-place edit control is currently enabled.
- bool IsCurrentCellReadOnly () const

  Returns true if the current cell is read-only.
- bool IsEditable () const

  Returns false if the whole grid has been set as read-only or true otherwise.
- bool IsReadOnly (int row, int col) const

  Returns true if the cell at the specified location can't be edited.
- void RegisterDataType (const wxString &typeName, wxGridCellRenderer *renderer, wxGridCellEditor *editor)

  Register a new data type.
- void SaveEditControlValue ()

  Sets the value of the current grid cell to the current in-place edit control value.
- void SetCellEditor (int row, int col, wxGridCellEditor *editor)

  Sets the editor for the grid cell at the specified location.
- void SetCellRenderer (int row, int col, wxGridCellRenderer *renderer)

  Sets the renderer for the grid cell at the specified location.
- void SetCellValue (int row, int col, const wxString &s)

  Sets the string value for the cell at the specified location.
- void SetCellValue (const wxGridCellCoords &coords, const wxString &s)

  Sets the string value for the cell at the specified location.
- void SetCellValue (const wxString &val, int row, int col)
- void SetColFormatBool (int col)

  Sets the specified column to display boolean values.
- void SetColFormatCustom (int col, const wxString &typeName)

  Sets the specified column to display data in a custom format.
- void SetColFormatFloat (int col, int width=-1, int precision=-1)

  Sets the specified column to display floating point values with the given width and precision.
- void SetColFormatNumber (int col)

  Sets the specified column to display integer values.
- void SetDefaultEditor (wxGridCellEditor *editor)

  Sets the default editor for grid cells.
- void SetDefaultRenderer (wxGridCellRenderer *renderer)

  Sets the default renderer for grid cells.
- void SetReadOnly (int row, int col, bool isReadOnly=true)

  Makes the cell at the specified location read-only or editable.
- void ShowCellEditControl ()

  Displays the in-place cell edit control for the current cell.

Column and Row Sizes

See also

Column and Row Sizes

- void AutoSize ()

  Automatically sets the height and width of all rows and columns to fit their contents.
- void AutoSizeColLabelSize (int col)

  Automatically adjusts width of the column to fit its label.
- void AutoSizeColumn (int col, bool setAsMin=true)

  Automatically sizes the column to fit its contents.
- void AutoSizeColumns (bool setAsMin=true)

  Automatically sizes all columns to fit their contents.
- void AutoSizeRow (int row, bool setAsMin=true)

  Automatically sizes the row to fit its contents.

- void AutoSizeRowLabelSize (int col)

  Automatically adjusts height of the row to fit its label.
- void AutoSizeRows (bool setAsMin=true)

  Automatically sizes all rows to fit their contents.
- bool GetCellOverflow (int row, int col) const

  Returns true if the cell value can overflow.
- int GetColLabelSize () const

  Returns the current height of the column labels.
- int GetColMinimalAcceptableWidth () const

  Returns the minimal width to which a column may be resized.
- int GetColSize (int col) const

  Returns the width of the specified column.
- bool IsColShown (int col) const

  Returns true if the specified column is not currently hidden.
- bool GetDefaultCellOverflow () const

  Returns true if the cells can overflow by default.
- int GetDefaultColLabelSize () const

  Returns the default height for column labels.
- int GetDefaultColSize () const

  Returns the current default width for grid columns.
- int GetDefaultRowLabelSize () const

  Returns the default width for the row labels.
- int GetDefaultRowSize () const

  Returns the current default height for grid rows.
- int GetRowMinimalAcceptableHeight () const

  Returns the minimal size to which rows can be resized.
- int GetRowLabelSize () const

  Returns the current width of the row labels.
- int GetRowSize (int row) const

  Returns the height of the specified row.
- bool IsRowShown (int row) const

  Returns true if the specified row is not currently hidden.
- void SetCellOverflow (int row, int col, bool allow)

  Sets the overflow permission of the cell.
- void SetColLabelSize (int height)

  Sets the height of the column labels.
- void SetColMinimalAcceptableWidth (int width)

  Sets the minimal width to which the user can resize columns.
- void SetColMinimalWidth (int col, int width)

  Sets the minimal width for the specified column col.
- void SetColSize (int col, int width)

  Sets the width of the specified column.
- void HideCol (int col)

  Hides the specified column.
- void ShowCol (int col)

  Shows the previously hidden column by resizing it to non-0 size.
- void SetDefaultCellOverflow (bool allow)

  Sets the default overflow permission of the cells.
- void SetDefaultColSize (int width, bool resizeExistingCols=false)

  Sets the default width for columns in the grid.
- void SetDefaultRowSize (int height, bool resizeExistingRows=false)

  Sets the default height for rows in the grid.
- void SetRowLabelSize (int width)

  Sets the width of the row labels.
- void SetRowMinimalAcceptableHeight (int height)

  Sets the minimal row height used by default.
- void SetRowMinimalHeight (int row, int height)

  Sets the minimal height for the specified row.
- void SetRowSize (int row, int height)

Sets the height of the specified row.

- void HideRow (int col)

  Hides the specified row.
- void ShowRow (int col)

  Shows the previously hidden row.
- wxGridSizesInfo GetColSizes () const

  Get size information for all columns at once.
- wxGridSizesInfo GetRowSizes () const

  Get size information for all row at once.
- void SetColSizes (const wxGridSizesInfo &sizeInfo)

  Restore all columns sizes.
- void SetRowSizes (const wxGridSizesInfo &sizeInfo)

  Restore all rows sizes.
- void SetCellSize (int row, int col, int num_rows, int num_cols)

  Set the size of the cell.
- CellSpan GetCellSize (int row, int col, int *num_rows, int *num_cols) const

  Get the size of the cell in number of cells covered by it.
- wxSize GetCellSize (const wxGridCellCoords &coords)

  Get the number of rows and columns allocated for this cell.

User-Resizing and Dragging

Functions controlling various interactive mouse operations.

By default, columns and rows can be resized by dragging the edges of their labels (this can be disabled using DisableDragColSize() and DisableDragRowSize() methods). And if grid line dragging is enabled with EnableDragGridSize() they can also be resized by dragging the right or bottom edge of the grid cells.

Columns can also be moved to interactively change their order but this needs to be explicitly enabled with EnableDragColMove().

- bool CanDragCell () const

  Return true if the dragging of cells is enabled or false otherwise.
- bool CanDragColMove () const

  Returns true if columns can be moved by dragging with the mouse.
- bool CanDragColSize (int col) const

  Returns true if the given column can be resized by dragging with the mouse.
- bool CanDragGridSize () const

  Return true if the dragging of grid lines to resize rows and columns is enabled or false otherwise.
- bool CanDragRowSize (int row) const

  Returns true if the given row can be resized by dragging with the mouse.
- void DisableColResize (int col)

  Disable interactive resizing of the specified column.
- void DisableRowResize (int row)

  Disable interactive resizing of the specified row.
- void DisableDragColMove ()

  Disables column moving by dragging with the mouse.
- void DisableDragColSize ()

  Disables column sizing by dragging with the mouse.
- void DisableDragGridSize ()

  Disable mouse dragging of grid lines to resize rows and columns.
- void DisableDragRowSize ()

  Disables row sizing by dragging with the mouse.
- void EnableDragCell (bool enable=true)

  Enables or disables cell dragging with the mouse.
- void EnableDragColMove (bool enable=true)

  Enables or disables column moving by dragging with the mouse.
- void EnableDragColSize (bool enable=true)

  Enables or disables column sizing by dragging with the mouse.
- void EnableDragGridSize (bool enable=true)

  Enables or disables row and column resizing by dragging gridlines with the mouse.

- void EnableDragRowSize (bool enable=true)

  Enables or disables row sizing by dragging with the mouse.
- int GetColAt (int colPos) const

  Returns the column ID of the specified column position.
- int GetColPos (int colID) const

  Returns the position of the specified column.
- void SetColPos (int colID, int newPos)

  Sets the position of the specified column.
- void SetColumnsOrder (const wxArrayInt &order)

  Sets the positions of all columns at once.
- void ResetColPos ()

  Resets the position of the columns to the default.

Cursor Movement

- int GetGridCursorCol () const

  Returns the current grid cell column position.
- int GetGridCursorRow () const

  Returns the current grid cell row position.
- void GoToCell (int row, int col)

  Make the given cell current and ensure it is visible.
- void GoToCell (const wxGridCellCoords &coords)

  Make the given cell current and ensure it is visible.
- bool MoveCursorDown (bool expandSelection)

  Moves the grid cursor down by one row.
- bool MoveCursorDownBlock (bool expandSelection)

  Moves the grid cursor down in the current column such that it skips to the beginning or end of a block of non-empty cells.
- bool MoveCursorLeft (bool expandSelection)

  Moves the grid cursor left by one column.
- bool MoveCursorLeftBlock (bool expandSelection)

  Moves the grid cursor left in the current row such that it skips to the beginning or end of a block of non-empty cells.
- bool MoveCursorRight (bool expandSelection)

  Moves the grid cursor right by one column.
- bool MoveCursorRightBlock (bool expandSelection)

  Moves the grid cursor right in the current row such that it skips to the beginning or end of a block of non-empty cells.
- bool MoveCursorUp (bool expandSelection)

  Moves the grid cursor up by one row.
- bool MoveCursorUpBlock (bool expandSelection)

  Moves the grid cursor up in the current column such that it skips to the beginning or end of a block of non-empty cells.
- bool MovePageDown ()

  Moves the grid cursor down by some number of rows so that the previous bottom visible row becomes the top visible row.
- bool MovePageUp ()

  Moves the grid cursor up by some number of rows so that the previous top visible row becomes the bottom visible row.
- void SetGridCursor (int row, int col)

  Set the grid cursor to the specified cell.
- void SetGridCursor (const wxGridCellCoords &coords)

  Set the grid cursor to the specified cell.
- void SetTabBehaviour (TabBehaviour behaviour)

  Set the grid's behaviour when the user presses the TAB key.

User Selection

- void ClearSelection ()

  Deselects all cells that are currently selected.

- wxGridCellCoordsArray GetSelectedCells () const
  Returns an array of individually selected cells.
- wxArrayInt GetSelectedCols () const
  Returns an array of selected columns.
- wxArrayInt GetSelectedRows () const
  Returns an array of selected rows.
- wxColour GetSelectionBackground () const
  Returns the colour used for drawing the selection background.
- wxGridCellCoordsArray GetSelectionBlockBottomRight () const
  Returns an array of the bottom right corners of blocks of selected cells.
- wxGridCellCoordsArray GetSelectionBlockTopLeft () const
  Returns an array of the top left corners of blocks of selected cells.
- wxColour GetSelectionForeground () const
  Returns the colour used for drawing the selection foreground.
- wxGridSelectionModes GetSelectionMode () const
  Returns the current selection mode.
- bool IsInSelection (int row, int col) const
  Returns true if the given cell is selected.
- bool IsInSelection (const wxGridCellCoords &coords) const
  Returns true if the given cell is selected.
- bool IsSelection () const
  Returns true if there are currently any selected cells, rows, columns or blocks.
- void SelectAll ()
  Selects all cells in the grid.
- void SelectBlock (int topRow, int leftCol, int bottomRow, int rightCol, bool addToSelected=false)
  Selects a rectangular block of cells.
- void SelectBlock (const wxGridCellCoords &topLeft, const wxGridCellCoords &bottomRight, bool addTo↩ Selected=false)
  Selects a rectangular block of cells.
- void SelectCol (int col, bool addToSelected=false)
  Selects the specified column.
- void SelectRow (int row, bool addToSelected=false)
  Selects the specified row.
- void SetSelectionBackground (const wxColour &c)
  Set the colour to be used for drawing the selection background.
- void SetSelectionForeground (const wxColour &c)
  Set the colour to be used for drawing the selection foreground.
- void SetSelectionMode (wxGridSelectionModes selmode)
  Set the selection behaviour of the grid.

Scrolling

- int GetScrollLineX () const
  Returns the number of pixels per horizontal scroll increment.
- int GetScrollLineY () const
  Returns the number of pixels per vertical scroll increment.
- bool IsVisible (int row, int col, bool wholeCellVisible=true) const
  Returns true if a cell is either entirely or at least partially visible in the grid window.
- bool IsVisible (const wxGridCellCoords &coords, bool wholeCellVisible=true) const
  Returns true if a cell is either entirely or at least partially visible in the grid window.
- void MakeCellVisible (int row, int col)
  Brings the specified cell into the visible grid cell area with minimal scrolling.
- void MakeCellVisible (const wxGridCellCoords &coords)
  Brings the specified cell into the visible grid cell area with minimal scrolling.
- void SetScrollLineX (int x)
  Sets the number of pixels per horizontal scroll increment.
- void SetScrollLineY (int y)
  Sets the number of pixels per vertical scroll increment.

Cell and Device Coordinate Translation

- wxRect BlockToDeviceRect (const wxGridCellCoords &topLeft, const wxGridCellCoords &bottomRight) const

  Convert grid cell coordinates to grid window pixel coordinates.
- wxRect CellToRect (int row, int col) const

  Return the rectangle corresponding to the grid cell's size and position in logical coordinates.
- wxRect CellToRect (const wxGridCellCoords &coords) const

  Return the rectangle corresponding to the grid cell's size and position in logical coordinates.
- int XToCol (int x, bool clipToMinMax=false) const

  Returns the column at the given pixel position.
- int XToEdgeOfCol (int x) const

  Returns the column whose right hand edge is close to the given logical x position.
- wxGridCellCoords XYToCell (int x, int y) const

  Translates logical pixel coordinates to the grid cell coordinates.
- wxGridCellCoords XYToCell (const wxPoint &pos) const

  Translates logical pixel coordinates to the grid cell coordinates.
- int YToEdgeOfRow (int y) const

  Returns the row whose bottom edge is close to the given logical y position.
- int YToRow (int y, bool clipToMinMax=false) const

  Returns the grid row that corresponds to the logical y coordinate.

Miscellaneous Functions

- bool AppendCols (int numCols=1, bool updateLabels=true)

  Appends one or more new columns to the right of the grid.
- bool AppendRows (int numRows=1, bool updateLabels=true)

  Appends one or more new rows to the bottom of the grid.
- bool AreHorzGridLinesClipped () const

  Return true if the horizontal grid lines stop at the last column boundary or false if they continue to the end of the window.
- bool AreVertGridLinesClipped () const

  Return true if the vertical grid lines stop at the last row boundary or false if they continue to the end of the window.
- void BeginBatch ()

  Increments the grid's batch count.
- void ClearGrid ()

  Clears all data in the underlying grid table and repaints the grid.
- void ClipHorzGridLines (bool clip)

  Change whether the horizontal grid lines are clipped by the end of the last column.
- void ClipVertGridLines (bool clip)

  Change whether the vertical grid lines are clipped by the end of the last row.
- bool DeleteCols (int pos=0, int numCols=1, bool updateLabels=true)

  Deletes one or more columns from a grid starting at the specified position.
- bool DeleteRows (int pos=0, int numRows=1, bool updateLabels=true)

  Deletes one or more rows from a grid starting at the specified position.
- void EndBatch ()

  Decrements the grid's batch count.
- virtual void Fit ()

  Overridden wxWindow method.
- void ForceRefresh ()

  Causes immediate repainting of the grid.
- int GetBatchCount ()

  Returns the number of times that BeginBatch() has been called without (yet) matching calls to EndBatch().
- int GetNumberCols () const

  Returns the total number of grid columns.
- int GetNumberRows () const

  Returns the total number of grid rows.
- wxGridCellAttr * GetOrCreateCellAttr (int row, int col) const

  Returns the attribute for the given cell creating one if necessary.

- wxGridTableBase * GetTable () const
  Returns a base pointer to the current table object.
- bool InsertCols (int pos=0, int numCols=1, bool updateLabels=true)
  Inserts one or more new columns into a grid with the first new column at the specified position.
- bool InsertRows (int pos=0, int numRows=1, bool updateLabels=true)
  Inserts one or more new rows into a grid with the first new row at the specified position.
- void RefreshAttr (int row, int col)
  Invalidates the cached attribute for the given cell.
- void Render (wxDC &dc, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, const wxGridCellCoords &topLeft=wxGridCellCoords(-1,-1), const wxGridCellCoords &bottomRight=wxGridCellCoords(-1,-1), int style=wxGRID_DRAW_DEFAULT)
  Draws part or all of a wxGrid on a wxDC for printing or display.
- void SetColAttr (int col, wxGridCellAttr *attr)
  Sets the cell attributes for all cells in the specified column.
- void SetMargins (int extraWidth, int extraHeight)
  Sets the extra margins used around the grid area.
- void SetRowAttr (int row, wxGridCellAttr *attr)
  Sets the cell attributes for all cells in the specified row.
- wxArrayInt CalcRowLabelsExposed (const wxRegion &reg)
  Appends one or more new columns to the right of the grid.
- wxArrayInt CalcColLabelsExposed (const wxRegion &reg)
  Appends one or more new columns to the right of the grid.
- wxGridCellCoordsArray CalcCellsExposed (const wxRegion &reg)
  Appends one or more new columns to the right of the grid.

Sorting support.

wxGrid doesn't provide any support for sorting the data but it does generate events allowing the user code to sort it and supports displaying the sort indicator in the column used for sorting.

To use wxGrid sorting support you need to handle wxEVT_GRID_COL_SORT event (and not veto it) and resort the data displayed in the grid. The grid will automatically update the sorting indicator on the column which was clicked.

You can also call the functions in this section directly to update the sorting indicator. Once again, they don't do anything with the grid data, it remains your responsibility to actually sort it appropriately.

- int GetSortingColumn () const
  Return the column in which the sorting indicator is currently displayed.
- bool IsSortingBy (int col) const
  Return true if this column is currently used for sorting.
- bool IsSortOrderAscending () const
  Return true if the current sorting order is ascending or false if it is descending.
- void SetSortingColumn (int col, bool ascending=true)
  Set the column to display the sorting indicator in and its direction.
- void UnsetSortingColumn ()
  Remove any currently shown sorting indicator.

Accessors for component windows.

Return the various child windows of wxGrid.

wxGrid is an empty parent window for 4 children representing the column labels window (top), the row labels window (left), the corner window (top left) and the main grid window. It may be necessary to use these individual windows and not the wxGrid window itself if you need to handle events for them (this can be done using wxEvtHandler::Connect() or wxWindow::PushEventHandler()) or do something else requiring the use of the correct window pointer. Notice that you should not, however, change these windows (e.g. reposition them or draw over them) because they are managed by wxGrid itself.

- wxWindow * GetGridWindow () const
  Return the main grid window containing the grid cells.
- wxWindow * GetGridRowLabelWindow () const

Return the row labels window.

- wxWindow * GetGridColLabelWindow () const

  Return the column labels window.

- wxWindow * GetGridCornerLabelWindow () const

  Return the window in the top left grid corner.

- wxHeaderCtrl * GetGridColHeader () const

  Return the header control used for column labels display.

Protected Member Functions

- bool CanHaveAttributes () const

  Returns true if this grid has support for cell attributes.

- int GetColMinimalWidth (int col) const

  Get the minimal width of the given column/row.

- int GetColRight (int col) const

  Returns the coordinate of the right border specified column.

- int GetColLeft (int col) const

  Returns the coordinate of the left border specified column.

- int GetRowMinimalHeight (int col) const

  Returns the minimal size for the given column.

21.298.2 Member Enumeration Documentation

enum wxGrid::CellSpan

Return values for GetCellSize().

Since

2.9.1

Enumerator

CellSpan_Inside This cell is inside a span covered by another cell.

CellSpan_None This is a normal, non-spanning cell.

CellSpan_Main This cell spans several physical wxGrid cells.

enum wxGrid::TabBehaviour

Constants defining different support built-in TAB handling behaviours.

The elements of this enum determine what happens when TAB is pressed when the cursor is in the rightmost column (or Shift-TAB is pressed when the cursor is in the leftmost one).

See also

SetTabBehaviour(), `wxEVT_GRID_TABBING`

Since

2.9.5

Enumerator

Tab_Stop Do nothing, this is default.

Tab_Wrap Move to the beginning of the next (or the end of the previous) row.

Tab_Leave Move to the next (or the previous) control after the grid.

enum wxGrid::wxGridSelectionModes

Different selection modes supported by the grid.

Enumerator

wxGridSelectCells The default selection mode allowing selection of the individual cells as well as of the entire rows and columns.

wxGridSelectRows The selection mode allowing the selection of the entire rows only. The user won't be able to select any cells or columns in this mode.

wxGridSelectColumns The selection mode allowing the selection of the entire columns only. The user won't be able to select any cells or rows in this mode.

wxGridSelectRowsOrColumns The selection mode allowing the user to select either the entire columns or the entire rows but not individual cells nor blocks. Notice that while this constant is defined as

```
wxGridSelectColumns | wxGridSelectRows
```

this doesn't mean that all the other combinations are valid – at least currently they are not.

Since

2.9.1

21.298.3 Constructor & Destructor Documentation

wxGrid::wxGrid ( )

Default constructor.

You must call Create() to really create the grid window and also call CreateGrid() or SetTable() to initialize the grid contents.

wxGrid::wxGrid (wxWindow * *parent*, wxWindowID *id*, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, long *style* = wxWANTS_CHARS, const wxString & *name* = `wxGridNameStr`)

Constructor creating the grid window.

You must call either CreateGrid() or SetTable() to initialize the grid contents before using it.

virtual wxGrid::~wxGrid ( ) `[virtual]`

Destructor.

This will also destroy the associated grid table unless you passed a table object to the grid and specified that the grid should not take ownership of the table (see SetTable()).

21.298.4 Member Function Documentation

bool wxGrid::AppendCols (int *numCols* = `1`, bool *updateLabels* = `true`)

Appends one or more new columns to the right of the grid.

The *updateLabels* argument is not used at present. If you are using a derived grid table class you will need to override wxGridTableBase::AppendCols(). See InsertCols() for further information.

Returns

true on success or false if appending columns failed.

bool wxGrid::AppendRows (int *numRows* = `1`, bool *updateLabels* = `true`)

Appends one or more new rows to the bottom of the grid.

The *updateLabels* argument is not used at present. If you are using a derived grid table class you will need to override wxGridTableBase::AppendRows(). See InsertRows() for further information.

Returns

true on success or false if appending rows failed.

bool wxGrid::AreHorzGridLinesClipped ( ) const

Return true if the horizontal grid lines stop at the last column boundary or false if they continue to the end of the window.

The default is to clip grid lines.

See also

ClipHorzGridLines(), AreVertGridLinesClipped()

bool wxGrid::AreVertGridLinesClipped ( ) const

Return true if the vertical grid lines stop at the last row boundary or false if they continue to the end of the window.

The default is to clip grid lines.

See also

ClipVertGridLines(), AreHorzGridLinesClipped()

void wxGrid::AutoSize ( )

Automatically sets the height and width of all rows and columns to fit their contents.

void wxGrid::AutoSizeColLabelSize (int *col*)

Automatically adjusts width of the column to fit its label.

void wxGrid::AutoSizeColumn (int *col*, bool *setAsMin* = `true`)

Automatically sizes the column to fit its contents.

If *setAsMin* is true the calculated width will also be set as the minimal width for the column.

void wxGrid::AutoSizeColumns (bool *setAsMin* = `true`)

Automatically sizes all columns to fit their contents.

If *setAsMin* is true the calculated widths will also be set as the minimal widths for the columns.

void wxGrid::AutoSizeRow (int *row*, bool *setAsMin* = `true`)

Automatically sizes the row to fit its contents.

If *setAsMin* is true the calculated height will also be set as the minimal height for the row.

void wxGrid::AutoSizeRowLabelSize (int *col*)

Automatically adjusts height of the row to fit its label.

void wxGrid::AutoSizeRows (bool *setAsMin* = `true`)

Automatically sizes all rows to fit their contents.

If *setAsMin* is true the calculated heights will also be set as the minimal heights for the rows.

void wxGrid::BeginBatch ( )

Increments the grid's batch count.

When the count is greater than zero repainting of the grid is suppressed. Each call to BeginBatch must be matched by a later call to EndBatch(). Code that does a lot of grid modification can be enclosed between BeginBatch() and EndBatch() calls to avoid screen flicker. The final EndBatch() call will cause the grid to be repainted.

Notice that you should use wxGridUpdateLocker which ensures that there is always a matching EndBatch() call for this BeginBatch() if possible instead of calling this method directly.

wxRect wxGrid::BlockToDeviceRect (const wxGridCellCoords & *topLeft*, const wxGridCellCoords & *bottomRight*) const

Convert grid cell coordinates to grid window pixel coordinates.

This function returns the rectangle that encloses the block of cells limited by *topLeft* and *bottomRight* cell in device coords and clipped to the client size of the grid window.

See also

CellToRect()

wxGridCellCoordsArray wxGrid::CalcCellsExposed (const wxRegion & *reg*)

Appends one or more new columns to the right of the grid.

The *updateLabels* argument is not used at present. If you are using a derived grid table class you will need to override wxGridTableBase::AppendCols(). See InsertCols() for further information.

Returns

true on success or false if appending columns failed.

wxArrayInt wxGrid::CalcColLabelsExposed (const wxRegion & *reg*)

Appends one or more new columns to the right of the grid.

The *updateLabels* argument is not used at present. If you are using a derived grid table class you will need to override wxGridTableBase::AppendCols(). See InsertCols() for further information.

Returns

true on success or false if appending columns failed.

wxArrayInt wxGrid::CalcRowLabelsExposed (const wxRegion & *reg*)

Appends one or more new columns to the right of the grid.

The *updateLabels* argument is not used at present. If you are using a derived grid table class you will need to override wxGridTableBase::AppendCols(). See InsertCols() for further information.

Returns

true on success or false if appending columns failed.

bool wxGrid::CanDragCell ( ) const

Return true if the dragging of cells is enabled or false otherwise.

bool wxGrid::CanDragColMove ( ) const

Returns true if columns can be moved by dragging with the mouse.

Columns can be moved by dragging on their labels.

bool wxGrid::CanDragColSize (int *col*) const

Returns true if the given column can be resized by dragging with the mouse.

This function returns true if resizing the columns interactively is globally enabled, i.e. if DisableDragColSize() hadn't been called, and if this column wasn't explicitly marked as non-resizable with DisableColResize().

bool wxGrid::CanDragGridSize ( ) const

Return true if the dragging of grid lines to resize rows and columns is enabled or false otherwise.

bool wxGrid::CanDragRowSize (int *row*) const

Returns true if the given row can be resized by dragging with the mouse.

This is the same as CanDragColSize() but for rows.

bool wxGrid::CanEnableCellControl ( ) const

Returns true if the in-place edit control for the current grid cell can be used and false otherwise.

This function always returns false for the read-only cells.

bool wxGrid::CanHaveAttributes ( ) const `[protected]`

Returns true if this grid has support for cell attributes.

The grid supports attributes if it has the associated table which, in turn, has attributes support, i.e. wxGridTableBase::CanHaveAttributes() returns true.

wxRect wxGrid::CellToRect (int *row,* int *col*) const

Return the rectangle corresponding to the grid cell's size and position in logical coordinates.

See also

BlockToDeviceRect()

wxRect wxGrid::CellToRect (const wxGridCellCoords & *coords*) const

Return the rectangle corresponding to the grid cell's size and position in logical coordinates.

See also

BlockToDeviceRect()

void wxGrid::ClearGrid ( )

Clears all data in the underlying grid table and repaints the grid.

The table is not deleted by this function. If you are using a derived table class then you need to override wxGrid↩ TableBase::Clear() for this function to have any effect.

void wxGrid::ClearSelection ( )

Deselects all cells that are currently selected.

void wxGrid::ClipHorzGridLines (bool *clip*)

Change whether the horizontal grid lines are clipped by the end of the last column.

By default the grid lines are not drawn beyond the end of the last column but after calling this function with *clip* set to false they will be drawn across the entire grid window.

See also

AreHorzGridLinesClipped(), ClipVertGridLines()

void wxGrid::ClipVertGridLines (bool *clip*)

Change whether the vertical grid lines are clipped by the end of the last row.

By default the grid lines are not drawn beyond the end of the last row but after calling this function with *clip* set to false they will be drawn across the entire grid window.

See also

AreVertGridLinesClipped(), ClipHorzGridLines()

bool wxGrid::Create (wxWindow * *parent*, wxWindowID *id*, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, long *style* = wxWANTS_CHARS, const wxString & *name* = `wxGridNameStr`)

Creates the grid window for an object initialized using the default constructor.

You must call either CreateGrid() or SetTable() to initialize the grid contents before using it.

bool wxGrid::CreateGrid (int *numRows,* int *numCols,* wxGridSelectionModes *selmode* = wxGridSelectCells)

Creates a grid with the specified initial number of rows and columns.

Call this directly after the grid constructor. When you use this function wxGrid will create and manage a simple table of string values for you. All of the grid data will be stored in memory.

For applications with more complex data types or relationships, or for dealing with very large datasets, you should derive your own grid table class and pass a table object to the grid with SetTable().

bool wxGrid::DeleteCols (int *pos* = 0, int *numCols* = 1, bool *updateLabels* = true)

Deletes one or more columns from a grid starting at the specified position.

The *updateLabels* argument is not used at present. If you are using a derived grid table class you will need to override wxGridTableBase::DeleteCols(). See InsertCols() for further information.

Returns

true on success or false if deleting columns failed.

bool wxGrid::DeleteRows (int *pos* = 0, int *numRows* = 1, bool *updateLabels* = true)

Deletes one or more rows from a grid starting at the specified position.

The *updateLabels* argument is not used at present. If you are using a derived grid table class you will need to override wxGridTableBase::DeleteRows(). See InsertRows() for further information.

Returns

true on success or false if appending rows failed.

void wxGrid::DisableCellEditControl ( )

Disables in-place editing of grid cells.

Equivalent to calling EnableCellEditControl(false).

void wxGrid::DisableColResize (int *col*)

Disable interactive resizing of the specified column.

This method allows to disable resizing of an individual column in a grid where the columns are otherwise resizable (which is the case by default).

Notice that currently there is no way to make some columns resizable in a grid where columns can't be resized by default as there doesn't seem to be any need for this in practice. There is also no way to make the column marked as fixed using this method resizable again because it is supposed that fixed columns are used for static parts of the grid and so should remain fixed during the entire grid lifetime.

Also notice that disabling interactive column resizing will not prevent the program from changing the column size.

See also

EnableDragColSize()

void wxGrid::DisableDragColMove ( )

Disables column moving by dragging with the mouse.

Equivalent to passing false to EnableDragColMove().

void wxGrid::DisableDragColSize ( )

Disables column sizing by dragging with the mouse.

Equivalent to passing false to EnableDragColSize().

void wxGrid::DisableDragGridSize ( )

Disable mouse dragging of grid lines to resize rows and columns.

Equivalent to passing false to EnableDragGridSize()

void wxGrid::DisableDragRowSize ( )

Disables row sizing by dragging with the mouse.

Equivalent to passing false to EnableDragRowSize().

void wxGrid::DisableRowResize (int *row*)

Disable interactive resizing of the specified row.

This is the same as DisableColResize() but for rows.

See also

EnableDragRowSize()

virtual void wxGrid::DrawCellHighlight (wxDC & *dc,* const wxGridCellAttr * *attr*) [virtual]

virtual void wxGrid::DrawColLabel (wxDC & *dc,* int *col*) [virtual]

virtual void wxGrid::DrawColLabels (wxDC & *dc,* const wxArrayInt & *cols*) [virtual]

virtual void wxGrid::DrawCornerLabel (wxDC & *dc*) [virtual]

virtual void wxGrid::DrawRowLabel (wxDC & *dc,* int *row*) [virtual]

virtual void wxGrid::DrawRowLabels (wxDC & *dc,* const wxArrayInt & *rows*) [virtual]

void wxGrid::DrawTextRectangle (wxDC & *dc,* const wxString & *text,* const wxRect & *rect,* int *horizontalAlignment* = wxALIGN_LEFT, int *verticalAlignment* = wxALIGN_TOP, int *textOrientation* = wxHORIZONTAL) const

void wxGrid::DrawTextRectangle (wxDC & *dc,* const wxArrayString & *lines,* const wxRect & *rect,* int *horizontalAlignment* = wxALIGN_LEFT, int *verticalAlignment* = wxALIGN_TOP, int *textOrientation* = wxHORIZONTAL) const

void wxGrid::EnableCellEditControl (bool *enable* = true)

Enables or disables in-place editing of grid cell data.

The grid will issue either a wxEVT_GRID_EDITOR_SHOWN or wxEVT_GRID_EDITOR_HIDDEN event.

void wxGrid::EnableDragCell (bool *enable* = `true`)

Enables or disables cell dragging with the mouse.

void wxGrid::EnableDragColMove (bool *enable* = `true`)

Enables or disables column moving by dragging with the mouse.

void wxGrid::EnableDragColSize (bool *enable* = `true`)

Enables or disables column sizing by dragging with the mouse.

See also

DisableColResize()

void wxGrid::EnableDragGridSize (bool *enable* = `true`)

Enables or disables row and column resizing by dragging gridlines with the mouse.

void wxGrid::EnableDragRowSize (bool *enable* = `true`)

Enables or disables row sizing by dragging with the mouse.

See also

DisableRowResize()

void wxGrid::EnableEditing (bool *edit*)

Makes the grid globally editable or read-only.

If the edit argument is false this function sets the whole grid as read-only. If the argument is true the grid is set to the default state where cells may be editable. In the default state you can set single grid cells and whole rows and columns to be editable or read-only via wxGridCellAttr::SetReadOnly(). For single cells you can also use the shortcut function SetReadOnly().

For more information about controlling grid cell attributes see the wxGridCellAttr class and the wxGrid Overview.

void wxGrid::EnableGridLines (bool *enable* = `true`)

Turns the drawing of grid lines on or off.

void wxGrid::EndBatch ( )

Decrements the grid's batch count.

When the count is greater than zero repainting of the grid is suppressed. Each previous call to BeginBatch() must be matched by a later call to EndBatch(). Code that does a lot of grid modification can be enclosed between BeginBatch() and EndBatch() calls to avoid screen flicker. The final EndBatch() will cause the grid to be repainted.

See also

wxGridUpdateLocker

virtual void wxGrid::Fit ( ) [virtual]

Overridden wxWindow method.

void wxGrid::ForceRefresh ( )

Causes immediate repainting of the grid.

Use this instead of the usual wxWindow::Refresh().

int wxGrid::GetBatchCount ( )

Returns the number of times that BeginBatch() has been called without (yet) matching calls to EndBatch().

While the grid's batch count is greater than zero the display will not be updated.

void wxGrid::GetCellAlignment (int *row,* int *col,* int * *horiz,* int * *vert*) const

Sets the arguments to the horizontal and vertical text alignment values for the grid cell at the specified location.

Horizontal alignment will be one of `wxALIGN_LEFT`, `wxALIGN_CENTRE` or `wxALIGN_RIGHT`.

Vertical alignment will be one of `wxALIGN_TOP`, `wxALIGN_CENTRE` or `wxALIGN_BOTTOM`.

wxColour wxGrid::GetCellBackgroundColour (int *row,* int *col*) const

Returns the background colour of the cell at the specified location.

wxGridCellEditor* wxGrid::GetCellEditor (int *row,* int *col*) const

Returns a pointer to the editor for the cell at the specified location.

See wxGridCellEditor and the wxGrid Overview for more information about cell editors and renderers.

The caller must call DecRef() on the returned pointer.

wxFont wxGrid::GetCellFont (int *row,* int *col*) const

Returns the font for text in the grid cell at the specified location.

wxColour wxGrid::GetCellHighlightColour ( ) const

int wxGrid::GetCellHighlightPenWidth ( ) const

int wxGrid::GetCellHighlightROPenWidth ( ) const

bool wxGrid::GetCellOverflow (int *row,* int *col*) const

Returns true if the cell value can overflow.

A cell can overflow if the next cell in the row is empty.

wxGridCellRenderer* wxGrid::GetCellRenderer (int *row,* int *col*) const

Returns a pointer to the renderer for the grid cell at the specified location.

See wxGridCellRenderer and the wxGrid Overview for more information about cell editors and renderers.

The caller must call DecRef() on the returned pointer.

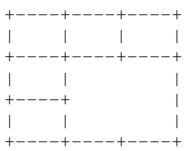
CellSpan wxGrid::GetCellSize (int *row,* int *col,* int * *num_rows,* int * *num_cols*) const

Get the size of the cell in number of cells covered by it.

For normal cells, the function fills both *num_rows* and *num_cols* with 1 and returns CellSpan_None. For cells which span multiple cells, i.e. for which SetCellSize() had been called, the returned values are the same ones as were passed to SetCellSize() call and the function return value is CellSpan_Main.

More unexpectedly, perhaps, the returned values may be *negative* for the cells which are inside a span covered by a cell occupying multiple rows or columns. They correspond to the offset of the main cell of the span from the cell passed to this functions and the function returns CellSpan_Inside value to indicate this.

As an example, consider a 3*3 grid with the cell (1, 1) (the one in the middle) having a span of 2 rows and 2 columns, i.e. the grid looks like



Then the function returns 2 and 2 in *num_rows* and *num_cols* for the cell (1, 1) itself and -1 and -1 for the cell (2, 2) as well as -1 and 0 for the cell (2, 1).

Parameters

row	The row of the cell.
col	The column of the cell.
num_rows	Pointer to variable receiving the number of rows, must not be NULL.
num_cols	Pointer to variable receiving the number of columns, must not be NULL.

Returns

The kind of this cell span (the return value is new in wxWidgets 2.9.1, this function was void in previous wxWidgets versions).

wxSize wxGrid::GetCellSize (const wxGridCellCoords & *coords*)

Get the number of rows and columns allocated for this cell.

This overload doesn't return a CellSpan value but the values returned may still be negative, see GetCellSize(int, int, int *, int *) for details.

wxColour wxGrid::GetCellTextColour (int *row,* int *col*) const

Returns the text colour for the grid cell at the specified location.

wxString wxGrid::GetCellValue (int *row,* int *col*) const

Returns the string contained in the cell at the specified location.

For simple applications where a grid object automatically uses a default grid table of string values you use this function together with SetCellValue() to access cell values. For more complex applications where you have derived your own grid table class that contains various data types (e.g. numeric, boolean or user-defined custom types) then you only use this function for those cells that contain string values.

See wxGridTableBase::CanGetValueAs() and the wxGrid Overview for more information.

wxString wxGrid::GetCellValue (const wxGridCellCoords & *coords*) const

Returns the string contained in the cell at the specified location.

For simple applications where a grid object automatically uses a default grid table of string values you use this function together with SetCellValue() to access cell values. For more complex applications where you have derived your own grid table class that contains various data types (e.g. numeric, boolean or user-defined custom types) then you only use this function for those cells that contain string values.

See wxGridTableBase::CanGetValueAs() and the wxGrid Overview for more information.

int wxGrid::GetColAt (int *colPos*) const

Returns the column ID of the specified column position.

virtual wxPen wxGrid::GetColGridLinePen (int *col*) [virtual]

Returns the pen used for vertical grid lines.

This virtual function may be overridden in derived classes in order to change the appearance of individual grid lines for the given column *col*.

See GetRowGridLinePen() for an example.

void wxGrid::GetColLabelAlignment (int * *horiz*, int * *vert*) const

Sets the arguments to the current column label alignment values.

Horizontal alignment will be one of `wxALIGN_LEFT`, `wxALIGN_CENTRE` or `wxALIGN_RIGHT`.

Vertical alignment will be one of `wxALIGN_TOP`, `wxALIGN_CENTRE` or `wxALIGN_BOTTOM`.

int wxGrid::GetColLabelSize ( ) const

Returns the current height of the column labels.

int wxGrid::GetColLabelTextOrientation ( ) const

Returns the orientation of the column labels (either `wxHORIZONTAL` or `wxVERTICAL`).

wxString wxGrid::GetColLabelValue (int *col*) const

Returns the specified column label.

The default grid table class provides column labels of the form A,B...Z,AA,AB...ZZ,AAA... If you are using a custom grid table you can override wxGridTableBase::GetColLabelValue() to provide your own labels.

int wxGrid::GetColLeft (int *col*) const [protected]

Returns the coordinate of the left border specified column.

int wxGrid::GetColMinimalAcceptableWidth ( ) const

Returns the minimal width to which a column may be resized.

Use SetColMinimalAcceptableWidth() to change this value globally or SetColMinimalWidth() to do it for individual columns.

See also

GetRowMinimalAcceptableHeight()

int wxGrid::GetColMinimalWidth (int *col*) const `[protected]`

Get the minimal width of the given column/row.

The value returned by this function may be different than that returned by GetColMinimalAcceptableWidth() if SetColMinimalWidth() had been called for this column.

int wxGrid::GetColPos (int *colID*) const

Returns the position of the specified column.

int wxGrid::GetColRight (int *col*) const `[protected]`

Returns the coordinate of the right border specified column.

int wxGrid::GetColSize (int *col*) const

Returns the width of the specified column.

wxGridSizesInfo wxGrid::GetColSizes ( ) const

Get size information for all columns at once.

This method is useful when the information about all column widths needs to be saved. The widths can be later restored using SetColSizes().

See also

wxGridSizesInfo, GetRowSizes()

void wxGrid::GetDefaultCellAlignment (int * *horiz,* int * *vert*) const

Returns the default cell alignment.

Horizontal alignment will be one of `wxALIGN_LEFT`, `wxALIGN_CENTRE` or `wxALIGN_RIGHT`.

Vertical alignment will be one of `wxALIGN_TOP`, `wxALIGN_CENTRE` or `wxALIGN_BOTTOM`.

See also

SetDefaultCellAlignment()

wxColour wxGrid::GetDefaultCellBackgroundColour ( ) const

Returns the current default background colour for grid cells.

wxFont wxGrid::GetDefaultCellFont ( ) const

Returns the current default font for grid cell text.

bool wxGrid::GetDefaultCellOverflow ( ) const

Returns true if the cells can overflow by default.

wxColour wxGrid::GetDefaultCellTextColour ( ) const

Returns the current default colour for grid cell text.

int wxGrid::GetDefaultColLabelSize ( ) const

Returns the default height for column labels.

int wxGrid::GetDefaultColSize ( ) const

Returns the current default width for grid columns.

wxGridCellEditor* wxGrid::GetDefaultEditor ( ) const

Returns a pointer to the current default grid cell editor.

See wxGridCellEditor and the wxGrid Overview for more information about cell editors and renderers.

virtual wxGridCellEditor* wxGrid::GetDefaultEditorForCell (int *row*, int *col*) const [virtual]

Returns the default editor for the specified cell.

The base class version returns the editor appropriate for the current cell type but this method may be overridden in the derived classes to use custom editors for some cells by default.

Notice that the same may be achieved in a usually simpler way by associating a custom editor with the given cell or cells.

The caller must call DecRef() on the returned pointer.

wxGridCellEditor* wxGrid::GetDefaultEditorForCell (const wxGridCellCoords & *c*) const

Returns the default editor for the specified cell.

The base class version returns the editor appropriate for the current cell type but this method may be overridden in the derived classes to use custom editors for some cells by default.

Notice that the same may be achieved in a usually simpler way by associating a custom editor with the given cell or cells.

The caller must call DecRef() on the returned pointer.

virtual wxGridCellEditor* wxGrid::GetDefaultEditorForType (const wxString & *typeName*) const [virtual]

Returns the default editor for the cells containing values of the given type.

The base class version returns the editor which was associated with the specified *typeName* when it was registered RegisterDataType() but this function may be overridden to return something different. This allows to override an editor used for one of the standard types.

The caller must call DecRef() on the returned pointer.

virtual wxPen wxGrid::GetDefaultGridLinePen ( ) [virtual]

Returns the pen used for grid lines.

This virtual function may be overridden in derived classes in order to change the appearance of grid lines. Note that currently the pen width must be 1.

See also

GetColGridLinePen(), GetRowGridLinePen()

wxGridCellRenderer* wxGrid::GetDefaultRenderer ( ) const

Returns a pointer to the current default grid cell renderer.

See wxGridCellRenderer and the wxGrid Overview for more information about cell editors and renderers.

The caller must call DecRef() on the returned pointer.

virtual wxGridCellRenderer* wxGrid::GetDefaultRendererForCell (int *row*, int *col*) const [virtual]

Returns the default renderer for the given cell.

The base class version returns the renderer appropriate for the current cell type but this method may be overridden in the derived classes to use custom renderers for some cells by default.

The caller must call DecRef() on the returned pointer.

virtual wxGridCellRenderer* wxGrid::GetDefaultRendererForType (const wxString & *typeName*) const [virtual]

Returns the default renderer for the cell containing values of the given type.

See also

GetDefaultEditorForType()

int wxGrid::GetDefaultRowLabelSize ( ) const

Returns the default width for the row labels.

int wxGrid::GetDefaultRowSize ( ) const

Returns the current default height for grid rows.

wxHeaderCtrl* wxGrid::GetGridColHeader ( ) const

Return the header control used for column labels display.

This function can only be called if UseNativeColHeader() had been called.

wxWindow* wxGrid::GetGridColLabelWindow ( ) const

Return the column labels window.

This window is not shown if the columns labels were hidden using HideColLabels().

Depending on whether UseNativeColHeader() was called or not this can be either a wxHeaderCtrl or a plain wxWindow. This function returns a valid window pointer in either case but in the former case you can also use GetGridColHeader() to access it if you need wxHeaderCtrl-specific functionality.

wxWindow* wxGrid::GetGridCornerLabelWindow ( ) const

Return the window in the top left grid corner.

This window is shown only of both columns and row labels are shown and normally doesn't contain anything. Clicking on it is handled by wxGrid however and can be used to select the entire grid.

int wxGrid::GetGridCursorCol ( ) const

Returns the current grid cell column position.

int wxGrid::GetGridCursorRow ( ) const

Returns the current grid cell row position.

wxColour wxGrid::GetGridLineColour ( ) const

Returns the colour used for grid lines.

See also

GetDefaultGridLinePen()

wxWindow* wxGrid::GetGridRowLabelWindow ( ) const

Return the row labels window.

This window is not shown if the row labels were hidden using HideRowLabels().

wxWindow* wxGrid::GetGridWindow ( ) const

Return the main grid window containing the grid cells.

This window is always shown.

wxColour wxGrid::GetLabelBackgroundColour ( ) const

Returns the colour used for the background of row and column labels.

wxFont wxGrid::GetLabelFont ( ) const

Returns the font used for row and column labels.

wxColour wxGrid::GetLabelTextColour ( ) const

Returns the colour used for row and column label text.

int wxGrid::GetNumberCols ( ) const

Returns the total number of grid columns.

This is the same as the number of columns in the underlying grid table.

int wxGrid::GetNumberRows ( ) const

Returns the total number of grid rows.

This is the same as the number of rows in the underlying grid table.

wxGridCellAttr* wxGrid::GetOrCreateCellAttr (int *row*, int *col*) const

Returns the attribute for the given cell creating one if necessary.

If the cell already has an attribute, it is returned. Otherwise a new attribute is created, associated with the cell and returned. In any case the caller must call DecRef() on the returned pointer.

This function may only be called if CanHaveAttributes() returns true.

virtual wxPen wxGrid::GetRowGridLinePen (int *row*) [virtual]

Returns the pen used for horizontal grid lines.

This virtual function may be overridden in derived classes in order to change the appearance of individual grid line for the given *row*.

Example:

```
// in a grid displaying music notation, use a solid black pen between
// octaves (C0=row 127, C1=row 115 etc.)
wxPen MidiGrid::GetRowGridLinePen(int row)
{
    if ( row % 12 == 7 )
        return wxPen(*wxBLACK, 1, wxSOLID);
    else
        return GetDefaultGridLinePen();
}
```

void wxGrid::GetRowLabelAlignment (int * *horiz*, int * *vert*) const

Returns the alignment used for row labels.

Horizontal alignment will be one of wxALIGN_LEFT, wxALIGN_CENTRE or wxALIGN_RIGHT.

Vertical alignment will be one of wxALIGN_TOP, wxALIGN_CENTRE or wxALIGN_BOTTOM.

int wxGrid::GetRowLabelSize ( ) const

Returns the current width of the row labels.

wxString wxGrid::GetRowLabelValue (int *row*) const

Returns the specified row label.

The default grid table class provides numeric row labels. If you are using a custom grid table you can override wxGridTableBase::GetRowLabelValue() to provide your own labels.

int wxGrid::GetRowMinimalAcceptableHeight ( ) const

Returns the minimal size to which rows can be resized.

Use SetRowMinimalAcceptableHeight() to change this value globally or SetRowMinimalHeight() to do it for individual cells.

See also

GetColMinimalAcceptableWidth()

int wxGrid::GetRowMinimalHeight (int *col*) const `[protected]`

Returns the minimal size for the given column.

The value returned by this function may be different than that returned by GetRowMinimalAcceptableHeight() if SetRowMinimalHeight() had been called for this row.

int wxGrid::GetRowSize (int *row*) const

Returns the height of the specified row.

wxGridSizesInfo wxGrid::GetRowSizes ( ) const

Get size information for all row at once.

See also

wxGridSizesInfo, GetColSizes()

int wxGrid::GetScrollLineX ( ) const

Returns the number of pixels per horizontal scroll increment.

The default is 15.

See also

GetScrollLineY(), SetScrollLineX(), SetScrollLineY()

int wxGrid::GetScrollLineY ( ) const

Returns the number of pixels per vertical scroll increment.

The default is 15.

See also

GetScrollLineX(), SetScrollLineX(), SetScrollLineY()

wxGridCellCoordsArray wxGrid::GetSelectedCells ( ) const

Returns an array of individually selected cells.

Notice that this array does *not* contain all the selected cells in general as it doesn't include the cells selected as part of column, row or block selection. You must use this method, GetSelectedCols(), GetSelectedRows() and GetSelectionBlockTopLeft() and GetSelectionBlockBottomRight() methods to obtain the entire selection in general.

Please notice this behaviour is by design and is needed in order to support grids of arbitrary size (when an entire column is selected in a grid with a million of columns, we don't want to create an array with a million of entries in this function, instead it returns an empty array and GetSelectedCols() returns an array containing one element).

wxArrayInt wxGrid::GetSelectedCols ( ) const

Returns an array of selected columns.

Please notice that this method alone is not sufficient to find all the selected columns as it contains only the columns which were individually selected but not those being part of the block selection or being selected in virtue of all of their cells being selected individually, please see GetSelectedCells() for more details.

wxArrayInt wxGrid::GetSelectedRows ( ) const

Returns an array of selected rows.

Please notice that this method alone is not sufficient to find all the selected rows as it contains only the rows which were individually selected but not those being part of the block selection or being selected in virtue of all of their cells being selected individually, please see GetSelectedCells() for more details.

wxColour wxGrid::GetSelectionBackground ( ) const

Returns the colour used for drawing the selection background.

wxGridCellCoordsArray wxGrid::GetSelectionBlockBottomRight ( ) const

Returns an array of the bottom right corners of blocks of selected cells.

Please see GetSelectedCells() for more information about the selection representation in wxGrid.

See also

GetSelectionBlockTopLeft()

wxGridCellCoordsArray wxGrid::GetSelectionBlockTopLeft ( ) const

Returns an array of the top left corners of blocks of selected cells.

Please see GetSelectedCells() for more information about the selection representation in wxGrid.

See also

GetSelectionBlockBottomRight()

wxColour wxGrid::GetSelectionForeground ( ) const

Returns the colour used for drawing the selection foreground.

wxGridSelectionModes wxGrid::GetSelectionMode ( ) const

Returns the current selection mode.

See also

SetSelectionMode().

int wxGrid::GetSortingColumn ( ) const

Return the column in which the sorting indicator is currently displayed.

Returns `wxNOT_FOUND` if sorting indicator is not currently displayed at all.

See also

SetSortingColumn()

wxGridTableBase* wxGrid::GetTable ( ) const

Returns a base pointer to the current table object.

The returned pointer is still owned by the grid.

void wxGrid::GoToCell (int *row,* int *col*)

Make the given cell current and ensure it is visible.

This method is equivalent to calling MakeCellVisible() and SetGridCursor() and so, as with the latter, a `wxEVT_GRID_SELECT_CELL` event is generated by it and the selected cell doesn't change if the event is vetoed.

void wxGrid::GoToCell (const wxGridCellCoords & *coords*)

Make the given cell current and ensure it is visible.

This method is equivalent to calling MakeCellVisible() and SetGridCursor() and so, as with the latter, a `wxEVT_GRID_SELECT_CELL` event is generated by it and the selected cell doesn't change if the event is vetoed.

bool wxGrid::GridLinesEnabled ( ) const

Returns true if drawing of grid lines is turned on, false otherwise.

void wxGrid::HideCellEditControl ( )

Hides the in-place cell edit control.

void wxGrid::HideCol (int *col*)

Hides the specified column.

To show the column later you need to call SetColSize() with non-0 width or ShowCol() to restore the previous column width.

If the column is already hidden, this method doesn't do anything.

Parameters

col	The column index.

void wxGrid::HideColLabels ( )

Hides the column labels by calling SetColLabelSize() with a size of 0.

Show labels again by calling that method with a width greater than 0.

void wxGrid::HideRow (int *col*)

Hides the specified row.

To show the row later you need to call SetRowSize() with non-0 width or ShowRow() to restore its original height.

If the row is already hidden, this method doesn't do anything.

Parameters

col	The row index.

void wxGrid::HideRowLabels ( )

Hides the row labels by calling SetRowLabelSize() with a size of 0.

The labels can be shown again by calling SetRowLabelSize() with a width greater than 0.

bool wxGrid::InsertCols (int *pos* = `0`, int *numCols* = `1`, bool *updateLabels* = `true`)

Inserts one or more new columns into a grid with the first new column at the specified position.

Notice that inserting the columns in the grid requires grid table cooperation: when this method is called, grid object begins by requesting the underlying grid table to insert new columns. If this is successful the table notifies the grid and the grid updates the display. For a default grid (one where you have called CreateGrid()) this process is automatic. If you are using a custom grid table (specified with SetTable()) then you must override wxGridTable↩Base::InsertCols() in your derived table class.

Parameters

pos	The position which the first newly inserted column will have.
numCols	The number of columns to insert.
updateLabels	Currently not used.

Returns

true if the columns were successfully inserted, false if an error occurred (most likely the table couldn't be updated).

bool wxGrid::InsertRows (int *pos* = `0`, int *numRows* = `1`, bool *updateLabels* = `true`)

Inserts one or more new rows into a grid with the first new row at the specified position.

Notice that you must implement wxGridTableBase::InsertRows() if you use a grid with a custom table, please see InsertCols() for more information.

Parameters

pos	The position which the first newly inserted row will have.
numRows	The number of rows to insert.
updateLabels	Currently not used.

Returns

true if the rows were successfully inserted, false if an error occurred (most likely the table couldn't be updated).

bool wxGrid::IsCellEditControlEnabled ( ) const

Returns true if the in-place edit control is currently enabled.

bool wxGrid::IsColShown (int *col*) const

Returns true if the specified column is not currently hidden.

bool wxGrid::IsCurrentCellReadOnly ( ) const

Returns true if the current cell is read-only.

See also

SetReadOnly(), IsReadOnly()

bool wxGrid::IsEditable ( ) const

Returns false if the whole grid has been set as read-only or true otherwise.

See EnableEditing() for more information about controlling the editing status of grid cells.

bool wxGrid::IsInSelection (int *row,* int *col*) const

Returns true if the given cell is selected.

bool wxGrid::IsInSelection (const wxGridCellCoords & *coords*) const

Returns true if the given cell is selected.

bool wxGrid::IsReadOnly (int *row,* int *col*) const

Returns true if the cell at the specified location can't be edited.

See also

SetReadOnly(), IsCurrentCellReadOnly()

bool wxGrid::IsRowShown (int *row*) const

Returns true if the specified row is not currently hidden.

bool wxGrid::IsSelection ( ) const

Returns true if there are currently any selected cells, rows, columns or blocks.

bool wxGrid::IsSortingBy (int *col*) const

Return true if this column is currently used for sorting.

See also

GetSortingColumn()

bool wxGrid::IsSortOrderAscending ( ) const

Return true if the current sorting order is ascending or false if it is descending.

It only makes sense to call this function if GetSortingColumn() returns a valid column index and not `wxNOT_FOUND`.

See also

SetSortingColumn()

bool wxGrid::IsVisible (int *row*, int *col*, bool *wholeCellVisible* = `true`) const

Returns true if a cell is either entirely or at least partially visible in the grid window.

By default, the cell must be entirely visible for this function to return true but if *wholeCellVisible* is false, the function returns true even if the cell is only partially visible.

bool wxGrid::IsVisible (const wxGridCellCoords & *coords*, bool *wholeCellVisible* = `true`) const

Returns true if a cell is either entirely or at least partially visible in the grid window.

By default, the cell must be entirely visible for this function to return true but if *wholeCellVisible* is false, the function returns true even if the cell is only partially visible.

void wxGrid::MakeCellVisible (int *row*, int *col*)

Brings the specified cell into the visible grid cell area with minimal scrolling.

Does nothing if the cell is already visible.

void wxGrid::MakeCellVisible (const wxGridCellCoords & *coords*)

Brings the specified cell into the visible grid cell area with minimal scrolling.

Does nothing if the cell is already visible.

bool wxGrid::MoveCursorDown (bool *expandSelection*)

Moves the grid cursor down by one row.

If a block of cells was previously selected it will expand if the argument is true or be cleared if the argument is false.

bool wxGrid::MoveCursorDownBlock (bool *expandSelection*)

Moves the grid cursor down in the current column such that it skips to the beginning or end of a block of non-empty cells.

If a block of cells was previously selected it will expand if the argument is true or be cleared if the argument is false.

bool wxGrid::MoveCursorLeft (bool *expandSelection*)

Moves the grid cursor left by one column.

If a block of cells was previously selected it will expand if the argument is true or be cleared if the argument is false.

bool wxGrid::MoveCursorLeftBlock (bool *expandSelection*)

Moves the grid cursor left in the current row such that it skips to the beginning or end of a block of non-empty cells.

If a block of cells was previously selected it will expand if the argument is true or be cleared if the argument is false.

bool wxGrid::MoveCursorRight (bool *expandSelection*)

Moves the grid cursor right by one column.

If a block of cells was previously selected it will expand if the argument is true or be cleared if the argument is false.

bool wxGrid::MoveCursorRightBlock (bool *expandSelection*)

Moves the grid cursor right in the current row such that it skips to the beginning or end of a block of non-empty cells.

If a block of cells was previously selected it will expand if the argument is true or be cleared if the argument is false.

bool wxGrid::MoveCursorUp (bool *expandSelection*)

Moves the grid cursor up by one row.

If a block of cells was previously selected it will expand if the argument is true or be cleared if the argument is false.

bool wxGrid::MoveCursorUpBlock (bool *expandSelection*)

Moves the grid cursor up in the current column such that it skips to the beginning or end of a block of non-empty cells.

If a block of cells was previously selected it will expand if the argument is true or be cleared if the argument is false.

bool wxGrid::MovePageDown ( )

Moves the grid cursor down by some number of rows so that the previous bottom visible row becomes the top visible row.

bool wxGrid::MovePageUp ( )

Moves the grid cursor up by some number of rows so that the previous top visible row becomes the bottom visible row.

bool wxGrid::ProcessTableMessage (wxGridTableMessage & *msg*)

Receive and handle a message from the table.

void wxGrid::RefreshAttr (int *row*, int *col*)

Invalidates the cached attribute for the given cell.

For efficiency reasons, wxGrid may cache the recently used attributes (currently it caches only the single most recently used one, in fact) which can result in the cell appearance not being refreshed even when the attribute returned by your custom wxGridCellAttrProvider-derived class has changed. To force the grid to refresh the cell attribute, this function may be used. Notice that calling it will not result in actually redrawing the cell, you still need to call wxWindow::RefreshRect() to invalidate the area occupied by the cell in the window to do this. Also note that you don't need to call this function if you store the attributes in wxGrid itself, i.e. use its SetAttr() and similar methods, it is only useful when using a separate custom attributes provider.

Parameters

row	The row of the cell whose attribute needs to be queried again.
col	The column of the cell whose attribute needs to be queried again.

Since

2.9.2

void wxGrid::RegisterDataType (const wxString & *typeName*, wxGridCellRenderer * *renderer*, wxGridCellEditor * *editor*)

Register a new data type.

The data types allow to naturally associate specific renderers and editors to the cells containing values of the given type. For example, the grid automatically registers a data type with the name `wxGRID_VALUE_STRING` which uses wxGridCellStringRenderer and wxGridCellTextEditor as its renderer and editor respectively – this is the data type used by all the cells of the default wxGridStringTable, so this renderer and editor are used by default for all grid cells.

However if a custom table returns `wxGRID_VALUE_BOOL` from its wxGridTableBase::GetTypeName() method, then wxGridCellBoolRenderer and wxGridCellBoolEditor are used for it because the grid also registers a boolean data type with this name.

And as this mechanism is completely generic, you may register your own data types using your own custom renderers and editors. Just remember that the table must identify a cell as being of the given type for them to be used for this cell.

Parameters

typeName	Name of the new type. May be any string, but if the type name is the same as the name of an already registered type, including one of the standard ones (which are `wxGRID_VALUE_STRING`, `wxGRID_VALUE_BOOL`, `wxGRID_VALUE_NUMBER`, `wxGRID_VALUE_FLOAT` and `wxGRID_VALUE_CHOICE`), then the new registration information replaces the previously used renderer and editor.

renderer	The renderer to use for the cells of this type. Its ownership is taken by the grid, i.e. it will call DecRef() on this pointer when it doesn't need it any longer.
editor	The editor to use for the cells of this type. Its ownership is also taken by the grid.

void wxGrid::Render (wxDC & *dc*, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, const wxGridCellCoords & *topLeft* = wxGridCellCoords (-1, -1), const wxGridCellCoords & *bottomRight* = wxGridCellCoords (-1, -1), int *style* = wxGRID_DRAW_DEFAULT)

Draws part or all of a wxGrid on a wxDC for printing or display.

Pagination can be accomplished by using sequential Render() calls with appropriate values in wxGridCellCoords topLeft and bottomRight.

Parameters

dc	The wxDC to be drawn on.
pos	The position on the wxDC where rendering should begin. If not specified drawing will begin at the wxDC MaxX() and MaxY().
size	The size of the area on the wxDC that the rendered wxGrid should occupy. If not specified the drawing will be scaled to fit the available dc width or height. The wxGrid's aspect ratio is maintained whether or not size is specified.
topLeft	The top left cell of the block to be drawn. Defaults to (0, 0).
bottomRight	The bottom right cell of the block to be drawn. Defaults to row and column counts.
style	A combination of values from wxGridRenderStyle.

Since

2.9.4

void wxGrid::ResetColPos ( )

Resets the position of the columns to the default.

void wxGrid::SaveEditControlValue ( )

Sets the value of the current grid cell to the current in-place edit control value.

This is called automatically when the grid cursor moves from the current cell to a new cell. It is also a good idea to call this function when closing a grid since any edits to the final cell location will not be saved otherwise.

void wxGrid::SelectAll ( )

Selects all cells in the grid.

void wxGrid::SelectBlock (int *topRow*, int *leftCol*, int *bottomRow*, int *rightCol*, bool *addToSelected* = false)

Selects a rectangular block of cells.

If *addToSelected* is false then any existing selection will be deselected; if true the column will be added to the existing selection.

void wxGrid::SelectBlock (const wxGridCellCoords & *topLeft*, const wxGridCellCoords & *bottomRight*, bool *addToSelected* = false)

Selects a rectangular block of cells.

If *addToSelected* is false then any existing selection will be deselected; if true the column will be added to the existing selection.

void wxGrid::SelectCol (int *col,* bool *addToSelected* = `false`)

Selects the specified column.

If *addToSelected* is false then any existing selection will be deselected; if true the column will be added to the existing selection.

This method won't select anything if the current selection mode is wxGridSelectRows.

void wxGrid::SelectRow (int *row,* bool *addToSelected* = `false`)

Selects the specified row.

If *addToSelected* is false then any existing selection will be deselected; if true the row will be added to the existing selection.

This method won't select anything if the current selection mode is wxGridSelectColumns.

void wxGrid::SetCellAlignment (int *row,* int *col,* int *horiz,* int *vert*)

Sets the horizontal and vertical alignment for grid cell text at the specified location.

Horizontal alignment should be one of `wxALIGN_LEFT`, `wxALIGN_CENTRE` or `wxALIGN_RIGHT`.

Vertical alignment should be one of `wxALIGN_TOP`, `wxALIGN_CENTRE` or `wxALIGN_BOTTOM`.

void wxGrid::SetCellAlignment (int *align,* int *row,* int *col*)

Sets the horizontal and vertical alignment for grid cell text at the specified location.

Horizontal alignment should be one of `wxALIGN_LEFT`, `wxALIGN_CENTRE` or `wxALIGN_RIGHT`.

Vertical alignment should be one of `wxALIGN_TOP`, `wxALIGN_CENTRE` or `wxALIGN_BOTTOM`.

Deprecated Please use SetCellAlignment(row, col, horiz, vert) instead.

void wxGrid::SetCellBackgroundColour (int *row,* int *col,* const **wxColour & *colour*)**

Set the background colour for the given cell or all cells by default.

void wxGrid::SetCellEditor (int *row,* int *col,* **wxGridCellEditor * *editor*)**

Sets the editor for the grid cell at the specified location.

The grid will take ownership of the pointer.

See wxGridCellEditor and the wxGrid Overview for more information about cell editors and renderers.

void wxGrid::SetCellFont (int *row,* int *col,* const **wxFont & *font*)**

Sets the font for text in the grid cell at the specified location.

void wxGrid::SetCellHighlightColour (const wxColour &)

void wxGrid::SetCellHighlightPenWidth (int *width*)

void wxGrid::SetCellHighlightROPenWidth (int *width*)

void wxGrid::SetCellOverflow (int *row,* int *col,* bool *allow*)

Sets the overflow permission of the cell.

void wxGrid::SetCellRenderer (int *row,* int *col,* wxGridCellRenderer * *renderer*)

Sets the renderer for the grid cell at the specified location.

The grid will take ownership of the pointer.

See wxGridCellRenderer and the wxGrid Overview for more information about cell editors and renderers.

void wxGrid::SetCellSize (int *row,* int *col,* int *num_rows,* int *num_cols*)

Set the size of the cell.

Specifying a value of more than 1 in *num_rows* or *num_cols* will make the cell at (*row*, *col*) span the block of the specified size, covering the other cells which would be normally shown in it. Passing 1 for both arguments resets the cell to normal appearance.

See also

GetCellSize()

Parameters

row	The row of the cell.
col	The column of the cell.
num_rows	Number of rows to be occupied by this cell, must be >= 1.
num_cols	Number of columns to be occupied by this cell, must be >= 1.

void wxGrid::SetCellTextColour (int *row,* int *col,* const wxColour & *colour*)

Sets the text colour for the given cell.

void wxGrid::SetCellTextColour (const wxColour & *val,* int *row,* int *col*)

Sets the text colour for the given cell.

Deprecated Please use SetCellTextColour(row, col, colour)

void wxGrid::SetCellTextColour (const wxColour & *colour*)

Sets the text colour for all cells by default.

Deprecated Please use SetDefaultCellTextColour(colour) instead.

void wxGrid::SetCellValue (int *row,* int *col,* const wxString & *s*)

Sets the string value for the cell at the specified location.

For simple applications where a grid object automatically uses a default grid table of string values you use this function together with GetCellValue() to access cell values. For more complex applications where you have derived your own grid table class that contains various data types (e.g. numeric, boolean or user-defined custom types) then you only use this function for those cells that contain string values.

See wxGridTableBase::CanSetValueAs() and the wxGrid Overview for more information.

void wxGrid::SetCellValue (const wxGridCellCoords & *coords,* const wxString & *s*)

Sets the string value for the cell at the specified location.

For simple applications where a grid object automatically uses a default grid table of string values you use this function together with GetCellValue() to access cell values. For more complex applications where you have derived your own grid table class that contains various data types (e.g. numeric, boolean or user-defined custom types) then you only use this function for those cells that contain string values.

See wxGridTableBase::CanSetValueAs() and the wxGrid Overview for more information.

void wxGrid::SetCellValue (const wxString & *val,* int *row,* int *col*)

Deprecated Please use SetCellValue(int,int,const wxString&) or SetCellValue(const wxGridCellCoords&,const wxString&) instead.

Sets the string value for the cell at the specified location.

For simple applications where a grid object automatically uses a default grid table of string values you use this function together with GetCellValue() to access cell values. For more complex applications where you have derived your own grid table class that contains various data types (e.g. numeric, boolean or user-defined custom types) then you only use this function for those cells that contain string values.

See wxGridTableBase::CanSetValueAs() and the wxGrid Overview for more information.

void wxGrid::SetColAttr (int *col,* wxGridCellAttr * *attr*)

Sets the cell attributes for all cells in the specified column.

For more information about controlling grid cell attributes see the wxGridCellAttr cell attribute class and the wxGrid Overview.

void wxGrid::SetColFormatBool (int *col*)

Sets the specified column to display boolean values.

See also

SetColFormatCustom()

void wxGrid::SetColFormatCustom (int *col,* const wxString & *typeName*)

Sets the specified column to display data in a custom format.

This method provides an alternative to defining a custom grid table which would return *typeName* from its GetTypeName() method for the cells in this column: while it doesn't really change the type of the cells in this column, it does associate the renderer and editor used for the cells of the specified type with them.

See the wxGrid Overview for more information on working with custom data types.

void wxGrid::SetColFormatFloat (int *col,* int *width* = -1, int *precision* = -1)

Sets the specified column to display floating point values with the given width and precision.

See also

SetColFormatCustom()

void wxGrid::SetColFormatNumber (int *col*)

Sets the specified column to display integer values.

See also

SetColFormatCustom()

void wxGrid::SetColLabelAlignment (int *horiz,* int *vert*)

Sets the horizontal and vertical alignment of column label text.

Horizontal alignment should be one of `wxALIGN_LEFT`, `wxALIGN_CENTRE` or `wxALIGN_RIGHT`. Vertical alignment should be one of `wxALIGN_TOP`, `wxALIGN_CENTRE` or `wxALIGN_BOTTOM`.

void wxGrid::SetColLabelSize (int *height*)

Sets the height of the column labels.

If *height* equals to `wxGRID_AUTOSIZE` then height is calculated automatically so that no label is truncated. Note that this could be slow for a large table.

void wxGrid::SetColLabelTextOrientation (int *textOrientation*)

Sets the orientation of the column labels (either `wxHORIZONTAL` or `wxVERTICAL`).

void wxGrid::SetColLabelValue (int *col,* const wxString & *value*)

Set the value for the given column label.

If you are using a custom grid table you must override wxGridTableBase::SetColLabelValue() for this to have any effect.

void wxGrid::SetColMinimalAcceptableWidth (int *width*)

Sets the minimal *width* to which the user can resize columns.

See also

GetColMinimalAcceptableWidth()

void wxGrid::SetColMinimalWidth (int *col,* int *width*)

Sets the minimal *width* for the specified column *col*.

It is usually best to call this method during grid creation as calling it later will not resize the column to the given minimal width even if it is currently narrower than it.

width must be greater than the minimal acceptable column width as returned by GetColMinimalAcceptableWidth().

void wxGrid::SetColPos (int *colID,* int *newPos*)

Sets the position of the specified column.

void wxGrid::SetColSize (int *col,* int *width*)

Sets the width of the specified column.

Parameters

col	The column index.
width	The new column width in pixels, 0 to hide the column or -1 to fit the column width to its label width.

void wxGrid::SetColSizes (const wxGridSizesInfo & *sizeInfo*)

Restore all columns sizes.

This is usually called with wxGridSizesInfo object previously returned by GetColSizes().

See also

SetRowSizes()

void wxGrid::SetColumnsOrder (const wxArrayInt & *order*)

Sets the positions of all columns at once.

This method takes an array containing the indices of the columns in their display order, i.e. uses the same convention as wxHeaderCtrl::SetColumnsOrder().

void wxGrid::SetDefaultCellAlignment (int *horiz,* int *vert*)

Sets the default horizontal and vertical alignment for grid cell text.

Horizontal alignment should be one of `wxALIGN_LEFT`, `wxALIGN_CENTRE` or `wxALIGN_RIGHT`. Vertical alignment should be one of `wxALIGN_TOP`, `wxALIGN_CENTRE` or `wxALIGN_BOTTOM`.

void wxGrid::SetDefaultCellBackgroundColour (const wxColour & *colour*)

Sets the default background colour for grid cells.

void wxGrid::SetDefaultCellFont (const wxFont & *font*)

Sets the default font to be used for grid cell text.

void wxGrid::SetDefaultCellOverflow (bool *allow*)

Sets the default overflow permission of the cells.

void wxGrid::SetDefaultCellTextColour (const wxColour & *colour*)

Sets the current default colour for grid cell text.

void wxGrid::SetDefaultColSize (int *width*, bool *resizeExistingCols* = `false`)

Sets the default width for columns in the grid.

This will only affect columns subsequently added to the grid unless *resizeExistingCols* is true.

If *width* is less than GetColMinimalAcceptableWidth(), then the minimal acceptable width is used instead of it.

void wxGrid::SetDefaultEditor (wxGridCellEditor * *editor*)

Sets the default editor for grid cells.

The grid will take ownership of the pointer.

See wxGridCellEditor and the wxGrid Overview for more information about cell editors and renderers.

void wxGrid::SetDefaultRenderer (wxGridCellRenderer * *renderer*)

Sets the default renderer for grid cells.

The grid will take ownership of the pointer.

See wxGridCellRenderer and the wxGrid Overview for more information about cell editors and renderers.

void wxGrid::SetDefaultRowSize (int *height*, bool *resizeExistingRows* = `false`)

Sets the default height for rows in the grid.

This will only affect rows subsequently added to the grid unless *resizeExistingRows* is true.

If *height* is less than GetRowMinimalAcceptableHeight(), then the minimal acceptable height is used instead of it.

void wxGrid::SetGridCursor (int *row*, int *col*)

Set the grid cursor to the specified cell.

The grid cursor indicates the current cell and can be moved by the user using the arrow keys or the mouse.

Calling this function generates a `wxEVT_GRID_SELECT_CELL` event and if the event handler vetoes this event, the cursor is not moved.

This function doesn't make the target call visible, use GoToCell() to do this.

void wxGrid::SetGridCursor (const wxGridCellCoords & *coords*)

Set the grid cursor to the specified cell.

The grid cursor indicates the current cell and can be moved by the user using the arrow keys or the mouse.

Calling this function generates a `wxEVT_GRID_SELECT_CELL` event and if the event handler vetoes this event, the cursor is not moved.

This function doesn't make the target call visible, use GoToCell() to do this.

void wxGrid::SetGridLineColour (const wxColour & *colour*)

Sets the colour used to draw grid lines.

void wxGrid::SetLabelBackgroundColour (const wxColour & *colour*)

Sets the background colour for row and column labels.

void wxGrid::SetLabelFont (const wxFont & *font*)

Sets the font for row and column labels.

void wxGrid::SetLabelTextColour (const wxColour & *colour*)

Sets the colour for row and column label text.

void wxGrid::SetMargins (int *extraWidth,* int *extraHeight*)

Sets the extra margins used around the grid area.

A grid may occupy more space than needed for its data display and this function allows to set how big this extra space is

void wxGrid::SetReadOnly (int *row,* int *col,* bool *isReadOnly* = `true`)

Makes the cell at the specified location read-only or editable.

See also

IsReadOnly()

void wxGrid::SetRowAttr (int *row,* wxGridCellAttr * *attr*)

Sets the cell attributes for all cells in the specified row.

The grid takes ownership of the attribute pointer.

See the wxGridCellAttr class for more information about controlling cell attributes.

void wxGrid::SetRowLabelAlignment (int *horiz,* int *vert*)

Sets the horizontal and vertical alignment of row label text.

Horizontal alignment should be one of `wxALIGN_LEFT`, `wxALIGN_CENTRE` or `wxALIGN_RIGHT`. Vertical alignment should be one of `wxALIGN_TOP`, `wxALIGN_CENTRE` or `wxALIGN_BOTTOM`.

void wxGrid::SetRowLabelSize (int *width*)

Sets the width of the row labels.

If *width* equals `wxGRID_AUTOSIZE` then width is calculated automatically so that no label is truncated. Note that this could be slow for a large table.

void wxGrid::SetRowLabelValue (int *row,* const wxString & *value*)

Sets the value for the given row label.

If you are using a derived grid table you must override wxGridTableBase::SetRowLabelValue() for this to have any effect.

void wxGrid::SetRowMinimalAcceptableHeight (int *height*)

Sets the minimal row *height* used by default.

See SetColMinimalAcceptableWidth() for more information.

void wxGrid::SetRowMinimalHeight (int *row,* int *height*)

Sets the minimal *height* for the specified *row*.

See SetColMinimalWidth() for more information.

void wxGrid::SetRowSize (int *row,* int *height*)

Sets the height of the specified row.

See SetColSize() for more information.

void wxGrid::SetRowSizes (const wxGridSizesInfo & *sizeInfo*)

Restore all rows sizes.

See also

SetColSizes()

void wxGrid::SetScrollLineX (int *x*)

Sets the number of pixels per horizontal scroll increment.

The default is 15.

See also

GetScrollLineX(), GetScrollLineY(), SetScrollLineY()

void wxGrid::SetScrollLineY (int *y*)

Sets the number of pixels per vertical scroll increment.

The default is 15.

See also

GetScrollLineX(), GetScrollLineY(), SetScrollLineX()

void wxGrid::SetSelectionBackground (const wxColour & *c*)

Set the colour to be used for drawing the selection background.

void wxGrid::SetSelectionForeground (const wxColour & *c*)

Set the colour to be used for drawing the selection foreground.

void wxGrid::SetSelectionMode (wxGridSelectionModes *selmode*)

Set the selection behaviour of the grid.

The existing selection is converted to conform to the new mode if possible and discarded otherwise (e.g. any individual selected cells are deselected if the new mode allows only the selection of the entire rows or columns).

void wxGrid::SetSortingColumn (int *col*, bool *ascending* = `true`)

Set the column to display the sorting indicator in and its direction.

Parameters

col	The column to display the sorting indicator in or `wxNOT_FOUND` to remove any currently displayed sorting indicator.
ascending	If true, display the ascending sort indicator, otherwise display the descending sort indicator.

See also

GetSortingColumn(), IsSortOrderAscending()

void wxGrid::SetTabBehaviour (TabBehaviour *behaviour*)

Set the grid's behaviour when the user presses the TAB key.

Pressing the TAB key moves the grid cursor right in the current row, if there is a cell at the right and, similarly, Shift-TAB moves the cursor to the left in the current row if it's not in the first column.

What happens if the cursor can't be moved because it it's already at the beginning or end of the row can be configured using this function, see wxGrid::TabBehaviour documentation for the detailed description.

IF none of the standard behaviours is appropriate, you can always handle `wxEVT_GRID_TABBING` event directly to implement a custom TAB-handling logic.

Since

2.9.5

bool wxGrid::SetTable (wxGridTableBase * *table*, bool *takeOwnership* = `false`, wxGridSelectionModes *selmode* = wxGridSelectCells)

Passes a pointer to a custom grid table to be used by the grid.

This should be called after the grid constructor and before using the grid object. If *takeOwnership* is set to true then the table will be deleted by the wxGrid destructor.

Use this function instead of CreateGrid() when your application involves complex or non-string data or data sets that are too large to fit wholly in memory.

void wxGrid::SetUseNativeColLabels (bool *native* = `true`)

Call this in order to make the column labels use a native look by using wxRendererNative::DrawHeaderButton() internally.

There is no equivalent method for drawing row columns as there is not native look for that. This option is useful when using wxGrid for displaying tables and not as a spread-sheet.

See also

UseNativeColHeader()

void wxGrid::ShowCellEditControl ( )

Displays the in-place cell edit control for the current cell.

void wxGrid::ShowCol (int *col*)

Shows the previously hidden column by resizing it to non-0 size.

The column is shown again with the same width that it had before HideCol() call.

If the column is currently shown, this method doesn't do anything.

See also

HideCol(), SetColSize()

void wxGrid::ShowRow (int *col*)

Shows the previously hidden row.

The row is shown again with the same height that it had before HideRow() call.

If the row is currently shown, this method doesn't do anything.

See also

HideRow(), SetRowSize()

void wxGrid::UnsetSortingColumn ( )

Remove any currently shown sorting indicator.

This is equivalent to calling SetSortingColumn() with `wxNOT_FOUND` first argument.

void wxGrid::UseNativeColHeader (bool *native* = `true`)

Enable the use of native header window for column labels.

If this function is called with true argument, a wxHeaderCtrl is used instead to display the column labels instead of drawing them in wxGrid code itself. This has the advantage of making the grid look and feel perfectly the same as native applications (using SetUseNativeColLabels() the grid can be made to look more natively but it still doesn't feel natively, notably the column resizing and dragging still works slightly differently as it is implemented in wxWidgets itself) but results in different behaviour for column and row headers, for which there is no equivalent function, and, most importantly, is unsuitable for grids with huge numbers of columns as wxHeaderCtrl doesn't support virtual mode. Because of this, by default the grid does not use the native header control but you should call this function to enable it if you are using the grid to display tabular data and don't have thousands of columns in it.

Another difference between the default behaviour and the native header behaviour is that the latter provides the user with a context menu (which appears on right clicking the header) allowing to rearrange the grid columns if CanDragColMove() returns true. If you want to prevent this from happening for some reason, you need to define a handler for `wxEVT_GRID_LABEL_RIGHT_CLICK` event which simply does nothing (in particular doesn't skip the event) as this will prevent the default right click handling from working.

Also note that currently `wxEVT_GRID_LABEL_RIGHT_DCLICK` event is not generated for the column labels if the native columns header is used (but this limitation could possibly be lifted in the future).

int wxGrid::XToCol (int *x*, bool *clipToMinMax* = `false`) const

Returns the column at the given pixel position.

Parameters

x	The x position to evaluate.
clipToMinMax	If true, rather than returning `wxNOT_FOUND`, it returns either the first or last column depending on whether *x* is too far to the left or right respectively.

Returns

The column index or `wxNOT_FOUND`.

int wxGrid::XToEdgeOfCol (int *x*) const

Returns the column whose right hand edge is close to the given logical *x* position.

If no column edge is near to this position `wxNOT_FOUND` is returned.

wxGridCellCoords wxGrid::XYToCell (int *x*, int *y*) const

Translates logical pixel coordinates to the grid cell coordinates.

Notice that this function expects logical coordinates on input so if you use this function in a mouse event handler you need to translate the mouse position, which is expressed in device coordinates, to logical ones.

See also

XToCol(), YToRow()

wxGridCellCoords wxGrid::XYToCell (const wxPoint & *pos*) const

Translates logical pixel coordinates to the grid cell coordinates.

Notice that this function expects logical coordinates on input so if you use this function in a mouse event handler you need to translate the mouse position, which is expressed in device coordinates, to logical ones.

See also

XToCol(), YToRow()

int wxGrid::YToEdgeOfRow (int *y*) const

Returns the row whose bottom edge is close to the given logical *y* position.

If no row edge is near to this position `wxNOT_FOUND` is returned.

int wxGrid::YToRow (int *y*, bool *clipToMinMax* = `false`) const

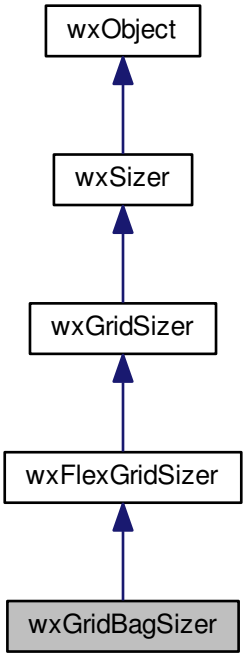
Returns the grid row that corresponds to the logical *y* coordinate.

Returns `wxNOT_FOUND` if there is no row at the *y* position.

21.299 wxGridBagSizer Class Reference

```
#include <wx/gbsizer.h>
```

Inheritance diagram for wxGridBagSizer:



21.299.1 Detailed Description

A wxSizer that can lay out items in a virtual grid like a wxFlexGridSizer but in this case explicit positioning of the items is allowed using wxGBPosition, and items can optionally span more than one row and/or column using wxGBSpan.

Library: wxCore

Category: Window Layout

Public Member Functions

- wxGridBagSizer (int vgap=0, int hgap=0)

  Constructor, with optional parameters to specify the gap between the rows and columns.
- wxSize CalcMin ()

  Called when the managed size of the sizer is needed or when layout needs done.
- wxGBSizerItem * FindItemAtPoint (const wxPoint &pt)

  Return the sizer item located at the point given in pt, or NULL if there is no item at that point.
- wxGBSizerItem * FindItemAtPosition (const wxGBPosition &pos)

  Return the sizer item for the given grid cell, or NULL if there is no item at that position.
- wxGBSizerItem * FindItemWithData (const wxObject *userData)

  Return the sizer item that has a matching user data (it only compares pointer values) or NULL if not found.
- wxSize GetCellSize (int row, int col) const

Get the size of the specified cell, including hgap and vgap.

- wxSize GetEmptyCellSize () const

  Get the size used for cells in the grid with no item.

- void RecalcSizes ()

  Called when the managed size of the sizer is needed or when layout needs done.

- void SetEmptyCellSize (const wxSize &sz)

  Set the size used for cells in the grid with no item.

- wxSizerItem * Add (wxWindow *window, const wxGBPosition &pos, const wxGBSpan &span=wxDefaultSpan, int flag=0, int border=0, wxObject *userData=NULL)

  Adds the given item to the given position.

- wxSizerItem * Add (wxSizer *sizer, const wxGBPosition &pos, const wxGBSpan &span=wxDefaultSpan, int flag=0, int border=0, wxObject *userData=NULL)

  Adds the given item to the given position.

- wxSizerItem * Add (wxGBSizerItem *item)

  Adds the given item to the given position.

- wxSizerItem * Add (int width, int height, const wxGBPosition &pos, const wxGBSpan &span=wxDefaultSpan, int flag=0, int border=0, wxObject *userData=NULL)

  Adds a spacer to the given position.

- bool CheckForIntersection (wxGBSizerItem *item, wxGBSizerItem *excludeItem=NULL)

  Look at all items and see if any intersect (or would overlap) the given item.

- bool CheckForIntersection (const wxGBPosition &pos, const wxGBSpan &span, wxGBSizerItem *excludeItem=NULL)

  Look at all items and see if any intersect (or would overlap) the given item.

- wxGBSizerItem * FindItem (wxWindow *window)

  Find the sizer item for the given window or subsizer, returns NULL if not found.

- wxGBSizerItem * FindItem (wxSizer *sizer)

  Find the sizer item for the given window or subsizer, returns NULL if not found.

- wxGBPosition GetItemPosition (wxWindow *window)

  Get the grid position of the specified item.

- wxGBPosition GetItemPosition (wxSizer *sizer)

  Get the grid position of the specified item.

- wxGBPosition GetItemPosition (size_t index)

  Get the grid position of the specified item.

- wxGBSpan GetItemSpan (wxWindow *window)

  Get the row/col spanning of the specified item.

- wxGBSpan GetItemSpan (wxSizer *sizer)

  Get the row/col spanning of the specified item.

- wxGBSpan GetItemSpan (size_t index)

  Get the row/col spanning of the specified item.

- bool SetItemPosition (wxWindow *window, const wxGBPosition &pos)

  Set the grid position of the specified item.

- bool SetItemPosition (wxSizer *sizer, const wxGBPosition &pos)

  Set the grid position of the specified item.

- bool SetItemPosition (size_t index, const wxGBPosition &pos)

  Set the grid position of the specified item.

- bool SetItemSpan (wxWindow *window, const wxGBSpan &span)

  Set the row/col spanning of the specified item.
- bool SetItemSpan (wxSizer *sizer, const wxGBSpan &span)

  Set the row/col spanning of the specified item.
- bool SetItemSpan (size_t index, const wxGBSpan &span)

  Set the row/col spanning of the specified item.

Additional Inherited Members

21.299.2 Constructor & Destructor Documentation

wxGridBagSizer::wxGridBagSizer (int *vgap* = 0, int *hgap* = 0)

Constructor, with optional parameters to specify the gap between the rows and columns.

21.299.3 Member Function Documentation

wxSizerItem* wxGridBagSizer::Add (wxWindow * *window*, const wxGBPosition & *pos*, const wxGBSpan & *span* = wxDefaultSpan, int *flag* = 0, int *border* = 0, wxObject * *userData* = NULL)

Adds the given item to the given position.

Returns

A valid pointer if the item was successfully placed at the given position, or NULL if something was already there.

wxSizerItem* wxGridBagSizer::Add (wxSizer * *sizer*, const wxGBPosition & *pos*, const wxGBSpan & *span* = wxDefaultSpan, int *flag* = 0, int *border* = 0, wxObject * *userData* = NULL)

Adds the given item to the given position.

Returns

A valid pointer if the item was successfully placed at the given position, or NULL if something was already there.

wxSizerItem* wxGridBagSizer::Add (wxGBSizerItem * *item*)

Adds the given item to the given position.

Returns

A valid pointer if the item was successfully placed at the given position, or NULL if something was already there.

wxSizerItem* wxGridBagSizer::Add (int *width*, int *height*, const wxGBPosition & *pos*, const wxGBSpan & *span* = wxDefaultSpan, int *flag* = 0, int *border* = 0, wxObject * *userData* = NULL)

Adds a spacer to the given position.

width and *height* specify the dimension of the spacer to be added.

Returns

A valid pointer if the spacer was successfully placed at the given position, or NULL if something was already there.

wxSize wxGridBagSizer::CalcMin ( ) [virtual]

Called when the managed size of the sizer is needed or when layout needs done.

Reimplemented from wxFlexGridSizer.

bool wxGridBagSizer::CheckForIntersection (wxGBSizerItem * *item*, wxGBSizerItem * *excludeItem* = NULL)

Look at all items and see if any intersect (or would overlap) the given item.

Returns true if so, false if there would be no overlap. If an *excludeItem* is given then it will not be checked for intersection, for example it may be the item we are checking the position of.

bool wxGridBagSizer::CheckForIntersection (const wxGBPosition & *pos*, const wxGBSpan & *span*, wxGBSizerItem * *excludeItem* = NULL)

Look at all items and see if any intersect (or would overlap) the given item.

Returns true if so, false if there would be no overlap. If an *excludeItem* is given then it will not be checked for intersection, for example it may be the item we are checking the position of.

wxGBSizerItem* wxGridBagSizer::FindItem (wxWindow * *window*)

Find the sizer item for the given window or subsizer, returns NULL if not found.

(non-recursive)

wxGBSizerItem* wxGridBagSizer::FindItem (wxSizer * *sizer*)

Find the sizer item for the given window or subsizer, returns NULL if not found.

(non-recursive)

wxGBSizerItem* wxGridBagSizer::FindItemAtPoint (const wxPoint & *pt*)

Return the sizer item located at the point given in pt, or NULL if there is no item at that point.

The (x,y) coordinates in *pt* correspond to the client coordinates of the window using the sizer for layout. (non-recursive)

wxGBSizerItem* wxGridBagSizer::FindItemAtPosition (const wxGBPosition & *pos*)

Return the sizer item for the given grid cell, or NULL if there is no item at that position.

(non-recursive)

wxGBSizerItem* wxGridBagSizer::FindItemWithData (const wxObject * *userData*)

Return the sizer item that has a matching user data (it only compares pointer values) or NULL if not found.

(non-recursive)

wxSize wxGridBagSizer::GetCellSize (int *row,* int *col*) const

Get the size of the specified cell, including hgap and vgap.

Only valid after window layout has been performed.

wxSize wxGridBagSizer::GetEmptyCellSize ( ) const

Get the size used for cells in the grid with no item.

wxGBPosition wxGridBagSizer::GetItemPosition (wxWindow * *window*)

Get the grid position of the specified item.

wxGBPosition wxGridBagSizer::GetItemPosition (wxSizer * *sizer*)

Get the grid position of the specified item.

wxGBPosition wxGridBagSizer::GetItemPosition (size_t *index*)

Get the grid position of the specified item.

wxGBSpan wxGridBagSizer::GetItemSpan (wxWindow * *window*)

Get the row/col spanning of the specified item.

wxGBSpan wxGridBagSizer::GetItemSpan (wxSizer * *sizer*)

Get the row/col spanning of the specified item.

wxGBSpan wxGridBagSizer::GetItemSpan (size_t *index*)

Get the row/col spanning of the specified item.

void wxGridBagSizer::RecalcSizes ( ) [virtual]

Called when the managed size of the sizer is needed or when layout needs done.

Reimplemented from wxFlexGridSizer.

void wxGridBagSizer::SetEmptyCellSize (const wxSize & *sz*)

Set the size used for cells in the grid with no item.

bool wxGridBagSizer::SetItemPosition (wxWindow * *window,* const wxGBPosition & *pos*)

Set the grid position of the specified item.

Returns true on success. If the move is not allowed (because an item is already there) then false is returned.

bool wxGridBagSizer::SetItemPosition (wxSizer * *sizer,* const wxGBPosition & *pos*)

Set the grid position of the specified item.

Returns true on success. If the move is not allowed (because an item is already there) then false is returned.

bool wxGridBagSizer::SetItemPosition (size_t *index,* const wxGBPosition & *pos*)

Set the grid position of the specified item.

Returns true on success. If the move is not allowed (because an item is already there) then false is returned.

bool wxGridBagSizer::SetItemSpan (wxWindow * *window,* const wxGBSpan & *span*)

Set the row/col spanning of the specified item.

Returns true on success. If the move is not allowed (because an item is already there) then false is returned.

bool wxGridBagSizer::SetItemSpan (wxSizer * *sizer,* const wxGBSpan & *span*)

Set the row/col spanning of the specified item.

Returns true on success. If the move is not allowed (because an item is already there) then false is returned.

bool wxGridBagSizer::SetItemSpan (size_t *index,* const wxGBSpan & *span*)

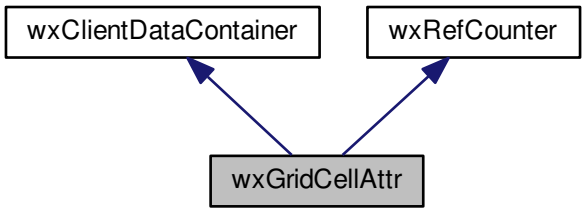
Set the row/col spanning of the specified item.

Returns true on success. If the move is not allowed (because an item is already there) then false is returned.

21.300 wxGridCellAttr Class Reference

`#include <wx/grid.h>`

Inheritance diagram for wxGridCellAttr:



21.300.1 Detailed Description

This class can be used to alter the cells' appearance in the grid by changing their attributes from the defaults.

An object of this class may be returned by wxGridTableBase::GetAttr().

Library: wxAdvanced

Category: Grid Related Classes

Public Types

- enum wxAttrKind {
  Any,
  Cell,
  Row,
  Col }

  Kind of the attribute to retrieve.

Public Member Functions

- wxGridCellAttr (wxGridCellAttr *attrDefault=NULL)

  Default constructor.
- wxGridCellAttr (const wxColour &colText, const wxColour &colBack, const wxFont &font, int hAlign, int vAlign)

  Constructor specifying some of the often used attributes.
- wxGridCellAttr * Clone () const

  Creates a new copy of this object.
- void DecRef ()

  This class is reference counted: it is created with ref count of 1, so calling DecRef() once will delete it.
- void GetAlignment (int *hAlign, int *vAlign) const

  Get the alignment to use for the cell with the given attribute.
- const wxColour & GetBackgroundColour () const

  Returns the background colour.
- wxGridCellEditor * GetEditor (const wxGrid *grid, int row, int col) const

  Returns the cell editor.
- const wxFont & GetFont () const

  Returns the font.
- void GetNonDefaultAlignment (int *hAlign, int *vAlign) const

  Get the alignment defined by this attribute.
- wxGridCellRenderer * GetRenderer (const wxGrid *grid, int row, int col) const

  Returns the cell renderer.
- const wxColour & GetTextColour () const

  Returns the text colour.
- bool HasAlignment () const

  Returns true if this attribute has a valid alignment set.
- bool HasBackgroundColour () const

  Returns true if this attribute has a valid background colour set.
- bool HasEditor () const

  Returns true if this attribute has a valid cell editor set.
- bool HasFont () const

  Returns true if this attribute has a valid font set.
- bool HasRenderer () const

  Returns true if this attribute has a valid cell renderer set.
- bool HasTextColour () const

  Returns true if this attribute has a valid text colour set.
- void IncRef ()

This class is reference counted: it is created with ref count of 1, so calling DecRef() once will delete it.

- bool IsReadOnly () const

  Returns true if this cell is set as read-only.
- void SetAlignment (int hAlign, int vAlign)

  Sets the alignment.
- void SetBackgroundColour (const wxColour &colBack)

  Sets the background colour.
- void SetDefAttr (wxGridCellAttr *defAttr)
- void SetEditor (wxGridCellEditor *editor)

  Sets the editor to be used with the cells with this attribute.
- void SetFont (const wxFont &font)

  Sets the font.
- void SetReadOnly (bool isReadOnly=true)

  Sets the cell as read-only.
- void SetRenderer (wxGridCellRenderer *renderer)

  Sets the renderer to be used for cells with this attribute.
- void SetTextColour (const wxColour &colText)

  Sets the text colour.

Protected Member Functions

- virtual ~wxGridCellAttr ()

  The destructor is private because only DecRef() can delete us.

21.300.2 Member Enumeration Documentation

enum wxGridCellAttr::wxAttrKind

Kind of the attribute to retrieve.

See also

wxGridCellAttrProvider::GetAttr(), wxGridTableBase::GetAttr()

Enumerator

Any Return the combined effective attribute for the cell.

Cell Return the attribute explicitly set for this cell.

Row Return the attribute set for this cells row.

Col Return the attribute set for this cells column.

21.300.3 Constructor & Destructor Documentation

wxGridCellAttr::wxGridCellAttr (wxGridCellAttr * *attrDefault* = NULL)

Default constructor.

wxGridCellAttr::wxGridCellAttr (const wxColour & *colText*, const wxColour & *colBack*, const wxFont & *font*, int *hAlign*, int *vAlign*)

Constructor specifying some of the often used attributes.

virtual wxGridCellAttr::~wxGridCellAttr ( ) [protected], [virtual]

The destructor is private because only DecRef() can delete us.

21.300.4 Member Function Documentation

wxGridCellAttr* wxGridCellAttr::Clone ( ) const

Creates a new copy of this object.

void wxGridCellAttr::DecRef ( )

This class is reference counted: it is created with ref count of 1, so calling DecRef() once will delete it.

Calling IncRef() allows to lock it until the matching DecRef() is called.

void wxGridCellAttr::GetAlignment (int * *hAlign*, int * *vAlign*) const

Get the alignment to use for the cell with the given attribute.

If this attribute doesn't specify any alignment, the default attribute alignment is used (which can be changed using wxGrid::SetDefaultCellAlignment() but is left and top by default).

Notice that *hAlign* and *vAlign* values are always overwritten by this function, use GetNonDefaultAlignment() if this is not desirable.

Parameters

hAlign	Horizontal alignment is returned here if this argument is non-NULL. It is one of wxALIGN_LEFT, wxALIGN_CENTRE or wxALIGN_RIGHT.
vAlign	Vertical alignment is returned here if this argument is non-NULL. It is one of wxALIGN_TOP, wxALIGN_CENTRE or wxALIGN_BOTTOM.

const wxColour& wxGridCellAttr::GetBackgroundColour ( ) const

Returns the background colour.

wxGridCellEditor* wxGridCellAttr::GetEditor (const wxGrid * *grid*, int *row*, int *col*) const

Returns the cell editor.

const wxFont& wxGridCellAttr::GetFont ( ) const

Returns the font.

void wxGridCellAttr::GetNonDefaultAlignment (int * *hAlign*, int * *vAlign*) const

Get the alignment defined by this attribute.

Unlike GetAlignment() this function only modifies *hAlign* and *vAlign* if this attribute does define a non-default alignment. This means that they must be initialized before calling this function and that their values will be preserved unchanged if they are different from wxALIGN_INVALID.

For example, the following fragment can be used to use the cell alignment if one is defined but right-align its contents by default (instead of left-aligning it by default) while still using the default vertical alignment:

```
int hAlign = wxALIGN_RIGHT,
    vAlign = wxALIGN_INVALID;
attr.GetNonDefaultAlignment(&hAlign, &vAlign);
```

Since

2.9.1

wxGridCellRenderer* wxGridCellAttr::GetRenderer (const wxGrid * *grid,* int *row,* int *col*) const

Returns the cell renderer.

const wxColour& wxGridCellAttr::GetTextColour ( ) const

Returns the text colour.

bool wxGridCellAttr::HasAlignment ( ) const

Returns true if this attribute has a valid alignment set.

bool wxGridCellAttr::HasBackgroundColour ( ) const

Returns true if this attribute has a valid background colour set.

bool wxGridCellAttr::HasEditor ( ) const

Returns true if this attribute has a valid cell editor set.

bool wxGridCellAttr::HasFont ( ) const

Returns true if this attribute has a valid font set.

bool wxGridCellAttr::HasRenderer ( ) const

Returns true if this attribute has a valid cell renderer set.

bool wxGridCellAttr::HasTextColour ( ) const

Returns true if this attribute has a valid text colour set.

void wxGridCellAttr::IncRef ( )

This class is reference counted: it is created with ref count of 1, so calling DecRef() once will delete it.

Calling IncRef() allows to lock it until the matching DecRef() is called.

bool wxGridCellAttr::IsReadOnly ( ) const

Returns true if this cell is set as read-only.

void wxGridCellAttr::SetAlignment (int *hAlign,* int *vAlign*)

Sets the alignment.

hAlign can be one of `wxALIGN_LEFT`, `wxALIGN_CENTRE` or `wxALIGN_RIGHT` and *vAlign* can be one of `wxALIGN_TOP`, `wxALIGN_CENTRE` or `wxALIGN_BOTTOM`.

void wxGridCellAttr::SetBackgroundColour (const wxColour & *colBack*)

Sets the background colour.

void wxGridCellAttr::SetDefAttr (wxGridCellAttr * *defAttr*)

Todo Needs documentation.

void wxGridCellAttr::SetEditor (wxGridCellEditor * *editor*)

Sets the editor to be used with the cells with this attribute.

void wxGridCellAttr::SetFont (const wxFont & *font*)

Sets the font.

void wxGridCellAttr::SetReadOnly (bool *isReadOnly* = `true`)

Sets the cell as read-only.

void wxGridCellAttr::SetRenderer (wxGridCellRenderer * *renderer*)

Sets the renderer to be used for cells with this attribute.

Takes ownership of the pointer.

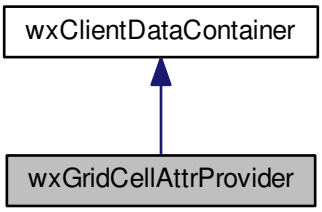
void wxGridCellAttr::SetTextColour (const wxColour & *colText*)

Sets the text colour.

21.301 wxGridCellAttrProvider Class Reference

`#include <wx/grid.h>`

Inheritance diagram for wxGridCellAttrProvider:



21.301.1 Detailed Description

Class providing attributes to be used for the grid cells.

This class both defines an interface which grid cell attributes providers should implement – and which can be implemented differently in derived classes – and a default implementation of this interface which is often good enough to be used without modification, especially with not very large grids for which the efficiency of attributes storage hardly matters (see the discussion below).

An object of this class can be associated with a wxGrid using wxGridTableBase::SetAttrProvider() but it's not necessary to call it if you intend to use the default provider as it is used by wxGridTableBase by default anyhow.

Notice that while attributes provided by this class can be set for individual cells using SetAttr() or the entire rows or columns using SetRowAttr() and SetColAttr() they are always retrieved using GetAttr() function.

The default implementation of this class stores the attributes passed to its SetAttr(), SetRowAttr() and SetColAttr() in a straightforward way. A derived class may use its knowledge about how the attributes are used in your program to implement it much more efficiently: for example, using a special background colour for all even-numbered rows can be implemented by simply returning the same attribute from GetAttr() if the row number is even instead of having to store N/2 row attributes where N is the total number of rows in the grid.

Notice that objects of this class can't be copied.

Public Member Functions

- wxGridCellAttrProvider ()

  Trivial default constructor.
- virtual ~wxGridCellAttrProvider ()

  Destructor releases any attributes held by this class.
- virtual wxGridCellAttr * GetAttr (int row, int col, wxGridCellAttr::wxAttrKind kind) const

  Get the attribute to use for the specified cell.

- virtual void SetAttr (wxGridCellAttr *attr, int row, int col)

  Setting attributes.
- virtual void SetRowAttr (wxGridCellAttr *attr, int row)

  Set attribute for the specified row.
- virtual void SetColAttr (wxGridCellAttr *attr, int col)

  Set attribute for the specified column.

- virtual const wxGridColumnHeaderRenderer & GetColumnHeaderRenderer (int col)

Getting header renderers.

- virtual const wxGridRowHeaderRenderer & GetRowHeaderRenderer (int row)

  Return the renderer used for drawing row headers.

- virtual const wxGridCornerHeaderRenderer & GetCornerRenderer ()

  Return the renderer used for drawing the corner window.

21.301.2 Constructor & Destructor Documentation

wxGridCellAttrProvider::wxGridCellAttrProvider ( )

Trivial default constructor.

virtual wxGridCellAttrProvider::~wxGridCellAttrProvider ( ) [virtual]

Destructor releases any attributes held by this class.

21.301.3 Member Function Documentation

virtual wxGridCellAttr* wxGridCellAttrProvider::GetAttr (int *row,* int *col,* wxGridCellAttr::wxAttrKind *kind*) const [virtual]

Get the attribute to use for the specified cell.

If wxGridCellAttr::Any is used as *kind* value, this function combines the attributes set for this cell using SetAttr() and those for its row or column (set with SetRowAttr() or SetColAttr() respectively), with the cell attribute having the highest precedence.

Notice that the caller must call DecRef() on the returned pointer if it is non-NULL.

Parameters

row	The row of the cell.
col	The column of the cell.
kind	The kind of the attribute to return.

Returns

The attribute to use which should be DecRef()'d by caller or NULL if no attributes are defined for this cell.

virtual const wxGridColumnHeaderRenderer& wxGridCellAttrProvider::GetColumnHeaderRenderer (int *col*) [virtual]

Getting header renderers.

These functions return the renderers for the given row or column header label and the corner window. Unlike cell attributes, these objects are not reference counted and are never NULL so they are returned by reference and not pointer and DecRef() shouldn't (and can't) be called for them.

All these functions were added in wxWidgets 2.9.1. Return the renderer used for drawing column headers.

By default wxGridColumnHeaderRendererDefault is returned.

See also

wxGrid::SetUseNativeColLabels(), wxGrid::UseNativeColHeader()

Since

2.9.1

virtual const wxGridCornerHeaderRenderer& wxGridCellAttrProvider::GetCornerRenderer ( ) [virtual]

Return the renderer used for drawing the corner window.

By default wxGridCornerHeaderRendererDefault is returned.

Since

2.9.1

virtual const wxGridRowHeaderRenderer& wxGridCellAttrProvider::GetRowHeaderRenderer (int *row*) [virtual]

Return the renderer used for drawing row headers.

By default wxGridRowHeaderRendererDefault is returned.

Since

2.9.1

virtual void wxGridCellAttrProvider::SetAttr (wxGridCellAttr * *attr,* int *row,* int *col*) [virtual]

Setting attributes.

All these functions take ownership of the attribute passed to them, i.e. will call DecRef() on it themselves later and so it should not be destroyed by the caller. And the attribute can be NULL to reset a previously set value.Set attribute for the specified cell.

virtual void wxGridCellAttrProvider::SetColAttr (wxGridCellAttr * *attr,* int *col*) [virtual]

Set attribute for the specified column.

virtual void wxGridCellAttrProvider::SetRowAttr (wxGridCellAttr * *attr,* int *row*) [virtual]

Set attribute for the specified row.

21.302 wxGridCellAutoWrapStringEditor Class Reference

```
#include <wx/grid.h>
```

21.304.3 Member Function Documentation

static bool wxGridCellBoolEditor::IsTrueValue (const wxString & *value*) `[static]`

Returns true if the given *value* is equal to the string representation of the truth value we currently use (see UseStringValues()).

static void wxGridCellBoolEditor::UseStringValues (const wxString & *valueTrue* = "1", const wxString & *valueFalse* = wxEmptyString) `[static]`

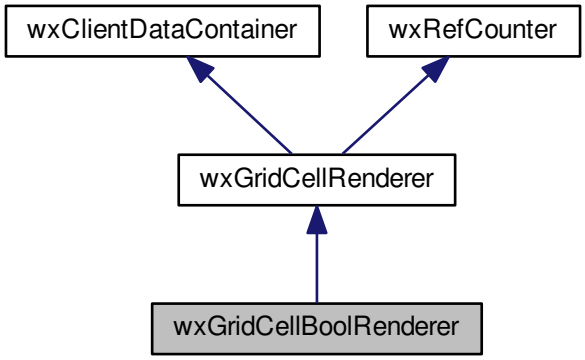
This method allows you to customize the values returned by GetValue() for the cell using this editor.

By default, the default values of the arguments are used, i.e. "1" is returned if the cell is checked and an empty string otherwise.

21.305 wxGridCellBoolRenderer Class Reference

```
#include <wx/grid.h>
```

Inheritance diagram for wxGridCellBoolRenderer:



21.305.1 Detailed Description

This class may be used to format boolean data in a cell.

Library: wxAdvanced

Category: Grid Related Classes

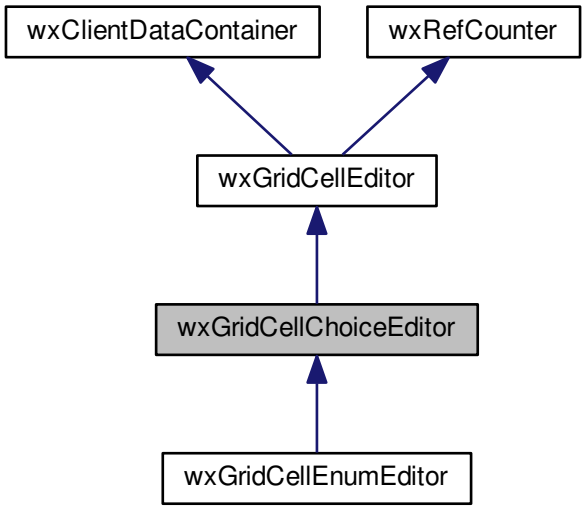
wxGridCellBoolRenderer::wxGridCellBoolRenderer ( )

Default constructor.

21.306 wxGridCellChoiceEditor Class Reference

`#include <wx/grid.h>`

Inheritance diagram for wxGridCellChoiceEditor:



21.306.1 Detailed Description

Grid cell editor for string data providing the user a choice from a list of strings.

Library: wxAdvanced

Category: Grid Related Classes

See also

wxGridCellEditor, wxGridCellAutoWrapStringEditor, wxGridCellBoolEditor, wxGridCellEnumEditor, wxGridCellFloatEditor, wxGridCellNumberEditor, wxGridCellTextEditor

Public Member Functions

- wxGridCellChoiceEditor (size_t count=0, const wxString choices[]=NULL, bool allowOthers=false)

  Choice cell renderer ctor.
- wxGridCellChoiceEditor (const wxArrayString &choices, bool allowOthers=false)

  Choice cell renderer ctor.
- virtual void SetParameters (const wxString &params)

  Parameters string format is "item1[,item2[...,itemN]]".

Additional Inherited Members

21.306.2 Constructor & Destructor Documentation

wxGridCellChoiceEditor::wxGridCellChoiceEditor (size_t *count* = `0`, const wxString *choices[]* = `NULL`, bool *allowOthers* = `false`)

Choice cell renderer ctor.

Parameters

count	Number of strings from which the user can choose.
choices	An array of strings from which the user can choose.
allowOthers	If allowOthers is true, the user can type a string not in choices array.

wxGridCellChoiceEditor::wxGridCellChoiceEditor (const wxArrayString & *choices*, bool *allowOthers* = `false`)

Choice cell renderer ctor.

Parameters

choices	An array of strings from which the user can choose.
allowOthers	If allowOthers is true, the user can type a string not in choices array.

21.306.3 Member Function Documentation

virtual void wxGridCellChoiceEditor::SetParameters (const wxString & *params*) `[virtual]`

Parameters string format is "item1[,item2[...,itemN]]".

21.307 wxGridCellCoords Class Reference

`#include <wx/grid.h>`

21.307.1 Detailed Description

Represents coordinates of a grid cell.

An object of this class is simply a (row, column) pair.

Public Member Functions

- wxGridCellCoords ()
  Default constructor initializes the object to invalid state.
- wxGridCellCoords (int row, int col)
  Constructor taking a row and a column.
- int GetRow () const
  Return the row of the coordinate.
- void SetRow (int n)
  Set the row of the coordinate.
- int GetCol () const
  Return the column of the coordinate.
- void SetCol (int n)
  Set the column of the coordinate.
- void Set (int row, int col)
  Set the row and column of the coordinate.
- wxGridCellCoords & operator= (const wxGridCellCoords &other)
  Assignment operator for coordinate types.
- bool operator== (const wxGridCellCoords &other) const
  Equality operator.
- bool operator!= (const wxGridCellCoords &other) const
  Inequality operator.
- bool operator! () const
  Checks whether the coordinates are invalid.

21.307.2 Constructor & Destructor Documentation

wxGridCellCoords::wxGridCellCoords ( )

Default constructor initializes the object to invalid state.

Initially the row and column are both invalid (-1) and so operator!() for an uninitialized wxGridCellCoords returns false.

wxGridCellCoords::wxGridCellCoords (int *row,* int *col*)

Constructor taking a row and a column.

21.307.3 Member Function Documentation

int wxGridCellCoords::GetCol ( ) const

Return the column of the coordinate.

int wxGridCellCoords::GetRow ( ) const

Return the row of the coordinate.

bool wxGridCellCoords::operator! ( ) const

Checks whether the coordinates are invalid.

Returns false only if both row and column are -1. Notice that if either row or column (but not both) are -1, this method returns true even if the object is invalid. This is done because objects in such state should actually never exist, i.e. either both coordinates should be -1 or none of them should be -1.

bool wxGridCellCoords::operator!= (const wxGridCellCoords & *other*) const

Inequality operator.

wxGridCellCoords& wxGridCellCoords::operator= (const wxGridCellCoords & *other*)

Assignment operator for coordinate types.

bool wxGridCellCoords::operator== (const wxGridCellCoords & *other*) const

Equality operator.

void wxGridCellCoords::Set (int *row,* int *col*)

Set the row and column of the coordinate.

void wxGridCellCoords::SetCol (int *n*)

Set the column of the coordinate.

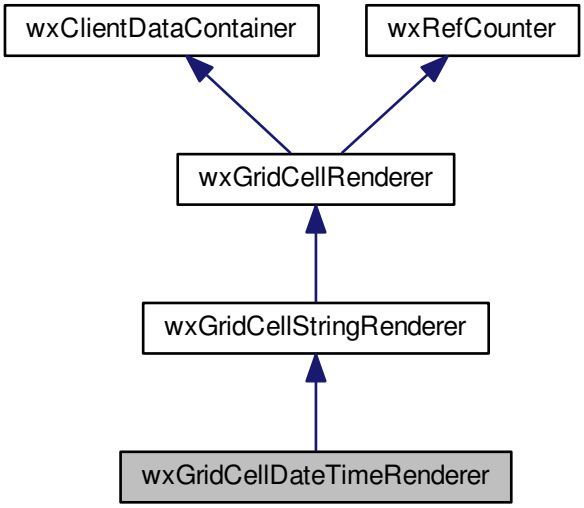
void wxGridCellCoords::SetRow (int *n*)

Set the row of the coordinate.

21.308 wxGridCellDateTimeRenderer Class Reference

```
#include <wx/grid.h>
```

Inheritance diagram for wxGridCellDateTimeRenderer:



21.308.1 Detailed Description

This class may be used to format a date/time data in a cell.

The class wxDateTime is used internally to display the local date/time or to parse the string date entered in the cell thanks to the defined format.

Library: wxAdvanced

Category: Grid Related Classes

See also

wxGridCellRenderer, wxGridCellAutoWrapStringRenderer, wxGridCellBoolRenderer, wxGridCellEnumRenderer, wxGridCellFloatRenderer, wxGridCellNumberRenderer, wxGridCellStringRenderer

Public Member Functions

- wxGridCellDateTimeRenderer (const wxString &outformat=wxDefaultDateTimeFormat, const wxString &informat=wxDefaultDateTimeFormat)

  Date/time renderer constructor.
- virtual void SetParameters (const wxString &params)

  Sets the strptime()-like format string which will be used to parse the date/time.

Additional Inherited Members

21.308.2 Constructor & Destructor Documentation

wxGridCellDateTimeRenderer::wxGridCellDateTimeRenderer (const wxString & *outformat* = `wxDefaultDateTimeFormat`**, const wxString & *informat* =** `wxDefaultDateTimeFormat` **)**

Date/time renderer constructor.

Parameters

outformat	strptime()-like format string used the parse the output date/time.
informat	strptime()-like format string used to parse the string entered in the cell.

21.308.3 Member Function Documentation

virtual void wxGridCellDateTimeRenderer::SetParameters (const wxString & *params*) `[virtual]`

Sets the strptime()-like format string which will be used to parse the date/time.

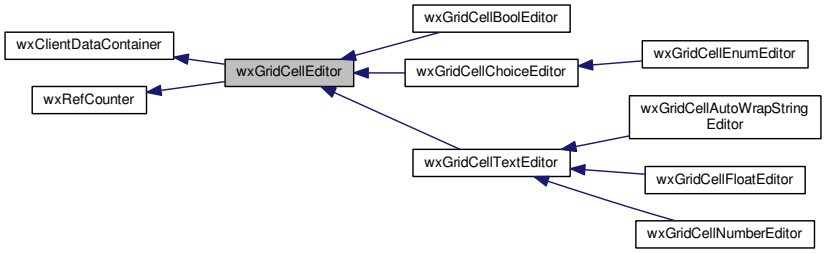
Parameters

params	strptime()-like format string used to parse the date/time.

21.309 wxGridCellEditor Class Reference

`#include <wx/grid.h>`

Inheritance diagram for wxGridCellEditor:



21.309.1 Detailed Description

This class is responsible for providing and manipulating the in-place edit controls for the grid.

Instances of wxGridCellEditor (actually, instances of derived classes since it is an abstract class) can be associated with the cell attributes for individual cells, rows, columns, or even for the entire grid.

Library: wxAdvanced

Category: Grid Related Classes

See also

wxGridCellAutoWrapStringEditor, wxGridCellBoolEditor, wxGridCellChoiceEditor, wxGridCellEnumEditor, wxGridCellFloatEditor, wxGridCellNumberEditor, wxGridCellTextEditor

Public Member Functions

- wxGridCellEditor ()

Default constructor.

- virtual void BeginEdit (int row, int col, wxGrid *grid)=0

  Fetch the value from the table and prepare the edit control to begin editing.

- virtual wxGridCellEditor * Clone () const =0

  Create a new object which is the copy of this one.

- virtual void Create (wxWindow *parent, wxWindowID id, wxEvtHandler *evtHandler)=0

  Creates the actual edit control.

- virtual void Destroy ()

  Final cleanup.

- virtual bool EndEdit (int row, int col, const wxGrid *grid, const wxString &oldval, wxString *newval)=0

  End editing the cell.

- virtual void ApplyEdit (int row, int col, wxGrid *grid)=0

  Effectively save the changes in the grid.

- virtual void HandleReturn (wxKeyEvent &event)

  Some types of controls on some platforms may need some help with the Return key.

- bool IsCreated ()

  Returns true if the edit control has been created.

- virtual void PaintBackground (wxDC &dc, const wxRect &rectCell, wxGridCellAttr &attr)

  Draws the part of the cell not occupied by the control: the base class version just fills it with background colour from the attribute.

- virtual void Reset ()=0

  Reset the value in the control back to its starting value.

- virtual void SetSize (const wxRect &rect)

  Size and position the edit control.

- virtual void Show (bool show, wxGridCellAttr *attr=NULL)

  Show or hide the edit control, use the specified attributes to set colours/fonts for it.

- virtual void StartingClick ()

  If the editor is enabled by clicking on the cell, this method will be called.

- virtual void StartingKey (wxKeyEvent &event)

  If the editor is enabled by pressing keys on the grid, this will be called to let the editor do something about that first key if desired.

- virtual wxString GetValue () const =0

  Returns the value currently in the editor control.

- wxControl * GetControl () const

  Get the wxControl used by this editor.

- void SetControl (wxControl *control)

  Set the wxControl that will be used by this cell editor for editing the value.

Protected Member Functions

- virtual ~wxGridCellEditor ()

  The destructor is private because only DecRef() can delete us.

21.309.2 Constructor & Destructor Documentation

wxGridCellEditor::wxGridCellEditor ( )

Default constructor.

virtual wxGridCellEditor::~wxGridCellEditor ( ) [protected], [virtual]

The destructor is private because only DecRef() can delete us.

21.309.3 Member Function Documentation

virtual void wxGridCellEditor::ApplyEdit (int *row,* int *col,* wxGrid * *grid*) [pure virtual]

Effectively save the changes in the grid.

This function should save the value of the control in the grid. It is called only after EndEdit() returns true.

virtual void wxGridCellEditor::BeginEdit (int *row,* int *col,* wxGrid * *grid*) [pure virtual]

Fetch the value from the table and prepare the edit control to begin editing.

This function should save the original value of the grid cell at the given *row* and *col* and show the control allowing the user to change it.

See also

EndEdit()

virtual wxGridCellEditor* wxGridCellEditor::Clone ( ) const [pure virtual]

Create a new object which is the copy of this one.

virtual void wxGridCellEditor::Create (wxWindow * *parent,* wxWindowID *id,* wxEvtHandler * *evtHandler*) [pure virtual]

Creates the actual edit control.

virtual void wxGridCellEditor::Destroy ( ) [virtual]

Final cleanup.

virtual bool wxGridCellEditor::EndEdit (int *row,* int *col,* const wxGrid * *grid,* const wxString & *oldval,* wxString * *newval*) [pure virtual]

End editing the cell.

This function must check if the current value of the editing control is valid and different from the original value (available as *oldval* in its string form and possibly saved internally using its real type by BeginEdit()). If it isn't, it just returns false, otherwise it must do the following:

- Save the new value internally so that ApplyEdit() could apply it.
- Fill *newval* (which is never NULL) with the string representation of the new value.
- Return true

Notice that it must *not* modify the grid as the change could still be vetoed.

If the user-defined wxEVT_GRID_CELL_CHANGING event handler doesn't veto this change, ApplyEdit() will be called next.

wxControl* wxGridCellEditor::GetControl ( ) const

Get the wxControl used by this editor.

virtual wxString wxGridCellEditor::GetValue ( ) const [pure virtual]

Returns the value currently in the editor control.

virtual void wxGridCellEditor::HandleReturn (wxKeyEvent & *event*) [virtual]

Some types of controls on some platforms may need some help with the Return key.

bool wxGridCellEditor::IsCreated ( )

Returns true if the edit control has been created.

virtual void wxGridCellEditor::PaintBackground (wxDC & *dc,* const wxRect & *rectCell,* wxGridCellAttr & *attr*) [virtual]

Draws the part of the cell not occupied by the control: the base class version just fills it with background colour from the attribute.

virtual void wxGridCellEditor::Reset ( ) [pure virtual]

Reset the value in the control back to its starting value.

void wxGridCellEditor::SetControl (wxControl * *control*)

Set the wxControl that will be used by this cell editor for editing the value.

virtual void wxGridCellEditor::SetSize (const wxRect & *rect*) [virtual]

Size and position the edit control.

virtual void wxGridCellEditor::Show (bool *show,* wxGridCellAttr * *attr* = NULL) [virtual]

Show or hide the edit control, use the specified attributes to set colours/fonts for it.

virtual void wxGridCellEditor::StartingClick ( ) [virtual]

If the editor is enabled by clicking on the cell, this method will be called.

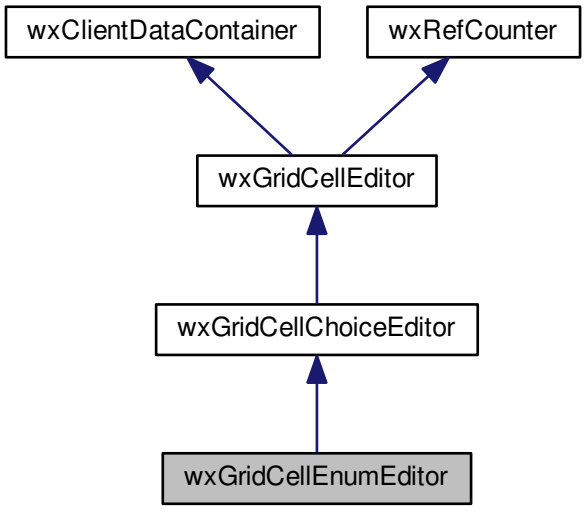
virtual void wxGridCellEditor::StartingKey (wxKeyEvent & *event*) [virtual]

If the editor is enabled by pressing keys on the grid, this will be called to let the editor do something about that first key if desired.

21.310 wxGridCellEnumEditor Class Reference

`#include <wx/grid.h>`

Inheritance diagram for wxGridCellEnumEditor:



21.310.1 Detailed Description

Grid cell editor which displays an enum number as a textual equivalent (eg.

data in cell is 0,1,2 ... n the cell could be displayed as "John","Fred"..."Bob" in the combo choice box).

Library: wxAdvanced

Category: Grid Related Classes

See also

  Enum cell editor ctor.

Additional Inherited Members

21.310.2 Constructor & Destructor Documentation

wxGridCellEnumEditor::wxGridCellEnumEditor (const wxString & *choices* = wxEmptyString)

Enum cell editor ctor.

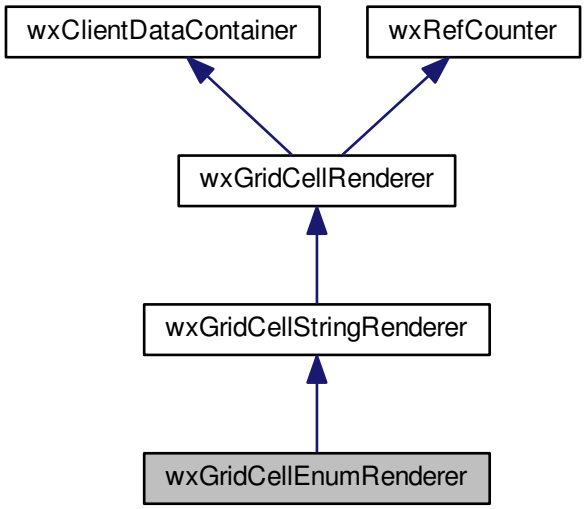
Parameters

choices	Comma separated choice parameters "item1[,item2[...,itemN]]".

21.311 wxGridCellEnumRenderer Class Reference

`#include <wx/grid.h>`

Inheritance diagram for wxGridCellEnumRenderer:



21.311.1 Detailed Description

This class may be used to render in a cell a number as a textual equivalent.

The corresponding text strings are specified as comma-separated items in the string passed to this renderer ctor or SetParameters() method. For example, if this string is `"John,Fred,Bob"` the cell will be rendered as "John", "Fred" or "Bob" if its contents is 0, 1 or 2 respectively.

  Float cell renderer ctor.
- int GetFormat () const

  Returns the specifier used to format the data to string.
- int GetPrecision () const

  Returns the precision.
- int GetWidth () const

  Returns the width.
- void SetFormat (int format)

  Set the format to use for display the number.
- virtual void SetParameters (const wxString &params)

The parameters string format is "width[,precision[,format]]" where `format` should be chosen between f|e|g|E|G (f is used by default)

- void SetPrecision (int precision)

  Sets the precision.

- void SetWidth (int width)

  Sets the width.

Additional Inherited Members

21.313.2 Constructor & Destructor Documentation

wxGridCellFloatRenderer::wxGridCellFloatRenderer (int *width* = −1, int *precision* = −1, int *format* = wxGRID_FLOAT_FORMAT_DEFAULT)

Float cell renderer ctor.

Parameters

width	Minimum number of characters to be shown.
precision	Number of digits after the decimal dot.
format	The format used to display the string, must be a combination of wxGridCellFloatFormat enum elements. This parameter is only available since wxWidgets 2.9.3.

21.313.3 Member Function Documentation

int wxGridCellFloatRenderer::GetFormat ( ) const

Returns the specifier used to format the data to string.

The returned value is a combination of wxGridCellFloatFormat elements.

Since

2.9.3

int wxGridCellFloatRenderer::GetPrecision ( ) const

Returns the precision.

int wxGridCellFloatRenderer::GetWidth ( ) const

Returns the width.

void wxGridCellFloatRenderer::SetFormat (int *format*)

Set the format to use for display the number.

Parameters

format	Must be a combination of wxGridCellFloatFormat enum elements.

Since

2.9.3

virtual void wxGridCellFloatRenderer::SetParameters (const wxString & *params*) `[virtual]`

The parameters string format is "width[,precision[,format]]" where `format` should be chosen between f|e|g|E|G (f is used by default)

void wxGridCellFloatRenderer::SetPrecision (int *precision*)

Sets the precision.

void wxGridCellFloatRenderer::SetWidth (int *width*)

Sets the width.

21.314 wxGridCellNumberEditor Class Reference

`#include <wx/grid.h>`

wxGridCellAutoWrapStringRenderer, wxGridCellBoolRenderer, wxGridCellDateTimeRenderer, wxGridCellEnumRenderer, wxGridCellFloatRenderer, wxGridCellNumberRenderer, wxGridCellStringRenderer

Public Member Functions

- wxGridCellRenderer ()
- virtual wxGridCellRenderer * Clone () const =0

  This function must be implemented in derived classes to return a copy of itself.
- virtual void Draw (wxGrid &grid, wxGridCellAttr &attr, wxDC &dc, const wxRect &rect, int row, int col, bool isSelected)=0

  Draw the given cell on the provided DC inside the given rectangle using the style specified by the attribute and the default or selected state corresponding to the isSelected value.
- virtual wxSize GetBestSize (wxGrid &grid, wxGridCellAttr &attr, wxDC &dc, int row, int col)=0

  Get the preferred size of the cell for its contents.
- virtual wxSize GetBestHeight (wxGrid &grid, wxGridCellAttr &attr, wxDC &dc, int row, int col, int width)

  Get the preferred height of the cell at the given width.
- virtual wxSize GetBestWidth (wxGrid &grid, wxGridCellAttr &attr, wxDC &dc, int row, int col, int height)

  Get the preferred width of the cell at the given height.

Protected Member Functions

- virtual ~wxGridCellRenderer ()

  The destructor is private because only DecRef() can delete us.

21.316.2 Constructor & Destructor Documentation

wxGridCellRenderer::wxGridCellRenderer ( )

virtual wxGridCellRenderer::~wxGridCellRenderer ( ) [protected], [virtual]

The destructor is private because only DecRef() can delete us.

21.316.3 Member Function Documentation

virtual wxGridCellRenderer* wxGridCellRenderer::Clone ( ) const [pure virtual]

This function must be implemented in derived classes to return a copy of itself.

virtual void wxGridCellRenderer::Draw (wxGrid & *grid*, wxGridCellAttr & *attr*, wxDC & *dc*, const wxRect & *rect*, int *row*, int *col*, bool *isSelected*) [pure virtual]

Draw the given cell on the provided DC inside the given rectangle using the style specified by the attribute and the default or selected state corresponding to the isSelected value.

This pure virtual function has a default implementation which will prepare the DC using the given attribute: it will draw the rectangle with the background colour from attr and set the text colour and font.

virtual wxSize wxGridCellRenderer::GetBestHeight (wxGrid & *grid*, wxGridCellAttr & *attr*, wxDC & *dc*, int *row*, int *col*, int *width*) [virtual]

Get the preferred height of the cell at the given width.

Some renderers may not have a well-defined best size, but only be able to provide the best height at the given width, e.g. this is the case of the standard wxGridCellAutoWrapStringRenderer. In this case, they should override this method, in addition to GetBestSize().

See also

GetBestWidth()

Since

3.1.0

virtual wxSize wxGridCellRenderer::GetBestSize (wxGrid & *grid*, wxGridCellAttr & *attr*, wxDC & *dc*, int *row*, int *col*) [pure virtual]

Get the preferred size of the cell for its contents.

This method must be overridden in the derived classes to return the minimal fitting size for displaying the content of the given grid cell.

See also

GetBestHeight(), GetBestWidth()

virtual wxSize wxGridCellRenderer::GetBestWidth (wxGrid & *grid,* wxGridCellAttr & *attr,* wxDC & *dc,* int *row,* int *col,* int *height*) `[virtual]`

Get the preferred width of the cell at the given height.

See GetBestHeight(), this method is symmetric to it.

Since

3.1.0

21.317 wxGridCellStringRenderer Class Reference

`#include <wx/grid.h>`

wxGridRowHeaderRendererDefault

Since

2.9.1

Public Member Functions

- virtual void DrawBorder (const wxGrid &grid, wxDC &dc, wxRect &rect) const

  Implement border drawing for the column labels.

21.320.2 Member Function Documentation

virtual void wxGridColumnHeaderRendererDefault::DrawBorder (const wxGrid & *grid,* wxDC & *dc,* wxRect & *rect*) const `[virtual]`

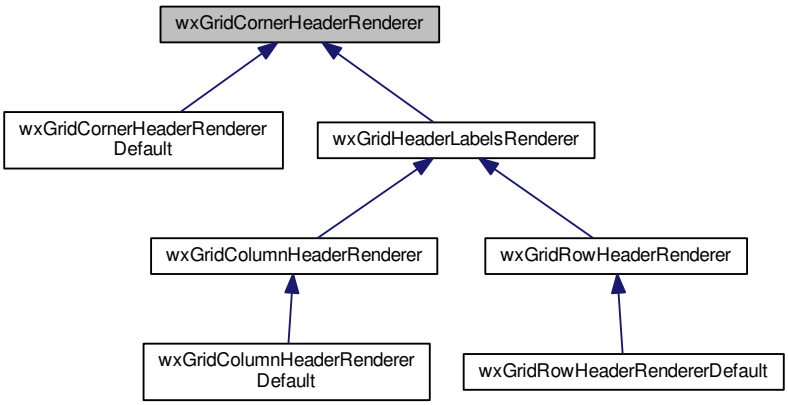
Implement border drawing for the column labels.

Implements wxGridCornerHeaderRenderer.

21.321 wxGridCornerHeaderRenderer Class Reference

`#include <wx/grid.h>`

Inheritance diagram for wxGridCornerHeaderRenderer:



21.321.1 Detailed Description

Base class for corner window renderer.

This is the simplest of all header renderers and only has a single function.

See also

wxGridCellAttrProvider::GetCornerRenderer()

Since

2.9.1

Public Member Functions

- virtual void DrawBorder (const wxGrid &grid, wxDC &dc, wxRect &rect) const =0

  Called by the grid to draw the corner window border.

21.321.2 Member Function Documentation

virtual void wxGridCornerHeaderRenderer::DrawBorder (const wxGrid & *grid*, wxDC & *dc*, wxRect & *rect*) const `[pure virtual]`

Called by the grid to draw the corner window border.

This method is responsible for drawing the border inside the given *rect* and adjusting the rectangle size to correspond to the area inside the border, i.e. usually call wxRect::Deflate() to account for the border width.

Parameters

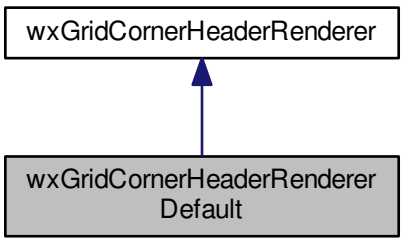
grid	The grid whose corner window is being drawn.
dc	The device context to use for drawing.
rect	Input/output parameter which contains the border rectangle on input and should be updated to contain the area inside the border on function return.

Implemented in wxGridCornerHeaderRendererDefault, wxGridColumnHeaderRendererDefault, and wxGridRowHeaderRendererDefault.

21.322 wxGridCornerHeaderRendererDefault Class Reference

`#include <wx/grid.h>`

Inheritance diagram for wxGridCornerHeaderRendererDefault:



21.322.1 Detailed Description

Default corner window renderer.

  Implement border drawing for the corner window.

21.322.2 Member Function Documentation

virtual void wxGridCornerHeaderRendererDefault::DrawBorder (const wxGrid & *grid,* wxDC & *dc,* wxRect & *rect*) const `[virtual]`

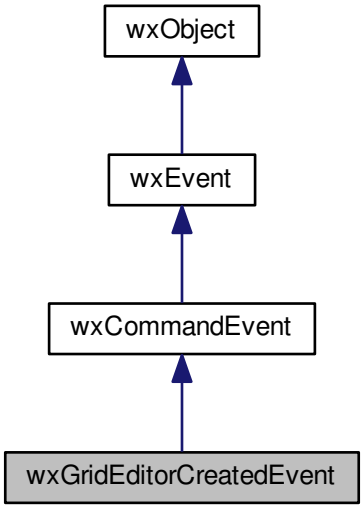
Implement border drawing for the corner window.

Implements wxGridCornerHeaderRenderer.

21.323 wxGridEditorCreatedEvent Class Reference

`#include <wx/grid.h>`

Inheritance diagram for wxGridEditorCreatedEvent:



21.323.1 Detailed Description

Events using this class

The following event handler macros redirect the events to member function handlers '**func**' with prototypes like: void handlerFuncName(wxGridEditorCreatedEvent& event)

Event macros:

- EVT_GRID_EDITOR_CREATED(func): The editor for a cell was created. Processes a `wxEVT_GRID_E↩DITOR_CREATED` event type.
- EVT_GRID_CMD_EDITOR_CREATED(id, func): The editor for a cell was created; variant taking a window identifier. Processes a `wxEVT_GRID_EDITOR_CREATED` event type.

Library: wxAdvanced

Category: Grid Related Classes, Events

Public Member Functions

- wxGridEditorCreatedEvent ()

  Default constructor.
- wxGridEditorCreatedEvent (int id, wxEventType type, wxObject *obj, int row, int col, wxControl *ctrl)

  Constructor for initializing all event attributes.
- int GetCol ()

  Returns the column at which the event occurred.
- wxControl * GetControl ()

  Returns the edit control.
- int GetRow ()

  Returns the row at which the event occurred.
- void SetCol (int col)

  Sets the column at which the event occurred.
- void SetControl (wxControl *ctrl)

  Sets the edit control.
- void SetRow (int row)

  Sets the row at which the event occurred.

21.323.2 Constructor & Destructor Documentation

wxGridEditorCreatedEvent::wxGridEditorCreatedEvent ( )

Default constructor.

wxGridEditorCreatedEvent::wxGridEditorCreatedEvent (int *id*, wxEventType *type*, wxObject * *obj*, int *row*, int *col*, wxControl * *ctrl*)

Constructor for initializing all event attributes.

21.323.3 Member Function Documentation

int wxGridEditorCreatedEvent::GetCol ( )

Returns the column at which the event occurred.

wxControl* wxGridEditorCreatedEvent::GetControl ( )

Returns the edit control.

int wxGridEditorCreatedEvent::GetRow ( )

Returns the row at which the event occurred.

void wxGridEditorCreatedEvent::SetCol (int *col*)

Sets the column at which the event occurred.

void wxGridEditorCreatedEvent::SetControl (wxControl * *ctrl*)

Sets the edit control.

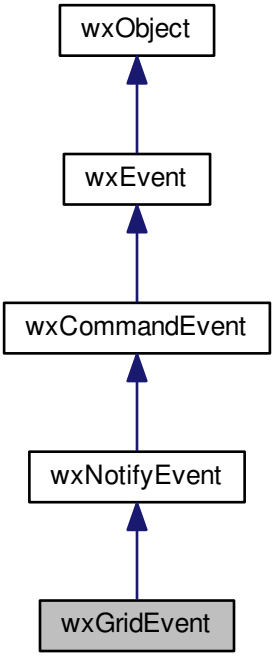
void wxGridEditorCreatedEvent::SetRow (int *row*)

Sets the row at which the event occurred.

21.324 wxGridEvent Class Reference

`#include <wx/grid.h>`

Inheritance diagram for wxGridEvent:



21.324.1 Detailed Description

This event class contains information about various grid events.

Notice that all grid event table macros are available in two versions: `EVT_GRID_XXX` and `EVT_GRID_CMD_X↩XX`. The only difference between the two is that the former doesn't allow to specify the grid window identifier and so takes a single parameter, the event handler, but is not suitable if there is more than one grid control in the window where the event table is used (as it would catch the events from all the grids). The version with `CMD` takes the id as

first argument and the event handler as the second one and so can be used with multiple grids as well. Otherwise there are no difference between the two and only the versions without the id are documented below for brevity.

Events using this class

The following event handler macros redirect the events to member function handlers '**func**' with prototypes like: void handlerFuncName(wxGridEvent& event)

Event macros:

- EVT_GRID_CELL_CHANGING(func): The user is about to change the data in a cell. The new cell value as string is available from GetString() event object method. This event can be vetoed if the change is not allowed. Processes a `wxEVT_GRID_CELL_CHANGING` event type.
- EVT_GRID_CELL_CHANGED(func): The user changed the data in a cell. The old cell value as string is available from GetString() event object method. Notice that vetoing this event still works for backwards compatibility reasons but any new code should only veto EVT_GRID_CELL_CHANGING event and not this one. Processes a `wxEVT_GRID_CELL_CHANGED` event type.
- EVT_GRID_CELL_LEFT_CLICK(func): The user clicked a cell with the left mouse button. Processes a `wxEVT_GRID_CELL_LEFT_CLICK` event type.
- EVT_GRID_CELL_LEFT_DCLICK(func): The user double-clicked a cell with the left mouse button. Processes a `wxEVT_GRID_CELL_LEFT_DCLICK` event type.
- EVT_GRID_CELL_RIGHT_CLICK(func): The user clicked a cell with the right mouse button. Processes a `wxEVT_GRID_CELL_RIGHT_CLICK` event type.
- EVT_GRID_CELL_RIGHT_DCLICK(func): The user double-clicked a cell with the right mouse button. Processes a `wxEVT_GRID_CELL_RIGHT_DCLICK` event type.
- EVT_GRID_EDITOR_HIDDEN(func): The editor for a cell was hidden. Processes a `wxEVT_GRID_EDITOR_HIDDEN` event type.
- EVT_GRID_EDITOR_SHOWN(func): The editor for a cell was shown. Processes a `wxEVT_GRID_EDITOR_SHOWN` event type.
- EVT_GRID_LABEL_LEFT_CLICK(func): The user clicked a label with the left mouse button. Processes a `wxEVT_GRID_LABEL_LEFT_CLICK` event type.
- EVT_GRID_LABEL_LEFT_DCLICK(func): The user double-clicked a label with the left mouse button. Processes a `wxEVT_GRID_LABEL_LEFT_DCLICK` event type.
- EVT_GRID_LABEL_RIGHT_CLICK(func): The user clicked a label with the right mouse button. Processes a `wxEVT_GRID_LABEL_RIGHT_CLICK` event type.
- EVT_GRID_LABEL_RIGHT_DCLICK(func): The user double-clicked a label with the right mouse button. Processes a `wxEVT_GRID_LABEL_RIGHT_DCLICK` event type.
- EVT_GRID_SELECT_CELL(func): The given cell was made current, either by user or by the program via a call to SetGridCursor() or GoToCell(). Processes a `wxEVT_GRID_SELECT_CELL` event type.
- EVT_GRID_COL_MOVE(func): The user tries to change the order of the columns in the grid by dragging the column specified by GetCol(). This event can be vetoed to either prevent the user from reordering the column change completely (but notice that if you don't want to allow it at all, you simply shouldn't call wxGrid::EnableDragColMove() in the first place), vetoed but handled in some way in the handler, e.g. by really moving the column to the new position at the associated table level, or allowed to proceed in which case wxGrid::SetColPos() is used to reorder the columns display order without affecting the use of the column indices otherwise. This event macro corresponds to `wxEVT_GRID_COL_MOVE` event type.

- EVT_GRID_COL_SORT(func): This event is generated when a column is clicked by the user and its name is explained by the fact that the custom reaction to a click on a column is to sort the grid contents by this column. However the grid itself has no special support for sorting and it's up to the handler of this event to update the associated table. But if the event is handled (and not vetoed) the grid supposes that the table was indeed resorted and updates the column to indicate the new sort order and refreshes itself. This event macro corresponds to `wxEVT_GRID_COL_SORT` event type.
- EVT_GRID_TABBING(func): This event is generated when the user presses TAB or Shift-TAB in the grid. It can be used to customize the simple default TAB handling logic, e.g. to go to the next non-empty cell instead of just the next cell. See also wxGrid::SetTabBehaviour(). This event is new since wxWidgets 2.9.5.

Library: wxAdvanced

Category: Grid Related Classes, Events

Public Member Functions

- wxGridEvent ()

  Default constructor.
- wxGridEvent (int id, wxEventType type, wxObject *obj, int row=-1, int col=-1, int x=-1, int y=-1, bool sel=true, const wxKeyboardState &kbd=wxKeyboardState())

  Constructor for initializing all event attributes.
- bool AltDown () const

  Returns true if the Alt key was down at the time of the event.
- bool ControlDown () const

  Returns true if the Control key was down at the time of the event.
- virtual int GetCol ()

  Column at which the event occurred.
- wxPoint GetPosition ()

  Position in pixels at which the event occurred.
- virtual int GetRow ()

  Row at which the event occurred.
- bool MetaDown () const

  Returns true if the Meta key was down at the time of the event.
- bool Selecting ()

  Returns true if the user is selecting grid cells, or false if deselecting.
- bool ShiftDown () const

  Returns true if the Shift key was down at the time of the event.

Additional Inherited Members

21.324.2 Constructor & Destructor Documentation

wxGridEvent::wxGridEvent ( )

Default constructor.

wxGridEvent::wxGridEvent (int *id*, wxEventType *type*, wxObject * *obj*, int *row* = -1, int *col* = -1, int *x* = -1, int *y* = -1, bool *sel* = true, const wxKeyboardState & *kbd* = wxKeyboardState())

Constructor for initializing all event attributes.

21.324.3 Member Function Documentation

bool wxGridEvent::AltDown ( ) const

Returns true if the Alt key was down at the time of the event.

bool wxGridEvent::ControlDown ( ) const

Returns true if the Control key was down at the time of the event.

virtual int wxGridEvent::GetCol ( ) [virtual]

Column at which the event occurred.

Notice that for a `wxEVT_GRID_SELECT_CELL` event this column is the column of the newly selected cell while the previously selected cell can be retrieved using wxGrid::GetGridCursorCol().

wxPoint wxGridEvent::GetPosition ( )

Position in pixels at which the event occurred.

virtual int wxGridEvent::GetRow ( ) [virtual]

Row at which the event occurred.

Notice that for a `wxEVT_GRID_SELECT_CELL` event this row is the row of the newly selected cell while the previously selected cell can be retrieved using wxGrid::GetGridCursorRow().

bool wxGridEvent::MetaDown ( ) const

Returns true if the Meta key was down at the time of the event.

bool wxGridEvent::Selecting ( )

Returns true if the user is selecting grid cells, or false if deselecting.

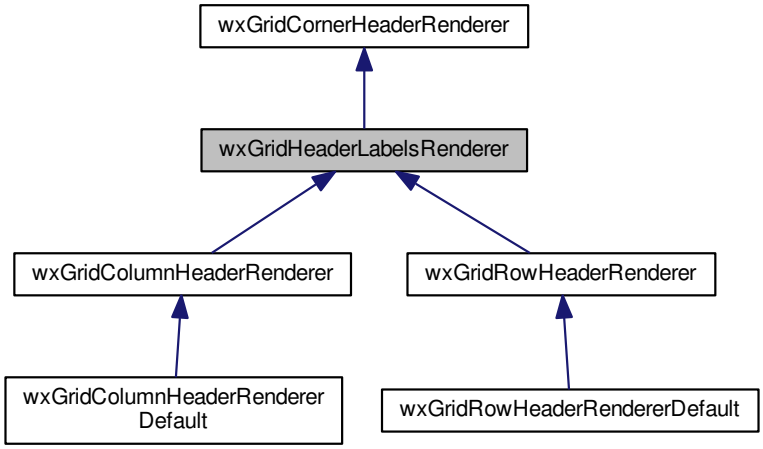
bool wxGridEvent::ShiftDown ( ) const

Returns true if the Shift key was down at the time of the event.

21.325 wxGridHeaderLabelsRenderer Class Reference

`#include <wx/grid.h>`

Inheritance diagram for wxGridHeaderLabelsRenderer:



21.325.1 Detailed Description

Common base class for row and column headers renderers.

  Constructor for initializing all event attributes.
- bool AltDown () const

  Returns true if the Alt key was down at the time of the event.
- bool ControlDown () const

  Returns true if the Control key was down at the time of the event.
- wxGridCellCoords GetBottomRightCoords ()

  Top left corner of the rectangular area that was (de)selected.
- int GetBottomRow ()

  Bottom row of the rectangular area that was (de)selected.
- int GetLeftCol ()

  Left column of the rectangular area that was (de)selected.
- int GetRightCol ()

  Right column of the rectangular area that was (de)selected.
- wxGridCellCoords GetTopLeftCoords ()

  Top left corner of the rectangular area that was (de)selected.
- int GetTopRow ()

  Top row of the rectangular area that was (de)selected.
- bool MetaDown () const

  Returns true if the Meta key was down at the time of the event.
- bool Selecting ()

  Returns true if the area was selected, false otherwise.
- bool ShiftDown () const

  Returns true if the Shift key was down at the time of the event.

Additional Inherited Members

21.326.2 Constructor & Destructor Documentation

wxGridRangeSelectEvent::wxGridRangeSelectEvent ( )

Default constructor.

wxGridRangeSelectEvent::wxGridRangeSelectEvent (int *id*, wxEventType *type*, wxObject ∗ *obj*, const wxGridCellCoords & *topLeft*, const wxGridCellCoords & *bottomRight*, bool *sel* = `true`, const wxKeyboardState & *kbd* = wxKeyboardState `()`)

Constructor for initializing all event attributes.

21.326.3 Member Function Documentation

bool wxGridRangeSelectEvent::AltDown ( ) const

Returns true if the Alt key was down at the time of the event.

bool wxGridRangeSelectEvent::ControlDown ( ) const

Returns true if the Control key was down at the time of the event.

wxGridCellCoords wxGridRangeSelectEvent::GetBottomRightCoords ( )

Top left corner of the rectangular area that was (de)selected.

int wxGridRangeSelectEvent::GetBottomRow ( )

Bottom row of the rectangular area that was (de)selected.

int wxGridRangeSelectEvent::GetLeftCol ( )

Left column of the rectangular area that was (de)selected.

int wxGridRangeSelectEvent::GetRightCol ( )

Right column of the rectangular area that was (de)selected.

wxGridCellCoords wxGridRangeSelectEvent::GetTopLeftCoords ( )

Top left corner of the rectangular area that was (de)selected.

int wxGridRangeSelectEvent::GetTopRow ( )

Top row of the rectangular area that was (de)selected.

bool wxGridRangeSelectEvent::MetaDown ( ) const

Returns true if the Meta key was down at the time of the event.

bool wxGridRangeSelectEvent::Selecting ( )

Returns true if the area was selected, false otherwise.

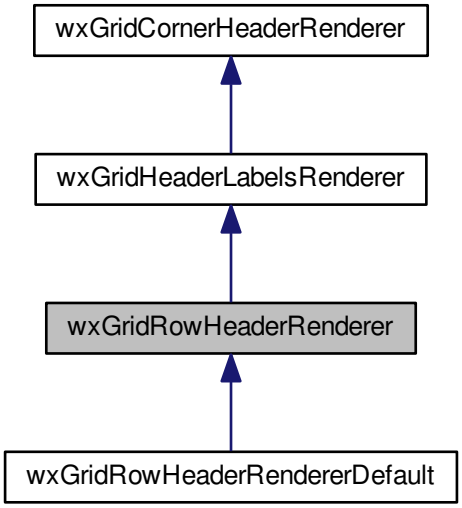
bool wxGridRangeSelectEvent::ShiftDown ( ) const

Returns true if the Shift key was down at the time of the event.

21.327 wxGridRowHeaderRenderer Class Reference

`#include <wx/grid.h>`

Inheritance diagram for wxGridRowHeaderRenderer:



21.327.1 Detailed Description

Base class for row headers renderer.

This is the same as wxGridHeaderLabelsRenderer currently but we still use a separate class for it to distinguish it from wxGridColumnHeaderRenderer.

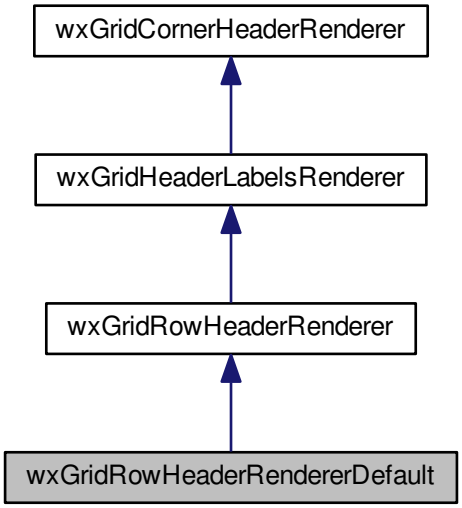
2.9.1

Additional Inherited Members

21.328 wxGridRowHeaderRendererDefault Class Reference

`#include <wx/grid.h>`

Inheritance diagram for wxGridRowHeaderRendererDefault:



21.328.1 Detailed Description

Default row header renderer.

You may derive from this class if you need to only override one of its methods (i.e. either DrawLabel() or DrawBorder()) but continue to use the default implementation for the other one.

See also

wxGridColumnHeaderRendererDefault

Since

2.9.1

Public Member Functions

- virtual void DrawBorder (const wxGrid &grid, wxDC &dc, wxRect &rect) const

  Implement border drawing for the row labels.

21.328.2 Member Function Documentation

virtual void wxGridRowHeaderRendererDefault::DrawBorder (const wxGrid & *grid,* wxDC & *dc,* wxRect & *rect*) const `[virtual]`

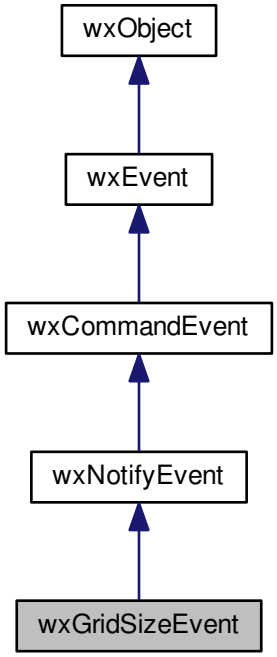
Implement border drawing for the row labels.

Implements wxGridCornerHeaderRenderer.

21.329 wxGridSizeEvent Class Reference

`#include <wx/grid.h>`

Inheritance diagram for wxGridSizeEvent:



21.329.1 Detailed Description

This event class contains information about a row/column resize event.

Events using this class

The following event handler macros redirect the events to member function handlers '**func**' with prototypes like: void handlerFuncName(wxGridSizeEvent& event)

Event macros:

- EVT_GRID_CMD_COL_SIZE(id, func): The user resized a column, corresponds to `wxEVT_GRID_COL_SIZE` event type.

- EVT_GRID_CMD_ROW_SIZE(id, func): The user resized a row, corresponds to `wxEVT_GRID_ROW_SIZE` event type.
- EVT_GRID_COL_SIZE(func): Same as EVT_GRID_CMD_COL_SIZE() but uses `wxID_ANY` id.
- EVT_GRID_COL_AUTO_SIZE(func): This event is sent when a column must be resized to its best size, e.g. when the user double clicks the column divider. The default implementation simply resizes the column to fit the column label (but not its contents as this could be too slow for big grids). This macro corresponds to `wxEVT_GRID_COL_AUTO_SIZE` event type and is new since wxWidgets 2.9.5.
- EVT_GRID_ROW_SIZE(func): Same as EVT_GRID_CMD_ROW_SIZE() but uses `wxID_ANY` id.

Library: wxAdvanced

  Constructor for initializing all event attributes.
- bool AltDown () const

  Returns true if the Alt key was down at the time of the event.
- bool ControlDown () const

  Returns true if the Control key was down at the time of the event.
- wxPoint GetPosition ()

  Position in pixels at which the event occurred.
- int GetRowOrCol ()

  Row or column at that was resized.
- bool MetaDown () const

  Returns true if the Meta key was down at the time of the event.
- bool ShiftDown () const

  Returns true if the Shift key was down at the time of the event.

Additional Inherited Members

21.329.2 Constructor & Destructor Documentation

wxGridSizeEvent::wxGridSizeEvent ( )

Default constructor.

wxGridSizeEvent::wxGridSizeEvent (int *id*, wxEventType *type*, wxObject * *obj*, int *rowOrCol* = −1, int *x* = −1, int *y* = −1, const wxKeyboardState & *kbd* = wxKeyboardState())

Constructor for initializing all event attributes.

21.329.3 Member Function Documentation

bool wxGridSizeEvent::AltDown ( ) const

Returns true if the Alt key was down at the time of the event.

bool wxGridSizeEvent::ControlDown ( ) const

Returns true if the Control key was down at the time of the event.

wxPoint wxGridSizeEvent::GetPosition ( )

Position in pixels at which the event occurred.

int wxGridSizeEvent::GetRowOrCol ( )

Row or column at that was resized.

bool wxGridSizeEvent::MetaDown ( ) const

Returns true if the Meta key was down at the time of the event.

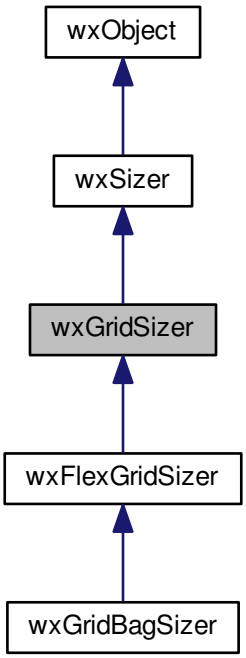
bool wxGridSizeEvent::ShiftDown ( ) const

Returns true if the Shift key was down at the time of the event.

21.330 wxGridSizer Class Reference

```
#include <wx/sizer.h>
```

Inheritance diagram for wxGridSizer:



21.330.1 Detailed Description

A grid sizer is a sizer which lays out its children in a two-dimensional table with all table fields having the same size, i.e.

the width of each field is the width of the widest child, the height of each field is the height of the tallest child.

Library: wxCore

Additional Inherited Members

21.330.2 Constructor & Destructor Documentation

wxGridSizer::wxGridSizer (int *cols*, int *vgap*, int *hgap*)

wxGridSizer constructors.

Usually only the number of columns in the flex grid sizer needs to be specified using *cols* argument. The number of rows will be deduced automatically depending on the number of the elements added to the sizer.

If a constructor form with *rows* parameter is used (and the value of *rows* argument is not zero, meaning "unspecified") the sizer will check that no more than `cols*rows` elements are added to it, i.e. that no more than the given number of *rows* is used. Adding less than maximally allowed number of items is not an error however.

Finally, it is also possible to specify the number of rows and use 0 for *cols*. In this case, the sizer will use the given fixed number of rows and as many columns as necessary.

The *gap* (or *vgap* and *hgap*, which correspond to the height and width of the wxSize object) argument defines the size of the padding between the rows (its vertical component, or *vgap*) and columns (its horizontal component, or *hgap*), in pixels.

Since

2.9.1 (except for the four argument overload)

wxGridSizer::wxGridSizer (int *cols*, const wxSize & *gap* = wxSize(0, 0))

wxGridSizer constructors.

Usually only the number of columns in the flex grid sizer needs to be specified using *cols* argument. The number of rows will be deduced automatically depending on the number of the elements added to the sizer.

If a constructor form with *rows* parameter is used (and the value of *rows* argument is not zero, meaning "unspecified") the sizer will check that no more than `cols*rows` elements are added to it, i.e. that no more than the given number of *rows* is used. Adding less than maximally allowed number of items is not an error however.

21.330.3 Member Function Documentation

virtual wxSize wxGridSizer::CalcMin ( ) [virtual]

This method is abstract and has to be overwritten by any derived class.

Here, the sizer will do the actual calculation of its children's minimal sizes.

Implements wxSizer.

Reimplemented in wxFlexGridSizer, and wxGridBagSizer.

int wxGridSizer::GetCols ( ) const

Returns the number of columns that has been specified for the sizer.

Returns zero if the sizer is automatically adjusting the number of columns depending on number of its children. To get the effective number of columns or rows being currently used, see GetEffectiveColsCount()

int wxGridSizer::GetEffectiveColsCount ( ) const

Returns the number of columns currently used by the sizer.

This will depend on the number of children the sizer has if the sizer is automatically adjusting the number of columns/rows.

Since

2.9.1

int wxGridSizer::GetEffectiveRowsCount ( ) const

Returns the number of rows currently used by the sizer.

This will depend on the number of children the sizer has if the sizer is automatically adjusting the number of columns/rows.

Since

2.9.1

int wxGridSizer::GetHGap ( ) const

Returns the horizontal gap (in pixels) between cells in the sizer.

int wxGridSizer::GetRows ( ) const

Returns the number of rows that has been specified for the sizer.

Returns zero if the sizer is automatically adjusting the number of rows depending on number of its children. To get the effective number of columns or rows being currently used, see GetEffectiveRowsCount().

int wxGridSizer::GetVGap ( ) const

Returns the vertical gap (in pixels) between the cells in the sizer.

virtual void wxGridSizer::RecalcSizes ( ) [virtual]

This method is abstract and has to be overwritten by any derived class.

Here, the sizer will do the actual calculation of its children's positions and sizes.

Implements wxSizer.

Reimplemented in wxFlexGridSizer, and wxGridBagSizer.

void wxGridSizer::SetCols (int *cols*)

Sets the number of columns in the sizer.

void wxGridSizer::SetHGap (int *gap*)

Sets the horizontal gap (in pixels) between cells in the sizer.

void wxGridSizer::SetRows (int *rows*)

Sets the number of rows in the sizer.

void wxGridSizer::SetVGap (int *gap*)

Sets the vertical gap (in pixels) between the cells in the sizer.

21.331 wxGridSizesInfo Class Reference

```
#include <wx/grid.h>
```

21.331.1 Detailed Description

wxGridSizesInfo stores information about sizes of all wxGrid rows or columns.

It assumes that most of the rows or columns (which are both called elements here as the difference between them doesn't matter at this class level) have the default size and so stores it separately. And it uses a wxHashMap to store the sizes of all elements which have the non-default size.

This structure is particularly useful for serializing the sizes of all wxGrid elements at once.

Library: wxAdvanced

Category: Grid Related Classes

Public Member Functions

- wxGridSizesInfo ()

Default constructor.

- wxGridSizesInfo (int defSize, const wxArrayInt &allSizes)

  Constructor.

- int GetSize (unsigned pos) const

  Get the element size.

Public Attributes

- int m_sizeDefault

  Default size.

- wxUnsignedToIntHashMap m_customSizes

  Map with element indices as keys and their sizes as values.

21.331.2 Constructor & Destructor Documentation

wxGridSizesInfo::wxGridSizesInfo ( )

Default constructor.

m_sizeDefault and m_customSizes must be initialized later.

wxGridSizesInfo::wxGridSizesInfo (int *defSize*, const wxArrayInt & *allSizes*)

Constructor.

This constructor is used by wxGrid::GetRowSizes() and GetColSizes() methods. User code will usually use the default constructor instead.

Parameters

defSize	The default element size.
allSizes	Array containing the sizes of *all* elements, including those which have the default size.

21.331.3 Member Function Documentation

int wxGridSizesInfo::GetSize (unsigned *pos*) const

Get the element size.

Parameters

pos	The index of the element.

Returns

The size for this element, using m_customSizes if *pos* is in it or m_sizeDefault otherwise.

21.331.4 Member Data Documentation

wxUnsignedToIntHashMap wxGridSizesInfo::m_customSizes

Map with element indices as keys and their sizes as values.

This map only contains the elements with non-default size.

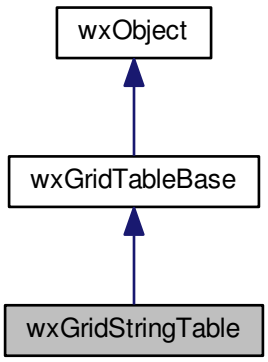
int wxGridSizesInfo::m_sizeDefault

Default size.

21.332 wxGridStringTable Class Reference

`#include <wx/grid.h>`

Inheritance diagram for wxGridStringTable:



21.332.1 Detailed Description

Simplest type of data table for a grid for small tables of strings that are stored in memory.

Public Member Functions

- wxGridStringTable ()
- wxGridStringTable (int numRows, int numCols)
- virtual int GetNumberRows ()

  Must be overridden to return the number of rows in the table.
- virtual int GetNumberCols ()

  Must be overridden to return the number of columns in the table.
- virtual wxString GetValue (int row, int col)

  Must be overridden to implement accessing the table values as text.
- virtual void SetValue (int row, int col, const wxString &value)

  Must be overridden to implement setting the table values as text.
- void Clear ()

  Clear the table contents.
- bool InsertRows (size_t pos=0, size_t numRows=1)

  Insert additional rows into the table.
- bool AppendRows (size_t numRows=1)

  Append additional rows at the end of the table.
- bool DeleteRows (size_t pos=0, size_t numRows=1)

Delete rows from the table.

- bool InsertCols (size_t pos=0, size_t numCols=1)

  Exactly the same as InsertRows() but for columns.
- bool AppendCols (size_t numCols=1)

  Exactly the same as AppendRows() but for columns.
- bool DeleteCols (size_t pos=0, size_t numCols=1)

  Exactly the same as DeleteRows() but for columns.
- void SetRowLabelValue (int row, const wxString &)

  Set the given label for the specified row.
- void SetColLabelValue (int col, const wxString &)

  Exactly the same as SetRowLabelValue() but for columns.
- wxString GetRowLabelValue (int row)

  Return the label of the specified row.
- wxString GetColLabelValue (int col)

  Return the label of the specified column.

Additional Inherited Members

21.332.2 Constructor & Destructor Documentation

wxGridStringTable::wxGridStringTable ( )

wxGridStringTable::wxGridStringTable (int *numRows*, int *numCols*)

21.332.3 Member Function Documentation

bool wxGridStringTable::AppendCols (size_t *numCols* = `1`) `[virtual]`

Exactly the same as AppendRows() but for columns.

Reimplemented from wxGridTableBase.

bool wxGridStringTable::AppendRows (size_t *numRows* = `1`) `[virtual]`

Append additional rows at the end of the table.

This method is provided in addition to InsertRows() as some data models may only support appending rows to them but not inserting them at arbitrary locations. In such case you may implement this method only and leave InsertRows() unimplemented.

Parameters

numRows	The number of rows to add.

Reimplemented from wxGridTableBase.

void wxGridStringTable::Clear ( ) `[virtual]`

Clear the table contents.

This method is used by wxGrid::ClearGrid().

Reimplemented from wxGridTableBase.

bool wxGridStringTable::DeleteCols (size_t *pos* = 0, size_t *numCols* = 1) [virtual]

Exactly the same as DeleteRows() but for columns.

Reimplemented from wxGridTableBase.

bool wxGridStringTable::DeleteRows (size_t *pos* = 0, size_t *numRows* = 1) [virtual]

Delete rows from the table.

Notice that currently deleting a row intersecting a multi-cell (see SetCellSize()) is not supported and will result in a crash.

Parameters

pos	The first row to delete.
numRows	The number of rows to delete.

Reimplemented from wxGridTableBase.

wxString wxGridStringTable::GetColLabelValue (int *col*) [virtual]

Return the label of the specified column.

Reimplemented from wxGridTableBase.

virtual int wxGridStringTable::GetNumberCols ( ) [virtual]

Must be overridden to return the number of columns in the table.

For backwards compatibility reasons, this method is not const. Use GetColsCount() instead of it in const methods of derived table classes,

Implements wxGridTableBase.

virtual int wxGridStringTable::GetNumberRows ( ) [virtual]

Must be overridden to return the number of rows in the table.

For backwards compatibility reasons, this method is not const. Use GetRowsCount() instead of it in const methods of derived table classes.

Implements wxGridTableBase.

wxString wxGridStringTable::GetRowLabelValue (int *row*) [virtual]

Return the label of the specified row.

Reimplemented from wxGridTableBase.

virtual wxString wxGridStringTable::GetValue (int *row*, int *col*) [virtual]

Must be overridden to implement accessing the table values as text.

Implements wxGridTableBase.

bool wxGridStringTable::InsertCols (size_t *pos* = 0, size_t *numCols* = 1) [virtual]

Exactly the same as InsertRows() but for columns.

Reimplemented from wxGridTableBase.

bool wxGridStringTable::InsertRows (size_t *pos* = 0, size_t *numRows* = 1) [virtual]

Insert additional rows into the table.

Parameters

pos	The position of the first new row.
numRows	The number of rows to insert.

Reimplemented from wxGridTableBase.

void wxGridStringTable::SetColLabelValue (int *col*, const wxString & *label*) [virtual]

Exactly the same as SetRowLabelValue() but for columns.

Reimplemented from wxGridTableBase.

void wxGridStringTable::SetRowLabelValue (int *row*, const wxString & *label*) [virtual]

Set the given label for the specified row.

The default version does nothing, i.e. the label is not stored. You must override this method in your derived class if you wish wxGrid::SetRowLabelValue() to work.

Reimplemented from wxGridTableBase.

virtual void wxGridStringTable::SetValue (int *row*, int *col*, const wxString & *value*) [virtual]

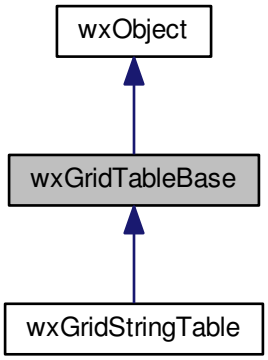
Must be overridden to implement setting the table values as text.

Implements wxGridTableBase.

21.333 wxGridTableBase Class Reference

```
#include <wx/grid.h>
```

Inheritance diagram for wxGridTableBase:



21.333.1 Detailed Description

The almost abstract base class for grid tables.

A grid table is responsible for storing the grid data and, indirectly, grid cell attributes. The data can be stored in the way most convenient for the application but has to be provided in string form to wxGrid. It is also possible to provide cells values in other formats if appropriate, e.g. as numbers.

This base class is not quite abstract as it implements a trivial strategy for storing the attributes by forwarding it to wxGridCellAttrProvider and also provides stubs for some other functions. However it does have a number of pure virtual methods which must be implemented in the derived classes.

See also

wxGridStringTable

Library: wxAdvanced

Category: Grid Related Classes

Public Member Functions

- wxGridTableBase ()

  Default constructor.
- virtual ~wxGridTableBase ()

  Destructor frees the attribute provider if it was created.
- virtual int GetNumberRows ()=0

  Must be overridden to return the number of rows in the table.
- virtual int GetNumberCols ()=0

  Must be overridden to return the number of columns in the table.
- int GetRowsCount () const

  Return the number of rows in the table.
- int GetColsCount () const

Return the number of columns in the table.

- virtual void SetView (wxGrid *grid)

  Called by the grid when the table is associated with it.

- virtual wxGrid * GetView () const

  Returns the last grid passed to SetView().

- virtual bool CanHaveAttributes ()

  Returns true if this table supports attributes or false otherwise.

Table Cell Accessors

- virtual bool IsEmptyCell (int row, int col)

  May be overridden to implement testing for empty cells.

- bool IsEmpty (const wxGridCellCoords &coords)

  Same as IsEmptyCell() but taking wxGridCellCoords.

- virtual wxString GetValue (int row, int col)=0

  Must be overridden to implement accessing the table values as text.

- virtual void SetValue (int row, int col, const wxString &value)=0

  Must be overridden to implement setting the table values as text.

- virtual wxString GetTypeName (int row, int col)

  Returns the type of the value in the given cell.

- virtual bool CanGetValueAs (int row, int col, const wxString &typeName)

  Returns true if the value of the given cell can be accessed as if it were of the specified type.

- virtual bool CanSetValueAs (int row, int col, const wxString &typeName)

  Returns true if the value of the given cell can be set as if it were of the specified type.

- virtual long GetValueAsLong (int row, int col)

  Returns the value of the given cell as a long.

- virtual double GetValueAsDouble (int row, int col)

  Returns the value of the given cell as a double.

- virtual bool GetValueAsBool (int row, int col)

  Returns the value of the given cell as a boolean.

- virtual void * GetValueAsCustom (int row, int col, const wxString &typeName)

  Returns the value of the given cell as a user-defined type.

- virtual void SetValueAsLong (int row, int col, long value)

  Sets the value of the given cell as a long.

- virtual void SetValueAsDouble (int row, int col, double value)

  Sets the value of the given cell as a double.

- virtual void SetValueAsBool (int row, int col, bool value)

  Sets the value of the given cell as a boolean.

- virtual void SetValueAsCustom (int row, int col, const wxString &typeName, void *value)

  Sets the value of the given cell as a user-defined type.

Table Structure Modifiers

Notice that none of these functions are pure virtual as they don't have to be implemented if the table structure is never modified after creation, i.e.

neither rows nor columns are never added or deleted but that you do need to implement them if they are called, i.e. if your code either calls them directly or uses the matching wxGrid methods, as by default they simply do nothing which is definitely inappropriate.

- virtual void Clear ()

  Clear the table contents.

- virtual bool InsertRows (size_t pos=0, size_t numRows=1)

  Insert additional rows into the table.

- virtual bool AppendRows (size_t numRows=1)

  Append additional rows at the end of the table.

- virtual bool DeleteRows (size_t pos=0, size_t numRows=1)

  Delete rows from the table.

- virtual bool InsertCols (size_t pos=0, size_t numCols=1)

Exactly the same as InsertRows() but for columns.

- virtual bool AppendCols (size_t numCols=1)
  Exactly the same as AppendRows() but for columns.
- virtual bool DeleteCols (size_t pos=0, size_t numCols=1)
  Exactly the same as DeleteRows() but for columns.

Table Row and Column Labels

By default the numbers are used for labeling rows and Latin letters for labeling columns.

If the table has more than 26 columns, the pairs of letters are used starting from the 27-th one and so on, i.e. the sequence of labels is A, B, ..., Z, AA, AB, ..., AZ, BA, ..., ..., ZZ, AAA, ...

- virtual wxString GetRowLabelValue (int row)
  Return the label of the specified row.
- virtual wxString GetColLabelValue (int col)
  Return the label of the specified column.
- virtual void SetRowLabelValue (int row, const wxString &label)
  Set the given label for the specified row.
- virtual void SetColLabelValue (int col, const wxString &label)
  Exactly the same as SetRowLabelValue() but for columns.

Attributes Management

By default the attributes management is delegated to wxGridCellAttrProvider class.

You may override the methods in this section to handle the attributes directly if, for example, they can be computed from the cell values.

- void SetAttrProvider (wxGridCellAttrProvider *attrProvider)
  Associate this attributes provider with the table.
- wxGridCellAttrProvider * GetAttrProvider () const
  Returns the attribute provider currently being used.
- virtual wxGridCellAttr * GetAttr (int row, int col, wxGridCellAttr::wxAttrKind kind)
  Return the attribute for the given cell.
- virtual void SetAttr (wxGridCellAttr *attr, int row, int col)
  Set attribute of the specified cell.
- virtual void SetRowAttr (wxGridCellAttr *attr, int row)
  Set attribute of the specified row.
- virtual void SetColAttr (wxGridCellAttr *attr, int col)
  Set attribute of the specified column.

Additional Inherited Members

21.333.2 Constructor & Destructor Documentation

wxGridTableBase::wxGridTableBase ( )

Default constructor.

virtual wxGridTableBase::~wxGridTableBase ( ) [virtual]

Destructor frees the attribute provider if it was created.

21.333.3 Member Function Documentation

virtual bool wxGridTableBase::AppendCols (size_t *numCols* = 1) [virtual]

Exactly the same as AppendRows() but for columns.

Reimplemented in wxGridStringTable.

virtual bool wxGridTableBase::AppendRows (size_t *numRows* = 1) [virtual]

Append additional rows at the end of the table.

This method is provided in addition to InsertRows() as some data models may only support appending rows to them but not inserting them at arbitrary locations. In such case you may implement this method only and leave InsertRows() unimplemented.

Parameters

numRows	The number of rows to add.

Reimplemented in wxGridStringTable.

virtual bool wxGridTableBase::CanGetValueAs (int *row*, int *col*, const wxString & *typeName*) [virtual]

Returns true if the value of the given cell can be accessed as if it were of the specified type.

By default the cells can only be accessed as strings. Note that a cell could be accessible in different ways, e.g. a numeric cell may return true for `wxGRID_VALUE_NUMBER` but also for `wxGRID_VALUE_STRING` indicating that the value can be coerced to a string form.

virtual bool wxGridTableBase::CanHaveAttributes ( ) [virtual]

Returns true if this table supports attributes or false otherwise.

By default, the table automatically creates a wxGridCellAttrProvider when this function is called if it had no attribute provider before and returns true.

virtual bool wxGridTableBase::CanSetValueAs (int *row*, int *col*, const wxString & *typeName*) [virtual]

Returns true if the value of the given cell can be set as if it were of the specified type.

See also

CanGetValueAs()

virtual void wxGridTableBase::Clear ( ) [virtual]

Clear the table contents.

This method is used by wxGrid::ClearGrid().

Reimplemented in wxGridStringTable.

virtual bool wxGridTableBase::DeleteCols (size_t *pos* = 0, size_t *numCols* = 1) [virtual]

Exactly the same as DeleteRows() but for columns.

Reimplemented in wxGridStringTable.

virtual bool wxGridTableBase::DeleteRows (size_t *pos* = 0, size_t *numRows* = 1) [virtual]

Delete rows from the table.

Notice that currently deleting a row intersecting a multi-cell (see SetCellSize()) is not supported and will result in a crash.

Parameters

pos	The first row to delete.
numRows	The number of rows to delete.

Reimplemented in wxGridStringTable.

virtual wxGridCellAttr* wxGridTableBase::GetAttr (int *row*, int *col*, wxGridCellAttr::wxAttrKind *kind*) [virtual]

Return the attribute for the given cell.

By default this function is simply forwarded to wxGridCellAttrProvider::GetAttr() but it may be overridden to handle attributes directly in the table.

wxGridCellAttrProvider* wxGridTableBase::GetAttrProvider ( ) const

Returns the attribute provider currently being used.

This function may return NULL if the attribute provider hasn't been neither associated with this table by SetAttrProvider() nor created on demand by any other methods.

virtual wxString wxGridTableBase::GetColLabelValue (int *col*) [virtual]

Return the label of the specified column.

Reimplemented in wxGridStringTable.

int wxGridTableBase::GetColsCount ( ) const

Return the number of columns in the table.

This method is not virtual and is only provided as a convenience for the derived classes which can't call GetNumberCols() without a `const_cast` from their const methods.

virtual int wxGridTableBase::GetNumberCols ( ) [pure virtual]

Must be overridden to return the number of columns in the table.

For backwards compatibility reasons, this method is not const. Use GetColsCount() instead of it in const methods of derived table classes,

Implemented in wxGridStringTable.

virtual int wxGridTableBase::GetNumberRows ( ) [pure virtual]

Must be overridden to return the number of rows in the table.

For backwards compatibility reasons, this method is not const. Use GetRowsCount() instead of it in const methods of derived table classes.

Implemented in wxGridStringTable.

virtual wxString wxGridTableBase::GetRowLabelValue (int *row*) [virtual]

Return the label of the specified row.

Reimplemented in wxGridStringTable.

int wxGridTableBase::GetRowsCount ( ) const

Return the number of rows in the table.

This method is not virtual and is only provided as a convenience for the derived classes which can't call GetNumberRows() without a `const_cast` from their const methods.

virtual wxString wxGridTableBase::GetTypeName (int *row*, int *col*) [virtual]

Returns the type of the value in the given cell.

By default all cells are strings and this method returns `wxGRID_VALUE_STRING`.

virtual wxString wxGridTableBase::GetValue (int *row*, int *col*) [pure virtual]

Must be overridden to implement accessing the table values as text.

Implemented in wxGridStringTable.

virtual bool wxGridTableBase::GetValueAsBool (int *row*, int *col*) [virtual]

Returns the value of the given cell as a boolean.

This should only be called if CanGetValueAs() returns true when called with `wxGRID_VALUE_BOOL` argument. Default implementation always return false.

virtual void* wxGridTableBase::GetValueAsCustom (int *row*, int *col*, const wxString & *typeName*) [virtual]

Returns the value of the given cell as a user-defined type.

This should only be called if CanGetValueAs() returns true when called with *typeName*. Default implementation always return NULL.

virtual double wxGridTableBase::GetValueAsDouble (int *row*, int *col*) [virtual]

Returns the value of the given cell as a double.

This should only be called if CanGetValueAs() returns true when called with `wxGRID_VALUE_FLOAT` argument. Default implementation always return 0.0.

virtual long wxGridTableBase::GetValueAsLong (int *row*, int *col*) [virtual]

Returns the value of the given cell as a long.

This should only be called if CanGetValueAs() returns true when called with `wxGRID_VALUE_NUMBER` argument. Default implementation always return 0.

virtual wxGrid* wxGridTableBase::GetView ( ) const [virtual]

Returns the last grid passed to SetView().

virtual bool wxGridTableBase::InsertCols (size_t *pos* = 0, size_t *numCols* = 1) [virtual]

Exactly the same as InsertRows() but for columns.

Reimplemented in wxGridStringTable.

virtual bool wxGridTableBase::InsertRows (size_t *pos* = 0, size_t *numRows* = 1) [virtual]

Insert additional rows into the table.

Parameters

pos	The position of the first new row.
numRows	The number of rows to insert.

Reimplemented in wxGridStringTable.

bool wxGridTableBase::IsEmpty (const wxGridCellCoords & *coords*)

Same as IsEmptyCell() but taking wxGridCellCoords.

Notice that this method is not virtual, only IsEmptyCell() should be overridden.

virtual bool wxGridTableBase::IsEmptyCell (int *row*, int *col*) [virtual]

May be overridden to implement testing for empty cells.

This method is used by the grid to test if the given cell is not used and so whether a neighbouring cell may overflow into it. By default it only returns true if the value of the given cell, as returned by GetValue(), is empty.

virtual void wxGridTableBase::SetAttr (wxGridCellAttr * *attr*, int *row*, int *col*) [virtual]

Set attribute of the specified cell.

By default this function is simply forwarded to wxGridCellAttrProvider::SetAttr().

The table takes ownership of *attr*, i.e. will call DecRef() on it.

void wxGridTableBase::SetAttrProvider (wxGridCellAttrProvider * *attrProvider*)

Associate this attributes provider with the table.

The table takes ownership of *attrProvider* pointer and will delete it when it doesn't need it any more. The pointer can be NULL, however this won't disable attributes management in the table but will just result in a default attributes being recreated the next time any of the other functions in this section is called. To completely disable the attributes support, should this be needed, you need to override CanHaveAttributes() to return false.

virtual void wxGridTableBase::SetColAttr (wxGridCellAttr * *attr*, int *col*) [virtual]

Set attribute of the specified column.

By default this function is simply forwarded to wxGridCellAttrProvider::SetColAttr().

The table takes ownership of *attr*, i.e. will call DecRef() on it.

virtual void wxGridTableBase::SetColLabelValue (int *col*, const wxString & *label*) [virtual]

Exactly the same as SetRowLabelValue() but for columns.

Reimplemented in wxGridStringTable.

virtual void wxGridTableBase::SetRowAttr (wxGridCellAttr * *attr*, int *row*) [virtual]

Set attribute of the specified row.

By default this function is simply forwarded to wxGridCellAttrProvider::SetRowAttr().

The table takes ownership of *attr*, i.e. will call DecRef() on it.

virtual void wxGridTableBase::SetRowLabelValue (int *row,* const wxString & *label*) `[virtual]`

Set the given label for the specified row.

The default version does nothing, i.e. the label is not stored. You must override this method in your derived class if you wish wxGrid::SetRowLabelValue() to work.

Reimplemented in wxGridStringTable.

virtual void wxGridTableBase::SetValue (int *row,* int *col,* const wxString & *value*) `[pure virtual]`

Must be overridden to implement setting the table values as text.

Implemented in wxGridStringTable.

virtual void wxGridTableBase::SetValueAsBool (int *row,* int *col,* bool *value*) `[virtual]`

Sets the value of the given cell as a boolean.

This should only be called if CanSetValueAs() returns true when called with `wxGRID_VALUE_BOOL` argument. Default implementation doesn't do anything.

virtual void wxGridTableBase::SetValueAsCustom (int *row,* int *col,* const wxString & *typeName,* void * *value*) `[virtual]`

Sets the value of the given cell as a user-defined type.

This should only be called if CanSetValueAs() returns true when called with *typeName*. Default implementation doesn't do anything.

virtual void wxGridTableBase::SetValueAsDouble (int *row,* int *col,* double *value*) `[virtual]`

Sets the value of the given cell as a double.

This should only be called if CanSetValueAs() returns true when called with `wxGRID_VALUE_FLOAT` argument. Default implementation doesn't do anything.

virtual void wxGridTableBase::SetValueAsLong (int *row,* int *col,* long *value*) `[virtual]`

Sets the value of the given cell as a long.

This should only be called if CanSetValueAs() returns true when called with `wxGRID_VALUE_NUMBER` argument. Default implementation doesn't do anything.

virtual void wxGridTableBase::SetView (wxGrid * *grid*) `[virtual]`

Called by the grid when the table is associated with it.

The default implementation stores the pointer and returns it from its GetView() and so only makes sense if the table cannot be associated with more than one grid at a time.

21.334 wxGridTableMessage Class Reference

`#include <wx/grid.h>`

21.334.1 Detailed Description

A simple class used to pass messages from the table to the grid.

Library: wxAdvanced

21.335 wxGridUpdateLocker Class Reference

```
#include <wx/grid.h>
```

21.335.1 Detailed Description

This small class can be used to prevent wxGrid from redrawing during its lifetime by calling wxGrid::BeginBatch() in its constructor and wxGrid::EndBatch() in its destructor.

It is typically used in a function performing several operations with a grid which would otherwise result in flicker. For example:

```
void MyFrame::Foo()
{
    m_grid = new wxGrid(this, ...);

    wxGridUpdateLocker noUpdates(m_grid);
    m_grid-AppendColumn();
    // ... many other operations with m_grid ...
    m_grid-AppendRow();

    // destructor called, grid refreshed
}
```

Using this class is easier and safer than calling wxGrid::BeginBatch() and wxGrid::EndBatch() because you don't risk missing the call the latter (due to an exception for example).

Library: wxAdvanced

Category: Grid Related Classes

Public Member Functions

- wxGridUpdateLocker (wxGrid *grid=NULL)

  Creates an object preventing the updates of the specified grid.
- ~wxGridUpdateLocker ()

  Destructor reenables updates for the grid this object is associated with.
- void Create (wxGrid *grid)

  This method can be called if the object had been constructed using the default constructor.

21.335.2 Constructor & Destructor Documentation

wxGridUpdateLocker::wxGridUpdateLocker (wxGrid * *grid* = NULL)

Creates an object preventing the updates of the specified *grid*.

The parameter could be NULL in which case nothing is done. If *grid* is non-NULL then the grid must exist for longer than this wxGridUpdateLocker object itself.

The default constructor could be followed by a call to Create() to set the grid object later.

wxGridUpdateLocker::~wxGridUpdateLocker ( )

Destructor reenables updates for the grid this object is associated with.

21.335.3 Member Function Documentation

void wxGridUpdateLocker::Create (wxGrid * *grid*)

This method can be called if the object had been constructed using the default constructor.

It must not be called more than once.

21.336 wxGUIEventLoop Class Reference

wxGUIEventLoop::wxGUIEventLoop ( )

virtual wxGUIEventLoop::~wxGUIEventLoop ( ) [virtual]

21.337 wxHashMap Class Reference

`#include <wx/hashmap.h>`

21.337.1 Detailed Description

This is a simple, type-safe, and reasonably efficient hash map class, whose interface is a subset of the interface of STL containers.

In particular, the interface is modelled after std::map, and the various, non-standard, std::hash_map (http://www.cppreference.com/wiki/stl/map/start).

Example:

```
class MyClass { ... };

// declare a hash map with string keys and int values
WX_DECLARE_STRING_HASH_MAP( int, MyHash5 );
// same, with int keys and MyClass* values
WX_DECLARE_HASH_MAP( int, MyClass*, wxIntegerHash, wxIntegerEqual, MyHash1 );
// same, with wxString keys and int values
WX_DECLARE_STRING_HASH_MAP( int, MyHash3 );
// same, with wxString keys and values
WX_DECLARE_STRING_HASH_MAP( wxString, MyHash2 );

MyHash1 h1;
MyHash2 h2;

// store and retrieve values
h1[1] = new MyClass( 1 );
h1[10000000] = NULL;
h1[50000] = new MyClass( 2 );
h2["Bill"] = "ABC";
wxString tmp = h2["Bill"];
// since element with key "Joe" is not present, this will return
// the default value, which is an empty string in the case of wxString
MyClass tmp2 = h2["Joe"];

// iterate over all the elements in the class
MyHash2::iterator it;
for( it = h2.begin(); it != h2.end(); ++it )
{
    wxString key = it->first, value = it->second;
    // do something useful with key and value
}
```

21.337.2 Declaring new hash table types

```
WX_DECLARE_STRING_HASH_MAP( VALUE_T,     // type of the values
                            CLASSNAME ); // name of the class
```

Declares a hash map class named CLASSNAME, with wxString keys and VALUE_T values.

```
WX_DECLARE_VOIDPTR_HASH_MAP( VALUE_T,     // type of the values
                             CLASSNAME ); // name of the class
```

Declares a hash map class named CLASSNAME, with void* keys and VALUE_T values.

```
WX_DECLARE_HASH_MAP( KEY_T,      // type of the keys
                     VALUE_T,    // type of the values
                     HASH_T,     // hasher
                     KEY_EQ_T,   // key equality predicate
                     CLASSNAME); // name of the class
```

The HASH_T and KEY_EQ_T are the types used for the hashing function and key comparison. wxWidgets provides three predefined hashing functions: `wxIntegerHash` for integer types (int, long, short, and their unsigned counterparts), `wxStringHash` for strings (wxString, wxChar*, char*), and `wxPointerHash` for any kind of pointer. Similarly three equality predicates: `wxIntegerEqual`, `wxStringEqual`, `wxPointerEqual` are provided. Using this you could declare a hash map mapping int values to wxString like this:

```
WX_DECLARE_HASH_MAP( int,
                     wxString,
                     wxIntegerHash,
                     wxIntegerEqual,
                     MyHash );

// using an user-defined class for keys
class MyKey { ... };

// hashing function
class MyKeyHash
{
public:
    MyKeyHash() { }

    unsigned long operator()( const MyKey& k ) const
        {
            // compute the hash
        }

    MyKeyHash& operator=(const MyKeyHash&) { return *this; }
};

// comparison operator
class MyKeyEqual
{
public:
    MyKeyEqual() { }
    bool operator()( const MyKey& a, const MyKey& b ) const
        {
           // compare for equality
        }

    MyKeyEqual& operator=(const MyKeyEqual&) { return *this; }
};

WX_DECLARE_HASH_MAP( MyKey,      // type of the keys
                     SOME_TYPE,  // any type you like
                     MyKeyHash,  // hasher
                     MyKeyEqual, // key equality predicate
                     CLASSNAME); // name of the class
```

21.337.3 Types

In the documentation below you should replace wxHashMap with the name you used in the class declaration.

- wxHashMap::key_type: Type of the hash keys.
- wxHashMap::mapped_type: Type of the values stored in the hash map.
- wxHashMap::value_type: Equivalent to struct { key_type first; mapped_type second }.
- wxHashMap::iterator: Used to enumerate all the elements in a hash map; it is similar to a value_type*.
- wxHashMap::const_iterator: Used to enumerate all the elements in a constant hash map; it is similar to a const value_type*.
- wxHashMap::size_type: Used for sizes.
- wxHashMap::Insert_Result: The return value for insert().

21.337.4 Iterators

An iterator is similar to a pointer, and so you can use the usual pointer operations: ++it (and it++) to move to the next element, *it to access the element pointed to, it->first (it->second) to access the key (value) of the element pointed to.

Hash maps provide forward only iterators, this means that you can't use –it, it + 3, it1 - it2.

21.337.5 Predefined hashmap types

wxWidgets defines the following hashmap types:

- wxLongToLongHashMap (uses long both for keys and values)
- wxStringToStringHashMap (uses wxString both for keys and values)

Library: wxBase

Category: Containers

Public Member Functions

- wxHashMap (size_type size=10)
  The size parameter is just a hint, the table will resize automatically to preserve performance.
- wxHashMap (const wxHashMap &map)
  Copy constructor.
- void clear ()
  Removes all elements from the hash map.
- size_type count (const key_type &key) const
  Counts the number of elements with the given key present in the map.
- bool empty () const
  Returns true if the hash map does not contain any elements, false otherwise.
- Insert_Result insert (const value_type &v)
  Inserts the given value in the hash map.
- mapped_type operator[] (const key_type &key)
  Use the key as an array subscript.
- size_type size () const
  Returns the number of elements in the map.

- const_iterator begin () const
  Returns an iterator pointing at the first element of the hash map.
- iterator begin ()
  Returns an iterator pointing at the first element of the hash map.

- const_iterator end () const
  Returns an iterator pointing at the one-after-the-last element of the hash map.
- iterator end ()
  Returns an iterator pointing at the one-after-the-last element of the hash map.

- size_type erase (const key_type &key)
  Erases the element with the given key, and returns the number of elements erased (either 0 or 1).
- void erase (iterator it)
  Erases the element pointed to by the iterator.
- void erase (const_iterator it)
  Erases the element with the given key, and returns the number of elements erased (either 0 or 1).

- iterator find (const key_type &key) const
  If an element with the given key is present, the functions returns an iterator pointing at that element, otherwise an invalid iterator is returned.
- const_iterator find (const key_type &key) const
  If an element with the given key is present, the functions returns an iterator pointing at that element, otherwise an invalid iterator is returned.

21.337.6 Constructor & Destructor Documentation

wxHashMap::wxHashMap (size_type *size* = 10)

The size parameter is just a hint, the table will resize automatically to preserve performance.

wxHashMap::wxHashMap (const wxHashMap & *map*)

Copy constructor.

21.337.7 Member Function Documentation

const_iterator wxHashMap::begin ( ) const

Returns an iterator pointing at the first element of the hash map.

Please remember that hash maps do not guarantee ordering.

iterator wxHashMap::begin ( )

Returns an iterator pointing at the first element of the hash map.

Please remember that hash maps do not guarantee ordering.

void wxHashMap::clear ( )

Removes all elements from the hash map.

size_type wxHashMap::count (const key_type & *key*) const

Counts the number of elements with the given key present in the map.

This function returns only 0 or 1.

bool wxHashMap::empty ( ) const

Returns true if the hash map does not contain any elements, false otherwise.

const_iterator wxHashMap::end ( ) const

Returns an iterator pointing at the one-after-the-last element of the hash map.

Please remember that hash maps do not guarantee ordering.

iterator wxHashMap::end ( )

Returns an iterator pointing at the one-after-the-last element of the hash map.

Please remember that hash maps do not guarantee ordering.

size_type wxHashMap::erase (const key_type & *key*)

Erases the element with the given key, and returns the number of elements erased (either 0 or 1).

void wxHashMap::erase (iterator *it*)

Erases the element pointed to by the iterator.

After the deletion the iterator is no longer valid and must not be used.

void wxHashMap::erase (const_iterator *it*)

Erases the element with the given key, and returns the number of elements erased (either 0 or 1).

iterator wxHashMap::find (const key_type & *key*) const

If an element with the given key is present, the functions returns an iterator pointing at that element, otherwise an invalid iterator is returned.

```
hashmap.find( non_existent_key ) == hashmap.end()
```

const_iterator wxHashMap::find (const key_type & *key*) const

If an element with the given key is present, the functions returns an iterator pointing at that element, otherwise an invalid iterator is returned.

```
hashmap.find( non_existent_key ) == hashmap.end()
```

Insert_Result wxHashMap::insert (const value_type & *v*)

Inserts the given value in the hash map.

The return value is equivalent to a

```
std::pair<wxHashMap::iterator, bool>
```

The iterator points to the inserted element, the boolean value is true if *v* was actually inserted.

mapped_type wxHashMap::operator[] (const key_type & *key*)

Use the key as an array subscript.

The only difference is that if the given key is not present in the hash map, an element with the default `value_type()` is inserted in the table.

size_type wxHashMap::size ( ) const

Returns the number of elements in the map.

21.338 wxHashSet Class Reference

```
#include <wx/hashset.h>
```

21.338.1 Detailed Description

This is a simple, type-safe, and reasonably efficient hash set class, whose interface is a subset of the interface of STL containers.

The interface is similar to std::tr1::hash_set or std::set classes but notice that, unlike std::set, the contents of a hash set is not sorted.

Example:

```
class MyClass { ... };

// same, with MyClass* keys (only uses pointer equality!)
WX_DECLARE_HASH_SET( MyClass*, wxPointerHash, wxPointerEqual, MySet1 );
// same, with int keys
WX_DECLARE_HASH_SET( int, wxIntegerHash, wxIntegerEqual, MySet2 );
// declare a hash set with string keys
WX_DECLARE_HASH_SET( wxString, wxStringHash, wxStringEqual, MySet3 );

MySet1 h1;
MySet2 h1;
MySet3 h3;

// store and retrieve values
h1.insert( new MyClass( 1 ) );

h3.insert( "foo" );
h3.insert( "bar" );
h3.insert( "baz" );

int size = h3.size(); // now is three
bool has_foo = h3.find( "foo" ) != h3.end();

h3.insert( "bar" ); // still has size three

// iterate over all the elements in the class
MySet3::iterator it;
for( it = h3.begin(); it != h3.end(); ++it )
{
    wxString key = *it;
    // do something useful with key
}
```

21.338.2 Declaring new hash set types

```
WX_DECLARE_HASH_SET( KEY_T,      // type of the keys
                     HASH_T,     // hasher
                     KEY_EQ_T,   // key equality predicate
                     CLASSNAME); // name of the class
```

The HASH_T and KEY_EQ_T are the types used for the hashing function and key comparison. wxWidgets provides three predefined hashing functions: wxIntegerHash for integer types (int, long, short, and their unsigned counterparts), wxStringHash for strings (wxString, wxChar*, char*), and wxPointerHash for any kind of pointer. Similarly three equality predicates: wxIntegerEqual, wxStringEqual, wxPointerEqual are provided. Using this you could declare a hash set using int values like this:

```
WX_DECLARE_HASH_SET( int,
                     wxIntegerHash,
                     wxIntegerEqual,
                     MySet );

// using an user-defined class for keys
class MyKey { ... };

// hashing function
class MyKeyHash
{
public:
    MyKeyHash() { }

    unsigned long operator()( const MyKey& k ) const
        {
            // compute the hash
        }

    MyKeyHash& operator=(const MyKeyHash&) { return *this; }
};
```

```
// comparison operator
class MyKeyEqual
{
public:
    MyKeyEqual() { }
    bool operator()( const MyKey& a, const MyKey& b ) const
        {
            // compare for equality
        }

    MyKeyEqual& operator=(const MyKeyEqual&) { return *this; }
};

WX_DECLARE_HASH_SET( MyKey,      // type of the keys
                     MyKeyHash,  // hasher
                     MyKeyEqual, // key equality predicate
                     CLASSNAME); // name of the class
```

21.338.3 Types

In the documentation below you should replace wxHashSet with the name you used in the class declaration.

- wxHashSet::key_type: Type of the hash keys
- wxHashSet::mapped_type: Type of hash keys
- wxHashSet::value_type: Type of hash keys
- wxHashSet::iterator: Used to enumerate all the elements in a hash set; it is similar to a value_type*
- wxHashSet::const_iterator: Used to enumerate all the elements in a constant hash set; it is similar to a const value_type*
- wxHashSet::size_type: Used for sizes
- wxHashSet::Insert_Result: The return value for insert()

21.338.4 Iterators

An iterator is similar to a pointer, and so you can use the usual pointer operations: ++it (and it++) to move to the next element, *it to access the element pointed to, *it to access the value of the element pointed to. Hash sets provide forward only iterators, this means that you can't use –it, it + 3, it1 - it2.

Library: wxBase

Category: Containers

Public Member Functions

- wxHashSet (size_type size=10)

  The size parameter is just a hint, the table will resize automatically to preserve performance.
- wxHashSet (const wxHashSet &set)

  Copy constructor.
- void clear ()

  Removes all elements from the hash set.
- size_type count (const key_type &key) const

  Counts the number of elements with the given key present in the set.
- bool empty () const

Returns true if the hash set does not contain any elements, false otherwise.

- size_type erase (const key_type &key)

  Erases the element with the given key, and returns the number of elements erased (either 0 or 1).
- Insert_Result insert (const value_type &v)

  Inserts the given value in the hash set.
- size_type size () const

  Returns the number of elements in the set.

- const_iterator begin () const

  Returns an iterator pointing at the first element of the hash set.
- iterator begin ()

  Returns an iterator pointing at the first element of the hash set.

- const_iterator end () const

  Returns an iterator pointing at the one-after-the-last element of the hash set.
- iterator end ()

  Returns an iterator pointing at the one-after-the-last element of the hash set.

- void erase (iterator it)

  Erases the element pointed to by the iterator.
- void erase (const_iterator it)

  Erases the element pointed to by the iterator.

- iterator find (const key_type &key) const

  If an element with the given key is present, the functions returns an iterator pointing at that element, otherwise an invalid iterator is returned.
- const_iterator find (const key_type &key) const

  If an element with the given key is present, the functions returns an iterator pointing at that element, otherwise an invalid iterator is returned.

21.338.5 Constructor & Destructor Documentation

wxHashSet::wxHashSet (size_type *size* = `10`)

The size parameter is just a hint, the table will resize automatically to preserve performance.

wxHashSet::wxHashSet (const wxHashSet & *set*)

Copy constructor.

21.338.6 Member Function Documentation

const_iterator wxHashSet::begin ( ) const

Returns an iterator pointing at the first element of the hash set.

Please remember that hash sets do not guarantee ordering.

iterator wxHashSet::begin ( )

Returns an iterator pointing at the first element of the hash set.

Please remember that hash sets do not guarantee ordering.

void wxHashSet::clear ( )

Removes all elements from the hash set.

size_type wxHashSet::count (const key_type & *key*) const

Counts the number of elements with the given key present in the set.

This function returns only 0 or 1.

bool wxHashSet::empty ( ) const

Returns true if the hash set does not contain any elements, false otherwise.

const_iterator wxHashSet::end ( ) const

Returns an iterator pointing at the one-after-the-last element of the hash set.

Please remember that hash sets do not guarantee ordering.

iterator wxHashSet::end ( )

Returns an iterator pointing at the one-after-the-last element of the hash set.

Please remember that hash sets do not guarantee ordering.

size_type wxHashSet::erase (const key_type & *key*)

Erases the element with the given key, and returns the number of elements erased (either 0 or 1).

void wxHashSet::erase (iterator *it*)

Erases the element pointed to by the iterator.

After the deletion the iterator is no longer valid and must not be used.

void wxHashSet::erase (const_iterator *it*)

Erases the element pointed to by the iterator.

After the deletion the iterator is no longer valid and must not be used.

iterator wxHashSet::find (const key_type & *key*) const

If an element with the given key is present, the functions returns an iterator pointing at that element, otherwise an invalid iterator is returned.

i.e.

```
hashset.find( non_existent_key ) == hashset.end()
```

const_iterator wxHashSet::find (const key_type & *key*) const

If an element with the given key is present, the functions returns an iterator pointing at that element, otherwise an invalid iterator is returned.

i.e.

```
hashset.find( non_existent_key ) == hashset.end()
```

Insert_Result wxHashSet::insert (const value_type & *v*)

Inserts the given value in the hash set.

The return value is equivalent to a

```
std::pair<wxHashMap::iterator, bool>
```

The iterator points to the inserted element, the boolean value is true if *v* was actually inserted.

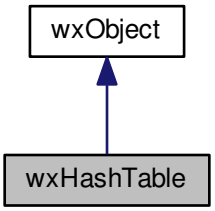
size_type wxHashSet::size ( ) const

Returns the number of elements in the set.

21.339 wxHashTable Class Reference

`#include <wx/hash.h>`

Inheritance diagram for wxHashTable:



21.339.1 Detailed Description

Deprecated Please note that this class is retained for backward compatibility reasons; you should use wxHashMap.

This class provides hash table functionality for wxWidgets, and for an application if it wishes. Data can be hashed on an integer or string key.

Example:

```
wxHashTable table(wxKEY_STRING);

wxPoint *point = new wxPoint(100, 200);
```

```
table.Put("point 1", point);

....

wxPoint *found_point = (wxPoint *)table.Get("point 1");
```

A hash table is implemented as an array of pointers to lists. When no data has been stored, the hash table takes only a little more space than this array (default size is 1000). When a data item is added, an integer is constructed from the integer or string key that is within the bounds of the array. If the array element is NULL, a new (keyed) list is created for the element. Then the data object is appended to the list, storing the key in case other data objects need to be stored in the list also (when a 'collision' occurs).

Retrieval involves recalculating the array index from the key, and searching along the keyed list for the data object whose stored key matches the passed key. Obviously this is quicker when there are fewer collisions, so hashing will become inefficient if the number of items to be stored greatly exceeds the size of the hash table.

Library: wxBase

Category: Containers

wxList

Public Member Functions

- wxHashTable (wxKeyType key_type=wxKEY_INTEGER, size_t size=1000)

  Constructor.
- virtual ~wxHashTable ()

  Destroys the hash table.
- void BeginFind ()

  The counterpart of Next().
- void Clear ()

  Clears the hash table of all nodes (but as usual, doesn't delete user data).
- void DeleteContents (bool flag)

  If set to true data stored in hash table will be deleted when hash table object is destroyed.
- size_t GetCount () const

  Returns the number of elements in the hash table.
- wxHashTable::Node * Next ()

  If the application wishes to iterate through all the data in the hash table, it can call BeginFind() and then loop on Next().
- wxObject * Delete (long key)

  Deletes entry in hash table and returns the user's data (if found).
- wxObject * Delete (const wxString &key)

  Deletes entry in hash table and returns the user's data (if found).
- wxObject * Get (long key)

  Gets data from the hash table, using an integer or string key (depending on which has table constructor was used).
- wxObject * Get (const char *key)

  Gets data from the hash table, using an integer or string key (depending on which has table constructor was used).
- void Put (long key, wxObject *object)

  Inserts data into the hash table, using an integer or string key (depending on which has table constructor was used).
- void Put (const char *key, wxObject *object)

  Inserts data into the hash table, using an integer or string key (depending on which has table constructor was used).

Static Public Member Functions

- static long MakeKey (const wxString &string)
  Makes an integer key out of a string.

Additional Inherited Members

21.339.2 Constructor & Destructor Documentation

wxHashTable::wxHashTable (wxKeyType *key_type* = `wxKEY_INTEGER`, size_t *size* = `1000`)

Constructor.

key_type is one of wxKEY_INTEGER, or wxKEY_STRING, and indicates what sort of keying is required. *size* is optional.

virtual wxHashTable::~wxHashTable ( ) `[virtual]`

Destroys the hash table.

21.339.3 Member Function Documentation

void wxHashTable::BeginFind ( )

The counterpart of Next().

If the application wishes to iterate through all the data in the hash table, it can call BeginFind() and then loop on Next().

void wxHashTable::Clear ( )

Clears the hash table of all nodes (but as usual, doesn't delete user data).

wxObject* wxHashTable::Delete (long *key*)

Deletes entry in hash table and returns the user's data (if found).

wxObject* wxHashTable::Delete (const wxString & *key*)

Deletes entry in hash table and returns the user's data (if found).

void wxHashTable::DeleteContents (bool *flag*)

If set to true data stored in hash table will be deleted when hash table object is destroyed.

wxObject* wxHashTable::Get (long *key*)

Gets data from the hash table, using an integer or string key (depending on which has table constructor was used).

wxObject* wxHashTable::Get (const char * *key*)

Gets data from the hash table, using an integer or string key (depending on which has table constructor was used).

size_t wxHashTable::GetCount ( ) const

Returns the number of elements in the hash table.

static long wxHashTable::MakeKey (const wxString & *string*) [static]

Makes an integer key out of a string.

An application may wish to make a key explicitly (for instance when combining two data values to form a key).

wxHashTable::Node* wxHashTable::Next ( )

If the application wishes to iterate through all the data in the hash table, it can call BeginFind() and then loop on Next().

This function returns a **wxHashTable::Node** pointer (or NULL if there are no more nodes).

The return value is functionally equivalent to **wxNode** but might not be implemented as a **wxNode**. The user will probably only wish to use the wxNode::GetData() method to retrieve the data; the node may also be deleted.

void wxHashTable::Put (long *key,* wxObject * *object*)

Inserts data into the hash table, using an integer or string key (depending on which has table constructor was used).

The key string is copied and stored by the hash table implementation.

void wxHashTable::Put (const char * *key,* wxObject * *object*)

Inserts data into the hash table, using an integer or string key (depending on which has table constructor was used).

The key string is copied and stored by the hash table implementation.

21.340 wxHeaderButtonParams Struct Reference

`#include <wx/renderer.h>`

21.340.1 Detailed Description

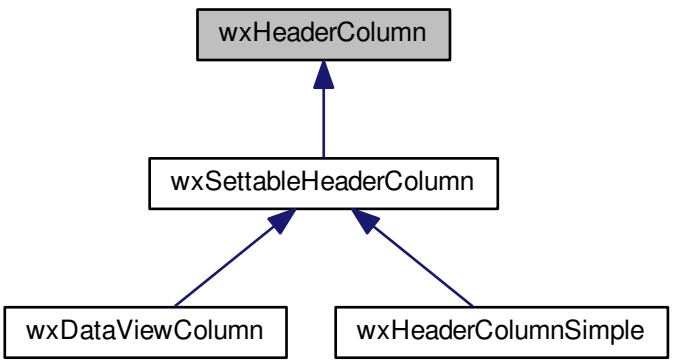
21.341 wxHeaderColumn Class Reference

`#include <wx/headercol.h>`

Inheritance diagram for wxHeaderColumn:



21.341.1 Detailed Description

Represents a column header in controls displaying tabular data such as wxDataViewCtrl or wxGrid.

Notice that this is an abstract base class which is implemented (usually using the information stored in the associated control) by the different controls using wxHeaderCtrl. As the control only needs to retrieve the information about the column, this class defines only the methods for accessing the various column properties but not for changing them as the setters might not be needed at all, e.g. if the column attributes can only be changed via the methods of the main associated control (this is the case for wxGrid for example). If you do want to allow changing them directly using the column itself, you should inherit from wxSettableHeaderColumn instead of this class.

Finally, if you don't already store the column information at all anywhere, you should use the concrete wxHeaderColumnSimple class and wxHeaderCtrlSimple.

Library: wxCore

Category: Controls

Public Member Functions

- virtual wxString GetTitle () const =0

  Get the text shown in the column header.
- virtual wxBitmap GetBitmap () const =0

  Returns the bitmap in the header of the column, if any.
- virtual int GetWidth () const =0

  Returns the current width of the column.
- virtual int GetMinWidth () const =0

  Return the minimal column width.
- virtual wxAlignment GetAlignment () const =0

  Returns the current column alignment.
- virtual int GetFlags () const =0

  Get the column flags.
- bool HasFlag (int flag) const

  Return true if the specified flag is currently set for this column.
- virtual bool IsResizeable () const

  Return true if the column can be resized by the user.
- virtual bool IsSortable () const

  Returns true if the column can be clicked by user to sort the control contents by the field in this column.
- virtual bool IsReorderable () const

  Returns true if the column can be dragged by user to change its order.
- virtual bool IsHidden () const

  Returns true if the column is currently hidden.
- bool IsShown () const

  Returns true if the column is currently shown.
- virtual bool IsSortKey () const =0

  Returns true if the column is currently used for sorting.
- virtual bool IsSortOrderAscending () const =0

  Returns true, if the sort order is ascending.

21.341.2 Member Function Documentation

virtual wxAlignment wxHeaderColumn::GetAlignment ( ) const [pure virtual]

Returns the current column alignment.

Returns

One of wxALIGN_CENTRE, wxALIGN_LEFT or wxALIGN_RIGHT.

Implemented in wxHeaderColumnSimple.

virtual wxBitmap wxHeaderColumn::GetBitmap ( ) const [pure virtual]

Returns the bitmap in the header of the column, if any.

If the column has no associated bitmap, wxNullBitmap should be returned.

Implemented in wxHeaderColumnSimple.

virtual int wxHeaderColumn::GetFlags ( ) const [pure virtual]

Get the column flags.

This method retrieves all the flags at once, you can also use HasFlag() to test for any individual flag or IsResizeable(), IsSortable(), IsReorderable() and IsHidden() to test for particular flags.

Implemented in wxHeaderColumnSimple.

virtual int wxHeaderColumn::GetMinWidth ( ) const [pure virtual]

Return the minimal column width.

Returns

The minimal width such that the user can't resize the column to lesser size (notice that it is still possible to set the column width to smaller value from the program code). Return 0 from here to allow resizing the column to arbitrarily small size.

Implemented in wxHeaderColumnSimple.

virtual wxString wxHeaderColumn::GetTitle ( ) const [pure virtual]

Get the text shown in the column header.

Implemented in wxHeaderColumnSimple.

virtual int wxHeaderColumn::GetWidth ( ) const [pure virtual]

Returns the current width of the column.

Returns

Width of the column in pixels, never wxCOL_WIDTH_DEFAULT or wxCOL_WIDTH_AUTOSIZE.

Implemented in wxHeaderColumnSimple.

bool wxHeaderColumn::HasFlag (int *flag*) const

Return true if the specified flag is currently set for this column.

virtual bool wxHeaderColumn::IsHidden ( ) const `[virtual]`

Returns true if the column is currently hidden.

This corresponds to wxCOL_HIDDEN flag which is off by default.

virtual bool wxHeaderColumn::IsReorderable ( ) const `[virtual]`

Returns true if the column can be dragged by user to change its order.

This corresponds to wxCOL_REORDERABLE flag which is on by default.

virtual bool wxHeaderColumn::IsResizeable ( ) const `[virtual]`

Return true if the column can be resized by the user.

Equivalent to HasFlag(wxCOL_RESIZABLE).

bool wxHeaderColumn::IsShown ( ) const

Returns true if the column is currently shown.

This corresponds to the absence of wxCOL_HIDDEN flag.

virtual bool wxHeaderColumn::IsSortable ( ) const `[virtual]`

Returns true if the column can be clicked by user to sort the control contents by the field in this column.

This corresponds to wxCOL_SORTABLE flag which is off by default.

virtual bool wxHeaderColumn::IsSortKey ( ) const `[pure virtual]`

Returns true if the column is currently used for sorting.

Implemented in wxHeaderColumnSimple.

virtual bool wxHeaderColumn::IsSortOrderAscending ( ) const `[pure virtual]`

Returns true, if the sort order is ascending.

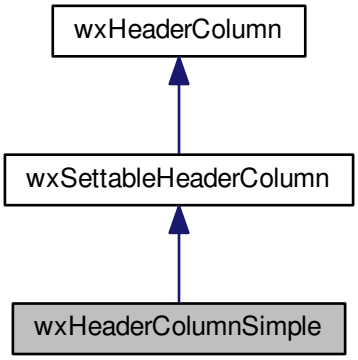
Notice that it only makes sense to call this function if the column is used for sorting at all, i.e. if IsSortKey() returns true.

Implemented in wxHeaderColumnSimple.

21.342 wxHeaderColumnSimple Class Reference

`#include <wx/headercol.h>`

Inheritance diagram for wxHeaderColumnSimple:



21.342.1 Detailed Description

Simple container for the information about the column.

This is a concrete class implementing all wxSettableHeaderColumn class methods in a trivial way, i.e. by just storing the information in the object itself. It is used by and with wxHeaderCtrlSimple, e.g.

```
wxHeaderCtrlSimple * header = new wxHeaderCtrlSimple(...);
wxHeaderColumnSimple col("Title");
col.SetWidth(100);
col.SetSortable(100);
header->AppendColumn(col);
```

Trivial implementations of the base class pure virtual functions.

Implements wxSettableHeaderColumn.

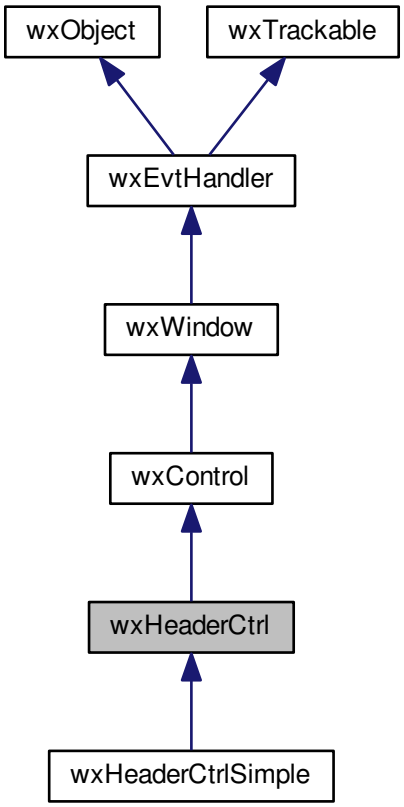
21.343 wxHeaderCtrl Class Reference

`#include <wx/headerctrl.h>`

Inheritance diagram for wxHeaderCtrl:



21.343.1 Detailed Description

wxHeaderCtrl is the control containing the column headings which is usually used for display of tabular data.

It is used as part of wxGrid, in generic version wxDataViewCtrl and report view of wxListCtrl but can be also used independently. In general this class is meant to be used as part of another control which already stores the column information somewhere as it can't be used directly: instead you need to inherit from it and implement the GetColumn() method to provide column information. See wxHeaderCtrlSimple for a concrete control class which can be used directly.

In addition to labeling the columns, the control has the following features:

- Column reordering support, either by explicitly configuring the columns order and calling SetColumnsOrder() or by dragging the columns interactively (if enabled).
- Display of the icons in the header: this is often used to display a sort or reverse sort indicator when the column header is clicked.

Notice that this control itself doesn't do anything other than displaying the column headers. In particular column reordering and sorting must still be supported by the associated control displaying the real data under the header. Also remember to call ScrollWindow() method of the control if the associated data display window has a horizontal scrollbar, otherwise the headers wouldn't align with the data when the window is scrolled.

This control is implemented using the native header control under MSW systems and a generic implementation elsewhere.

21.343.2 Future Improvements

Some features are supported by the native MSW control and so could be easily implemented in this version of wxHeaderCtrl but need to be implemented in the generic version as well to be really useful. Please let us know if you need or, better, plan to work on implementing, any of them:

- Displaying bitmaps instead of or together with the text
- Custom drawn headers
- Filters associated with a column.

Styles

This class supports the following styles:

- wxHD_ALLOW_REORDER: If this style is specified (it is by default), the user can reorder the control columns by dragging them.
- wxHD_ALLOW_HIDE: If this style is specified, the control shows a popup menu allowing the user to change the columns visibility on right mouse click. Notice that the program can always hide or show the columns, this style only affects the users capability to do it.
- wxHD_DEFAULT_STYLE: Symbolic name for the default control style, currently equal to `wxHD_ALLOW_REORDER`.

Events emitted by this class

The following event handler macros redirect the events to member function handlers '**func**' with prototypes like: void handlerFuncName(wxHeaderCtrlEvent& event)

Event macros for events emitted by this class:

- EVT_HEADER_CLICK(id, func): A column heading was clicked.
- EVT_HEADER_RIGHT_CLICK(id, func): A column heading was right clicked.
- EVT_HEADER_MIDDLE_CLICK(id, func): A column heading was clicked with the middle mouse button.
- EVT_HEADER_DCLICK(id, func): A column heading was double clicked.
- EVT_HEADER_RIGHT_DCLICK(id, func): A column heading was right double clicked.
- EVT_HEADER_MIDDLE_DCLICK(id, func): A column heading was double clicked with the middle mouse button.
- EVT_HEADER_SEPARATOR_DCLICK(id, func): Separator to the right of the specified column was double clicked (this action is commonly used to resize the column to fit its contents width and the control provides UpdateColumnWidthToFit() method to make implementing this easier).
- EVT_HEADER_BEGIN_RESIZE(id, func): The user started to drag the separator to the right of the column with the specified index (this can only happen for the columns for which wxHeaderColumn::IsResizeable() returns true). The event can be vetoed to prevent the column from being resized. If it isn't, the resizing and end resize (or dragging cancelled) events will be generated later.
- EVT_HEADER_RESIZING(id, func): The user is dragging the column with the specified index resizing it and its current width is wxHeaderCtrlEvent::GetWidth(). The event can be vetoed to stop the dragging operation completely at any time.

- EVT_HEADER_END_RESIZE(id, func): The user stopped dragging the column by releasing the mouse. The column should normally be resized to the value of wxHeaderCtrlEvent::GetWidth().
- EVT_HEADER_BEGIN_REORDER(id, func): The user started to drag the column with the specified index (this can only happen for the controls with wxHD_ALLOW_REORDER style). This event can be vetoed to prevent the column from being reordered, otherwise the end reorder message will be generated later.
- EVT_HEADER_END_REORDER(id, func): The user dropped the column in its new location. The event can be vetoed to prevent the column from being placed at the new position or handled to update the display of the data in the associated control to match the new column location (available from wxHeaderCtrlEvent::GetNewOrder()).
- EVT_HEADER_DRAGGING_CANCELLED(id, func): The resizing or reordering operation currently in progress was cancelled. This can happen if the user pressed Esc key while dragging the mouse or the mouse capture was lost for some other reason. You only need to handle this event if your application entered into some modal mode when resizing or reordering began, in which case it should handle this event in addition to the matching end resizing or reordering ones.

wxGrid, wxListCtrl, wxDataViewCtrl

Public Member Functions

- wxHeaderCtrl ()

  Default constructor not creating the underlying window.
- wxHeaderCtrl (wxWindow *parent, wxWindowID winid=wxID_ANY, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, long style=wxHD_DEFAULT_STYLE, const wxString &name=wxHeaderCtrlNameStr)

  Constructor creating the window.
- bool Create (wxWindow *parent, wxWindowID winid=wxID_ANY, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, long style=wxHD_DEFAULT_STYLE, const wxString &name=wxHeaderCtrlNameStr)

  Create the header control window.
- void SetColumnCount (unsigned int count)

  Set the number of columns in the control.
- unsigned int GetColumnCount () const

  Return the number of columns in the control.
- bool IsEmpty () const

  Return whether the control has any columns.
- void UpdateColumn (unsigned int idx)

  Update the column with the given index.
- void SetColumnsOrder (const wxArrayInt &order)

  Change the columns display order.
- wxArrayInt GetColumnsOrder () const

  Return the array describing the columns display order.
- unsigned int GetColumnAt (unsigned int pos) const

  Return the index of the column displayed at the given position.
- unsigned int GetColumnPos (unsigned int idx) const

Get the position at which this column is currently displayed.

- void ResetColumnsOrder ()

  Reset the columns order to the natural one.

- bool ShowColumnsMenu (const wxPoint &pt, const wxString &title=wxString())

  Show the popup menu allowing the user to show or hide the columns.

- void AddColumnsItems (wxMenu &menu, int idColumnsBase=0)

  Helper function appending the checkable items corresponding to all the columns to the given menu.

- bool ShowCustomizeDialog ()

  Show the column customization dialog.

- int GetColumnTitleWidth (const wxHeaderColumn &col)

  Returns width needed for given column's title.

Static Public Member Functions

- static void MoveColumnInOrderArray (wxArrayInt &order, unsigned int idx, unsigned int pos)

  Helper function to manipulate the array of column indices.

Protected Member Functions

- virtual const wxHeaderColumn & GetColumn (unsigned int idx) const =0

  Method to be implemented by the derived classes to return the information for the given column.

- virtual void UpdateColumnVisibility (unsigned int idx, bool show)

  Method called when the column visibility is changed by the user.

- virtual void UpdateColumnsOrder (const wxArrayInt &order)

  Method called when the columns order is changed in the customization dialog.

- virtual bool UpdateColumnWidthToFit (unsigned int idx, int widthTitle)

  Method which may be implemented by the derived classes to allow double clicking the column separator to resize the column to fit its contents.

- virtual void OnColumnCountChanging (unsigned int count)

  Can be overridden in the derived class to update internal data structures when the number of the columns in the control changes.

Additional Inherited Members

21.343.3 Constructor & Destructor Documentation

wxHeaderCtrl::wxHeaderCtrl ( )

Default constructor not creating the underlying window.

You must use Create() after creating the object using this constructor.

wxHeaderCtrl::wxHeaderCtrl (wxWindow * *parent*, wxWindowID *winid* = wxID_ANY, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, long *style* = wxHD_DEFAULT_STYLE, const wxString & *name* = `wxHeaderCtrlNameStr`)

Constructor creating the window.

Please see Create() for the parameters documentation.

21.343.4 Member Function Documentation

void wxHeaderCtrl::AddColumnsItems (wxMenu & *menu*, int *idColumnsBase* = 0)

Helper function appending the checkable items corresponding to all the columns to the given menu.

This function is used by ShowColumnsMenu() but can also be used if you show your own custom columns menu and still want all the columns shown in it. It appends menu items with column labels as their text and consecutive ids starting from *idColumnsBase* to the menu and checks the items corresponding to the currently visible columns.

Example of use:

```
wxMenu menu;
menu.Append(100, "Some custom command");
menu.AppendSeparator();
AddColumnsItems(menu, 200);
const int rc = GetPopupMenuSelectionFromUser(menu, pt);
if ( rc >= 200 )
    ... toggle visibility of the column rc-200 ...
```

Parameters

menu	The menu to append the items to. It may be currently empty or not.
idColumnsBase	The id for the menu item corresponding to the first column, the other ones are consecutive starting from it. It should be positive.

bool wxHeaderCtrl::Create (wxWindow * *parent*, wxWindowID *winid* = wxID_ANY, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, long *style* = wxHD_DEFAULT_STYLE, const wxString & *name* = wxHeaderCtrlNameStr)

Create the header control window.

Parameters

parent	The parent window. The header control should be typically positioned along the top edge of this window.
winid	Id of the control or wxID_ANY if you don't care.
pos	The initial position of the control.
size	The initial size of the control (usually not very useful as this control will typically be resized to have the same width as the associated data display control).
style	The control style, wxHD_DEFAULT_STYLE by default. Notice that the default style allows the user to reorder the columns by dragging them and you need to explicitly turn this feature off by using `wxHD_DEFAULT_STYLE & ~wxHD_ALLOW_REORDER` if this is undesirable.
name	The name of the control.

virtual const wxHeaderColumn& wxHeaderCtrl::GetColumn (unsigned int *idx*) const [protected], [pure virtual]

Method to be implemented by the derived classes to return the information for the given column.

Parameters

idx	The column index, between 0 and the value last passed to SetColumnCount().

unsigned int wxHeaderCtrl::GetColumnAt (unsigned int *pos*) const

Return the index of the column displayed at the given position.

Parameters

pos	The display position, e.g. 0 for the left-most column, 1 for the next one and so on until GetColumnCount() - 1.

See also

GetColumnPos()

unsigned int wxHeaderCtrl::GetColumnCount ( ) const

Return the number of columns in the control.

Returns

Number of columns as previously set by SetColumnCount().

See also

IsEmpty()

unsigned int wxHeaderCtrl::GetColumnPos (unsigned int *idx*) const

Get the position at which this column is currently displayed.

Notice that a valid position is returned even for the hidden columns currently.

Parameters

idx	The column index, must be less than GetColumnCount().

See also

GetColumnAt()

wxArrayInt wxHeaderCtrl::GetColumnsOrder ( ) const

Return the array describing the columns display order.

For the controls without wxHD_ALLOW_REORDER style the returned array will be the same as was passed to SetColumnsOrder() previously or define the default order (with n-th element being n) if it hadn't been called. But for the controls with wxHD_ALLOW_REORDER style, the columns can be also reordered by user.

int wxHeaderCtrl::GetColumnTitleWidth (const wxHeaderColumn & *col*)

Returns width needed for given column's title.

Since

2.9.4

bool wxHeaderCtrl::IsEmpty ( ) const

Return whether the control has any columns.

See also

GetColumnCount()

static void wxHeaderCtrl::MoveColumnInOrderArray (wxArrayInt & *order*, unsigned int *idx*, unsigned int *pos*) [static]

Helper function to manipulate the array of column indices.

This function reshuffles the array of column indices indexed by positions (i.e. using the same convention as for SetColumnsOrder()) so that the column with the given index is found at the specified position.

Parameters

order	Array containing the indices of columns in order of their positions.
idx	The index of the column to move.
pos	The new position for the column *idx*.

virtual void wxHeaderCtrl::OnColumnCountChanging (unsigned int *count*) [protected], [virtual]

Can be overridden in the derived class to update internal data structures when the number of the columns in the control changes.

This method is called by SetColumnCount() before effectively changing the number of columns.

The base class version does nothing but it is good practice to still call it from the overridden version in the derived class.

void wxHeaderCtrl::ResetColumnsOrder ( )

Reset the columns order to the natural one.

After calling this function, the column with index `idx` appears at position `idx` in the control.

void wxHeaderCtrl::SetColumnCount (unsigned int *count*)

Set the number of columns in the control.

The control will use GetColumn() to get information about all the new columns and refresh itself, i.e. this method also has the same effect as calling UpdateColumn() for all columns but it should only be used if the number of columns really changed.

void wxHeaderCtrl::SetColumnsOrder (const wxArrayInt & *order*)

Change the columns display order.

The display order defines the order in which the columns appear on the screen and does *not* affect the interpretation of indices by all the other class methods.

The *order* array specifies the column indices corresponding to the display positions.

Parameters

order	A permutation of all column indices, i.e. an array of size GetColumnsOrder() containing all column indices exactly once. The n-th element of this array defines the index of the column shown at the n-th position from left (for the default left-to-right writing direction).

See also

wxListCtrl::SetColumnsOrder()

bool wxHeaderCtrl::ShowColumnsMenu (const wxPoint & *pt*, const wxString & *title* = wxString())

Show the popup menu allowing the user to show or hide the columns.

This functions shows the popup menu containing all columns with check marks for the ones which are currently shown and allows the user to check or uncheck them to toggle their visibility. It is called from the default EVT_HEADER_RIGHT_CLICK handler for the controls which have wxHD_ALLOW_HIDE style. And if the column has wxHD_ALLOW_REORDER style as well, the menu also contains an item to customize the columns shown using which results in ShowCustomizeDialog() being called, please see its description for more details.

If a column was toggled, UpdateColumnVisibility() virtual function is called so it must be implemented for the controls with wxHD_ALLOW_HIDE style or if you call this function explicitly.

Parameters

pt	The position of the menu, in the header window coordinates.
title	The title for the menu if not empty.

Returns

true if a column was shown or hidden or false if nothing was done, e.g. because the menu was cancelled.

bool wxHeaderCtrl::ShowCustomizeDialog ( )

Show the column customization dialog.

This function displays a modal dialog containing the list of all columns which the user can use to reorder them as well as show or hide individual columns.

If the user accepts the changes done in the dialog, the virtual methods UpdateColumnVisibility() and UpdateColumnsOrder() will be called so they must be overridden in the derived class if this method is ever called. Please notice that the user will be able to invoke it interactively from the header popup menu if the control has both wxHD_ALLOW_HIDE and wxHD_ALLOW_REORDER styles.

See also

wxRearrangeDialog

void wxHeaderCtrl::UpdateColumn (unsigned int *idx*)

Update the column with the given index.

When the value returned by GetColumn() changes, this method must be called to notify the control about the change and update the visual display to match the new column data.

Parameters

idx	The column index, must be less than GetColumnCount().

virtual void wxHeaderCtrl::UpdateColumnsOrder (const wxArrayInt & *order*) [protected], [virtual]

Method called when the columns order is changed in the customization dialog.

This method is only called from ShowCustomizeDialog() when the user changes the order of columns. In particular it is *not* called if a single column changes place because the user dragged it to the new location, the EVT_HEADER_END_REORDER event handler should be used to react to this.

A typical implementation in a derived class will update the display order of the columns in the associated control, if any. Notice that there is no need to call SetColumnsOrder() from it as wxHeaderCtrl does it itself.

The base class version doesn't do anything and must be overridden if this method is called.

Parameters

order	The new column order. This array uses the same convention as SetColumnsOrder().

virtual void wxHeaderCtrl::UpdateColumnVisibility (unsigned int *idx*, bool *show*) [protected], [virtual]

Method called when the column visibility is changed by the user.

This method is called from ShowColumnsMenu() or ShowCustomizeDialog() when the user interactively hides or shows a column. A typical implementation will simply update the internally stored column state. Notice that there is no need to call UpdateColumn() from this method as it is already done by wxHeaderCtrl itself.

The base class version doesn't do anything and must be overridden if this method is called.

Parameters

idx	The index of the column whose visibility was toggled.
show	The new visibility value, true if the column is now shown or false if it is not hidden.

virtual bool wxHeaderCtrl::UpdateColumnWidthToFit (unsigned int *idx*, int *widthTitle*) [protected], [virtual]

Method which may be implemented by the derived classes to allow double clicking the column separator to resize the column to fit its contents.

When a separator is double clicked, the default handler of EVT_HEADER_SEPARATOR_DCLICK event calls this function and refreshes the column if it returns true so to implement the resizing of the column to fit its width on header double click you need to implement this method using logic similar to this example:

```
class MyHeaderColumn : public wxHeaderColumn
{
public:
    ...

    void SetWidth(int width) { m_width = width; }
    virtual int GetWidth() const { return m_width; }

private:
    int m_width;
};

class MyHeaderCtrl : public wxHeaderCtrl
{
public:
protected:
    virtual wxHeaderColumn& GetColumn(unsigned int idx) const
    {
        return m_cols[idx];
    }

    virtual bool UpdateColumnWidthToFit(unsigned int idx, int widthTitle)
    {
        int widthContents = ... compute minimal width for column idx ...
        m_cols[idx].SetWidth(wxMax(widthContents, widthTitle));
        return true;
    }

    wxVector<MyHeaderColumn> m_cols;
};
```

Base class version simply returns false.

Parameters

idx	The zero-based index of the column to update.
widthTitle	Contains minimal width needed to display the column header itself and will usually be used as a starting point for the fitting width calculation.

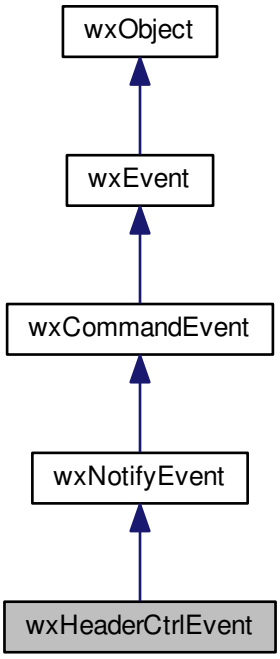
Returns

true to indicate that the column was resized, i.e. GetColumn() now returns the new width value, and so must be refreshed or false meaning that the control didn't reach to the separator double click.

21.344 wxHeaderCtrlEvent Class Reference

`#include <wx/headerctrl.h>`

Inheritance diagram for wxHeaderCtrlEvent:



21.344.1 Detailed Description

Event class representing the events generated by wxHeaderCtrl.

Library: wxCore

Category: Events

wxHeaderCtrl

Public Member Functions

- wxHeaderCtrlEvent (wxEventType commandType=wxEVT_NULL, int winid=0)

- wxHeaderCtrlEvent (const wxHeaderCtrlEvent &event)
- int GetColumn () const

  Return the index of the column affected by this event.
- void SetColumn (int col)
- int GetWidth () const

  Return the current width of the column.
- void SetWidth (int width)
- unsigned int GetNewOrder () const

  Return the new order of the column.
- void SetNewOrder (unsigned int order)

Additional Inherited Members

21.344.2 Constructor & Destructor Documentation

wxHeaderCtrlEvent::wxHeaderCtrlEvent (wxEventType *commandType* = wxEVT_NULL, int *winid* = 0)

wxHeaderCtrlEvent::wxHeaderCtrlEvent (const wxHeaderCtrlEvent & *event*)

21.344.3 Member Function Documentation

int wxHeaderCtrlEvent::GetColumn ( ) const

Return the index of the column affected by this event.

This method can be called for all header control events.

unsigned int wxHeaderCtrlEvent::GetNewOrder ( ) const

Return the new order of the column.

This method can only be called for a reorder event for which it indicates the tentative new position for the column GetColumn() selected by the user. If the event is not vetoed, this will become the new column position in wxHeaderCtrl::GetColumnsOrder().

int wxHeaderCtrlEvent::GetWidth ( ) const

Return the current width of the column.

This method can only be called for the dragging events.

void wxHeaderCtrlEvent::SetColumn (int *col*)

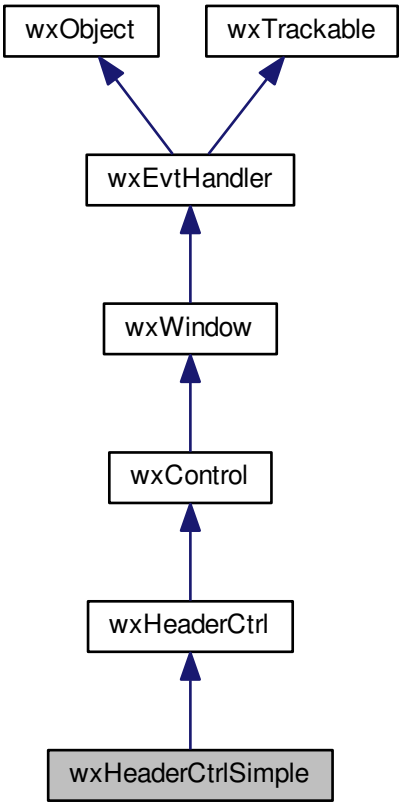
void wxHeaderCtrlEvent::SetNewOrder (unsigned int *order*)

void wxHeaderCtrlEvent::SetWidth (int *width*)

21.345 wxHeaderCtrlSimple Class Reference

```
#include <wx/headerctrl.h>
```

Inheritance diagram for wxHeaderCtrlSimple:



21.345.1 Detailed Description

wxHeaderCtrlSimple is a concrete header control which can be used directly, without inheriting from it as you need to do when using wxHeaderCtrl itself.

When using it, you need to use simple AppendColumn(), InsertColumn() and DeleteColumn() methods instead of setting the number of columns with SetColumnCount() and returning the information about them from the overridden GetColumn().

Library: wxCore

Category: Controls

  Constructor creating the window.
- void InsertColumn (const wxHeaderColumnSimple &col, unsigned int idx)

  Insert the column at the given position.
- void AppendColumn (const wxHeaderColumnSimple &col)

  Append the column to the end of the control.
- void DeleteColumn (unsigned int idx)

  Delete the column at the given position.
- void ShowColumn (unsigned int idx, bool show=true)

  Show or hide the column.
- void HideColumn (unsigned int idx)

  Hide the column with the given index.
- void ShowSortIndicator (unsigned int idx, bool sortOrder=true)

  Update the column sort indicator.
- void RemoveSortIndicator ()

  Remove the sort indicator from the column being used as sort key.

Protected Member Functions

- virtual int GetBestFittingWidth (unsigned int idx) const

  This function can be overridden in the classes deriving from this control instead of overriding UpdateColumnWidthToFit().

Additional Inherited Members

21.345.2 Constructor & Destructor Documentation

wxHeaderCtrlSimple::wxHeaderCtrlSimple ( )

Default constructor not creating the underlying window.

You must use Create() after creating the object using this constructor.

wxHeaderCtrlSimple::wxHeaderCtrlSimple (wxWindow * *parent*, wxWindowID *winid* = wxID_ANY, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, long *style* = wxHD_DEFAULT_STYLE, const wxString & *name* = `wxHeaderCtrlNameStr`)

Constructor creating the window.

Please see the base class wxHeaderCtrl::Create() method for the parameters description.

21.345.3 Member Function Documentation

void wxHeaderCtrlSimple::AppendColumn (const wxHeaderColumnSimple & *col*)

Append the column to the end of the control.

See also

InsertColumn()

void wxHeaderCtrlSimple::DeleteColumn (unsigned int *idx*)

Delete the column at the given position.

See also

InsertColumn(), AppendColumn()

virtual int wxHeaderCtrlSimple::GetBestFittingWidth (unsigned int *idx*) const `[protected], [virtual]`

This function can be overridden in the classes deriving from this control instead of overriding UpdateColumnWidthToFit().

To implement automatic column resizing to fit its contents width when the column divider is double clicked, you need to simply return the fitting width for the given column *idx* from this method, the control will automatically use the biggest value between the one returned from here and the one needed for the display of the column title itself.

The base class version returns -1 indicating that this function is not implemented.

void wxHeaderCtrlSimple::HideColumn (unsigned int *idx*)

Hide the column with the given index.

This is the same as calling

```
ShowColumn(idx, false)
```

.

Parameters

idx	The index of the column to show or hide, from 0 to GetColumnCount().

void wxHeaderCtrlSimple::InsertColumn (const wxHeaderColumnSimple & *col*, unsigned int *idx*)

Insert the column at the given position.

Parameters

col	The column to insert. Notice that because of the existence of implicit conversion from wxString to wxHeaderColumn a string can be passed directly here.
idx	The position of the new column, from 0 to GetColumnCount(). Using GetColumnCount() means to append the column to the end.

See also

AppendColumn()

void wxHeaderCtrlSimple::RemoveSortIndicator ( )

Remove the sort indicator from the column being used as sort key.

See also

ShowSortIndicator

void wxHeaderCtrlSimple::ShowColumn (unsigned int *idx,* bool *show* = `true`)

Show or hide the column.

Initially the column is shown by default or hidden if it was added with wxCOL_HIDDEN flag set.

When a column is hidden, it doesn't appear at all on the screen but its index is still taken into account when working with other columns. E.g. if there are three columns 0, 1 and 2 and the column 1 is hidden you still need to use index 2 to refer to the last visible column.

Parameters

idx	The index of the column to show or hide, from 0 to GetColumnCount().
show	Indicates whether the column should be shown (default) or hidden.

void wxHeaderCtrlSimple::ShowSortIndicator (unsigned int *idx,* bool *sortOrder* = `true`)

Update the column sort indicator.

The sort indicator, if shown, is typically an arrow pointing upwards or downwards depending on whether the control contents is sorted in ascending or descending order.

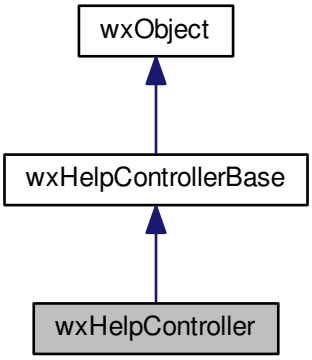
Parameters

idx	The column to set the sort indicator for. If `-1` is given, then the currently shown sort indicator will be removed.
sortOrder	If true or false show the sort indicator corresponding to ascending or descending sort order respectively.

21.346 wxHelpController Class Reference

`#include <wx/help.h>`

Inheritance diagram for wxHelpController:



21.346.1 Detailed Description

This is an alias for one of a family of help controller classes which is most appropriate for the current platform.

A help controller allows an application to display help, at the contents or at a particular topic, and shut the help program down on termination. This avoids proliferation of many instances of the help viewer whenever the user requests a different topic via the application's menus or buttons.

Typically, an application will create a help controller instance when it starts, and immediately call wxHelpController::Initialize to associate a filename with it. The help viewer will only get run, however, just before the first call to display something.

Most help controller classes actually derive from wxHelpControllerBase and have names of the form wxXXXHelpController or wxHelpControllerXXX. An appropriate class is aliased to the name wxHelpController for each platform, as follows:

- On desktop Windows, wxCHMHelpController is used (MS HTML Help).
- On Windows CE, wxWinceHelpController is used.
- On all other platforms, wxHtmlHelpController is used if wxHTML is compiled into wxWidgets; otherwise wxExtHelpController is used (for invoking an external browser).

The remaining help controller classes need to be named explicitly by an application that wishes to make use of them.

The following help controller classes are defined:

- wxWinHelpController, for controlling Windows Help.
- wxCHMHelpController, for controlling MS HTML Help. To use this, you need to set wxUSE_MS_HTML_HELP to 1 in setup.h and have the htmlhelp.h header from Microsoft's HTML Help kit. (You don't need the VC++-specific htmlhelp.lib because wxWidgets loads necessary DLL at runtime and so it works with all compilers.)
- wxBestHelpController, for controlling MS HTML Help or, if Microsoft's runtime is not available, wxHtmlHelpController. You need to provide **both** CHM and HTB versions of the help file. For wxMSW only.
- wxExtHelpController, for controlling external browsers under Unix. The default browser is Netscape Navigator. The 'help' sample shows its use.
- wxWinceHelpController, for controlling a simple .htm help controller for Windows CE applications.
- wxHtmlHelpController, a sophisticated help controller using wxHTML, in a similar style to the Microsoft HTML Help viewer and using some of the same files. Although it has an API compatible with other help controllers, it has more advanced features, so it is recommended that you use the specific API for this class instead. Note that if you use .zip or .htb formats for your books, you must add this line to your application initialization:

  ```
  wxFileSystem::AddHandler(new wxArchiveFSHandler);
  ```

  or nothing will be shown in your help window.

Library: wxCore

Category: Help

wxHtmlHelpController, wxHTML Overview

Public Member Functions

- wxHelpController (wxWindow *parentWindow=NULL)

  Constructs a help instance object, but does not invoke the help viewer.

Additional Inherited Members

21.346.2 Constructor & Destructor Documentation

wxHelpController::wxHelpController (wxWindow * *parentWindow* = NULL)

Constructs a help instance object, but does not invoke the help viewer.

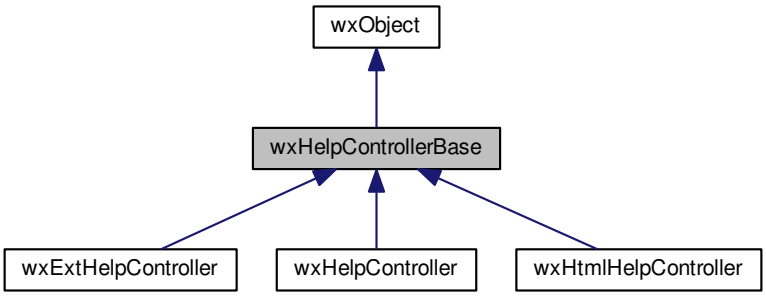
If you provide a window, it will be used by some help controller classes, such as wxCHMHelpController, wxWinHelpController and wxHtmlHelpController, as the parent for the help window instead of the value of wxApp::GetTopWindow.

You can also change the parent window later with SetParentWindow().

21.347 wxHelpControllerBase Class Reference

`#include <wx/help.h>`

Inheritance diagram for wxHelpControllerBase:



21.347.1 Detailed Description

This is the abstract base class a family of classes by which applications may invoke a help viewer to provide on-line help.

A help controller allows an application to display help, at the contents or at a particular topic, and shut the help program down on termination. This avoids proliferation of many instances of the help viewer whenever the user requests a different topic via the application's menus or buttons.

Typically, an application will create a help controller instance when it starts, and immediately call wxHelpController::Initialize to associate a filename with it. The help viewer will only get run, however, just before the first call to display something.

wxHelpController, wxHtmlHelpController, wxHTML Overview

Public Member Functions

- wxHelpControllerBase (wxWindow *parentWindow=NULL)

  Constructs a help instance object, but does not invoke the help viewer.
- ~wxHelpControllerBase ()

  Destroys the help instance, closing down the viewer if it is running.
- virtual bool DisplayBlock (long blockNo)=0

  If the help viewer is not running, runs it and displays the file at the given block number.
- virtual bool DisplayContents ()=0

  If the help viewer is not running, runs it and displays the contents.
- virtual bool DisplayContextPopup (int contextId)

  Displays the section as a popup window using a context id.
- virtual bool DisplaySection (const wxString &section)

  If the help viewer is not running, runs it and displays the given section.
- virtual bool DisplaySection (int sectionNo)=0

  If the help viewer is not running, runs it and displays the given section.
- virtual bool DisplayTextPopup (const wxString &text, const wxPoint &pos)

  Displays the text in a popup window, if possible.
- virtual wxFrame * GetFrameParameters (wxSize *size=NULL, wxPoint *pos=NULL, bool *newFrameEachTime=NULL)

  For wxHtmlHelpController, returns the latest frame size and position settings and whether a new frame is drawn with each invocation.
- virtual wxWindow * GetParentWindow () const

  Returns the window to be used as the parent for the help window.
- virtual bool KeywordSearch (const wxString &keyWord, wxHelpSearchMode mode=wxHELP_SEARCH_ALL)=0

  If the help viewer is not running, runs it, and searches for sections matching the given keyword.
- virtual bool LoadFile (const wxString &file=wxEmptyString)=0

  If the help viewer is not running, runs it and loads the given file.
- virtual void OnQuit ()

  Overridable member called when this application's viewer is quit by the user.
- virtual bool Quit ()=0

  If the viewer is running, quits it by disconnecting.
- virtual void SetFrameParameters (const wxString &titleFormat, const wxSize &size, const wxPoint &pos=wxDefaultPosition, bool newFrameEachTime=false)

  Set the parameters of the frame window.
- virtual void SetParentWindow (wxWindow *parentWindow)

  Sets the window to be used as the parent for the help window.
- virtual void SetViewer (const wxString &viewer, long flags=wxHELP_NETSCAPE)

  Sets detailed viewer information.

- virtual bool Initialize (const wxString &file)

  Initializes the help instance with a help filename, and optionally a server socket number if using wxHelp (now obsolete).
- virtual bool Initialize (const wxString &file, int server)

  Initializes the help instance with a help filename, and optionally a server socket number if using wxHelp (now obsolete).

Additional Inherited Members

21.347.2 Constructor & Destructor Documentation

wxHelpControllerBase::wxHelpControllerBase (wxWindow * *parentWindow* = NULL)

Constructs a help instance object, but does not invoke the help viewer.

If you provide a window, it will be used by some help controller classes, such as wxCHMHelpController, wxWinHelpController and wxHtmlHelpController, as the parent for the help window instead of the value of wxApp::GetTopWindow.

You can also change the parent window later with SetParentWindow().

wxHelpControllerBase::~wxHelpControllerBase ( )

Destroys the help instance, closing down the viewer if it is running.

21.347.3 Member Function Documentation

virtual bool wxHelpControllerBase::DisplayBlock (long *blockNo*) [pure virtual]

If the help viewer is not running, runs it and displays the file at the given block number.

- *WinHelp:* Refers to the context number.
- *MS* HTML Help: Refers to the context number.
- *External* HTML help: the same as for DisplaySection().
- *wxHtmlHelpController: sectionNo* is an identifier as specified in the .hhc file. See Help Files Format.

Deprecated This function is for backward compatibility only, and applications should use DisplaySection() instead.

Implemented in wxExtHelpController.

virtual bool wxHelpControllerBase::DisplayContents ( ) [pure virtual]

If the help viewer is not running, runs it and displays the contents.

Implemented in wxHtmlHelpController, and wxExtHelpController.

virtual bool wxHelpControllerBase::DisplayContextPopup (int *contextId*) [virtual]

Displays the section as a popup window using a context id.

Returns false if unsuccessful or not implemented.

virtual bool wxHelpControllerBase::DisplaySection (const wxString & *section*) [virtual]

If the help viewer is not running, runs it and displays the given section.

The interpretation of section differs between help viewers. For most viewers, this call is equivalent to KeywordSearch. For MS HTML Help, wxHTML help and external HTML help, if section has a .htm or .html extension, that HTML file will be displayed; otherwise a keyword search is done.

Reimplemented in wxExtHelpController.

virtual bool wxHelpControllerBase::DisplaySection (int *sectionNo*) `[pure virtual]`

If the help viewer is not running, runs it and displays the given section.

- *WinHelp*, MS HTML Help *sectionNo* is a context id.
- *External* HTML help: wxExtHelpController implements *sectionNo* as an id in a map file, which is of the form:
- *wxHtmlHelpController: sectionNo* is an identifier as specified in the .hhc file. See Help Files Format. See also the help sample for notes on how to specify section numbers for various help file formats.

Implemented in wxExtHelpController.

virtual bool wxHelpControllerBase::DisplayTextPopup (const wxString & *text*, const wxPoint & *pos*) `[virtual]`

Displays the text in a popup window, if possible.

Returns false if unsuccessful or not implemented.

virtual wxFrame* wxHelpControllerBase::GetFrameParameters (wxSize * *size* = NULL, wxPoint * *pos* = NULL, bool * *newFrameEachTime* = NULL) `[virtual]`

For wxHtmlHelpController, returns the latest frame size and position settings and whether a new frame is drawn with each invocation.

For all other help controllers, this function does nothing and just returns NULL.

Parameters

size	The most recent frame size.
pos	The most recent frame position.
newFrameEachTime	true if a new frame is drawn with each invocation.

Reimplemented in wxExtHelpController.

virtual wxWindow* wxHelpControllerBase::GetParentWindow ( ) const `[virtual]`

Returns the window to be used as the parent for the help window.

This window is used by wxCHMHelpController, wxWinHelpController and wxHtmlHelpController.

virtual bool wxHelpControllerBase::Initialize (const wxString & *file*) `[virtual]`

Initializes the help instance with a help filename, and optionally a server socket number if using wxHelp (now obsolete).

Does not invoke the help viewer. This must be called directly after the help instance object is created and before any attempts to communicate with the viewer.

You may omit the file extension and a suitable one will be chosen. For wxHtmlHelpController, the extensions zip, htb and hhp will be appended while searching for a suitable file. For WinHelp, the hlp extension is appended.

Reimplemented in wxExtHelpController.

virtual bool wxHelpControllerBase::Initialize (const wxString & *file*, int *server*) `[virtual]`

Initializes the help instance with a help filename, and optionally a server socket number if using wxHelp (now obsolete).

Does not invoke the help viewer. This must be called directly after the help instance object is created and before any attempts to communicate with the viewer.

You may omit the file extension and a suitable one will be chosen. For wxHtmlHelpController, the extensions zip, htb and hhp will be appended while searching for a suitable file. For WinHelp, the hlp extension is appended.

virtual bool wxHelpControllerBase::KeywordSearch (const wxString & *keyWord,* wxHelpSearchMode *mode* = wxHELP_SEARCH_ALL) [pure virtual]

If the help viewer is not running, runs it, and searches for sections matching the given keyword.

If one match is found, the file is displayed at this section. The optional parameter allows to search the index (wxH↩ ELP_SEARCH_INDEX) but this currently is only supported by the wxHtmlHelpController.

- *WinHelp*, MS HTML Help: If more than one match is found, the first topic is displayed.
- *External* HTML help, simple wxHTML help: If more than one match is found, a choice of topics is displayed.
- *wxHtmlHelpController:* see wxHtmlHelpController::KeywordSearch.

Implemented in wxHtmlHelpController, and wxExtHelpController.

virtual bool wxHelpControllerBase::LoadFile (const wxString & *file* = wxEmptyString) [pure virtual]

If the help viewer is not running, runs it and loads the given file.

If the filename is not supplied or is empty, the file specified in Initialize() is used.

If the viewer is already displaying the specified file, it will not be reloaded. This member function may be used before each display call in case the user has opened another file.

wxHtmlHelpController ignores this call.

Implemented in wxExtHelpController.

virtual void wxHelpControllerBase::OnQuit ( ) [virtual]

Overridable member called when this application's viewer is quit by the user.

This does not work for all help controllers.

Reimplemented in wxExtHelpController.

virtual bool wxHelpControllerBase::Quit ( ) [pure virtual]

If the viewer is running, quits it by disconnecting.

For Windows Help, the viewer will only close if no other application is using it.

Implemented in wxExtHelpController.

virtual void wxHelpControllerBase::SetFrameParameters (const wxString & *titleFormat,* const wxSize & *size,* const wxPoint & *pos* = wxDefaultPosition, bool *newFrameEachTime* = false) [virtual]

Set the parameters of the frame window.

For wxHtmlHelpController, *titleFormat* specifies the title string format (with `%s` being replaced by the actual page title) and *size* and *position* specify the geometry of the frame.

For all other help controllers this function has no effect.

Finally, *newFrameEachTime* is always ignored currently.

Reimplemented in wxExtHelpController.

virtual void wxHelpControllerBase::SetParentWindow (wxWindow * *parentWindow*) [virtual]

Sets the window to be used as the parent for the help window.

This is used by wxCHMHelpController, wxWinHelpController and wxHtmlHelpController.

virtual void wxHelpControllerBase::SetViewer (const wxString & *viewer,* long *flags* = wxHELP_NETSCAPE) [virtual]

Sets detailed viewer information.

So far this is only relevant to wxExtHelpController. Some examples of usage:

```
m_help.SetViewer("kdehelp");
m_help.SetViewer("gnome-help-browser");
m_help.SetViewer("netscape", wxHELP_NETSCAPE);
```

Parameters

viewer	This defaults to "netscape" for wxExtHelpController.
flags	This defaults to wxHELP_NETSCAPE for wxExtHelpController, indicating that the viewer is a variant of Netscape Navigator.

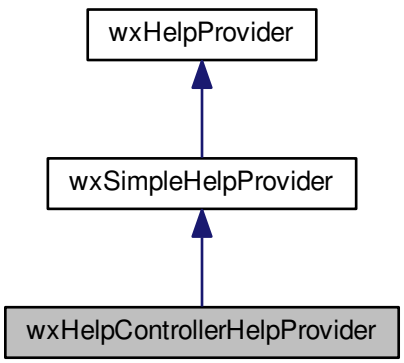
Todo modernize this function with wxLaunchDefaultBrowser

Reimplemented in wxExtHelpController.

21.348 wxHelpControllerHelpProvider Class Reference

`#include <wx/cshelp.h>`

Inheritance diagram for wxHelpControllerHelpProvider:



21.348.1 Detailed Description

wxHelpControllerHelpProvider is an implementation of wxHelpProvider which supports both context identifiers and plain text help strings.

If the help text is an integer, it is passed to wxHelpController::DisplayContextPopup(). Otherwise, it shows the string in a tooltip as per wxSimpleHelpProvider. If you use this with a wxCHMHelpController instance on windows, it will use the native style of tip window instead of wxTipWindow.

You can use the convenience function wxContextId() to convert an integer context id to a string for passing to wxWindow::SetHelpText().

Public Member Functions

- wxHelpControllerHelpProvider (wxHelpControllerBase *hc=NULL)

  Note that the instance doesn't own the help controller.
- wxHelpControllerBase * GetHelpController () const

  Returns the help controller associated with this help provider.
- void SetHelpController (wxHelpControllerBase *hc)

  Sets the help controller associated with this help provider.

Additional Inherited Members

21.348.2 Constructor & Destructor Documentation

wxHelpControllerHelpProvider::wxHelpControllerHelpProvider (wxHelpControllerBase * *hc* = NULL)

Note that the instance doesn't own the help controller.

The help controller should be deleted separately.

21.348.3 Member Function Documentation

wxHelpControllerBase* wxHelpControllerHelpProvider::GetHelpController ( ) const

Returns the help controller associated with this help provider.

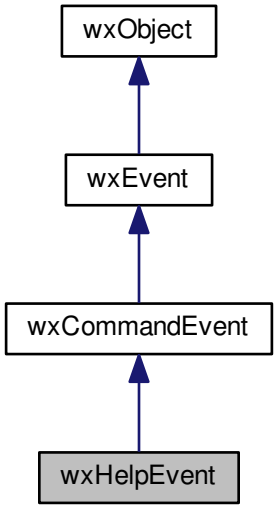
void wxHelpControllerHelpProvider::SetHelpController (wxHelpControllerBase * *hc*)

Sets the help controller associated with this help provider.

21.349 wxHelpEvent Class Reference

`#include <wx/event.h>`

Inheritance diagram for wxHelpEvent:



21.349.1 Detailed Description

A help event is sent when the user has requested context-sensitive help.

This can either be caused by the application requesting context-sensitive help mode via wxContextHelp, or (on MS Windows) by the system generating a WM_HELP message when the user pressed F1 or clicked on the query button in a dialog caption.

A help event is sent to the window that the user clicked on, and is propagated up the window hierarchy until the event is processed or there are no more event handlers.

The application should call wxEvent::GetId to check the identity of the clicked-on window, and then either show some suitable help or call wxEvent::Skip() if the identifier is unrecognised.

Calling Skip is important because it allows wxWidgets to generate further events for ancestors of the clicked-on window. Otherwise it would be impossible to show help for container windows, since processing would stop after the first window found.

Events using this class

The following event handler macros redirect the events to member function handlers '**func**' with prototypes like: void handlerFuncName(wxHelpEvent& event)

Event macros:

- EVT_HELP(id, func): Process a `wxEVT_HELP` event.
- EVT_HELP_RANGE(id1, id2, func): Process a `wxEVT_HELP` event for a range of ids.

Library: wxCore

Category: Events

wxContextHelp, wxDialog, Events and Event Handling

Public Types

- enum Origin {
  Origin_Unknown,
  Origin_Keyboard,
  Origin_HelpButton }

  Indicates how a wxHelpEvent was generated.

Public Member Functions

- wxHelpEvent (wxEventType type=wxEVT_NULL, wxWindowID winid=0, const wxPoint &pt=wxDefaultPosition, wxHelpEvent::Origin origin=Origin_Unknown)

  Constructor.
- wxHelpEvent::Origin GetOrigin () const

  Returns the origin of the help event which is one of the wxHelpEvent::Origin values.
- const wxPoint & GetPosition () const

  Returns the left-click position of the mouse, in screen coordinates.
- void SetOrigin (wxHelpEvent::Origin origin)

  Set the help event origin, only used internally by wxWidgets normally.
- void SetPosition (const wxPoint &pt)

  Sets the left-click position of the mouse, in screen coordinates.

Additional Inherited Members

21.349.2 Member Enumeration Documentation

enum wxHelpEvent::Origin

Indicates how a wxHelpEvent was generated.

Enumerator

Origin_Unknown unrecognized event source.

Origin_Keyboard event generated from F1 key press.

Origin_HelpButton event generated by wxContextHelp or from the [?] button on the title bar (Windows).

21.349.3 Constructor & Destructor Documentation

wxHelpEvent::wxHelpEvent (wxEventType *type* = wxEVT_NULL, wxWindowID *winid* = 0, const wxPoint & *pt* = wxDefaultPosition, wxHelpEvent::Origin *origin* = Origin_Unknown)

Constructor.

21.349.4 Member Function Documentation

wxHelpEvent::Origin wxHelpEvent::GetOrigin ( ) const

Returns the origin of the help event which is one of the wxHelpEvent::Origin values.

The application may handle events generated using the keyboard or mouse differently, e.g. by using wxGetMouse↩ Position() for the mouse events.

See also

SetOrigin()

const wxPoint& wxHelpEvent::GetPosition ( ) const

Returns the left-click position of the mouse, in screen coordinates.

This allows the application to position the help appropriately.

void wxHelpEvent::SetOrigin (wxHelpEvent::Origin *origin*)

Set the help event origin, only used internally by wxWidgets normally.

See also

GetOrigin()

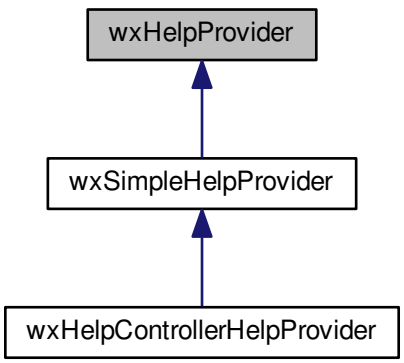
void wxHelpEvent::SetPosition (const wxPoint & *pt*)

Sets the left-click position of the mouse, in screen coordinates.

21.350 wxHelpProvider Class Reference

`#include <wx/cshelp.h>`

Inheritance diagram for wxHelpProvider:



21.350.1 Detailed Description

wxHelpProvider is an abstract class used by a program implementing context-sensitive help to show the help text for the given window.

The current help provider must be explicitly set by the application using Set().

Library: wxCore

Category: Help

See also

wxContextHelp, wxContextHelpButton, wxSimpleHelpProvider, wxHelpControllerHelpProvider, wxWindow::SetHelpText(), wxWindow::GetHelpTextAtPoint()

Public Member Functions

- virtual ~wxHelpProvider ()

  Virtual destructor for any base class.
- virtual void AddHelp (wxWindowBase *window, const wxString &text)

  Associates the text with the given window.
- virtual void AddHelp (wxWindowID id, const wxString &text)

  Associates the text with the given ID.
- virtual wxString GetHelp (const wxWindowBase *window)=0

  This version associates the given text with all windows with this id.
- virtual void RemoveHelp (wxWindowBase *window)

  Removes the association between the window pointer and the help text.
- virtual bool ShowHelp (wxWindowBase *window)

  Shows help for the given window.
- virtual bool ShowHelpAtPoint (wxWindowBase *window, const wxPoint &point, wxHelpEvent::Origin origin)

  This function may be overridden to show help for the window when it should depend on the position inside the window, By default this method forwards to ShowHelp(), so it is enough to only implement the latter if the help doesn't depend on the position.

Static Public Member Functions

- static wxHelpProvider * Get ()

  Returns pointer to help provider instance.
- static wxHelpProvider * Set (wxHelpProvider *helpProvider)

  Set the current, application-wide help provider.

21.350.2 Constructor & Destructor Documentation

virtual wxHelpProvider::~wxHelpProvider ( ) [virtual]

Virtual destructor for any base class.

21.350.3 Member Function Documentation

virtual void wxHelpProvider::AddHelp (wxWindowBase * *window,* const wxString & *text*) `[virtual]`

Associates the text with the given window.

Remarks

Although all help providers have these functions to allow making wxWindow::SetHelpText() work, not all of them implement the functions.

virtual void wxHelpProvider::AddHelp (wxWindowID *id,* const wxString & *text*) `[virtual]`

Associates the text with the given ID.

This help text will be shown for all windows with ID *id*, unless they have more specific help text associated using the other AddHelp() prototype. May be used to set the same help string for all Cancel buttons in the application, for example.

Remarks

Although all help providers have these functions to allow making wxWindow::SetHelpText() work, not all of them implement the functions.

static wxHelpProvider* wxHelpProvider::Get ( ) `[static]`

Returns pointer to help provider instance.

Unlike some other classes, the help provider is not created on demand. This must be explicitly done by the application using Set().

virtual wxString wxHelpProvider::GetHelp (const wxWindowBase * *window*) `[pure virtual]`

This version associates the given text with all windows with this id.

May be used to set the same help string for all Cancel buttons in the application, for example.

virtual void wxHelpProvider::RemoveHelp (wxWindowBase * *window*) `[virtual]`

Removes the association between the window pointer and the help text.

This is called by the wxWindow destructor. Without this, the table of help strings will fill up and when window pointers are reused, the wrong help string will be found.

static wxHelpProvider* wxHelpProvider::Set (wxHelpProvider * *helpProvider*) `[static]`

Set the current, application-wide help provider.

Returns

Pointer to previous help provider or NULL if there wasn't any.

virtual bool wxHelpProvider::ShowHelp (wxWindowBase * *window*) `[virtual]`

Shows help for the given window.

Override this function if the help doesn't depend on the exact position inside the window, otherwise you need to override ShowHelpAtPoint(). Returns true if help was shown, or false if no help was available for this window.

virtual bool wxHelpProvider::ShowHelpAtPoint (wxWindowBase * *window,* const wxPoint & *point,* wxHelpEvent::Origin *origin*) `[virtual]`

This function may be overridden to show help for the window when it should depend on the position inside the window, By default this method forwards to ShowHelp(), so it is enough to only implement the latter if the help doesn't depend on the position.

Parameters

window	Window to show help text for.
point	Coordinates of the mouse at the moment of help event emission.
origin	Help event origin, see wxHelpEvent::GetOrigin.

Returns

true if help was shown, or false if no help was available for this window.

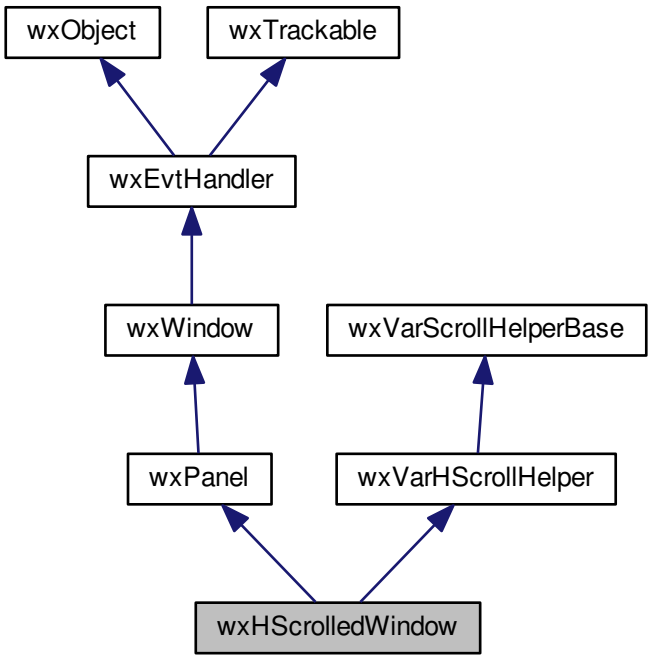
Since

2.7.0

21.351 wxHScrolledWindow Class Reference

`#include <wx/vscroll.h>`

Inheritance diagram for wxHScrolledWindow:



21.351.1 Detailed Description

In the name of this class, "H" stands for "horizontal" because it can be used for scrolling columns of variable widths.

It is not necessary to know the widths of all columns in advance – only those which are shown on the screen need to be measured.

In any case, this is a generalization of wxScrolled which can be only used when all columns have the same widths. It lacks some other wxScrolled features however, notably it can't scroll specific pixel sizes of the window or its exact client area size.

To use this class, you need to derive from it and implement the OnGetColumnWidth() pure virtual method. You also must call SetColumnCount() to let the base class know how many columns it should display, but from that moment on the scrolling is handled entirely by wxHScrolledWindow. You only need to draw the visible part of contents in your `OnPaint()` method as usual. You should use GetVisibleColumnsBegin() and GetVisibleColumnsEnd() to select the lines to display. Note that the device context origin is not shifted so the first visible column always appears at the point (0, 0) in physical as well as logical coordinates.

Library: wxCore

Category: Miscellaneous Windows

See also

wxHVScrolledWindow, wxVScrolledWindow

Public Member Functions

- wxHScrolledWindow ()

  Default constructor, you must call Create() later.
- wxHScrolledWindow (wxWindow *parent, wxWindowID id=wxID_ANY, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, long style=0, const wxString &name=wxPanelNameStr)

  This is the normal constructor, no need to call Create() after using this constructor.
- bool Create (wxWindow *parent, wxWindowID id=wxID_ANY, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, long style=0, const wxString &name=wxPanelNameStr)

  Same as the non-default constructor, but returns a status code: true if ok, false if the window couldn't be created.

Additional Inherited Members

21.351.2 Constructor & Destructor Documentation

wxHScrolledWindow::wxHScrolledWindow ( )

Default constructor, you must call Create() later.

wxHScrolledWindow::wxHScrolledWindow (wxWindow * *parent*, wxWindowID *id* = wxID_ANY, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, long *style* = `0`, const wxString & *name* = `wxPanelNameStr`)

This is the normal constructor, no need to call Create() after using this constructor.

Note

`wxHSCROLL` is always automatically added to the style, there is no need to specify it explicitly.

Parameters

parent	The parent window, must not be NULL.
id	The identifier of this window, wxID_ANY by default.
pos	The initial window position.
size	The initial window size.
style	The window style. There are no special style bits defined for this class.
name	The name for this window; usually not used.

21.351.3 Member Function Documentation

bool wxHScrolledWindow::Create (wxWindow * *parent*, wxWindowID *id* = wxID_ANY, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, long *style* = 0, const wxString & *name* = wxPanelNameStr)

Same as the non-default constructor, but returns a status code: true if ok, false if the window couldn't be created.

Just as with the constructor, the wxHSCROLL style is always used, there is no need to specify it explicitly.

21.352 wxHtmlBookRecord Class Reference

`#include <wx/html/helpdata.h>`

21.352.1 Detailed Description

Helper class for wxHtmlHelpData.

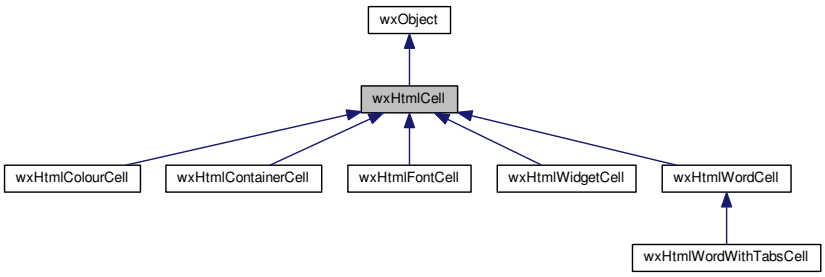
21.353 wxHtmlCell Class Reference

`#include <wx/html/htmlcell.h>`

Inheritance diagram for wxHtmlCell:



21.353.1 Detailed Description

Internal data structure.

It represents fragments of parsed HTML page, the so-called **cell** - a word, picture, table, horizontal line and so on. It is used by wxHtmlWindow and wxHtmlWinParser to represent HTML page in memory.

You can divide cells into two groups : *visible* cells with non-zero width and height and *helper* cells (usually with zero width and height) that perform special actions such as color or font change.

Library: wxHTML

Category: HTML

See also

Cells and Containers, wxHtmlContainerCell

Public Member Functions

- wxHtmlCell ()

  Constructor.
- virtual bool AdjustPagebreak (int *pagebreak, const wxArrayInt &known_pagebreaks, int pageHeight) const

  This method is used to adjust pagebreak position.
- virtual void Draw (wxDC &dc, int x, int y, int view_y1, int view_y2, wxHtmlRenderingInfo &info)

  Renders the cell.
- virtual void DrawInvisible (wxDC &dc, int x, int y, wxHtmlRenderingInfo &info)

  This method is called instead of Draw() when the cell is certainly out of the screen (and thus invisible).
- virtual const wxHtmlCell * Find (int condition, const void *param) const

  Returns pointer to itself if this cell matches condition (or if any of the cells following in the list matches), NULL otherwise.
- int GetDescent () const

  Returns descent value of the cell (m_Descent member).
- virtual wxHtmlCell * GetFirstChild () const

  Returns pointer to the first cell in the list.
- int GetHeight () const

  Returns height of the cell (m_Height member).
- const wxString & GetId () const

  Returns unique cell identifier if there is any, the empty string otherwise.
- virtual wxHtmlLinkInfo * GetLink (int x=0, int y=0) const

  Returns hypertext link if associated with this cell or NULL otherwise.
- virtual wxCursor GetMouseCursor (wxHtmlWindowInterface *window) const

  Returns cursor to show when mouse pointer is over the cell.
- virtual wxCursor GetMouseCursorAt (wxHtmlWindowInterface *window, const wxPoint &rePos) const

  Returns cursor to show when mouse pointer is over the specified point.
- wxHtmlCell * GetNext () const

  Returns pointer to the next cell in list (see htmlcell.h if you're interested in details).
- wxHtmlContainerCell * GetParent () const

  Returns pointer to parent container.
- int GetPosX () const

  Returns X position within parent (the value is relative to parent's upper left corner).
- int GetPosY () const

  Returns Y position within parent (the value is relative to parent's upper left corner).
- int GetWidth () const

  Returns width of the cell (m_Width member).
- virtual void Layout (int w)

  Layouts the cell.
- virtual bool ProcessMouseClick (wxHtmlWindowInterface *window, const wxPoint &pos, const wxMouseEvent &event)

  This function is simple event handler.
- void SetId (const wxString &id)

  Sets unique cell identifier.
- void SetLink (const wxHtmlLinkInfo &link)

  Sets the hypertext link associated with this cell.
- void SetNext (wxHtmlCell *cell)

  Sets the next cell in the list.

- void SetParent (wxHtmlContainerCell *p)

  Sets parent container of this cell.
- virtual void SetPos (int x, int y)

  Sets the cell's position within parent container.

Additional Inherited Members

21.353.2 Constructor & Destructor Documentation

wxHtmlCell::wxHtmlCell ( )

Constructor.

21.353.3 Member Function Documentation

virtual bool wxHtmlCell::AdjustPagebreak (int * *pagebreak,* const wxArrayInt & *known_pagebreaks,* int *pageHeight*) const `[virtual]`

This method is used to adjust pagebreak position.

The first parameter is a variable that contains the y-coordinate of the page break (= horizontal line that should not be crossed by words, images etc.). If this cell cannot be divided into two pieces (each one on another page) then it either moves the pagebreak a few pixels up, if possible, or, if the cell cannot fit on the page at all, then the cell is forced to split unconditionally.

Returns true if pagebreak was modified, false otherwise.

Parameters

pagebreak	position in pixel of the pagebreak.
known_↩ pagebreaks	the list of the previous pagebreaks
pageHeight	the height in pixel of the page drawable area

Usage:

```
while (container->AdjustPagebreak(&p, kp, ph)) {}
```

virtual void wxHtmlCell::Draw (wxDC & *dc,* int *x,* int *y,* int *view_y1,* int *view_y2,* wxHtmlRenderingInfo & *info*) `[virtual]`

Renders the cell.

Parameters

dc	Device context to which the cell is to be drawn.
x,y	Coordinates of parent's upper left corner (origin). You must add this to m_PosX,m_PosY when passing coordinates to dc's methods Example: `dc->DrawText("hello", x + m_PosX, y + m_PosY)`

view_y1	y-coord of the first line visible in window. This is used to optimize rendering speed.
view_y2	y-coord of the last line visible in window. This is used to optimize rendering speed.
info	Additional information for the rendering of the cell.

virtual void wxHtmlCell::DrawInvisible (wxDC & *dc*, int *x*, int *y*, wxHtmlRenderingInfo & *info*) [virtual]

This method is called instead of Draw() when the cell is certainly out of the screen (and thus invisible).

This is not nonsense - some tags (like wxHtmlColourCell or font setter) must be drawn even if they are invisible!

Parameters

dc	Device context to which the cell is to be drawn.
x,y	Coordinates of parent's upper left corner. You must add this to m_PosX,m_PosY when passing coordinates to dc's methods Example: `dc->DrawText("hello", x + m_PosX, y + m_PosY)`
info	Additional information for the rendering of the cell.

virtual const wxHtmlCell* wxHtmlCell::Find (int *condition*, const void * *param*) const [virtual]

Returns pointer to itself if this cell matches condition (or if any of the cells following in the list matches), NULL otherwise.

(In other words if you call top-level container's Find() it will return pointer to the first cell that matches the condition)

It is recommended way how to obtain pointer to particular cell or to cell of some type (e.g. wxHtmlAnchorCell reacts on wxHTML_COND_ISANCHOR condition).

Parameters

condition	Unique integer identifier of condition
param	Optional parameters

int wxHtmlCell::GetDescent ( ) const

Returns descent value of the cell (m_Descent member).

See explanation:

virtual wxHtmlCell* wxHtmlCell::GetFirstChild ( ) const [virtual]

Returns pointer to the first cell in the list.

You can then use child's GetNext() method to obtain pointer to the next cell in list.

Note

This shouldn't be used by the end user. If you need some way of finding particular cell in the list, try Find() method instead.

int wxHtmlCell::GetHeight ( ) const

Returns height of the cell (m_Height member).

const wxString& wxHtmlCell::GetId ( ) const

Returns unique cell identifier if there is any, the empty string otherwise.

virtual wxHtmlLinkInfo* wxHtmlCell::GetLink (int *x* = 0, int *y* = 0) const [virtual]

Returns hypertext link if associated with this cell or NULL otherwise.

See wxHtmlLinkInfo. (Note: this makes sense only for visible tags).

Parameters

x,y	Coordinates of position where the user pressed mouse button. These coordinates are used e.g. by COLORMAP. Values are relative to the upper left corner of THIS cell (i.e. from 0 to m_Width or m_Height)

virtual wxCursor wxHtmlCell::GetMouseCursor (wxHtmlWindowInterface * *window*) const [virtual]

Returns cursor to show when mouse pointer is over the cell.

Parameters

window	interface to the parent HTML window

See also

GetMouseCursorAt()

virtual wxCursor wxHtmlCell::GetMouseCursorAt (wxHtmlWindowInterface * *window*, const wxPoint & *rePos*) const [virtual]

Returns cursor to show when mouse pointer is over the specified point.

This function should be overridden instead of GetMouseCursorAt() if the cursor should depend on the exact position of the mouse in the window.

Parameters

window	interface to the parent HTML window
rePos	Position to show cursor.

Since

3.0

wxHtmlCell* wxHtmlCell::GetNext ( ) const

Returns pointer to the next cell in list (see htmlcell.h if you're interested in details).

wxHtmlContainerCell* wxHtmlCell::GetParent ( ) const

Returns pointer to parent container.

int wxHtmlCell::GetPosX ( ) const

Returns X position within parent (the value is relative to parent's upper left corner).

The returned value is meaningful only if parent's Layout() was called before!

int wxHtmlCell::GetPosY ( ) const

Returns Y position within parent (the value is relative to parent's upper left corner).

The returned value is meaningful only if parent's Layout() was called before!

int wxHtmlCell::GetWidth ( ) const

Returns width of the cell (m_Width member).

virtual void wxHtmlCell::Layout (int *w*) [virtual]

Layouts the cell.

This method performs two actions:

1. adjusts the cell's width according to the fact that maximal possible width is *w* (this has sense when working with horizontal lines, tables etc.)
2. prepares layout (=fill-in m_PosX, m_PosY (and sometimes m_Height) members) based on actual width *w*

It must be called before displaying cells structure because m_PosX and m_PosY are undefined (or invalid) before calling Layout().

virtual bool wxHtmlCell::ProcessMouseClick (wxHtmlWindowInterface * *window*, const wxPoint & *pos*, const wxMouseEvent & *event*) [virtual]

This function is simple event handler.

Each time the user clicks mouse button over a cell within wxHtmlWindow this method of that cell is called. Default behaviour is to call wxHtmlWindow::LoadPage.

Parameters

window	interface to the parent HTML window
pos	coordinates of mouse click (this is relative to cell's origin
event	mouse event that triggered the call

Returns

true if a link was clicked, false otherwise.

Since

2.7.0 (before OnMouseClick() method served a similar purpose).

Note

If you need more "advanced" event handling you should use wxHtmlBinderCell instead.

void wxHtmlCell::SetId (const wxString & *id*)

Sets unique cell identifier.

Default value is no identifier, i.e. empty string.

void wxHtmlCell::SetLink (const wxHtmlLinkInfo & *link*)

Sets the hypertext link associated with this cell.

(Default value is wxHtmlLinkInfo("", "") (no link))

void wxHtmlCell::SetNext (wxHtmlCell * *cell*)

Sets the next cell in the list.

This shouldn't be called by user - it is to be used only by wxHtmlContainerCell::InsertCell.

void wxHtmlCell::SetParent (wxHtmlContainerCell * *p*)

Sets parent container of this cell.

This is called from wxHtmlContainerCell::InsertCell.

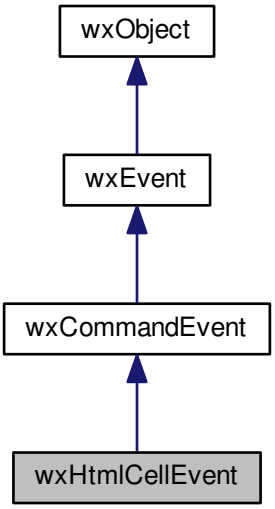
virtual void wxHtmlCell::SetPos (int *x*, int *y*) `[virtual]`

Sets the cell's position within parent container.

21.354 wxHtmlCellEvent Class Reference

`#include <wx/html/htmlwin.h>`

Inheritance diagram for wxHtmlCellEvent:



21.354.1 Detailed Description

This event class is used for the events generated by wxHtmlWindow.

Events using this class

The following event handler macros redirect the events to member function handlers '**func**' with prototypes like: void handlerFuncName(wxHtmlCellEvent& event)

Event macros:

- EVT_HTML_CELL_HOVER(id, func): User moved the mouse over a wxHtmlCell.
- EVT_HTML_CELL_CLICKED(id, func): User clicked on a wxHtmlCell. When handling this event, remember to use wxHtmlCell::SetLinkClicked(true) if the cell contains a link.

Library: wxHTML

Category: HTML

Public Member Functions

- wxHtmlCellEvent (wxEventType commandType, int id, wxHtmlCell *cell, const wxPoint &point, const wxMouseEvent &ev)

  The constructor is not normally used by the user code.
- wxHtmlCell * GetCell () const

  Returns the wxHtmlCellEvent associated with the event.

- bool GetLinkClicked () const

  Returns true if SetLinkClicked(true) has previously been called; false otherwise.

- wxPoint GetPoint () const

  Returns the wxPoint associated with the event.

- void SetLinkClicked (bool linkclicked)

  Call this function with linkclicked set to true if the cell which has been clicked contained a link or false otherwise (which is the default).

Additional Inherited Members

21.354.2 Constructor & Destructor Documentation

wxHtmlCellEvent::wxHtmlCellEvent (wxEventType *commandType,* int *id,* wxHtmlCell * *cell,* const wxPoint & *point,* const wxMouseEvent & *ev*)

The constructor is not normally used by the user code.

21.354.3 Member Function Documentation

wxHtmlCell* wxHtmlCellEvent::GetCell ( ) const

Returns the wxHtmlCellEvent associated with the event.

bool wxHtmlCellEvent::GetLinkClicked ( ) const

Returns true if SetLinkClicked(true) has previously been called; false otherwise.

wxPoint wxHtmlCellEvent::GetPoint ( ) const

Returns the wxPoint associated with the event.

void wxHtmlCellEvent::SetLinkClicked (bool *linkclicked*)

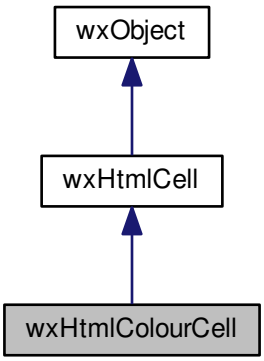
Call this function with *linkclicked* set to true if the cell which has been clicked contained a link or false otherwise (which is the default).

With this function the event handler can return info to the wxHtmlWindow which sent the event.

21.355 wxHtmlColourCell Class Reference

`#include <wx/html/htmlcell.h>`

Inheritance diagram for wxHtmlColourCell:



21.355.1 Detailed Description

This cell changes the colour of either the background or the foreground.

Library: wxHTML

Category: HTML

Public Member Functions

- wxHtmlColourCell (const wxColour &clr, int flags=wxHTML_CLR_FOREGROUND)

  Constructor.

Additional Inherited Members

21.355.2 Constructor & Destructor Documentation

wxHtmlColourCell::wxHtmlColourCell (const wxColour & *clr,* int *flags* = wxHTML_CLR_FOREGROUND)

Constructor.

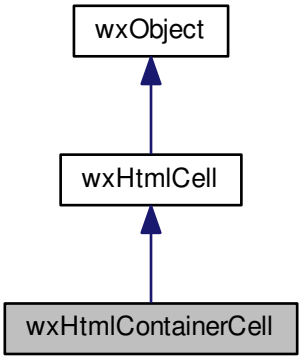
Parameters

clr	The color
flags	Can be one of following: • wxHTML_CLR_FOREGROUND: change color of text • wxHTML_CLR_BACKGROUND: change background color

21.356 wxHtmlContainerCell Class Reference

`#include <wx/html/htmlcell.h>`

Inheritance diagram for wxHtmlContainerCell:



21.356.1 Detailed Description

The wxHtmlContainerCell class is an implementation of a cell that may contain more cells in it.

It is heavily used in the wxHTML layout algorithm.

Library: wxHTML

Category: HTML

See also

Cells and Containers

Public Member Functions

- wxHtmlContainerCell (wxHtmlContainerCell *parent)

  Constructor.
- int GetAlignHor () const

  Returns container's horizontal alignment.
- int GetAlignVer () const

  Returns container's vertical alignment.
- wxColour GetBackgroundColour ()

  Returns the background colour of the container or `wxNullColour` if no background colour is set.
- int GetIndent (int ind) const

  Returns the indentation.
- int GetIndentUnits (int ind) const

  *Returns the units of indentation for ind where ind is one of the **wxHTML_INDENT_*** constants.*

- void InsertCell (wxHtmlCell *cell)

  Inserts a new cell into the container.
- void SetAlign (const wxHtmlTag &tag)

  Sets the container's alignment (both horizontal and vertical) according to the values stored in tag.
- void SetAlignHor (int al)

  Sets the container's horizontal alignment.
- void SetAlignVer (int al)

  Sets the container's vertical alignment.
- void SetBackgroundColour (const wxColour &clr)

  Sets the background colour for this container.
- void SetBorder (const wxColour &clr1, const wxColour &clr2, int border=1)

  Sets the border (frame) colours.
- void SetIndent (int i, int what, int units=wxHTML_UNITS_PIXELS)

  Sets the indentation (free space between borders of container and subcells).
- void SetMinHeight (int h, int align=wxHTML_ALIGN_TOP)

  Sets minimal height of the container.
- void SetWidthFloat (int w, int units)

  Sets floating width adjustment.
- void SetWidthFloat (const wxHtmlTag &tag, double pixel_scale=1.0)

  Sets floating width adjustment.

Additional Inherited Members

21.356.2 Constructor & Destructor Documentation

wxHtmlContainerCell::wxHtmlContainerCell (wxHtmlContainerCell * *parent*)

Constructor.

parent is pointer to parent container or NULL.

21.356.3 Member Function Documentation

int wxHtmlContainerCell::GetAlignHor ( ) const

Returns container's horizontal alignment.

int wxHtmlContainerCell::GetAlignVer ( ) const

Returns container's vertical alignment.

wxColour wxHtmlContainerCell::GetBackgroundColour ( )

Returns the background colour of the container or `wxNullColour` if no background colour is set.

int wxHtmlContainerCell::GetIndent (int *ind*) const

Returns the indentation.

ind is one of the **wxHTML_INDENT_*** constants.

Note

You must call GetIndentUnits() with same *ind* parameter in order to correctly interpret the returned integer value. It is NOT always in pixels!

int wxHtmlContainerCell::GetIndentUnits (int *ind*) const

Returns the units of indentation for *ind* where *ind* is one of the **wxHTML_INDENT**_∗ constants.

void wxHtmlContainerCell::InsertCell (wxHtmlCell ∗ *cell*)

Inserts a new cell into the container.

void wxHtmlContainerCell::SetAlign (const wxHtmlTag & *tag*)

Sets the container's alignment (both horizontal and vertical) according to the values stored in *tag*.

(Tags `ALIGN` parameter is extracted.) In fact it is only a front-end to SetAlignHor() and SetAlignVer().

void wxHtmlContainerCell::SetAlignHor (int *al*)

Sets the container's *horizontal* alignment.

During wxHtmlCell::Layout each line is aligned according to *al* value.

Parameters

al	new horizontal alignment. May be one of these values: • wxHTML_ALIGN_LEFT: lines are left-aligned (default) • wxHTML_ALIGN_JUSTIFY: lines are justified • wxHTML_ALIGN_CENTER: lines are centered • wxHTML_ALIGN_RIGHT: lines are right-aligned

void wxHtmlContainerCell::SetAlignVer (int *al*)

Sets the container's *vertical* alignment.

This is per-line alignment!

Parameters

al	new vertical alignment. May be one of these values: • wxHTML_ALIGN_BOTTOM: cells are over the line (default) • wxHTML_ALIGN_CENTER: cells are centered on line • wxHTML_ALIGN_TOP: cells are under the line

void wxHtmlContainerCell::SetBackgroundColour (const wxColour & *clr*)

Sets the background colour for this container.

void wxHtmlContainerCell::SetBorder (const wxColour & *clr1,* const wxColour & *clr2,* int *border* = 1)

Sets the border (frame) colours.

A border is a rectangle around the container.

Parameters

clr1	Colour of top and left lines
clr2	Colour of bottom and right lines
border	Size of the border in pixels

void wxHtmlContainerCell::SetIndent (int *i,* int *what,* int *units* = wxHTML_UNITS_PIXELS)

Sets the indentation (free space between borders of container and subcells).

Parameters

i	Indentation value.
what	Determines which of the four borders we're setting. It is OR combination of following constants: • wxHTML_INDENT_TOP: top border • wxHTML_INDENT_BOTTOM: bottom • wxHTML_INDENT_LEFT: left • wxHTML_INDENT_RIGHT: right • wxHTML_INDENT_HORIZONTAL: left and right • wxHTML_INDENT_VERTICAL: top and bottom • wxHTML_INDENT_ALL: all 4 borders
units	Units of i. This parameter affects interpretation of value. • wxHTML_UNITS_PIXELS: *i* is number of pixels • wxHTML_UNITS_PERCENT: *i* is interpreted as percents of width of parent container

void wxHtmlContainerCell::SetMinHeight (int *h,* int *align* = wxHTML_ALIGN_TOP)

Sets minimal height of the container.

When container's wxHtmlCell::Layout is called, m_Height is set depending on layout of subcells to the height of area covered by layed-out subcells. Calling this method guarantees you that the height of container is never smaller than *h* - even if the subcells cover much smaller area.

Parameters

h	The minimal height.
align	If height of the container is lower than the minimum height, empty space must be inserted somewhere in order to ensure minimal height. This parameter is one of wxHTML_ALIGN_TOP, wxHTML_ALIGN_BOTTOM, wxHTML_ALIGN_CENTER. It refers to the contents, not to the empty place.

void wxHtmlContainerCell::SetWidthFloat (int *w,* int *units*)

Sets floating width adjustment.

The normal behaviour of container is that its width is the same as the width of parent container (and thus you can have only one sub-container per line). You can change this by setting the floating width adjustment.

Parameters

w	Width of the container. If the value is negative it means complement to full width of parent container. E.g. `SetWidthFloat(-50, wxHTML_UNITS_PIXELS)` sets the width of container to parent's width minus 50 pixels. This is useful when creating tables - you can call SetWidthFloat(50) and SetWidthFloat(-50).
units	Units of w This parameter affects the interpretation of value. • wxHTML_UNITS_PIXELS: *w* is number of pixels • wxHTML_UNITS_PERCENT: *w* is interpreted as percents of width of parent container

void wxHtmlContainerCell::SetWidthFloat (const wxHtmlTag & *tag,* double *pixel_scale* = `1.0`)

Sets floating width adjustment.

The normal behaviour of container is that its width is the same as the width of parent container (and thus you can have only one sub-container per line). You can change this by setting the floating width adjustment.

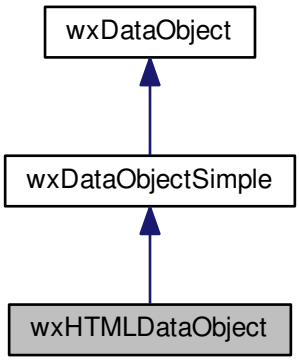
Parameters

tag	In the second version of method, *w* and *units* info is extracted from tag's WIDTH parameter.
pixel_scale	This is number of real pixels that equals to 1 HTML pixel.

21.357 wxHTMLDataObject Class Reference

`#include <wx/dataobj.h>`

Inheritance diagram for wxHTMLDataObject:



21.357.1 Detailed Description

wxHTMLDataObject is used for working with HTML-formatted text.

Library: wxCore

Category: Clipboard and Drag & Drop

See also

wxDataObject, wxDataObjectSimple

Public Member Functions

- wxHTMLDataObject (const wxString &html=wxEmptyString)

  Constructor.
- virtual wxString GetHTML () const

  Returns the HTML string.
- virtual void SetHTML (const wxString &html)

  Sets the HTML string.

Additional Inherited Members

21.357.2 Constructor & Destructor Documentation

wxHTMLDataObject::wxHTMLDataObject (const wxString & *html* = wxEmptyString)

Constructor.

21.357.3 Member Function Documentation

virtual wxString wxHTMLDataObject::GetHTML ( ) const `[virtual]`

Returns the HTML string.

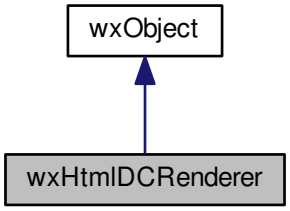
virtual void wxHTMLDataObject::SetHTML (const wxString & *html*) `[virtual]`

Sets the HTML string.

21.358 wxHtmlDCRenderer Class Reference

`#include <wx/html/htmprint.h>`

Inheritance diagram for wxHtmlDCRenderer:



21.358.1 Detailed Description

This class can render HTML document into a specified area of a DC.

You can use it in your own printing code, although use of wxHtmlEasyPrinting or wxHtmlPrintout is strongly recommended.

Library: wxHTML

Category: HTML

Public Member Functions

- wxHtmlDCRenderer ()

  Constructor.
- int GetTotalWidth () const

  Returns the width of the HTML text in pixels.
- int GetTotalHeight () const

  Returns the height of the HTML text in pixels.
- int Render (int x, int y, wxArrayInt &known_pagebreaks, int from=0, int dont_render=false, int to=INT_MAX)

Renders HTML text to the DC.

- void SetDC (wxDC *dc, double pixel_scale=1.0)

  Assign DC instance to the renderer.
- void SetFonts (const wxString &normal_face, const wxString &fixed_face, const int *sizes=NULL)

  This function sets font sizes and faces.
- void SetStandardFonts (int size=-1, const wxString &normal_face=wxEmptyString, const wxString &fixed_face=wxEmptyString)

  Sets font sizes to be relative to the given size or the system default size; use either specified or default font.
- void SetHtmlText (const wxString &html, const wxString &basepath=wxEmptyString, bool isdir=true)

  Assign text to the renderer.
- void SetSize (int width, int height)

  Set size of output rectangle, in pixels.

Additional Inherited Members

21.358.2 Constructor & Destructor Documentation

wxHtmlDCRenderer::wxHtmlDCRenderer ( )

Constructor.

21.358.3 Member Function Documentation

int wxHtmlDCRenderer::GetTotalHeight ( ) const

Returns the height of the HTML text in pixels.

This is important if area height (see wxHtmlDCRenderer::SetSize) is smaller that total height and thus the page cannot fit into it. In that case you're supposed to call Render() as long as its return value is smaller than GetTotalHeight()'s.

See also

GetTotalWidth()

int wxHtmlDCRenderer::GetTotalWidth ( ) const

Returns the width of the HTML text in pixels.

This can be compared with the width parameter of SetSize() to check if the document being printed fits into the page boundary.

See also

GetTotalHeight()

Since

2.9.0

int wxHtmlDCRenderer::Render (int *x*, int *y*, wxArrayInt & *known_pagebreaks*, int *from* = `0`, int *dont_render* = `false`, int *to* = `INT_MAX`)

Renders HTML text to the DC.

Parameters

x,y	position of upper-left corner of printing rectangle (see SetSize()).
known_↩ pagebreaks	

Todo docme

Parameters

from	y-coordinate of the very first visible cell.
dont_render	if true then this method only returns y coordinate of the next page and does not output anything.
to	y-coordinate of the last visible cell.

Returned value is y coordinate of first cell than didn't fit onto page. Use this value as from in next call to Render() in order to print multipages document.

Note

The following three methods **must** always be called before any call to Render(), in this order:

- SetDC()
- SetSize()
- SetHtmlText()

Render() changes the DC's user scale and does NOT restore it.

void wxHtmlDCRenderer::SetDC (wxDC * *dc*, double *pixel_scale* = 1.0)

Assign DC instance to the renderer.

pixel_scale can be used when rendering to high-resolution DCs (e.g. printer) to adjust size of pixel metrics. (Many dimensions in HTML are given in pixels – e.g. image sizes. 300x300 image would be only one inch wide on typical printer. With pixel_scale = 3.0 it would be 3 inches.)

void wxHtmlDCRenderer::SetFonts (const wxString & *normal_face*, const wxString & *fixed_face*, const int * *sizes* = NULL)

This function sets font sizes and faces.

Parameters

normal_face	This is face name for normal (i.e. non-fixed) font. It can be either empty string (then the default face is chosen) or platform-specific face name. Examples are "helvetica" under Unix or "Times New Roman" under Windows.
fixed_face	The same thing for fixed face (<TT>..</TT>)
sizes	This is an array of 7 items of int type. The values represent size of font with HTML size from -2 to +4 (<FONT SIZE=-2> to <FONT SIZE=+4>). Default sizes are used if sizes is NULL.

Default font sizes are defined by constants wxHTML_FONT_SIZE_1, wxHTML_FONT_SIZE_2, ..., wxHTML_FO↩ NT_SIZE_7. Note that they differ among platforms. Default face names are empty strings.

See also

SetSize()

void wxHtmlDCRenderer::SetHtmlText (const wxString & *html*, const wxString & *basepath* = wxEmptyString, bool *isdir* = true)

Assign text to the renderer.

Render() then draws the text onto DC.

Parameters

html	HTML text. This is not a filename.
basepath	base directory (html string would be stored there if it was in file). It is used to determine path for loading images, for example.
isdir	false if basepath is filename, true if it is directory name (see wxFileSystem for detailed explanation).

void wxHtmlDCRenderer::SetSize (int *width*, int *height*)

Set size of output rectangle, in pixels.

Note that you **can't** change width of the rectangle between calls to Render() ! (You can freely change height.)

void wxHtmlDCRenderer::SetStandardFonts (int *size* = −1, const wxString & *normal_face* = wxEmptyString, const wxString & *fixed_face* = wxEmptyString)

Sets font sizes to be relative to the given size or the system default size; use either specified or default font.

Parameters

size	Point size of the default HTML text
normal_face	This is face name for normal (i.e. non-fixed) font. It can be either empty string (then the default face is chosen) or platform-specific face name. Examples are "helvetica" under Unix or "Times New Roman" under Windows.
fixed_face	The same thing for fixed face (<TT>..</TT>)

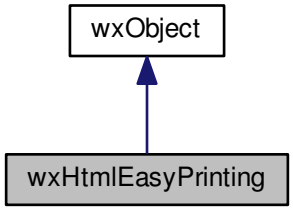
SetSize()

21.359 wxHtmlEasyPrinting Class Reference

`#include <wx/html/htmprint.h>`

Inheritance diagram for wxHtmlEasyPrinting:



21.359.1 Detailed Description

This class provides very simple interface to printing architecture.

It allows you to print HTML documents using only a few commands.

Note

Do not create this class on the stack only. You should create an instance on app startup and use this instance for all printing operations. The reason is that this class stores various settings in it.

Library: wxHTML

Category: HTML, Printing Framework

Public Member Functions

- wxHtmlEasyPrinting (const wxString &name="Printing", wxWindow *parentWindow=NULL)

  Constructor.
- const wxString & GetName () const

  Returns the current name being used for preview frames and setup dialogs.
- wxPageSetupDialogData * GetPageSetupData ()

  Returns a pointer to wxPageSetupDialogData instance used by this class.
- wxWindow * GetParentWindow () const

  Gets the parent window for dialogs.
- wxPrintData * GetPrintData ()

  Returns pointer to wxPrintData instance used by this class.
- void PageSetup ()

  Display page setup dialog and allows the user to modify settings.
- bool PreviewFile (const wxString &htmlfile)

  Preview HTML file.
- bool PreviewText (const wxString &htmltext, const wxString &basepath=wxEmptyString)

  Preview HTML text (not file!).
- bool PrintFile (const wxString &htmlfile)

  Print HTML file.
- bool PrintText (const wxString &htmltext, const wxString &basepath=wxEmptyString)

  Print HTML text (not file!).
- void SetFonts (const wxString &normal_face, const wxString &fixed_face, const int *sizes=NULL)

  Sets fonts.
- void SetName (const wxString &name)

  Sets the name used for preview frames and setup dialogs.
- void SetStandardFonts (int size=-1, const wxString &normal_face=wxEmptyString, const wxString &fixed_face=wxEmptyString)

  Sets default font sizes and/or default font size.
- void SetFooter (const wxString &footer, int pg=wxPAGE_ALL)

  Set page footer.
- void SetHeader (const wxString &header, int pg=wxPAGE_ALL)

  Set page header.
- void SetParentWindow (wxWindow *window)

  Sets the parent window for dialogs.

Private Member Functions

- virtual bool CheckFit (const wxSize &pageArea, const wxSize &docArea) const

  Check whether the document fits into the page area.

Additional Inherited Members

21.359.2 Constructor & Destructor Documentation

wxHtmlEasyPrinting::wxHtmlEasyPrinting (const wxString & *name* = "Printing", wxWindow * *parentWindow* = NULL)

Constructor.

Parameters

name	Name of the printing object. Used by preview frames and setup dialogs.
parentWindow	pointer to the window that will own the preview frame and setup dialogs. May be NULL.

21.359.3 Member Function Documentation

virtual bool wxHtmlEasyPrinting::CheckFit (const wxSize & *pageArea*, const wxSize & *docArea*) const [private], [virtual]

Check whether the document fits into the page area.

This function is called by the base class OnPreparePrinting() implementation and by default checks whether the document fits into *pageArea* horizontally and warns the user if it does not, giving him the possibility to cancel printing in this case (presumably in order to change some layout options and retry it again).

You may override it to either suppress this check if truncation of the HTML being printed is acceptable or, on the contrary, add more checks to it, e.g. for the fit in the vertical direction if the document should always appear on a single page.

Returns

true if wxHtmlPrintout should continue or false to cancel printing.

Since

2.9.0

const wxString& wxHtmlEasyPrinting::GetName ( ) const

Returns the current name being used for preview frames and setup dialogs.

Since

2.8.11 / 2.9.1

wxPageSetupDialogData* wxHtmlEasyPrinting::GetPageSetupData ( )

Returns a pointer to wxPageSetupDialogData instance used by this class.

You can set its parameters (via SetXXXX methods).

wxWindow* wxHtmlEasyPrinting::GetParentWindow ( ) const

Gets the parent window for dialogs.

wxPrintData* wxHtmlEasyPrinting::GetPrintData ( )

Returns pointer to wxPrintData instance used by this class.

You can set its parameters (via SetXXXX methods).

void wxHtmlEasyPrinting::PageSetup ( )

Display page setup dialog and allows the user to modify settings.

bool wxHtmlEasyPrinting::PreviewFile (const wxString & *htmlfile*)

Preview HTML file.

Returns false in case of error – call wxPrinter::GetLastError to get detailed information about the kind of the error.

bool wxHtmlEasyPrinting::PreviewText (const wxString & *htmltext,* const wxString & *basepath* = wxEmptyString)

Preview HTML text (not file!).

Returns false in case of error – call wxPrinter::GetLastError to get detailed information about the kind of the error.

Parameters

htmltext	HTML text.
basepath	base directory (html string would be stored there if it was in file). It is used to determine path for loading images, for example.

bool wxHtmlEasyPrinting::PrintFile (const wxString & *htmlfile*)

Print HTML file.

Returns false in case of error – call wxPrinter::GetLastError to get detailed information about the kind of the error.

bool wxHtmlEasyPrinting::PrintText (const wxString & *htmltext,* const wxString & *basepath* = wxEmptyString)

Print HTML text (not file!).

Returns false in case of error – call wxPrinter::GetLastError to get detailed information about the kind of the error.

Parameters

htmltext	HTML text.
basepath	base directory (html string would be stored there if it was in file). It is used to determine path for loading images, for example.

void wxHtmlEasyPrinting::SetFonts (const wxString & *normal_face,* const wxString & *fixed_face,* const int * *sizes* = NULL)

Sets fonts.

See wxHtmlDCRenderer::SetFonts for detailed description.

void wxHtmlEasyPrinting::SetFooter (const wxString & *footer,* int *pg* = wxPAGE_ALL)

Set page footer.

The following macros can be used inside it: @DATE@ is replaced by the current date in default format @PAGEN↩ UM@ is replaced by page number @PAGESCNT@ is replaced by total number of pages @TIME@ is replaced by the current time in default format @TITLE@ is replaced with the title of the document

Parameters

footer	HTML text to be used as footer.
pg	one of wxPAGE_ODD, wxPAGE_EVEN and wxPAGE_ALL constants.

void wxHtmlEasyPrinting::SetHeader (const wxString & *header,* int *pg* = wxPAGE_ALL)

Set page header.

The following macros can be used inside it:

- @DATE@ is replaced by the current date in default format
- @PAGENUM@ is replaced by page number
- @PAGESCNT@ is replaced by total number of pages
- @TIME@ is replaced by the current time in default format
- @TITLE@ is replaced with the title of the document

Parameters

header	HTML text to be used as header.
pg	one of wxPAGE_ODD, wxPAGE_EVEN and wxPAGE_ALL constants.

void wxHtmlEasyPrinting::SetName (const wxString & *name*)

Sets the name used for preview frames and setup dialogs.

Since

2.8.11 / 2.9.1

void wxHtmlEasyPrinting::SetParentWindow (wxWindow * *window*)

Sets the parent window for dialogs.

void wxHtmlEasyPrinting::SetStandardFonts (int *size* = -1, const wxString & *normal_face* = wxEmptyString, const wxString & *fixed_face* = wxEmptyString)

Sets default font sizes and/or default font size.

See wxHtmlDCRenderer::SetStandardFonts for detailed description.

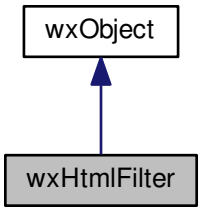
SetFonts()

21.360 wxHtmlFilter Class Reference

`#include <wx/html/htmlfilt.h>`

Inheritance diagram for wxHtmlFilter:



21.360.1 Detailed Description

This class is the parent class of input filters for wxHtmlWindow.

It allows you to read and display files of different file formats.

Library: wxHTML

Category: HTML

See also

Input Filters

Public Member Functions

- wxHtmlFilter ()

  Constructor.
- virtual bool CanRead (const wxFSFile &file) const =0

  Returns true if this filter is capable of reading file file.
- virtual wxString ReadFile (const wxFSFile &file) const =0

  Reads the file and returns string with HTML document.

Additional Inherited Members

21.360.2 Constructor & Destructor Documentation

wxHtmlFilter::wxHtmlFilter ( )

Constructor.

21.360.3 Member Function Documentation

virtual bool wxHtmlFilter::CanRead (const wxFSFile & *file*) const `[pure virtual]`

Returns true if this filter is capable of reading file *file*.

Example:

```
bool MyFilter::CanRead(const wxFSFile& file)
{
    return (file.GetMimeType() == "application/x-ugh");
}
```

virtual wxString wxHtmlFilter::ReadFile (const wxFSFile & *file*) const `[pure virtual]`

Reads the file and returns string with HTML document.

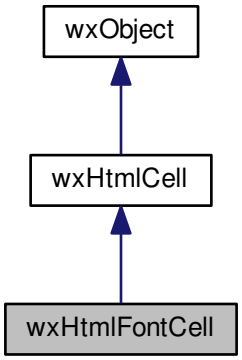
Example:

```
wxString MyImgFilter::ReadFile(const wxFSFile& file)
{
    return "<html><body><img src=\"" + file.GetLocation() +
           "\"></body></html>";
}
```

21.361 wxHtmlFontCell Class Reference

`#include <wx/html/htmlcell.h>`

Inheritance diagram for wxHtmlFontCell:



21.361.1 Detailed Description

This cell represents a font change in the document stream.

Library: wxHTML

Category: HTML

Public Member Functions

- wxHtmlFontCell (wxFont *font)

Additional Inherited Members

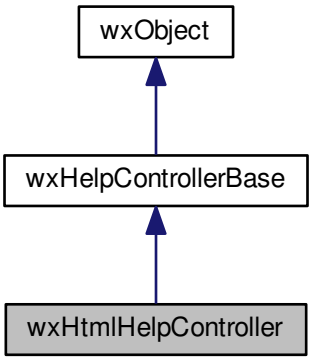
21.361.2 Constructor & Destructor Documentation

wxHtmlFontCell::wxHtmlFontCell (wxFont * *font*)

21.362 wxHtmlHelpController Class Reference

`#include <wx/html/helpctrl.h>`

Inheritance diagram for wxHtmlHelpController:



21.362.1 Detailed Description

This help controller provides an easy way of displaying HTML help in your application (see HTML Sample, test example).

The help system is based on **books** (see wxHtmlHelpController::AddBook). A book is a logical section of documentation (for example "User's Guide" or "Programmer's Guide" or "C++ Reference" or "wxWidgets Reference"). The help controller can handle as many books as you want.

Although this class has an API compatible with other wxWidgets help controllers as documented by wxHelpController, it is recommended that you use the enhanced capabilities of wxHtmlHelpController's API.

wxHTML uses Microsoft's HTML Help Workshop project files (.hhp, .hhk, .hhc) as its native format. The file format is described in Help Files Format. The directory `helpfiles` in the HTML Sample contains sample project files.

Note that the Microsoft's HTML Help Workshop (`http://www.microsoft.com/downloads/details.aspx?FamilyID=00535334-c8a6-452f-9aa0-d597d16580cc`) also runs on other platforms using WINE (`http://www.winehq.org/`) and it can be used to create the .hpp, .hhk and .hhc files through a friendly GUI. The commercial tool HelpBlocks (`http://www.helpblocks.com`) can also create these files.

Library: wxHTML

Category: Help, HTML

wxBestHelpController, wxHtmlHelpFrame, wxHtmlHelpDialog, wxHtmlHelpWindow, wxHtmlModalHelp

Public Member Functions

- wxHtmlHelpController (int style=wxHF_DEFAULT_STYLE, wxWindow *parentWindow=NULL)

  Constructor.
- wxHtmlHelpController (wxWindow *parentWindow, int style=wxHF_DEFAULT_STYLE)
- bool AddBook (const wxFileName &bookFile, bool showWaitMsg=false)

  Adds a book (i.e.
- bool AddBook (const wxString &bookUrl, bool showWaitMsg=false)

  Adds a book (i.e.
- bool Display (const wxString &x)

  Displays page x.
- bool Display (int id)

  This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.
  This alternative form is used to search help contents by numeric IDs.
- virtual bool DisplayContents ()

  Displays help window and focuses contents panel.
- bool DisplayIndex ()

  Displays help window and focuses index panel.
- virtual bool KeywordSearch (const wxString &keyword, wxHelpSearchMode mode=wxHELP_SEARCH_ALL)

  Displays the help window, focuses search panel and starts searching.
- virtual void ReadCustomization (wxConfigBase *cfg, const wxString &path=wxEmptyString)

  Reads the controller's setting (position of window, etc.)
- void SetShouldPreventAppExit (bool enable)

  Sets whether the help frame should prevent application from exiting if it's the only remaining top level window.
- void SetTempDir (const wxString &path)

  Sets the path for storing temporary files - cached binary versions of index and contents files.
- void SetTitleFormat (const wxString &format)

  Sets format of title of the frame.
- void UseConfig (wxConfigBase *config, const wxString &rootpath=wxEmptyString)

  Associates the config object with the controller.
- virtual void WriteCustomization (wxConfigBase *cfg, const wxString &path=wxEmptyString)

  Stores controllers setting (position of window etc.)
- wxHtmlHelpWindow * GetHelpWindow ()

  Get the current help window.
- void SetHelpWindow (wxHtmlHelpWindow *helpWindow)

  Set the help window to be managed by this controller.
- wxHtmlHelpFrame * GetFrame ()

  Returns the current help frame.
- wxHtmlHelpDialog * GetDialog ()

  Returns the current help dialog.

Protected Member Functions

- virtual wxHtmlHelpDialog * CreateHelpDialog (wxHtmlHelpData *data)

  This protected virtual method may be overridden so that when specifying the `wxHF_DIALOG` *style, the controller uses a different dialog.*

- virtual wxHtmlHelpFrame * CreateHelpFrame (wxHtmlHelpData *data)

  This protected virtual method may be overridden so that the controller uses a different frame.

Additional Inherited Members

21.362.2 Constructor & Destructor Documentation

wxHtmlHelpController::wxHtmlHelpController (**int** ***style*** **= wxHF_DEFAULT_STYLE,** **wxWindow** * ***parentWindow*** **=** `NULL` **)**

Constructor.

Parameters

style	This is a combination of these flags: • wxHF_TOOLBAR: The help window has a toolbar. • wxHF_FLAT_TOOLBAR: The help window has a toolbar with flat buttons (aka coolbar). • wxHF_CONTENTS: The help window has a contents panel. • wxHF_INDEX: The help window has an index panel. • wxHF_SEARCH: The help window has a search panel. • wxHF_BOOKMARKS: The help window has bookmarks controls. • wxHF_OPEN_FILES: Allows user to open arbitrary HTML document. • wxHF_PRINT: The toolbar contains "print" button. • wxHF_MERGE_BOOKS: The contents pane does not show book nodes. All books are merged together and appear as single book to the user. • wxHF_ICONS_BOOK: All nodes in contents pane have a book icon. This is how Microsoft's HTML help viewer behaves. • wxHF_ICONS_FOLDER: Book nodes in contents pane have a book icon, book's sections have a folder icon. This is the default. • wxHF_ICONS_BOOK_CHAPTER: Both book nodes and nodes of top-level sections of a book (i.e. chapters) have a book icon, all other sections (sections, subsections, ...) have a folder icon. • wxHF_EMBEDDED: Specifies that the help controller controls an embedded window of class wxHtmlHelpWindow that should not be destroyed when the controller is destroyed. • wxHF_DIALOG: Specifies that the help controller should create a dialog containing the help window. • wxHF_FRAME: Specifies that the help controller should create a frame containing the help window. This is the default if neither wxHF_DIALOG nor wxHF_EMBEDDED is specified. • wxHF_MODAL: Specifies that the help controller should create a modal dialog containing the help window (used with the wxHF_DIALOG style). • wxHF_DEFAULT_STYLE: wxHF_TOOLBAR | wxHF_CONTENTS | wxHF_INDEX | wxHF_SEARCH | wxHF_BOOKMARKS | wxHF_PRINT
parentWindow	This is an optional window to be used as the parent for the help window.

wxHtmlHelpController::wxHtmlHelpController (wxWindow * *parentWindow,* int *style* = wxHF_DEFAULT_STYLE)

21.362.3 Member Function Documentation

bool wxHtmlHelpController::AddBook (const wxFileName & *bookFile,* bool *showWaitMsg* = `false`)

Adds a book (i.e.

a .hhp file; an HTML Help Workshop project file) into the list of loaded books.

This must be called at least once before displaying any help. *bookFile* or *bookUrl* may be either "`.hhp`" file or a ZIP archive that contains an arbitrary number of "`.hhp`" files in its top-level directory. This ZIP archive must have

".zip" or ".htb" extension (the latter stands for "HTML book"). In other words,

```
AddBook(wxFileName("help.zip"))
```

is possible and is the recommended way.

Parameters

bookFile	Help book filename. It is recommended to use this prototype instead of the one taking URL, because it is less error-prone.
showWaitMsg	If true then a decoration-less window with progress message is displayed.

bool wxHtmlHelpController::AddBook (const wxString & *bookUrl*, bool *showWaitMsg* = false)

Adds a book (i.e.

a .hhp file; an HTML Help Workshop project file) into the list of loaded books.

See the other overload for additional info.

Parameters

bookUrl	Help book URL (note that syntax of filename and URL is different on most platforms).
showWaitMsg	If true then a decoration-less window with progress message is displayed.

virtual wxHtmlHelpDialog* wxHtmlHelpController::CreateHelpDialog (wxHtmlHelpData * *data*) [protected], [virtual]

This protected virtual method may be overridden so that when specifying the wxHF_DIALOG style, the controller uses a different dialog.

virtual wxHtmlHelpFrame* wxHtmlHelpController::CreateHelpFrame (wxHtmlHelpData * *data*) [protected], [virtual]

This protected virtual method may be overridden so that the controller uses a different frame.

bool wxHtmlHelpController::Display (const wxString & *x*)

Displays page *x*.

This is THE important function - it is used to display the help in application. You can specify the page in many ways:

- as direct filename of HTML document
- as chapter name (from contents) or as a book name
- as some word from index
- even as any word (will be searched)

Looking for the page runs in these steps:

1. try to locate file named x (if x is for example "doc/howto.htm")
2. try to open starting page of book named x
3. try to find x in contents (if x is for example "How To ...")
4. try to find x in index (if x is for example "How To ...")
5. switch to Search panel and start searching

bool wxHtmlHelpController::Display (int *id*)

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.

This alternative form is used to search help contents by numeric IDs.

virtual bool wxHtmlHelpController::DisplayContents ( ) [virtual]

Displays help window and focuses contents panel.

Implements wxHelpControllerBase.

bool wxHtmlHelpController::DisplayIndex ( )

Displays help window and focuses index panel.

wxHtmlHelpDialog* wxHtmlHelpController::GetDialog ( )

Returns the current help dialog.

(May be NULL.)

wxHtmlHelpFrame* wxHtmlHelpController::GetFrame ( )

Returns the current help frame.

(May be NULL.)

wxHtmlHelpWindow* wxHtmlHelpController::GetHelpWindow ( )

Get the current help window.

virtual bool wxHtmlHelpController::KeywordSearch (const wxString & *keyword,* wxHelpSearchMode *mode* = wxHELP_SEARCH_ALL) [virtual]

Displays the help window, focuses search panel and starts searching.

Returns true if the keyword was found. Optionally it searches through the index (mode = `wxHELP_SEARCH_INDEX`), default the content (mode = `wxHELP_SEARCH_ALL`).

Note

KeywordSearch() searches only pages listed in `".hhc"` file(s). You should list all pages in the contents file.

Implements wxHelpControllerBase.

virtual void wxHtmlHelpController::ReadCustomization (wxConfigBase * *cfg,* const wxString & *path* = wxEmptyString) [virtual]

Reads the controller's setting (position of window, etc.)

void wxHtmlHelpController::SetHelpWindow (wxHtmlHelpWindow * *helpWindow*)

Set the help window to be managed by this controller.

This makes it possible to have a help window that might not be in a wxHtmlHelpFrame or dialog but is embedded in some other window in the application. Be sure to use the wxHF_EMBEDDED style in this case.

void wxHtmlHelpController::SetShouldPreventAppExit (bool *enable*)

Sets whether the help frame should prevent application from exiting if it's the only remaining top level window.

Parameters

enable	If true, the application will not quit unless the help frame is closed. Default is false, i.e. the application does exit if only the help window remains opened.

See also

wxApp::SetExitOnFrameDelete()

Since

2.9.2

void wxHtmlHelpController::SetTempDir (const wxString & *path*)

Sets the path for storing temporary files - cached binary versions of index and contents files.

These binary forms are much faster to read. Default value is empty string (empty string means that no cached data are stored). Note that these files are *not* deleted when program exits.

Once created these cached files will be used in all subsequent executions of your application. If cached files become older than corresponding `".hhp"` file (e.g. if you regenerate documentation) it will be refreshed.

void wxHtmlHelpController::SetTitleFormat (const wxString & *format*)

Sets format of title of the frame.

Must contain exactly one "%s" (for title of displayed HTML page).

void wxHtmlHelpController::UseConfig (wxConfigBase * *config*, const wxString & *rootpath* = wxEmptyString)

Associates the *config* object with the controller.

If there is associated config object, wxHtmlHelpController automatically reads and writes settings (including wxHtmlWindow's settings) when needed. The only thing you must do is create wxConfig object and call UseConfig().

If you do not use UseConfig(), wxHtmlHelpController will use the default wxConfig object if available (for details see wxConfigBase::Get and wxConfigBase::Set).

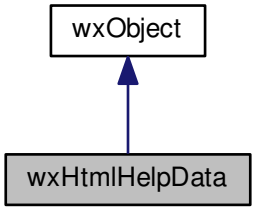
virtual void wxHtmlHelpController::WriteCustomization (wxConfigBase * *cfg*, const wxString & *path* = wxEmptyString) [virtual]

Stores controllers setting (position of window etc.)

21.363 wxHtmlHelpData Class Reference

`#include <wx/html/helpdata.h>`

Inheritance diagram for wxHtmlHelpData:



21.363.1 Detailed Description

This class is used by wxHtmlHelpController and wxHtmlHelpFrame to access HTML help items.

It is internal class and should not be used directly - except for the case you're writing your own HTML help controller.

Library: wxHTML

Category: Help, HTML

Public Member Functions

- wxHtmlHelpData ()

  Constructor.
- bool AddBook (const wxString &book_url)

  Adds new book.
- wxString FindPageById (int id)

  Returns page's URL based on integer ID stored in project.
- wxString FindPageByName (const wxString &page)

  Returns page's URL based on its (file)name.
- const wxHtmlBookRecArray & GetBookRecArray () const

  Returns array with help books info.
- const wxHtmlHelpDataItems & GetContentsArray () const

  Returns reference to array with contents entries.
- const wxHtmlHelpDataItems & GetIndexArray () const

  Returns reference to array with index entries.
- void SetTempDir (const wxString &path)

  Sets the temporary directory where binary cached versions of MS HTML Workshop files will be stored.

Additional Inherited Members

21.363.2 Constructor & Destructor Documentation

wxHtmlHelpData::wxHtmlHelpData ( )

Constructor.

21.363.3 Member Function Documentation

bool wxHtmlHelpData::AddBook (const wxString & *book_url*)

Adds new book.

book_url is URL (not filename!) of HTML help project (hhp) or ZIP file that contains arbitrary number of .hhp projects (this zip file can have either .zip or .htb extension, htb stands for "html book").

Returns success.

wxString wxHtmlHelpData::FindPageById (int *id*)

Returns page's URL based on integer ID stored in project.

wxString wxHtmlHelpData::FindPageByName (const wxString & *page*)

Returns page's URL based on its (file)name.

const wxHtmlBookRecArray& wxHtmlHelpData::GetBookRecArray ( ) const

Returns array with help books info.

const wxHtmlHelpDataItems& wxHtmlHelpData::GetContentsArray ( ) const

Returns reference to array with contents entries.

const wxHtmlHelpDataItems& wxHtmlHelpData::GetIndexArray ( ) const

Returns reference to array with index entries.

void wxHtmlHelpData::SetTempDir (const wxString & *path*)

Sets the temporary directory where binary cached versions of MS HTML Workshop files will be stored.

(This is turned off by default and you can enable this feature by setting non-empty temp dir.)

21.364 wxHtmlHelpDataItem Class Reference

`#include <wx/html/helpdata.h>`

21.364.1 Detailed Description

Helper class for wxHtmlHelpData.

Public Member Functions

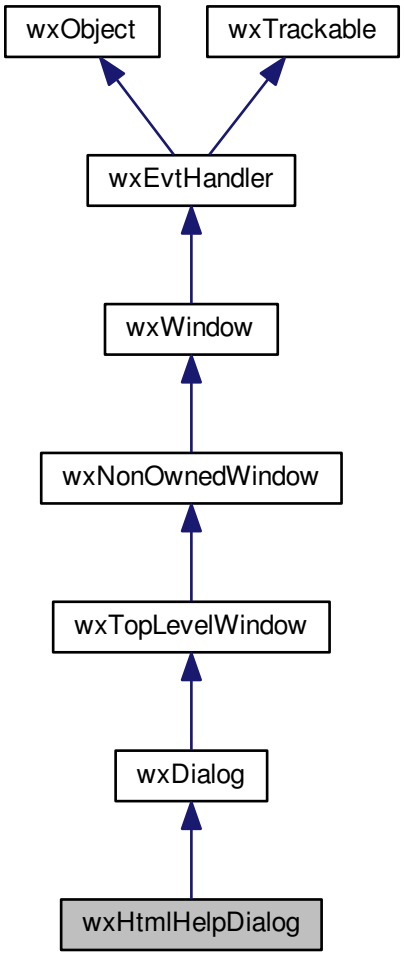
21.365 wxHtmlHelpDialog Class Reference

```
#include <wx/html/helpdlg.h>
```

Inheritance diagram for wxHtmlHelpDialog:



21.365.1 Detailed Description

This class is used by wxHtmlHelpController to display help.

It is an internal class and should not be used directly - except for the case when you're writing your own HTML help controller.

Library: wxHTML

Category: Help, HTML

Public Member Functions

- wxHtmlHelpDialog (wxHtmlHelpData *data=NULL)

- wxHtmlHelpDialog (wxWindow *parent, wxWindowID id, const wxString &title=wxEmptyString, int style=wxHF_DEFAULT_STYLE, wxHtmlHelpData *data=NULL)

  Constructor.
- virtual void AddToolbarButtons (wxToolBar *toolBar, int style)

  You may override this virtual method to add more buttons to the help window's toolbar.
- bool Create (wxWindow *parent, wxWindowID id, const wxString &title=wxEmptyString, int style=wxHF_DEFAULT_STYLE)

  Creates the dialog.
- wxHtmlHelpController * GetController () const

  Returns the help controller associated with the dialog.
- void SetController (wxHtmlHelpController *controller)

  Sets the help controller associated with the dialog.
- void SetTitleFormat (const wxString &format)

  Sets the dialog's title format.

Additional Inherited Members

21.365.2 Constructor & Destructor Documentation

wxHtmlHelpDialog::wxHtmlHelpDialog (wxHtmlHelpData * *data* = NULL)

wxHtmlHelpDialog::wxHtmlHelpDialog (wxWindow * *parent*, wxWindowID *id*, const wxString & *title* = wxEmptyString, int *style* = wxHF_DEFAULT_STYLE, wxHtmlHelpData * *data* = NULL)

Constructor.

For the possible values of *style*, please see wxHtmlHelpController.

21.365.3 Member Function Documentation

virtual void wxHtmlHelpDialog::AddToolbarButtons (wxToolBar * *toolBar*, int *style*) [virtual]

You may override this virtual method to add more buttons to the help window's toolbar.

toolBar is a pointer to the toolbar and *style* is the style flag as passed to the Create() method.

wxToolBar::Realize is called immediately after returning from this function.

bool wxHtmlHelpDialog::Create (wxWindow * *parent*, wxWindowID *id*, const wxString & *title* = wxEmptyString, int *style* = wxHF_DEFAULT_STYLE)

Creates the dialog.

See the constructor for a description of the parameters.

wxHtmlHelpController* wxHtmlHelpDialog::GetController ( ) const

Returns the help controller associated with the dialog.

void wxHtmlHelpDialog::SetController (wxHtmlHelpController * *controller*)

Sets the help controller associated with the dialog.

void wxHtmlHelpDialog::SetTitleFormat (const wxString & *format*)

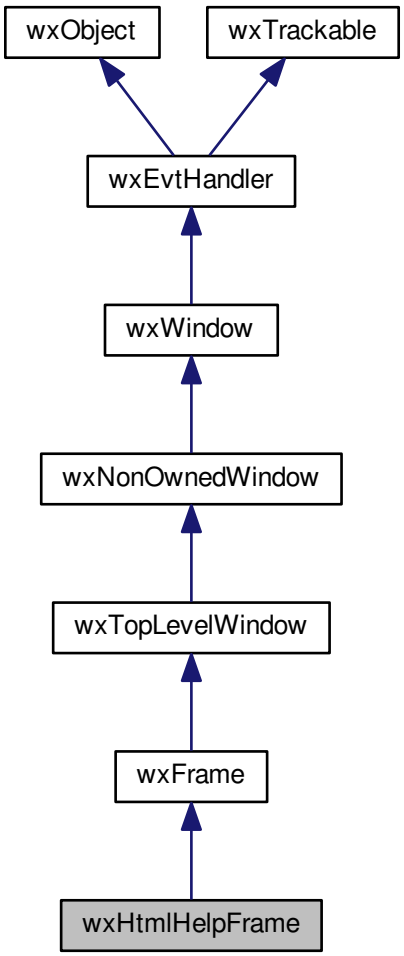
Sets the dialog's title format.

format must contain exactly one "%s" (it will be replaced by the page title).

21.366 wxHtmlHelpFrame Class Reference

`#include <wx/html/helpfrm.h>`

Inheritance diagram for wxHtmlHelpFrame:



21.366.1 Detailed Description

This class is used by wxHtmlHelpController to display help.

It is an internal class and should not be used directly - except for the case when you're writing your own HTML help controller.

Library: wxHTML

Category: Help, HTML

Public Member Functions

- wxHtmlHelpFrame (wxHtmlHelpData *data=NULL)
- wxHtmlHelpFrame (wxWindow *parent, wxWindowID id, const wxString &title=wxEmptyString, int style=wxHF_DEFAULT_STYLE, wxHtmlHelpData *data=NULL, wxConfigBase *config=NULL, const wxString &rootpath=wxEmptyString)

  Constructor.
- virtual void AddToolbarButtons (wxToolBar *toolBar, int style)

  You may override this virtual method to add more buttons to the help window's toolbar.
- bool Create (wxWindow *parent, wxWindowID id, const wxString &title=wxEmptyString, int style=wxHF_DEFAULT_STYLE, wxConfigBase *config=NULL, const wxString &rootpath=wxEmptyString)

  Creates the frame.
- wxHtmlHelpController * GetController () const

  Returns the help controller associated with the frame.
- void SetController (wxHtmlHelpController *controller)

  Sets the help controller associated with the frame.
- void SetTitleFormat (const wxString &format)

  Sets the frame's title format.

Additional Inherited Members

21.366.2 Constructor & Destructor Documentation

wxHtmlHelpFrame::wxHtmlHelpFrame (wxHtmlHelpData * *data* = NULL)

wxHtmlHelpFrame::wxHtmlHelpFrame (wxWindow * *parent*, wxWindowID *id*, const wxString & *title* = wxEmptyString, int *style* = wxHF_DEFAULT_STYLE, wxHtmlHelpData * *data* = NULL, wxConfigBase * *config* = NULL, const wxString & *rootpath* = wxEmptyString)

Constructor.

For the possible values of *style*, please see wxHtmlHelpController.

21.366.3 Member Function Documentation

virtual void wxHtmlHelpFrame::AddToolbarButtons (wxToolBar * *toolBar*, int *style*) [virtual]

You may override this virtual method to add more buttons to the help window's toolbar.

toolBar is a pointer to the toolbar and *style* is the style flag as passed to the Create() method.

wxToolBar::Realize is called immediately after returning from this function.

bool wxHtmlHelpFrame::Create (wxWindow * *parent*, wxWindowID *id*, const wxString & *title* = wxEmptyString, int *style* = wxHF_DEFAULT_STYLE, wxConfigBase * *config* = NULL, const wxString & *rootpath* = wxEmptyString)

Creates the frame.

See the constructor for a description of the parameters.

wxHtmlHelpController* **wxHtmlHelpFrame::GetController ( ) const**

Returns the help controller associated with the frame.

void wxHtmlHelpFrame::SetController (wxHtmlHelpController * *controller*)

Sets the help controller associated with the frame.

void wxHtmlHelpFrame::SetTitleFormat (const wxString & *format*)

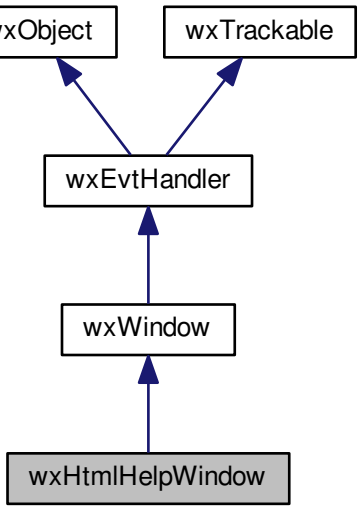
Sets the frame's title format.

format must contain exactly one "%s" (it will be replaced by the page title).

21.367 wxHtmlHelpWindow Class Reference

`#include <wx/html/helpwnd.h>`

Inheritance diagram for wxHtmlHelpWindow:



21.367.1 Detailed Description

This class is used by wxHtmlHelpController to display help within a frame or dialog, but you can use it yourself to create an embedded HTML help window.

For example:

```
// m_embeddedHelpWindow is a wxHtmlHelpWindow
// m_embeddedHtmlHelp is a wxHtmlHelpController

// Create embedded HTML Help window
m_embeddedHelpWindow = new wxHtmlHelpWindow;
m_embeddedHtmlHelp.UseConfig(config, rootPath); // Set your own config object here
```

```
m_embeddedHtmlHelp.SetHelpWindow(m_embeddedHelpWindow);
m_embeddedHelpWindow->Create(this, wxID_ANY, wxDefaultPosition,
      GetClientSize(),
                           wxTAB_TRAVERSAL|wxBORDER_NONE,
      wxHF_DEFAULT_STYLE);
m_embeddedHtmlHelp.AddBook(wxFileName(wxT("doc.zip")));
```

You should pass the style wxHF_EMBEDDED to the style parameter of wxHtmlHelpController to allow the embedded window to be destroyed independently of the help controller.

Library: wxHTML

Category: Help, HTML

Public Member Functions

- wxHtmlHelpWindow (wxHtmlHelpData *data=NULL)
- wxHtmlHelpWindow (wxWindow *parent, int wxWindowID, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, int style=wxTAB_TRAVERSAL|wxBORDER_NONE, int helpStyle=wxHF_DEFAULT_STYLE, wxHtmlHelpData *data=NULL)

  Constructor.
- bool Create (wxWindow *parent, wxWindowID id, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, int style=wxTAB_TRAVERSAL|wxBORDER_NONE, int helpStyle=wxHF_DEFAULT_STYLE)

  Creates the help window.
- bool Display (const wxString &x)

  Displays page x.
- bool Display (const int id)

  This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.
  This form takes numeric ID as the parameter (uses an extension to MS format, param name="ID" value=id).
- bool DisplayContents ()

  Displays contents panel.
- bool DisplayIndex ()

  Displays index panel.
- wxHtmlHelpData * GetData ()

  Returns the wxHtmlHelpData object, which is usually a pointer to the controller's data.
- bool KeywordSearch (const wxString &keyword, wxHelpSearchMode mode=wxHELP_SEARCH_ALL)

  Search for given keyword.
- void ReadCustomization (wxConfigBase *cfg, const wxString &path=wxEmptyString)

  Reads the user's settings for this window.
- void UseConfig (wxConfigBase *config, const wxString &rootpath=wxEmptyString)

  Associates a wxConfig object with the help window.
- void WriteCustomization (wxConfigBase *cfg, const wxString &path=wxEmptyString)

  Saves the user's settings for this window.
- void RefreshLists ()

  Refresh all panels.
- wxHtmlHelpController * GetController () const
- void SetController (wxHtmlHelpController *controller)

Protected Member Functions

- void CreateSearch ()

  Creates search panel.
- virtual void AddToolbarButtons (wxToolBar *toolBar, int style)

  You may override this virtual method to add more buttons to the help window's toolbar.
- void CreateContents ()

  Creates contents panel.
- void CreateIndex ()

  Creates index panel.

Additional Inherited Members

21.367.2 Constructor & Destructor Documentation

wxHtmlHelpWindow::wxHtmlHelpWindow (wxHtmlHelpData * *data* = NULL)

wxHtmlHelpWindow::wxHtmlHelpWindow (wxWindow * *parent*, int *wxWindowID*, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, int *style* = wxTAB_TRAVERSAL|wxBORDER_NONE, int *helpStyle* = wxHF_DEFAULT_STYLE, wxHtmlHelpData * *data* = NULL)

Constructor.

For the values of *helpStyle*, please see the documentation for wxHtmlHelpController.

21.367.3 Member Function Documentation

virtual void wxHtmlHelpWindow::AddToolbarButtons (wxToolBar * *toolBar*, int *style*) [protected], [virtual]

You may override this virtual method to add more buttons to the help window's toolbar.

toolBar is a pointer to the toolbar and *style* is the style flag as passed to the Create() method.

wxToolBar::Realize is called immediately after returning from this function. See samples/html/helpview for an example.

bool wxHtmlHelpWindow::Create (wxWindow * *parent*, wxWindowID *id*, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, int *style* = wxTAB_TRAVERSAL|wxBORDER_NONE, int *helpStyle* = wxHF_DEFAULT_STYLE)

Creates the help window.

See the constructor for a description of the parameters.

void wxHtmlHelpWindow::CreateContents ( ) [protected]

Creates contents panel.

(May take some time.)

void wxHtmlHelpWindow::CreateIndex ( ) [protected]

Creates index panel.

(May take some time.)

void wxHtmlHelpWindow::CreateSearch ( ) [protected]

Creates search panel.

bool wxHtmlHelpWindow::Display (const wxString & *x*)

Displays page x.

If not found it will give the user the choice of searching books. Looking for the page runs in these steps:

1. try to locate file named x (if x is for example "doc/howto.htm")
2. try to open starting page of book x
3. try to find x in contents (if x is for example "How To ...")
4. try to find x in index (if x is for example "How To ...")

bool wxHtmlHelpWindow::Display (const int *id*)

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.

This form takes numeric ID as the parameter (uses an extension to MS format, param name="ID" value=id).

bool wxHtmlHelpWindow::DisplayContents ( )

Displays contents panel.

bool wxHtmlHelpWindow::DisplayIndex ( )

Displays index panel.

wxHtmlHelpController* wxHtmlHelpWindow::GetController ( ) const

wxHtmlHelpData* wxHtmlHelpWindow::GetData ( )

Returns the wxHtmlHelpData object, which is usually a pointer to the controller's data.

bool wxHtmlHelpWindow::KeywordSearch (const wxString & *keyword,* wxHelpSearchMode *mode* = wxHELP_SEARCH_ALL)

Search for given keyword.

Optionally it searches through the index (mode = `wxHELP_SEARCH_INDEX`), default the content (mode = `wxHELP_SEARCH_ALL`).

void wxHtmlHelpWindow::ReadCustomization (wxConfigBase * *cfg,* const wxString & *path* = wxEmptyString)

Reads the user's settings for this window.

See also

wxHtmlHelpController::ReadCustomization

void wxHtmlHelpWindow::RefreshLists ( )

Refresh all panels.

This is necessary if a new book was added.

void wxHtmlHelpWindow::SetController (wxHtmlHelpController * *controller*)

void wxHtmlHelpWindow::UseConfig (wxConfigBase * *config*, const wxString & *rootpath* = wxEmptyString)

Associates a wxConfig object with the help window.

It is recommended that you use wxHtmlHelpController::UseConfig instead.

void wxHtmlHelpWindow::WriteCustomization (wxConfigBase * *cfg*, const wxString & *path* = wxEmptyString)

Saves the user's settings for this window.

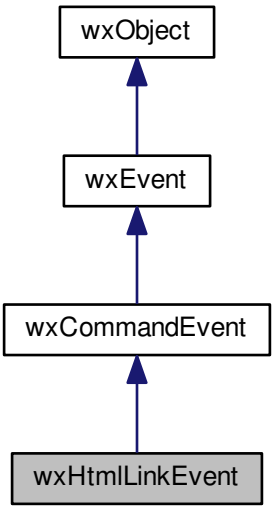
See also

wxHtmlHelpController::WriteCustomization

21.368 wxHtmlLinkEvent Class Reference

`#include <wx/html/htmlwin.h>`

Inheritance diagram for wxHtmlLinkEvent:



21.368.1 Detailed Description

This event class is used for the events generated by wxHtmlWindow.

Events using this class

The following event handler macros redirect the events to member function handlers '**func**' with prototypes like: void handlerFuncName(wxHtmlLinkEvent& event)

Event macros:

- EVT_HTML_LINK_CLICKED(id, func): User clicked on an hyperlink.

Library: wxHTML

Category: HTML

Public Member Functions

- wxHtmlLinkEvent (int id, const wxHtmlLinkInfo &linkinfo)

  The constructor is not normally used by the user code.

- const wxHtmlLinkInfo & GetLinkInfo () const

  Returns the wxHtmlLinkInfo which contains info about the cell clicked and the hyperlink it contains.

Additional Inherited Members

21.368.2 Constructor & Destructor Documentation

wxHtmlLinkEvent::wxHtmlLinkEvent (int *id,* const wxHtmlLinkInfo & *linkinfo*)

The constructor is not normally used by the user code.

21.368.3 Member Function Documentation

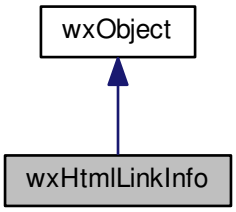
const wxHtmlLinkInfo& wxHtmlLinkEvent::GetLinkInfo ( ) const

Returns the wxHtmlLinkInfo which contains info about the cell clicked and the hyperlink it contains.

21.369 wxHtmlLinkInfo Class Reference

```
#include <wx/html/htmlcell.h>
```

Inheritance diagram for wxHtmlLinkInfo:



21.369.1 Detailed Description

This class stores all necessary information about hypertext links (as represented by <A> tag in HTML documents).

In current implementation it stores URL and target frame name.

Note

Frames are not currently supported by wxHTML!

Library: wxHTML

Category: HTML

Public Member Functions

- wxHtmlLinkInfo ()
  Default ctor.
- wxHtmlLinkInfo (const wxString &href, const wxString &target=wxEmptyString)
  Construct hypertext link from HREF (aka URL) and TARGET (name of target frame).
- const wxMouseEvent * GetEvent () const
  Return pointer to event that generated OnLinkClicked() event.
- wxString GetHref () const
  Return HREF value of the <A> tag.
- const wxHtmlCell * GetHtmlCell () const
  Return pointer to the cell that was clicked.
- wxString GetTarget () const
  Return TARGET value of the <A> tag (this value is used to specify in which frame should be the page pointed by GetHref() Href opened).

Additional Inherited Members

21.369.2 Constructor & Destructor Documentation

wxHtmlLinkInfo::wxHtmlLinkInfo ( )

Default ctor.

wxHtmlLinkInfo::wxHtmlLinkInfo (const wxString & *href,* const wxString & *target* = wxEmptyString)

Construct hypertext link from HREF (aka URL) and TARGET (name of target frame).

21.369.3 Member Function Documentation

const wxMouseEvent* wxHtmlLinkInfo::GetEvent ( ) const

Return pointer to event that generated OnLinkClicked() event.

Valid only within wxHtmlWindow::OnLinkClicked, NULL otherwise.

wxString wxHtmlLinkInfo::GetHref ( ) const

Return *HREF* value of the <A> tag.

const wxHtmlCell* wxHtmlLinkInfo::GetHtmlCell ( ) const

Return pointer to the cell that was clicked.

Valid only within wxHtmlWindow::OnLinkClicked, NULL otherwise.

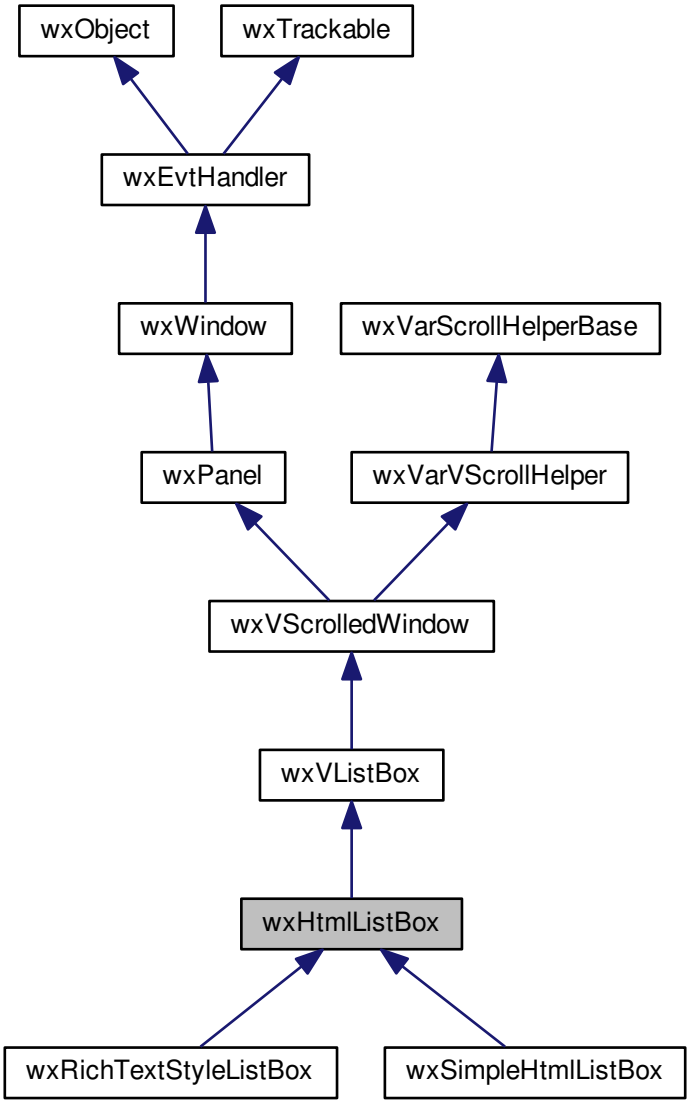
wxString wxHtmlLinkInfo::GetTarget ( ) const

Return *TARGET* value of the <A> tag (this value is used to specify in which frame should be the page pointed by GetHref() Href opened).

21.370 wxHtmlListBox Class Reference

`#include <wx/htmllbox.h>`

Inheritance diagram for wxHtmlListBox:



21.370.1 Detailed Description

wxHtmlListBox is an implementation of wxVListBox which shows HTML content in the listbox rows.

This is still an abstract base class and you will need to derive your own class from it (see htlbox sample for the example) but you will only need to override a single wxHtmlListBox::OnGetItem function.

Events emitted by this class

The following event handler macros redirect the events to member function handlers '**func**' with prototypes like: void handlerFuncName(wxHtmlCellEvent& event) or void handlerFuncName(wxHtmlLinkEvent& event)

Event macros for events emitted by this class:

- EVT_HTML_CELL_CLICKED(id, func): A wxHtmlCell was clicked.
- EVT_HTML_CELL_HOVER(id, func): The mouse passed over a wxHtmlCell.
- EVT_HTML_LINK_CLICKED(id, func): A wxHtmlCell which contains an hyperlink was clicked.

Library: wxHTML

Category: Controls

See also

wxSimpleHtmlListBox

Public Member Functions

- wxHtmlListBox (wxWindow *parent, wxWindowID id=wxID_ANY, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, long style=0, const wxString &name=wxHtmlListBoxNameStr)

  Normal constructor which calls Create() internally.
- wxHtmlListBox ()

  Default constructor, you must call Create() later.
- virtual ~wxHtmlListBox ()

  Destructor cleans up whatever resources we use.
- bool Create (wxWindow *parent, wxWindowID id=wxID_ANY, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, long style=0, const wxString &name=wxHtmlListBoxNameStr)

  Creates the control and optionally sets the initial number of items in it (it may also be set or changed later with wxVListBox::SetItemCount).
- wxFileSystem & GetFileSystem () const

  Returns the wxFileSystem used by the HTML parser of this object.
- const wxFileSystem & GetFileSystem () const

  Returns the wxFileSystem used by the HTML parser of this object.

Protected Member Functions

- virtual void OnLinkClicked (size_t n, const wxHtmlLinkInfo &link)

  Called when the user clicks on hypertext link.
- virtual wxColour GetSelectedTextBgColour (const wxColour &colBg) const

  This virtual function may be overridden to change the appearance of the background of the selected cells in the same way as GetSelectedTextColour().
- virtual wxColour GetSelectedTextColour (const wxColour &colFg) const

  This virtual function may be overridden to customize the appearance of the selected cells.
- virtual wxString OnGetItemMarkup (size_t n) const

  This function may be overridden to decorate HTML returned by OnGetItem().
- virtual wxString OnGetItem (size_t n) const =0

  This method must be implemented in the derived class and should return the body (i.e. without `html` nor `body` tags) of the HTML fragment for the given item.

Additional Inherited Members

21.370.2 Constructor & Destructor Documentation

wxHtmlListBox::wxHtmlListBox (wxWindow * *parent*, wxWindowID *id* = wxID_ANY, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, long *style* = 0, const wxString & *name* = wxHtmlListBoxNameStr)

Normal constructor which calls Create() internally.

wxHtmlListBox::wxHtmlListBox ( )

Default constructor, you must call Create() later.

virtual wxHtmlListBox::~wxHtmlListBox ( ) [virtual]

Destructor cleans up whatever resources we use.

21.370.3 Member Function Documentation

bool wxHtmlListBox::Create (wxWindow * *parent*, wxWindowID *id* = wxID_ANY, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, long *style* = 0, const wxString & *name* = wxHtmlListBoxNameStr)

Creates the control and optionally sets the initial number of items in it (it may also be set or changed later with wxVListBox::SetItemCount).

There are no special styles defined for wxHtmlListBox, in particular the wxListBox styles (with the exception of wxLB_MULTIPLE) cannot be used here.

Returns true on success or false if the control couldn't be created

wxFileSystem& wxHtmlListBox::GetFileSystem ( ) const

Returns the wxFileSystem used by the HTML parser of this object.

The file system object is used to resolve the paths in HTML fragments displayed in the control and you should use wxFileSystem::ChangePathTo if you use relative paths for the images or other resources embedded in your HTML.

const wxFileSystem& wxHtmlListBox::GetFileSystem ( ) const

Returns the wxFileSystem used by the HTML parser of this object.

The file system object is used to resolve the paths in HTML fragments displayed in the control and you should use wxFileSystem::ChangePathTo if you use relative paths for the images or other resources embedded in your HTML.

virtual wxColour wxHtmlListBox::GetSelectedTextBgColour (const wxColour & *colBg*) const [protected], [virtual]

This virtual function may be overridden to change the appearance of the background of the selected cells in the same way as GetSelectedTextColour().

It should be rarely, if ever, used because wxVListBox::SetSelectionBackground allows to change the selection background for all cells at once and doing anything more fancy is probably going to look strangely.

See also

GetSelectedTextColour()

virtual wxColour wxHtmlListBox::GetSelectedTextColour (const wxColour & *colFg*) const `[protected], [virtual]`

This virtual function may be overridden to customize the appearance of the selected cells.

It is used to determine how the colour *colFg* is going to look inside selection. By default all original colours are completely ignored and the standard, system-dependent, selection colour is used but the program may wish to override this to achieve some custom appearance.

See also

GetSelectedTextBgColour(), wxVListBox::SetSelectionBackground, wxSystemSettings::GetColour

virtual wxString wxHtmlListBox::OnGetItem (size_t *n*) const `[protected], [pure virtual]`

This method must be implemented in the derived class and should return the body (i.e. without `html` nor `body` tags) of the HTML fragment for the given item.

Note that this function should always return a text fragment for the *n* item which renders with the same height both when it is selected and when it's not: i.e. if you call, inside your OnGetItem() implementation, `IsSelected(n)` to make the items appear differently when they are selected, then you should make sure that the returned HTML fragment will render with the same height or else you'll see some artifacts when the user selects an item.

Implemented in wxRichTextStyleListBox.

virtual wxString wxHtmlListBox::OnGetItemMarkup (size_t *n*) const `[protected], [virtual]`

This function may be overridden to decorate HTML returned by OnGetItem().

virtual void wxHtmlListBox::OnLinkClicked (size_t *n*, const wxHtmlLinkInfo & *link*) `[protected], [virtual]`

Called when the user clicks on hypertext link.

Does nothing by default. Overloading this method is deprecated; intercept the event instead.

Parameters

n	Index of the item containing the link.
link	Description of the link.

See also

wxHtmlLinkInfo.

21.371 wxHtmlModalHelp Class Reference

`#include <wx/html/helpctrl.h>`

21.371.1 Detailed Description

This class uses wxHtmlHelpController to display help in a modal dialog.

This is useful on platforms such as wxMac where if you display help from a modal dialog, the help window must itself be a modal dialog.

Create objects of this class on the stack, for example:

```
// The help can be browsed during the lifetime of this object; when the
// user quits the help, program execution will continue.
wxHtmlModalHelp help(parent, "help", "My topic");
```

Library: wxHTML

Category: Help, HTML

Public Member Functions

- wxHtmlModalHelp (wxWindow *parent, const wxString &helpFile, const wxString &topic=wxEmptyString, int style=wxHF_DEFAULT_STYLE|wxHF_DIALOG|wxHF_MODAL)

  The ctor.

21.371.2 Constructor & Destructor Documentation

wxHtmlModalHelp::wxHtmlModalHelp (wxWindow * *parent,* const wxString & *helpFile,* const wxString & *topic =* wxEmptyString, int *style =* wxHF_DEFAULT_STYLE|wxHF_DIALOG|wxHF_MODAL)

The ctor.

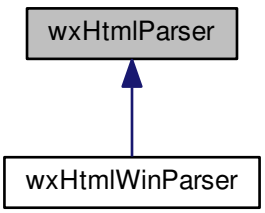
Parameters

parent	is the parent of the dialog.
helpFile	is the HTML help file to show.
topic	is an optional topic. If this is empty, the help contents will be shown.
style	is a combination of the flags described in the wxHtmlHelpController documentation.

21.372 wxHtmlParser Class Reference

`#include <wx/html/htmlpars.h>`

Inheritance diagram for wxHtmlParser:



21.372.1 Detailed Description

Classes derived from this handle the **generic** parsing of HTML documents: it scans the document and divide it into blocks of tags (where one block consists of beginning and ending tag and of text between these two tags).

It is independent from wxHtmlWindow and can be used as stand-alone parser.

It uses system of tag handlers to parse the HTML document. Tag handlers are not statically shared by all instances but are created for each wxHtmlParser instance. The reason is that the handler may contain document-specific temporary data used during parsing (e.g. complicated structures like tables).

Typically the user calls only the wxHtmlParser::Parse method.

Library: wxHTML

Category: HTML

See also

Cells and Containers, Tag Handlers, wxHtmlTag

Public Member Functions

- wxHtmlParser ()
  Constructor.
- virtual void AddTagHandler (wxHtmlTagHandler *handler)
  Adds handler to the internal list (hash table) of handlers.
- virtual void AddWord (const wxString &txt)
  Must be overwritten in derived class.
- void DoParsing (const const_iterator &begin_pos, const const_iterator &end_pos)
  Parses the m_Source from begin_pos to end_pos - 1.
- void DoParsing ()
  Parses the whole m_Source.
- virtual void DoneParser ()
  This must be called after DoParsing().
- wxFileSystem * GetFS () const
  Returns pointer to the file system.
- virtual wxObject * GetProduct ()=0
  Returns product of parsing.
- const wxString * GetSource ()
  Returns pointer to the source being parsed.
- virtual void InitParser (const wxString &source)
  Setups the parser for parsing the source string.
- virtual wxFSFile * OpenURL (wxHtmlURLType type, const wxString &url) const
  Opens given URL and returns `wxFSFile` object that can be used to read data from it.
- wxObject * Parse (const wxString &source)
  Proceeds parsing of the document.
- void PopTagHandler ()
  Restores parser's state before last call to PushTagHandler().
- void PushTagHandler (wxHtmlTagHandler *handler, const wxString &tags)
  Forces the handler to handle additional tags (not returned by wxHtmlTagHandler::GetSupportedTags).
- void SetFS (wxFileSystem *fs)
  Sets the virtual file system that will be used to request additional files.
- virtual void StopParsing ()
  Call this function to interrupt parsing from a tag handler.

Protected Member Functions

- virtual void AddTag (const wxHtmlTag &tag)

  This may (and may not) be overwritten in derived class.

21.372.2 Constructor & Destructor Documentation

wxHtmlParser::wxHtmlParser ( )

Constructor.

21.372.3 Member Function Documentation

virtual void wxHtmlParser::AddTag (const wxHtmlTag & *tag*) `[protected], [virtual]`

This may (and may not) be overwritten in derived class.

This method is called each time new tag is about to be added. *tag* contains information about the tag. (See wxHtmlTag for details.)

Default (wxHtmlParser) behaviour is this: first it finds a handler capable of handling this tag and then it calls handler's HandleTag() method.

virtual void wxHtmlParser::AddTagHandler (wxHtmlTagHandler * *handler*) `[virtual]`

Adds handler to the internal list (hash table) of handlers.

This method should not be called directly by user but rather by derived class' constructor.

This adds the handler to this **instance** of wxHtmlParser, not to all objects of this class! (Static front-end to AddTagHandler is provided by wxHtmlWinParser).

All handlers are deleted on object deletion.

virtual void wxHtmlParser::AddWord (const wxString & *txt*) `[virtual]`

Must be overwritten in derived class.

This method is called by DoParsing() each time a part of text is parsed. *txt* is NOT only one word, it is substring of input. It is not formatted or preprocessed (so white spaces are unmodified).

virtual void wxHtmlParser::DoneParser ( ) `[virtual]`

This must be called after DoParsing().

void wxHtmlParser::DoParsing (const const_iterator & *begin_pos*, const const_iterator & *end_pos*)

Parses the m_Source from *begin_pos* to *end_pos* - 1.

void wxHtmlParser::DoParsing ( )

Parses the whole m_Source.

wxFileSystem* wxHtmlParser::GetFS ( ) const

Returns pointer to the file system.

Because each tag handler has reference to it is parent parser it can easily request the file by calling:

```
wxFSFile *f = m_Parser -> GetFS() -> OpenFile("image.jpg");
```

virtual wxObject* wxHtmlParser::GetProduct ( ) [pure virtual]

Returns product of parsing.

Returned value is result of parsing of the document.

The type of this result depends on internal representation in derived parser (but it must be derived from wxObject!). See wxHtmlWinParser for details.

const wxString* wxHtmlParser::GetSource ( )

Returns pointer to the source being parsed.

virtual void wxHtmlParser::InitParser (const wxString & *source*) [virtual]

Setups the parser for parsing the *source* string.

(Should be overridden in derived class)

virtual wxFSFile* wxHtmlParser::OpenURL (wxHtmlURLType *type*, const wxString & *url*) const [virtual]

Opens given URL and returns wxFSFile object that can be used to read data from it.

This method may return NULL in one of two cases: either the URL doesn't point to any valid resource or the URL is blocked by overridden implementation of *OpenURL* in derived class.

Parameters

type	Indicates type of the resource. Is one of: • wxHTML_URL_PAGE: Opening a HTML page. • wxHTML_URL_IMAGE: Opening an image. • wxHTML_URL_OTHER: Opening a resource that doesn't fall into any other category.
url	URL being opened.

Note

Always use this method in tag handlers instead of GetFS()->OpenFile() because it can block the URL and is thus more secure. Default behaviour is to call wxHtmlWindow::OnOpeningURL of the associated wxHtmlWindow object (which may decide to block the URL or redirect it to another one),if there's any, and always open the URL if the parser is not used with wxHtmlWindow. Returned wxFSFile object is not guaranteed to point to url, it might have been redirected!

wxObject* wxHtmlParser::Parse (const wxString & *source*)

Proceeds parsing of the document.

This is end-user method. You can simply call it when you need to obtain parsed output (which is parser-specific).

The method does these things:

1. calls InitParser(source)
2. calls DoParsing()
3. calls GetProduct()
4. calls DoneParser()
5. returns value returned by GetProduct()

You shouldn't use InitParser(), DoParsing(), GetProduct() or DoneParser() directly.

void wxHtmlParser::PopTagHandler ( )

Restores parser's state before last call to PushTagHandler().

void wxHtmlParser::PushTagHandler (wxHtmlTagHandler * *handler*, const wxString & *tags*)

Forces the handler to handle additional tags (not returned by wxHtmlTagHandler::GetSupportedTags).

The handler should already be added to this parser.

Parameters

handler	the handler
tags	List of tags (in same format as GetSupportedTags()'s return value). The parser will redirect these tags to handler (until call to PopTagHandler()).

Example:

Imagine you want to parse following pseudo-html structure:

```
<myitems>
    <param name="one" value="1">
    <param name="two" value="2">
</myitems>

<execute>
    <param program="text.exe">
</execute>
```

It is obvious that you cannot use only one tag handler for <param> tag. Instead you must use context-sensitive handlers for <param> inside <myitems> and <param> inside <execute>. This is the preferred solution:

```
TAG_HANDLER_BEGIN(MYITEM, "MYITEMS")
    TAG_HANDLER_PROC(tag)
    {
        // ...something...

        m_Parser -> PushTagHandler(this, "PARAM");
        ParseInner(tag);
        m_Parser -> PopTagHandler();

        // ...something...
    }
TAG_HANDLER_END(MYITEM)
```

void wxHtmlParser::SetFS (wxFileSystem * *fs*)

Sets the virtual file system that will be used to request additional files.

(For example `IMG` tag handler requests wxFSFile with the image data.)

virtual void wxHtmlParser::StopParsing ( ) [virtual]

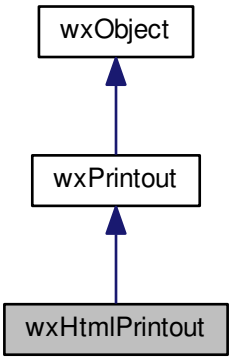
Call this function to interrupt parsing from a tag handler.

No more tags will be parsed afterward. This function may only be called from Parse() or any function called by it (i.e. from tag handlers).

21.373 wxHtmlPrintout Class Reference

`#include <wx/html/htmprint.h>`

Inheritance diagram for wxHtmlPrintout:



21.373.1 Detailed Description

This class serves as printout class for HTML documents.

Library: wxHTML

Category: HTML, Printing Framework

Public Member Functions

- wxHtmlPrintout (const wxString &title="Printout")

  Constructor.
- void SetFonts (const wxString &normal_face, const wxString &fixed_face, const int *sizes=NULL)

  This function sets font sizes and faces.
- void SetFooter (const wxString &footer, int pg=wxPAGE_ALL)

  Set page footer.
- void SetHeader (const wxString &header, int pg=wxPAGE_ALL)

  Set page header.
- void SetHtmlFile (const wxString &htmlfile)

*Prepare the class for printing this HTML **file**.*

- void SetHtmlText (const wxString &html, const wxString &basepath=wxEmptyString, bool isdir=true)

  Prepare the class for printing this HTML text.
- void SetMargins (float top=25.2, float bottom=25.2, float left=25.2, float right=25.2, float spaces=5)

  Sets margins in millimeters.

Static Public Member Functions

- static void AddFilter (wxHtmlFilter *filter)

  Adds a filter to the static list of filters for wxHtmlPrintout.

Additional Inherited Members

21.373.2 Constructor & Destructor Documentation

wxHtmlPrintout::wxHtmlPrintout (const wxString & *title* = "Printout")

Constructor.

21.373.3 Member Function Documentation

static void wxHtmlPrintout::AddFilter (wxHtmlFilter * *filter*) [static]

Adds a filter to the static list of filters for wxHtmlPrintout.

See wxHtmlFilter for further information.

void wxHtmlPrintout::SetFonts (const wxString & *normal_face*, const wxString & *fixed_face*, const int * *sizes* = NULL)

This function sets font sizes and faces.

See wxHtmlWindow::SetFonts for detailed description.

void wxHtmlPrintout::SetFooter (const wxString & *footer*, int *pg* = wxPAGE_ALL)

Set page footer.

The following macros can be used inside it:

- @DATE@ is replaced by the current date in default format
- @PAGENUM@ is replaced by page number
- @PAGESCNT@ is replaced by total number of pages
- @TIME@ is replaced by the current time in default format
- @TITLE@ is replaced with the title of the document

Parameters

footer	HTML text to be used as footer.
pg	one of wxPAGE_ODD, wxPAGE_EVEN and wxPAGE_ALL constants.

void wxHtmlPrintout::SetHeader (const wxString & *header,* int *pg* = wxPAGE_ALL)

Set page header.

The following macros can be used inside it:

- @DATE@ is replaced by the current date in default format
- @PAGENUM@ is replaced by page number
- @PAGESCNT@ is replaced by total number of pages
- @TIME@ is replaced by the current time in default format
- @TITLE@ is replaced with the title of the document

Parameters

header	HTML text to be used as header.
pg	one of wxPAGE_ODD, wxPAGE_EVEN and wxPAGE_ALL constants.

void wxHtmlPrintout::SetHtmlFile (const wxString & *htmlfile*)

Prepare the class for printing this HTML **file**.

The file may be located on any virtual file system or it may be normal file.

void wxHtmlPrintout::SetHtmlText (const wxString & *html,* const wxString & *basepath* = wxEmptyString, bool *isdir* = `true`)

Prepare the class for printing this HTML text.

Parameters

html	HTML text. (NOT file!)
basepath	base directory (html string would be stored there if it was in file). It is used to determine path for loading images, for example.
isdir	false if basepath is filename, true if it is directory name (see wxFileSystem for detailed explanation).

void wxHtmlPrintout::SetMargins (float *top* = `25.2`, float *bottom* = `25.2`, float *left* = `25.2`, float *right* = `25.2`, float *spaces* = `5`)

Sets margins in millimeters.

Defaults to 1 inch for margins and 0.5cm for space between text and header and/or footer.

21.374 wxHtmlRenderingInfo Class Reference

`#include <wx/html/htmlcell.h>`

21.374.1 Detailed Description

This class contains information given to cells when drawing them.

Contains rendering state, selection information and rendering style object that can be used to customize the output.

Library: wxHTML

Category: HTML

21.376 wxHtmlRenderingStyle Class Reference

`#include <wx/html/htmlcell.h>`

21.376.1 Detailed Description

wxHtmlSelection is data holder with information about text selection.

Allows HTML rendering customizations.

Selection is defined by two positions (beginning and end of the selection) and two leaf(!) cells at these positions.

Library: wxHTML

Category: HTML

This class is used when rendering wxHtmlCells as a callback.

Library: wxHTML

Category: HTML

21.378 wxHtmlTag Class Reference

`#include <wx/html/htmltag.h>`

21.378.1 Detailed Description

This class represents a single HTML tag.

It is used by tag handlers.

Library: wxHTML

Category: HTML

Public Member Functions

- wxString GetAllParams () const

  Returns a string containing all parameters.
- int GetBeginPos () const

  Returns beginning position of the text between this tag and paired ending tag.
- int GetEndPos1 () const

  Returns ending position of the text between this tag and paired ending tag.
- int GetEndPos2 () const

  Returns ending position 2 of the text between this tag and paired ending tag.
- wxString GetName () const

  Returns tag's name.
- wxString GetParam (const wxString &par, bool with_quotes=false) const

  Returns the value of the parameter.
- bool GetParamAsColour (const wxString &par, wxColour ∗clr) const

  Interprets tag parameter par as colour specification and saves its value into wxColour variable pointed by clr.
- bool GetParamAsInt (const wxString &par, int ∗value) const

  Interprets tag parameter par as an integer and saves its value into int variable pointed by value.
- bool GetParamAsString (const wxString &par, wxString ∗value) const

  Get the value of the parameter.
- bool HasEnding () const

  Returns true if this tag is paired with ending tag, false otherwise.
- bool HasParam (const wxString &par) const

  Returns true if the tag has a parameter of the given name.
- int ScanParam (const wxString &par, const wchar_t ∗format, void ∗value) const

  This method scans the given parameter.
- int ScanParam (const wxString &par, const char ∗format, void ∗value) const

  This method scans the given parameter.

Static Public Member Functions

- static bool ParseAsColour (const wxString &str, wxColour ∗clr)

  Parses the given string as an HTML colour.

Protected Member Functions

- wxHtmlTag (wxHtmlTag *parent, const wxString *source, const const_iterator &pos, const const_iterator &end_pos, wxHtmlTagsCache *cache, wxHtmlEntitiesParser *entParser)

  Constructor.

21.378.2 Constructor & Destructor Documentation

wxHtmlTag::wxHtmlTag (wxHtmlTag * *parent,* const wxString * *source,* const const_iterator & *pos,* const const_iterator & *end_pos,* wxHtmlTagsCache * *cache,* wxHtmlEntitiesParser * *entParser*) `[protected]`

Constructor.

You will probably never have to construct a wxHtmlTag object yourself. Feel free to ignore the constructor parameters. Have a look at `src/html/htmlpars.cpp` if you're interested in creating it.

21.378.3 Member Function Documentation

wxString wxHtmlTag::GetAllParams ( ) const

Returns a string containing all parameters.

Example: tag contains <FONT SIZE=+2 COLOR="#000000">. Call to tag.GetAllParams() would return `'SIZE=+2 COLOR="#000000"'`.

int wxHtmlTag::GetBeginPos ( ) const

Returns beginning position of the text *between* this tag and paired ending tag.

See explanation (returned position is marked with '|'):

```
bla bla bla <MYTAG> bla bla internal text</MYTAG> bla bla
                  |
```

Deprecated

Todo provide deprecation description

int wxHtmlTag::GetEndPos1 ( ) const

Returns ending position of the text *between* this tag and paired ending tag.

See explanation (returned position is marked with '|'):

```
bla bla bla <MYTAG> bla bla internal text</MYTAG> bla bla
                                          |
```

Deprecated

Todo provide deprecation description

int wxHtmlTag::GetEndPos2 ( ) const

Returns ending position 2 of the text *between* this tag and paired ending tag.

See explanation (returned position is marked with '|'):

```
bla bla bla <MYTAG> bla bla internal text</MYTAG> bla bla
                                                |
```

Deprecated

Todo provide deprecation description

wxString wxHtmlTag::GetName ( ) const

Returns tag's name.

The name is always in uppercase and it doesn't contain " or '/' characters. (So the name of <FONT SIZE=+2> tag is "FONT" and name of </table> is "TABLE").

wxString wxHtmlTag::GetParam (const wxString & *par*, bool *with_quotes* = `false`) const

Returns the value of the parameter.

You should check whether the parameter exists or not (use wxHtmlTag::HasParam) first or use GetParamAsString() if you need to distinguish between non-specified and empty parameter values.

Parameters

par	The parameter's name.
with_quotes	true if you want to get quotes as well. See example.

Example:

```
...
// you have wxHtmlTag variable tag which is equal to the
// HTML tag <FONT SIZE=+2 COLOR="#0000FF">
dummy = tag.GetParam("SIZE");
// dummy == "+2"
dummy = tag.GetParam("COLOR");
// dummy == "#0000FF"
dummy = tag.GetParam("COLOR", true);
// dummy == "\"#0000FF\"" -- see the difference!!
```

bool wxHtmlTag::GetParamAsColour (const wxString & *par*, wxColour * *clr*) const

Interprets tag parameter *par* as colour specification and saves its value into wxColour variable pointed by *clr*.

Returns true on success and false if *par* is not colour specification or if the tag has no such parameter.

See also

ParseAsColour()

bool wxHtmlTag::GetParamAsInt (const wxString & *par*, int * *value*) const

Interprets tag parameter *par* as an integer and saves its value into int variable pointed by *value*.

Returns true on success and false if *par* is not an integer or if the tag has no such parameter.

bool wxHtmlTag::GetParamAsString (const wxString & *par,* wxString * *value*) const

Get the value of the parameter.

If the tag doesn't have such parameter at all, simply returns false. Otherwise, fills *value* with the parameter value and returns true.

Parameters

par	The parameter's name.
value	Pointer to the string to be filled with the parameter value, must be non-NULL.

Since

3.0

bool wxHtmlTag::HasEnding ( ) const

Returns true if this tag is paired with ending tag, false otherwise.

See the example of HTML document:

```
<html><body>
Hello<p>
How are you?
<p align=center>This is centered...</p>
Oops<br>Oooops!
</body></html>
```

In this example tags HTML and BODY have ending tags, first P and BR doesn't have ending tag while the second P has. The third P tag (which is ending itself) of course doesn't have ending tag.

bool wxHtmlTag::HasParam (const wxString & *par*) const

Returns true if the tag has a parameter of the given name.

Example: <FONT SIZE=+2 COLOR="\#FF00FF"> has two parameters named "SIZE" and "COLOR".

Parameters

par	the parameter you're looking for.

static bool wxHtmlTag::ParseAsColour (const wxString & *str,* wxColour * *clr*) [static]

Parses the given string as an HTML colour.

This function recognizes the standard named HTML 4 colours as well as the usual RGB syntax.

Since

2.9.1

See also

wxColour::Set()

Returns

true if the string was successfully parsed and *clr* was filled with the result or false otherwise.

int wxHtmlTag::ScanParam (const wxString & *par,* const wchar_t * *format,* void * *value*) const

This method scans the given parameter.

Usage is exactly the same as sscanf's usage except that you don't pass a string but a parameter name as the first argument and you can only retrieve one value (i.e. you can use only one "%" element in *format*).

Parameters

par	The name of the tag you want to query
format	scanf()-like format string.
value	pointer to a variable to store the value in

int wxHtmlTag::ScanParam (const wxString & *par,* const char * *format,* void * *value*) const

This method scans the given parameter.

Usage is exactly the same as sscanf's usage except that you don't pass a string but a parameter name as the first argument and you can only retrieve one value (i.e. you can use only one "%" element in *format*).

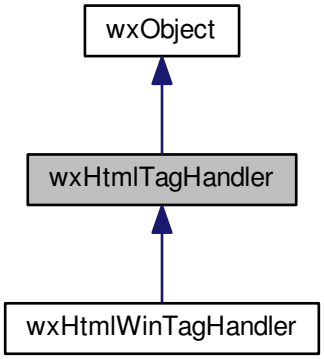
Parameters

par	The name of the tag you want to query
format	scanf()-like format string.
value	pointer to a variable to store the value in

21.379 wxHtmlTagHandler Class Reference

`#include <wx/html/htmlpars.h>`

Inheritance diagram for wxHtmlTagHandler:



21.379.1 Detailed Description

Todo describe me

Library: wxHTML

Category: HTML

See also

Tag Handlers, wxHtmlTag

Public Member Functions

- wxHtmlTagHandler ()

  Constructor.
- virtual wxString GetSupportedTags ()=0

  Returns list of supported tags.
- virtual bool HandleTag (const wxHtmlTag &tag)=0

  This is the core method of each handler.
- virtual void SetParser (wxHtmlParser *parser)

  Assigns parser to this handler.
- wxHtmlParser * GetParser () const

  Returns the parser associated with this tag handler.

Protected Member Functions

- void ParseInner (const wxHtmlTag &tag)

  This method calls parser's wxHtmlParser::DoParsing method for the string between this tag and the paired ending tag:
- void ParseInnerSource (const wxString &source)

  Parses given source as if it was tag's inner code (see wxHtmlParser::GetInnerSource).

Protected Attributes

- wxHtmlParser * m_Parser

  This attribute is used to access parent parser.

21.379.2 Constructor & Destructor Documentation

wxHtmlTagHandler::wxHtmlTagHandler ( )

Constructor.

21.379.3 Member Function Documentation

wxHtmlParser* wxHtmlTagHandler::GetParser ( ) const

Returns the parser associated with this tag handler.

Since

2.9.5

virtual wxString wxHtmlTagHandler::GetSupportedTags ( ) [pure virtual]

Returns list of supported tags.

The list is in uppercase and tags are delimited by ','. Example: `"I,B,FONT,P"`

virtual bool wxHtmlTagHandler::HandleTag (const wxHtmlTag & *tag*) [pure virtual]

This is the core method of each handler.

It is called each time one of supported tags is detected. *tag* contains all necessary info (see wxHtmlTag for details).

Example:

```
bool MyHandler::HandleTag(const wxHtmlTag& tag)
{
    ...
    // change state of parser (e.g. set bold face)
    ParseInner(tag);
    ...
    // restore original state of parser
}
```

You shouldn't call ParseInner() if the tag is not paired with an ending one.

Returns

true if ParseInner() was called, false otherwise.

void wxHtmlTagHandler::ParseInner (const wxHtmlTag & *tag*) [protected]

This method calls parser's wxHtmlParser::DoParsing method for the string between this tag and the paired ending tag:

```
...<A HREF="x.htm">Hello, world!</A>...
```

In this example, a call to ParseInner() (with *tag* pointing to A tag) will parse 'Hello, world!'.

void wxHtmlTagHandler::ParseInnerSource (const wxString & *source*) [protected]

Parses given source as if it was tag's inner code (see wxHtmlParser::GetInnerSource).

Unlike ParseInner(), this method lets you specify the source code to parse. This is useful when you need to modify the inner text before parsing.

virtual void wxHtmlTagHandler::SetParser (wxHtmlParser * *parser*) [virtual]

Assigns *parser* to this handler.

Each **instance** of handler is guaranteed to be called only from the one parser.

21.379.4 Member Data Documentation

wxHtmlParser* wxHtmlTagHandler::m_Parser [protected]

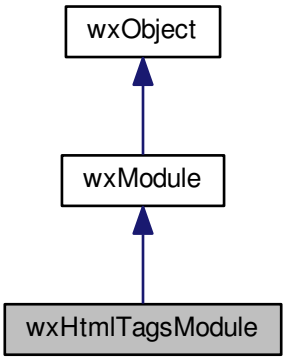
This attribute is used to access parent parser.

It is protected so that it can't be accessed by user but can be accessed from derived classes.

21.380 wxHtmlTagsModule Class Reference

`#include <wx/html/winpars.h>`

Inheritance diagram for wxHtmlTagsModule:



21.380.1 Detailed Description

This class provides easy way of filling wxHtmlWinParser's table of tag handlers.

It is used almost exclusively together with the set of TAGS_MODULE_* macros

Library: wxHTML

Category: HTML

See also

Tag Handlers, wxHtmlTagHandler, wxHtmlWinTagHandler

Public Member Functions

- virtual void FillHandlersTable (wxHtmlWinParser *parser)

  You must override this method.

Additional Inherited Members

21.380.2 Member Function Documentation

virtual void wxHtmlTagsModule::FillHandlersTable (wxHtmlWinParser * *parser*) `[virtual]`

You must override this method.

In most common case its body consists only of lines of the following type:

```
parser -> AddTagHandler(new MyHandler);
```

It's recommended to use the **TAGS_MODULE_*** macros.

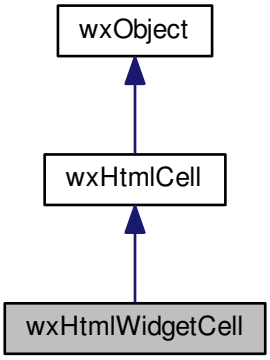
Parameters

parser	Pointer to the parser that requested tables filling.

21.381 wxHtmlWidgetCell Class Reference

`#include <wx/html/htmlcell.h>`

Inheritance diagram for wxHtmlWidgetCell:



21.381.1 Detailed Description

wxHtmlWidgetCell is a class that provides a connection between HTML cells and widgets (an object derived from wxWindow).

You can use it to display things like forms, input boxes etc. in an HTML window.

wxHtmlWidgetCell takes care of resizing and moving window.

Library: wxHTML

Category: HTML

Public Member Functions

- wxHtmlWidgetCell (wxWindow *wnd, int w=0)

  Constructor.

Additional Inherited Members

21.381.2 Constructor & Destructor Documentation

wxHtmlWidgetCell::wxHtmlWidgetCell (wxWindow * *wnd*, int *w* = 0)

Constructor.

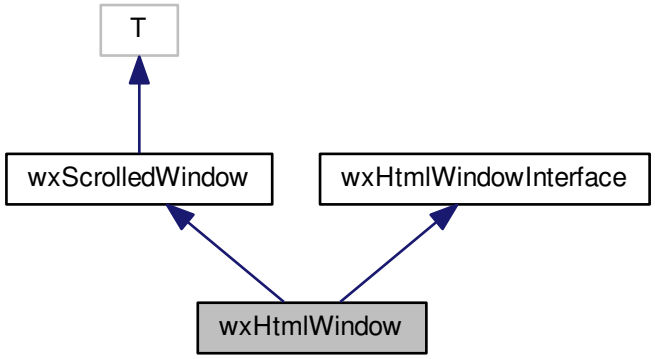
Parameters

wnd	Connected window. It is parent window **must** be the wxHtmlWindow object within which it is displayed!
w	Floating width. If non-zero width of wnd window is adjusted so that it is always w percents of parent container's width. (For example w = 100 means that the window will always have same width as parent container).

21.382 wxHtmlWindow Class Reference

`#include <wx/html/htmlwin.h>`

Inheritance diagram for wxHtmlWindow:



21.382.1 Detailed Description

wxHtmlWindow is probably the only class you will directly use unless you want to do something special (like adding new tag handlers or MIME filters).

The purpose of this class is to display rich content pages (either local file or downloaded via HTTP protocol) in a window based on a subset of the HTML standard. The width of the window is constant - given in the constructor - and virtual height is changed dynamically depending on page size. Once the window is created you can set its content by calling SetPage() with raw HTML, LoadPage() with a wxFileSystem location or LoadFile() with a filename.

Note

If you want complete HTML/CSS support as well as a Javascript engine, see instead wxWebView.
wxHtmlWindow uses the wxImage class for displaying images, as such you need to initialize the handlers for any image formats you use before loading a page. See wxInitAllImageHandlers and wxImage::AddHandler.

Styles

This class supports the following styles:

- wxHW_SCROLLBAR_NEVER: Never display scrollbars, not even when the page is larger than the window.
- wxHW_SCROLLBAR_AUTO: Display scrollbars only if page's size exceeds window's size.

- wxHW_NO_SELECTION: Don't allow the user to select text.

Events emitted by this class

The following event handler macros redirect the events to member function handlers '**func**' with prototypes like: void handlerFuncName(wxHtmlCellEvent& event) or void handlerFuncName(wxHtmlLinkEvent& event)

Event macros for events emitted by this class:

- EVT_HTML_CELL_CLICKED(id, func): A wxHtmlCell was clicked.
- EVT_HTML_CELL_HOVER(id, func): The mouse passed over a wxHtmlCell.
- EVT_HTML_LINK_CLICKED(id, func): A wxHtmlCell which contains an hyperlink was clicked.

Library: wxHTML

Category: HTML

See also

wxHtmlLinkEvent, wxHtmlCellEvent

Public Member Functions

- wxHtmlWindow ()

  Default ctor.
- wxHtmlWindow (wxWindow *parent, wxWindowID id=wxID_ANY, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, long style=wxHW_DEFAULT_STYLE, const wxString &name="html↩ Window")

  Constructor.
- bool AppendToPage (const wxString &source)

  Appends HTML fragment to currently displayed text and refreshes the window.
- wxHtmlContainerCell * GetInternalRepresentation () const

  Returns pointer to the top-level container.
- wxString GetOpenedAnchor () const

  Returns anchor within currently opened page (see wxHtmlWindow::GetOpenedPage).
- wxString GetOpenedPage () const

  Returns full location of the opened page.
- wxString GetOpenedPageTitle () const

  Returns title of the opened page or wxEmptyString if the current page does not contain <TITLE> tag.
- wxFrame * GetRelatedFrame () const

  Returns the related frame.
- bool HistoryBack ()

  Moves back to the previous page.
- bool HistoryCanBack ()

  Returns true if it is possible to go back in the history i.e.
- bool HistoryCanForward ()

  Returns true if it is possible to go forward in the history i.e.
- void HistoryClear ()

  Clears history.
- bool HistoryForward ()

Moves to next page in history.

- bool LoadFile (const wxFileName &filename)

  Loads an HTML page from a file and displays it.
- virtual bool LoadPage (const wxString &location)

  Unlike SetPage() this function first loads the HTML page from location and then displays it.
- virtual void OnLinkClicked (const wxHtmlLinkInfo &link)

  Called when user clicks on hypertext link.
- virtual wxHtmlOpeningStatus OnOpeningURL (wxHtmlURLType type, const wxString &url, wxString *redirect) const

  Called when an URL is being opened (either when the user clicks on a link or an image is loaded).
- virtual void OnSetTitle (const wxString &title)

  Called on parsing <TITLE> tag.
- virtual void ReadCustomization (wxConfigBase *cfg, wxString path=wxEmptyString)

  This reads custom settings from wxConfig.
- void SelectAll ()

  Selects all text in the window.
- void SelectLine (const wxPoint &pos)

  Selects the line of text that pos points at.
- void SelectWord (const wxPoint &pos)

  Selects the word at position pos.
- wxString SelectionToText ()

  Returns the current selection as plain text.
- void SetBorders (int b)

  This function sets the space between border of window and HTML contents.
- void SetFonts (const wxString &normal_face, const wxString &fixed_face, const int *sizes=NULL)

  This function sets font sizes and faces.
- void SetStandardFonts (int size=-1, const wxString &normal_face=wxEmptyString, const wxString &fixed_face=wxEmptyString)

  Sets default font sizes and/or default font size.
- virtual bool SetPage (const wxString &source)

  Sets the source of a page and displays it, for example:
- void SetRelatedFrame (wxFrame *frame, const wxString &format)

  Sets the frame in which page title will be displayed.
- void SetRelatedStatusBar (int index)

  ***After** calling SetRelatedFrame(), this sets statusbar slot where messages will be displayed.*
- void SetRelatedStatusBar (wxStatusBar *statusbar, int index=0)

  ***Sets** the associated statusbar where messages will be displayed.*
- wxString ToText ()

  Returns content of currently displayed page as plain text.
- virtual void WriteCustomization (wxConfigBase *cfg, wxString path=wxEmptyString)

  Saves custom settings into wxConfig.

Static Public Member Functions

- static void AddFilter (wxHtmlFilter *filter)

  Adds input filter to the static list of available filters.
- static wxCursor GetDefaultHTMLCursor (HTMLCursor type)

  Retrieves the default cursor for a given HTMLCursor type.
- static void SetDefaultHTMLCursor (HTMLCursor type, const wxCursor &cursor)

  Sets the default cursor for a given HTMLCursor type.

Protected Member Functions

- virtual bool OnCellClicked (wxHtmlCell *cell, wxCoord x, wxCoord y, const wxMouseEvent &event)

  This method is called when a mouse button is clicked inside wxHtmlWindow.
- virtual void OnCellMouseHover (wxHtmlCell *cell, wxCoord x, wxCoord y)

  This method is called when a mouse moves over an HTML cell.

Additional Inherited Members

21.382.2 Constructor & Destructor Documentation

wxHtmlWindow::wxHtmlWindow ( )

Default ctor.

wxHtmlWindow::wxHtmlWindow (wxWindow * *parent*, wxWindowID *id* = wxID_ANY, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, long *style* = wxHW_DEFAULT_STYLE, const wxString & *name* = "htmlWindow")

Constructor.

The parameters are the same as wxScrolled::wxScrolled() constructor.

21.382.3 Member Function Documentation

static void wxHtmlWindow::AddFilter (wxHtmlFilter * *filter*) [static]

Adds input filter to the static list of available filters.

These filters are present by default:

- text/html MIME type
- image/* MIME types
- Plain Text filter (this filter is used if no other filter matches)

bool wxHtmlWindow::AppendToPage (const wxString & *source*)

Appends HTML fragment to currently displayed text and refreshes the window.

Parameters

source	HTML code fragment

Returns

false if an error occurred, true otherwise.

static wxCursor wxHtmlWindow::GetDefaultHTMLCursor (HTMLCursor *type*) [static]

Retrieves the default cursor for a given HTMLCursor type.

Parameters

type	HTMLCursor type to retrieve.

Since

3.1.0

wxHtmlContainerCell* **wxHtmlWindow::GetInternalRepresentation ( ) const**

Returns pointer to the top-level container.

See also

Cells and Containers, Printing Framework Overview

wxString wxHtmlWindow::GetOpenedAnchor ( ) const

Returns anchor within currently opened page (see wxHtmlWindow::GetOpenedPage).

If no page is opened or if the displayed page wasn't produced by call to LoadPage(), empty string is returned.

wxString wxHtmlWindow::GetOpenedPage ( ) const

Returns full location of the opened page.

If no page is opened or if the displayed page wasn't produced by call to LoadPage(), empty string is returned.

wxString wxHtmlWindow::GetOpenedPageTitle ( ) const

Returns title of the opened page or wxEmptyString if the current page does not contain <TITLE> tag.

wxFrame* **wxHtmlWindow::GetRelatedFrame ( ) const**

Returns the related frame.

bool wxHtmlWindow::HistoryBack ( )

Moves back to the previous page.

Only pages displayed using LoadPage() are stored in history list.

bool wxHtmlWindow::HistoryCanBack ( )

Returns true if it is possible to go back in the history i.e.

HistoryBack() won't fail.

bool wxHtmlWindow::HistoryCanForward ( )

Returns true if it is possible to go forward in the history i.e.

HistoryForward() won't fail.

void wxHtmlWindow::HistoryClear ( )

Clears history.

bool wxHtmlWindow::HistoryForward ( )

Moves to next page in history.

Only pages displayed using LoadPage() are stored in history list.

bool wxHtmlWindow::LoadFile (const wxFileName & *filename*)

Loads an HTML page from a file and displays it.

Returns

false if an error occurred, true otherwise

See also

LoadPage()

virtual bool wxHtmlWindow::LoadPage (const wxString & *location*) [virtual]

Unlike SetPage() this function first loads the HTML page from *location* and then displays it.

Parameters

location	The address of the document. See the wxFileSystem Overview for details on the address format and wxFileSystem for a description of how the file is opened.

Returns

false if an error occurred, true otherwise

See also

LoadFile()

virtual bool wxHtmlWindow::OnCellClicked (wxHtmlCell * *cell*, wxCoord *x*, wxCoord *y*, const wxMouseEvent & *event*) [protected], [virtual]

This method is called when a mouse button is clicked inside wxHtmlWindow.

The default behaviour is to emit a wxHtmlCellEvent and, if the event was not processed or skipped, call OnLink↩Clicked() if the cell contains an hypertext link.

Overloading this method is deprecated; intercept the event instead.

Parameters

cell	The cell inside which the mouse was clicked, always a simple (i.e. non-container) cell

x	The logical x coordinate of the click point
y	The logical y coordinate of the click point
event	The mouse event containing other information about the click

Returns

true if a link was clicked, false otherwise.

virtual void wxHtmlWindow::OnCellMouseHover (wxHtmlCell * *cell*, wxCoord *x*, wxCoord *y*) [protected], [virtual]

This method is called when a mouse moves over an HTML cell.

Default behaviour is to emit a wxHtmlCellEvent.

Overloading this method is deprecated; intercept the event instead.

Parameters

cell	The cell inside which the mouse is currently, always a simple (i.e. non-container) cell
x	The logical x coordinate of the click point
y	The logical y coordinate of the click point

virtual void wxHtmlWindow::OnLinkClicked (const wxHtmlLinkInfo & *link*) [virtual]

Called when user clicks on hypertext link.

Default behaviour is to emit a wxHtmlLinkEvent and, if the event was not processed or skipped, call LoadPage() and do nothing else.

Overloading this method is deprecated; intercept the event instead.

Also see wxHtmlLinkInfo.

virtual wxHtmlOpeningStatus wxHtmlWindow::OnOpeningURL (wxHtmlURLType *type*, const wxString & *url*, wxString * *redirect*) const [virtual]

Called when an URL is being opened (either when the user clicks on a link or an image is loaded).

The URL will be opened only if OnOpeningURL() returns `wxHTML_OPEN`. This method is called by wxHtmlParser::OpenURL.

You can override OnOpeningURL() to selectively block some URLs (e.g. for security reasons) or to redirect them elsewhere. Default behaviour is to always return `wxHTML_OPEN`.

Parameters

type	Indicates type of the resource. Is one of • wxHTML_URL_PAGE: Opening a HTML page. • wxHTML_URL_IMAGE: Opening an image. • wxHTML_URL_OTHER: Opening a resource that doesn't fall into any other category.

url	URL being opened.
redirect	Pointer to wxString variable that must be filled with an URL if OnOpeningURL() returns `wx↩HTML_REDIRECT`.

The return value is:

- wxHTML_OPEN: Open the URL.
- wxHTML_BLOCK: Deny access to the URL, wxHtmlParser::OpenURL will return NULL.
- wxHTML_REDIRECT: Don't open url, redirect to another URL. OnOpeningURL() must fill *redirect with the new URL. OnOpeningURL() will be called again on returned URL.

virtual void wxHtmlWindow::OnSetTitle (const wxString & *title*) [virtual]

Called on parsing <TITLE> tag.

virtual void wxHtmlWindow::ReadCustomization (wxConfigBase * *cfg*, wxString *path* = wxEmptyString) [virtual]

This reads custom settings from wxConfig.

It uses the path 'path' if given, otherwise it saves info into currently selected path. The values are stored in sub-path `wxHtmlWindow`. Read values: all things set by SetFonts(), SetBorders().

Parameters

cfg	wxConfig from which you want to read the configuration.
path	Optional path in config tree. If not given current path is used.

void wxHtmlWindow::SelectAll ( )

Selects all text in the window.

See also

SelectLine(), SelectWord()

wxString wxHtmlWindow::SelectionToText ( )

Returns the current selection as plain text.

Returns an empty string if no text is currently selected.

void wxHtmlWindow::SelectLine (const wxPoint & *pos*)

Selects the line of text that *pos* points at.

Note that *pos* is relative to the top of displayed page, not to window's origin, use wxScrolled::CalcUnscrolled↩Position() to convert physical coordinate.

See also

SelectAll(), SelectWord()

void wxHtmlWindow::SelectWord (const wxPoint & *pos*)

Selects the word at position *pos*.

Note that *pos* is relative to the top of displayed page, not to window's origin, use wxScrolled::CalcUnscrolled↩ Position() to convert physical coordinate.

See also

SelectAll(), SelectLine()

void wxHtmlWindow::SetBorders (int *b*)

This function sets the space between border of window and HTML contents.

See image:

Parameters

b	indentation from borders in pixels

static void wxHtmlWindow::SetDefaultHTMLCursor (HTMLCursor *type*, const wxCursor & *cursor*) [static]

Sets the default cursor for a given HTMLCursor type.

These cursors are used for all wxHtmlWindow objects by default, but can be overridden on a per-window basis.

Parameters

type	HTMLCursor type to retrieve.
cursor	The default cursor for the specified cursor type.

Since

3.1.0

void wxHtmlWindow::SetFonts (const wxString & *normal_face*, const wxString & *fixed_face*, const int * *sizes* = NULL)

This function sets font sizes and faces.

See wxHtmlDCRenderer::SetFonts for detailed description.

See also

SetSize()

virtual bool wxHtmlWindow::SetPage (const wxString & *source*) [virtual]

Sets the source of a page and displays it, for example:

```
htmlwin -> SetPage("<html><body>Hello, world!</body></html>");
```

If you want to load a document from some location use LoadPage() instead.

Parameters

source	The HTML to be displayed.

Returns

false if an error occurred, true otherwise.

void wxHtmlWindow::SetRelatedFrame (wxFrame * *frame*, const wxString & *format*)

Sets the frame in which page title will be displayed.

format is the format of the frame title, e.g. "HtmlHelp : %s". It must contain exactly one s. This s is substituted with HTML page title.

void wxHtmlWindow::SetRelatedStatusBar (int *index*)

After calling SetRelatedFrame(), this sets statusbar slot where messages will be displayed.

(Default is -1 = no messages.)

Parameters

index	Statusbar slot number (0..n)

void wxHtmlWindow::SetRelatedStatusBar (wxStatusBar * *statusbar*, int *index* = 0)

Sets the associated statusbar where messages will be displayed.

Call this instead of SetRelatedFrame() if you want statusbar updates only, no changing of the frame title.

Parameters

statusbar	Statusbar pointer
index	Statusbar slot number (0..n)

Since

2.9.0

void wxHtmlWindow::SetStandardFonts (int *size* = -1, const wxString & *normal_face* = wxEmptyString, const wxString & *fixed_face* = wxEmptyString)

Sets default font sizes and/or default font size.

See wxHtmlDCRenderer::SetStandardFonts for detailed description.

See also

SetFonts()

wxString wxHtmlWindow::ToText ( )

Returns content of currently displayed page as plain text.

virtual void wxHtmlWindow::WriteCustomization (wxConfigBase * *cfg*, wxString *path* = wxEmptyString) [virtual]

Saves custom settings into wxConfig.

It uses the path 'path' if given, otherwise it saves info into currently selected path. Regardless of whether the path is given or not, the function creates sub-path wxHtmlWindow.

Saved values: all things set by SetFonts(), SetBorders().

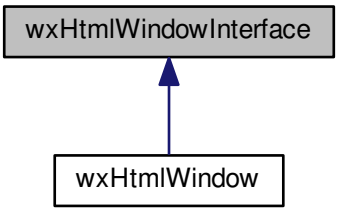
Parameters

cfg	wxConfig to which you want to save the configuration.
path	Optional path in config tree. If not given, the current path is used.

21.383 wxHtmlWindowInterface Class Reference

#include <wx/html/htmlwin.h>

Inheritance diagram for wxHtmlWindowInterface:



21.383.1 Detailed Description

Abstract interface to a HTML rendering window (such as wxHtmlWindow or wxHtmlListBox) that is passed to wxHtmlWinParser.

It encapsulates all communication from the parser to the window.

Public Types

- enum HTMLCursor {
  HTMLCursor_Default,
  HTMLCursor_Link,
  HTMLCursor_Text }

  Type of mouse cursor.

Public Member Functions

- wxHtmlWindowInterface ()

  Ctor.
- virtual ~wxHtmlWindowInterface ()

- virtual void SetHTMLWindowTitle (const wxString &title)=0

  Called by the parser to set window's title to given text.
- virtual void OnHTMLLinkClicked (const wxHtmlLinkInfo &link)=0

  Called when a link is clicked.
- virtual wxHtmlOpeningStatus OnHTMLOpeningURL (wxHtmlURLType type, const wxString &url, wxString *redirect) const =0

  Called when the parser needs to open another URL (e.g.
- virtual wxPoint HTMLCoordsToWindow (wxHtmlCell *cell, const wxPoint &pos) const =0

  Converts coordinates pos relative to given cell to physical coordinates in the window.
- virtual wxWindow * GetHTMLWindow ()=0

  Returns the window used for rendering (may be NULL).
- virtual wxColour GetHTMLBackgroundColour () const =0

  Returns background colour to use by default.
- virtual void SetHTMLBackgroundColour (const wxColour &clr)=0

  Sets window's background to colour clr.
- virtual void SetHTMLBackgroundImage (const wxBitmap &bmpBg)=0

  Sets window's background to given bitmap.
- virtual void SetHTMLStatusText (const wxString &text)=0

  Sets status bar text.
- virtual wxCursor GetHTMLCursor (wxHtmlWindowInterface::HTMLCursor type) const =0

  Returns mouse cursor of given type.

21.383.2 Member Enumeration Documentation

enum wxHtmlWindowInterface::HTMLCursor

Type of mouse cursor.

Enumerator

HTMLCursor_Default Standard mouse cursor (typically an arrow)

HTMLCursor_Link Cursor shown over links.

HTMLCursor_Text Cursor shown over selectable text.

21.383.3 Constructor & Destructor Documentation

wxHtmlWindowInterface::wxHtmlWindowInterface ( )

Ctor.

virtual wxHtmlWindowInterface::~wxHtmlWindowInterface ( ) [virtual]

21.383.4 Member Function Documentation

virtual wxColour wxHtmlWindowInterface::GetHTMLBackgroundColour ( ) const [pure virtual]

Returns background colour to use by default.

virtual wxCursor wxHtmlWindowInterface::GetHTMLCursor (wxHtmlWindowInterface::HTMLCursor *type*) const [pure virtual]

Returns mouse cursor of given *type*.

virtual wxWindow* wxHtmlWindowInterface::GetHTMLWindow ( ) [pure virtual]

Returns the window used for rendering (may be NULL).

virtual wxPoint wxHtmlWindowInterface::HTMLCoordsToWindow (wxHtmlCell * *cell,* const wxPoint & *pos*) const [pure virtual]

Converts coordinates *pos* relative to given *cell* to physical coordinates in the window.

virtual void wxHtmlWindowInterface::OnHTMLLinkClicked (const wxHtmlLinkInfo & *link*) [pure virtual]

Called when a link is clicked.

Parameters

link	information about the clicked link

virtual wxHtmlOpeningStatus wxHtmlWindowInterface::OnHTMLOpeningURL (wxHtmlURLType *type,* const wxString & *url,* wxString * *redirect*) const [pure virtual]

Called when the parser needs to open another URL (e.g.

an image).

Parameters

type	Type of the URL request (e.g. image)
url	URL the parser wants to open
redirect	If the return value is wxHTML_REDIRECT, then the URL to redirect to will be stored in this variable (the pointer must never be NULL)

Returns

indicator of how to treat the request

virtual void wxHtmlWindowInterface::SetHTMLBackgroundColour (const wxColour & *clr*) [pure virtual]

Sets window's background to colour *clr*.

virtual void wxHtmlWindowInterface::SetHTMLBackgroundImage (const wxBitmap & *bmpBg*) [pure virtual]

Sets window's background to given bitmap.

virtual void wxHtmlWindowInterface::SetHTMLStatusText (const wxString & *text*) [pure virtual]

Sets status bar text.

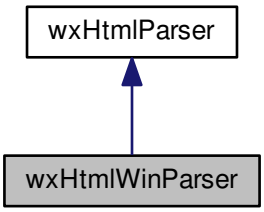
virtual void wxHtmlWindowInterface::SetHTMLWindowTitle (const wxString & *title*) [pure virtual]

Called by the parser to set window's title to given text.

21.384 wxHtmlWinParser Class Reference

`#include <wx/html/winpars.h>`

Inheritance diagram for wxHtmlWinParser:



21.384.1 Detailed Description

This class is derived from wxHtmlParser and its main goal is to parse HTML input so that it can be displayed in wxHtmlWindow.

It uses a special wxHtmlWinTagHandler.

Note

The product of parsing is a wxHtmlCell (resp. wxHtmlContainer) object.

Library: wxHTML

Category: HTML

See also

Tag Handlers

Public Member Functions

- wxHtmlWinParser (wxHtmlWindowInterface *wndIface=NULL)

  Constructor.
- wxHtmlContainerCell * CloseContainer ()

  Closes the container, sets actual container to the parent one and returns pointer to it (see Cells and Containers).
- virtual wxFont * CreateCurrentFont ()

  Creates font based on current setting (see SetFontSize(), SetFontBold(), SetFontItalic(), SetFontFixed(), wxHtmlWinParser::SetFontUnderlined) and returns pointer to it.
- const wxColour & GetActualColor () const

  Returns actual text colour.
- int GetAlign () const

  Returns default horizontal alignment.
- int GetCharHeight () const

Returns (average) char height in standard font.

- int GetCharWidth () const

  Returns average char width in standard font.

- wxHtmlContainerCell * GetContainer () const

  Returns pointer to the currently opened container (see Cells and Containers).

- wxDC * GetDC ()

  Returns pointer to the DC used during parsing.

- wxEncodingConverter * GetEncodingConverter () const

  Returns wxEncodingConverter class used to do conversion between the input encoding and the output encoding.

- int GetFontBold () const

  Returns true if actual font is bold, false otherwise.

- wxString GetFontFace () const

  Returns actual font face name.

- int GetFontFixed () const

  Returns true if actual font is fixed face, false otherwise.

- int GetFontItalic () const

  Returns true if actual font is italic, false otherwise.

- int GetFontSize () const

  Returns actual font size (HTML size varies from -2 to +4)

- int GetFontUnderlined () const

  Returns true if actual font is underlined, false otherwise.

- wxFontEncoding GetInputEncoding () const

  Returns input encoding.

- const wxHtmlLinkInfo & GetLink () const

  Returns actual hypertext link.

- const wxColour & GetLinkColor () const

  Returns the colour of hypertext link text.

- wxFontEncoding GetOutputEncoding () const

  Returns output encoding, i.e.

- wxHtmlWindowInterface * GetWindowInterface ()

  Returns associated window (wxHtmlWindow).

- wxHtmlContainerCell * OpenContainer ()

  Opens new container and returns pointer to it (see Cells and Containers).

- void SetActualColor (const wxColour &clr)

  Sets actual text colour.

- void SetAlign (int a)

  Sets default horizontal alignment (see wxHtmlContainerCell::SetAlignHor).

- wxHtmlContainerCell * SetContainer (wxHtmlContainerCell *c)

  Allows you to directly set opened container.

- virtual void SetDC (wxDC *dc, double pixel_scale=1.0e+0)

  Sets the DC.

- void SetFontBold (int x)

  Sets bold flag of actualfont.

- void SetFontFace (const wxString &face)

  Sets current font face to face.

- void SetFontFixed (int x)

  Sets fixed face flag of actualfont.

- void SetFontItalic (int x)

  Sets italic flag of actualfont.

- void SetFontSize (int s)

  Sets actual font size (HTML size varies from 1 to 7).

- void SetFontUnderlined (int x)

  Sets underlined flag of actualfont.
- void SetFonts (const wxString &normal_face, const wxString &fixed_face, const int *sizes=0)

  Sets fonts.
- void SetInputEncoding (wxFontEncoding enc)

  Sets input encoding.
- void SetLink (const wxHtmlLinkInfo &link)

  Sets actual hypertext link.
- void SetLinkColor (const wxColour &clr)

  Sets colour of hypertext link.

Static Public Member Functions

- static void AddModule (wxHtmlTagsModule *module)

  Adds module() to the list of wxHtmlWinParser tag handler.

Additional Inherited Members

21.384.2 Constructor & Destructor Documentation

wxHtmlWinParser::wxHtmlWinParser (wxHtmlWindowInterface * *wndIface* = NULL)

Constructor.

Don't use the default one, use the constructor with *wndIface* parameter (*wndIface* is a pointer to interface object for the associated wxHtmlWindow or other HTML rendering window such as wxHtmlListBox).

21.384.3 Member Function Documentation

static void wxHtmlWinParser::AddModule (wxHtmlTagsModule * *module*) [static]

Adds module() to the list of wxHtmlWinParser tag handler.

wxHtmlContainerCell* wxHtmlWinParser::CloseContainer ( )

Closes the container, sets actual container to the parent one and returns pointer to it (see Cells and Containers).

virtual wxFont* wxHtmlWinParser::CreateCurrentFont ( ) [virtual]

Creates font based on current setting (see SetFontSize(), SetFontBold(), SetFontItalic(), SetFontFixed(), wxHtmlWinParser::SetFontUnderlined) and returns pointer to it.

If the font was already created only a pointer is returned.

const wxColour& wxHtmlWinParser::GetActualColor ( ) const

Returns actual text colour.

int wxHtmlWinParser::GetAlign ( ) const

Returns default horizontal alignment.

int wxHtmlWinParser::GetCharHeight ( ) const

Returns (average) char height in standard font.

It is used as DC-independent metrics.

Note

This function doesn't return the *actual* height. If you want to know the height of the current font, call `GetDC->GetCharHeight()`.

int wxHtmlWinParser::GetCharWidth ( ) const

Returns average char width in standard font.

It is used as DC-independent metrics.

Note

This function doesn't return the *actual* width. If you want to know the height of the current font, call `GetDC->GetCharWidth()`.

wxHtmlContainerCell* wxHtmlWinParser::GetContainer ( ) const

Returns pointer to the currently opened container (see Cells and Containers).

Common use:

```
m_WParser -> GetContainer() -> InsertCell(new ...);
```

wxDC* wxHtmlWinParser::GetDC ( )

Returns pointer to the DC used during parsing.

wxEncodingConverter* wxHtmlWinParser::GetEncodingConverter ( ) const

Returns wxEncodingConverter class used to do conversion between the input encoding and the output encoding.

int wxHtmlWinParser::GetFontBold ( ) const

Returns true if actual font is bold, false otherwise.

wxString wxHtmlWinParser::GetFontFace ( ) const

Returns actual font face name.

int wxHtmlWinParser::GetFontFixed ( ) const

Returns true if actual font is fixed face, false otherwise.

int wxHtmlWinParser::GetFontItalic ( ) const

Returns true if actual font is italic, false otherwise.

int wxHtmlWinParser::GetFontSize ( ) const

Returns actual font size (HTML size varies from -2 to +4)

int wxHtmlWinParser::GetFontUnderlined ( ) const

Returns true if actual font is underlined, false otherwise.

wxFontEncoding wxHtmlWinParser::GetInputEncoding ( ) const

Returns input encoding.

const wxHtmlLinkInfo& wxHtmlWinParser::GetLink ( ) const

Returns actual hypertext link.

(This value has a non-empty wxHtmlLinkInfo::GetHref Href string if the parser is between <A> and </A> tags, wxEmptyString otherwise.)

const wxColour& wxHtmlWinParser::GetLinkColor ( ) const

Returns the colour of hypertext link text.

wxFontEncoding wxHtmlWinParser::GetOutputEncoding ( ) const

Returns output encoding, i.e.

closest match to document's input encoding that is supported by operating system.

wxHtmlWindowInterface* wxHtmlWinParser::GetWindowInterface ( )

Returns associated window (wxHtmlWindow).

This may be NULL! (You should always test if it is non-NULL. For example `TITLE` handler sets window title only if some window is associated, otherwise it does nothing.

wxHtmlContainerCell* wxHtmlWinParser::OpenContainer ( )

Opens new container and returns pointer to it (see Cells and Containers).

void wxHtmlWinParser::SetActualColor (const wxColour & *clr*)

Sets actual text colour.

Note: this DOESN'T change the colour! You must create wxHtmlColourCell yourself.

void wxHtmlWinParser::SetAlign (int *a*)

Sets default horizontal alignment (see wxHtmlContainerCell::SetAlignHor).

Alignment of newly opened container is set to this value.

wxHtmlContainerCell* wxHtmlWinParser::SetContainer (wxHtmlContainerCell * *c*)

Allows you to directly set opened container.

This is not recommended - you should use OpenContainer() wherever possible.

virtual void wxHtmlWinParser::SetDC (wxDC * *dc*, double *pixel_scale* = `1.0e+0`) [virtual]

Sets the DC.

This must be called before wxHtmlParser::Parse!

pixel_scale can be used when rendering to high-resolution DCs (e.g. printer) to adjust size of pixel metrics. (Many dimensions in HTML are given in pixels – e.g. image sizes. 300x300 image would be only one inch wide on typical printer. With pixel_scale = 3.0 it would be 3 inches.)

void wxHtmlWinParser::SetFontBold (int *x*)

Sets bold flag of actualfont.

x is either true of false.

void wxHtmlWinParser::SetFontFace (const wxString & *face*)

Sets current font face to *face*.

This affects either fixed size font or proportional, depending on context (whether the parser is inside `<TT>` tag or not).

void wxHtmlWinParser::SetFontFixed (int *x*)

Sets fixed face flag of actualfont.

x is either true of false.

void wxHtmlWinParser::SetFontItalic (int *x*)

Sets italic flag of actualfont.

x is either true of false.

void wxHtmlWinParser::SetFonts (const wxString & *normal_face*, const wxString & *fixed_face*, const int * *sizes* = `0`)

Sets fonts.

See wxHtmlWindow::SetFonts for detailed description.

void wxHtmlWinParser::SetFontSize (int *s*)

Sets actual font size (HTML size varies from 1 to 7).

void wxHtmlWinParser::SetFontUnderlined (int *x*)

Sets underlined flag of actualfont.

x is either true of false.

void wxHtmlWinParser::SetInputEncoding (wxFontEncoding *enc*)

Sets input encoding.

The parser uses this information to build conversion tables from document's encoding to some encoding supported by operating system.

void wxHtmlWinParser::SetLink (const wxHtmlLinkInfo & *link*)

Sets actual hypertext link.

Empty link is represented by wxHtmlLinkInfo with *Href* equal to wxEmptyString.

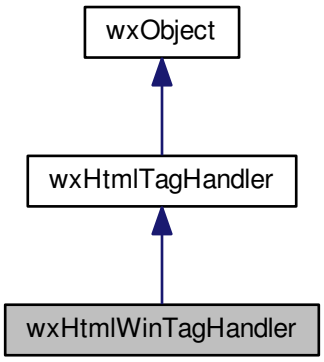
void wxHtmlWinParser::SetLinkColor (const wxColour & *clr*)

Sets colour of hypertext link.

21.385 wxHtmlWinTagHandler Class Reference

`#include <wx/html/winpars.h>`

Inheritance diagram for wxHtmlWinTagHandler:



21.385.1 Detailed Description

This is basically wxHtmlTagHandler except that it is extended with protected member m_WParser pointing to the wxHtmlWinParser object (value of this member is identical to wxHtmlParser's m_Parser).

Library: wxHTML

Category: HTML

Public Member Functions

- wxHtmlWinTagHandler ()

  Constructor.

- virtual void SetParser (wxHtmlWinParser *parser)

  Assigns parser to this handler.

Protected Attributes

- wxHtmlWinParser * m_WParser

  Value of this attribute is identical to value of m_Parser.

Additional Inherited Members

21.385.2 Constructor & Destructor Documentation

wxHtmlWinTagHandler::wxHtmlWinTagHandler ( )

Constructor.

21.385.3 Member Function Documentation

virtual void wxHtmlWinTagHandler::SetParser (wxHtmlWinParser * *parser*) `[virtual]`

Assigns *parser* to this handler.

Each **instance** of handler is guaranteed to be called only from the one parser.

21.385.4 Member Data Documentation

wxHtmlWinParser* wxHtmlWinTagHandler::m_WParser `[protected]`

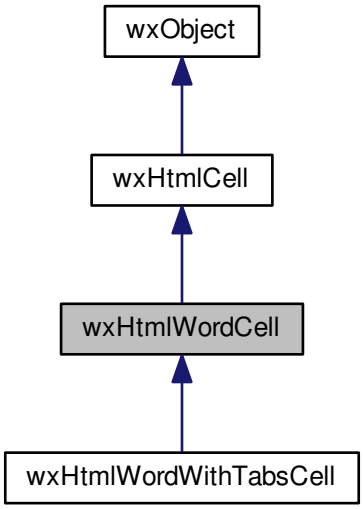
Value of this attribute is identical to value of m_Parser.

The only difference is that m_WParser points to wxHtmlWinParser object while m_Parser points to wxHtmlParser object. (The same object, but overcast.)

21.386 wxHtmlWordCell Class Reference

`#include <wx/html/htmlcell.h>`

Inheritance diagram for wxHtmlWordCell:



21.386.1 Detailed Description

This html cell represents a single word or text fragment in the document stream.

Library: wxHTML

Category: HTML

Public Member Functions

- wxHtmlWordCell (const wxString &word, const wxDC &dc)

Additional Inherited Members

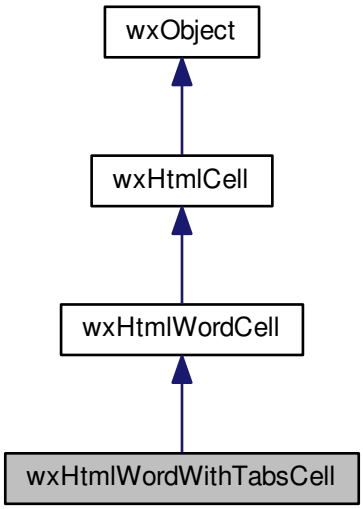
21.386.2 Constructor & Destructor Documentation

wxHtmlWordCell::wxHtmlWordCell (const wxString & *word,* const wxDC & *dc*)

21.387 wxHtmlWordWithTabsCell Class Reference

```
#include <wx/html/htmlcell.h>
```

Inheritance diagram for wxHtmlWordWithTabsCell:



21.387.1 Detailed Description

wxHtmlWordCell is a specialization for storing text fragments with embedded tab characters.

Library: wxHTML

Category: HTML

Public Member Functions

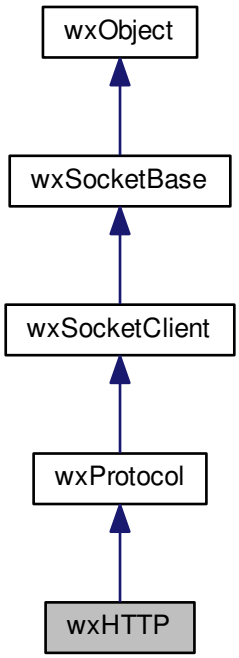
21.388 wxHTTP Class Reference

```
#include <wx/protocol/http.h>
```

Inheritance diagram for wxHTTP:



21.388.1 Detailed Description

wxHTTP can be used to establish a connection to an HTTP server.

wxHTTP can thus be used to create a (basic) HTTP **client**.

Library: wxNet

Category: Networking

See also

wxSocketBase, wxURL

Public Member Functions

- wxHTTP ()

  Default constructor.
- virtual ~wxHTTP ()

  Destructor will close the connection if connected.
- wxString GetHeader (const wxString &header) const

  Returns the data attached with a field whose name is specified by header.
- virtual wxInputStream * GetInputStream (const wxString &path)

Creates a new input stream on the specified path.

- int GetResponse () const

  Returns the HTTP response code returned by the server.

- void SetMethod (const wxString &method)

  Set HTTP method.

- void SetHeader (const wxString &header, const wxString &h_data)

  It sets data of a field to be sent during the next request to the HTTP server.

- wxString GetCookie (const wxString &cookie) const

  Returns the value of a cookie.

- bool HasCookies () const

  Returns true if there were cookies.

- bool SetPostBuffer (const wxString &contentType, const wxMemoryBuffer &data)

  Set the binary data to be posted to the server.

- bool SetPostText (const wxString &contentType, const wxString &data, const wxMBConv &conv=wxConvU↩ TF8)

  Set the text to be posted to the server.

- virtual bool Connect (const wxString &host)

  Connect to the HTTP server.

- virtual bool Connect (const wxString &host, unsigned short port)

  Connect to the HTTP server.

- virtual bool Connect (const wxSockAddress &addr, bool wait)

  Connect to the HTTP server.

Additional Inherited Members

21.388.2 Constructor & Destructor Documentation

wxHTTP::wxHTTP ( )

Default constructor.

virtual wxHTTP::~wxHTTP ( ) [virtual]

Destructor will close the connection if connected.

21.388.3 Member Function Documentation

virtual bool wxHTTP::Connect (const wxString & *host*) [virtual]

Connect to the HTTP server.

By default, connection is made to the port 80 of the specified *host*. You may connect to a non-default port by specifying it explicitly using the second overload.

Currently wxHTTP only supports IPv4.

For the overload taking wxSockAddress, the *wait* argument is ignored.

virtual bool wxHTTP::Connect (const wxString & *host,* unsigned short *port*) `[virtual]`

Connect to the HTTP server.

By default, connection is made to the port 80 of the specified *host*. You may connect to a non-default port by specifying it explicitly using the second overload.

Currently wxHTTP only supports IPv4.

For the overload taking wxSockAddress, the *wait* argument is ignored.

virtual bool wxHTTP::Connect (const wxSockAddress & *addr,* bool *wait*) `[virtual]`

Connect to the HTTP server.

By default, connection is made to the port 80 of the specified *host*. You may connect to a non-default port by specifying it explicitly using the second overload.

Currently wxHTTP only supports IPv4.

For the overload taking wxSockAddress, the *wait* argument is ignored.

Reimplemented from wxSocketClient.

wxString wxHTTP::GetCookie (const wxString & *cookie*) const

Returns the value of a cookie.

wxString wxHTTP::GetHeader (const wxString & *header*) const

Returns the data attached with a field whose name is specified by *header*.

If the field doesn't exist, it will return an empty string and not a NULL string.

Note

The header is not case-sensitive, i.e. "CONTENT-TYPE" and "content-type" represent the same header.

virtual wxInputStream* wxHTTP::GetInputStream (const wxString & *path*) `[virtual]`

Creates a new input stream on the specified path.

Notice that this stream is unseekable, i.e. SeekI() and TellI() methods shouldn't be used.

Note that you can still know the size of the file you are getting using wxStreamBase::GetSize(). However there is a limitation: in HTTP protocol, the size is not always specified so sometimes (size_t)-1 can returned to indicate that the size is unknown. In such case, you may want to use wxInputStream::LastRead() method in a loop to get the total size.

Returns

Returns the initialized stream. You must delete it yourself once you don't use it anymore and this must be done before the wxHTTP object itself is destroyed. The destructor closes the network connection. The next time you will try to get a file the network connection will have to be reestablished, but you don't have to take care of this since wxHTTP reestablishes it automatically.

See also

wxInputStream

Implements wxProtocol.

int wxHTTP::GetResponse ( ) const

Returns the HTTP response code returned by the server.

Please refer to RFC 2616 for the list of responses.

bool wxHTTP::HasCookies ( ) const

Returns true if there were cookies.

void wxHTTP::SetHeader (const wxString & *header*, const wxString & *h_data*)

It sets data of a field to be sent during the next request to the HTTP server.

The field name is specified by *header* and the content by *h_data*. This is a low level function and it assumes that you know what you are doing.

void wxHTTP::SetMethod (const wxString & *method*)

Set HTTP method.

Set `common` or expanded HTTP method.

Overrides GET or POST methods that is used by default.

Parameters

method	HTTP method name, e.g. "GET".

Since

3.0

See also

SetPostBuffer(), SetPostText()

bool wxHTTP::SetPostBuffer (const wxString & *contentType*, const wxMemoryBuffer & *data*)

Set the binary data to be posted to the server.

If a non-empty buffer is passed to this method, the next request will be an HTTP `POST` instead of the default HTTP `GET` and the given *data* will be posted as the body of this request.

For textual data a more convenient SetPostText() can be used instead.

Parameters

contentType	The value of HTTP "Content-Type" header, e.g. "image/png".
data	The data to post.

Returns

true if any data was passed in or false if the buffer was empty.

Since

2.9.4

bool wxHTTP::SetPostText (const wxString & *contentType,* const wxString & *data,* const wxMBConv & *conv* = wxConvUTF8)

Set the text to be posted to the server.

After a successful call to this method, the request will use HTTP `POST` instead of the default `GET` when it's executed.

Use SetPostBuffer() if you need to post non-textual data.

Parameters

contentType	The value of HTTP "Content-Type" header, e.g. "text/html; charset=UTF-8".
data	The data to post.
conv	The conversion to use to convert *data* contents to a byte stream. Its value should be consistent with the charset parameter specified in *contentType*.

Returns

true if string was non-empty and was successfully converted using the given *conv* or false otherwise (in this case this request won't be `POST'ed` correctly).

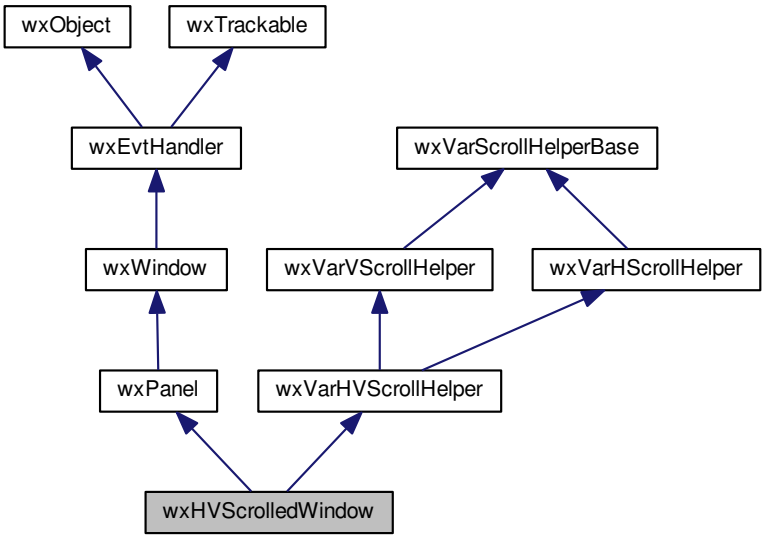
Since

2.9.4

21.389 wxHVScrolledWindow Class Reference

`#include <wx/vscroll.h>`

Inheritance diagram for wxHVScrolledWindow:



21.389.1 Detailed Description

This window inherits all functionality of both vertical and horizontal, variable scrolled windows.

It automatically handles everything needed to scroll both axis simultaneously with both variable row heights and variable column widths.

In any case, this is a generalization of wxScrolled which can be only used when all rows and columns are the same size. It lacks some other wxScrolled features however, notably it can't scroll specific pixel sizes of the window or its exact client area size.

To use this class, you must derive from it and implement both the OnGetRowHeight() and OnGetColumnWidth() pure virtual methods to let the base class know how many rows and columns it should display. You also need to set the total rows and columns the window contains, but from that moment on the scrolling is handled entirely by wxHVScrolledWindow. You only need to draw the visible part of contents in your `OnPaint()` method as usual. You should use GetVisibleBegin() and GetVisibleEnd() to select the lines to display. Note that the device context origin is not shifted so the first visible row and column always appear at the point (0, 0) in physical as well as logical coordinates.

Library: wxCore

Category: Miscellaneous Windows

See also

wxHScrolledWindow, wxVScrolledWindow

Public Member Functions

- wxHVScrolledWindow ()

  Default constructor, you must call Create() later.
- wxHVScrolledWindow (wxWindow *parent, wxWindowID id=wxID_ANY, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, long style=0, const wxString &name=wxPanelNameStr)

  This is the normal constructor, no need to call Create() after using this constructor.
- bool Create (wxWindow *parent, wxWindowID id=wxID_ANY, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, long style=0, const wxString &name=wxPanelNameStr)

  Same as the non-default constructor, but returns a status code: true if ok, false if the window couldn't be created.

Additional Inherited Members

21.389.2 Constructor & Destructor Documentation

wxHVScrolledWindow::wxHVScrolledWindow ( )

Default constructor, you must call Create() later.

wxHVScrolledWindow::wxHVScrolledWindow (wxWindow * *parent*, wxWindowID *id* = wxID_ANY, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, long *style* = `0`, const wxString & *name* = `wxPanelNameStr`)

This is the normal constructor, no need to call Create() after using this constructor.

Note

`wxHSCROLL` and `wxVSCROLL` are always automatically added to the style, there is no need to specify it explicitly.

Parameters

parent	The parent window, must not be NULL.
id	The identifier of this window, wxID_ANY by default.
pos	The initial window position.
size	The initial window size.
style	The window style. There are no special style bits defined for this class.
name	The name for this window; usually not used.

21.389.3 Member Function Documentation

bool wxHVScrolledWindow::Create (wxWindow * *parent*, wxWindowID *id* = wxID_ANY, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, long *style* = `0`, const wxString & *name* = `wxPanelNameStr`)

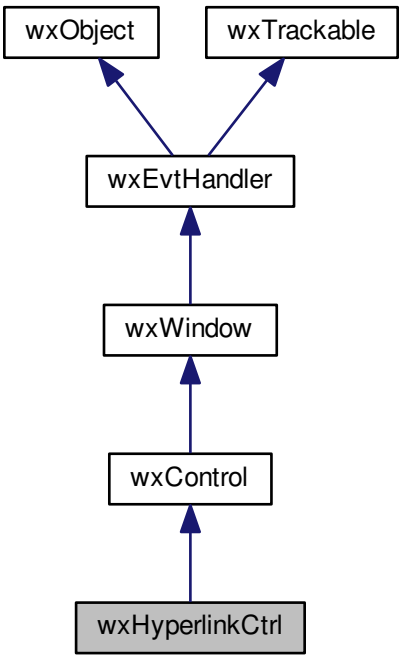
Same as the non-default constructor, but returns a status code: true if ok, false if the window couldn't be created.

Just as with the constructor, the `wxHSCROLL` and `wxVSCROLL` styles are always used, there is no need to specify them explicitly.

21.390 wxHyperlinkCtrl Class Reference

`#include <wx/hyperlink.h>`

Inheritance diagram for wxHyperlinkCtrl:



21.390.1 Detailed Description

This class shows a static text element which links to an URL.

Appearance and behaviour is completely customizable.

In fact, when the user clicks on the hyperlink, a wxHyperlinkEvent is sent but if that event is not handled (or it's skipped; see wxEvent::Skip), then a call to wxLaunchDefaultBrowser() is done with the hyperlink's URL.

Note that standard wxWindow functions like wxWindow::SetBackgroundColour, wxWindow::SetFont, wxWindow::SetCursor, wxWindow::SetLabel can be used to customize appearance of the hyperlink.

Styles

This class supports the following styles:

- wxHL_ALIGN_LEFT: Align the text to the left.
- wxHL_ALIGN_RIGHT: Align the text to the right. This style is not supported under Windows XP but is supported under all the other Windows versions.
- wxHL_ALIGN_CENTRE: Center the text (horizontally). This style is not supported by the native MSW implementation used under Windows XP and later.
- wxHL_CONTEXTMENU: Pop up a context menu when the hyperlink is right-clicked. The context menu contains a "Copy URL" menu item which is automatically handled by the hyperlink and which just copies in the clipboard the URL (not the label) of the control.
- wxHL_DEFAULT_STYLE: The default style for wxHyperlinkCtrl: wxBORDER_NONE|wxHL_CONTEXTMENU|wxHL_ALIGN_CENTRE.

Events emitted by this class

The following event handler macros redirect the events to member function handlers '**func**' with prototypes like: void handlerFuncName(wxHyperlinkEvent& event)

Event macros for events emitted by this class:

- EVT_HYPERLINK(id, func): The hyperlink was (left) clicked. If this event is not handled in user's code (or it's skipped; see wxEvent::Skip), then a call to wxLaunchDefaultBrowser is done with the hyperlink's URL.

Currently this class is implemented using native support in wxGTK and wxMSW (under Windows XP and later only) and a generic version is used by the other ports.

wxURL, wxHyperlinkEvent

Public Member Functions

- wxHyperlinkCtrl ()
- wxHyperlinkCtrl (wxWindow *parent, wxWindowID id, const wxString &label, const wxString &url, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, long style=wxHL_DEFAULT_STYLE, const wxString &name=wxHyperlinkCtrlNameStr)

Constructor.

- bool Create (wxWindow *parent, wxWindowID id, const wxString &label, const wxString &url, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, long style=wxHL_DEFAULT_STYLE, const wxString &name=wxHyperlinkCtrlNameStr)

  Creates the hyperlink control.
- virtual wxColour GetHoverColour () const

  Returns the colour used to print the label of the hyperlink when the mouse is over the control.
- virtual wxColour GetNormalColour () const

  Returns the colour used to print the label when the link has never been clicked before (i.e. the link has not been visited) and the mouse is not over the control.
- virtual wxString GetURL () const

  Returns the URL associated with the hyperlink.
- virtual bool GetVisited () const =0

  Returns true if the hyperlink has already been clicked by the user at least one time.
- virtual wxColour GetVisitedColour () const

  Returns the colour used to print the label when the mouse is not over the control and the link has already been clicked before (i.e. the link has been visited).
- virtual void SetHoverColour (const wxColour &colour)

  Sets the colour used to print the label of the hyperlink when the mouse is over the control.
- virtual void SetNormalColour (const wxColour &colour)

  Sets the colour used to print the label when the link has never been clicked before (i.e. the link has not been visited) and the mouse is not over the control.
- virtual void SetURL (const wxString &url)

  Sets the URL associated with the hyperlink.
- virtual void SetVisited (bool visited=true)=0

  Marks the hyperlink as visited (see wxHyperlinkCtrl::SetVisitedColour).
- virtual void SetVisitedColour (const wxColour &colour)

  Sets the colour used to print the label when the mouse is not over the control and the link has already been clicked before (i.e. the link has been visited).

Additional Inherited Members

21.390.2 Constructor & Destructor Documentation

wxHyperlinkCtrl::wxHyperlinkCtrl ( )

wxHyperlinkCtrl::wxHyperlinkCtrl (wxWindow * *parent*, wxWindowID *id*, const wxString & *label*, const wxString & *url*, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, long *style* = wxHL_DEFAULT_STYLE, const wxString & *name* = `wxHyperlinkCtrlNameStr`)

Constructor.

See Create() for more info.

21.390.3 Member Function Documentation

bool wxHyperlinkCtrl::Create (wxWindow * *parent*, wxWindowID *id*, const wxString & *label*, const wxString & *url*, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, long *style* = wxHL_DEFAULT_STYLE, const wxString & *name* = `wxHyperlinkCtrlNameStr`)

Creates the hyperlink control.

Parameters

parent	Parent window. Must not be NULL.
id	Window identifier. A value of wxID_ANY indicates a default value.
label	The label of the hyperlink.
url	The URL associated with the given label.
pos	Window position.
size	Window size. If the wxDefaultSize is specified then the window is sized appropriately.
style	Window style. See wxHyperlinkCtrl.
name	Window name.

virtual wxColour wxHyperlinkCtrl::GetHoverColour ( ) const `[virtual]`

Returns the colour used to print the label of the hyperlink when the mouse is over the control.

virtual wxColour wxHyperlinkCtrl::GetNormalColour ( ) const `[virtual]`

Returns the colour used to print the label when the link has never been clicked before (i.e. the link has not been *visited*) and the mouse is not over the control.

virtual wxString wxHyperlinkCtrl::GetURL ( ) const `[virtual]`

Returns the URL associated with the hyperlink.

virtual bool wxHyperlinkCtrl::GetVisited ( ) const `[pure virtual]`

Returns true if the hyperlink has already been clicked by the user at least one time.

virtual wxColour wxHyperlinkCtrl::GetVisitedColour ( ) const `[virtual]`

Returns the colour used to print the label when the mouse is not over the control and the link has already been clicked before (i.e. the link has been *visited*).

virtual void wxHyperlinkCtrl::SetHoverColour (const wxColour & *colour*) `[virtual]`

Sets the colour used to print the label of the hyperlink when the mouse is over the control.

virtual void wxHyperlinkCtrl::SetNormalColour (const wxColour & *colour*) `[virtual]`

Sets the colour used to print the label when the link has never been clicked before (i.e. the link has not been *visited*) and the mouse is not over the control.

virtual void wxHyperlinkCtrl::SetURL (const wxString & *url*) `[virtual]`

Sets the URL associated with the hyperlink.

virtual void wxHyperlinkCtrl::SetVisited (bool *visited* = `true`) `[pure virtual]`

Marks the hyperlink as visited (see wxHyperlinkCtrl::SetVisitedColour).

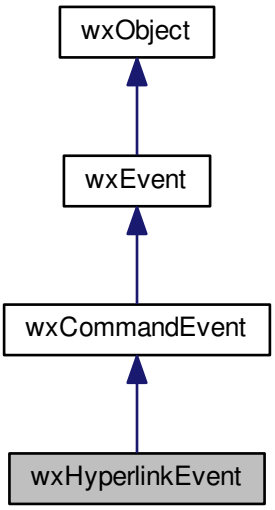
virtual void wxHyperlinkCtrl::SetVisitedColour (const wxColour & *colour*) `[virtual]`

Sets the colour used to print the label when the mouse is not over the control and the link has already been clicked before (i.e. the link has been *visited*).

21.391 wxHyperlinkEvent Class Reference

`#include <wx/hyperlink.h>`

Inheritance diagram for wxHyperlinkEvent:



21.391.1 Detailed Description

This event class is used for the events generated by wxHyperlinkCtrl.

Events using this class

The following event handler macros redirect the events to member function handlers '**func**' with prototypes like: void handlerFuncName(wxHyperlinkEvent& event)

Event macros:

- EVT_HYPERLINK(id, func): User clicked on an hyperlink.

Library: wxAdvanced

Category: Events

Public Member Functions

- wxHyperlinkEvent (wxObject *generator, int id, const wxString &url)

  The constructor is not normally used by the user code.
- wxString GetURL () const

  Returns the URL of the hyperlink where the user has just clicked.
- void SetURL (const wxString &url)

  Sets the URL associated with the event.

Additional Inherited Members

21.391.2 Constructor & Destructor Documentation

wxHyperlinkEvent::wxHyperlinkEvent (wxObject * *generator,* int *id,* const wxString & *url*)

The constructor is not normally used by the user code.

21.391.3 Member Function Documentation

wxString wxHyperlinkEvent::GetURL ( ) const

Returns the URL of the hyperlink where the user has just clicked.

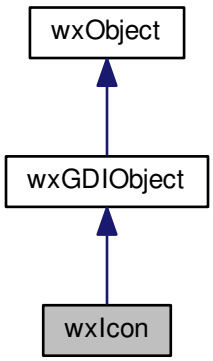
void wxHyperlinkEvent::SetURL (const wxString & *url*)

Sets the URL associated with the event.

21.392 wxIcon Class Reference

`#include <wx/icon.h>`

Inheritance diagram for wxIcon:



21.392.1 Detailed Description

An icon is a small rectangular bitmap usually used for denoting a minimized application.

It differs from a wxBitmap in always having a mask associated with it for transparent drawing. On some platforms, icons and bitmaps are implemented identically, since there is no real distinction between a wxBitmap with a mask and an icon; and there is no specific icon format on some platforms (X-based applications usually standardize on XPMs for small bitmaps and icons). However, some platforms (such as Windows) make the distinction, so a separate class is provided.

Remarks

It is usually desirable to associate a pertinent icon with a frame. Icons can also be used for other purposes, for example with wxTreeCtrl and wxListCtrl. Icons have different formats on different platforms therefore separate icons will usually be created for the different environments. Platform-specific methods for creating a wxIcon structure are catered for, and this is an occasion where conditional compilation will probably be required. Note that a new icon must be created for every time the icon is to be used for a new window. In Windows, the icon will not be reloaded if it has already been used. An icon allocated to a frame will be deleted when the frame is deleted. For more information please see Bitmaps and Icons.

Library: wxCore

Category: Graphics Device Interface (GDI)

Predefined objects/pointers: wxNullIcon

Bitmaps and Icons, Supported Bitmap File Formats, wxDC::DrawIcon, wxCursor

Public Member Functions

- wxIcon ()

  Default ctor.
- wxIcon (const wxIcon &icon)

  Copy ctor.
- wxIcon (const char bits[], int width, int height)

  Creates an icon from an array of bits.
- wxIcon (const char ∗const ∗bits)

  Creates a bitmap from XPM data.
- wxIcon (const wxString &name, wxBitmapType type=wxICON_DEFAULT_TYPE, int desiredWidth=-1, int desiredHeight=-1)

  Loads an icon from a file or resource.
- wxIcon (const wxIconLocation &loc)

  Loads an icon from the specified location.
- virtual ∼wxIcon ()

  Destructor.
- bool CreateFromHICON (WXHICON icon)

  Attach a Windows icon handle.
- wxIcon ConvertToDisabled (unsigned char brightness=255) const

  Returns disabled (dimmed) version of the icon.
- void CopyFromBitmap (const wxBitmap &bmp)

  Copies bmp bitmap to this icon.
- int GetDepth () const

Gets the colour depth of the icon.

- int GetHeight () const

  Gets the height of the icon in pixels.

- int GetWidth () const

  Gets the width of the icon in pixels.

- virtual bool IsOk () const

  Returns true if icon data is present.

- bool LoadFile (const wxString &name, wxBitmapType type=wxICON_DEFAULT_TYPE, int desiredWidth=-1, int desiredHeight=-1)

  Loads an icon from a file or resource.

- void SetDepth (int depth)

  Sets the depth member (does not affect the icon data).

- void SetHeight (int height)

  Sets the height member (does not affect the icon data).

- void SetWidth (int width)

  Sets the width member (does not affect the icon data).

- wxIcon & operator= (const wxIcon &icon)

  Assignment operator, using Reference Counting.

Additional Inherited Members

21.392.2 Constructor & Destructor Documentation

wxIcon::wxIcon ( )

Default ctor.

Constructs an icon object with no data; an assignment or another member function such as LoadFile() must be called subsequently.

wxIcon::wxIcon (const wxIcon & *icon*)

Copy ctor.

wxIcon::wxIcon (const char *bits[],* int *width,* int *height*)

Creates an icon from an array of bits.

You should only use this function for monochrome bitmaps (depth 1) in portable programs: in this case the bits parameter should contain an XBM image.

For other bit depths, the behaviour is platform dependent: under Windows, the data is passed without any changes to the underlying CreateBitmap() API. Under other platforms, only monochrome bitmaps may be created using this constructor and wxImage should be used for creating colour bitmaps from static data.

Parameters

bits	Specifies an array of pixel values.
width	The width of the image.
height	The height of the image.

wxPerl Note: In wxPerl use Wx::Icon->newBits(bits, width, height, depth = -1);

Availability: only available for the wxMSW, wxOSX ports.

wxIcon::wxIcon (const char *const * *bits*)

Creates a bitmap from XPM data.

To use this constructor, you must first include an XPM file. For example, assuming that the file mybitmap.xpm contains an XPM array of character pointers called *mybitmap:*

```
#include "mybitmap.xpm"
...
wxIcon *icon = new wxIcon(mybitmap);
```

A macro, wxICON, is available which creates an icon using an XPM on the appropriate platform, or an icon resource on Windows.

```
wxIcon icon(wxICON(sample));

// Equivalent to:
#if defined(__WXGTK__) || defined(__WXMOTIF__)
wxIcon icon(sample_xpm);
#endif

#if defined(__WXMSW__)
wxIcon icon("sample");
#endif
```

wxPerl Note: In wxPerl use Wx::Icon->newFromXPM(data).

wxIcon::wxIcon (const wxString & *name*, wxBitmapType *type* = wxICON_DEFAULT_TYPE, int *desiredWidth* = -1, int *desiredHeight* = -1)

Loads an icon from a file or resource.

Parameters

name	This can refer to a resource name or a filename under MS Windows and X. Its meaning is determined by the *type* parameter.
type	May be one of the wxBitmapType values and indicates which type of bitmap should be loaded. See the note in the class detailed description. Note that the wxICON_DEFAULT_TYP↩ E constant has different value under different wxWidgets ports. See the icon.h header for the value it takes for a specific port.
desiredWidth	Specifies the desired width of the icon. This parameter only has an effect in Windows where icon resources can contain several icons of different sizes.
desiredHeight	Specifies the desired height of the icon. This parameter only has an effect in Windows where icon resources can contain several icons of different sizes.

See also

LoadFile()

wxIcon::wxIcon (const wxIconLocation & *loc*)

Loads an icon from the specified location.

virtual wxIcon::~wxIcon ( ) [virtual]

Destructor.

See Object Destruction for more info.

If the application omits to delete the icon explicitly, the icon will be destroyed automatically by wxWidgets when the application exits.

Warning

Do not delete an icon that is selected into a memory device context.

21.392.3 Member Function Documentation

wxIcon wxIcon::ConvertToDisabled (unsigned char *brightness* = 255) const

Returns disabled (dimmed) version of the icon.

This method is available in wxIcon only under wxMSW, other ports only have it in wxBitmap. You can always use wxImage::ConvertToDisabled() and create the icon from wxImage manually however.

Availability: only available for the wxMSW port.

Since

2.9.0

void wxIcon::CopyFromBitmap (const wxBitmap & *bmp*)

Copies *bmp* bitmap to this icon.

Under MS Windows the bitmap must have mask colour set.

See also

LoadFile()

bool wxIcon::CreateFromHICON (WXHICON *icon*)

Attach a Windows icon handle.

This wxMSW-specific method allows to assign a native Windows HICON (which must be castes to WXHICON opaque handle type) to wxIcon. Notice that this means that the HICON will be destroyed by wxIcon when it is destroyed.

Returns

true if successful.

Availability: only available for the wxMSW port.

Since

2.9.5

int wxIcon::GetDepth ( ) const

Gets the colour depth of the icon.

A value of 1 indicates a monochrome icon.

int wxIcon::GetHeight ( ) const

Gets the height of the icon in pixels.

See also

GetWidth()

int wxIcon::GetWidth ( ) const

Gets the width of the icon in pixels.

See also

GetHeight()

virtual bool wxIcon::IsOk ( ) const `[virtual]`

Returns true if icon data is present.

bool wxIcon::LoadFile (const wxString & *name*, wxBitmapType *type* = `wxICON_DEFAULT_TYPE`, int *desiredWidth* = `-1`, int *desiredHeight* = `-1`)

Loads an icon from a file or resource.

Parameters

name	Either a filename or a Windows resource name. The meaning of name is determined by the *type* parameter.
type	One of the wxBitmapType values; see the note in the class detailed description. Note that the wxICON_DEFAULT_TYPE constant has different value under different wxWidgets ports. See the icon.h header for the value it takes for a specific port.
desiredWidth	Specifies the desired width of the icon. This parameter only has an effect in Windows where icon resources can contain several icons of different sizes.
desiredHeight	Specifies the desired height of the icon. This parameter only has an effect in Windows where icon resources can contain several icons of different sizes.

Returns

true if the operation succeeded, false otherwise.

wxIcon& wxIcon::operator= (const wxIcon & *icon*)

Assignment operator, using Reference Counting.

Parameters

icon	Icon to assign.

void wxIcon::SetDepth (int *depth*)

Sets the depth member (does not affect the icon data).

Parameters

depth	Icon depth.

void wxIcon::SetHeight (int *height*)

Sets the height member (does not affect the icon data).

Parameters

height	Icon height in pixels.

void wxIcon::SetWidth (int *width*)

Sets the width member (does not affect the icon data).

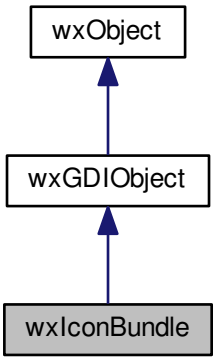
Parameters

width	Icon width in pixels.

21.393 wxIconBundle Class Reference

`#include <wx/iconbndl.h>`

Inheritance diagram for wxIconBundle:



21.393.1 Detailed Description

This class contains multiple copies of an icon in different sizes.

It is typically used in wxDialog::SetIcons and wxTopLevelWindow::SetIcons.

Library: wxCore

Category: Graphics Device Interface (GDI)

Predefined objects/pointers: wxNullIconBundle

Public Types

- enum {
  FALLBACK_NONE = 0,
  FALLBACK_SYSTEM = 1,
  FALLBACK_NEAREST_LARGER = 2 }

  The elements of this enum determine what happens if GetIcon() doesn't find the icon of exactly the requested size.

Public Member Functions

- wxIconBundle ()

  Default ctor.
- wxIconBundle (const wxString &file, wxBitmapType type=wxBITMAP_TYPE_ANY)

  Initializes the bundle with the icon(s) found in the file.
- wxIconBundle (wxInputStream &stream, wxBitmapType type=wxBITMAP_TYPE_ANY)

  Initializes the bundle with the icon(s) found in the stream.
- wxIconBundle (const wxIcon &icon)

  Initializes the bundle with a single icon.
- wxIconBundle (const wxIconBundle &ic)

  Copy constructor.
- virtual ~wxIconBundle ()

  Destructor.
- void AddIcon (const wxString &file, wxBitmapType type=wxBITMAP_TYPE_ANY)

  Adds all the icons contained in the file to the bundle; if the collection already contains icons with the same width and height, they are replaced by the new ones.
- void AddIcon (wxInputStream &stream, wxBitmapType type=wxBITMAP_TYPE_ANY)

  Adds all the icons contained in the stream to the bundle; if the collection already contains icons with the same width and height, they are replaced by the new ones.
- void AddIcon (const wxIcon &icon)

  Adds the icon to the collection; if the collection already contains an icon with the same width and height, it is replaced by the new one.
- wxIcon GetIcon (const wxSize &size, int flags=FALLBACK_SYSTEM) const

  Returns the icon with the given size.
- wxIcon GetIcon (wxCoord size=wxDefaultCoord, int flags=FALLBACK_SYSTEM) const

  Same as.
- wxIcon GetIconOfExactSize (const wxSize &size) const

  Returns the icon with exactly the given size or wxNullIcon if this size is not available.
- size_t GetIconCount () const

  return the number of available icons
- wxIcon GetIconByIndex (size_t n) const

  return the icon at index (must be < GetIconCount())
- bool IsEmpty () const

  Returns true if the bundle doesn't contain any icons, false otherwise (in which case a call to GetIcon() with default parameter should return a valid icon).
- wxIconBundle & operator= (const wxIconBundle &ic)

  Assignment operator, using reference counting.

Additional Inherited Members

21.393.2 Member Enumeration Documentation

anonymous enum

The elements of this enum determine what happens if GetIcon() doesn't find the icon of exactly the requested size.

Since

2.9.4

Enumerator

FALLBACK_NONE Return invalid icon if exact size is not found.

FALLBACK_SYSTEM Return the icon of the system icon size if exact size is not found. May be combined with other non-NONE enum elements to determine what happens if the system icon size is not found neither.

FALLBACK_NEAREST_LARGER Return the icon of closest larger size or, if there is no icon of larger size in the bundle, the closest icon of smaller size.

21.393.3 Constructor & Destructor Documentation

wxIconBundle::wxIconBundle ( )

Default ctor.

wxIconBundle::wxIconBundle (const wxString & *file,* wxBitmapType *type* = wxBITMAP_TYPE_ANY)

Initializes the bundle with the icon(s) found in the file.

wxIconBundle::wxIconBundle (wxInputStream & *stream,* wxBitmapType *type* = wxBITMAP_TYPE_ANY)

Initializes the bundle with the icon(s) found in the stream.

Notice that the *stream* must be seekable, at least if it contains more than one icon. The stream pointer is positioned after the last icon read from the stream when this function returns.

Since

2.9.0

wxIconBundle::wxIconBundle (const wxIcon & *icon*)

Initializes the bundle with a single icon.

wxIconBundle::wxIconBundle (const wxIconBundle & *ic*)

Copy constructor.

virtual wxIconBundle::~wxIconBundle ( ) [virtual]

Destructor.

21.393.4 Member Function Documentation

void wxIconBundle::AddIcon (const wxString & *file,* wxBitmapType *type* = wxBITMAP_TYPE_ANY)

Adds all the icons contained in the file to the bundle; if the collection already contains icons with the same width and height, they are replaced by the new ones.

void wxIconBundle::AddIcon (wxInputStream & *stream,* wxBitmapType *type* = wxBITMAP_TYPE_ANY)

Adds all the icons contained in the stream to the bundle; if the collection already contains icons with the same width and height, they are replaced by the new ones.

Notice that, as well as in the constructor loading the icon bundle from stream, the *stream* must be seekable, at least if more than one icon is to be loaded from it.

Since

2.9.0

void wxIconBundle::AddIcon (const wxIcon & *icon*)

Adds the icon to the collection; if the collection already contains an icon with the same width and height, it is replaced by the new one.

wxIcon wxIconBundle::GetIcon (const wxSize & *size,* int *flags* = FALLBACK_SYSTEM) const

Returns the icon with the given size.

If *size* is wxDefaultSize, it is interpreted as the standard system icon size, i.e. the size returned by wxSystemSettings::GetMetric() for `wxSYS_ICON_X` and `wxSYS_ICON_Y`.

If the bundle contains an icon with exactly the requested size, it's always returned. Otherwise, the behaviour depends on the flags. If only wxIconBundle::FALLBACK_NONE is given, the function returns an invalid icon. If wxIconBundle::FALLBACK_SYSTEM is given, it tries to find the icon of standard system size, regardless of the size passed as parameter. Otherwise, or if the icon system size is not found neither, but wxIconBundle::FALLBACK_NEAREST_LARGER flag is specified, the function returns the smallest icon of the size larger than the requested one or, if this fails too, just the icon closest to the specified size.

The *flags* parameter is available only since wxWidgets 2.9.4.

wxIcon wxIconBundle::GetIcon (wxCoord *size* = wxDefaultCoord, int *flags* = FALLBACK_SYSTEM) const

Same as.

```
GetIcon( wxSize( size, size ) )
```

.

wxIcon wxIconBundle::GetIconByIndex (size_t *n*) const

return the icon at index (must be $<$ GetIconCount())

size_t wxIconBundle::GetIconCount ( ) const

return the number of available icons

wxIcon wxIconBundle::GetIconOfExactSize (const wxSize & *size*) const

Returns the icon with exactly the given size or wxNullIcon if this size is not available.

bool wxIconBundle::IsEmpty ( ) const

Returns true if the bundle doesn't contain any icons, false otherwise (in which case a call to GetIcon() with default parameter should return a valid icon).

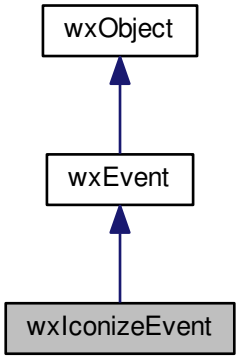
wxIconBundle& wxIconBundle::operator= (const wxIconBundle & *ic*)

Assignment operator, using reference counting.

21.394 wxIconizeEvent Class Reference

`#include <wx/event.h>`

Inheritance diagram for wxIconizeEvent:



21.394.1 Detailed Description

An event being sent when the frame is iconized (minimized) or restored.

Currently only wxMSW and wxGTK generate such events.

Availability: only available for the wxMSW, wxGTK ports.

Events using this class

The following event handler macros redirect the events to member function handlers '**func**' with prototypes like: void handlerFuncName(wxIconizeEvent& event)

Event macros:

- EVT_ICONIZE(func): Process a `wxEVT_ICONIZE` event.

Library: wxCore

Category: Events

See also

Events and Event Handling, wxTopLevelWindow::Iconize, wxTopLevelWindow::IsIconized

Public Member Functions

- wxIconizeEvent (int id=0, bool iconized=true)

  Constructor.
- bool IsIconized () const

  Returns true if the frame has been iconized, false if it has been restored.
- bool Iconized () const

Additional Inherited Members

21.394.2 Constructor & Destructor Documentation

wxIconizeEvent::wxIconizeEvent (int *id* = `0`, bool *iconized* = `true`)

Constructor.

21.394.3 Member Function Documentation

bool wxIconizeEvent::Iconized ( ) const

Deprecated This function is deprecated in favour of IsIconized().

bool wxIconizeEvent::IsIconized ( ) const

Returns true if the frame has been iconized, false if it has been restored.

21.395 wxIconLocation Class Reference

```
#include <wx/iconloc.h>
```

21.395.1 Detailed Description

wxIconLocation is a tiny class describing the location of an (external, i.e.

not embedded into the application resources) icon. For most platforms it simply contains the file name but under some others (notably Windows) the same file may contain multiple icons and so this class also stores the index of the icon inside the file.

In any case, its details should be of no interest to the application code and most of them are not even documented here (on purpose) as it is only meant to be used as an opaque class: the application may get the object of this class from somewhere and the only reasonable thing to do with it later is to create a wxIcon from it.

Library: wxBase

Category: Graphics Device Interface (GDI)

See also

wxIcon, wxFileType::GetIcon

Public Member Functions

- bool IsOk () const

  Returns true if the object is valid, i.e. was properly initialized, and false otherwise.
- void SetFileName (const wxString &filename)
- const wxString & GetFileName () const

21.395.2 Member Function Documentation

const wxString& wxIconLocation::GetFileName ( ) const

bool wxIconLocation::IsOk ( ) const

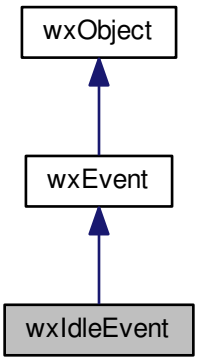
Returns true if the object is valid, i.e. was properly initialized, and false otherwise.

void wxIconLocation::SetFileName (const wxString & *filename*)

21.396 wxIdleEvent Class Reference

`#include <wx/event.h>`

Inheritance diagram for wxIdleEvent:



21.396.1 Detailed Description

This class is used for idle events, which are generated when the system becomes idle.

Note that, unless you do something specifically, the idle events are not sent if the system remains idle once it has become it, e.g. only a single idle event will be generated until something else resulting in more normal events happens and only then is the next idle event sent again.

If you need to ensure a continuous stream of idle events, you can either use wxIdleEvent::RequestMore method in your handler or call wxWakeUpIdle() periodically (for example from a timer event handler), but note that both of these approaches (and especially the first one) increase the system load and so should be avoided if possible.

By default, idle events are sent to all windows, including even the hidden ones because they may be shown if some condition is met from their `wxEVT_IDLE` (or related `wxEVT_UPDATE_UI`) handler. The children of hidden windows do not receive idle events however as they can't change their state in any way noticeable by the user. Finally, the global wxApp object also receives these events, as usual, so it can be used for any global idle time processing.

If sending idle events to all windows is causing a significant overhead in your application, you can call wxIdleEvent::SetMode with the value wxIDLE_PROCESS_SPECIFIED, and set the wxWS_EX_PROCESS_IDLE extra window style for every window which should receive idle events, all the other ones will not receive them in this case.

Events using this class

The following event handler macros redirect the events to member function handlers '**func**' with prototypes like: void handlerFuncName(wxIdleEvent& event)

Event macros:

- EVT_IDLE(func): Process a `wxEVT_IDLE` event.

Library: wxBase

Category: Events

21.396.2 Delayed Action Mechanism

wxIdleEvent can be used to perform some action "at slightly later time". This can be necessary in several circumstances when, for whatever reason, something can't be done in the current event handler. For example, if a mouse event handler is called with the mouse button pressed, the mouse can be currently captured and some operations with it – notably capturing it again – might be impossible or lead to undesirable results. If you still want to capture it, you can do it from `wxEVT_IDLE` handler when it is called the next time instead of doing it immediately.

This can be achieved in two different ways: when using static event tables, you will need a flag indicating to the (always connected) idle event handler whether the desired action should be performed. The originally called handler would then set it to indicate that it should indeed be done and the idle handler itself would reset it to prevent it from doing the same action again.

Using dynamically connected event handlers things are even simpler as the original event handler can simply wxEvtHandler::Connect() or wxEvtHandler::Bind() the idle event handler which would only be executed then and could wxEvtHandler::Disconnect() or wxEvtHandler::Unbind() itself.

See also

Events and Event Handling, wxUpdateUIEvent, wxWindow::OnInternalIdle

Public Member Functions

- wxIdleEvent ()

  Constructor.
- bool MoreRequested () const

Returns true if the OnIdle function processing this event requested more processing time.

- void RequestMore (bool needMore=true)

  Tells wxWidgets that more processing is required.

Static Public Member Functions

- static wxIdleMode GetMode ()

  Static function returning a value specifying how wxWidgets will send idle events: to all windows, or only to those which specify that they will process the events.

- static void SetMode (wxIdleMode mode)

  Static function for specifying how wxWidgets will send idle events: to all windows, or only to those which specify that they will process the events.

Additional Inherited Members

21.396.3 Constructor & Destructor Documentation

wxIdleEvent::wxIdleEvent ( )

Constructor.

21.396.4 Member Function Documentation

static wxIdleMode wxIdleEvent::GetMode ( ) [static]

Static function returning a value specifying how wxWidgets will send idle events: to all windows, or only to those which specify that they will process the events.

See also

SetMode().

bool wxIdleEvent::MoreRequested ( ) const

Returns true if the OnIdle function processing this event requested more processing time.

See also

RequestMore()

void wxIdleEvent::RequestMore (bool *needMore* = true)

Tells wxWidgets that more processing is required.

This function can be called by an OnIdle handler for a window or window event handler to indicate that wxApp::↩ OnIdle should forward the OnIdle event once more to the application windows.

If no window calls this function during OnIdle, then the application will remain in a passive event loop (not calling OnIdle) until a new event is posted to the application by the windowing system.

See also

MoreRequested()

static void wxIdleEvent::SetMode (wxIdleMode *mode*) `[static]`

Static function for specifying how wxWidgets will send idle events: to all windows, or only to those which specify that they will process the events.

Parameters

mode	Can be one of the wxIdleMode values. The default is wxIDLE_PROCESS_ALL.

21.397 wxIdManager Class Reference

```
#include <wx/windowid.h>
```

21.397.1 Detailed Description

wxIdManager is responsible for allocating and releasing window IDs.

It is used by wxWindow::NewControlId() and wxWindow::UnreserveControlId(), and can also be used be used directly.

Library: wxCore

Category: Application and System configuration

See also

wxWindow::NewControlId(), wxWindow::UnreserveControlId(), Window IDs

Static Public Member Functions

- static wxWindowID ReserveId (int count=1)

  Called directly by wxWindow::NewControlId(), this function will create a new ID or range of IDs.

- static void UnreserveId (wxWindowID id, int count=1)

  Called directly by wxWindow::UnreserveControlId(), this function will unreserve an ID or range of IDs that is currently reserved.

21.397.2 Member Function Documentation

static wxWindowID wxIdManager::ReserveId (int *count* = 1) [static]

Called directly by wxWindow::NewControlId(), this function will create a new ID or range of IDs.

The IDs will be reserved until assigned to a wxWindowIDRef() or unreserved with UnreserveControlId(). Only ID values that are not assigned to a wxWindowIDRef() need to be unreserved.

Parameters

count	The number of sequential IDs to reserve.

Returns

The value of the first ID in the sequence, or wxID_NONE.

static void wxIdManager::UnreserveId (wxWindowID *id,* int *count* = 1) [static]

Called directly by wxWindow::UnreserveControlId(), this function will unreserve an ID or range of IDs that is currently reserved.

This should only be called for IDs returned by ReserveControlId() that have NOT been assigned to a wxWindowI↩ DRef (see Window IDs).

Parameters

id	The first of the range of IDs to unreserve.
count	The number of sequential IDs to unreserve.

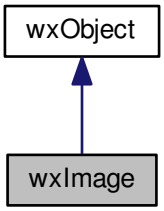
Returns

The value of the first ID in the sequence, or wxID_NONE.

21.398 wxImage Class Reference

`#include <wx/image.h>`

Inheritance diagram for wxImage:



21.398.1 Detailed Description

This class encapsulates a platform-independent image.

An image can be created from data, or using wxBitmap::ConvertToImage. An image can be loaded from a file in a variety of formats, and is extensible to new formats via image format handlers. Functions are available to set and get image bits, so it can be used for basic image manipulation.

A wxImage cannot (currently) be drawn directly to a wxDC. Instead, a platform-specific wxBitmap object must be created from it using the wxBitmap::wxBitmap(wxImage,int depth) constructor. This bitmap can then be drawn in a device context, using wxDC::DrawBitmap.

More on the difference between wxImage and wxBitmap: wxImage is just a buffer of RGB bytes with an optional buffer for the alpha bytes. It is all generic, platform independent and image file format independent code. It includes generic code for scaling, resizing, clipping, and other manipulations of the image data. OTOH, wxBitmap is intended to be a wrapper of whatever is the native image format that is quickest/easiest to draw to a DC or to be the target of the drawing operations performed on a wxMemoryDC. By splitting the responsibilities between wxImage/wxBitmap like this then it's easier to use generic code shared by all platforms and image types for generic operations and platform specific code where performance or compatibility is needed.

One colour value of the image may be used as a mask colour which will lead to the automatic creation of a wxMask object associated to the bitmap object.

21.398.2 Alpha channel support

Starting from wxWidgets 2.5.0 wxImage supports alpha channel data, that is in addition to a byte for the red, green and blue colour components for each pixel it also stores a byte representing the pixel opacity.

An alpha value of 0 corresponds to a transparent pixel (null opacity) while a value of 255 means that the pixel is 100% opaque. The constants wxIMAGE_ALPHA_TRANSPARENT and wxIMAGE_ALPHA_OPAQUE can be used to indicate those values in a more readable form.

While all images have RGB data, not all images have an alpha channel. Before using wxImage::GetAlpha you should check if this image contains an alpha channel with wxImage::HasAlpha. Currently the BMP, PNG, TGA, and TIFF format handlers have full alpha channel support for loading so if you want to use alpha you have to use one of these formats. If you initialize the image alpha channel yourself using wxImage::SetAlpha, you should save it in either PNG, TGA, or TIFF format to avoid losing it as these are the only handlers that currently support saving with alpha.

21.398.3 Available image handlers

The following image handlers are available. wxBMPHandler is always installed by default. To use other image formats, install the appropriate handler with wxImage::AddHandler or call wxInitAllImageHandlers().

- wxBMPHandler: For loading (including alpha support) and saving, always installed.
- wxPNGHandler: For loading and saving. Includes alpha support.
- wxJPEGHandler: For loading and saving.
- wxGIFHandler: For loading and saving (see below).
- wxPCXHandler: For loading and saving (see below).
- wxPNMHandler: For loading and saving (see below).
- wxTIFFHandler: For loading and saving. Includes alpha support.
- wxTGAHandler: For loading and saving. Includes alpha support.
- wxIFFHandler: For loading only.
- wxXPMHandler: For loading and saving.
- wxICOHandler: For loading and saving.
- wxCURHandler: For loading and saving.
- wxANIHandler: For loading only.

When saving in PCX format, wxPCXHandler will count the number of different colours in the image; if there are 256 or less colours, it will save as 8 bit, else it will save as 24 bit.

Loading PNMs only works for ASCII or raw RGB images. When saving in PNM format, wxPNMHandler will always save as raw RGB.

Saving GIFs requires images of maximum 8 bpp (see wxQuantize), and the alpha channel converted to a mask (see wxImage::ConvertAlphaToMask). Saving an animated GIF requires images of the same size (see wxGIFHandler↩ ::SaveAnimation)

Library: wxCore

Category: Graphics Device Interface (GDI)

Predefined objects/pointers: wxNullImage

See also

wxBitmap, wxInitAllImageHandlers(), wxPixelData

Classes

- class HSVValue

  A simple class which stores hue, saturation and value as doubles in the range 0.0-1.0.
- class RGBValue

  A simple class which stores red, green and blue values as 8 bit unsigned integers in the range of 0-255.

Public Member Functions

- wxImage ()

  Creates an empty wxImage object without an alpha channel.
- wxImage (int width, int height, bool clear=true)

  Creates an image with the given size and clears it if requested.
- wxImage (const wxSize &sz, bool clear=true)

  This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.
- wxImage (int width, int height, unsigned char ∗data, bool static_data=false)

  Creates an image from data in memory.
- wxImage (const wxSize &sz, unsigned char ∗data, bool static_data=false)

  This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.
- wxImage (int width, int height, unsigned char ∗data, unsigned char ∗alpha, bool static_data=false)

  Creates an image from data in memory.
- wxImage (const wxSize &sz, unsigned char ∗data, unsigned char ∗alpha, bool static_data=false)

  This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.
- wxImage (const char ∗const ∗xpmData)

  Creates an image from XPM data.
- wxImage (const wxString &name, wxBitmapType type=wxBITMAP_TYPE_ANY, int index=-1)

  Creates an image from a file.
- wxImage (const wxString &name, const wxString &mimetype, int index=-1)

  Creates an image from a file using MIME-types to specify the type.
- wxImage (wxInputStream &stream, wxBitmapType type=wxBITMAP_TYPE_ANY, int index=-1)

  Creates an image from a stream.
- wxImage (wxInputStream &stream, const wxString &mimetype, int index=-1)

  Creates an image from a stream using MIME-types to specify the type.
- virtual ∼wxImage ()

  Destructor.

Image creation, initialization and deletion functions

- wxImage Copy () const

  Returns an identical copy of this image.
- bool Create (int width, int height, bool clear=true)

  Creates a fresh image.
- bool Create (const wxSize &sz, bool clear=true)

  This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.
- bool Create (int width, int height, unsigned char ∗data, bool static_data=false)

  Creates a fresh image.
- bool Create (const wxSize &sz, unsigned char ∗data, bool static_data=false)

  This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.
- bool Create (int width, int height, unsigned char ∗data, unsigned char ∗alpha, bool static_data=false)

Creates a fresh image.

- bool Create (const wxSize &sz, unsigned char *data, unsigned char *alpha, bool static_data=false)

  This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.
- void Clear (unsigned char value=0)

  Initialize the image data with zeroes (the default) or with the byte value given as value.
- void Destroy ()

  Destroys the image data.
- void InitAlpha ()

  Initializes the image alpha channel data.

Image manipulation functions

- wxImage Blur (int blurRadius) const

  Blurs the image in both horizontal and vertical directions by the specified pixel blurRadius.
- wxImage BlurHorizontal (int blurRadius) const

  Blurs the image in the horizontal direction only.
- wxImage BlurVertical (int blurRadius) const

  Blurs the image in the vertical direction only.
- wxImage Mirror (bool horizontally=true) const

  Returns a mirrored copy of the image.
- void Paste (const wxImage &image, int x, int y)

  Copy the data of the given image to the specified position in this image.
- void Replace (unsigned char r1, unsigned char g1, unsigned char b1, unsigned char r2, unsigned char g2, unsigned char b2)

  Replaces the colour specified by r1,g1,b1 by the colour r2,g2,b2.
- wxImage & Rescale (int width, int height, wxImageResizeQuality quality=wxIMAGE_QUALITY_NORMAL)

  Changes the size of the image in-place by scaling it: after a call to this function,the image will have the given width and height.
- wxImage & Resize (const wxSize &size, const wxPoint &pos, int red=-1, int green=-1, int blue=-1)

  Changes the size of the image in-place without scaling it by adding either a border with the given colour or cropping as necessary.
- wxImage Rotate (double angle, const wxPoint &rotationCentre, bool interpolating=true, wxPoint *offset↩ AfterRotation=NULL) const

  Rotates the image about the given point, by angle radians.
- wxImage Rotate90 (bool clockwise=true) const

  Returns a copy of the image rotated 90 degrees in the direction indicated by clockwise.
- wxImage Rotate180 () const

  Returns a copy of the image rotated by 180 degrees.
- void RotateHue (double angle)

  Rotates the hue of each pixel in the image by angle, which is a double in the range of -1.0 to +1.0, where -1.0 corresponds to -360 degrees and +1.0 corresponds to +360 degrees.
- wxImage Scale (int width, int height, wxImageResizeQuality quality=wxIMAGE_QUALITY_NORMAL) const

  Returns a scaled version of the image.
- wxImage Size (const wxSize &size, const wxPoint &pos, int red=-1, int green=-1, int blue=-1) const

  Returns a resized version of this image without scaling it by adding either a border with the given colour or cropping as necessary.

Conversion functions

- bool ConvertAlphaToMask (unsigned char threshold=wxIMAGE_ALPHA_THRESHOLD)

  If the image has alpha channel, this method converts it to mask.
- bool ConvertAlphaToMask (unsigned char mr, unsigned char mg, unsigned char mb, unsigned char threshold=wxIMAGE_ALPHA_THRESHOLD)

  If the image has alpha channel, this method converts it to mask using the specified colour as the mask colour.
- wxImage ConvertToGreyscale (double weight_r, double weight_g, double weight_b) const

  Returns a greyscale version of the image.
- wxImage ConvertToGreyscale () const

Returns a greyscale version of the image.

- wxImage ConvertToMono (unsigned char r, unsigned char g, unsigned char b) const
  Returns monochromatic version of the image.
- wxImage ConvertToDisabled (unsigned char brightness=255) const
  Returns disabled (dimmed) version of the image.

Miscellaneous functions

- unsigned long ComputeHistogram (wxImageHistogram &histogram) const
  Computes the histogram of the image.
- bool FindFirstUnusedColour (unsigned char *r, unsigned char *g, unsigned char *b, unsigned char startR=1, unsigned char startG=0, unsigned char startB=0) const
  Finds the first colour that is never used in the image.
- wxImage & operator= (const wxImage &image)
  Assignment operator, using reference counting.

Getters

- unsigned char * GetAlpha () const
  Returns pointer to the array storing the alpha values for this image.
- unsigned char * GetData () const
  Returns the image data as an array.
- unsigned char GetAlpha (int x, int y) const
  Return alpha value at given pixel location.
- unsigned char GetRed (int x, int y) const
  Returns the red intensity at the given coordinate.
- unsigned char GetGreen (int x, int y) const
  Returns the green intensity at the given coordinate.
- unsigned char GetBlue (int x, int y) const
  Returns the blue intensity at the given coordinate.
- unsigned char GetMaskRed () const
  Gets the red value of the mask colour.
- unsigned char GetMaskGreen () const
  Gets the green value of the mask colour.
- unsigned char GetMaskBlue () const
  Gets the blue value of the mask colour.
- int GetWidth () const
  Gets the width of the image in pixels.
- int GetHeight () const
  Gets the height of the image in pixels.
- wxSize GetSize () const
  Returns the size of the image in pixels.
- wxString GetOption (const wxString &name) const
  Gets a user-defined string-valued option.
- int GetOptionInt (const wxString &name) const
  Gets a user-defined integer-valued option.
- bool GetOrFindMaskColour (unsigned char *r, unsigned char *g, unsigned char *b) const
  Get the current mask colour or find a suitable unused colour that could be used as a mask colour.
- const wxPalette & GetPalette () const
  Returns the palette associated with the image.
- wxImage GetSubImage (const wxRect &rect) const
  Returns a sub image of the current one as long as the rect belongs entirely to the image.
- wxBitmapType GetType () const
  Gets the type of image found by LoadFile() or specified with SaveFile().
- bool HasAlpha () const
  Returns true if this image has alpha channel, false otherwise.
- bool HasMask () const
  Returns true if there is a mask active, false otherwise.
- bool HasOption (const wxString &name) const

Returns true if the given option is present.

- bool IsOk () const

  Returns true if image data is present.
- bool IsTransparent (int x, int y, unsigned char threshold=wxIMAGE_ALPHA_THRESHOLD) const

  Returns true if the given pixel is transparent, i.e. either has the mask colour if this image has a mask or if this image has alpha channel and alpha value of this pixel is strictly less than threshold.

Loading and saving functions

- virtual bool LoadFile (wxInputStream &stream, wxBitmapType type=wxBITMAP_TYPE_ANY, int index=-1)

  Loads an image from an input stream.
- virtual bool LoadFile (const wxString &name, wxBitmapType type=wxBITMAP_TYPE_ANY, int index=-1)

  Loads an image from a file.
- virtual bool LoadFile (const wxString &name, const wxString &mimetype, int index=-1)

  Loads an image from a file.
- virtual bool LoadFile (wxInputStream &stream, const wxString &mimetype, int index=-1)

  Loads an image from an input stream.
- virtual bool SaveFile (wxOutputStream &stream, const wxString &mimetype) const

  Saves an image in the given stream.
- virtual bool SaveFile (const wxString &name, wxBitmapType type) const

  Saves an image in the named file.
- virtual bool SaveFile (const wxString &name, const wxString &mimetype) const

  Saves an image in the named file.
- virtual bool SaveFile (const wxString &name) const

  Saves an image in the named file.
- virtual bool SaveFile (wxOutputStream &stream, wxBitmapType type) const

  Saves an image in the given stream.

Setters

- void SetAlpha (unsigned char *alpha=NULL, bool static_data=false)

  This function is similar to SetData() and has similar restrictions.
- void SetAlpha (int x, int y, unsigned char alpha)

  Sets the alpha value for the given pixel.
- void ClearAlpha ()

  Removes the alpha channel from the image.
- void SetData (unsigned char *data, bool static_data=false)

  Sets the image data without performing checks.
- void SetData (unsigned char *data, int new_width, int new_height, bool static_data=false)

  This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.
- void SetMask (bool hasMask=true)

  Specifies whether there is a mask or not.
- void SetMaskColour (unsigned char red, unsigned char green, unsigned char blue)

  Sets the mask colour for this image (and tells the image to use the mask).
- bool SetMaskFromImage (const wxImage &mask, unsigned char mr, unsigned char mg, unsigned char mb)

  Sets image's mask so that the pixels that have RGB value of mr,mg,mb in mask will be masked in the image.
- void SetOption (const wxString &name, const wxString &value)

  Sets a user-defined option.
- void SetOption (const wxString &name, int value)

  This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.
- void SetPalette (const wxPalette &palette)

  Associates a palette with the image.
- void SetRGB (int x, int y, unsigned char r, unsigned char g, unsigned char b)

  Set the color of the pixel at the given x and y coordinate.
- void SetRGB (const wxRect &rect, unsigned char red, unsigned char green, unsigned char blue)

  Sets the colour of the pixels within the given rectangle.
- void SetType (wxBitmapType type)

  Set the type of image returned by GetType().

Static Public Member Functions

- static bool CanRead (const wxString &filename)

  Returns true if at least one of the available image handlers can read the file with the given name.
- static bool CanRead (wxInputStream &stream)

  Returns true if at least one of the available image handlers can read the data in the given stream.
- static wxString GetImageExtWildcard ()

  Iterates all registered wxImageHandler objects, and returns a string containing file extension masks suitable for passing to file open/save dialog boxes.
- static wxImage::HSVValue RGBtoHSV (const wxImage::RGBValue &rgb)

  Converts a color in RGB color space to HSV color space.
- static wxImage::RGBValue HSVtoRGB (const wxImage::HSVValue &hsv)

  Converts a color in HSV color space to RGB color space.

Handler management functions

- static void AddHandler (wxImageHandler *handler)

  Register an image handler.
- static void CleanUpHandlers ()

  Deletes all image handlers.
- static wxImageHandler * FindHandler (const wxString &name)

  Finds the handler with the given name.
- static wxImageHandler * FindHandler (const wxString &extension, wxBitmapType imageType)

  Finds the handler associated with the given extension and type.
- static wxImageHandler * FindHandler (wxBitmapType imageType)

  Finds the handler associated with the given image type.
- static wxImageHandler * FindHandlerMime (const wxString &mimetype)

  Finds the handler associated with the given MIME type.
- static wxList & GetHandlers ()

  Returns the static list of image format handlers.
- static void InitStandardHandlers ()

  Internal use only.
- static void InsertHandler (wxImageHandler *handler)

  Adds a handler at the start of the static list of format handlers.
- static bool RemoveHandler (const wxString &name)

  Finds the handler with the given name, and removes it.

- static int GetImageCount (const wxString &filename, wxBitmapType type=wxBITMAP_TYPE_ANY)

  If the image file contains more than one image and the image handler is capable of retrieving these individually, this function will return the number of available images.
- static int GetImageCount (wxInputStream &stream, wxBitmapType type=wxBITMAP_TYPE_ANY)

  If the image file contains more than one image and the image handler is capable of retrieving these individually, this function will return the number of available images.

Additional Inherited Members

21.398.4 Constructor & Destructor Documentation

wxImage::wxImage ( )

Creates an empty wxImage object without an alpha channel.

wxImage::wxImage (int *width*, int *height*, bool *clear* = `true`)

Creates an image with the given size and clears it if requested.

Does not create an alpha channel.

Parameters

width	Specifies the width of the image.
height	Specifies the height of the image.
clear	If true, initialize the image to black.

wxImage::wxImage (const wxSize & *sz*, bool *clear* = `true`)

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.

wxImage::wxImage (int *width*, int *height*, unsigned char * *data*, bool *static_data* = `false`)

Creates an image from data in memory.

If *static_data* is false then the wxImage will take ownership of the data and free it afterwards. For this, it has to be allocated with *malloc*.

Parameters

width	Specifies the width of the image.
height	Specifies the height of the image.
data	A pointer to RGB data
static_data	Indicates if the data should be free'd after use

wxImage::wxImage (const wxSize & *sz*, unsigned char * *data*, bool *static_data* = `false`)

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.

wxImage::wxImage (int *width*, int *height*, unsigned char * *data*, unsigned char * *alpha*, bool *static_data* = `false`)

Creates an image from data in memory.

If *static_data* is false then the wxImage will take ownership of the data and free it afterwards. For this, it has to be allocated with *malloc*.

Parameters

width	Specifies the width of the image.
height	Specifies the height of the image.
data	A pointer to RGB data
alpha	A pointer to alpha-channel data
static_data	Indicates if the data should be free'd after use

wxImage::wxImage (const wxSize & *sz*, unsigned char * *data*, unsigned char * *alpha*, bool *static_data* = `false`)

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.

wxImage::wxImage (const char *const * *xpmData*)

Creates an image from XPM data.

Parameters

xpmData	A pointer to XPM image data.

wxPerl Note: Not supported by wxPerl.

wxImage::wxImage (const wxString & *name*, wxBitmapType *type* = wxBITMAP_TYPE_ANY, int *index* = -1)

Creates an image from a file.

Parameters

name	Name of the file from which to load the image.
type	May be one of the following: • wxBITMAP_TYPE_BMP: Load a Windows bitmap file. • wxBITMAP_TYPE_GIF: Load a GIF bitmap file. • wxBITMAP_TYPE_JPEG: Load a JPEG bitmap file. • wxBITMAP_TYPE_PNG: Load a PNG bitmap file. • wxBITMAP_TYPE_PCX: Load a PCX bitmap file. • wxBITMAP_TYPE_PNM: Load a PNM bitmap file. • wxBITMAP_TYPE_TIFF: Load a TIFF bitmap file. • wxBITMAP_TYPE_TGA: Load a TGA bitmap file. • wxBITMAP_TYPE_XPM: Load a XPM bitmap file. • wxBITMAP_TYPE_ICO: Load a Windows icon file (ICO). • wxBITMAP_TYPE_CUR: Load a Windows cursor file (CUR). • wxBITMAP_TYPE_ANI: Load a Windows animated cursor file (ANI). • wxBITMAP_TYPE_ANY: Will try to autodetect the format.

index	Index of the image to load in the case that the image file contains multiple images. This is only used by GIF, ICO and TIFF handlers. The default value (-1) means "choose the default image" and is interpreted as the first image (index=0) by the GIF and TIFF handler and as the largest and most colourful one by the ICO handler.

Remarks

Depending on how wxWidgets has been configured and by which handlers have been loaded, not all formats may be available. Any handler other than BMP must be previously initialized with wxImage::AddHandler or wxInitAllImageHandlers.

Note

You can use GetOptionInt() to get the hotspot when loading cursor files:

```
int hotspot_x = image.GetOptionInt(wxIMAGE_OPTION_CUR_HOTSPOT_X);
int hotspot_y = image.GetOptionInt(wxIMAGE_OPTION_CUR_HOTSPOT_Y);
```

See also

LoadFile()

wxImage::wxImage (const wxString & *name*, const wxString & *mimetype*, int *index* = -1)

Creates an image from a file using MIME-types to specify the type.

Parameters

name	Name of the file from which to load the image.
mimetype	MIME type string (for example 'image/jpeg')
index	See description in wxImage(const wxString&, wxBitmapType, int) overload.

wxImage::wxImage (wxInputStream & *stream*, wxBitmapType *type* = wxBITMAP_TYPE_ANY, int *index* = -1)

Creates an image from a stream.

Parameters

stream	Opened input stream from which to load the image. Currently, the stream must support seeking.
type	See description in wxImage(const wxString&, wxBitmapType, int) overload.
index	See description in wxImage(const wxString&, wxBitmapType, int) overload.

wxImage::wxImage (wxInputStream & *stream*, const wxString & *mimetype*, int *index* = -1)

Creates an image from a stream using MIME-types to specify the type.

Parameters

stream	Opened input stream from which to load the image. Currently, the stream must support seeking.

mimetype	MIME type string (for example 'image/jpeg')
index	See description in wxImage(const wxString&, wxBitmapType, int) overload.

virtual wxImage::~wxImage ( ) [virtual]

Destructor.

See reference-counted object destruction for more info.

21.398.5 Member Function Documentation

static void wxImage::AddHandler (wxImageHandler * *handler*) [static]

Register an image handler.

Typical example of use:

```
wxImage::AddHandler(new wxPNGHandler);
```

See Available image handlers for a list of the available handlers. You can also use wxInitAllImageHandlers() to add handlers for all the image formats supported by wxWidgets at once.

Parameters

handler	A heap-allocated handler object which will be deleted by wxImage if it is removed later by RemoveHandler() or at program shutdown.

wxImage wxImage::Blur (int *blurRadius*) const

Blurs the image in both horizontal and vertical directions by the specified pixel *blurRadius*.

This should not be used when using a single mask colour for transparency.

See also

BlurHorizontal(), BlurVertical()

wxImage wxImage::BlurHorizontal (int *blurRadius*) const

Blurs the image in the horizontal direction only.

This should not be used when using a single mask colour for transparency.

See also

Blur(), BlurVertical()

wxImage wxImage::BlurVertical (int *blurRadius*) const

Blurs the image in the vertical direction only.

This should not be used when using a single mask colour for transparency.

See also

Blur(), BlurHorizontal()

static bool wxImage::CanRead (const wxString & *filename*) `[static]`

Returns true if at least one of the available image handlers can read the file with the given name.

See wxImageHandler::CanRead for more info.

static bool wxImage::CanRead (wxInputStream & *stream*) `[static]`

Returns true if at least one of the available image handlers can read the data in the given stream.

See wxImageHandler::CanRead for more info.

static void wxImage::CleanUpHandlers ( ) `[static]`

Deletes all image handlers.

This function is called by wxWidgets on exit.

void wxImage::Clear (unsigned char *value* = 0)

Initialize the image data with zeroes (the default) or with the byte value given as *value*.

Since

2.9.0

void wxImage::ClearAlpha ( )

Removes the alpha channel from the image.

This function should only be called if the image has alpha channel data, use HasAlpha() to check for this.

Since

2.9.1

unsigned long wxImage::ComputeHistogram (wxImageHistogram & *histogram*) const

Computes the histogram of the image.

histogram is a reference to wxImageHistogram object. wxImageHistogram is a specialization of wxHashMap "template" and is defined as follows:

```
class WXDLLEXPORT wxImageHistogramEntry
{
public:
    wxImageHistogramEntry() : index(0), value(0) {}
    unsigned long index;
    unsigned long value;
};

WX_DECLARE_EXPORTED_HASH_MAP(unsigned long, wxImageHistogramEntry,
                             wxIntegerHash, wxIntegerEqual,
                             wxImageHistogram);
```

Returns

Returns number of colours in the histogram.

bool wxImage::ConvertAlphaToMask (unsigned char *threshold* = wxIMAGE_ALPHA_THRESHOLD)

If the image has alpha channel, this method converts it to mask.

If the image has an alpha channel, all pixels with alpha value less than *threshold* are replaced with the mask colour and the alpha channel is removed. Otherwise nothing is done.

The mask colour is chosen automatically using FindFirstUnusedColour() by this function, see the overload below if you this is not appropriate.

Returns

Returns true on success, false on error.

bool wxImage::ConvertAlphaToMask (unsigned char *mr*, unsigned char *mg*, unsigned char *mb*, unsigned char *threshold* = wxIMAGE_ALPHA_THRESHOLD)

If the image has alpha channel, this method converts it to mask using the specified colour as the mask colour.

If the image has an alpha channel, all pixels with alpha value less than *threshold* are replaced with the mask colour and the alpha channel is removed. Otherwise nothing is done.

Since

2.9.0

Parameters

mr	The red component of the mask colour.
mg	The green component of the mask colour.
mb	The blue component of the mask colour.
threshold	Pixels with alpha channel values below the given threshold are considered to be transparent, i.e. the corresponding mask pixels are set. Pixels with the alpha values above the threshold are considered to be opaque.

Returns

Returns true on success, false on error.

wxImage wxImage::ConvertToDisabled (unsigned char *brightness* = 255) const

Returns disabled (dimmed) version of the image.

Since

2.9.0

wxImage wxImage::ConvertToGreyscale (double *weight_r*, double *weight_g*, double *weight_b*) const

Returns a greyscale version of the image.

The returned image uses the luminance component of the original to calculate the greyscale. Defaults to using the standard ITU-T BT.601 when converting to YUV, where every pixel equals (R $*$ *weight_r*) + (G $*$ *weight_g*) + (B $*$ *weight_b*).

wxImage wxImage::ConvertToGreyscale ( ) const

Returns a greyscale version of the image.

Since

2.9.0

wxImage wxImage::ConvertToMono (unsigned char *r*, unsigned char *g*, unsigned char *b*) const

Returns monochromatic version of the image.

The returned image has white colour where the original has (r,g,b) colour and black colour everywhere else.

wxImage wxImage::Copy ( ) const

Returns an identical copy of this image.

bool wxImage::Create (int *width*, int *height*, bool *clear* = `true`)

Creates a fresh image.

See wxImage::wxImage(int,int,bool) for more info.

Returns

true if the call succeeded, false otherwise.

bool wxImage::Create (const wxSize & *sz*, bool *clear* = `true`)

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.

bool wxImage::Create (int *width*, int *height*, unsigned char * *data*, bool *static_data* = `false`)

Creates a fresh image.

See wxImage::wxImage(int,int,unsigned char*,bool) for more info.

Returns

true if the call succeeded, false otherwise.

bool wxImage::Create (const wxSize & *sz*, unsigned char * *data*, bool *static_data* = `false`)

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.

bool wxImage::Create (int *width*, int *height*, unsigned char * *data*, unsigned char * *alpha*, bool *static_data* = `false`)

Creates a fresh image.

See wxImage::wxImage(int,int,unsigned char*,unsigned char*,bool) for more info.

Returns

true if the call succeeded, false otherwise.

bool wxImage::Create (const wxSize & *sz*, unsigned char * *data*, unsigned char * *alpha*, bool *static_data* = `false`)

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.

void wxImage::Destroy ( )

Destroys the image data.

bool wxImage::FindFirstUnusedColour (unsigned char * *r*, unsigned char * *g*, unsigned char * *b*, unsigned char *startR* = `1`, unsigned char *startG* = `0`, unsigned char *startB* = `0`) const

Finds the first colour that is never used in the image.

The search begins at given initial colour and continues by increasing R, G and B components (in this order) by 1 until an unused colour is found or the colour space exhausted.

The parameters *r*, *g*, *b* are pointers to variables to save the colour.

The parameters *startR*, *startG*, *startB* define the initial values of the colour. The returned colour will have RGB values equal to or greater than these.

Returns

Returns false if there is no unused colour left, true on success.

Note

This method involves computing the histogram, which is a computationally intensive operation.

static wxImageHandler* wxImage::FindHandler (const wxString & *name*) `[static]`

Finds the handler with the given name.

Parameters

name	The handler name.

Returns

A pointer to the handler if found, NULL otherwise.

See also

wxImageHandler

static wxImageHandler* wxImage::FindHandler (const wxString & *extension*, wxBitmapType *imageType*) `[static]`

Finds the handler associated with the given extension and type.

Parameters

extension	The file extension, such as "bmp".
imageType	The image type; one of the wxBitmapType values.

Returns

A pointer to the handler if found, NULL otherwise.

See also

wxImageHandler

static wxImageHandler* wxImage::FindHandler (wxBitmapType *imageType*) [static]

Finds the handler associated with the given image type.

Parameters

imageType	The image type; one of the wxBitmapType values.

Returns

A pointer to the handler if found, NULL otherwise.

See also

wxImageHandler

static wxImageHandler* wxImage::FindHandlerMime (const wxString & *mimetype*) [static]

Finds the handler associated with the given MIME type.

Parameters

mimetype	MIME type.

Returns

A pointer to the handler if found, NULL otherwise.

See also

wxImageHandler

unsigned char* wxImage::GetAlpha ( ) const

Returns pointer to the array storing the alpha values for this image.

This pointer is NULL for the images without the alpha channel. If the image does have it, this pointer may be used to directly manipulate the alpha values which are stored as the RGB ones.

unsigned char wxImage::GetAlpha (int *x*, int *y*) const

Return alpha value at given pixel location.

unsigned char wxImage::GetBlue (int *x*, int *y*) const

Returns the blue intensity at the given coordinate.

unsigned char* wxImage::GetData ( ) const

Returns the image data as an array.

This is most often used when doing direct image manipulation. The return value points to an array of characters in RGBRGBRGB... format in the top-to-bottom, left-to-right order, that is the first RGB triplet corresponds to the first pixel of the first row, the second one — to the second pixel of the first row and so on until the end of the first row, with second row following after it and so on.

You should not delete the returned pointer nor pass it to SetData().

unsigned char wxImage::GetGreen (int *x*, int *y*) const

Returns the green intensity at the given coordinate.

static wxList& wxImage::GetHandlers ( ) [static]

Returns the static list of image format handlers.

See also

wxImageHandler

int wxImage::GetHeight ( ) const

Gets the height of the image in pixels.

See also

GetWidth(), GetSize()

static int wxImage::GetImageCount (const wxString & *filename*, wxBitmapType *type* = wxBITMAP_TYPE_ANY) [static]

If the image file contains more than one image and the image handler is capable of retrieving these individually, this function will return the number of available images.

For the overload taking the parameter *filename*, that's the name of the file to query. For the overload taking the parameter *stream*, that's the opened input stream with image data.

See wxImageHandler::GetImageCount() for more info.

The parameter *type* may be one of the following values:

- wxBITMAP_TYPE_BMP: Load a Windows bitmap file.
- wxBITMAP_TYPE_GIF: Load a GIF bitmap file.
- wxBITMAP_TYPE_JPEG: Load a JPEG bitmap file.
- wxBITMAP_TYPE_PNG: Load a PNG bitmap file.
- wxBITMAP_TYPE_PCX: Load a PCX bitmap file.

- wxBITMAP_TYPE_PNM: Load a PNM bitmap file.
- wxBITMAP_TYPE_TIFF: Load a TIFF bitmap file.
- wxBITMAP_TYPE_TGA: Load a TGA bitmap file.
- wxBITMAP_TYPE_XPM: Load a XPM bitmap file.
- wxBITMAP_TYPE_ICO: Load a Windows icon file (ICO).
- wxBITMAP_TYPE_CUR: Load a Windows cursor file (CUR).
- wxBITMAP_TYPE_ANI: Load a Windows animated cursor file (ANI).
- wxBITMAP_TYPE_ANY: Will try to autodetect the format.

Returns

Number of available images. For most image handlers, this is 1 (exceptions are TIFF and ICO formats as well as animated GIFs for which this function returns the number of frames in the animation).

static int wxImage::GetImageCount (wxInputStream & *stream,* wxBitmapType *type* = wxBITMAP_TYPE_ANY) `[static]`

If the image file contains more than one image and the image handler is capable of retrieving these individually, this function will return the number of available images.

For the overload taking the parameter *filename*, that's the name of the file to query. For the overload taking the parameter *stream*, that's the opened input stream with image data.

See wxImageHandler::GetImageCount() for more info.

The parameter *type* may be one of the following values:

- wxBITMAP_TYPE_BMP: Load a Windows bitmap file.
- wxBITMAP_TYPE_GIF: Load a GIF bitmap file.
- wxBITMAP_TYPE_JPEG: Load a JPEG bitmap file.
- wxBITMAP_TYPE_PNG: Load a PNG bitmap file.
- wxBITMAP_TYPE_PCX: Load a PCX bitmap file.
- wxBITMAP_TYPE_PNM: Load a PNM bitmap file.
- wxBITMAP_TYPE_TIFF: Load a TIFF bitmap file.
- wxBITMAP_TYPE_TGA: Load a TGA bitmap file.
- wxBITMAP_TYPE_XPM: Load a XPM bitmap file.
- wxBITMAP_TYPE_ICO: Load a Windows icon file (ICO).
- wxBITMAP_TYPE_CUR: Load a Windows cursor file (CUR).
- wxBITMAP_TYPE_ANI: Load a Windows animated cursor file (ANI).
- wxBITMAP_TYPE_ANY: Will try to autodetect the format.

Returns

Number of available images. For most image handlers, this is 1 (exceptions are TIFF and ICO formats as well as animated GIFs for which this function returns the number of frames in the animation).

static wxString wxImage::GetImageExtWildcard ( ) [static]

Iterates all registered wxImageHandler objects, and returns a string containing file extension masks suitable for passing to file open/save dialog boxes.

Returns

The format of the returned string is "(*.ext1;*.ext2)|*.ext1;*.ext2". It is usually a good idea to prepend a description before passing the result to the dialog. Example:

```
wxFileDialog FileDlg( this, "Choose Image", ::wxGetCwd(), "",
                      _("Image Files ") + wxImage::GetImageExtWildcard(),
                      wxFD_OPEN );
```

See also

wxImageHandler

unsigned char wxImage::GetMaskBlue ( ) const

Gets the blue value of the mask colour.

unsigned char wxImage::GetMaskGreen ( ) const

Gets the green value of the mask colour.

unsigned char wxImage::GetMaskRed ( ) const

Gets the red value of the mask colour.

wxString wxImage::GetOption (const wxString & *name*) const

Gets a user-defined string-valued option.

Generic options:

- wxIMAGE_OPTION_FILENAME: The name of the file from which the image was loaded.

Options specific to wxGIFHandler:

- wxIMAGE_OPTION_GIF_COMMENT: The comment text that is read from or written to the GIF file. In an animated GIF each frame can have its own comment. If there is only a comment in the first frame of a GIF it will not be repeated in other frames.

Parameters

name	The name of the option, case-insensitive.

Returns

The value of the option or an empty string if not found. Use HasOption() if an empty string can be a valid option value.

See also

SetOption(), GetOptionInt(), HasOption()

int wxImage::GetOptionInt (const wxString & *name*) const

Gets a user-defined integer-valued option.

The function is case-insensitive to *name*. If the given option is not present, the function returns 0. Use HasOption() if 0 is a possibly valid value for the option.

Generic options:

- `wxIMAGE_OPTION_MAX_WIDTH` and `wxIMAGE_OPTION_MAX_HEIGHT`: If either of these options is specified, the loaded image will be scaled down (preserving its aspect ratio) so that its width is less than the max width given if it is not 0 *and* its height is less than the max height given if it is not 0. This is typically used for loading thumbnails and the advantage of using these options compared to calling Rescale() after loading is that some handlers (only JPEG one right now) support rescaling the image during loading which is vastly more efficient than loading the entire huge image and rescaling it later (if these options are not supported by the handler, this is still what happens however). These options must be set before calling LoadFile() to have any effect.

- `wxIMAGE_OPTION_ORIGINAL_WIDTH` and `wxIMAGE_OPTION_ORIGINAL_HEIGHT`: These options will return the original size of the image if either `wxIMAGE_OPTION_MAX_WIDTH` or `wxIMAGE_OPTION_MAX_HEIGHT` is specified.

  Since

  2.9.3

- `wxIMAGE_OPTION_QUALITY`: JPEG quality used when saving. This is an integer in 0..100 range with 0 meaning very poor and 100 excellent (but very badly compressed). This option is currently ignored for the other formats.

- `wxIMAGE_OPTION_RESOLUTIONUNIT`: The value of this option determines whether the resolution of the image is specified in centimetres or inches, see wxImageResolution enum elements.

- `wxIMAGE_OPTION_RESOLUTION`, `wxIMAGE_OPTION_RESOLUTIONX` and `wxIMAGE_OPTION_RESOLUTIONY`: These options define the resolution of the image in the units corresponding to `wxIMAGE_OPTION_RESOLUTIONUNIT` options value. The first option can be set before saving the image to set both horizontal and vertical resolution to the same value. The X and Y options are set by the image handlers if they support the image resolution (currently BMP, JPEG and TIFF handlers do) and the image provides the resolution information and can be queried after loading the image.

Options specific to wxPNGHandler:

- `wxIMAGE_OPTION_PNG_FORMAT`: Format for saving a PNG file, see wxImagePNGType for the supported values.
- `wxIMAGE_OPTION_PNG_BITDEPTH`: Bit depth for every channel (R/G/B/A).
- `wxIMAGE_OPTION_PNG_FILTER`: Filter for saving a PNG file, see libpng (`http://www.libpng.org/pub/png/libpng-1.2.5-manual.html`) for possible values (e.g. PNG_FILTER_NONE, PNG_FILTER_SUB, PNG_FILTER_UP, etc).
- `wxIMAGE_OPTION_PNG_COMPRESSION_LEVEL`: Compression level (0..9) for saving a PNG file. An high value creates smaller-but-slower PNG file. Note that unlike other formats (e.g. JPEG) the PNG format is always lossless and thus this compression level doesn't tradeoff the image quality.
- `wxIMAGE_OPTION_PNG_COMPRESSION_MEM_LEVEL`: Compression memory usage level (1..9) for saving a PNG file. An high value means the saving process consumes more memory, but may create smaller PNG file.
- `wxIMAGE_OPTION_PNG_COMPRESSION_STRATEGY`: Possible values are 0 for default strategy, 1 for filter, and 2 for Huffman-only. You can use OptiPNG (`http://optipng.sourceforge.net/`) to get a suitable value for your application.

- wxIMAGE_OPTION_PNG_COMPRESSION_BUFFER_SIZE: Internal buffer size (in bytes) for saving a PNG file. Ideally this should be as big as the resulting PNG file. Use this option if your application produces images with small size variation.

Options specific to wxTIFFHandler:

- wxIMAGE_OPTION_TIFF_BITSPERSAMPLE: Number of bits per sample (channel). Currently values of 1 and 8 are supported. A value of 1 results in a black and white image. A value of 8 (the default) can mean greyscale or RGB, depending on the value of wxIMAGE_OPTION_TIFF_SAMPLESPERPIXEL.
- wxIMAGE_OPTION_TIFF_SAMPLESPERPIXEL: Number of samples (channels) per pixel. Currently values of 1 and 3 are supported. A value of 1 results in either a greyscale (by default) or black and white image, depending on the value of wxIMAGE_OPTION_TIFF_BITSPERSAMPLE. A value of 3 (the default) will result in an RGB image.
- wxIMAGE_OPTION_TIFF_COMPRESSION: Compression type. By default it is set to 1 (COMPRESSION_NONE). Typical other values are 5 (COMPRESSION_LZW) and 7 (COMPRESSION_JPEG). See tiff.h for more options.
- wxIMAGE_OPTION_TIFF_PHOTOMETRIC: Specifies the photometric interpretation. By default it is set to 2 (PHOTOMETRIC_RGB) for RGB images and 0 (PHOTOMETRIC_MINISWHITE) for greyscale or black and white images. It can also be set to 1 (PHOTOMETRIC_MINISBLACK) to treat the lowest value as black and highest as white. If you want a greyscale image it is also sufficient to only specify wxIMAGE_OPTION_TIFF_PHOTOMETRIC and set it to either PHOTOMETRIC_MINISWHITE or PHOTOMETRIC_MINISBLACK. The other values are taken care of.

Note

Be careful when combining the options wxIMAGE_OPTION_TIFF_SAMPLESPERPIXEL, wxIMAGE_OPTION_TIFF_BITSPERSAMPLE, and wxIMAGE_OPTION_TIFF_PHOTOMETRIC. While some measures are taken to prevent illegal combinations and/or values, it is still easy to abuse them and come up with invalid results in the form of either corrupted images or crashes.

Parameters

name	The name of the option, case-insensitive.

Returns

The value of the option or 0 if not found. Use HasOption() if 0 can be a valid option value.

See also

SetOption(), GetOption()

bool wxImage::GetOrFindMaskColour (unsigned char * *r*, unsigned char * *g*, unsigned char * *b*) const

Get the current mask colour or find a suitable unused colour that could be used as a mask colour.

Returns true if the image currently has a mask.

const wxPalette& wxImage::GetPalette ( ) const

Returns the palette associated with the image.

Currently the palette is only used when converting to wxBitmap under Windows.

Some of the wxImage handlers have been modified to set the palette if one exists in the image file (usually 256 or less colour images in GIF or PNG format).

unsigned char wxImage::GetRed (int *x*, int *y*) const

Returns the red intensity at the given coordinate.

wxSize wxImage::GetSize ( ) const

Returns the size of the image in pixels.

Since

2.9.0

See also

GetHeight(), GetWidth()

wxImage wxImage::GetSubImage (const wxRect & *rect*) const

Returns a sub image of the current one as long as the rect belongs entirely to the image.

wxBitmapType wxImage::GetType ( ) const

Gets the type of image found by LoadFile() or specified with SaveFile().

Since

2.9.0

int wxImage::GetWidth ( ) const

Gets the width of the image in pixels.

See also

GetHeight(), GetSize()

bool wxImage::HasAlpha ( ) const

Returns true if this image has alpha channel, false otherwise.

See also

GetAlpha(), SetAlpha()

bool wxImage::HasMask ( ) const

Returns true if there is a mask active, false otherwise.

bool wxImage::HasOption (const wxString & *name*) const

Returns true if the given option is present.

The function is case-insensitive to *name*.

The lists of the currently supported options are in GetOption() and GetOptionInt() function docs.

See also

SetOption(), GetOption(), GetOptionInt()

static wxImage::RGBValue wxImage::HSVtoRGB (const wxImage::HSVValue & *hsv*) [static]

Converts a color in HSV color space to RGB color space.

void wxImage::InitAlpha ( )

Initializes the image alpha channel data.

It is an error to call it if the image already has alpha data. If it doesn't, alpha data will be by default initialized to all pixels being fully opaque. But if the image has a mask colour, all mask pixels will be completely transparent.

static void wxImage::InitStandardHandlers ( ) [static]

Internal use only.

Adds standard image format handlers. It only install wxBMPHandler for the time being, which is used by wxBitmap.

This function is called by wxWidgets on startup, and shouldn't be called by the user.

See also

wxImageHandler, wxInitAllImageHandlers(), wxQuantize

static void wxImage::InsertHandler (wxImageHandler * *handler*) [static]

Adds a handler at the start of the static list of format handlers.

Parameters

handler	A new image format handler object. There is usually only one instance of a given handler class in an application session.

See also

wxImageHandler

bool wxImage::IsOk ( ) const

Returns true if image data is present.

bool wxImage::IsTransparent (int *x*, int *y*, unsigned char *threshold* = wxIMAGE_ALPHA_THRESHOLD) const

Returns true if the given pixel is transparent, i.e. either has the mask colour if this image has a mask or if this image has alpha channel and alpha value of this pixel is strictly less than *threshold*.

virtual bool wxImage::LoadFile (wxInputStream & *stream,* wxBitmapType *type* = wxBITMAP_TYPE_ANY, int *index* = -1) [virtual]

Loads an image from an input stream.

Parameters

stream	Opened input stream from which to load the image. Currently, the stream must support seeking.
type	May be one of the following: • wxBITMAP_TYPE_BMP: Load a Windows bitmap file. • wxBITMAP_TYPE_GIF: Load a GIF bitmap file. • wxBITMAP_TYPE_JPEG: Load a JPEG bitmap file. • wxBITMAP_TYPE_PNG: Load a PNG bitmap file. • wxBITMAP_TYPE_PCX: Load a PCX bitmap file. • wxBITMAP_TYPE_PNM: Load a PNM bitmap file. • wxBITMAP_TYPE_TIFF: Load a TIFF bitmap file. • wxBITMAP_TYPE_TGA: Load a TGA bitmap file. • wxBITMAP_TYPE_XPM: Load a XPM bitmap file. • wxBITMAP_TYPE_ICO: Load a Windows icon file (ICO). • wxBITMAP_TYPE_CUR: Load a Windows cursor file (CUR). • wxBITMAP_TYPE_ANI: Load a Windows animated cursor file (ANI). • wxBITMAP_TYPE_ANY: Will try to autodetect the format.

index	Index of the image to load in the case that the image file contains multiple images. This is only used by GIF, ICO and TIFF handlers. The default value (-1) means "choose the default image" and is interpreted as the first image (index=0) by the GIF and TIFF handler and as the largest and most colourful one by the ICO handler.

Returns

true if the operation succeeded, false otherwise. If the optional index parameter is out of range, false is returned and a call to wxLogError() takes place.

Remarks

Depending on how wxWidgets has been configured, not all formats may be available.

Note

You can use GetOptionInt() to get the hotspot when loading cursor files:

```
int hotspot_x = image.GetOptionInt(wxIMAGE_OPTION_CUR_HOTSPOT_X);
int hotspot_y = image.GetOptionInt(wxIMAGE_OPTION_CUR_HOTSPOT_Y);
```

See also

SaveFile()

virtual bool wxImage::LoadFile (const wxString & *name*, wxBitmapType *type* = wxBITMAP_TYPE_ANY, int *index* = -1) [virtual]

Loads an image from a file.

If no handler type is provided, the library will try to autodetect the format.

Parameters

name	Name of the file from which to load the image.
type	See the description in the LoadFile(wxInputStream&, wxBitmapType, int) overload.
index	See the description in the LoadFile(wxInputStream&, wxBitmapType, int) overload.

virtual bool wxImage::LoadFile (const wxString & *name*, const wxString & *mimetype*, int *index* = -1) [virtual]

Loads an image from a file.

If no handler type is provided, the library will try to autodetect the format.

Parameters

name	Name of the file from which to load the image.
mimetype	MIME type string (for example 'image/jpeg')
index	See the description in the LoadFile(wxInputStream&, wxBitmapType, int) overload.

virtual bool wxImage::LoadFile (wxInputStream & *stream*, const wxString & *mimetype*, int *index* = -1) [virtual]

Loads an image from an input stream.

Parameters

stream	Opened input stream from which to load the image. Currently, the stream must support seeking.
mimetype	MIME type string (for example 'image/jpeg')
index	See the description in the LoadFile(wxInputStream&, wxBitmapType, int) overload.

wxImage wxImage::Mirror (bool *horizontally* = `true`) const

Returns a mirrored copy of the image.

The parameter *horizontally* indicates the orientation.

wxImage& wxImage::operator= (const wxImage & *image*)

Assignment operator, using reference counting.

Parameters

image	Image to assign.

Returns

Returns 'this' object.

void wxImage::Paste (const wxImage & *image,* int *x,* int *y*)

Copy the data of the given *image* to the specified position in this image.

static bool wxImage::RemoveHandler (const wxString & *name*) `[static]`

Finds the handler with the given name, and removes it.

The handler is also deleted.

Parameters

name	The handler name.

Returns

true if the handler was found and removed, false otherwise.

See also

wxImageHandler

void wxImage::Replace (unsigned char *r1,* unsigned char *g1,* unsigned char *b1,* unsigned char *r2,* unsigned char *g2,* unsigned char *b2*)

Replaces the colour specified by *r1*,g1,b1 by the colour *r2*,g2,b2.

wxImage& wxImage::Rescale (int *width,* int *height,* wxImageResizeQuality *quality* = wxIMAGE_QUALITY_NORMAL)

Changes the size of the image in-place by scaling it: after a call to this function,the image will have the given width and height.

For a description of the *quality* parameter, see the Scale() function. Returns the (modified) image itself.

See also

Scale()

wxImage& wxImage::Resize (const wxSize & *size,* const wxPoint & *pos,* int *red* = -1, int *green* = -1, int *blue* = -1)

Changes the size of the image in-place without scaling it by adding either a border with the given colour or cropping as necessary.

The image is pasted into a new image with the given *size* and background colour at the position *pos* relative to the upper left of the new image.

If *red* = green = blue = -1 then use either the current mask colour if set or find, use, and set a suitable mask colour for any newly exposed areas.

Returns

The (modified) image itself.

See also

Size()

static wxImage::HSVValue wxImage::RGBtoHSV (const wxImage::RGBValue & *rgb*) [static]

Converts a color in RGB color space to HSV color space.

wxImage wxImage::Rotate (double *angle,* const wxPoint & *rotationCentre,* bool *interpolating* = true, wxPoint * *offsetAfterRotation* = NULL) const

Rotates the image about the given point, by *angle* radians.

Passing true to *interpolating* results in better image quality, but is slower.

If the image has a mask, then the mask colour is used for the uncovered pixels in the rotated image background. Else, black (rgb 0, 0, 0) will be used.

Returns the rotated image, leaving this image intact.

wxImage wxImage::Rotate180 ( ) const

Returns a copy of the image rotated by 180 degrees.

Since

2.9.2

wxImage wxImage::Rotate90 (bool *clockwise* = true) const

Returns a copy of the image rotated 90 degrees in the direction indicated by *clockwise*.

void wxImage::RotateHue (double *angle*)

Rotates the hue of each pixel in the image by *angle*, which is a double in the range of -1.0 to +1.0, where -1.0 corresponds to -360 degrees and +1.0 corresponds to +360 degrees.

virtual bool wxImage::SaveFile (wxOutputStream & *stream*, const wxString & *mimetype*) const `[virtual]`

Saves an image in the given stream.

Parameters

stream	Opened output stream to save the image to.
mimetype	MIME type.

Returns

true if the operation succeeded, false otherwise.

Remarks

Depending on how wxWidgets has been configured, not all formats may be available.

Note

You can use SetOption() to set the hotspot when saving an image into a cursor file (default hotspot is in the centre of the image):

```
image.SetOption(wxIMAGE_OPTION_CUR_HOTSPOT_X, hotspotX);
image.SetOption(wxIMAGE_OPTION_CUR_HOTSPOT_Y, hotspotY);
```

See also

LoadFile()

virtual bool wxImage::SaveFile (const wxString & *name*, wxBitmapType *type*) const `[virtual]`

Saves an image in the named file.

Parameters

name	Name of the file to save the image to.
type	Currently these types can be used: • wxBITMAP_TYPE_BMP: Save a BMP image file. • wxBITMAP_TYPE_JPEG: Save a JPEG image file. • wxBITMAP_TYPE_PNG: Save a PNG image file. • wxBITMAP_TYPE_PCX: Save a PCX image file (tries to save as 8-bit if possible, falls back to 24-bit otherwise). • wxBITMAP_TYPE_PNM: Save a PNM image file (as raw RGB always). • wxBITMAP_TYPE_TIFF: Save a TIFF image file. • wxBITMAP_TYPE_XPM: Save a XPM image file. • wxBITMAP_TYPE_ICO: Save a Windows icon file (ICO). The size may be up to 255 wide by 127 high. A single image is saved in 8 colors at the size supplied. • wxBITMAP_TYPE_CUR: Save a Windows cursor file (CUR).

virtual bool wxImage::SaveFile (const wxString & *name*, const wxString & *mimetype*) const `[virtual]`

Saves an image in the named file.

Parameters

name	Name of the file to save the image to.
mimetype	MIME type.

virtual bool wxImage::SaveFile (const wxString & *name*) const `[virtual]`

Saves an image in the named file.

File type is determined from the extension of the file name. Note that this function may fail if the extension is not recognized! You can use one of the forms above to save images to files with non-standard extensions.

Parameters

name	Name of the file to save the image to.

virtual bool wxImage::SaveFile (wxOutputStream & *stream*, wxBitmapType *type*) const `[virtual]`

Saves an image in the given stream.

Parameters

stream	Opened output stream to save the image to.
type	MIME type.

wxImage wxImage::Scale (int *width*, int *height*, wxImageResizeQuality *quality* = wxIMAGE_QUALITY_NORMAL) const

Returns a scaled version of the image.

This is also useful for scaling bitmaps in general as the only other way to scale bitmaps is to blit a wxMemoryDC into another wxMemoryDC.

The parameter *quality* determines what method to use for resampling the image, see wxImageResizeQuality documentation.

It should be noted that although using `wxIMAGE_QUALITY_HIGH` produces much nicer looking results it is a slower method. Downsampling will use the box averaging method which seems to operate very fast. If you are upsampling larger images using this method you will most likely notice that it is a bit slower and in extreme cases it will be quite substantially slower as the bicubic algorithm has to process a lot of data.

It should also be noted that the high quality scaling may not work as expected when using a single mask colour for transparency, as the scaling will blur the image and will therefore remove the mask partially. Using the alpha channel will work.

Example:

```
// get the bitmap from somewhere
wxBitmap bmp = ...;

// rescale it to have size of 32*32
if ( bmp.GetWidth() != 32 || bmp.GetHeight() != 32 )
{
    wxImage image = bmp.ConvertToImage();
    bmp = wxBitmap(image.Scale(32, 32));

    // another possibility:
    image.Rescale(32, 32);
    bmp = image;
}
```

See also

Rescale()

void wxImage::SetAlpha (unsigned char * *alpha* = NULL, bool *static_data* = false)

This function is similar to SetData() and has similar restrictions.

The pointer passed to it may however be NULL in which case the function will allocate the alpha array internally – this is useful to add alpha channel data to an image which doesn't have any.

If the pointer is not NULL, it must have one byte for each image pixel and be allocated with malloc(). wxImage takes ownership of the pointer and will free it unless *static_data* parameter is set to true – in this case the caller should do it.

void wxImage::SetAlpha (int *x*, int *y*, unsigned char *alpha*)

Sets the alpha value for the given pixel.

This function should only be called if the image has alpha channel data, use HasAlpha() to check for this.

void wxImage::SetData (unsigned char * *data*, bool *static_data* = false)

Sets the image data without performing checks.

The data given must have the size (width*height*3) or results will be unexpected. Don't use this method if you aren't sure you know what you are doing.

The data must have been allocated with `malloc()`, **NOT** with `operator new`.

If *static_data* is false, after this call the pointer to the data is owned by the wxImage object, that will be responsible for deleting it. Do not pass to this function a pointer obtained through GetData().

void wxImage::SetData (unsigned char * *data*, int *new_width*, int *new_height*, bool *static_data* = false)

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.

void wxImage::SetMask (bool *hasMask* = true)

Specifies whether there is a mask or not.

The area of the mask is determined by the current mask colour.

void wxImage::SetMaskColour (unsigned char *red*, unsigned char *green*, unsigned char *blue*)

Sets the mask colour for this image (and tells the image to use the mask).

bool wxImage::SetMaskFromImage (const wxImage & *mask*, unsigned char *mr*, unsigned char *mg*, unsigned char *mb*)

Sets image's mask so that the pixels that have RGB value of mr,mg,mb in mask will be masked in the image.

This is done by first finding an unused colour in the image, setting this colour as the mask colour and then using this colour to draw all pixels in the image who corresponding pixel in mask has given RGB value.

The parameter *mask* is the mask image to extract mask shape from. It must have the same dimensions as the image.

The parameters *mr*, *mg*, *mb* are the RGB values of the pixels in mask that will be used to create the mask.

Returns

Returns false if mask does not have same dimensions as the image or if there is no unused colour left. Returns true if the mask was successfully applied.

Note

Note that this method involves computing the histogram, which is a computationally intensive operation.

void wxImage::SetOption (const wxString & *name,* const wxString & *value*)

Sets a user-defined option.

The function is case-insensitive to *name*.

For example, when saving as a JPEG file, the option **quality** is used, which is a number between 0 and 100 (0 is terrible, 100 is very good).

The lists of the currently supported options are in GetOption() and GetOptionInt() function docs.

See also

GetOption(), GetOptionInt(), HasOption()

void wxImage::SetOption (const wxString & *name,* int *value*)

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.

void wxImage::SetPalette (const wxPalette & *palette*)

Associates a palette with the image.

The palette may be used when converting wxImage to wxBitmap (MSW only at present) or in file save operations (none as yet).

void wxImage::SetRGB (int *x,* int *y,* unsigned char *r,* unsigned char *g,* unsigned char *b*)

Set the color of the pixel at the given x and y coordinate.

void wxImage::SetRGB (const wxRect & *rect,* unsigned char *red,* unsigned char *green,* unsigned char *blue*)

Sets the colour of the pixels within the given rectangle.

This routine performs bounds-checks for the coordinate so it can be considered a safe way to manipulate the data.

void wxImage::SetType (wxBitmapType *type*)

Set the type of image returned by GetType().

This method is mostly used internally by the library but can also be called from the user code if the image was created from data in the given bitmap format without using LoadFile() (which would set the type correctly automatically).

Notice that the image must be created before this function is called.

Since

2.9.0

Parameters

type	One of bitmap type constants, `wxBITMAP_TYPE_INVALID` is a valid value for it and can be used to reset the bitmap type to default but `wxBITMAP_TYPE_MAX` is not allowed here.

wxImage wxImage::Size (const wxSize & *size*, const wxPoint & *pos*, int *red* = `-1`, int *green* = `-1`, int *blue* = `-1`) const

Returns a resized version of this image without scaling it by adding either a border with the given colour or cropping as necessary.

The image is pasted into a new image with the given *size* and background colour at the position *pos* relative to the upper left of the new image.

If *red* = green = blue = -1 then the areas of the larger image not covered by this image are made transparent by filling them with the image mask colour (which will be allocated automatically if it isn't currently set).

Otherwise, the areas will be filled with the colour with the specified RGB components.

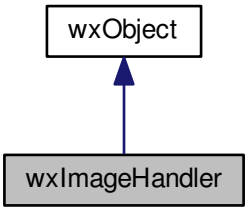
Resize()

21.399 wxImageHandler Class Reference

`#include <wx/image.h>`

Inheritance diagram for wxImageHandler:



21.399.1 Detailed Description

This is the base class for implementing image file loading/saving, and image creation from data.

It is used within wxImage and is not normally seen by the application.

If you wish to extend the capabilities of wxImage, derive a class from wxImageHandler and add the handler using wxImage::AddHandler in your application initialization.

Note that all wxImageHandlers provided by wxWidgets are part of the wxCore library. For details about the default handlers, please see the section Available image handlers in the wxImage class documentation.

21.399.2 Note (Legal Issue)

This software is based in part on the work of the Independent JPEG Group. (Applies when wxWidgets is linked with JPEG support. wxJPEGHandler uses libjpeg created by IJG.)

Predefined objects/pointers: wxNullImage

Library: wxCore

Category: Graphics Device Interface (GDI)

See also

wxImage, wxInitAllImageHandlers()

Public Member Functions

- wxImageHandler ()

  Default constructor.
- virtual ~wxImageHandler ()

  Destroys the wxImageHandler object.
- bool CanRead (wxInputStream &stream)

  Returns true if this handler supports the image format contained in the given stream.
- bool CanRead (const wxString &filename)

  Returns true if this handler supports the image format contained in the file with the given name.
- const wxString & GetExtension () const

  Gets the preferred file extension associated with this handler.
- const wxArrayString & GetAltExtensions () const

  Returns the other file extensions associated with this handler.
- virtual int GetImageCount (wxInputStream &stream)

  If the image file contains more than one image and the image handler is capable of retrieving these individually, this function will return the number of available images.
- const wxString & GetMimeType () const

  Gets the MIME type associated with this handler.
- const wxString & GetName () const

  Gets the name of this handler.
- wxBitmapType GetType () const

  Gets the image type associated with this handler.
- virtual bool LoadFile (wxImage *image, wxInputStream &stream, bool verbose=true, int index=-1)

  Loads a image from a stream, putting the resulting data into image.
- virtual bool SaveFile (wxImage *image, wxOutputStream &stream, bool verbose=true)

  Saves a image in the output stream.
- void SetExtension (const wxString &extension)

  Sets the preferred file extension associated with this handler.
- void SetAltExtensions (const wxArrayString &extensions)

  Sets the alternative file extensions associated with this handler.
- void SetMimeType (const wxString &mimetype)

  Sets the handler MIME type.
- void SetName (const wxString &name)

  Sets the handler name.

Static Public Member Functions

- static wxVersionInfo GetLibraryVersionInfo ()

  Retrieve the version information about the image library used by this handler.

Protected Member Functions

- virtual int DoGetImageCount (wxInputStream &stream)

  Called to get the number of images available in a multi-image file type, if supported.
- virtual bool DoCanRead (wxInputStream &stream)=0

  Called to test if this handler can read an image from the given stream.

Additional Inherited Members

21.399.3 Constructor & Destructor Documentation

wxImageHandler::wxImageHandler ( )

Default constructor.

In your own default constructor, initialise the members m_name, m_extension and m_type.

virtual wxImageHandler::~wxImageHandler ( ) [virtual]

Destroys the wxImageHandler object.

21.399.4 Member Function Documentation

bool wxImageHandler::CanRead (wxInputStream & *stream*)

Returns true if this handler supports the image format contained in the given stream.

This function doesn't modify the current stream position (because it restores the original position before returning; this however requires the stream to be seekable; see wxStreamBase::IsSeekable).

bool wxImageHandler::CanRead (const wxString & *filename*)

Returns true if this handler supports the image format contained in the file with the given name.

This function doesn't modify the current stream position (because it restores the original position before returning; this however requires the stream to be seekable; see wxStreamBase::IsSeekable).

virtual bool wxImageHandler::DoCanRead (wxInputStream & *stream*) [protected], [pure virtual]

Called to test if this handler can read an image from the given stream.

NOTE: this function is allowed to change the current stream position since CallDoCanRead() will take care of restoring it later

virtual int wxImageHandler::DoGetImageCount (wxInputStream & *stream*) [protected], [virtual]

Called to get the number of images available in a multi-image file type, if supported.

NOTE: this function is allowed to change the current stream position since GetImageCount() will take care of restoring it later

const wxArrayString& wxImageHandler::GetAltExtensions ( ) const

Returns the other file extensions associated with this handler.

The preferred extension for this handler is returned by GetExtension().

Since

2.9.0

const wxString& wxImageHandler::GetExtension ( ) const

Gets the preferred file extension associated with this handler.

See also

GetAltExtensions()

virtual int wxImageHandler::GetImageCount (wxInputStream & *stream*) [virtual]

If the image file contains more than one image and the image handler is capable of retrieving these individually, this function will return the number of available images.

Parameters

stream	Opened input stream for reading image data. This function doesn't modify the current stream position (because it restores the original position before returning; this however requires the stream to be seekable; see wxStreamBase::IsSeekable).

Returns

Number of available images. For most image handlers, this is 1 (exceptions are TIFF and ICO formats as well as animated GIFs for which this function returns the number of frames in the animation).

static wxVersionInfo wxImageHandler::GetLibraryVersionInfo ( ) [static]

Retrieve the version information about the image library used by this handler.

This method is not present in wxImageHandler class itself but is present in a few of the classes deriving from it, currently wxJPEGHandler, wxPNGHandler and wxTIFFHandler. It returns the information about the version of the image library being used for the corresponding handler implementation.

Since

2.9.2

const wxString& wxImageHandler::GetMimeType ( ) const

Gets the MIME type associated with this handler.

const wxString& wxImageHandler::GetName ( ) const

Gets the name of this handler.

wxBitmapType wxImageHandler::GetType ( ) const

Gets the image type associated with this handler.

virtual bool wxImageHandler::LoadFile (wxImage * *image*, wxInputStream & *stream*, bool *verbose* = `true`, int *index* = `-1`) [virtual]

Loads a image from a stream, putting the resulting data into *image*.

If the image file contains more than one image and the image handler is capable of retrieving these individually, *index* indicates which image to read from the stream.

Parameters

image	The image object which is to be affected by this operation.
stream	Opened input stream for reading image data.
verbose	If set to true, errors reported by the image handler will produce wxLogMessages.
index	The index of the image in the file (starting from zero).

Returns

true if the operation succeeded, false otherwise.

See also

wxImage::LoadFile, wxImage::SaveFile, SaveFile()

virtual bool wxImageHandler::SaveFile (wxImage * *image*, wxOutputStream & *stream*, bool *verbose* = `true`) [virtual]

Saves a image in the output stream.

Parameters

image	The image object which is to be affected by this operation.
stream	Opened output stream for writing the data.
verbose	If set to true, errors reported by the image handler will produce wxLogMessages.

Returns

true if the operation succeeded, false otherwise.

See also

wxImage::LoadFile, wxImage::SaveFile, LoadFile()

void wxImageHandler::SetAltExtensions (const wxArrayString & *extensions*)

Sets the alternative file extensions associated with this handler.

Parameters

extensions	Array of file extensions.

See also

SetExtension()

Since

2.9.0

void wxImageHandler::SetExtension (const wxString & *extension*)

Sets the preferred file extension associated with this handler.

Parameters

extension	File extension without leading dot.

See also

SetAltExtensions()

void wxImageHandler::SetMimeType (const wxString & *mimetype*)

Sets the handler MIME type.

Parameters

mimetype	Handler MIME type.

void wxImageHandler::SetName (const wxString & *name*)

Sets the handler name.

Parameters

name	Handler name.

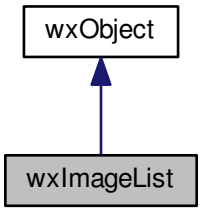
21.401 wxImageList Class Reference

```
#include <wx/imaglist.h>
```

Inheritance diagram for wxImageList:



21.401.1 Detailed Description

A wxImageList contains a list of images, which are stored in an unspecified form.

Images can have masks for transparent drawing, and can be made from a variety of sources including bitmaps and icons.

wxImageList is used principally in conjunction with wxTreeCtrl and wxListCtrl classes.

Library: wxCore

Category: Graphics Device Interface (GDI)

See also

wxTreeCtrl, wxListCtrl

Public Member Functions

- wxImageList ()

  Default ctor.
- wxImageList (int width, int height, bool mask=true, int initialCount=1)

  Constructor specifying the image size, whether image masks should be created, and the initial size of the list.
- int Add (const wxBitmap &bitmap, const wxBitmap &mask=wxNullBitmap)

  Adds a new image or images using a bitmap and optional mask bitmap.
- int Add (const wxBitmap &bitmap, const wxColour &maskColour)

  Adds a new image or images using a bitmap and mask colour.
- int Add (const wxIcon &icon)

  Adds a new image using an icon.
- bool Create (int width, int height, bool mask=true, int initialCount=1)

  Initializes the list.
- virtual bool Draw (int index, wxDC &dc, int x, int y, int flags=wxIMAGELIST_DRAW_NORMAL, bool solid↩ Background=false)

  Draws a specified image onto a device context.
- wxBitmap GetBitmap (int index) const

  Returns the bitmap corresponding to the given index.

- wxIcon GetIcon (int index) const

  Returns the icon corresponding to the given index.
- virtual int GetImageCount () const

  Returns the number of images in the list.
- virtual bool GetSize (int index, int &width, int &height) const

  Retrieves the size of the images in the list.
- bool Remove (int index)

  Removes the image at the given position.
- bool RemoveAll ()

  Removes all the images in the list.
- bool Replace (int index, const wxBitmap &bitmap, const wxBitmap &mask=wxNullBitmap)

  Replaces the existing image with the new image.
- bool Replace (int index, const wxIcon &icon)

  Replaces the existing image with the new image.

Additional Inherited Members

21.401.2 Constructor & Destructor Documentation

wxImageList::wxImageList ( )

Default ctor.

wxImageList::wxImageList (int *width*, int *height*, bool *mask* = `true`, int *initialCount* = `1`)

Constructor specifying the image size, whether image masks should be created, and the initial size of the list.

Parameters

width	Width of the images in the list.
height	Height of the images in the list.
mask	true if masks should be created for all images.
initialCount	The initial size of the list.

See also

Create()

21.401.3 Member Function Documentation

int wxImageList::Add (const wxBitmap & *bitmap*, const wxBitmap & *mask* = wxNullBitmap)

Adds a new image or images using a bitmap and optional mask bitmap.

Parameters

bitmap	Bitmap representing the opaque areas of the image.
mask	Monochrome mask bitmap, representing the transparent areas of the image.

Returns

The new zero-based image index.

Remarks

The original bitmap or icon is not affected by the Add() operation, and can be deleted afterwards. If the bitmap is wider than the images in the list, then the bitmap will automatically be split into smaller images, each matching the dimensions of the image list. This does not apply when adding icons.

int wxImageList::Add (const wxBitmap & *bitmap*, const wxColour & *maskColour*)

Adds a new image or images using a bitmap and mask colour.

Parameters

bitmap	Bitmap representing the opaque areas of the image.
maskColour	Colour indicating which parts of the image are transparent.

Returns

The new zero-based image index.

Remarks

The original bitmap or icon is not affected by the Add() operation, and can be deleted afterwards. If the bitmap is wider than the images in the list, then the bitmap will automatically be split into smaller images, each matching the dimensions of the image list. This does not apply when adding icons.

int wxImageList::Add (const wxIcon & *icon*)

Adds a new image using an icon.

Parameters

icon	Icon to use as the image.

Returns

The new zero-based image index.

Remarks

The original bitmap or icon is not affected by the Add() operation, and can be deleted afterwards. If the bitmap is wider than the images in the list, then the bitmap will automatically be split into smaller images, each matching the dimensions of the image list. This does not apply when adding icons.

Availability: only available for the wxMSW, wxOSX ports.

bool wxImageList::Create (int *width*, int *height*, bool *mask* = `true`, int *initialCount* = `1`)

Initializes the list.

See wxImageList() for details.

virtual bool wxImageList::Draw (int *index*, wxDC & *dc*, int *x*, int *y*, int *flags* = wxIMAGELIST_DRAW_NORMAL, bool *solidBackground* = `false`) `[virtual]`

Draws a specified image onto a device context.

Parameters

index	Image index, starting from zero.
dc	Device context to draw on.
x	X position on the device context.
y	Y position on the device context.
flags	How to draw the image. A bitlist of a selection of the following: • wxIMAGELIST_DRAW_NORMAL: Draw the image normally. • wxIMAGELIST_DRAW_TRANSPARENT: Draw the image with transparency. • wxIMAGELIST_DRAW_SELECTED: Draw the image in selected state. • wxIMAGELIST_DRAW_FOCUSED: Draw the image in a focused state.
solidBackground	For optimisation - drawing can be faster if the function is told that the background is solid.

wxBitmap wxImageList::GetBitmap (int *index*) const

Returns the bitmap corresponding to the given index.

wxIcon wxImageList::GetIcon (int *index*) const

Returns the icon corresponding to the given index.

virtual int wxImageList::GetImageCount ( ) const `[virtual]`

Returns the number of images in the list.

virtual bool wxImageList::GetSize (int *index,* int & *width,* int & *height*) const `[virtual]`

Retrieves the size of the images in the list.

Currently, the *index* parameter is ignored as all images in the list have the same size.

Parameters

index	currently unused, should be 0
width	receives the width of the images in the list
height	receives the height of the images in the list

Returns

true if the function succeeded, false if it failed (for example, if the image list was not yet initialized).

bool wxImageList::Remove (int *index*)

Removes the image at the given position.

bool wxImageList::RemoveAll ( )

Removes all the images in the list.

bool wxImageList::Replace (int *index,* const wxBitmap & *bitmap,* const wxBitmap & *mask* = wxNullBitmap)

Replaces the existing image with the new image.

Windows only.

Parameters

index	The index of the bitmap to be replaced.
bitmap	Bitmap representing the opaque areas of the image.
mask	Monochrome mask bitmap, representing the transparent areas of the image.

Returns

true if the replacement was successful, false otherwise.

Remarks

The original bitmap or icon is not affected by the Replace() operation, and can be deleted afterwards.

bool wxImageList::Replace (int *index,* const wxIcon & *icon*)

Replaces the existing image with the new image.

Parameters

index	The index of the bitmap to be replaced.
icon	Icon to use as the image.

Returns

true if the replacement was successful, false otherwise.

Remarks

The original bitmap or icon is not affected by the Replace() operation, and can be deleted afterwards.

Availability: only available for the wxMSW, wxOSX ports.

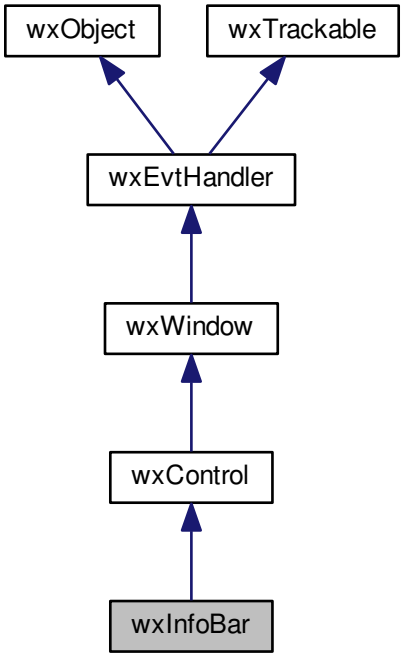
21.403 wxInfoBar Class Reference

`#include <wx/infobar.h>`

Inheritance diagram for wxInfoBar:



21.403.1 Detailed Description

An info bar is a transient window shown at top or bottom of its parent window to display non-critical information to the user.

This class provides another way to show messages to the user, intermediate between message boxes and status bar messages. The message boxes are modal and thus interrupt the users work flow and should be used sparingly for this reason. However status bar messages are often too easy not to notice at all. An info bar provides a way to present the messages which has a much higher chance to be noticed by the user but without being annoying.

Info bar may show an icon (on the left), text message and, optionally, buttons allowing the user to react to the information presented. It always has a close button at the right allowing the user to dismiss it so it isn't necessary to provide a button just to close it.

wxInfoBar calls its parent wxWindow::Layout() method and assumes that it will change the parent layout appropriately depending on whether the info bar itself is shown or hidden. Usually this is achieved by simply using a sizer for the parent window layout and adding wxInfoBar to this sizer as one of the items. Considering the usual placement of the info bars, normally this sizer should be a vertical wxBoxSizer and the bar its first or last element so the simplest possible example of using this class would be:

```
class MyFrame : public wxFrame
{
    ...

    wxInfoBar *m_infoBar;
};

MyFrame::MyFrame()
{
    ...
    m_infoBar = new wxInfoBar(this);
```

```
    wxSizer *sizer = new wxBoxSizer(wxVERTICAL);
    sizer->Add(m_infoBar, wxSizerFlags().Expand());
    ... add other frame controls to the sizer ...
    SetSizer(sizer);
}

void MyFrame::SomeMethod()
{
    m_infoBar->ShowMessage("Something happened", wxICON_INFORMATION);
}
```

See the dialogs sample for more sophisticated examples.

Currently this class is implemented generically (i.e. in the same platform-independent way for all ports) and also natively in wxGTK but the native implementation requires a recent – as of this writing – GTK+ 2.18 version.

Library: wxCore

Category: Miscellaneous Windows

wxStatusBar, wxMessageDialog

Since

2.9.1

Public Member Functions

- wxInfoBar ()

  Default constructor.
- wxInfoBar (wxWindow *parent, wxWindowID winid=wxID_ANY)

  Constructor creating the info bar window.
- bool Create (wxWindow *parent, wxWindowID winid=wxID_ANY)

  Create the info bar window.
- void AddButton (wxWindowID btnid, const wxString &label=wxString())

  Add a button to be shown in the info bar.
- virtual void Dismiss ()

  Hide the info bar window.
- void RemoveButton (wxWindowID btnid)

  Remove a button previously added by AddButton().
- void ShowMessage (const wxString &msg, int flags=wxICON_NONE)

  Show a message in the bar.
- virtual size_t GetButtonCount () const

  Returns the number of currently shown buttons.
- virtual wxWindowID GetButtonId (size_t idx) const

  Returns the ID of the button at the given position.
- virtual bool HasButtonId (wxWindowID btnid) const

  Returns whether a button with the given ID is currently shown.

Generic version customization methods.

All these methods exist in the generic version of the class only.

The generic version uses wxWindow::ShowWithEffect() function to progressively show it on the platforms which support it (currently only wxMSW). The methods here allow to change the default effect used (or disable it entirely) and change its duration.

- void SetShowHideEffects (wxShowEffect showEffect, wxShowEffect hideEffect)
  Set the effects to use when showing and hiding the bar.
- wxShowEffect GetShowEffect () const
  Return the effect currently used for showing the bar.
- wxShowEffect GetHideEffect () const
  Return the effect currently used for hiding the bar.
- void SetEffectDuration (int duration)
  Set the duration of the animation used when showing or hiding the bar.
- int GetEffectDuration () const
  Return the effect animation duration currently used.
- virtual bool SetFont (const wxFont &font)
  Overridden base class methods changes the font of the text message.

Additional Inherited Members

21.403.2 Constructor & Destructor Documentation

wxInfoBar::wxInfoBar ( )

Default constructor.

Use Create() for the objects created using this constructor.

wxInfoBar::wxInfoBar (wxWindow * *parent*, wxWindowID *winid* = wxID_ANY)

Constructor creating the info bar window.

See also

Create()

21.403.3 Member Function Documentation

void wxInfoBar::AddButton (wxWindowID *btnid*, const wxString & *label* = wxString())

Add a button to be shown in the info bar.

The button added by this method will be shown to the right of the text (in LTR layout), with each successive button being added to the right of the previous one. If any buttons are added to the info bar using this method, the default "Close" button is not shown as it is assumed that the extra buttons already allow the user to close it.

Clicking the button will generate a normal EVT_COMMAND_BUTTON_CLICKED event which can be handled as usual. The default handler in wxInfoBar itself closes the window whenever a button in it is clicked so if you wish the info bar to be hidden when the button is clicked, simply call `event.Skip()` in the button handler to let the base class handler do it (calling Dismiss() explicitly works too, of course). On the other hand, if you don't skip the event, the info bar will remain opened so make sure to do it for at least some buttons to allow the user to close it.

Notice that the generic wxInfoBar implementation handles the button events itself and so they are not propagated to the info bar parent and you need to either inherit from wxInfoBar and handle them in your derived class or use wxEvtHandler::Connect(), as is done in the dialogs sample, to handle the button events in the parent frame.

Parameters

btnid	Id of the button. It will be used in the button message clicking this button will generate.

label	The label of the button. It may only be empty if *btnid* is one of the stock ids in which case the corresponding stock label (see wxGetStockLabel()) will be used.

bool wxInfoBar::Create (wxWindow * *parent*, wxWindowID *winid* = wxID_ANY)

Create the info bar window.

Notice that unlike most of the other wxWindow-derived classes, wxInfoBar is created hidden and is only shown when ShowMessage() is called. This is more convenient as usually the info bar is created to be shown at some later time and not immediately and so creating it hidden avoids the need to call Hide() explicitly from the code using it.

This should be only called if the object was created using its default constructor.

Parameters

parent	A valid parent window pointer.
winid	The id of the info bar window, usually unused as currently no events are generated by this class.

virtual void wxInfoBar::Dismiss ( ) [virtual]

Hide the info bar window.

This method hides the window and lays out the parent window to account for its disappearance (unlike a simple Hide()).

virtual size_t wxInfoBar::GetButtonCount ( ) const [virtual]

Returns the number of currently shown buttons.

This is simply the number of calls to AddButton() minus the number of calls to RemoveButton() so far.

Returns

The number of currently shown buttons, possibly 0.

Since

3.1.0

virtual wxWindowID wxInfoBar::GetButtonId (size_t *idx*) const [virtual]

Returns the ID of the button at the given position.

The positions of the buttons are counted in order of their addition.

Parameters

idx	The position of the button in 0 to GetButtonCount() range.

Returns

The ID of the button at the given position or wxID_NONE if it is out of range (this also results in an assertion failure).

Since

3.1.0

int wxInfoBar::GetEffectDuration ( ) const

Return the effect animation duration currently used.

wxShowEffect wxInfoBar::GetHideEffect ( ) const

Return the effect currently used for hiding the bar.

wxShowEffect wxInfoBar::GetShowEffect ( ) const

Return the effect currently used for showing the bar.

virtual bool wxInfoBar::HasButtonId (wxWindowID *btnid*) const [virtual]

Returns whether a button with the given ID is currently shown.

Parameters

btnid	ID of the button to check for.

Returns

true if the button with this ID is currently shown.

Since

3.1.0

void wxInfoBar::RemoveButton (wxWindowID *btnid*)

Remove a button previously added by AddButton().

Parameters

btnid	Id of the button to remove. If more than one button with the same id is used in the info bar (which is in any case not recommended), the last, i.e. most recently added, button with this id is removed.

void wxInfoBar::SetEffectDuration (int *duration*)

Set the duration of the animation used when showing or hiding the bar.

By default, 500ms duration is used.

Parameters

duration	Duration of the animation, in milliseconds.

virtual bool wxInfoBar::SetFont (const wxFont & *font*) [virtual]

Overridden base class methods changes the font of the text message.

wxInfoBar overrides this method to use the font passed to it for its text message part. By default a larger and bold version of the standard font is used.

This method is generic-only.

Reimplemented from wxWindow.

void wxInfoBar::SetShowHideEffects (wxShowEffect *showEffect*, wxShowEffect *hideEffect*)

Set the effects to use when showing and hiding the bar.

Either or both of the parameters can be set to wxSHOW_EFFECT_NONE to disable using effects entirely.

By default, the info bar uses wxSHOW_EFFECT_SLIDE_TO_BOTTOM effect for showing itself and wxSHOW_E↩FFECT_SLIDE_TO_TOP for hiding if it is the first element of the containing sizer and reverse effects if it's the last one. If it is neither the first nor the last element, no effect is used to avoid the use of an inappropriate one and this function must be called if an effect is desired.

Parameters

showEffect	The effect to use when showing the bar.
hideEffect	The effect to use when hiding the bar.

void wxInfoBar::ShowMessage (const wxString & *msg*, int *flags* = wxICON_NONE)

Show a message in the bar.

If the bar is currently hidden, it will be shown. Otherwise its message will be updated in place.

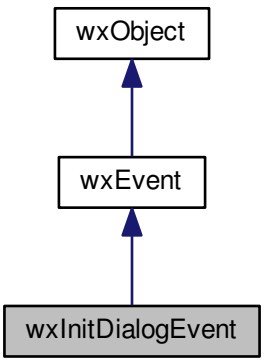
Parameters

msg	The text of the message.
flags	One of wxICON_NONE, wxICON_INFORMATION (default), wxICON_QUESTION, wxICO↩N_WARNING or wxICON_ERROR values. These flags have the same meaning as in wx↩MessageDialog for the generic version, i.e. show (or not, in case of wxICON_NONE) the corresponding icon in the bar but can be interpreted by the native versions. For example, the GTK+ native implementation doesn't show icons at all but uses this parameter to select the appropriate background colour for the notification.

21.404 wxInitDialogEvent Class Reference

`#include <wx/event.h>`

Inheritance diagram for wxInitDialogEvent:



21.404.1 Detailed Description

A wxInitDialogEvent is sent as a dialog or panel is being initialised.

Handlers for this event can transfer data to the window.

The default handler calls wxWindow::TransferDataToWindow.

Events using this class

The following event handler macros redirect the events to member function handlers '**func**' with prototypes like: void handlerFuncName(wxInitDialogEvent& event)

Event macros:

- EVT_INIT_DIALOG(func): Process a `wxEVT_INIT_DIALOG` event.

Library: wxCore

Category: Events

- ~wxInitializer ()

  This dtor only does clean up if we initialized the library properly.

21.405.2 Constructor & Destructor Documentation

wxInitializer::wxInitializer (int *argc* = `0`, wxChar ** *argv* = `NULL`)

Initializes the library.

Calls wxInitialize().

wxInitializer::~wxInitializer ( )

This dtor only does clean up if we initialized the library properly.

Calls wxUninitialize().

21.405.3 Member Function Documentation

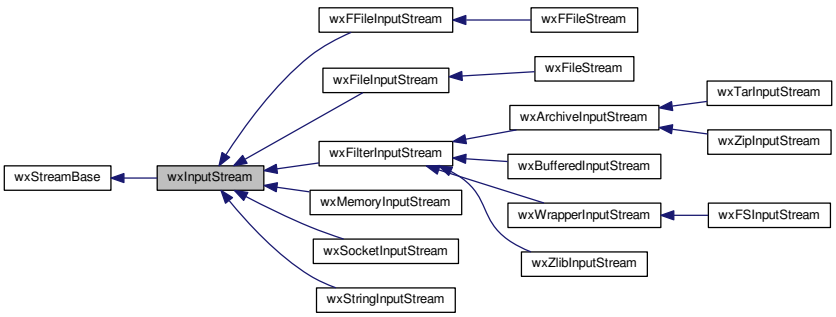
bool wxInitializer::IsOk ( ) const

Has the initialization been successful? (explicit test)

21.406 wxInputStream Class Reference

`#include <wx/stream.h>`

Inheritance diagram for wxInputStream:



21.406.1 Detailed Description

wxInputStream is an abstract base class which may not be used directly.

It is the base class of all streams which provide a Read() function, i.e. which can be used to read data from a source (e.g. a file, a socket, etc).

If you want to create your own input stream, you'll need to derive from this class and implement the protected OnSysRead() function only.

Library: wxBase

Category: Streams

Public Member Functions

- wxInputStream ()

  Creates a dummy input stream.
- virtual ~wxInputStream ()

  Destructor.
- virtual bool CanRead () const

  Returns true if some data is available in the stream right now, so that calling Read() wouldn't block.
- virtual bool Eof () const

  Returns true after an attempt has been made to read past the end of the stream.
- int GetC ()

  Returns the first character in the input queue and removes it, blocking until it appears if necessary.
- virtual size_t LastRead () const

  Returns the last number of bytes read.
- virtual char Peek ()

  Returns the first character in the input queue without removing it.
- virtual wxInputStream & Read (void *buffer, size_t size)

  Reads the specified amount of bytes and stores the data in buffer.
- wxInputStream & Read (wxOutputStream &stream_out)

  Reads data from the input queue and stores it in the specified output stream.
- bool ReadAll (void *buffer, size_t size)

  Reads exactly the specified number of bytes into the buffer.
- virtual wxFileOffset SeekI (wxFileOffset pos, wxSeekMode mode=wxFromStart)

  Changes the stream current position.
- virtual wxFileOffset TellI () const

  Returns the current stream position or wxInvalidOffset if it's not available (e.g.
- size_t Ungetch (const void *buffer, size_t size)

  This function is only useful in read mode.
- bool Ungetch (char c)

  This function acts like the previous one except that it takes only one character: it is sometimes shorter to use than the generic function.

Protected Member Functions

- size_t OnSysRead (void *buffer, size_t bufsize)=0

  Internal function.

21.406.2 Constructor & Destructor Documentation

wxInputStream::wxInputStream ( )

Creates a dummy input stream.

virtual wxInputStream::~wxInputStream ( ) [virtual]

Destructor.

21.406.3 Member Function Documentation

virtual bool wxInputStream::CanRead ( ) const [virtual]

Returns true if some data is available in the stream right now, so that calling Read() wouldn't block.

virtual bool wxInputStream::Eof ( ) const [virtual]

Returns true after an attempt has been made to read past the end of the stream.

int wxInputStream::GetC ( )

Returns the first character in the input queue and removes it, blocking until it appears if necessary.

On success returns a value between 0 - 255; on end of file returns `wxEOF`.

virtual size_t wxInputStream::LastRead ( ) const [virtual]

Returns the last number of bytes read.

size_t wxInputStream::OnSysRead (void * *buffer*, size_t *bufsize*) [protected], [pure virtual]

Internal function.

It is called when the stream wants to read data of the specified size *bufsize* and wants it to be placed inside *buffer*.

It should return the size that was actually read or zero if EOF has been reached or an error occurred (in this last case the internal `m_lasterror` variable should be set accordingly as well).

virtual char wxInputStream::Peek ( ) [virtual]

Returns the first character in the input queue without removing it.

virtual wxInputStream& wxInputStream::Read (void * *buffer*, size_t *size*) [virtual]

Reads the specified amount of bytes and stores the data in buffer.

To check if the call was successful you must use LastRead() to check if this call did actually read *size* bytes (if it didn't, GetLastError() should return a meaningful value).

Warning

The buffer absolutely needs to have at least the specified size.

Returns

This function returns a reference on the current object, so the user can test any states of the stream right away.

wxInputStream& wxInputStream::Read (wxOutputStream & *stream_out*)

Reads data from the input queue and stores it in the specified output stream.

The data is read until an error is raised by one of the two streams.

Returns

This function returns a reference on the current object, so the user can test any states of the stream right away.

bool wxInputStream::ReadAll (void * *buffer,* size_t *size*)

Reads exactly the specified number of bytes into the buffer.

Returns true only if the entire amount of data was read, otherwise false is returned and the number of bytes really read can be retrieved using LastRead(), as with Read().

This method uses repeated calls to Read() (which may return after reading less than the requested number of bytes) if necessary.

Warning

The buffer absolutely needs to have at least the specified size.

Since

2.9.5

virtual wxFileOffset wxInputStream::SeekI (wxFileOffset *pos,* wxSeekMode *mode* = wxFromStart) [virtual]

Changes the stream current position.

This operation in general is possible only for seekable streams (see wxStreamBase::IsSeekable()); non-seekable streams support only seeking positive amounts in mode `wxFromCurrent` (this is implemented by reading data and simply discarding it).

Parameters

pos	Offset to seek to.
mode	One of wxFromStart, wxFromEnd, wxFromCurrent.

Returns

The new stream position or wxInvalidOffset on error.

virtual wxFileOffset wxInputStream::TellI ( ) const [virtual]

Returns the current stream position or wxInvalidOffset if it's not available (e.g.

socket streams do not have a size nor a current stream position).

size_t wxInputStream::Ungetch (const void * *buffer*, size_t *size*)

This function is only useful in read mode.

It is the manager of the "Write-Back" buffer. This buffer acts like a temporary buffer where data which has to be read during the next read IO call are put. This is useful when you get a big block of data which you didn't want to read: you can replace them at the top of the input queue by this way.

Be very careful about this call in connection with calling SeekI() on the same stream. Any call to SeekI() will invalidate any previous call to this method (otherwise you could SeekI() to one position, "unread" a few bytes there, SeekI() to another position and data would be either lost or corrupted).

Returns

Returns the amount of bytes saved in the Write-Back buffer.

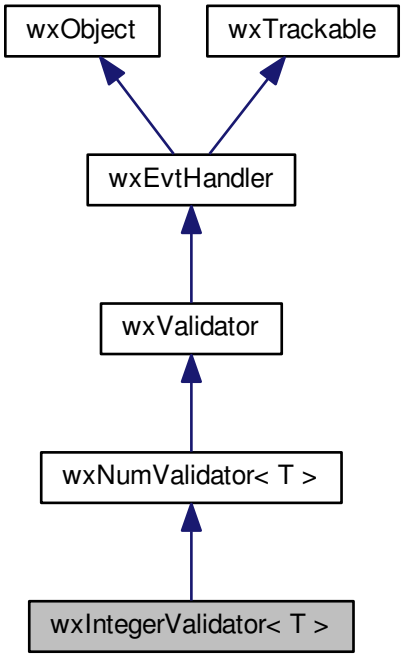
bool wxInputStream::Ungetch (char *c*)

This function acts like the previous one except that it takes only one character: it is sometimes shorter to use than the generic function.

21.407 wxIntegerValidator< T > Class Template Reference

`#include <wx/valnum.h>`

Inheritance diagram for wxIntegerValidator< T >:



21.407.1 Detailed Description

template<typename T>class wxIntegerValidator< T >

Validator for text entries used for integer entry.

This validator can be used with wxTextCtrl or wxComboBox (and potentially any other class implementing wxTextEntry interface) to check that only valid integer values can be entered into them.

This is a template class which can be instantiated for all the integer types (i.e. `short`, `int`, `long` and `long long` if available) as well as their unsigned versions.

By default this validator accepts any integer values in the range appropriate for its type, e.g. `INT_MIN..INT_MAX` for `int` or `0..USHRT_MAX` for `unsigned short`. This range can be restricted further by calling SetMin() and SetMax() or SetRange() methods inherited from the base class.

When the validator displays integers with thousands separators, the character used for the separators (usually "." or ",") depends on the locale set with wxLocale (note that you shouldn't change locale with setlocale() as this can result in a mismatch between the thousands separator used by wxLocale and the one used by the run-time library).

A simple example of using this class:

```
class MyDialog : public wxDialog
{
public:
    MyDialog()
    {
        ...
        // Allow positive integers and display them with thousands
        // separators.
        wxIntegerValidator<unsigned long>
            val(&m_value, wxNUM_VAL_THOUSANDS_SEPARATOR);

        // If the variable were of type "long" and not "unsigned long"
        // we would have needed to call val.SetMin(0) but as it is,
        // this is not needed.

        // Associate it with the text control:
        new wxTextCtrl(this, ..., val);
    }

private:
    unsigned long m_value;
};
```

For more information, please see wxValidator Overview.

Library: wxCore

Category: Validators

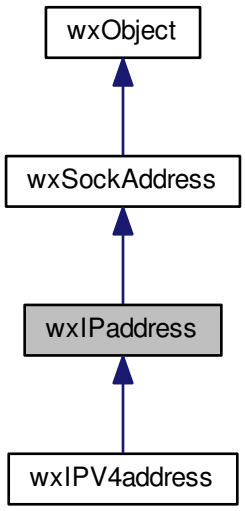
21.409 wxIPaddress Class Reference

`#include <wx/socket.h>`

Inheritance diagram for wxIPaddress:



21.409.1 Detailed Description

wxIPaddress is an abstract base class for all internet protocol address objects.

Currently, only wxIPV4address is implemented. An experimental implementation for IPV6, wxIPV6address, is being developed.

Library: wxNet

Category: Networking

Public Member Functions

- bool AnyAddress ()

  *Internally, this is the same as setting the IP address to **INADDR_ANY**.*
- virtual bool BroadcastAddress ()=0

  *Internally, this is the same as setting the IP address to **INADDR_BROADCAST**.*
- bool Hostname (const wxString &hostname)

  Set the address to hostname, which can be a host name or an IP-style address in a format dependent on implementation.
- wxString Hostname () const

  Returns the hostname which matches the IP address.
- virtual wxString IPAddress () const =0

  Returns a wxString containing the IP address.
- virtual bool IsLocalHost () const =0

  Determines if current address is set to localhost.
- bool LocalHost ()

  Set address to localhost.
- bool Service (const wxString &service)

  Set the port to that corresponding to the specified service.
- bool Service (unsigned short service)

  Set the port to that corresponding to the specified service.
- unsigned short Service () const

  Returns the current service.

Additional Inherited Members

21.409.2 Member Function Documentation

bool wxIPaddress::AnyAddress ( )

Internally, this is the same as setting the IP address to **INADDR_ANY**.

On IPV4 implementations, 0.0.0.0

On IPV6 implementations, ::

Returns

true on success, false if something went wrong.

virtual bool wxIPaddress::BroadcastAddress ( ) [pure virtual]

Internally, this is the same as setting the IP address to **INADDR_BROADCAST**.

On IPV4 implementations, 255.255.255.255

Returns

true on success, false if something went wrong.

bool wxIPaddress::Hostname (const wxString & *hostname*)

Set the address to hostname, which can be a host name or an IP-style address in a format dependent on implementation.

Returns

true on success, false if something goes wrong (invalid hostname or invalid IP address).

wxString wxIPaddress::Hostname ( ) const

Returns the hostname which matches the IP address.

virtual wxString wxIPaddress::IPAddress ( ) const `[pure virtual]`

Returns a wxString containing the IP address.

Implemented in wxIPV4address.

virtual bool wxIPaddress::IsLocalHost ( ) const `[pure virtual]`

Determines if current address is set to localhost.

Returns

true if address is localhost, false if internet address.

bool wxIPaddress::LocalHost ( )

Set address to localhost.

On IPV4 implementations, 127.0.0.1

On IPV6 implementations, ::1

Returns

true on success, false if something went wrong.

bool wxIPaddress::Service (const wxString & *service*)

Set the port to that corresponding to the specified service.

Returns

true on success, false if something goes wrong (invalid *service*).

bool wxIPaddress::Service (unsigned short *service*)

Set the port to that corresponding to the specified service.

Returns

true on success, false if something goes wrong (invalid *service*).

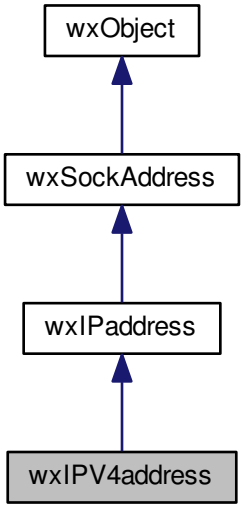
unsigned short wxIPaddress::Service ( ) const

Returns the current service.

21.410 wxIPV4address Class Reference

`#include <wx/socket.h>`

Inheritance diagram for wxIPV4address:



21.410.1 Detailed Description

A class for working with IPv4 network addresses.

Library: wxNet

Category: Networking

Public Member Functions

- bool AnyAddress ()

  Set address to any of the addresses of the current machine.
- bool Hostname (const wxString &hostname)

  Set the address to hostname, which can be a host name or an IP-style address in dot notation(`a.b.c.d`).
- virtual wxString Hostname () const

  Returns the hostname which matches the IP address.
- virtual wxString IPAddress () const

  Returns a wxString containing the IP address in dot quad (127.0.0.1) format.

- bool LocalHost ()

  Set address to localhost (127.0.0.1).
- bool Service (const wxString &service)

  Set the port to that corresponding to the specified service.
- bool Service (unsigned short service)

  Set the port to that corresponding to the specified service.
- unsigned short Service () const

  Returns the current service.

Additional Inherited Members

21.410.2 Member Function Documentation

bool wxIPV4address::AnyAddress ( )

Set address to any of the addresses of the current machine.

Whenever possible, use this function instead of LocalHost(), as this correctly handles multi-homed hosts and avoids other small problems. Internally, this is the same as setting the IP address to **INADDR_ANY**.

Returns

true on success, false if something went wrong.

bool wxIPV4address::Hostname (const wxString & *hostname*)

Set the address to hostname, which can be a host name or an IP-style address in dot notation(`a.b.c.d`).

Returns

true on success, false if something goes wrong (invalid hostname or invalid IP address).

virtual wxString wxIPV4address::Hostname ( ) const `[virtual]`

Returns the hostname which matches the IP address.

virtual wxString wxIPV4address::IPAddress ( ) const `[virtual]`

Returns a wxString containing the IP address in dot quad (127.0.0.1) format.

Implements wxIPaddress.

bool wxIPV4address::LocalHost ( )

Set address to localhost (127.0.0.1).

Whenever possible, use AnyAddress() instead of this one, as that one will correctly handle multi-homed hosts and avoid other small problems.

Returns

true on success, false if something went wrong.

bool wxIPV4address::Service (const wxString & *service*)

Set the port to that corresponding to the specified *service*.

Returns

true on success, false if something goes wrong (invalid *service*).

bool wxIPV4address::Service (unsigned short *service*)

Set the port to that corresponding to the specified *service*.

Returns

true on success, false if something goes wrong (invalid *service*).

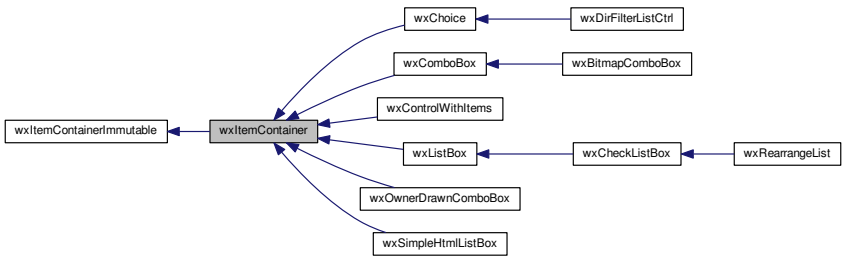
unsigned short wxIPV4address::Service ( ) const

Returns the current service.

21.411 wxItemContainer Class Reference

`#include <wx/ctrlsub.h>`

Inheritance diagram for wxItemContainer:



21.411.1 Detailed Description

This class is an abstract base class for some wxWidgets controls which contain several items such as wxListBox, wxCheckListBox, wxComboBox or wxChoice.

It defines an interface which is implemented by all controls which have string subitems each of which may be selected.

wxItemContainer extends wxItemContainerImmutable interface with methods for adding/removing items.

It defines the methods for accessing the controls items and although each of the derived classes implements them differently, they still all conform to the same interface.

The items in a wxItemContainer have (non-empty) string labels and, optionally, client data associated with them. Client data may be of two different kinds: either simple untyped (`void *`) pointers which are simply stored by the control but not used in any way by it, or typed pointers (wxClientData*) which are owned by the control meaning that the typed client data (and only it) will be deleted when an item is deleted using Delete() or the entire control is cleared using Clear(), which also happens when it is destroyed.

Finally note that in the same control all items must have client data of the same type (typed or untyped), if any. This type is determined by the first call to Append() (the version with client data pointer) or SetClientData().

Note that this is not a control, it's a mixin interface that classes have to derive from in addition to wxControl or wxWindow. Convenience class wxControlWithItems is provided for this purpose.

Library: wxCore

Category: Controls

See also

wxControlWithItems, wxItemContainerImmutable

Public Member Functions

- void Clear ()

  Removes all items from the control.
- void Delete (unsigned int n)

  Deletes an item from the control.
- wxClientData * DetachClientObject (unsigned int n)

  Returns the client object associated with the given item and transfers its ownership to the caller.
- bool HasClientData () const

  Returns true, if either untyped data (`void*`) or object data (wxClientData) is associated with the items of the control.*
- bool HasClientObjectData () const

  Returns true, if object data is associated with the items of the control.
- bool HasClientUntypedData () const

  Returns true, if untyped data (`void*`) is associated with the items of the control.

- int Append (const wxString &item)

  Appends item into the control.
- int Append (const wxString &item, void *clientData)

  Appends item into the control.
- int Append (const wxString &item, wxClientData *clientData)

  Appends item into the control.
- int Append (const wxArrayString &items)

  Appends several items at once into the control.
- template<typename T >
  int Append (const std::vector< T > &items)

  Appends several items at once into the control.
- int Append (const wxArrayString &items, void **clientData)

  Appends several items at once into the control.
- int Append (const wxArrayString &items, wxClientData **clientData)

  Appends several items at once into the control.
- int Append (unsigned int n, const wxString *items)

  Appends several items at once into the control.
- int Append (unsigned int n, const wxString *items, void **clientData)

  Appends several items at once into the control.
- int Append (unsigned int n, const wxString *items, wxClientData **clientData)

  Appends several items at once into the control.

- void * GetClientData (unsigned int n) const

  Returns a pointer to the client data associated with the given item (if any).
- wxClientData * GetClientObject (unsigned int n) const

  Returns a pointer to the client data associated with the given item (if any).
- void SetClientData (unsigned int n, void *data)

  Associates the given untyped client data pointer with the given item.
- void SetClientObject (unsigned int n, wxClientData *data)

  Associates the given typed client data pointer with the given item: the data object will be deleted when the item is deleted (either explicitly by using Delete() or implicitly when the control itself is destroyed).

- int Insert (const wxString &item, unsigned int pos)

  Inserts item into the control.
- int Insert (const wxString &item, unsigned int pos, void *clientData)

  Inserts item into the control.
- int Insert (const wxString &item, unsigned int pos, wxClientData *clientData)

  Inserts item into the control.
- int Insert (const wxArrayString &items, unsigned int pos)

  Inserts several items at once into the control.
- template<typename T >
  int Insert (const std::vector< T > &items)

  Inserts several items at once into the control.
- int Insert (const wxArrayString &items, unsigned int pos, void **clientData)

  Inserts several items at once into the control.
- int Insert (const wxArrayString &items, unsigned int pos, wxClientData **clientData)

  Inserts several items at once into the control.
- int Insert (unsigned int n, const wxString *items, unsigned int pos)

  Inserts several items at once into the control.
- int Insert (unsigned int n, const wxString *items, unsigned int pos, void **clientData)

  Inserts several items at once into the control.
- int Insert (unsigned int n, const wxString *items, unsigned int pos, wxClientData **clientData)

  Inserts several items at once into the control.

- void Set (const wxArrayString &items)

  Replaces the current control contents with the given items.
- template<typename T >
  void Set (const std::vector< T > &items)

  Replaces the current control contents with the given items.
- void Set (const wxArrayString &items, void **clientData)

  Replaces the current control contents with the given items.
- void Set (const wxArrayString &items, wxClientData **clientData)

  Replaces the current control contents with the given items.
- void Set (unsigned int n, const wxString *items)

  Replaces the current control contents with the given items.
- void Set (unsigned int n, const wxString *items, void **clientData)

  Replaces the current control contents with the given items.
- void Set (unsigned int n, const wxString *items, wxClientData **clientData)

  Replaces the current control contents with the given items.

21.411.2 Member Function Documentation

int wxItemContainer::Append (const wxString & *item*)

Appends item into the control.

Parameters

item	String to add.

Returns

The return value is the index of the newly inserted item. Note that this may be different from the last one if the control is sorted (e.g. has `wxLB_SORT` or `wxCB_SORT` style).

int wxItemContainer::Append (const wxString & *item,* void * *clientData*)

Appends item into the control.

Parameters

item	String to add.
clientData	Pointer to client data to associate with the new item.

Returns

The return value is the index of the newly inserted item. Note that this may be different from the last one if the control is sorted (e.g. has `wxLB_SORT` or `wxCB_SORT` style).

int wxItemContainer::Append (const wxString & *item,* wxClientData * *clientData*)

Appends item into the control.

Parameters

item	String to add.
clientData	Pointer to client data to associate with the new item.

Returns

The return value is the index of the newly inserted item. Note that this may be different from the last one if the control is sorted (e.g. has `wxLB_SORT` or `wxCB_SORT` style).

int wxItemContainer::Append (const wxArrayString & *items*)

Appends several items at once into the control.

Notice that calling this method is usually much faster than appending them one by one if you need to add a lot of items.

Parameters

items	Array of strings to insert.

template<typename T > int wxItemContainer::Append (const std::vector< T > & *items*)

Appends several items at once into the control.

This is the same as the overload taking wxArrayString, except that it works with the standard vector container.

The template argument `T` can be any type convertible to wxString, including wxString itself but also `std::string`, `char*` or `wchar_t*`.

Since

3.1.0

int wxItemContainer::Append (const wxArrayString & *items*, void ∗∗ *clientData*)

Appends several items at once into the control.

Notice that calling this method is usually much faster than appending them one by one if you need to add a lot of items.

Parameters

items	Array of strings to insert.
clientData	Array of client data pointers of the same size as *items* to associate with the new items.

int wxItemContainer::Append (const wxArrayString & *items*, wxClientData ∗∗ *clientData*)

Appends several items at once into the control.

Notice that calling this method is usually much faster than appending them one by one if you need to add a lot of items.

Parameters

items	Array of strings to insert.
clientData	Array of client data pointers of the same size as *items* to associate with the new items.

int wxItemContainer::Append (unsigned int *n*, const wxString ∗ *items*)

Appends several items at once into the control.

Notice that calling this method is usually much faster than appending them one by one if you need to add a lot of items.

Parameters

n	Number of items in the *items* array.
items	Array of strings of size *n*.

int wxItemContainer::Append (unsigned int *n*, const wxString ∗ *items*, void ∗∗ *clientData*)

Appends several items at once into the control.

Notice that calling this method is usually much faster than appending them one by one if you need to add a lot of items.

Parameters

n	Number of items in the *items* array.
items	Array of strings of size *n*.
clientData	Array of client data pointers of size *n* to associate with the new items.

int wxItemContainer::Append (unsigned int *n*, const wxString ∗ *items*, wxClientData ∗∗ *clientData*)

Appends several items at once into the control.

Notice that calling this method is usually much faster than appending them one by one if you need to add a lot of items.

Parameters

n	Number of items in the *items* array.
items	Array of strings of size *n*.
clientData	Array of client data pointers of size *n* to associate with the new items.

void wxItemContainer::Clear ( )

Removes all items from the control.

Clear() also deletes the client data of the existing items if it is owned by the control.

void wxItemContainer::Delete (unsigned int *n*)

Deletes an item from the control.

The client data associated with the item will be also deleted if it is owned by the control. Note that it is an error (signalled by an assert failure in debug builds) to remove an item with the index negative or greater or equal than the number of items in the control.

Parameters

n	The zero-based item index.

See also

Clear()

wxClientData* wxItemContainer::DetachClientObject (unsigned int *n*)

Returns the client object associated with the given item and transfers its ownership to the caller.

This method, unlike GetClientObject(), expects the caller to delete the returned pointer. It also replaces the internally stored pointer with NULL, i.e. completely detaches the client object pointer from the control.

It's an error to call this method unless HasClientObjectData() returns true.

Parameters

n	The zero-based item index.

Returns

The associated client object pointer to be deleted by caller or NULL.

Since

2.9.2

void* wxItemContainer::GetClientData (unsigned int *n*) const

Returns a pointer to the client data associated with the given item (if any).

It is an error to call this function for a control which doesn't have untyped client data at all although it is OK to call it even if the given item doesn't have any client data associated with it (but other items do).

Parameters

n	The zero-based position of the item.

Returns

A pointer to the client data, or NULL if not present.

wxClientData* wxItemContainer::GetClientObject (unsigned int *n*) const

Returns a pointer to the client data associated with the given item (if any).

It is an error to call this function for a control which doesn't have typed client data at all although it is OK to call it even if the given item doesn't have any client data associated with it (but other items do).

Notice that the returned pointer is still owned by the control and will be deleted by it, use DetachClientObject() if you want to remove the pointer from the control.

Parameters

n	The zero-based position of the item.

Returns

A pointer to the client data, or NULL if not present.

bool wxItemContainer::HasClientData ( ) const

Returns true, if either untyped data (`void*`) or object data (wxClientData*) is associated with the items of the control.

bool wxItemContainer::HasClientObjectData ( ) const

Returns true, if object data is associated with the items of the control.

Object data pointers have the type `wxClientData*` instead of `void*` and, importantly, are owned by the control, i.e. will be deleted by it, unlike their untyped counterparts.

bool wxItemContainer::HasClientUntypedData ( ) const

Returns true, if untyped data (`void*`) is associated with the items of the control.

int wxItemContainer::Insert (const wxString & *item*, unsigned int *pos*)

Inserts item into the control.

Parameters

item	String to add.
pos	Position to insert item before, zero based.

Returns

The return value is the index of the newly inserted item. If the insertion failed for some reason, -1 is returned.

int wxItemContainer::Insert (const wxString & *item*, unsigned int *pos*, void * *clientData*)

Inserts item into the control.

Parameters

item	String to add.
pos	Position to insert item before, zero based.
clientData	Pointer to client data to associate with the new item.

Returns

The return value is the index of the newly inserted item. If the insertion failed for some reason, -1 is returned.

int wxItemContainer::Insert (const wxString & *item*, unsigned int *pos*, wxClientData * *clientData*)

Inserts item into the control.

Parameters

item	String to add.
pos	Position to insert item before, zero based.
clientData	Pointer to client data to associate with the new item.

Returns

The return value is the index of the newly inserted item. If the insertion failed for some reason, -1 is returned.

int wxItemContainer::Insert (const wxArrayString & *items*, unsigned int *pos*)

Inserts several items at once into the control.

Notice that calling this method is usually much faster than inserting them one by one if you need to insert a lot of items.

Parameters

items	Array of strings to insert.
pos	Position to insert the items before, zero based.

Returns

The return value is the index of the last inserted item. If the insertion failed for some reason, -1 is returned.

template<typename T > int wxItemContainer::Insert (const std::vector< T > & *items*)

Inserts several items at once into the control.

This is the same as the overload taking wxArrayString, except that it works with the standard vector container.

The template argument `T` can be any type convertible to wxString, including wxString itself but also `std::string`, `char*` or `wchar_t*`.

Since

3.1.0

int wxItemContainer::Insert (const wxArrayString & *items*, unsigned int *pos*, void ** *clientData*)

Inserts several items at once into the control.

Notice that calling this method is usually much faster than inserting them one by one if you need to insert a lot of items.

Parameters

items	Array of strings to insert.
pos	Position to insert the items before, zero based.
clientData	Array of client data pointers of the same size as *items* to associate with the new items.

Returns

The return value is the index of the last inserted item. If the insertion failed for some reason, -1 is returned.

int wxItemContainer::Insert (const wxArrayString & *items,* unsigned int *pos,* wxClientData ∗∗ *clientData*)

Inserts several items at once into the control.

Notice that calling this method is usually much faster than inserting them one by one if you need to insert a lot of items.

Parameters

items	Array of strings to insert.
pos	Position to insert the items before, zero based.
clientData	Array of client data pointers of the same size as *items* to associate with the new items.

Returns

The return value is the index of the last inserted item. If the insertion failed for some reason, -1 is returned.

int wxItemContainer::Insert (unsigned int *n,* const wxString ∗ *items,* unsigned int *pos*)

Inserts several items at once into the control.

Notice that calling this method is usually much faster than inserting them one by one if you need to insert a lot of items.

Parameters

n	Number of items in the *items* array.
items	Array of strings of size *n*.
pos	Position to insert the items before, zero based.

Returns

The return value is the index of the last inserted item. If the insertion failed for some reason, -1 is returned.

int wxItemContainer::Insert (unsigned int *n,* const wxString ∗ *items,* unsigned int *pos,* void ∗∗ *clientData*)

Inserts several items at once into the control.

Notice that calling this method is usually much faster than inserting them one by one if you need to insert a lot of items.

Parameters

n	Number of items in the *items* array.

items	Array of strings of size *n*.
pos	Position to insert the new items before, zero based.
clientData	Array of client data pointers of size *n* to associate with the new items.

Returns

The return value is the index of the last inserted item. If the insertion failed for some reason, -1 is returned.

int wxItemContainer::Insert (unsigned int *n*, const wxString * *items*, unsigned int *pos*, wxClientData ** *clientData*)

Inserts several items at once into the control.

Notice that calling this method is usually much faster than inserting them one by one if you need to insert a lot of items.

Parameters

n	Number of items in the *items* array.
items	Array of strings of size *n*.
pos	Position to insert the new items before, zero based.
clientData	Array of client data pointers of size *n* to associate with the new items.

Returns

The return value is the index of the last inserted item. If the insertion failed for some reason, -1 is returned.

void wxItemContainer::Set (const wxArrayString & *items*)

Replaces the current control contents with the given items.

Notice that calling this method is usually much faster than appending them one by one if you need to add a lot of items.

Parameters

items	Array of strings to insert.

template<typename T > void wxItemContainer::Set (const std::vector< T > & *items*)

Replaces the current control contents with the given items.

This is the same as the overload taking wxArrayString, except that it works with the standard vector container.

The template argument `T` can be any type convertible to wxString, including wxString itself but also `std::string`, `char*` or `wchar_t*`.

Since

3.1.0

void wxItemContainer::Set (const wxArrayString & *items*, void ** *clientData*)

Replaces the current control contents with the given items.

Notice that calling this method is usually much faster than appending them one by one if you need to add a lot of items.

Parameters

items	Array of strings to insert.
clientData	Array of client data pointers of the same size as *items* to associate with the new items.

void wxItemContainer::Set (const wxArrayString & *items*, wxClientData ∗∗ *clientData*)

Replaces the current control contents with the given items.

Notice that calling this method is usually much faster than appending them one by one if you need to add a lot of items.

Parameters

items	Array of strings to insert.
clientData	Array of client data pointers of the same size as *items* to associate with the new items.

void wxItemContainer::Set (unsigned int *n*, const wxString ∗ *items*)

Replaces the current control contents with the given items.

Notice that calling this method is usually much faster than appending them one by one if you need to add a lot of items.

Parameters

n	Number of items in the *items* array.
items	Array of strings of size *n*.

void wxItemContainer::Set (unsigned int *n*, const wxString ∗ *items*, void ∗∗ *clientData*)

Replaces the current control contents with the given items.

Notice that calling this method is usually much faster than appending them one by one if you need to add a lot of items.

Parameters

n	Number of items in the *items* array.
items	Array of strings of size *n*.
clientData	Array of client data pointers of size *n* to associate with the new items.

void wxItemContainer::Set (unsigned int *n*, const wxString ∗ *items*, wxClientData ∗∗ *clientData*)

Replaces the current control contents with the given items.

Notice that calling this method is usually much faster than appending them one by one if you need to add a lot of items.

Parameters

n	Number of items in the *items* array.
items	Array of strings of size *n*.
clientData	Array of client data pointers of size *n* to associate with the new items.

void wxItemContainer::SetClientData (unsigned int *n*, void ∗ *data*)

Associates the given untyped client data pointer with the given item.

Note that it is an error to call this function if any typed client data pointers had been associated with the control items before.

Parameters

n	The zero-based item index.
data	The client data to associate with the item.

void wxItemContainer::SetClientObject (unsigned int *n*, wxClientData * *data*)

Associates the given typed client data pointer with the given item: the *data* object will be deleted when the item is deleted (either explicitly by using Delete() or implicitly when the control itself is destroyed).

Note that it is an error to call this function if any untyped client data pointers had been associated with the control items before.

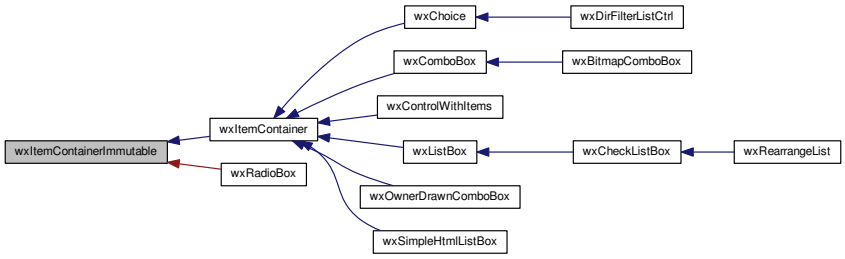
Parameters

n	The zero-based item index.
data	The client data to associate with the item.

21.412 wxItemContainerImmutable Class Reference

`#include <wx/ctrlsub.h>`

Inheritance diagram for wxItemContainerImmutable:



21.412.1 Detailed Description

wxItemContainer defines an interface which is implemented by all controls which have string subitems each of which may be selected.

It is decomposed in wxItemContainerImmutable which omits all methods adding/removing items and is used by wxRadioBox and wxItemContainer itself.

Note that this is not a control, it's a mixin interface that classes have to derive from in addition to wxControl or wxWindow.

Examples: wxListBox, wxCheckListBox, wxChoice and wxComboBox (which implements an extended interface deriving from this one)

Library: wxCore

Category: Controls

See also

wxControlWithItems, wxItemContainer

Public Member Functions

- wxItemContainerImmutable ()

  Constructor.

- virtual unsigned int GetCount () const =0

  Returns the number of items in the control.
- bool IsEmpty () const

  Returns true if the control is empty or false if it has some items.
- virtual wxString GetString (unsigned int n) const =0

  Returns the label of the item with the given index.
- wxArrayString GetStrings () const

  Returns the array of the labels of all items in the control.
- virtual void SetString (unsigned int n, const wxString &string)=0

  Sets the label for the given item.
- virtual int FindString (const wxString &string, bool caseSensitive=false) const

  Finds an item whose label matches the given string.

Selection

- virtual void SetSelection (int n)=0

  Sets the selection to the given item n or removes the selection entirely if n == `wxNOT_FOUND`.
- virtual int GetSelection () const =0

  Returns the index of the selected item or `wxNOT_FOUND` if no item is selected.
- bool SetStringSelection (const wxString &string)

  Selects the item with the specified string in the control.
- virtual wxString GetStringSelection () const

  Returns the label of the selected item or an empty string if no item is selected.
- void Select (int n)

  This is the same as SetSelection() and exists only because it is slightly more natural for controls which support multiple selection.

21.412.2 Constructor & Destructor Documentation

wxItemContainerImmutable::wxItemContainerImmutable ( )

Constructor.

21.412.3 Member Function Documentation

virtual int wxItemContainerImmutable::FindString (const wxString & *string*, bool *caseSensitive* = `false`) const `[virtual]`

Finds an item whose label matches the given string.

Parameters

string	String to find.
caseSensitive	Whether search is case sensitive (default is not).

Returns

The zero-based position of the item, or wxNOT_FOUND if the string was not found.

Reimplemented in wxListBox, wxComboBox, wxRadioBox, and wxChoice.

virtual unsigned int wxItemContainerImmutable::GetCount ( ) const `[pure virtual]`

Returns the number of items in the control.

See also

IsEmpty()

Implemented in wxRadioBox, wxComboBox, wxListBox, and wxChoice.

virtual int wxItemContainerImmutable::GetSelection ( ) const `[pure virtual]`

Returns the index of the selected item or `wxNOT_FOUND` if no item is selected.

Returns

The position of the current selection.

Remarks

This method can be used with single selection list boxes only, you should use wxListBox::GetSelections() for the list boxes with wxLB_MULTIPLE style.

See also

SetSelection(), GetStringSelection()

Implemented in wxRadioBox, wxComboBox, wxListBox, and wxChoice.

virtual wxString wxItemContainerImmutable::GetString (unsigned int *n*) const `[pure virtual]`

Returns the label of the item with the given index.

Parameters

n	The zero-based index.

Returns

The label of the item or an empty string if the position was invalid.

Implemented in wxRadioBox, wxListBox, wxComboBox, and wxChoice.

wxArrayString wxItemContainerImmutable::GetStrings ( ) const

Returns the array of the labels of all items in the control.

virtual wxString wxItemContainerImmutable::GetStringSelection ( ) const `[virtual]`

Returns the label of the selected item or an empty string if no item is selected.

See also

GetSelection()

Reimplemented in wxComboBox.

bool wxItemContainerImmutable::IsEmpty ( ) const

Returns true if the control is empty or false if it has some items.

See also

GetCount()

void wxItemContainerImmutable::Select (int *n*)

This is the same as SetSelection() and exists only because it is slightly more natural for controls which support multiple selection.

virtual void wxItemContainerImmutable::SetSelection (int *n*) `[pure virtual]`

Sets the selection to the given item *n* or removes the selection entirely if *n* == `wxNOT_FOUND`.

Note that this does not cause any command events to be emitted nor does it deselect any other items in the controls which support multiple selections.

Parameters

n	The string position to select, starting from zero.

See also

SetString(), SetStringSelection()

Implemented in wxComboBox, wxRadioBox, wxChoice, and wxListBox.

virtual void wxItemContainerImmutable::SetString (unsigned int *n*, const wxString & *string*) `[pure virtual]`

Sets the label for the given item.

Parameters

n	The zero-based item index.
string	The label to set.

Implemented in wxRadioBox, wxComboBox, wxListBox, and wxChoice.

bool wxItemContainerImmutable::SetStringSelection (const wxString & *string*)

Selects the item with the specified string in the control.

This method doesn't cause any command events to be emitted.

Notice that this method is case-insensitive, i.e. the string is compared with all the elements of the control case-insensitively and the first matching entry is selected, even if it doesn't have exactly the same case as this string and there is an exact match afterwards.

Parameters

string	The string to select.

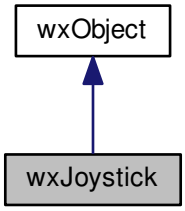
Returns

true if the specified string has been selected, false if it wasn't found in the control.

21.413 wxJoystick Class Reference

`#include <wx/joystick.h>`

Inheritance diagram for wxJoystick:



21.413.1 Detailed Description

wxJoystick allows an application to control one or more joysticks.

Library: wxAdvanced

Category: Miscellaneous

See also

wxJoystickEvent

Public Member Functions

- wxJoystick (int joystick=wxJOYSTICK1)
  Constructor.
- virtual ~wxJoystick ()
  Destroys the wxJoystick object.
- int GetButtonState () const
  Returns the state of the joystick buttons.
- bool GetButtonState (unsigned int id) const
  Returns the state of the specified joystick button.
- int GetManufacturerId () const
  Returns the manufacturer id.

- int GetMovementThreshold () const

  Returns the movement threshold, the number of steps outside which the joystick is deemed to have moved.
- int GetNumberAxes () const

  Returns the number of axes for this joystick.
- int GetNumberButtons () const

  Returns the number of buttons for this joystick.
- int GetPOVCTSPosition () const

  Returns the point-of-view position, expressed in continuous, one-hundredth of a degree units.
- int GetPOVPosition () const

  Returns the point-of-view position, expressed in continuous, one-hundredth of a degree units, but limited to return 0, 9000, 18000 or 27000.
- int GetPollingMax () const

  Returns the maximum polling frequency.
- int GetPollingMin () const

  Returns the minimum polling frequency.
- wxPoint GetPosition () const

  Returns the x, y position of the joystick.
- int GetPosition (unsigned int axis) const

  Returns the position of the specified joystick axis.
- int GetProductId () const

  Returns the product id for the joystick.
- wxString GetProductName () const

  Returns the product name for the joystick.
- int GetRudderMax () const

  Returns the maximum rudder position.
- int GetRudderMin () const

  Returns the minimum rudder position.
- int GetRudderPosition () const

  Returns the rudder position.
- int GetUMax () const

  Returns the maximum U position.
- int GetUMin () const

  Returns the minimum U position.
- int GetUPosition () const

  Gets the position of the fifth axis of the joystick, if it exists.
- int GetVMax () const

  Returns the maximum V position.
- int GetVMin () const

  Returns the minimum V position.
- int GetVPosition () const

  Gets the position of the sixth axis of the joystick, if it exists.
- int GetXMax () const

  Returns the maximum x position.
- int GetXMin () const

  Returns the minimum x position.
- int GetYMax () const

  Returns the maximum y position.
- int GetYMin () const

  Returns the minimum y position.
- int GetZMax () const

  Returns the maximum z position.

- int GetZMin () const

  Returns the minimum z position.
- int GetZPosition () const

  Returns the z position of the joystick.
- bool HasPOV () const

  Returns true if the joystick has a point of view control.
- bool HasPOV4Dir () const

  Returns true if the joystick point-of-view supports discrete values (centered, forward, backward, left, and right).
- bool HasPOVCTS () const

  Returns true if the joystick point-of-view supports continuous degree bearings.
- bool HasRudder () const

  Returns true if there is a rudder attached to the computer.
- bool HasU () const

  Returns true if the joystick has a U axis.
- bool HasV () const

  Returns true if the joystick has a V axis.
- bool HasZ () const

  Returns true if the joystick has a Z axis.
- bool IsOk () const

  Returns true if the joystick is functioning.
- bool ReleaseCapture ()

  *Releases the capture set by **SetCapture**.*
- bool SetCapture (wxWindow *win, int pollingFreq=0)

  Sets the capture to direct joystick events to win.
- void SetMovementThreshold (int threshold)

  Sets the movement threshold, the number of steps outside which the joystick is deemed to have moved.

Static Public Member Functions

- static int GetNumberJoysticks ()

  Returns the number of joysticks currently attached to the computer.

Additional Inherited Members

21.413.2 Constructor & Destructor Documentation

wxJoystick::wxJoystick (int *joystick* = wxJOYSTICK1)

Constructor.

joystick may be one of wxJOYSTICK1, wxJOYSTICK2, indicating the joystick controller of interest.

virtual wxJoystick::~wxJoystick ( ) [virtual]

Destroys the wxJoystick object.

21.413.3 Member Function Documentation

int wxJoystick::GetButtonState ( ) const

Returns the state of the joystick buttons.

Every button is mapped to a single bit in the returned integer, with the first button being mapped to the least significant bit, and so on.

A bitlist of wxJOY_BUTTONn identifiers, where n is 1, 2, 3 or 4 is available for historical reasons.

bool wxJoystick::GetButtonState (unsigned int *id*) const

Returns the state of the specified joystick button.

Parameters

id	The button id to report, from 0 to GetNumberButtons() - 1

int wxJoystick::GetManufacturerId ( ) const

Returns the manufacturer id.

int wxJoystick::GetMovementThreshold ( ) const

Returns the movement threshold, the number of steps outside which the joystick is deemed to have moved.

int wxJoystick::GetNumberAxes ( ) const

Returns the number of axes for this joystick.

int wxJoystick::GetNumberButtons ( ) const

Returns the number of buttons for this joystick.

static int wxJoystick::GetNumberJoysticks ( ) [static]

Returns the number of joysticks currently attached to the computer.

int wxJoystick::GetPollingMax ( ) const

Returns the maximum polling frequency.

int wxJoystick::GetPollingMin ( ) const

Returns the minimum polling frequency.

wxPoint wxJoystick::GetPosition ( ) const

Returns the x, y position of the joystick.

int wxJoystick::GetPosition (unsigned int *axis*) const

Returns the position of the specified joystick axis.

Parameters

axis	The joystick axis to report, from 0 to GetNumberAxes() - 1.

int wxJoystick::GetPOVCTSPosition ( ) const

Returns the point-of-view position, expressed in continuous, one-hundredth of a degree units.

Returns -1 on error.

int wxJoystick::GetPOVPosition ( ) const

Returns the point-of-view position, expressed in continuous, one-hundredth of a degree units, but limited to return 0, 9000, 18000 or 27000.

Returns -1 on error.

int wxJoystick::GetProductId ( ) const

Returns the product id for the joystick.

wxString wxJoystick::GetProductName ( ) const

Returns the product name for the joystick.

int wxJoystick::GetRudderMax ( ) const

Returns the maximum rudder position.

int wxJoystick::GetRudderMin ( ) const

Returns the minimum rudder position.

int wxJoystick::GetRudderPosition ( ) const

Returns the rudder position.

int wxJoystick::GetUMax ( ) const

Returns the maximum U position.

int wxJoystick::GetUMin ( ) const

Returns the minimum U position.

int wxJoystick::GetUPosition ( ) const

Gets the position of the fifth axis of the joystick, if it exists.

int wxJoystick::GetVMax ( ) const

Returns the maximum V position.

int wxJoystick::GetVMin ( ) const

Returns the minimum V position.

int wxJoystick::GetVPosition ( ) const

Gets the position of the sixth axis of the joystick, if it exists.

int wxJoystick::GetXMax ( ) const

Returns the maximum x position.

int wxJoystick::GetXMin ( ) const

Returns the minimum x position.

int wxJoystick::GetYMax ( ) const

Returns the maximum y position.

int wxJoystick::GetYMin ( ) const

Returns the minimum y position.

int wxJoystick::GetZMax ( ) const

Returns the maximum z position.

int wxJoystick::GetZMin ( ) const

Returns the minimum z position.

int wxJoystick::GetZPosition ( ) const

Returns the z position of the joystick.

bool wxJoystick::HasPOV ( ) const

Returns true if the joystick has a point of view control.

bool wxJoystick::HasPOV4Dir ( ) const

Returns true if the joystick point-of-view supports discrete values (centered, forward, backward, left, and right).

bool wxJoystick::HasPOVCTS ( ) const

Returns true if the joystick point-of-view supports continuous degree bearings.

bool wxJoystick::HasRudder ( ) const

Returns true if there is a rudder attached to the computer.

bool wxJoystick::HasU ( ) const

Returns true if the joystick has a U axis.

bool wxJoystick::HasV ( ) const

Returns true if the joystick has a V axis.

bool wxJoystick::HasZ ( ) const

Returns true if the joystick has a Z axis.

bool wxJoystick::IsOk ( ) const

Returns true if the joystick is functioning.

bool wxJoystick::ReleaseCapture ( )

Releases the capture set by **SetCapture**.

Returns

true if the capture release succeeded.

See also

SetCapture(), wxJoystickEvent

bool wxJoystick::SetCapture (wxWindow * *win*, int *pollingFreq* = 0)

Sets the capture to direct joystick events to *win*.

Parameters

win	The window that will receive joystick events.
pollingFreq	If zero, movement events are sent when above the threshold. If greater than zero, events are received every *pollingFreq* milliseconds.

Returns

true if the capture succeeded.

See also

ReleaseCapture(), wxJoystickEvent

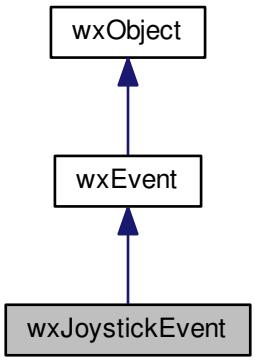
void wxJoystick::SetMovementThreshold (int *threshold*)

Sets the movement threshold, the number of steps outside which the joystick is deemed to have moved.

21.414 wxJoystickEvent Class Reference

`#include <wx/event.h>`

Inheritance diagram for wxJoystickEvent:



21.414.1 Detailed Description

This event class contains information about joystick events, particularly events received by windows.

Events using this class

The following event handler macros redirect the events to member function handlers '**func**' with prototypes like: void handlerFuncName(wxJoystickEvent& event)

Event macros:

- EVT_JOY_BUTTON_DOWN(func): Process a `wxEVT_JOY_BUTTON_DOWN` event.
- EVT_JOY_BUTTON_UP(func): Process a `wxEVT_JOY_BUTTON_UP` event.
- EVT_JOY_MOVE(func): Process a `wxEVT_JOY_MOVE` event.
- EVT_JOY_ZMOVE(func): Process a `wxEVT_JOY_ZMOVE` event.
- EVT_JOYSTICK_EVENTS(func): Processes all joystick events.

Public Member Functions

- wxJoystickEvent (wxEventType eventType=wxEVT_NULL, int state=0, int joystick=wxJOYSTICK1, int change=0)

  Constructor.
- bool ButtonDown (int button=wxJOY_BUTTON_ANY) const

  Returns true if the event was a down event from the specified button (or any button).
- bool ButtonIsDown (int button=wxJOY_BUTTON_ANY) const

  Returns true if the specified button (or any button) was in a down state.
- bool ButtonUp (int button=wxJOY_BUTTON_ANY) const

  Returns true if the event was an up event from the specified button (or any button).
- int GetButtonChange () const

  Returns the identifier of the button changing state.
- int GetButtonState () const

  Returns the down state of the buttons.
- int GetJoystick () const

  Returns the identifier of the joystick generating the event - one of wxJOYSTICK1 and wxJOYSTICK2.
- wxPoint GetPosition () const

  Returns the x, y position of the joystick event.
- int GetZPosition () const

  Returns the z position of the joystick event.
- bool IsButton () const

  Returns true if this was a button up or down event (not 'is any button down?').
- bool IsMove () const

  Returns true if this was an x, y move event.
- bool IsZMove () const

  Returns true if this was a z move event.

Additional Inherited Members

21.414.2 Constructor & Destructor Documentation

wxJoystickEvent::wxJoystickEvent (wxEventType *eventType* = wxEVT_NULL, int *state* = 0, int *joystick* = wxJOYSTICK1, int *change* = 0)

Constructor.

21.414.3 Member Function Documentation

bool wxJoystickEvent::ButtonDown (int *button* = wxJOY_BUTTON_ANY) const

Returns true if the event was a down event from the specified button (or any button).

Parameters

button	Can be `wxJOY_BUTTONn` where `n` is 1, 2, 3 or 4; or `wxJOY_BUTTON_ANY` to indicate any button down event.

bool wxJoystickEvent::ButtonIsDown (int *button* = wxJOY_BUTTON_ANY) const

Returns true if the specified button (or any button) was in a down state.

Parameters

button	Can be `wxJOY_BUTTONn` where `n` is 1, 2, 3 or 4; or `wxJOY_BUTTON_ANY` to indicate any button down event.

bool wxJoystickEvent::ButtonUp (int *button* = wxJOY_BUTTON_ANY) const

Returns true if the event was an up event from the specified button (or any button).

Parameters

button	Can be `wxJOY_BUTTONn` where `n` is 1, 2, 3 or 4; or `wxJOY_BUTTON_ANY` to indicate any button down event.

int wxJoystickEvent::GetButtonChange ( ) const

Returns the identifier of the button changing state.

This is a `wxJOY_BUTTONn` identifier, where `n` is one of 1, 2, 3, 4.

int wxJoystickEvent::GetButtonState ( ) const

Returns the down state of the buttons.

This is a `wxJOY_BUTTONn` identifier, where `n` is one of 1, 2, 3, 4.

int wxJoystickEvent::GetJoystick ( ) const

Returns the identifier of the joystick generating the event - one of wxJOYSTICK1 and wxJOYSTICK2.

wxPoint wxJoystickEvent::GetPosition ( ) const

Returns the x, y position of the joystick event.

These coordinates are valid for all the events except wxEVT_JOY_ZMOVE.

int wxJoystickEvent::GetZPosition ( ) const

Returns the z position of the joystick event.

This method can only be used for wxEVT_JOY_ZMOVE events.

bool wxJoystickEvent::IsButton ( ) const

Returns true if this was a button up or down event (*not* 'is any button down?').

bool wxJoystickEvent::IsMove ( ) const

Returns true if this was an x, y move event.

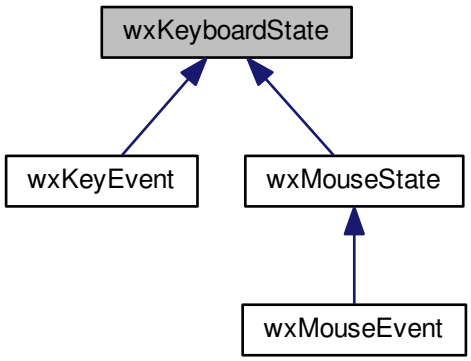
bool wxJoystickEvent::IsZMove ( ) const

Returns true if this was a z move event.

21.415 wxKeyboardState Class Reference

`#include <wx/kbdstate.h>`

Inheritance diagram for wxKeyboardState:



21.415.1 Detailed Description

Provides methods for testing the state of the keyboard modifier keys.

This class is used as a base class of wxKeyEvent and wxMouseState and, hence, indirectly, of wxMouseEvent, so its methods may be used to get information about the modifier keys which were pressed when the event occurred.

This class is implemented entirely inline in <wx/kbdstate.h> and thus has no linking requirements.

Library: None; this class implementation is entirely header-based.

Category: Events

Public Member Functions

- wxKeyboardState (bool controlDown=false, bool shiftDown=false, bool altDown=false, bool metaDown=false)

Constructor initializes the modifier key settings.

- int GetModifiers () const

  Return the bit mask of all pressed modifier keys.

- bool HasAnyModifiers () const

  Returns true if any modifiers at all are pressed.

- bool HasModifiers () const

  Returns true if Control or Alt are pressed.

- bool ControlDown () const

  Returns true if the Control key or Apple/Command key under OS X is pressed.

- bool RawControlDown () const

  Returns true if the Control key (also under OS X).

- bool ShiftDown () const

  Returns true if the Shift key is pressed.

- bool MetaDown () const

  Returns true if the Meta/Windows/Apple key is pressed.

- bool AltDown () const

  Returns true if the Alt key is pressed.

- bool CmdDown () const

  Returns true if the key used for command accelerators is pressed.

- void SetControlDown (bool down)
- void SetRawControlDown (bool down)
- void SetShiftDown (bool down)
- void SetAltDown (bool down)
- void SetMetaDown (bool down)

21.415.2 Constructor & Destructor Documentation

wxKeyboardState::wxKeyboardState (bool *controlDown* = `false`, bool *shiftDown* = `false`, bool *altDown* = `false`, bool *metaDown* = `false`)

Constructor initializes the modifier key settings.

By default, no modifiers are active.

21.415.3 Member Function Documentation

bool wxKeyboardState::AltDown ( ) const

Returns true if the Alt key is pressed.

Notice that GetModifiers() should usually be used instead of this one.

bool wxKeyboardState::CmdDown ( ) const

Returns true if the key used for command accelerators is pressed.

Same as ControlDown(). Deprecated.

Notice that GetModifiers() should usually be used instead of this one.

bool wxKeyboardState::ControlDown ( ) const

Returns true if the Control key or Apple/Command key under OS X is pressed.

This function doesn't distinguish between right and left control keys.

Notice that GetModifiers() should usually be used instead of this one.

int wxKeyboardState::GetModifiers ( ) const

Return the bit mask of all pressed modifier keys.

The return value is a combination of `wxMOD_ALT`, `wxMOD_CONTROL`, `wxMOD_SHIFT` and `wxMOD_META` bit masks. Additionally, `wxMOD_NONE` is defined as 0, i.e. corresponds to no modifiers (see HasAnyModifiers()) and `wxMOD_CMD` is either `wxMOD_CONTROL` (MSW and Unix) or `wxMOD_META` (Mac), see CmdDown(). See wxKeyModifier for the full list of modifiers.

Notice that this function is easier to use correctly than, for example, ControlDown() because when using the latter you also have to remember to test that none of the other modifiers is pressed:

```
if ( ControlDown() && !AltDown() && !ShiftDown() && !
      MetaDown() )
    ... handle Ctrl-XXX ...
```

and forgetting to do it can result in serious program bugs (e.g. program not working with European keyboard layout where `AltGr` key which is seen by the program as combination of CTRL and ALT is used). On the other hand, you can simply write:

```
if ( GetModifiers() == wxMOD_CONTROL )
    ... handle Ctrl-XXX ...
```

with this function.

bool wxKeyboardState::HasAnyModifiers ( ) const

Returns true if any modifiers at all are pressed.

This is equivalent to `GetModifiers() != wxMOD_NONE`.

Notice that this is different from HasModifiers() method which doesn't take e.g. Shift modifier into account. This method is most suitable for mouse events when any modifier, including Shift, can change the interpretation of the event.

Since

2.9.5

bool wxKeyboardState::HasModifiers ( ) const

Returns true if Control or Alt are pressed.

Checks if Control, Alt or, under OS X only, Command key are pressed (notice that the real Control key is still taken into account under OS X too).

This method returns false if only Shift is pressed for compatibility reasons and also because pressing Shift usually doesn't change the interpretation of key events, see HasAnyModifiers() if you want to take Shift into account as well.

bool wxKeyboardState::MetaDown ( ) const

Returns true if the Meta/Windows/Apple key is pressed.

This function tests the state of the key traditionally called Meta under Unix systems, Windows keys under MSW Notice that GetModifiers() should usually be used instead of this one.

See also

CmdDown()

bool wxKeyboardState::RawControlDown ( ) const

Returns true if the Control key (also under OS X).

This function doesn't distinguish between right and left control keys.

Notice that GetModifiers() should usually be used instead of this one.

void wxKeyboardState::SetAltDown (bool *down*)

void wxKeyboardState::SetControlDown (bool *down*)

void wxKeyboardState::SetMetaDown (bool *down*)

void wxKeyboardState::SetRawControlDown (bool *down*)

void wxKeyboardState::SetShiftDown (bool *down*)

bool wxKeyboardState::ShiftDown ( ) const

Returns true if the Shift key is pressed.

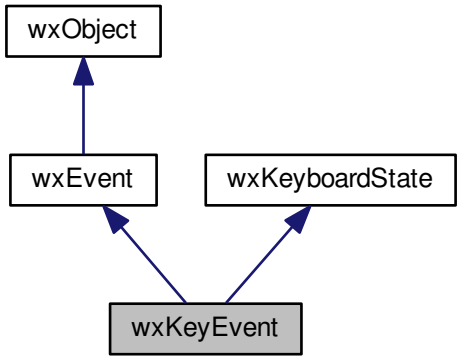
This function doesn't distinguish between right and left shift keys.

Notice that GetModifiers() should usually be used instead of this one.

21.416 wxKeyEvent Class Reference

```
#include <wx/event.h>
```

Inheritance diagram for wxKeyEvent:



21.416.1 Detailed Description

This event class contains information about key press and release events.

The main information carried by this event is the key being pressed or released. It can be accessed using either GetKeyCode() function or GetUnicodeKey(). For the printable characters, the latter should be used as it works for any keys, including non-Latin-1 characters that can be entered when using national keyboard layouts. GetKeyCode() should be used to handle special characters (such as cursor arrows keys or `HOME` or `INS` and so on) which correspond to wxKeyCode enum elements above the `WXK_START` constant. While GetKeyCode() also returns the character code for Latin-1 keys for compatibility, it doesn't work for Unicode characters in general and will return `WXK_NONE` for any non-Latin-1 ones. For this reason, it's recommended to always use GetUnicodeKey() and only fall back to GetKeyCode() if GetUnicodeKey() returned `WXK_NONE` meaning that the event corresponds to a non-printable special keys.

While both of these functions can be used with the events of `wxEVT_KEY_DOWN`, `wxEVT_KEY_UP` and `wxEVT_CHAR` types, the values returned by them are different for the first two events and the last one. For the latter, the key returned corresponds to the character that would appear in e.g. a text zone if the user pressed the key in it. As such, its value depends on the current state of the Shift key and, for the letters, on the state of Caps Lock modifier. For example, if `A` key is pressed without Shift being held down, wxKeyEvent of type `wxEVT_CHAR` generated for this key press will return (from either GetKeyCode() or GetUnicodeKey() as their meanings coincide for ASCII characters) key code of 97 corresponding the ASCII value of `a`. And if the same key is pressed but with Shift being held (or Caps Lock being active), then the key could would be 65, i.e. ASCII value of capital `A`.

However for the key down and up events the returned key code will instead be `A` independently of the state of the modifier keys i.e. it depends only on physical key being pressed and is not translated to its logical representation using the current keyboard state. Such untranslated key codes are defined as follows:

- For the letters they correspond to the *upper* case value of the letter.
- For the other alphanumeric keys (e.g. `7` or `+`), the untranslated key code corresponds to the character produced by the key when it is pressed without Shift. E.g. in standard US keyboard layout the untranslated key code for the key `=/+` in the upper right corner of the keyboard is 61 which is the ASCII value of `=`.
- For the rest of the keys (i.e. special non-printable keys) it is the same as the normal key code as no translation is used anyhow.

Notice that the first rule applies to all Unicode letters, not just the usual Latin-1 ones. However for non-Latin-1 letters only GetUnicodeKey() can be used to retrieve the key code as GetKeyCode() just returns `WXK_NONE` in this case.

To summarize: you should handle wxEVT_CHAR if you need the translated key and wxEVT_KEY_DOWN if you only need the value of the key itself, independent of the current keyboard state.

Note

Not all key down events may be generated by the user. As an example, wxEVT_KEY_DOWN with = key code can be generated using the standard US keyboard layout but not using the German one because the = key corresponds to Shift-0 key combination in this layout and the key code for it is 0, not =. Because of this you should avoid requiring your users to type key events that might be impossible to enter on their keyboard.

Another difference between key and char events is that another kind of translation is done for the latter ones when the Control key is pressed: char events for ASCII letters in this case carry codes corresponding to the ASCII value of Ctrl-Latter, i.e. 1 for Ctrl-A, 2 for Ctrl-B and so on until 26 for Ctrl-Z. This is convenient for terminal-like applications and can be completely ignored by all the other ones (if you need to handle Ctrl-A it is probably a better idea to use the key event rather than the char one). Notice that currently no translation is done for the presses of [, \,], ^ and _ keys which might be mapped to ASCII values from 27 to 31. Since version 2.9.2, the enum values WXK_CONTROL_A - WXK_CONTROL_Z can be used instead of the non-descriptive constant values 1-26.

Finally, modifier keys only generate key events but no char events at all. The modifiers keys are WXK_SHIFT, WXK_CONTROL, WXK_ALT and various WXK_WINDOWS_XXX from wxKeyCode enum.

Modifier keys events are special in one additional aspect: usually the keyboard state associated with a key press is well defined, e.g. wxKeyboardState::ShiftDown() returns true only if the Shift key was held pressed when the key that generated this event itself was pressed. There is an ambiguity for the key press events for Shift key itself however. By convention, it is considered to be already pressed when it is pressed and already released when it is released. In other words, wxEVT_KEY_DOWN event for the Shift key itself will have wxMOD_SHIFT in GetModifiers() and ShiftDown() will return true while the wxEVT_KEY_UP event for Shift itself will not have wxMOD_SHIFT in its modifiers and ShiftDown() will return false.

Tip: You may discover the key codes and modifiers generated by all the keys on your system interactively by running the Key Event Sample wxWidgets sample and pressing some keys in it.

Note

If a key down (EVT_KEY_DOWN) event is caught and the event handler does not call event.Skip() then the corresponding char event (EVT_CHAR) will not happen. This is by design and enables the programs that handle both types of events to avoid processing the same key twice. As a consequence, if you do not want to suppress the wxEVT_CHAR events for the keys you handle, always call event.Skip() in your wxEVT_KEY_DOWN handler. Not doing may also prevent accelerators defined using this key from working.
If a key is maintained in a pressed state, you will typically get a lot of (automatically generated) key down events but only one key up one at the end when the key is released so it is wrong to assume that there is one up event corresponding to each down one.
For Windows programmers: The key and char events in wxWidgets are similar to but slightly different from Windows WM_KEYDOWN and WM_CHAR events. In particular, Alt-x combination will generate a char event in wxWidgets (unless it is used as an accelerator) and almost all keys, including ones without ASCII equivalents, generate char events too.

Events using this class

The following event handler macros redirect the events to member function handlers '**func**' with prototypes like: void handlerFuncName(wxKeyEvent& event)

Event macros:

- EVT_KEY_DOWN(func): Process a wxEVT_KEY_DOWN event (any key has been pressed). If this event is handled and not skipped, wxEVT_CHAR will not be generated at all for this key press (but wxEVT_KEY_UP will be).
- EVT_KEY_UP(func): Process a wxEVT_KEY_UP event (any key has been released).
- EVT_CHAR(func): Process a wxEVT_CHAR event.

- EVT_CHAR_HOOK(func): Process a `wxEVT_CHAR_HOOK` event. Unlike all the other key events, this event is propagated upwards the window hierarchy which allows intercepting it in the parent window of the focused window to which it is sent initially (if there is no focused window, this event is sent to the wxApp global object). It is also generated before any other key events and so gives the parent window an opportunity to modify the keyboard handling of its children, e.g. it is used internally by wxWidgets in some ports to intercept pressing Esc key in any child of a dialog to close the dialog itself when it's pressed. By default, if this event is handled, i.e. the handler doesn't call wxEvent::Skip(), neither `wxEVT_KEY_DOWN` nor `wxEVT_CHAR` events will be generated (although `wxEVT_KEY_UP` still will be), i.e. it replaces the normal key events. However by calling the special DoAllowNextEvent() method you can handle `wxEVT_CHAR_HOOK` and still allow normal events generation. This is something that is rarely useful but can be required if you need to prevent a parent `wxEVT_CHAR_HOOK` handler from running without suppressing the normal key events. Finally notice that this event is not generated when the mouse is captured as it is considered that the window which has the capture should receive all the keyboard events too without allowing its parent wxTopLevelWindow to interfere with their processing.

Public Member Functions

- wxKeyEvent (wxEventType keyEventType=wxEVT_NULL)

  Constructor.
- int GetKeyCode () const

  Returns the key code of the key that generated this event.
- bool IsKeyInCategory (int category) const

  Returns true if the key is in the given key category.
- wxUint32 GetRawKeyCode () const

  Returns the raw key code for this event.
- wxUint32 GetRawKeyFlags () const

  Returns the low level key flags for this event.
- wxChar GetUnicodeKey () const

  Returns the Unicode character corresponding to this key event.
- wxCoord GetX () const

  Returns the X position (in client coordinates) of the event.
- wxCoord GetY () const

  Returns the Y position (in client coordinates) of the event.
- void DoAllowNextEvent ()

  Allow normal key events generation.
- bool IsNextEventAllowed () const

  Returns true if DoAllowNextEvent() had been called, false by default.

- wxPoint GetPosition () const

  Obtains the position (in client coordinates) at which the key was pressed.
- void GetPosition (wxCoord *x, wxCoord *y) const

  Obtains the position (in client coordinates) at which the key was pressed.

Additional Inherited Members

21.416.2 Constructor & Destructor Documentation

wxKeyEvent::wxKeyEvent (wxEventType *keyEventType* = wxEVT_NULL)

Constructor.

Currently, the only valid event types are `wxEVT_CHAR` and `wxEVT_CHAR_HOOK`.

21.416.3 Member Function Documentation

void wxKeyEvent::DoAllowNextEvent ( )

Allow normal key events generation.

Can be called from `wxEVT_CHAR_HOOK` handler to indicate that the generation of normal events should *not* be suppressed, as it happens by default when this event is handled.

The intended use of this method is to allow some window object to prevent `wxEVT_CHAR_HOOK` handler in its parent window from running by defining its own handler for this event. Without calling this method, this would result in not generating `wxEVT_KEY_DOWN` nor `wxEVT_CHAR` events at all but by calling it you can ensure that these events would still be generated, even if `wxEVT_CHAR_HOOK` event was handled.

Since

2.9.3

int wxKeyEvent::GetKeyCode ( ) const

Returns the key code of the key that generated this event.

ASCII symbols return normal ASCII values, while events from special keys such as "left cursor arrow" (`WXK_LEFT`) return values outside of the ASCII range. See wxKeyCode for a full list of the virtual key codes.

Note that this method returns a meaningful value only for special non-alphanumeric keys or if the user entered a Latin-1 character (this includes ASCII and the accented letters found in Western European languages but not letters of other alphabets such as e.g. Cyrillic). Otherwise it simply method returns `WXK_NONE` and GetUnicodeKey() should be used to obtain the corresponding Unicode character.

Using GetUnicodeKey() is in general the right thing to do if you are interested in the characters typed by the user, GetKeyCode() should be only used for special keys (for which GetUnicodeKey() returns `WXK_NONE`). To handle both kinds of keys you might write:

```
void MyHandler::OnChar(wxKeyEvent& event)
{
    wxChar uc = event.GetUnicodeKey();
    if ( uc != WXK_NONE )
    {
        // It's a "normal" character. Notice that this includes
        // control characters in 1..31 range, e.g. WXK_RETURN or
        // WXK_BACK, so check for them explicitly.
        if ( uc >= 32 )
        {
            wxLogMessage("You pressed '%c'", uc);
        }
        else
        {
            // It's a control character
            ...
        }
    }
    else // No Unicode equivalent.
    {
        // It's a special key, deal with all the known ones:
        switch ( event.GetKeyCode() )
```

```
        {
            case WXK_LEFT:
            case WXK_RIGHT:
                ... move cursor ...
                break;

            case WXK_F1:
                ... give help ...
                break;
        }
    }
}
```

wxPoint wxKeyEvent::GetPosition ( ) const

Obtains the position (in client coordinates) at which the key was pressed.

Notice that under most platforms this position is simply the current mouse pointer position and has no special relationship to the key event itself.

x and *y* may be NULL if the corresponding coordinate is not needed.

void wxKeyEvent::GetPosition (wxCoord * *x*, wxCoord * *y*) const

Obtains the position (in client coordinates) at which the key was pressed.

Notice that under most platforms this position is simply the current mouse pointer position and has no special relationship to the key event itself.

x and *y* may be NULL if the corresponding coordinate is not needed.

wxUint32 wxKeyEvent::GetRawKeyCode ( ) const

Returns the raw key code for this event.

The flags are platform-dependent and should only be used if the functionality provided by other wxKeyEvent methods is insufficient.

Under MSW, the raw key code is the value of `wParam` parameter of the corresponding message.

Under GTK, the raw key code is the `keyval` field of the corresponding GDK event.

Under OS X, the raw key code is the `keyCode` field of the corresponding NSEvent.

Note

Currently the raw key codes are not supported by all ports, use #ifdef wxHAS_RAW_KEY_CODES to determine if this feature is available.

wxUint32 wxKeyEvent::GetRawKeyFlags ( ) const

Returns the low level key flags for this event.

The flags are platform-dependent and should only be used if the functionality provided by other wxKeyEvent methods is insufficient.

Under MSW, the raw flags are just the value of `lParam` parameter of the corresponding message.

Under GTK, the raw flags contain the `hardware_keycode` field of the corresponding GDK event.

Under OS X, the raw flags contain the modifiers state.

Note

Currently the raw key flags are not supported by all ports, use #ifdef wxHAS_RAW_KEY_CODES to determine if this feature is available.

wxChar wxKeyEvent::GetUnicodeKey ( ) const

Returns the Unicode character corresponding to this key event.

If the key pressed doesn't have any character value (e.g. a cursor key) this method will return `WXK_NONE`. In this case you should use GetKeyCode() to retrieve the value of the key.

This function is only available in Unicode build, i.e. when `wxUSE_UNICODE` is 1.

wxCoord wxKeyEvent::GetX ( ) const

Returns the X position (in client coordinates) of the event.

See also

GetPosition()

wxCoord wxKeyEvent::GetY ( ) const

Returns the Y position (in client coordinates) of the event.

See also

GetPosition()

bool wxKeyEvent::IsKeyInCategory (int *category*) const

Returns true if the key is in the given key category.

Parameters

category	A bitwise combination of named wxKeyCategoryFlags constants.

Since

2.9.1

bool wxKeyEvent::IsNextEventAllowed ( ) const

Returns true if DoAllowNextEvent() had been called, false by default.

This method is used by wxWidgets itself to determine whether the normal key events should be generated after `wxEVT_CHAR_HOOK` processing.

Since

2.9.3

21.417 wxLanguageInfo Struct Reference

```
#include <wx/intl.h>
```

21.417.1 Detailed Description

Encapsulates a wxLanguage identifier together with OS-specific information related to that language.

wxPerl Note: In wxPerl `Wx::LanguageInfo` has only one method:

- Wx::LanguageInfo->new(language, canonicalName, WinLang, WinSubLang, Description)

Public Member Functions

- wxUint32 GetLCID () const

  Return the LCID corresponding to this language.
- wxString GetLocaleName () const

  Return the locale name corresponding to this language usable with `setlocale()` on the current system.

Public Attributes

- int Language

  wxLanguage id.
- wxString CanonicalName

  Canonical name of the language, e.g. `fr_FR`.
- wxString Description

  Human-readable name of the language.
- wxLayoutDirection LayoutDirection

  The layout direction used for this language.

- wxUint32 WinLang

  Win32 language identifiers (LANG_xxxx, SUBLANG_xxxx).
- wxUint32 WinSublang

  Win32 language identifiers (LANG_xxxx, SUBLANG_xxxx).

21.417.2 Member Function Documentation

wxUint32 wxLanguageInfo::GetLCID ( ) const

Return the LCID corresponding to this language.

Availability: only available for the wxMSW port.

wxString wxLanguageInfo::GetLocaleName ( ) const

Return the locale name corresponding to this language usable with `setlocale()` on the current system.

21.417.3 Member Data Documentation

wxString wxLanguageInfo::CanonicalName

Canonical name of the language, e.g. `fr_FR`.

wxString wxLanguageInfo::Description

Human-readable name of the language.

int wxLanguageInfo::Language

wxLanguage id.

It should be greater than `wxLANGUAGE_USER_DEFINED` when defining your own language info structure.

wxLayoutDirection wxLanguageInfo::LayoutDirection

The layout direction used for this language.

wxUint32 wxLanguageInfo::WinLang

Win32 language identifiers (LANG_xxxx, SUBLANG_xxxx).

Availability: only available for the wxMSW port.

wxUint32 wxLanguageInfo::WinSublang

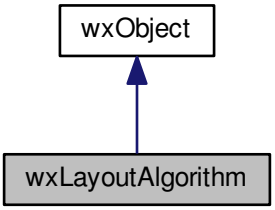
Win32 language identifiers (LANG_xxxx, SUBLANG_xxxx).

Availability: only available for the wxMSW port.

21.418 wxLayoutAlgorithm Class Reference

`#include <wx/laywin.h>`

Inheritance diagram for wxLayoutAlgorithm:



21.418.1 Detailed Description

wxLayoutAlgorithm implements layout of subwindows in MDI or SDI frames.

It sends a wxCalculateLayoutEvent event to children of the frame, asking them for information about their size. For MDI parent frames, the algorithm allocates the remaining space to the MDI client window (which contains the MDI child frames).

For SDI (normal) frames, a 'main' window is specified as taking up the remaining space.

Because the event system is used, this technique can be applied to any windows, which are not necessarily 'aware' of the layout classes (no virtual functions in wxWindow refer to wxLayoutAlgorithm or its events). However, you may wish to use wxSashLayoutWindow for your subwindows since this class provides handlers for the required

events, and accessors to specify the desired size of the window. The sash behaviour in the base class can be used, optionally, to make the windows user-resizable.

wxLayoutAlgorithm is typically used in IDE (integrated development environment) applications, where there are several resizable windows in addition to the MDI client window, or other primary editing window. Resizable windows might include toolbars, a project window, and a window for displaying error and warning messages.

When a window receives an OnCalculateLayout event, it should call SetRect in the given event object, to be the old supplied rectangle minus whatever space the window takes up. It should also set its own size accordingly. wxSash↩ LayoutWindow::OnCalculateLayout generates an OnQueryLayoutInfo event which it sends to itself to determine the orientation, alignment and size of the window, which it gets from internal member variables set by the application.

The algorithm works by starting off with a rectangle equal to the whole frame client area. It iterates through the frame children, generating wxLayoutAlgorithm::OnCalculateLayout events which subtract the window size and return the remaining rectangle for the next window to process. It is assumed (by wxSashLayoutWindow::OnCalculateLayout) that a window stretches the full dimension of the frame client, according to the orientation it specifies. For example, a horizontal window will stretch the full width of the remaining portion of the frame client area. In the other orientation, the window will be fixed to whatever size was specified by wxLayoutAlgorithm::OnQueryLayoutInfo. An alignment setting will make the window 'stick' to the left, top, right or bottom of the remaining client area. This scheme implies that order of window creation is important. Say you wish to have an extra toolbar at the top of the frame, a project window to the left of the MDI client window, and an output window above the status bar. You should therefore create the windows in this order: toolbar, output window, project window. This ensures that the toolbar and output window take up space at the top and bottom, and then the remaining height in-between is used for the project window.

wxLayoutAlgorithm is quite independent of the way in which wxLayoutAlgorithm::OnCalculateLayout chooses to interpret a window's size and alignment. Therefore you could implement a different window class with a new wx↩ LayoutAlgorithm::OnCalculateLayout event handler, that has a more sophisticated way of laying out the windows. It might allow specification of whether stretching occurs in the specified orientation, for example, rather than always assuming stretching. (This could, and probably should, be added to the existing implementation).

Note

wxLayoutAlgorithm has nothing to do with wxLayoutConstraints. It is an alternative way of specifying layouts for which the normal constraint system is unsuitable.

Events emitted by this class

The following event handler macros redirect the events to member function handlers '**func**' with prototypes like: void handlerFuncName(wxQueryLayoutInfoEvent& event) or void handlerFuncName(wxCalculateLayout↩ Event& event)

Event macros for events emitted by this class:

- EVT_QUERY_LAYOUT_INFO(func): Process a `wxEVT_QUERY_LAYOUT_INFO` event, to get size, orientation and alignment from a window. See wxQueryLayoutInfoEvent.
- EVT_CALCULATE_LAYOUT(func): Process a `wxEVT_CALCULATE_LAYOUT` event, which asks the window to take a 'bite' out of a rectangle provided by the algorithm. See wxCalculateLayoutEvent.

Note that the algorithm object does not respond to events, but itself generates the previous events in order to calculate window sizes.

Public Member Functions

- wxLayoutAlgorithm ()

  Default constructor.
- virtual ~wxLayoutAlgorithm ()

  Destructor.
- bool LayoutFrame (wxFrame *frame, wxWindow *mainWindow=NULL)

  Lays out the children of a normal frame.
- bool LayoutMDIFrame (wxMDIParentFrame *frame, wxRect *rect=NULL)

  Lays out the children of an MDI parent frame.
- bool LayoutWindow (wxWindow *parent, wxWindow *mainWindow=NULL)

  Lays out the children of a normal frame or other window.

Additional Inherited Members

21.418.2 Constructor & Destructor Documentation

wxLayoutAlgorithm::wxLayoutAlgorithm ( )

Default constructor.

virtual wxLayoutAlgorithm::~wxLayoutAlgorithm ( ) [virtual]

Destructor.

21.418.3 Member Function Documentation

bool wxLayoutAlgorithm::LayoutFrame (wxFrame * *frame*, wxWindow * *mainWindow* = NULL)

Lays out the children of a normal frame.

mainWindow is set to occupy the remaining space. This function simply calls LayoutWindow().

bool wxLayoutAlgorithm::LayoutMDIFrame (wxMDIParentFrame * *frame*, wxRect * *rect* = NULL)

Lays out the children of an MDI parent frame.

If *rect* is non-NULL, the given rectangle will be used as a starting point instead of the frame's client area. The MDI client window is set to occupy the remaining space.

bool wxLayoutAlgorithm::LayoutWindow (wxWindow * *parent*, wxWindow * *mainWindow* = NULL)

Lays out the children of a normal frame or other window.

mainWindow is set to occupy the remaining space. If this is not specified, then the last window that responds to a calculate layout event in query mode will get the remaining space (that is, a non-query OnCalculateLayout event will not be sent to this window and the window will be set to the remaining size).

wxString wxLinuxDistributionInfo::CodeName

The code name of the distribution; e.g. "jaunty".

wxString wxLinuxDistributionInfo::Description

The description of the distribution; e.g. "Ubuntu 9.04".

wxString wxLinuxDistributionInfo::Id

The id of the distribution; e.g. "Ubuntu".

wxString wxLinuxDistributionInfo::Release

The version of the distribution; e.g. "9.04".

21.421 wxList< T > Class Template Reference

`#include <wx/list.h>`

21.421.1 Detailed Description

template<typename T>class wxList< T >

The wxList<T> class provides linked list functionality.

This class has been rewritten to be type safe and to provide the full API of the STL std::list container and should be used like it. The exception is that wxList<T> actually stores pointers and therefore its iterators return pointers and not references to the actual objects in the list (see example below) and *value_type* is defined as *T**. wxList<T> destroys an object after removing it only if wxList<T>::DeleteContents has been called.

wxList<T> is not a real template and it requires that you declare and define each wxList<T> class in your program. This is done with *WX_DECLARE_LIST* and *WX_DEFINE_LIST* macros (see example). We hope that we'll be able to provide a proper template class providing both the STL `std::list` and the old wxList API in the future.

Please refer to the STL `std::list` documentation (see http://www.cppreference.com/wiki/stl/list/start) for further information on how to use the class. Below we documented both the supported STL and the legacy API that originated from the old wxList class and which can still be used alternatively for the same class.

Note that if you compile wxWidgets in STL mode (`wxUSE_STL` defined as 1) then wxList<T> will actually derive from `std::list` and just add a legacy compatibility layer for the old wxList class.

```
// this part might be in a header or source (.cpp) file
class MyListElement
{
    ... // whatever
};

// this macro declares and partly implements MyList class
WX_DECLARE_LIST(MyListElement, MyList);

...

// the only requirement for the rest is to be AFTER the full declaration of
// MyListElement (for WX_DECLARE_LIST forward declaration is enough), but
// usually it will be found in the source file and not in the header

#include <wx/listimpl.cpp>
WX_DEFINE_LIST(MyList);

MyList list;
MyListElement element;
list.Append(&element);     // ok
list.Append(17);           // error: incorrect type

// let's iterate over the list in STL syntax
MyList::iterator iter;
for (iter = list.begin(); iter != list.end(); ++iter)
```

```
{
    MyListElement *current = *iter;

    ...process the current element...
}

// the same with the legacy API from the old wxList class
MyList::compatibility_iterator node = list.GetFirst();
while (node)
{
    MyListElement *current = node->GetData();

    ...process the current element...

    node = node->GetNext();
}
```

For compatibility with previous versions wxList and wxStringList classes are still defined, but their usage is deprecated and they will disappear in the future versions completely. The use of the latter is especially discouraged as it is not only unsafe but is also much less efficient than wxArrayString class.

Template Parameters

T	The type stored in the wxList nodes.

Library: wxBase

Category: Containers

See also

wxArray<T>, wxVector<T>, wxNode<T>

Public Member Functions

- wxList ()

  Default constructor.
- wxList (size_t count, T *elements[])

  Constructor which initialized the list with an array of count elements.
- ~wxList ()

  Destroys the list, but does not delete the objects stored in the list unless you called DeleteContents(true).
- wxList< T >::compatibility_iterator Append (T *object)

  Appends the pointer to object to the list.
- void Clear ()

  Clears the list.
- void DeleteContents (bool destroy)

  If destroy is true, instructs the list to call delete on objects stored in the list whenever they are removed.
- bool DeleteNode (const compatibility_iterator &iter)

  Deletes the given element referred to by iter from the list if iter is a valid iterator.
- bool DeleteObject (T *object)

  Finds the given object and removes it from the list, returning true if successful.
- void Erase (const compatibility_iterator &iter)

  Removes element referred to be iter.
- wxList< T >::compatibility_iterator Find (T *object) const

  Returns the iterator referring to object or NULL if none found.
- size_t GetCount () const

  Returns the number of elements in the list.
- wxList< T >::compatibility_iterator GetFirst () const

Returns the first iterator in the list (NULL if the list is empty).

- wxList< T >::compatibility_iterator GetLast () const

  Returns the last iterator in the list (NULL if the list is empty).

- int IndexOf (T *obj) const

  Returns the index of obj within the list or `wxNOT_FOUND` if obj is not found in the list.

- wxList< T >::compatibility_iterator Insert (T *object)

  Inserts object at the beginning of the list.

- wxList< T >::compatibility_iterator Insert (size_t position, T *object)

  Inserts object at position.

- wxList< T >::compatibility_iterator Insert (compatibility_iterator iter, T *object)

  Inserts object before the object referred to be iter.

- bool IsEmpty () const

  Returns true if the list is empty, false otherwise.

- wxList< T >::compatibility_iterator Item (size_t index) const

  Returns the iterator referring to the object at the given index in the list.

- bool Member (T *object) const

  Check if the object is present in the list.

- wxList< T >::compatibility_iterator Nth (int n) const
- int Number () const
- void Sort (wxSortCompareFunction compfunc)

  Allows the sorting of arbitrary lists by giving a function to compare two list elements.

- void assign (const_iterator first, const const_iterator &last)

  Clears the list and item from first to last from another list to it.

- void assign (size_type n, const_reference v=value_type())

  Clears the list and adds n items with value v to it.

- reference back ()

  Returns the last item of the list.

- const_reference back () const

  Returns the last item of the list as a const reference.

- iterator begin ()

  Returns an iterator pointing to the beginning of the list.

- const_iterator begin () const

  Returns a const iterator pointing to the beginning of the list.

- void clear ()

  Removes all items from the list.

- bool empty () const

  Returns true if the list is empty.

- const_iterator end () const

  Returns a const iterator pointing at the end of the list.

- iterator end () const

  Returns a iterator pointing at the end of the list.

- iterator erase (const iterator &it)

  Erases the given item.

- iterator erase (const iterator &first, const iterator &last)

  Erases the items from first to last.

- reference front () const

  Returns the first item in the list.

- const_reference front () const

  Returns the first item in the list as a const reference.

- iterator insert (const iterator &it)

  Inserts an item at the head of the list.

- void insert (const iterator &it, size_type n)

  Inserts an item at the given position.
- void insert (const iterator &it, const_iterator first, const const_iterator &last)

  Inserts several items at the given position.
- size_type max_size () const

  Returns the largest possible size of the list.
- void pop_back ()

  Removes the last item from the list.
- void pop_front ()

  Removes the first item from the list.
- void push_back (const_reference v=value_type())

  Adds an item to end of the list.
- void push_front (const_reference v=value_type())

  Adds an item to the front of the list.
- reverse_iterator rbegin ()

  Returns a reverse iterator pointing to the beginning of the reversed list.
- const_reverse_iterator rbegin () const

  Returns a const reverse iterator pointing to the beginning of the reversed list.
- void remove (const_reference v)

  Removes an item from the list.
- reverse_iterator rend ()

  Returns a reverse iterator pointing to the end of the reversed list.
- const_reverse_iterator rend () const

  Returns a const reverse iterator pointing to the end of the reversed list.
- void resize (size_type n, value_type v=value_type())

  Resizes the list.
- void reverse ()

  Reverses the list.
- size_type size () const

  Returns the size of the list.
- wxVector< T > AsVector () const

  Returns a wxVector holding the list elements.

21.421.2 Constructor & Destructor Documentation

template<typename T > wxList< T >::wxList ( )

Default constructor.

template<typename T > wxList< T >::wxList (size_t *count*, T * *elements[]*)

Constructor which initialized the list with an array of *count* elements.

template<typename T > wxList< T >::~wxList ( )

Destroys the list, but does not delete the objects stored in the list unless you called DeleteContents(true).

21.421.3 Member Function Documentation

template<typename T > wxList<T>::compatibility_iterator wxList< T >::Append (T * *object*)

Appends the pointer to *object* to the list.

template<typename T > void wxList< T >::assign (const_iterator *first,* const const_iterator & *last*)

Clears the list and item from *first* to *last* from another list to it.

template<typename T > void wxList< T >::assign (size_type *n,* const_reference *v =* `value_type()`)

Clears the list and adds *n* items with value *v* to it.

template<typename T > wxVector<T> wxList< T >::AsVector ( ) const

Returns a wxVector holding the list elements.

Since

2.9.5

template<typename T > reference wxList< T >::back ( )

Returns the last item of the list.

template<typename T > const_reference wxList< T >::back ( ) const

Returns the last item of the list as a const reference.

template<typename T > iterator wxList< T >::begin ( )

Returns an iterator pointing to the beginning of the list.

template<typename T > const_iterator wxList< T >::begin ( ) const

Returns a const iterator pointing to the beginning of the list.

template<typename T > void wxList< T >::Clear ( )

Clears the list.

Deletes the actual objects if DeleteContents(true) was called previously.

template<typename T > void wxList< T >::clear ( )

Removes all items from the list.

template<typename T > void wxList< T >::DeleteContents (bool *destroy*)

If *destroy* is true, instructs the list to call *delete* on objects stored in the list whenever they are removed.
The default is false.

template<typename T > bool wxList< T >::DeleteNode (const compatibility_iterator & *iter*)

Deletes the given element referred to by *iter* from the list if *iter* is a valid iterator.
Returns true if successful.
Deletes the actual object if DeleteContents(true) was called previously.

template<typename T > bool wxList< T >::DeleteObject (T * *object*)

Finds the given *object* and removes it from the list, returning true if successful.
Deletes *object* if DeleteContents(true) was called previously.

template<typename T > bool wxList< T >::empty ( ) const

Returns true if the list is empty.

template<typename T > const_iterator wxList< T >::end ( ) const

Returns a const iterator pointing at the end of the list.

template<typename T > iterator wxList< T >::end ( ) const

Returns a iterator pointing at the end of the list.

template<typename T > void wxList< T >::Erase (const compatibility_iterator & *iter*)

Removes element referred to be *iter*.
Deletes the actual object if DeleteContents(true) was called previously.

template<typename T > iterator wxList< T >::erase (const iterator & *it*)

Erases the given item.

template<typename T > iterator wxList< T >::erase (const iterator & *first,* const iterator & *last*)

Erases the items from *first* to *last*.

template<typename T > wxList<T>::compatibility_iterator wxList< T >::Find (T * *object*) const

Returns the iterator referring to *object* or NULL if none found.

template<typename T > reference wxList< T >::front ( ) const

Returns the first item in the list.

template<typename T> const_reference wxList< T >::front ( ) const

Returns the first item in the list as a const reference.

template<typename T> size_t wxList< T >::GetCount ( ) const

Returns the number of elements in the list.

template<typename T> wxList<T>::compatibility_iterator wxList< T >::GetFirst ( ) const

Returns the first iterator in the list (NULL if the list is empty).

template<typename T> wxList<T>::compatibility_iterator wxList< T >::GetLast ( ) const

Returns the last iterator in the list (NULL if the list is empty).

template<typename T> int wxList< T >::IndexOf (T * *obj*) const

Returns the index of *obj* within the list or `wxNOT_FOUND` if *obj* is not found in the list.

template<typename T> wxList<T>::compatibility_iterator wxList< T >::Insert (T * *object*)

Inserts *object* at the beginning of the list.

template<typename T> wxList<T>::compatibility_iterator wxList< T >::Insert (size_t *position,* T * *object*)

Inserts *object* at *position*.

template<typename T> wxList<T>::compatibility_iterator wxList< T >::Insert (compatibility_iterator *iter,* T * *object*)

Inserts *object* before the object referred to be *iter*.

template<typename T> iterator wxList< T >::insert (const iterator & *it*)

Inserts an item at the head of the list.

template<typename T> void wxList< T >::insert (const iterator & *it,* size_type *n*)

Inserts an item at the given position.

template<typename T> void wxList< T >::insert (const iterator & *it,* const_iterator *first,* const const_iterator & *last*)

Inserts several items at the given position.

template<typename T> bool wxList< T >::IsEmpty ( ) const

Returns true if the list is empty, false otherwise.

template<typename T > wxList<T>::compatibility_iterator wxList< T >::Item (size_t *index*) const

Returns the iterator referring to the object at the given *index* in the list.

template<typename T > size_type wxList< T >::max_size ( ) const

Returns the largest possible size of the list.

template<typename T > bool wxList< T >::Member (T * *object*) const

Check if the object is present in the list.

See also

Find()

template<typename T > wxList<T>::compatibility_iterator wxList< T >::Nth (int *n*) const

Deprecated This function is deprecated, use Item() instead.

template<typename T > int wxList< T >::Number ( ) const

Deprecated This function is deprecated, use wxList::GetCount instead. Returns the number of elements in the list.

template<typename T > void wxList< T >::pop_back ( )

Removes the last item from the list.

template<typename T > void wxList< T >::pop_front ( )

Removes the first item from the list.

template<typename T > void wxList< T >::push_back (const_reference *v* = `value_type()`)

Adds an item to end of the list.

template<typename T > void wxList< T >::push_front (const_reference *v* = `value_type()`)

Adds an item to the front of the list.

template<typename T > reverse_iterator wxList< T >::rbegin ( )

Returns a reverse iterator pointing to the beginning of the reversed list.

template<typename T > const_reverse_iterator wxList< T >::rbegin ( ) const

Returns a const reverse iterator pointing to the beginning of the reversed list.

template<typename T > void wxList< T >::remove (const_reference *v*)

Removes an item from the list.

template<typename T > reverse_iterator wxList< T >::rend ( )

Returns a reverse iterator pointing to the end of the reversed list.

template<typename T > const_reverse_iterator wxList< T >::rend ( ) const

Returns a const reverse iterator pointing to the end of the reversed list.

template<typename T > void wxList< T >::resize (size_type *n*, value_type *v* = `value_type()`)

Resizes the list.

If the list is longer than *n*, then items are removed until the list becomes long *n*. If the list is shorter than *n* items with the value *v* are appended to the list until the list becomes long *n*.

template<typename T > void wxList< T >::reverse ( )

Reverses the list.

template<typename T > size_type wxList< T >::size ( ) const

Returns the size of the list.

template<typename T > void wxList< T >::Sort (wxSortCompareFunction *compfunc*)

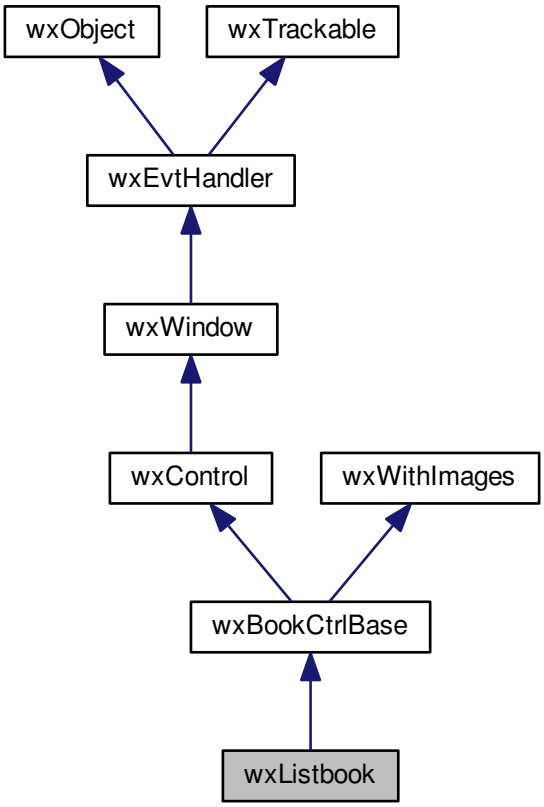
Allows the sorting of arbitrary lists by giving a function to compare two list elements.

We use the system **qsort** function for the actual sorting process.

21.422 wxListbook Class Reference

`#include <wx/listbook.h>`

Inheritance diagram for wxListbook:



21.422.1 Detailed Description

wxListbook is a class similar to wxNotebook but which uses a wxListCtrl to show the labels instead of the tabs.

The underlying wxListCtrl displays page labels in a one-column report view by default. Calling wxBookCtrl::Set↩ ImageList will implicitly switch the control to use an icon view.

For usage documentation of this class, please refer to the base abstract class wxBookCtrl. You can also use the Notebook Sample to see wxListbook in action.

Styles

This class supports the following styles:

- wxLB_DEFAULT: Choose the default location for the labels depending on the current platform (left everywhere except Mac where it is top).
- wxLB_TOP: Place labels above the page area.
- wxLB_LEFT: Place labels on the left side.
- wxLB_RIGHT: Place labels on the right side.
- wxLB_BOTTOM: Place labels below the page area.

Events emitted by this class

The following event handler macros redirect the events to member function handlers '**func**' with prototypes like: void handlerFuncName(wxBookCtrlEvent& event)

Event macros for events emitted by this class:

- EVT_LISTBOOK_PAGE_CHANGED(id, func): The page selection was changed. Processes a `wxEVT_LISTBOOK_PAGE_CHANGED` event.
- EVT_LISTBOOK_PAGE_CHANGING(id, func): The page selection is about to be changed. Processes a `wxEVT_LISTBOOK_PAGE_CHANGING` event. This event can be vetoed.

Library: wxCore

Category: Book Controls

wxBookCtrl, wxNotebook, Notebook Sample

Public Member Functions

- wxListbook ()

  Default ctor.
- wxListbook (wxWindow *parent, wxWindowID id, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, long style=0, const wxString &name=wxEmptyString)

  Constructs a listbook control.
- bool Create (wxWindow *parent, wxWindowID id, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, long style=0, const wxString &name=wxEmptyString)

  Create the list book control that has already been constructed with the default constructor.
- wxListView * GetListView () const

  Returns the wxListView associated with the control.

Additional Inherited Members

21.422.2 Constructor & Destructor Documentation

wxListbook::wxListbook ( )

Default ctor.

wxListbook::wxListbook (wxWindow * *parent*, wxWindowID *id*, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, long *style* = 0, const wxString & *name* = wxEmptyString)

Constructs a listbook control.

21.422.3 Member Function Documentation

bool wxListbook::Create (wxWindow * *parent*, wxWindowID *id*, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, long *style* = 0, const wxString & *name* = wxEmptyString)

Create the list book control that has already been constructed with the default constructor.

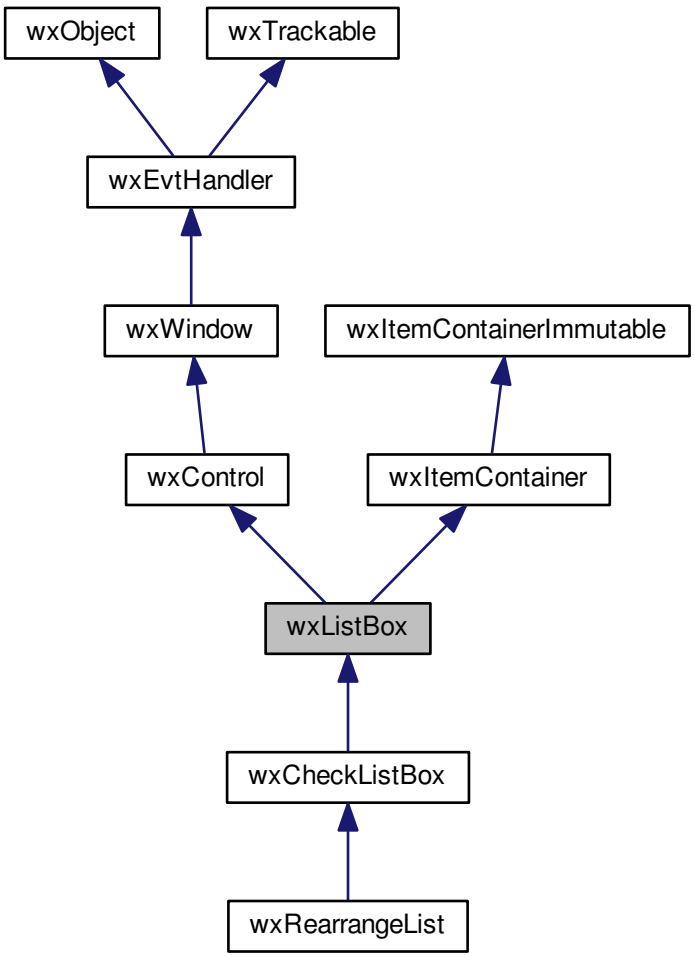
wxListView* wxListbook::GetListView ( ) const

Returns the wxListView associated with the control.

21.423 wxListBox Class Reference

`#include <wx/listbox.h>`

Inheritance diagram for wxListBox:



21.423.1 Detailed Description

A listbox is used to select one or more of a list of strings.

The strings are displayed in a scrolling box, with the selected string(s) marked in reverse video. A listbox can be single selection (if an item is selected, the previous selection is removed) or multiple selection (clicking an item toggles the item on or off independently of other selections).

List box elements are numbered from zero and while the maximal number of elements is unlimited, it is usually

better to use a virtual control, not requiring to add all the items to it at once, such as wxDataViewCtrl or wxListCtrl with `wxLC_VIRTUAL` style, once more than a few hundreds items need to be displayed because this control is not optimized, neither from performance nor from user interface point of view, for large number of items.

Notice that currently `TAB` characters in list box items text are not handled consistently under all platforms, so they should be replaced by spaces to display strings properly everywhere. The list box doesn't support any other control characters at all.

Styles

This class supports the following styles:

- wxLB_SINGLE: Single-selection list.
- wxLB_MULTIPLE: Multiple-selection list: the user can toggle multiple items on and off. This is the same as wxLB_EXTENDED in wxGTK2 port.
- wxLB_EXTENDED: Extended-selection list: the user can extend the selection by using `SHIFT` or `CTRL` keys together with the cursor movement keys or the mouse.
- wxLB_HSCROLL: Create horizontal scrollbar if contents are too wide (Windows only).
- wxLB_ALWAYS_SB: Always show a vertical scrollbar.
- wxLB_NEEDED_SB: Only create a vertical scrollbar if needed.
- wxLB_NO_SB: Don't create vertical scrollbar (wxMSW only).
- wxLB_SORT: The listbox contents are sorted in alphabetical order.

Note that `wxLB_SINGLE`, `wxLB_MULTIPLE` and `wxLB_EXTENDED` styles are mutually exclusive and you can specify at most one of them (single selection is the default). See also Window Styles.

Events emitted by this class

The following event handler macros redirect the events to member function handlers '**func**' with prototypes like: void handlerFuncName(wxCommandEvent& event)

Event macros for events emitted by this class:

- EVT_LISTBOX(id, func): Process a `wxEVT_LISTBOX` event, when an item on the list is selected or the selection changes.
- EVT_LISTBOX_DCLICK(id, func): Process a `wxEVT_LISTBOX_DCLICK` event, when the listbox is double-clicked.

Public Member Functions

- wxListBox ()

  Default constructor.
- wxListBox (wxWindow *parent, wxWindowID id, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, int n=0, const wxString choices[]=NULL, long style=0, const wxValidator &validator=wxDefaultValidator, const wxString &name=wxListBoxNameStr)

  Constructor, creating and showing a list box.
- wxListBox (wxWindow *parent, wxWindowID id, const wxPoint &pos, const wxSize &size, const wxArrayString &choices, long style=0, const wxValidator &validator=wxDefaultValidator, const wxString &name=wxListBoxNameStr)

  Constructor, creating and showing a list box.
- virtual ~wxListBox ()

  Destructor, destroying the list box.
- void Deselect (int n)

  Deselects an item in the list box.
- virtual void SetSelection (int n)

  Sets the selection to the given item n or removes the selection entirely if n == wxNOT_FOUND.
- virtual int GetSelection () const

  Returns the index of the selected item or wxNOT_FOUND if no item is selected.
- virtual bool SetStringSelection (const wxString &s, bool select)
- virtual bool SetStringSelection (const wxString &s)
- virtual int GetSelections (wxArrayInt &selections) const

  Fill an array of ints with the positions of the currently selected items.
- int HitTest (const wxPoint &point) const

  Returns the item located at point, or wxNOT_FOUND if there is no item located at point.
- int HitTest (int x, int y) const

  This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.
- void InsertItems (unsigned int nItems, const wxString *items, unsigned int pos)

  Insert the given number of strings before the specified position.
- void InsertItems (const wxArrayString &items, unsigned int pos)

  Insert the given number of strings before the specified position.
- virtual bool IsSelected (int n) const

  Determines whether an item is selected.
- void SetFirstItem (int n)

  Set the specified item to be the first visible item.
- void SetFirstItem (const wxString &string)

  Set the specified item to be the first visible item.
- virtual void EnsureVisible (int n)

  Ensure that the item with the given index is currently shown.
- virtual bool IsSorted () const

  Return true if the listbox has wxLB_SORT style.
- virtual unsigned int GetCount () const

  Returns the number of items in the control.
- virtual wxString GetString (unsigned int n) const

  Returns the label of the item with the given index.
- virtual void SetString (unsigned int n, const wxString &s)

  Sets the label for the given item.
- virtual int FindString (const wxString &s, bool bCase=false) const

  Finds an item whose label matches the given string.

- bool Create (wxWindow *parent, wxWindowID id, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, int n=0, const wxString choices[]=NULL, long style=0, const wxValidator &validator=wxDefaultValidator, const wxString &name=wxListBoxNameStr)

  Creates the listbox for two-step construction.

- bool Create (wxWindow *parent, wxWindowID id, const wxPoint &pos, const wxSize &size, const wxArrayString &choices, long style=0, const wxValidator &validator=wxDefaultValidator, const wxString &name=wxListBoxNameStr)

  Creates the listbox for two-step construction.

Additional Inherited Members

21.423.2 Constructor & Destructor Documentation

wxListBox::wxListBox ( )

Default constructor.

wxListBox::wxListBox (wxWindow * *parent*, wxWindowID *id*, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, int *n* = 0, const wxString *choices[]* = NULL, long *style* = 0, const wxValidator & *validator* = wxDefaultValidator, const wxString & *name* = wxListBoxNameStr)

Constructor, creating and showing a list box.

Parameters

parent	The parent window.
id	The ID of this control. A value of wxID_ANY indicates a default value.
pos	The initial position. If wxDefaultPosition is specified then a default position is chosen.
size	The initial size. If wxDefaultSize is specified then the window is sized appropriately.
n	Number of strings with which to initialise the control.
choices	The strings to use to initialize the control.
style	Window style. See wxListBox.
validator	The validator for this control.
name	The name of this class.

wxPerl Note: Not supported by wxPerl.

wxListBox::wxListBox (wxWindow * *parent*, wxWindowID *id*, const wxPoint & *pos*, const wxSize & *size*, const wxArrayString & *choices*, long *style* = 0, const wxValidator & *validator* = wxDefaultValidator, const wxString & *name* = wxListBoxNameStr)

Constructor, creating and showing a list box.

See the other wxListBox() constructor; the only difference is that this overload takes a wxArrayString instead of a pointer to an array of wxString.

wxPerl Note: Use an array reference for the *choices* parameter.

virtual wxListBox::~wxListBox ( ) [virtual]

Destructor, destroying the list box.

21.423.3 Member Function Documentation

bool wxListBox::Create (wxWindow * *parent*, wxWindowID *id*, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, int *n* = 0, const wxString *choices[]* = NULL, long *style* = 0, const wxValidator & *validator* = wxDefaultValidator, const wxString & *name* = wxListBoxNameStr)

Creates the listbox for two-step construction.

See wxListBox() for further details.

bool wxListBox::Create (wxWindow * *parent*, wxWindowID *id*, const wxPoint & *pos*, const wxSize & *size*, const wxArrayString & *choices*, long *style* = 0, const wxValidator & *validator* = wxDefaultValidator, const wxString & *name* = wxListBoxNameStr)

Creates the listbox for two-step construction.

See wxListBox() for further details.

void wxListBox::Deselect (int *n*)

Deselects an item in the list box.

Parameters

n	The zero-based item to deselect.

Remarks

This applies to multiple selection listboxes only.

virtual void wxListBox::EnsureVisible (int *n*) [virtual]

Ensure that the item with the given index is currently shown.

This method scrolls the listbox only if necessary and doesn't do anything if this item is already shown, unlike SetFirstItem().

virtual int wxListBox::FindString (const wxString & *string*, bool *caseSensitive* = false) const [virtual]

Finds an item whose label matches the given string.

Parameters

string	String to find.
caseSensitive	Whether search is case sensitive (default is not).

Returns

The zero-based position of the item, or wxNOT_FOUND if the string was not found.

Reimplemented from wxItemContainerImmutable.

virtual unsigned int wxListBox::GetCount ( ) const [virtual]

Returns the number of items in the control.

See also

IsEmpty()

Implements wxItemContainerImmutable.

virtual int wxListBox::GetSelection ( ) const `[virtual]`

Returns the index of the selected item or `wxNOT_FOUND` if no item is selected.

Returns

The position of the current selection.

Remarks

This method can be used with single selection list boxes only, you should use wxListBox::GetSelections() for the list boxes with wxLB_MULTIPLE style.

See also

SetSelection(), GetStringSelection()

Implements wxItemContainerImmutable.

virtual int wxListBox::GetSelections (wxArrayInt & *selections*) const `[virtual]`

Fill an array of ints with the positions of the currently selected items.

Parameters

selections	A reference to an wxArrayInt instance that is used to store the result of the query.

Returns

The number of selections.

Remarks

Use this with a multiple selection listbox.

wxPerl Note: In wxPerl this method takes no parameters and return the selected items as a list.

See also

wxControlWithItems::GetSelection, wxControlWithItems::GetStringSelection, wxControlWithItems::SetSelection

virtual wxString wxListBox::GetString (unsigned int *n*) const `[virtual]`

Returns the label of the item with the given index.

Parameters

n	The zero-based index.

Returns

The label of the item or an empty string if the position was invalid.

Implements wxItemContainerImmutable.

int wxListBox::HitTest (const wxPoint & *point*) const

Returns the item located at *point*, or `wxNOT_FOUND` if there is no item located at *point*.

It is currently implemented for wxMSW, wxMac and wxGTK2 ports.

Parameters

point	Point of item (in client coordinates) to obtain

Returns

Item located at point, or wxNOT_FOUND if unimplemented or the item does not exist.

Since

2.7.0

int wxListBox::HitTest (int *x*, int *y*) const

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.

void wxListBox::InsertItems (unsigned int *nItems*, const wxString * *items*, unsigned int *pos*)

Insert the given number of strings before the specified position.

Parameters

nItems	Number of items in the array items
items	Labels of items to be inserted
pos	Position before which to insert the items: if pos is 0 the items will be inserted in the beginning of the listbox

wxPerl Note: Not supported by wxPerl.

void wxListBox::InsertItems (const wxArrayString & *items*, unsigned int *pos*)

Insert the given number of strings before the specified position.

Parameters

items	Labels of items to be inserted
pos	Position before which to insert the items: if pos is 0 the items will be inserted in the beginning of the listbox

wxPerl Note: Use an array reference for the *items* parameter.

virtual bool wxListBox::IsSelected (int *n*) const [virtual]

Determines whether an item is selected.

Parameters

n	The zero-based item index.

Returns

true if the given item is selected, false otherwise.

virtual bool wxListBox::IsSorted ( ) const [virtual]

Return true if the listbox has wxLB_SORT style.

This method is mostly meant for internal use only.

void wxListBox::SetFirstItem (int *n*)

Set the specified item to be the first visible item.

Parameters

n	The zero-based item index that should be visible.

void wxListBox::SetFirstItem (const wxString & *string*)

Set the specified item to be the first visible item.

Parameters

string	The string that should be visible.

virtual void wxListBox::SetSelection (int *n*) [virtual]

Sets the selection to the given item *n* or removes the selection entirely if *n* == `wxNOT_FOUND`.

Note that this does not cause any command events to be emitted nor does it deselect any other items in the controls which support multiple selections.

Parameters

n	The string position to select, starting from zero.

See also

SetString(), SetStringSelection()

Implements wxItemContainerImmutable.

virtual void wxListBox::SetString (unsigned int *n,* const wxString & *string*) [virtual]

Sets the label for the given item.

Parameters

n	The zero-based item index.
string	The label to set.

Implements wxItemContainerImmutable.

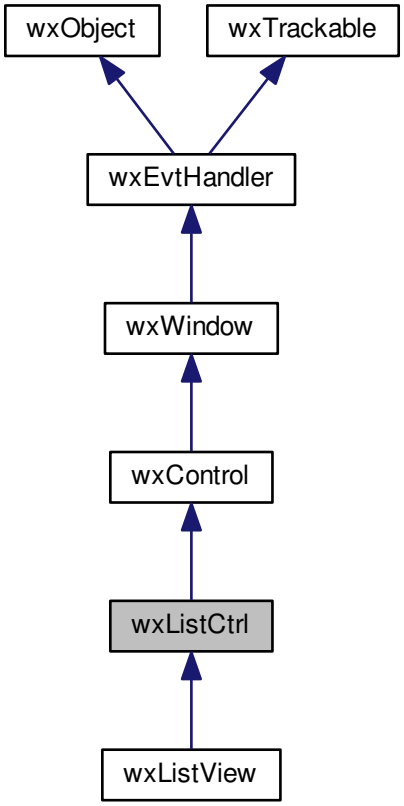
virtual bool wxListBox::SetStringSelection (const wxString & *s,* bool *select*) [virtual]

virtual bool wxListBox::SetStringSelection (const wxString & *s*) [virtual]

21.424 wxListCtrl Class Reference

```
#include <wx/listctrl.h>
```

Inheritance diagram for wxListCtrl:



21.424.1 Detailed Description

A list control presents lists in a number of formats: list view, report view, icon view and small icon view.

In any case, elements are numbered from zero. For all these modes, the items are stored in the control and must be added to it using wxListCtrl::InsertItem method.

A special case of report view quite different from the other modes of the list control is a virtual control in which the items data (including text, images and attributes) is managed by the main program and is requested by the control itself only when needed which allows to have controls with millions of items without consuming much memory. To use virtual list control you must use wxListCtrl::SetItemCount first and override at least wxListCtrl::OnGetItemText (and optionally wxListCtrl::OnGetItemImage or wxListCtrl::OnGetItemColumnImage and wxListCtrl::OnGetItemAttr) to return the information about the items when the control requests it.

Virtual list control can be used as a normal one except that no operations which can take time proportional to the number of items in the control happen – this is required to allow having a practically infinite number of items. For example, in a multiple selection virtual list control, the selections won't be sent when many items are selected at once because this could mean iterating over all the items.

Using many of wxListCtrl features is shown in the corresponding sample.

To intercept events from a list control, use the event table macros described in wxListEvent.

wxMac Note: Starting with wxWidgets 2.8, wxListCtrl uses a native implementation for report mode, and uses a generic implementation for other modes. You can use the generic implementation for report mode as well by setting

the `mac.listctrl.always_use_generic` system option (see wxSystemOptions) to 1.

Styles

This class supports the following styles:

- wxLC_LIST: Multicolumn list view, with optional small icons. Columns are computed automatically, i.e. you don't set columns as in `wxLC_REPORT`. In other words, the list wraps, unlike a wxListBox.
- wxLC_REPORT: Single or multicolumn report view, with optional header.
- wxLC_VIRTUAL: The application provides items text on demand. May only be used with `wxLC_REPORT`.
- wxLC_ICON: Large icon view, with optional labels.
- wxLC_SMALL_ICON: Small icon view, with optional labels.
- wxLC_ALIGN_TOP: Icons align to the top. Win32 default, Win32 only.
- wxLC_ALIGN_LEFT: Icons align to the left.
- wxLC_AUTOARRANGE: Icons arrange themselves. Win32 only.
- wxLC_EDIT_LABELS: Labels are editable: the application will be notified when editing starts.
- wxLC_NO_HEADER: No header in report mode.
- wxLC_SINGLE_SEL: Single selection (default is multiple).
- wxLC_SORT_ASCENDING: Sort in ascending order. (You must still supply a comparison callback in wxListCtrl::SortItems.)
- wxLC_SORT_DESCENDING: Sort in descending order. (You must still supply a comparison callback in wxListCtrl::SortItems.)
- wxLC_HRULES: Draws light horizontal rules between rows in report mode.
- wxLC_VRULES: Draws light vertical rules between columns in report mode.

Events emitted by this class

The following event handler macros redirect the events to member function handlers '**func**' with prototypes like: void handlerFuncName(wxListEvent& event)

Event macros for events emitted by this class:

- EVT_LIST_BEGIN_DRAG(id, func): Begin dragging with the left mouse button. Processes a `wxEVT_LIST_BEGIN_DRAG` event type.
- EVT_LIST_BEGIN_RDRAG(id, func): Begin dragging with the right mouse button. Processes a `wxEVT_LIST_BEGIN_RDRAG` event type.
- EVT_BEGIN_LABEL_EDIT(id, func): Begin editing a label. This can be prevented by calling Veto(). Processes a `wxEVT_LIST_BEGIN_LABEL_EDIT` event type.
- EVT_LIST_END_LABEL_EDIT(id, func): Finish editing a label. This can be prevented by calling Veto(). Processes a `wxEVT_LIST_END_LABEL_EDIT` event type.
- EVT_LIST_DELETE_ITEM(id, func): An item was deleted. Processes a `wxEVT_LIST_DELETE_ITEM` event type.
- EVT_LIST_DELETE_ALL_ITEMS(id, func): All items were deleted. Processes a `wxEVT_LIST_DELETE_ALL_ITEMS` event type.

- EVT_LIST_ITEM_SELECTED(id, func): The item has been selected. Processes a `wxEVT_LIST_ITEM_SELECTED` event type.
- EVT_LIST_ITEM_DESELECTED(id, func): The item has been deselected. Processes a `wxEVT_LIST_ITEM_DESELECTED` event type.
- EVT_LIST_ITEM_ACTIVATED(id, func): The item has been activated (ENTER or double click). Processes a `wxEVT_LIST_ITEM_ACTIVATED` event type.
- EVT_LIST_ITEM_FOCUSED(id, func): The currently focused item has changed. Processes a `wxEVT_LIST_ITEM_FOCUSED` event type.
- EVT_LIST_ITEM_MIDDLE_CLICK(id, func): The middle mouse button has been clicked on an item. This is only supported by the generic control. Processes a `wxEVT_LIST_ITEM_MIDDLE_CLICK` event type.
- EVT_LIST_ITEM_RIGHT_CLICK(id, func): The right mouse button has been clicked on an item. Processes a `wxEVT_LIST_ITEM_RIGHT_CLICK` event type.
- EVT_LIST_KEY_DOWN(id, func): A key has been pressed. Processes a `wxEVT_LIST_KEY_DOWN` event type.
- EVT_LIST_INSERT_ITEM(id, func): An item has been inserted. Processes a `wxEVT_LIST_INSERT_ITEM` event type.
- EVT_LIST_COL_CLICK(id, func): A column (m_col) has been left-clicked. Processes a `wxEVT_LIST_COL_CLICK` event type.
- EVT_LIST_COL_RIGHT_CLICK(id, func): A column (m_col) has been right-clicked. Processes a `wxEVT_LIST_COL_RIGHT_CLICK` event type.
- EVT_LIST_COL_BEGIN_DRAG(id, func): The user started resizing a column - can be vetoed. Processes a `wxEVT_LIST_COL_BEGIN_DRAG` event type.
- EVT_LIST_COL_DRAGGING(id, func): The divider between columns is being dragged. Processes a `wxEVT_LIST_COL_DRAGGING` event type.
- EVT_LIST_COL_END_DRAG(id, func): A column has been resized by the user. Processes a `wxEVT_LIST_COL_END_DRAG` event type.
- EVT_LIST_CACHE_HINT(id, func): Prepare cache for a virtual list control. Processes a `wxEVT_LIST_CACHE_HINT` event type.

wxListCtrl Overview, wxListView, wxListBox, wxTreeCtrl, wxImageList, wxListEvent, wxListItem, wxEditableListBox

Public Member Functions

- wxListCtrl ()

  Default constructor.
- wxListCtrl (wxWindow *parent, wxWindowID id, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, long style=wxLC_ICON, const wxValidator &validator=wxDefaultValidator, const wxString &name=wxListCtrlNameStr)

  Constructor, creating and showing a list control.
- virtual ~wxListCtrl ()

Destructor, destroying the list control.

- long AppendColumn (const wxString &heading, wxListColumnFormat format=wxLIST_FORMAT_LEFT, int width=-1)

  Adds a new column to the list control in report view mode.
- bool Arrange (int flag=wxLIST_ALIGN_DEFAULT)

  Arranges the items in icon or small icon view.
- void AssignImageList (wxImageList *imageList, int which)

  Sets the image list associated with the control and takes ownership of it (i.e.
- void ClearAll ()

  Deletes all items and all columns.
- bool Create (wxWindow *parent, wxWindowID id, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, long style=wxLC_ICON, const wxValidator &validator=wxDefaultValidator, const wxString &name=wxListCtrlNameStr)

  Creates the list control.
- bool DeleteAllItems ()

  Deletes all items in the list control.
- bool DeleteColumn (int col)

  Deletes a column.
- bool DeleteItem (long item)

  Deletes the specified item.
- wxTextCtrl * EditLabel (long item, wxClassInfo *textControlClass=wxCLASSINFO(wxTextCtrl))

  Starts editing the label of the given item.
- void EnableAlternateRowColours (bool enable=true)

  Enable alternating row background colours (also called zebra striping).
- void EnableBellOnNoMatch (bool on=true)

  Enable or disable a beep if there is no match for the currently entered text when searching for the item from keyboard.
- bool EndEditLabel (bool cancel)

  Finish editing the label.
- bool EnsureVisible (long item)

  Ensures this item is visible.
- long FindItem (long start, const wxString &str, bool partial=false)

  Find an item whose label matches this string, starting from start or the beginning if start is `-1`.
- long FindItem (long start, wxUIntPtr data)

  Find an item whose data matches this data, starting from start or the beginning if 'start' is `-1`.
- long FindItem (long start, const wxPoint &pt, int direction)

  Find an item nearest this position in the specified direction, starting from start or the beginning if start is -1.
- bool GetColumn (int col, wxListItem &item) const

  Gets information about this column.
- int GetColumnCount () const

  Returns the number of columns.
- int GetColumnIndexFromOrder (int pos) const

  Gets the column index from its position in visual order.
- int GetColumnOrder (int col) const

  Gets the column visual order position.
- int GetColumnWidth (int col) const

  Gets the column width (report view only).
- wxArrayInt GetColumnsOrder () const

  Returns the array containing the orders of all columns.
- int GetCountPerPage () const

  Gets the number of items that can fit vertically in the visible area of the list control (list or report view) or the total number of items in the list control (icon or small icon view).

- wxTextCtrl * GetEditControl () const

  Returns the edit control being currently used to edit a label.
- wxImageList * GetImageList (int which) const

  Returns the specified image list.
- bool GetItem (wxListItem &info) const

  Gets information about the item.
- wxColour GetItemBackgroundColour (long item) const

  Returns the colour for this item.
- int GetItemCount () const

  Returns the number of items in the list control.
- wxUIntPtr GetItemData (long item) const

  Gets the application-defined data associated with this item.
- wxFont GetItemFont (long item) const

  Returns the item's font.
- bool GetItemPosition (long item, wxPoint &pos) const

  Returns the position of the item, in icon or small icon view.
- bool GetItemRect (long item, wxRect &rect, int code=wxLIST_RECT_BOUNDS) const

  Returns the rectangle representing the item's size and position, in physical coordinates.
- wxSize GetItemSpacing () const

  Retrieves the spacing between icons in pixels: horizontal spacing is returned as x component of the wxSize object and the vertical spacing as its y component.
- int GetItemState (long item, long stateMask) const

  Gets the item state.
- wxString GetItemText (long item, int col=0) const

  Gets the item text for this item.
- wxColour GetItemTextColour (long item) const

  Returns the colour for this item.
- long GetNextItem (long item, int geometry=wxLIST_NEXT_ALL, int state=wxLIST_STATE_DONTCARE) const

  Searches for an item with the given geometry or state, starting from item but excluding the item itself.
- int GetSelectedItemCount () const

  Returns the number of selected items in the list control.
- bool GetSubItemRect (long item, long subItem, wxRect &rect, int code=wxLIST_RECT_BOUNDS) const

  Returns the rectangle representing the size and position, in physical coordinates, of the given subitem, i.e.
- wxColour GetTextColour () const

  Gets the text colour of the list control.
- long GetTopItem () const

  Gets the index of the topmost visible item when in list or report view.
- wxRect GetViewRect () const

  Returns the rectangle taken by all items in the control.
- void SetAlternateRowColour (const wxColour &colour)

  Set the alternative row background colour to a specific colour.
- long HitTest (const wxPoint &point, int &flags, long *ptrSubItem=NULL) const

  Determines which item (if any) is at the specified point, giving details in flags.
- bool InReportView () const

  Returns true if the control is currently using wxLC_REPORT style.
- long InsertColumn (long col, const wxListItem &info)

  For report view mode (only), inserts a column.
- long InsertColumn (long col, const wxString &heading, int format=wxLIST_FORMAT_LEFT, int width=wxLIST_AUTOSIZE)

  For report view mode (only), inserts a column.

- long InsertItem (wxListItem &info)

  Inserts an item, returning the index of the new item if successful, -1 otherwise.
- long InsertItem (long index, const wxString &label)

  Insert an string item.
- long InsertItem (long index, int imageIndex)

  Insert an image item.
- long InsertItem (long index, const wxString &label, int imageIndex)

  Insert an image/string item.
- bool IsVirtual () const

  Returns true if the control is currently in virtual report view.
- void RefreshItem (long item)

  Redraws the given item.
- void RefreshItems (long itemFrom, long itemTo)

  Redraws the items between itemFrom and itemTo.
- bool ScrollList (int dx, int dy)

  Scrolls the list control.
- virtual bool SetBackgroundColour (const wxColour &col)

  Sets the background colour.
- bool SetColumn (int col, wxListItem &item)

  Sets information about this column.
- bool SetColumnWidth (int col, int width)

  Sets the column width.
- bool SetColumnsOrder (const wxArrayInt &orders)

  Changes the order in which the columns are shown.
- void SetImageList (wxImageList *imageList, int which)

  Sets the image list associated with the control.
- bool SetItem (wxListItem &info)

  Sets the data of an item.
- long SetItem (long index, int column, const wxString &label, int imageId=-1)

  Sets an item string field at a particular column.
- void SetItemBackgroundColour (long item, const wxColour &col)

  Sets the background colour for this item.
- bool SetItemColumnImage (long item, long column, int image)

  Sets the image associated with the item.
- void SetItemCount (long count)

  This method can only be used with virtual list controls.
- bool SetItemData (long item, long data)

  Associates application-defined data with this item.
- void SetItemFont (long item, const wxFont &font)

  Sets the item's font.
- bool SetItemImage (long item, int image, int selImage=-1)

  Sets the unselected and selected images associated with the item.
- bool SetItemPosition (long item, const wxPoint &pos)

  Sets the position of the item, in icon or small icon view.
- bool SetItemPtrData (long item, wxUIntPtr data)

  Associates application-defined data with this item.
- bool SetItemState (long item, long state, long stateMask)

  Sets the item state.
- void SetItemText (long item, const wxString &text)

  Sets the item text for this item.
- void SetItemTextColour (long item, const wxColour &col)

Sets the colour for this item.

- void SetSingleStyle (long style, bool add=true)

  Adds or removes a single window style.

- void SetTextColour (const wxColour &col)

  Sets the text colour of the list control.

- void SetWindowStyleFlag (long style)

  Sets the whole window style, deleting all items.

- bool SortItems (wxListCtrlCompare fnSortCallBack, wxIntPtr data)

  Call this function to sort the items in the list control.

Protected Member Functions

- virtual wxListItemAttr * OnGetItemAttr (long item) const

  This function may be overridden in the derived class for a control with `wxLC_VIRTUAL` style.

- virtual wxListItemAttr * OnGetItemColumnAttr (long item, long column) const

  This function may be overridden in the derived class for a control with `wxLC_VIRTUAL` style.

- virtual int OnGetItemColumnImage (long item, long column) const

  Override this function in the derived class for a control with `wxLC_VIRTUAL` and `wxLC_REPORT` styles in order to specify the image index for the given line and column.

- virtual int OnGetItemImage (long item) const

  This function must be overridden in the derived class for a control with `wxLC_VIRTUAL` style having an "image list" (see SetImageList(); if the control doesn't have an image list, it is not necessary to override it).

- virtual wxString OnGetItemText (long item, long column) const

  *This function **must** be overridden in the derived class for a control with `wxLC_VIRTUAL` style.*

Additional Inherited Members

21.424.2 Constructor & Destructor Documentation

wxListCtrl::wxListCtrl ( )

Default constructor.

wxListCtrl::wxListCtrl (wxWindow * *parent*, wxWindowID *id*, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, long *style* = wxLC_ICON, const wxValidator & *validator* = wxDefaultValidator, const wxString & *name* = `wxListCtrlNameStr`)

Constructor, creating and showing a list control.

Parameters

parent	Parent window. Must not be NULL.
id	Window identifier. The value wxID_ANY indicates a default value.
pos	Window position. If wxDefaultPosition is specified then a default position is chosen.
size	Window size. If wxDefaultSize is specified then the window is sized appropriately.
style	Window style. See wxListCtrl.
validator	Window validator.
name	Window name.

See also

Create(), wxValidator

virtual wxListCtrl::~wxListCtrl ( ) [virtual]

Destructor, destroying the list control.

21.424.3 Member Function Documentation

long wxListCtrl::AppendColumn (const wxString & *heading*, wxListColumnFormat *format* = wxLIST_FORMAT_LEFT, int *width* = -1)

Adds a new column to the list control in report view mode.

This is just a convenient wrapper for InsertColumn() which adds the new column after all the existing ones without having to specify its position explicitly.

Since

2.9.4

bool wxListCtrl::Arrange (int *flag* = wxLIST_ALIGN_DEFAULT)

Arranges the items in icon or small icon view.

This only has effect on Win32. *flag* is one of:

- wxLIST_ALIGN_DEFAULT: Default alignment.
- wxLIST_ALIGN_LEFT: Align to the left side of the control.
- wxLIST_ALIGN_TOP: Align to the top side of the control.
- wxLIST_ALIGN_SNAP_TO_GRID: Snap to grid.

void wxListCtrl::AssignImageList (wxImageList * *imageList*, int *which*)

Sets the image list associated with the control and takes ownership of it (i.e.

the control will, unlike when using SetImageList(), delete the list when destroyed). *which* is one of `wxIMAGE_LIST_NORMAL`, `wxIMAGE_LIST_SMALL`, `wxIMAGE_LIST_STATE` (the last is unimplemented).

See also

SetImageList()

void wxListCtrl::ClearAll ( )

Deletes all items and all columns.

Note

This sends an event of type `wxEVT_LIST_DELETE_ALL_ITEMS` under all platforms.

bool wxListCtrl::Create (wxWindow * *parent*, wxWindowID *id*, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, long *style* = wxLC_ICON, const wxValidator & *validator* = wxDefaultValidator, const wxString & *name* = `wxListCtrlNameStr`)

Creates the list control.

See wxListCtrl() for further details.

bool wxListCtrl::DeleteAllItems ( )

Deletes all items in the list control.

This function does *not* send the `wxEVT_LIST_DELETE_ITEM` event because deleting many items from the control would be too slow then (unlike wxListCtrl::DeleteItem) but it does send the special `wxEVT_LIST_DELETE_ALL_ITEMS` event if the control was not empty. If it was already empty, nothing is done and no event is sent.

Returns

true if the items were successfully deleted or if the control was already empty, false if an error occurred while deleting the items.

bool wxListCtrl::DeleteColumn (int *col*)

Deletes a column.

bool wxListCtrl::DeleteItem (long *item*)

Deletes the specified item.

This function sends the `wxEVT_LIST_DELETE_ITEM` event for the item being deleted.

See also

DeleteAllItems()

wxTextCtrl* wxListCtrl::EditLabel (long *item*, wxClassInfo * *textControlClass* = wxCLASSINFO(wxTextCtrl))

Starts editing the label of the given item.

This function generates a `EVT_LIST_BEGIN_LABEL_EDIT` event which can be vetoed so that no text control will appear for in-place editing.

If the user changed the label (i.e. s/he does not press ESC or leave the text control without changes, a `EVT_LIST_END_LABEL_EDIT` event will be sent which can be vetoed as well.

void wxListCtrl::EnableAlternateRowColours (bool *enable* = `true`)

Enable alternating row background colours (also called zebra striping).

This method can only be called for the control in virtual report mode, i.e. having wxLC_REPORT and wxLC_VIRTUAL styles.

When enabling alternating colours, the appropriate colour for the even rows is chosen automatically depending on the default foreground and background colours which are used for the odd rows.

Parameters

enable	If true, enable alternating row background colours, i.e. different colours for the odd and even rows. If false, disable this feature and use the same background colour for all rows.

Since

2.9.5

See also

SetAlternateRowColour()

void wxListCtrl::EnableBellOnNoMatch (bool *on* = `true`)

Enable or disable a beep if there is no match for the currently entered text when searching for the item from keyboard.

The default is to not beep in this case except in wxMSW where the beep is always generated by the native control and cannot be disabled, i.e. calls to this function do nothing there.

Since

2.9.5

bool wxListCtrl::EndEditLabel (bool *cancel*)

Finish editing the label.

This method allows to programmatically end editing a list control item in place. Usually it will only be called when editing is in progress, i.e. if GetEditControl() returns non-NULL. In particular, do not call it from EVT_LIST_BEGIN_LABEL_EDIT handler as the edit control is not yet fully created by then, just veto the event in this handler instead to prevent the editing from even starting.

Notice that calling this method will result in EVT_LIST_END_LABEL_EDIT event being generated.

Currently only implemented in wxMSW.

Parameters

cancel	If true, discard the changes made by user, as if `Escape` key was pressed. Otherwise, accept the changes as if `Return` was pressed.

Returns

true if item editing was finished or false if no item as being edited.

bool wxListCtrl::EnsureVisible (long *item*)

Ensures this item is visible.

long wxListCtrl::FindItem (long *start*, const wxString & *str*, bool *partial* = `false`)

Find an item whose label matches this string, starting from start or the beginning if start is `-1`.

The string comparison is case insensitive.

If *partial* is true then this method will look for items which begin with *str*.

Returns

The next matching item if any or `-1` (wxNOT_FOUND) otherwise.

long wxListCtrl::FindItem (long *start*, wxUIntPtr *data*)

Find an item whose data matches this data, starting from start or the beginning if 'start' is `-1`.

wxPerl Note: In wxPerl this method is implemented as FindItemData(start, data).

Returns

The next matching item if any or `-1` (wxNOT_FOUND) otherwise.

long wxListCtrl::FindItem (long *start,* const wxPoint & *pt,* int *direction*)

Find an item nearest this position in the specified direction, starting from *start* or the beginning if *start* is -1.

wxPerl Note: In wxPerl this method is implemented as FindItemAtPos(start, pt, direction).

Returns

The next matching item if any or `-1` (wxNOT_FOUND) otherwise.

bool wxListCtrl::GetColumn (int *col,* wxListItem & *item*) const

Gets information about this column.

See SetItem() for more information.

wxPerl Note: In wxPerl this method takes only the *col* parameter and returns a `Wx::ListItem` (or `undef`).

int wxListCtrl::GetColumnCount ( ) const

Returns the number of columns.

int wxListCtrl::GetColumnIndexFromOrder (int *pos*) const

Gets the column index from its position in visual order.

After calling SetColumnsOrder(), the index returned by this function corresponds to the value of the element number *pos* in the array returned by GetColumnsOrder().

Please see SetColumnsOrder() documentation for an example and additional remarks about the columns ordering.

See also

GetColumnOrder()

int wxListCtrl::GetColumnOrder (int *col*) const

Gets the column visual order position.

This function returns the index of the column which appears at the given visual position, e.g. calling it with *col* equal to 0 returns the index of the first shown column.

Please see SetColumnsOrder() documentation for an example and additional remarks about the columns ordering.

See also

GetColumnsOrder(), GetColumnIndexFromOrder()

wxArrayInt wxListCtrl::GetColumnsOrder ( ) const

Returns the array containing the orders of all columns.

On error, an empty array is returned.

Please see SetColumnsOrder() documentation for an example and additional remarks about the columns ordering.

See also

GetColumnOrder(), GetColumnIndexFromOrder()

int wxListCtrl::GetColumnWidth (int *col*) const

Gets the column width (report view only).

int wxListCtrl::GetCountPerPage ( ) const

Gets the number of items that can fit vertically in the visible area of the list control (list or report view) or the total number of items in the list control (icon or small icon view).

wxTextCtrl* wxListCtrl::GetEditControl ( ) const

Returns the edit control being currently used to edit a label.

Returns NULL if no label is being edited.

Note

It is currently only implemented for wxMSW and the generic version, not for the native Mac OS X version.

wxImageList* wxListCtrl::GetImageList (int *which*) const

Returns the specified image list.

which may be one of:

- wxIMAGE_LIST_NORMAL: The normal (large icon) image list.
- wxIMAGE_LIST_SMALL: The small icon image list.
- wxIMAGE_LIST_STATE: The user-defined state image list (unimplemented).

bool wxListCtrl::GetItem (wxListItem & *info*) const

Gets information about the item.

See SetItem() for more information.

You must call *info.SetId()* to set the ID of item you're interested in before calling this method, and *info.SetMask()* with the flags indicating what fields you need to retrieve from *info*.

wxPerl Note: In wxPerl this method takes as parameter the ID of the item and (optionally) the column, and returns a Wx::ListItem object.

wxColour wxListCtrl::GetItemBackgroundColour (long *item*) const

Returns the colour for this item.

If the item has no specific colour, returns an invalid colour (and not the default background control of the control itself).

See also

GetItemTextColour()

int wxListCtrl::GetItemCount ( ) const

Returns the number of items in the list control.

wxUIntPtr wxListCtrl::GetItemData (long *item*) const

Gets the application-defined data associated with this item.

wxFont wxListCtrl::GetItemFont (long *item*) const

Returns the item's font.

bool wxListCtrl::GetItemPosition (long *item*, wxPoint & *pos*) const

Returns the position of the item, in icon or small icon view.

wxPerl Note: In wxPerl this method takes only the *item* parameter and returns a `Wx::Point` (or `undef`).

bool wxListCtrl::GetItemRect (long *item*, wxRect & *rect*, int *code* = wxLIST_RECT_BOUNDS) const

Returns the rectangle representing the item's size and position, in physical coordinates.

code is one of wxLIST_RECT_BOUNDS, wxLIST_RECT_ICON, wxLIST_RECT_LABEL.

wxPerl Note: In wxPerl this method takes only the *item* and *code* parameters and returns a `Wx::Rect` (or `undef`).

wxSize wxListCtrl::GetItemSpacing ( ) const

Retrieves the spacing between icons in pixels: horizontal spacing is returned as `x` component of the wxSize object and the vertical spacing as its `y` component.

int wxListCtrl::GetItemState (long *item*, long *stateMask*) const

Gets the item state.

For a list of state flags, see SetItem(). The *stateMask* indicates which state flags are of interest.

wxString wxListCtrl::GetItemText (long *item*, int *col* = `0`) const

Gets the item text for this item.

Parameters

item	Item (zero-based) index.
col	Item column (zero-based) index. Column 0 is the default. This parameter is new in wxWidgets 2.9.1.

wxColour wxListCtrl::GetItemTextColour (long *item*) const

Returns the colour for this item.

If the item has no specific colour, returns an invalid colour (and not the default foreground control of the control itself as this wouldn't allow distinguishing between items having the same colour as the current control foreground and items with default colour which, hence, have always the same colour as the control).

long wxListCtrl::GetNextItem (long *item*, int *geometry* = wxLIST_NEXT_ALL, int *state* = wxLIST_STATE_DONTCARE) const

Searches for an item with the given geometry or state, starting from *item* but excluding the *item* itself.

If *item* is -1, the first item that matches the specified flags will be returned. Returns the first item with given state following *item* or -1 if no such item found. This function may be used to find all selected items in the control like this:

```
long item = -1;
for ( ;; )
{
    item = listctrl->GetNextItem(item,
                                 wxLIST_NEXT_ALL,
                                 wxLIST_STATE_SELECTED);
    if ( item == -1 )
        break;

    // this item is selected - do whatever is needed with it
    wxLogMessage("Item %ld is selected.", item);
}
```

geometry can be one of:

- wxLIST_NEXT_ABOVE: Searches for an item above the specified item.
- wxLIST_NEXT_ALL: Searches for subsequent item by index.
- wxLIST_NEXT_BELOW: Searches for an item below the specified item.
- wxLIST_NEXT_LEFT: Searches for an item to the left of the specified item.
- wxLIST_NEXT_RIGHT: Searches for an item to the right of the specified item.

Note

this parameter is only supported by wxMSW currently and ignored on other platforms.

state can be a bitlist of the following:

- wxLIST_STATE_DONTCARE: Don't care what the state is.
- wxLIST_STATE_DROPHILITED: The item indicates it is a drop target.
- wxLIST_STATE_FOCUSED: The item has the focus.
- wxLIST_STATE_SELECTED: The item is selected.
- wxLIST_STATE_CUT: The item is selected as part of a cut and paste operation.

int wxListCtrl::GetSelectedItemCount ( ) const

Returns the number of selected items in the list control.

bool wxListCtrl::GetSubItemRect (long *item*, long *subItem*, wxRect & *rect*, int *code* = wxLIST_RECT_BOUNDS) const

Returns the rectangle representing the size and position, in physical coordinates, of the given subitem, i.e.

the part of the row *item* in the column *subItem*.

This method is only meaningful when the wxListCtrl is in the report mode. If *subItem* parameter is equal to the special value `wxLIST_GETSUBITEMRECT_WHOLEITEM` the return value is the same as for GetItemRect().

code can be one of `wxLIST_RECT_BOUNDS`, `wxLIST_RECT_ICON` or `wxLIST_RECT_LABEL`.

Since

2.7.0

wxColour wxListCtrl::GetTextColour ( ) const

Gets the text colour of the list control.

long wxListCtrl::GetTopItem ( ) const

Gets the index of the topmost visible item when in list or report view.

wxRect wxListCtrl::GetViewRect ( ) const

Returns the rectangle taken by all items in the control.

In other words, if the controls client size were equal to the size of this rectangle, no scrollbars would be needed and no free space would be left.

Note that this function only works in the icon and small icon views, not in list or report views (this is a limitation of the native Win32 control).

long wxListCtrl::HitTest (const wxPoint & *point*, int & *flags*, long * *ptrSubItem* = NULL) const

Determines which item (if any) is at the specified point, giving details in *flags*.

Returns index of the item or wxNOT_FOUND if no item is at the specified point.

flags will be a combination of the following flags:

- wxLIST_HITTEST_ABOVE: Above the client area.
- wxLIST_HITTEST_BELOW: Below the client area.
- wxLIST_HITTEST_NOWHERE: In the client area but below the last item.
- wxLIST_HITTEST_ONITEMICON: On the bitmap associated with an item.
- wxLIST_HITTEST_ONITEMLABEL: On the label (string) associated with an item.
- wxLIST_HITTEST_ONITEMRIGHT: In the area to the right of an item.
- wxLIST_HITTEST_ONITEMSTATEICON: On the state icon for a tree view item that is in a user-defined state.
- wxLIST_HITTEST_TOLEFT: To the right of the client area.
- wxLIST_HITTEST_TORIGHT: To the left of the client area.
- wxLIST_HITTEST_ONITEM: Combination of wxLIST_HITTEST_ONITEMICON, wxLIST_HITTEST_ONITEMLABEL, wxLIST_HITTEST_ONITEMSTATEICON.

If *ptrSubItem* is not NULL and the wxListCtrl is in the report mode the subitem (or column) number will also be provided. This feature is only available in version 2.7.0 or higher and is currently only implemented under wxMSW and requires at least comctl32.dll of version 4.70 on the host system or the value stored in *ptrSubItem* will be always -1. To compile this feature into wxWidgets library you need to have access to commctrl.h of version 4.70 that is provided by Microsoft.

wxPerl Note: In wxPerl this method only takes the *point* parameter and returns a 2-element list (item, flags).

bool wxListCtrl::InReportView ( ) const

Returns true if the control is currently using wxLC_REPORT style.

long wxListCtrl::InsertColumn (long *col,* const wxListItem & *info*)

For report view mode (only), inserts a column.

For more details, see SetItem(). Also see InsertColumn(long, const wxString&, int, int) overload for a usually more convenient alternative to this method and the description of how the item width is interpreted by this method.

long wxListCtrl::InsertColumn (long *col,* const wxString & *heading,* int *format* = wxLIST_FORMAT_LEFT, int *width* = wxLIST_AUTOSIZE)

For report view mode (only), inserts a column.

Insert a new column in the list control in report view mode at the given position specifying its most common attributes.

Notice that to set the image for the column you need to use Insert(long, const wxListItem&) overload and specify wxLIST_MASK_IMAGE in the item mask.

Parameters

col	The index where the column should be inserted. Valid indices are from 0 up to GetColumnCount() inclusive and the latter can be used to append the new column after the last existing one.
heading	The string specifying the column heading.
format	The flags specifying the control heading text alignment.
width	If positive, the width of the column in pixels. Otherwise it can be `wxLIST_AUTOSIZE` to choose the default size for the column or `wxLIST_AUTOSIZE_USEHEADER` to fit the column width to *heading* or to extend to fill all the remaining space for the last column. Notice that in case of `wxLIST_AUTOSIZE` fixed width is used as there are no items in this column to use for determining its best size yet. If you want to fit the column to its contents, use SetColumnWidth() after adding the items with values in this column.

Returns

The index of the inserted column or -1 if adding it failed.

long wxListCtrl::InsertItem (wxListItem & *info*)

Inserts an item, returning the index of the new item if successful, -1 otherwise.

Parameters

info	wxListItem object

long wxListCtrl::InsertItem (long *index,* const wxString & *label*)

Insert an string item.

Parameters

index	Index of the new item, supplied by the application
label	String label

wxPerl Note: In wxPerl this method is implemented as InsertStringItem(index, label).

long wxListCtrl::InsertItem (long *index,* int *imageIndex*)

Insert an image item.

Parameters

index	Index of the new item, supplied by the application
imageIndex	Index into the image list associated with this control and view style

wxPerl Note: In wxPerl this method is implemented as InsertImageItem(index, imageIndex).

long wxListCtrl::InsertItem (long *index,* const wxString & *label,* int *imageIndex*)

Insert an image/string item.

Parameters

index	Index of the new item, supplied by the application
label	String label
imageIndex	Index into the image list associated with this control and view style

wxPerl Note: In wxPerl this method is implemented as InsertImageStringItem(index, label, imageIndex).

bool wxListCtrl::IsVirtual ( ) const

Returns true if the control is currently in virtual report view.

virtual wxListItemAttr* wxListCtrl::OnGetItemAttr (long *item*) const [protected], [virtual]

This function may be overridden in the derived class for a control with `wxLC_VIRTUAL` style.

It should return the attribute for the specified `item` or NULL to use the default appearance parameters.

wxListCtrl will not delete the pointer or keep a reference of it. You can return the same wxListItemAttr pointer for every OnGetItemAttr() call.

The base class version always returns NULL.

See also

OnGetItemImage(), OnGetItemColumnImage(), OnGetItemText(), OnGetItemColumnAttr()

virtual wxListItemAttr* wxListCtrl::OnGetItemColumnAttr (long *item,* long *column*) const [protected], [virtual]

This function may be overridden in the derived class for a control with `wxLC_VIRTUAL` style.

It should return the attribute for the for the specified *item* and *column* or NULL to use the default appearance parameters.

The base class version returns `OnGetItemAttr(item)`.

Note

Currently this function is only called under wxMSW, the other ports only support OnGetItemAttr()

See also

OnGetItemAttr(), OnGetItemText(), OnGetItemImage(), OnGetItemColumnImage(),

virtual int wxListCtrl::OnGetItemColumnImage (long *item,* long *column*) const `[protected], [virtual]`

Override this function in the derived class for a control with `wxLC_VIRTUAL` and `wxLC_REPORT` styles in order to specify the image index for the given line and column.

The base class version always calls OnGetItemImage() for the first column, else it returns -1.

See also

OnGetItemText(), OnGetItemImage(), OnGetItemAttr(), OnGetItemColumnAttr()

virtual int wxListCtrl::OnGetItemImage (long *item*) const `[protected], [virtual]`

This function must be overridden in the derived class for a control with `wxLC_VIRTUAL` style having an "image list" (see SetImageList(); if the control doesn't have an image list, it is not necessary to override it).

It should return the index of the items image in the controls image list or -1 for no image.

In a control with `wxLC_REPORT` style, OnGetItemImage() only gets called for the first column of each line.

The base class version always returns -1.

See also

OnGetItemText(), OnGetItemColumnImage(), OnGetItemAttr()

virtual wxString wxListCtrl::OnGetItemText (long *item,* long *column*) const `[protected], [virtual]`

This function **must** be overridden in the derived class for a control with `wxLC_VIRTUAL` style.

It should return the string containing the text of the given *column* for the specified `item`.

See also

SetItemCount(), OnGetItemImage(), OnGetItemColumnImage(), OnGetItemAttr()

void wxListCtrl::RefreshItem (long *item*)

Redraws the given *item*.

This is only useful for the virtual list controls as without calling this function the displayed value of the item doesn't change even when the underlying data does change.

See also

RefreshItems()

void wxListCtrl::RefreshItems (long *itemFrom,* long *itemTo*)

Redraws the items between *itemFrom* and *itemTo*.

The starting item must be less than or equal to the ending one.

Just as RefreshItem() this is only useful for virtual list controls.

bool wxListCtrl::ScrollList (int *dx,* int *dy*)

Scrolls the list control.

If in icon, small icon or report view mode, *dx* specifies the number of pixels to scroll. If in list view mode, *dx* specifies the number of columns to scroll. *dy* always specifies the number of pixels to scroll vertically.

Note

This method is currently only implemented in the Windows version.

void wxListCtrl::SetAlternateRowColour (const wxColour & *colour*)

Set the alternative row background colour to a specific colour.

It is recommended to call EnableAlternateRowColours() instead of using these methods as native implementations of this control might support alternating row colours but not setting the exact colour to be used for them.

As EnableAlternateRowColours(), this method can only be used with controls having wxLC_REPORT and wxLC_VIRTUAL styles.

Parameters

colour	A valid alternative row background colour to enable alternating rows or invalid colour to disable them and use the same colour for all rows.

Since

2.9.5

virtual bool wxListCtrl::SetBackgroundColour (const wxColour & *col*) [virtual]

Sets the background colour.

Note that the wxWindow::GetBackgroundColour() function of wxWindow base class can be used to retrieve the current background colour.

Reimplemented from wxWindow.

bool wxListCtrl::SetColumn (int *col,* wxListItem & *item*)

Sets information about this column.

See SetItem() for more information.

bool wxListCtrl::SetColumnsOrder (const wxArrayInt & *orders*)

Changes the order in which the columns are shown.

By default, the columns of a list control appear on the screen in order of their indices, i.e. the column 0 appears first, the column 1 next and so on. However by using this function it is possible to arbitrarily reorder the columns visual order and the user can also rearrange the columns interactively by dragging them. In this case, the index of the column is not the same as its order and the functions GetColumnOrder() and GetColumnIndexFromOrder() should be used to translate between them. Notice that all the other functions still work with the column indices, i.e. the visual positioning of the columns on screen doesn't affect the code setting or getting their values for example.

The *orders* array must have the same number elements as the number of columns and contain each position exactly once. Its n-th element contains the index of the column to be shown in n-th position, so for a control with three columns passing an array with elements 2, 0 and 1 results in the third column being displayed first, the first one next and the second one last.

Example of using it:

```
wxListCtrl *list = new wxListCtrl(...);
for ( int i = 0; i < 3; i++ )
    list->InsertColumn(i, wxString::Format("Column %d", i));

wxArrayInt order(3);
order[0] = 2;
order[1] = 0;
order[2] = 1;
list->SetColumnsOrder(order);

// now list->GetColumnsOrder() will return order and
// list->GetColumnIndexFromOrder(n) will return order[n] and
// list->GetColumnOrder() will return 1, 2 and 0 for the column 0,
// 1 and 2 respectively
```

Please notice that this function makes sense for report view only and currently is only implemented in wxMSW port. To avoid explicit tests for **wxMSW** in your code, please use `wxHAS_LISTCTRL_COLUMN_ORDER` as this will allow it to start working under the other platforms when support for the column reordering is added there.

See also

GetColumnsOrder()

bool wxListCtrl::SetColumnWidth (int *col,* int *width*)

Sets the column width.

width can be a width in pixels or `wxLIST_AUTOSIZE` (-1) or `wxLIST_AUTOSIZE_USEHEADER` (-2).

`wxLIST_AUTOSIZE` will resize the column to the length of its longest item.

`wxLIST_AUTOSIZE_USEHEADER` will resize the column to the length of the header (Win32) or 80 pixels (other platforms).

In small or normal icon view, *col* must be -1, and the column width is set for all columns.

void wxListCtrl::SetImageList (**wxImageList** * *imageList,* int *which*)

Sets the image list associated with the control.

which is one of `wxIMAGE_LIST_NORMAL`, `wxIMAGE_LIST_SMALL`, `wxIMAGE_LIST_STATE` (the last is unimplemented).

This method does not take ownership of the image list, you have to delete it yourself.

See also

AssignImageList()

bool wxListCtrl::SetItem (**wxListItem** & *info*)

Sets the data of an item.

Using the wxListItem's mask and state mask, you can change only selected attributes of a wxListCtrl item.

long wxListCtrl::SetItem (long *index,* int *column,* const **wxString** & *label,* int *imageId* = -1)

Sets an item string field at a particular column.

void wxListCtrl::SetItemBackgroundColour (long *item,* const wxColour & *col*)

Sets the background colour for this item.

This function only works in report view mode. The colour can be retrieved using GetItemBackgroundColour().

bool wxListCtrl::SetItemColumnImage (long *item,* long *column,* int *image*)

Sets the image associated with the item.

In report view, you can specify the column. The image is an index into the image list associated with the list control.

void wxListCtrl::SetItemCount (long *count*)

This method can only be used with virtual list controls.

It is used to indicate to the control the number of items it contains. After calling it, the main program should be ready to handle calls to various item callbacks (such as wxListCtrl::OnGetItemText) for all items in the range from 0 to *count*.

Notice that the control is not necessarily redrawn after this call as it may be undesirable if an item which is not visible on the screen anyhow was added to or removed from a control displaying many items, if you do need to refresh the display you can just call Refresh() manually.

bool wxListCtrl::SetItemData (long *item,* long *data*)

Associates application-defined data with this item.

Notice that this function cannot be used to associate pointers with the control items, use SetItemPtrData() instead.

void wxListCtrl::SetItemFont (long *item,* const wxFont & *font*)

Sets the item's font.

bool wxListCtrl::SetItemImage (long *item,* int *image,* int *selImage* = `-1`)

Sets the unselected and selected images associated with the item.

The images are indices into the image list associated with the list control.

bool wxListCtrl::SetItemPosition (long *item,* const wxPoint & *pos*)

Sets the position of the item, in icon or small icon view.

Windows only.

bool wxListCtrl::SetItemPtrData (long *item,* wxUIntPtr *data*)

Associates application-defined data with this item.

The *data* parameter may be either an integer or a pointer cast to the `wxUIntPtr` type which is guaranteed to be large enough to be able to contain all integer types and pointers.

Since

2.8.4

bool wxListCtrl::SetItemState (long *item,* long *state,* long *stateMask*)

Sets the item state.

The *stateMask* is a combination of `wxLIST_STATE_XXX` constants described in wxListItem documentation. For each of the bits specified in *stateMask*, the corresponding state is set or cleared depending on whether *state* argument contains the same bit or not.

So to select an item you can use

```
list->SetItemState(item, wxLIST_STATE_SELECTED,
      wxLIST_STATE_SELECTED);
```

while to deselect it you should use

```
list->SetItemState(item, 0, wxLIST_STATE_SELECTED);
```

Consider using wxListView if possible to avoid dealing with this error-prone and confusing method.

void wxListCtrl::SetItemText (long *item,* const wxString & *text*)

Sets the item text for this item.

void wxListCtrl::SetItemTextColour (long *item,* const wxColour & *col*)

Sets the colour for this item.

This function only works in report view. The colour can be retrieved using GetItemTextColour().

void wxListCtrl::SetSingleStyle (long *style,* bool *add* = `true`)

Adds or removes a single window style.

void wxListCtrl::SetTextColour (const wxColour & *col*)

Sets the text colour of the list control.

void wxListCtrl::SetWindowStyleFlag (long *style*) `[virtual]`

Sets the whole window style, deleting all items.

Reimplemented from wxWindow.

bool wxListCtrl::SortItems (wxListCtrlCompare *fnSortCallBack,* wxIntPtr *data*)

Call this function to sort the items in the list control.

Sorting is done using the specified *fnSortCallBack* function. This function must have the following prototype:

```
int wxCALLBACK wxListCompareFunction(wxIntPtr item1, wxIntPtr item2,
      wxIntPtr sortData)
```

It is called each time when the two items must be compared and should return 0 if the items are equal, negative value if the first item is less than the second one and positive value if the first one is greater than the second one (the same convention as used by `qsort(3)`).

The parameter *item1* is the client data associated with the first item (**NOT** the index). The parameter *item2* is the client data associated with the second item (**NOT** the index). The parameter *data* is the value passed to SortItems() itself.

Notice that the control may only be sorted on client data associated with the items, so you must use SetItemData if you want to be able to sort the items in the control.

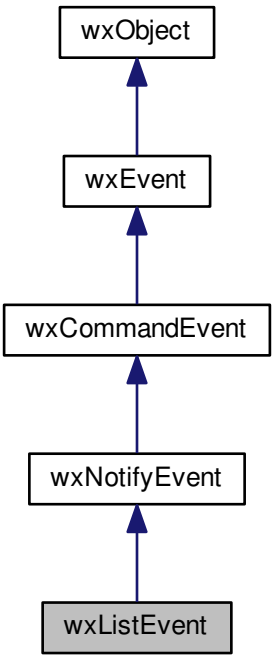
Please see the List Control Sample for an example of using this function.

wxPerl Note: In wxPerl the comparison function must take just two parameters; however, you may use a closure to achieve an effect similar to the SortItems third parameter.

21.425 wxListEvent Class Reference

`#include <wx/listctrl.h>`

Inheritance diagram for wxListEvent:



21.425.1 Detailed Description

A list event holds information about events associated with wxListCtrl objects.

Events using this class

The following event handler macros redirect the events to member function handlers '**func**' with prototypes like: void handlerFuncName(wxListEvent& event)

Event macros:

- EVT_LIST_BEGIN_DRAG(id, func): Begin dragging with the left mouse button.
- EVT_LIST_BEGIN_RDRAG(id, func): Begin dragging with the right mouse button.
- EVT_LIST_BEGIN_LABEL_EDIT(id, func): Begin editing a label. This can be prevented by calling Veto().
- EVT_LIST_END_LABEL_EDIT(id, func): Finish editing a label. This can be prevented by calling Veto().
- EVT_LIST_DELETE_ITEM(id, func): Delete an item.
- EVT_LIST_DELETE_ALL_ITEMS(id, func): Delete all items.
- EVT_LIST_ITEM_SELECTED(id, func): The item has been selected.
- EVT_LIST_ITEM_DESELECTED(id, func): The item has been deselected.
- EVT_LIST_ITEM_ACTIVATED(id, func): The item has been activated (ENTER or double click).
- EVT_LIST_ITEM_FOCUSED(id, func): The currently focused item has changed.
- EVT_LIST_ITEM_MIDDLE_CLICK(id, func): The middle mouse button has been clicked on an item.
- EVT_LIST_ITEM_RIGHT_CLICK(id, func): The right mouse button has been clicked on an item.
- EVT_LIST_KEY_DOWN(id, func): A key has been pressed. GetIndex() may be -1 if no item is selected.
- EVT_LIST_INSERT_ITEM(id, func): An item has been inserted.
- EVT_LIST_COL_CLICK(id, func): A column (m_col) has been left-clicked.
- EVT_LIST_COL_RIGHT_CLICK(id, func): A column (m_col) (which can be -1 if the click occurred outside any column) has been right-clicked.
- EVT_LIST_COL_BEGIN_DRAG(id, func): The user started resizing a column - can be vetoed.
- EVT_LIST_COL_DRAGGING(id, func): The divider between columns is being dragged.
- EVT_LIST_COL_END_DRAG(id, func): A column has been resized by the user.
- EVT_LIST_CACHE_HINT(id, func): Prepare cache for a virtual list control

Library: wxCore

wxListCtrl

Public Member Functions

- wxListEvent (wxEventType commandType=wxEVT_NULL, int id=0)

  Constructor.
- long GetCacheFrom () const

  For `EVT_LIST_CACHE_HINT` event only: return the first item which the list control advises us to cache.
- long GetCacheTo () const

  For `EVT_LIST_CACHE_HINT` event only: return the last item (inclusive) which the list control advises us to cache.
- int GetColumn () const

  The column position: it is only used with `COL` events.
- wxUIntPtr GetData () const

  The data.

- int GetImage () const

  The image.
- long GetIndex () const

  The item index.
- const wxListItem & GetItem () const

  An item object, used by some events.
- int GetKeyCode () const

  Key code if the event is a keypress event.
- const wxString & GetLabel () const

  The (new) item label for `EVT_LIST_END_LABEL_EDIT` event.
- long GetMask () const

  The mask.
- wxPoint GetPoint () const

  The position of the mouse pointer if the event is a drag event.
- const wxString & GetText () const

  The text.
- bool IsEditCancelled () const

  This method only makes sense for `EVT_LIST_END_LABEL_EDIT` message and returns true if it the label editing has been cancelled by the user (GetLabel() returns an empty string in this case but it doesn't allow the application to distinguish between really cancelling the edit and the admittedly rare case when the user wants to rename it to an empty string).

Additional Inherited Members

21.425.2 Constructor & Destructor Documentation

wxListEvent::wxListEvent (wxEventType *commandType* = wxEVT_NULL, int *id* = `0`)

Constructor.

21.425.3 Member Function Documentation

long wxListEvent::GetCacheFrom ( ) const

For `EVT_LIST_CACHE_HINT` event only: return the first item which the list control advises us to cache.

long wxListEvent::GetCacheTo ( ) const

For `EVT_LIST_CACHE_HINT` event only: return the last item (inclusive) which the list control advises us to cache.

int wxListEvent::GetColumn ( ) const

The column position: it is only used with `COL` events.

For the column dragging events, it is the column to the left of the divider being dragged, for the column click events it may be -1 if the user clicked in the list control header outside any column.

wxUIntPtr wxListEvent::GetData ( ) const

The data.

int wxListEvent::GetImage ( ) const

The image.

long wxListEvent::GetIndex ( ) const

The item index.

const wxListItem& wxListEvent::GetItem ( ) const

An item object, used by some events.

See also wxListCtrl::SetItem.

int wxListEvent::GetKeyCode ( ) const

Key code if the event is a keypress event.

const wxString& wxListEvent::GetLabel ( ) const

The (new) item label for `EVT_LIST_END_LABEL_EDIT` event.

long wxListEvent::GetMask ( ) const

The mask.

wxPoint wxListEvent::GetPoint ( ) const

The position of the mouse pointer if the event is a drag event.

const wxString& wxListEvent::GetText ( ) const

The text.

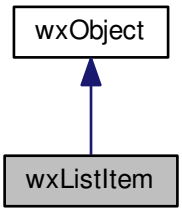
bool wxListEvent::IsEditCancelled ( ) const

This method only makes sense for `EVT_LIST_END_LABEL_EDIT` message and returns true if it the label editing has been cancelled by the user (GetLabel() returns an empty string in this case but it doesn't allow the application to distinguish between really cancelling the edit and the admittedly rare case when the user wants to rename it to an empty string).

21.426 wxListItem Class Reference

```
#include <wx/listctrl.h>
```

Inheritance diagram for wxListItem:



21.426.1 Detailed Description

This class stores information about a wxListCtrl item or column.

wxListItem is a class which contains information about:

- Zero based item position; see SetId() and GetId().
- Zero based column index; see SetColumn() and GetColumn().
- The label (or header for columns); see SetText() and GetText().
- The zero based index into an image list; see GetImage() and SetImage().
- Application defined data; see SetData() and GetData().
- For columns only: the width of the column; see SetWidth() and GetWidth().
- For columns only: the format of the column; one of `wxLIST_FORMAT_LEFT`, `wxLIST_FORMAT_RIGHT`, `wxLIST_FORMAT_CENTRE`. See SetAlign() and GetAlign().
- The state of the item; see SetState() and GetState(). This is a bitlist of the following flags:
  - `wxLIST_STATE_FOCUSED`: The item has the focus.
  - `wxLIST_STATE_SELECTED`: The item is selected.
  - `wxLIST_STATE_DONTCARE`: Don't care what the state is. Win32 only.
  - `wxLIST_STATE_DROPHILITED`: The item is highlighted to receive a drop event. Win32 only.
  - `wxLIST_STATE_CUT`: The item is in the cut state. Win32 only.
- A mask indicating which state flags are valid; this is a bitlist of the flags reported above for the item state. See SetStateMask() and GetStateMask().
- A mask indicating which fields of this class are valid; see SetMask() and GetMask(). This is a bitlist of the following flags:
  - `wxLIST_MASK_STATE`: The state field is valid.
  - `wxLIST_MASK_TEXT`: The label field is valid.
  - `wxLIST_MASK_IMAGE`: The image field is valid.
  - `wxLIST_MASK_DATA`: The application-defined data field is valid.
  - `wxLIST_MASK_WIDTH`: The column width field is valid.
  - `wxLIST_MASK_FORMAT`: The column format field is valid.

The wxListItem object can also contain item-specific colour and font information: for this you need to call one of SetTextColour(), SetBackgroundColour() or SetFont() functions on it passing it the colour/font to use. If the colour/font is not specified, the default list control colour/font is used.

wxListCtrl

Public Member Functions

- wxListItem ()

  Constructor.
- void Clear ()

  Resets the item state to the default.
- wxListColumnFormat GetAlign () const

  Returns the alignment for this item.
- wxColour GetBackgroundColour () const

  Returns the background colour for this item.
- int GetColumn () const

  Returns the zero-based column; meaningful only in report mode.
- wxUIntPtr GetData () const

  Returns client data associated with the control.
- wxFont GetFont () const

  Returns the font used to display the item.
- long GetId () const

  Returns the zero-based item position.
- int GetImage () const

  Returns the zero-based index of the image associated with the item into the image list.
- long GetMask () const

  Returns a bit mask indicating which fields of the structure are valid.
- long GetState () const

  Returns a bit field representing the state of the item.
- const wxString & GetText () const

  Returns the label/header text.
- wxColour GetTextColour () const

  Returns the text colour.
- int GetWidth () const

  Meaningful only for column headers in report mode.
- void SetAlign (wxListColumnFormat align)

  Sets the alignment for the item.
- void SetBackgroundColour (const wxColour &colBack)

  Sets the background colour for the item.
- void SetColumn (int col)

  Sets the zero-based column.
- void SetFont (const wxFont &font)

  Sets the font for the item.
- void SetId (long id)

  Sets the zero-based item position.
- void SetImage (int image)

  Sets the zero-based index of the image associated with the item into the image list.

- void SetMask (long mask)

  Sets the mask of valid fields.
- void SetState (long state)

  Sets the item state flags (note that the valid state flags are influenced by the value of the state mask, see wxListItem::SetStateMask).
- void SetStateMask (long stateMask)

  Sets the bitmask that is used to determine which of the state flags are to be set.
- void SetText (const wxString &text)

  Sets the text label for the item.
- void SetTextColour (const wxColour &colText)

  Sets the text colour for the item.
- void SetWidth (int width)

  Meaningful only for column headers in report mode.

- void SetData (long data)

  Sets client data for the item.
- void SetData (void *data)

  Sets client data for the item.

Additional Inherited Members

21.426.2 Constructor & Destructor Documentation

wxListItem::wxListItem ( )

Constructor.

21.426.3 Member Function Documentation

void wxListItem::Clear ( )

Resets the item state to the default.

wxListColumnFormat wxListItem::GetAlign ( ) const

Returns the alignment for this item.

Can be one of `wxLIST_FORMAT_LEFT`, `wxLIST_FORMAT_RIGHT` or `wxLIST_FORMAT_CENTRE`.

wxColour wxListItem::GetBackgroundColour ( ) const

Returns the background colour for this item.

int wxListItem::GetColumn ( ) const

Returns the zero-based column; meaningful only in report mode.

wxUIntPtr wxListItem::GetData ( ) const

Returns client data associated with the control.

Please note that client data is associated with the item and not with subitems.

wxFont wxListItem::GetFont ( ) const

Returns the font used to display the item.

long wxListItem::GetId ( ) const

Returns the zero-based item position.

int wxListItem::GetImage ( ) const

Returns the zero-based index of the image associated with the item into the image list.

long wxListItem::GetMask ( ) const

Returns a bit mask indicating which fields of the structure are valid.

Can be any combination of the following values:

- wxLIST_MASK_STATE: **GetState** is valid.
- wxLIST_MASK_TEXT: **GetText** is valid.
- wxLIST_MASK_IMAGE: **GetImage** is valid.
- wxLIST_MASK_DATA: **GetData** is valid.
- wxLIST_MASK_WIDTH: **GetWidth** is valid.
- wxLIST_MASK_FORMAT: **GetFormat** is valid.

long wxListItem::GetState ( ) const

Returns a bit field representing the state of the item.

Can be any combination of:

- wxLIST_STATE_DONTCARE: Don't care what the state is. Win32 only.
- wxLIST_STATE_DROPHILITED: The item is highlighted to receive a drop event. Win32 only.
- wxLIST_STATE_FOCUSED: The item has the focus.
- wxLIST_STATE_SELECTED: The item is selected.
- wxLIST_STATE_CUT: The item is in the cut state. Win32 only.

const wxString& wxListItem::GetText ( ) const

Returns the label/header text.

wxColour wxListItem::GetTextColour ( ) const

Returns the text colour.

int wxListItem::GetWidth ( ) const

Meaningful only for column headers in report mode.

Returns the column width.

void wxListItem::SetAlign (wxListColumnFormat *align*)

Sets the alignment for the item.

See also GetAlign()

void wxListItem::SetBackgroundColour (const wxColour & *colBack*)

Sets the background colour for the item.

void wxListItem::SetColumn (int *col*)

Sets the zero-based column.

Meaningful only in report mode.

void wxListItem::SetData (long *data*)

Sets client data for the item.

Please note that client data is associated with the item and not with subitems.

void wxListItem::SetData (void * *data*)

Sets client data for the item.

Please note that client data is associated with the item and not with subitems.

void wxListItem::SetFont (const wxFont & *font*)

Sets the font for the item.

void wxListItem::SetId (long *id*)

Sets the zero-based item position.

void wxListItem::SetImage (int *image*)

Sets the zero-based index of the image associated with the item into the image list.

void wxListItem::SetMask (long *mask*)

Sets the mask of valid fields.

See GetMask().

void wxListItem::SetState (long *state*)

Sets the item state flags (note that the valid state flags are influenced by the value of the state mask, see wxListItem::SetStateMask).

See GetState() for valid flag values.

void wxListItem::SetStateMask (long *stateMask*)

Sets the bitmask that is used to determine which of the state flags are to be set.

See also SetState().

void wxListItem::SetText (const wxString & *text*)

Sets the text label for the item.

void wxListItem::SetTextColour (const wxColour & *colText*)

Sets the text colour for the item.

void wxListItem::SetWidth (int *width*)

Meaningful only for column headers in report mode.

Sets the column width.

21.427 wxListItemAttr Class Reference

```
#include <wx/listctrl.h>
```

21.427.1 Detailed Description

Represents the attributes (color, font, ...) of a wxListCtrl's wxListItem.

Library: wxCore

Category: Data Structures

wxListCtrl Overview, wxListCtrl, wxListItem

Public Member Functions

- wxListItemAttr ()

  Default Constructor.
- wxListItemAttr (const wxColour &colText, const wxColour &colBack, const wxFont &font)

  Construct a wxListItemAttr with the specified foreground and background colors and font.
- const wxColour & GetBackgroundColour () const

  Returns the currently set background color.

- const wxFont & GetFont () const

  Returns the currently set font.
- const wxColour & GetTextColour () const

  Returns the currently set text color.
- bool HasBackgroundColour () const

  Returns true if the currently set background color is valid.
- bool HasFont () const

  Returns true if the currently set font is valid.
- bool HasTextColour () const

  Returns true if the currently set text color is valid.
- void SetBackgroundColour (const wxColour &colour)

  Sets a new background color.
- void SetFont (const wxFont &font)

  Sets a new font.
- void SetTextColour (const wxColour &colour)

  Sets a new text color.

21.427.2 Constructor & Destructor Documentation

wxListItemAttr::wxListItemAttr ( )

Default Constructor.

wxListItemAttr::wxListItemAttr (const wxColour & *colText,* const wxColour & *colBack,* const wxFont & *font*)

Construct a wxListItemAttr with the specified foreground and background colors and font.

21.427.3 Member Function Documentation

const wxColour& wxListItemAttr::GetBackgroundColour ( ) const

Returns the currently set background color.

const wxFont& wxListItemAttr::GetFont ( ) const

Returns the currently set font.

const wxColour& wxListItemAttr::GetTextColour ( ) const

Returns the currently set text color.

bool wxListItemAttr::HasBackgroundColour ( ) const

Returns true if the currently set background color is valid.

bool wxListItemAttr::HasFont ( ) const

Returns true if the currently set font is valid.

bool wxListItemAttr::HasTextColour ( ) const

Returns true if the currently set text color is valid.

void wxListItemAttr::SetBackgroundColour (const wxColour & *colour*)

Sets a new background color.

void wxListItemAttr::SetFont (const wxFont & *font*)

Sets a new font.

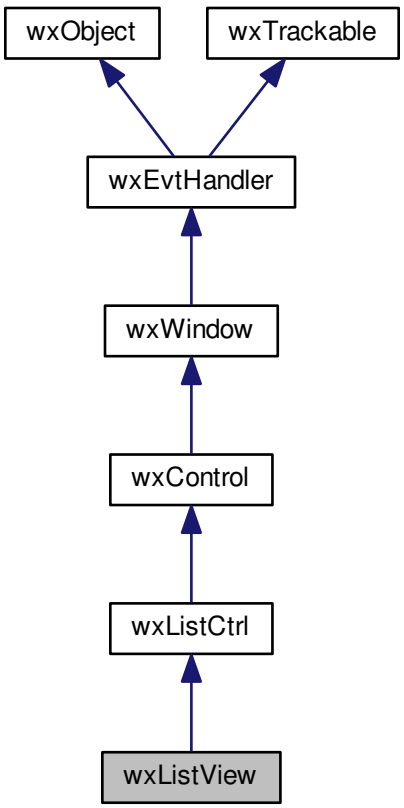
void wxListItemAttr::SetTextColour (const wxColour & *colour*)

Sets a new text color.

21.428 wxListView Class Reference

`#include <wx/listctrl.h>`

Inheritance diagram for wxListView:



21.428.1 Detailed Description

This class currently simply presents a simpler to use interface for the wxListCtrl – it can be thought of as a *façade* for that complicated class.

Using it is preferable to using wxListCtrl directly whenever possible because in the future some ports might implement wxListView but not the full set of wxListCtrl features.

Other than different interface, this class is identical to wxListCtrl. In particular, it uses the same events, same window styles and so on.

Library: wxCore

Category: Controls

wxListView::SetColumnImage

Public Member Functions

- wxListView ()

  Default constructor.
- wxListView (wxWindow *parent, wxWindowID id, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, long style=wxLC_ICON, const wxValidator &validator=wxDefaultValidator, const wxString &name=wxListCtrlNameStr)

  Constructor, creating and showing a listview control.
- virtual ~wxListView ()

  Destructor, destroying the listview control.
- void ClearColumnImage (int col)

  Resets the column image – after calling this function, no image will be shown.
- void Focus (long index)

  Sets focus to the item with the given index.
- long GetFirstSelected () const

  Returns the first selected item in a (presumably) multiple selection control.
- long GetFocusedItem () const

  Returns the currently focused item or -1 if none.
- long GetNextSelected (long item) const

  Used together with GetFirstSelected() to iterate over all selected items in the control.
- bool IsSelected (long index) const

  Returns true if the item with the given index is selected, false otherwise.
- void Select (long n, bool on=true)

  Selects or unselects the given item.
- void SetColumnImage (int col, int image)

  Sets the column image for the specified column.

Additional Inherited Members

21.428.2 Constructor & Destructor Documentation

wxListView::wxListView ( )

Default constructor.

wxListView::wxListView (wxWindow * *parent*, wxWindowID *id*, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, long *style* = wxLC_ICON, const wxValidator & *validator* = wxDefaultValidator, const wxString & *name* = `wxListCtrlNameStr`)

Constructor, creating and showing a listview control.

Parameters

parent	Parent window. Must not be NULL.
id	Window identifier. The value wxID_ANY indicates a default value.
pos	Window position. If wxDefaultPosition is specified then a default position is chosen.
size	Window size. If wxDefaultSize is specified then the window is sized appropriately.
style	Window style. See wxListCtrl.
validator	Window validator.
name	Window name.

See also

Create(), wxValidator

virtual wxListView::~wxListView ( ) [virtual]

Destructor, destroying the listview control.

21.428.3 Member Function Documentation

void wxListView::ClearColumnImage (int *col*)

Resets the column image – after calling this function, no image will be shown.

Parameters

col	the column to clear image for

See also

SetColumnImage()

void wxListView::Focus (long *index*)

Sets focus to the item with the given *index*.

long wxListView::GetFirstSelected ( ) const

Returns the first selected item in a (presumably) multiple selection control.

Together with GetNextSelected() it can be used to iterate over all selected items in the control.

Returns

The first selected item, if any, -1 otherwise.

long wxListView::GetFocusedItem ( ) const

Returns the currently focused item or -1 if none.

See also

IsSelected(), Focus()

long wxListView::GetNextSelected (long *item*) const

Used together with GetFirstSelected() to iterate over all selected items in the control.

Returns

Returns the next selected item or -1 if there are no more of them.

bool wxListView::IsSelected (long *index*) const

Returns true if the item with the given *index* is selected, false otherwise.

See also

GetFirstSelected(), GetNextSelected()

void wxListView::Select (long *n*, bool *on* = `true`)

Selects or unselects the given item.

Parameters

n	the item to select or unselect
on	if true (default), selects the item, otherwise unselects it

See also

wxListCtrl::SetItemState

void wxListView::SetColumnImage (int *col*, int *image*)

Sets the column image for the specified column.

To use the column images, the control must have a valid image list with at least one image.

Parameters

col	the column to set image for
image	the index of the column image in the controls image list

21.429 wxLocale Class Reference

`#include <wx/intl.h>`

21.429.1 Detailed Description

wxLocale class encapsulates all language-dependent settings and is a generalization of the C locale concept.

In wxWidgets this class manages current locale. It also initializes and activates wxTranslations object that manages message catalogs.

For a list of the supported languages, please see wxLanguage enum values. These constants may be used to specify the language in wxLocale::Init and are returned by wxLocale::GetSystemLanguage.

wxPerl Note: In wxPerl you can't use the '_' function name, so the `Wx::Locale` module can export the `gettext` and `gettext_noop` under any given name.

```
# this imports gettext ( equivalent to Wx::GetTranslation
# and gettext_noop ( a noop )
# into your module
use Wx::Locale qw(:default);

# ....

# use the functions
print gettext( "Panic!" );

button = Wx::Button-new( window, -1, gettext( "Label" ) );
```

If you need to translate a lot of strings, then adding gettext( ) around each one is a long task (that is why _( ) was introduced), so just choose a shorter name for gettext:

```
use Wx::Locale 'gettext' = 't',
               'gettext_noop' = 'gettext_noop';

# ...

# use the functions
print t( "Panic!!" );

# ...
```

Internationalization, Internationalization Sample, wxXLocale, wxTranslations

Public Member Functions

- wxLocale ()

  This is the default constructor and it does nothing to initialize the object: Init() must be used to do that.
- wxLocale (int language, int flags=wxLOCALE_LOAD_DEFAULT)

  See Init() for parameters description.
- wxLocale (const wxString &name, const wxString &shortName=wxEmptyString, const wxString &locale=wxEmptyString, bool bLoadDefault=true)

  See Init() for parameters description.
- virtual ~wxLocale ()

  The destructor, like the constructor, also has global side effects: the previously set locale is restored and so the changes described in Init() documentation are rolled back.
- bool AddCatalog (const wxString &domain)

  Calls wxTranslations::AddCatalog(const wxString&).
- bool AddCatalog (const wxString &domain, wxLanguage msgIdLanguage)

  Calls wxTranslations::AddCatalog(const wxString&, wxLanguage).
- bool AddCatalog (const wxString &domain, wxLanguage msgIdLanguage, const wxString &msgIdCharset)

  Calls wxTranslations::AddCatalog(const wxString&, wxLanguage, const wxString&).
- wxString GetCanonicalName () const

  Returns the canonical form of current locale name.
- wxString GetHeaderValue (const wxString &header, const wxString &domain=wxEmptyString) const

  Calls wxTranslations::GetHeaderValue().
- int GetLanguage () const

  Returns the wxLanguage constant of current language.
- const wxString & GetLocale () const

Returns the locale name as passed to the constructor or Init().

- const wxString & GetName () const

  Returns the current short name for the locale (as given to the constructor or the Init() function).

- virtual const wxString & GetString (const wxString &origString, const wxString &domain=wxEmptyString) const

  Calls wxGetTranslation(const wxString&, const wxString&).

- virtual const wxString & GetString (const wxString &origString, const wxString &origString2, unsigned n, const wxString &domain=wxEmptyString) const

  Calls wxGetTranslation(const wxString&, const wxString&, unsigned, const wxString&).

- wxString GetSysName () const

  Returns current platform-specific locale name as passed to setlocale().

- bool Init (int language=wxLANGUAGE_DEFAULT, int flags=wxLOCALE_LOAD_DEFAULT)

  Initializes the wxLocale instance.

- bool Init (const wxString &name, const wxString &shortName=wxEmptyString, const wxString &locale=wxEmptyString, bool bLoadDefault=true)

- bool IsLoaded (const wxString &domain) const

  Calls wxTranslations::IsLoaded().

- bool IsOk () const

  Returns true if the locale could be set successfully.

Static Public Member Functions

- static void AddCatalogLookupPathPrefix (const wxString &prefix)

  Calls wxFileTranslationsLoader::AddCatalogLookupPathPrefix().

- static void AddLanguage (const wxLanguageInfo &info)

  Adds custom, user-defined language to the database of known languages.

- static const wxLanguageInfo * FindLanguageInfo (const wxString &locale)

  This function may be used to find the language description structure for the given locale, specified either as a two letter ISO language code (for example, "pt"), a language code followed by the country code ("pt_BR") or a full, human readable, language description ("Portuguese-Brazil").

- static const wxLanguageInfo * GetLanguageInfo (int lang)

  Returns a pointer to wxLanguageInfo structure containing information about the given language or NULL if this language is unknown.

- static wxString GetLanguageName (int lang)

  Returns English name of the given language or empty string if this language is unknown.

- static wxString GetLanguageCanonicalName (int lang)

  Returns canonical name (see GetCanonicalName()) of the given language or empty string if this language is unknown.

- static wxFontEncoding GetSystemEncoding ()

  Tries to detect the user's default font encoding.

- static wxString GetSystemEncodingName ()

  Tries to detect the name of the user's default font encoding.

- static int GetSystemLanguage ()

  Tries to detect the user's default locale setting.

- static wxString GetInfo (wxLocaleInfo index, wxLocaleCategory cat=wxLOCALE_CAT_DEFAULT)

  Get the values of the given locale-dependent datum.

- static wxString GetOSInfo (wxLocaleInfo index, wxLocaleCategory cat=wxLOCALE_CAT_DEFAULT)

  Get the values of a locale datum in the OS locale.

- static bool IsAvailable (int lang)

  Check whether the operating system and/or C run time environment supports this locale.

21.429.2 Constructor & Destructor Documentation

wxLocale::wxLocale ( )

This is the default constructor and it does nothing to initialize the object: Init() must be used to do that.

wxLocale::wxLocale (int *language*, int *flags* = `wxLOCALE_LOAD_DEFAULT`)

See Init() for parameters description.

wxLocale::wxLocale (const wxString & *name*, const wxString & *shortName* = wxEmptyString, const wxString & *locale* = wxEmptyString, bool *bLoadDefault* = `true`)

See Init() for parameters description.

The call of this function has several global side effects which you should understand: first of all, the application locale is changed - note that this will affect many of standard C library functions such as printf() or strftime(). Second, this wxLocale object becomes the new current global locale for the application and so all subsequent calls to wxGetTranslation() will try to translate the messages using the message catalogs for this locale.

virtual wxLocale::~wxLocale ( ) `[virtual]`

The destructor, like the constructor, also has global side effects: the previously set locale is restored and so the changes described in Init() documentation are rolled back.

21.429.3 Member Function Documentation

bool wxLocale::AddCatalog (const wxString & *domain*)

Calls wxTranslations::AddCatalog(const wxString&).

bool wxLocale::AddCatalog (const wxString & *domain*, wxLanguage *msgIdLanguage*)

Calls wxTranslations::AddCatalog(const wxString&, wxLanguage).

bool wxLocale::AddCatalog (const wxString & *domain*, wxLanguage *msgIdLanguage*, const wxString & *msgIdCharset*)

Calls wxTranslations::AddCatalog(const wxString&, wxLanguage, const wxString&).

static void wxLocale::AddCatalogLookupPathPrefix (const wxString & *prefix*) `[static]`

Calls wxFileTranslationsLoader::AddCatalogLookupPathPrefix().

static void wxLocale::AddLanguage (const wxLanguageInfo & *info*) `[static]`

Adds custom, user-defined language to the database of known languages.

This database is used in conjunction with the first form of Init().

static const wxLanguageInfo* wxLocale::FindLanguageInfo (const wxString & *locale*) [static]

This function may be used to find the language description structure for the given locale, specified either as a two letter ISO language code (for example, "pt"), a language code followed by the country code ("pt_BR") or a full, human readable, language description ("Portuguese-Brazil").

Returns the information for the given language or NULL if this language is unknown. Note that even if the returned pointer is valid, the caller should *not* delete it.

See also

GetLanguageInfo()

wxString wxLocale::GetCanonicalName ( ) const

Returns the canonical form of current locale name.

Canonical form is the one that is used on UNIX systems: it is a two- or five-letter string in xx or xx_YY format, where xx is ISO 639 code of language and YY is ISO 3166 code of the country. Examples are "en", "en_GB", "en_US" or "fr_FR". This form is internally used when looking up message catalogs. Compare GetSysName().

wxString wxLocale::GetHeaderValue (const wxString & *header,* const wxString & *domain* = wxEmptyString) const

Calls wxTranslations::GetHeaderValue().

static wxString wxLocale::GetInfo (wxLocaleInfo *index,* wxLocaleCategory *cat* = wxLOCALE_CAT_DEFAULT) [static]

Get the values of the given locale-dependent datum.

This function returns the value of the locale-specific option specified by the given *index*.

Parameters

index	One of the elements of wxLocaleInfo enum.
cat	The category to use with the given index or wxLOCALE_CAT_DEFAULT if the index can only apply to a single category.

Returns

The option value or empty string if the function failed.

int wxLocale::GetLanguage ( ) const

Returns the wxLanguage constant of current language.

Note that you can call this function only if you used the form of Init() that takes wxLanguage argument.

static wxString wxLocale::GetLanguageCanonicalName (int *lang*) [static]

Returns canonical name (see GetCanonicalName()) of the given language or empty string if this language is unknown.

See GetLanguageInfo() for a remark about special meaning of `wxLANGUAGE_DEFAULT`.

Since

2.9.1

static const wxLanguageInfo* wxLocale::GetLanguageInfo (int *lang*) `[static]`

Returns a pointer to wxLanguageInfo structure containing information about the given language or NULL if this language is unknown.

Note that even if the returned pointer is valid, the caller should *not* delete it.

See AddLanguage() for the wxLanguageInfo description. As with Init(), `wxLANGUAGE_DEFAULT` has the special meaning if passed as an argument to this function and in this case the result of GetSystemLanguage() is used.

static wxString wxLocale::GetLanguageName (int *lang*) `[static]`

Returns English name of the given language or empty string if this language is unknown.

See GetLanguageInfo() for a remark about special meaning of `wxLANGUAGE_DEFAULT`.

const wxString& wxLocale::GetLocale ( ) const

Returns the locale name as passed to the constructor or Init().

This is a full, human-readable name, e.g. "English" or "French".

const wxString& wxLocale::GetName ( ) const

Returns the current short name for the locale (as given to the constructor or the Init() function).

static wxString wxLocale::GetOSInfo (wxLocaleInfo *index*, wxLocaleCategory *cat* = wxLOCALE_CAT_DEFAULT) `[static]`

Get the values of a locale datum in the OS locale.

This function is similar to GetInfo() and, in fact, identical to it under non-MSW systems. Under MSW it differs from it when no locale had been explicitly set: GetInfo() returns the values corresponding to the "C" locale used by the standard library functions, while this method returns the values used by the OS which, in Windows case, correspond to the user settings in the control panel.

Since

3.1.0

virtual const wxString& wxLocale::GetString (const wxString & *origString*, const wxString & *domain* = wxEmptyString) const `[virtual]`

Calls wxGetTranslation(const wxString&, const wxString&).

virtual const wxString& wxLocale::GetString (const wxString & *origString*, const wxString & *origString2*, unsigned *n*, const wxString & *domain* = wxEmptyString) const `[virtual]`

Calls wxGetTranslation(const wxString&, const wxString&, unsigned, const wxString&).

wxString wxLocale::GetSysName ( ) const

Returns current platform-specific locale name as passed to setlocale().

Compare GetCanonicalName().

static wxFontEncoding wxLocale::GetSystemEncoding ( ) [static]

Tries to detect the user's default font encoding.

Returns wxFontEncoding() value or `wxFONTENCODING_SYSTEM` if it couldn't be determined.

static wxString wxLocale::GetSystemEncodingName ( ) [static]

Tries to detect the name of the user's default font encoding.

This string isn't particularly useful for the application as its form is platform-dependent and so you should probably use GetSystemEncoding() instead.

Returns a user-readable string value or an empty string if it couldn't be determined.

static int wxLocale::GetSystemLanguage ( ) [static]

Tries to detect the user's default locale setting.

Returns the wxLanguage value or `wxLANGUAGE_UNKNOWN` if the language-guessing algorithm failed.

Note

This function works with *locales* and returns the user's default locale. This may be, and usually is, the same as their preferred UI language, but it's not the same thing. Use wxTranslation to obtain *language* information.

See also

wxTranslations::GetBestTranslation().

bool wxLocale::Init (int *language* = wxLANGUAGE_DEFAULT, int *flags* = `wxLOCALE_LOAD_DEFAULT`)

Initializes the wxLocale instance.

The call of this function has several global side effects which you should understand: first of all, the application locale is changed - note that this will affect many of standard C library functions such as printf() or strftime(). Second, this wxLocale object becomes the new current global locale for the application and so all subsequent calls to wxGetTranslation() will try to translate the messages using the message catalogs for this locale.

Parameters

language	wxLanguage identifier of the locale. `wxLANGUAGE_DEFAULT` has special meaning – wxLocale will use system's default language (see GetSystemLanguage()).
flags	Combination of the following: • wxLOCALE_LOAD_DEFAULT: Load the message catalog for the given locale containing the translations of standard wxWidgets messages automatically. • wxLOCALE_DONT_LOAD_DEFAULT: Negation of wxLOCALE_LOAD_DEFAULT.

Returns

true on success or false if the given locale couldn't be set.

bool wxLocale::Init (const wxString & *name*, const wxString & *shortName* = wxEmptyString, const wxString & *locale* = wxEmptyString, bool *bLoadDefault* = `true`)

Deprecated This form is deprecated, use the other one unless you know what you are doing.

Parameters

name	The name of the locale. Only used in diagnostic messages.
shortName	The standard 2 letter locale abbreviation; it is used as the directory prefix when looking for the message catalog files.
locale	The parameter for the call to setlocale(). Note that it is platform-specific.
bLoadDefault	May be set to false to prevent loading of the message catalog for the given locale containing the translations of standard wxWidgets messages. This parameter would be rarely used in normal circumstances.

static bool wxLocale::IsAvailable (int *lang*) `[static]`

Check whether the operating system and/or C run time environment supports this locale.

For example in Windows 2000 and Windows XP, support for many locales is not installed by default. Returns true if the locale is supported.

The argument *lang* is the wxLanguage identifier. To obtain this for a given a two letter ISO language code, use FindLanguageInfo() to obtain its wxLanguageInfo structure. See AddLanguage() for the wxLanguageInfo description.

Since

2.7.1.

bool wxLocale::IsLoaded (const wxString & *domain*) const

Calls wxTranslations::IsLoaded().

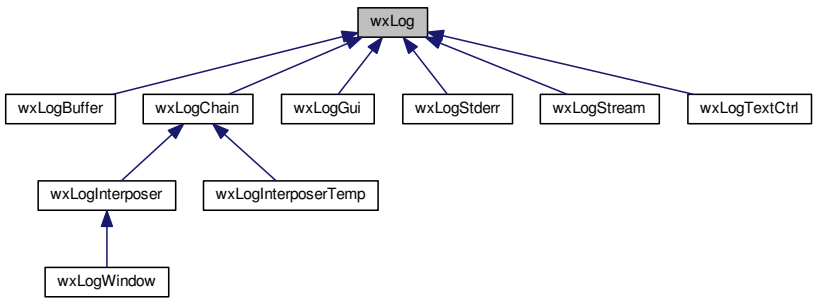
bool wxLocale::IsOk ( ) const

Returns true if the locale could be set successfully.

21.430 wxLog Class Reference

`#include <wx/log.h>`

Inheritance diagram for wxLog:



21.430.1 Detailed Description

wxLog class defines the interface for the *log targets* used by wxWidgets logging functions as explained in the Logging Overview.

The only situations when you need to directly use this class is when you want to derive your own log target because the existing ones don't satisfy your needs.

Otherwise, it is completely hidden behind the wxLogXXX() functions and you may not even know about its existence.

Note

For console-mode applications, the default target is wxLogStderr, so that all *wxLogXXX()* functions print on `stderr` when `wxUSE_GUI` = 0.

Library: wxBase

Category: Logging

See also

Logging Overview, wxLogXXX() functions

Public Member Functions

- wxLogFormatter * SetFormatter (wxLogFormatter *formatter)

  Sets the specified formatter as the active one.
- virtual void Flush ()

  Show all pending output and clear the buffer.
- void LogRecord (wxLogLevel level, const wxString &msg, const wxLogRecordInfo &info)

  Log the given record.

Static Public Member Functions

Trace mask functions

- static void AddTraceMask (const wxString &mask)

  Add the mask to the list of allowed masks for wxLogTrace().
- static void ClearTraceMasks ()

  Removes all trace masks previously set with AddTraceMask().
- static const wxArrayString & GetTraceMasks ()

  Returns the currently allowed list of string trace masks.
- static bool IsAllowedTraceMask (const wxString &mask)

  Returns true if the mask is one of allowed masks for wxLogTrace().
- static void RemoveTraceMask (const wxString &mask)

  Remove the mask from the list of allowed masks for wxLogTrace().

Log target functions

- static void DontCreateOnDemand ()

  Instructs wxLog to not create new log targets on the fly if there is none currently (see GetActiveTarget()).
- static wxLog * GetActiveTarget ()

  Returns the pointer to the active log target (may be NULL).
- static wxLog * SetActiveTarget (wxLog *logtarget)

  Sets the specified log target as the active one.
- static wxLog * SetThreadActiveTarget (wxLog *logger)

Sets a thread-specific log target.

- static void FlushActive ()

  Flushes the current log target if any, does nothing if there is none.
- static void Resume ()

  Resumes logging previously suspended by a call to Suspend().
- static void Suspend ()

  Suspends the logging until Resume() is called.

Log level functions

- static wxLogLevel GetLogLevel ()

  Returns the current log level limit.
- static bool IsLevelEnabled (wxLogLevel level, wxString component)

  Returns true if logging at this level is enabled for the current thread.
- static void SetComponentLevel (const wxString &component, wxLogLevel level)

  Sets the log level for the given component.
- static void SetLogLevel (wxLogLevel logLevel)

  Specifies that log messages with level greater (numerically) than logLevel should be ignored and not sent to the active log target.

Enable/disable features functions

- static bool EnableLogging (bool enable=true)

  Globally enable or disable logging.
- static bool IsEnabled ()

  Returns true if logging is enabled at all now.
- static bool GetRepetitionCounting ()

  Returns whether the repetition counting mode is enabled.
- static void SetRepetitionCounting (bool repetCounting=true)

  Enables logging mode in which a log message is logged once, and in case exactly the same message successively repeats one or more times, only the number of repetitions is logged.
- static const wxString & GetTimestamp ()

  Returns the current timestamp format string.
- static void SetTimestamp (const wxString &format)

  Sets the timestamp format prepended by the default log targets to all messages.
- static void DisableTimestamp ()

  Disables time stamping of the log messages.
- static bool GetVerbose ()

  Returns whether the verbose mode is currently active.
- static void SetVerbose (bool verbose=true)

  Activates or deactivates verbose mode in which the verbose messages are logged as the normal ones instead of being silently dropped.

Protected Member Functions

Logging callbacks.

The functions which should be overridden by custom log targets.

When defining a new log target, you have a choice between overriding DoLogRecord(), which provides maximal flexibility, DoLogTextAtLevel() which can be used if you don't intend to change the default log messages formatting but want to handle log messages of different levels differently or, in the simplest case, DoLogText().

- virtual void DoLogRecord (wxLogLevel level, const wxString &msg, const wxLogRecordInfo &info)

  Called to log a new record.
- virtual void DoLogTextAtLevel (wxLogLevel level, const wxString &msg)

  Called to log the specified string at given level.
- virtual void DoLogText (const wxString &msg)

  Called to log the specified string.

21.430.2 Member Function Documentation

static void wxLog::AddTraceMask (const wxString & *mask*) `[static]`

Add the *mask* to the list of allowed masks for wxLogTrace().

See also

RemoveTraceMask(), GetTraceMasks()

static void wxLog::ClearTraceMasks ( ) `[static]`

Removes all trace masks previously set with AddTraceMask().

See also

RemoveTraceMask()

static void wxLog::DisableTimestamp ( ) `[static]`

Disables time stamping of the log messages.

Notice that the current time stamp is only used by the default log formatter and custom formatters may ignore calls to this function.

Since

2.9.0

virtual void wxLog::DoLogRecord (wxLogLevel *level*, const wxString & *msg*, const wxLogRecordInfo & *info*) `[protected]`, `[virtual]`

Called to log a new record.

Any log message created by wxLogXXX() functions is passed to this method of the active log target. The default implementation prepends the timestamp and, for some log levels (e.g. error and warning), the corresponding prefix to *msg* and passes it to DoLogTextAtLevel().

You may override this method to implement custom formatting of the log messages or to implement custom filtering of log messages (e.g. you could discard all log messages coming from the given source file).

virtual void wxLog::DoLogText (const wxString & *msg*) `[protected]`, `[virtual]`

Called to log the specified string.

A simple implementation might just send the string to `stdout` or `stderr` or save it in a file (of course, the already existing wxLogStderr can be used for this).

The base class version of this function asserts so it must be overridden if you don't override DoLogRecord() or DoLogTextAtLevel().

virtual void wxLog::DoLogTextAtLevel (wxLogLevel *level*, const wxString & *msg*) `[protected]`, `[virtual]`

Called to log the specified string at given level.

The base class versions logs debug and trace messages on the system default debug output channel and passes all the other messages to DoLogText().

static void wxLog::DontCreateOnDemand ( ) [static]

Instructs wxLog to not create new log targets on the fly if there is none currently (see GetActiveTarget()).

(Almost) for internal use only: it is supposed to be called by the application shutdown code (where you don't want the log target to be automatically created anymore).

Note that this function also calls ClearTraceMasks().

static bool wxLog::EnableLogging (bool *enable* = true) [static]

Globally enable or disable logging.

Calling this function with false argument disables all log messages for the current thread.

See also

wxLogNull, IsEnabled()

Returns

The old state, i.e. true if logging was previously enabled and false if it was disabled.

virtual void wxLog::Flush ( ) [virtual]

Show all pending output and clear the buffer.

Some of wxLog implementations, most notably the standard wxLogGui class, buffer the messages (for example, to avoid showing the user a zillion of modal message boxes one after another – which would be really annoying). This function shows them all and clears the buffer contents. If the buffer is already empty, nothing happens.

If you override this method in a derived class, call the base class version first, before doing anything else.

Reimplemented in wxLogGui, and wxLogBuffer.

static void wxLog::FlushActive ( ) [static]

Flushes the current log target if any, does nothing if there is none.

When this method is called from the main thread context, it also flushes any previously buffered messages logged by the other threads. When it is called from the other threads it simply calls Flush() on the currently active log target, so it mostly makes sense to do this if a thread has its own logger set with SetThreadActiveTarget().

static wxLog* wxLog::GetActiveTarget ( ) [static]

Returns the pointer to the active log target (may be NULL).

Notice that if SetActiveTarget() hadn't been previously explicitly called, this function will by default try to create a log target by calling wxAppTraits::CreateLogTarget() which may be overridden in a user-defined traits class to change the default behaviour. You may also call DontCreateOnDemand() to disable this behaviour.

When this function is called from threads other than main one, auto-creation doesn't happen. But if the thread has a thread-specific log target previously set by SetThreadActiveTarget(), it is returned instead of the global one. Otherwise, the global log target is returned.

static wxLogLevel wxLog::GetLogLevel ( ) [static]

Returns the current log level limit.

All messages at levels strictly greater than the value returned by this function are not logged at all.

See also

SetLogLevel(), IsLevelEnabled()

static bool wxLog::GetRepetitionCounting ( ) [static]

Returns whether the repetition counting mode is enabled.

static const wxString& wxLog::GetTimestamp ( ) [static]

Returns the current timestamp format string.

Notice that the current time stamp is only used by the default log formatter and custom formatters may ignore this format.

static const wxArrayString& wxLog::GetTraceMasks ( ) [static]

Returns the currently allowed list of string trace masks.

See also

AddTraceMask().

static bool wxLog::GetVerbose ( ) [static]

Returns whether the verbose mode is currently active.

static bool wxLog::IsAllowedTraceMask (const wxString & *mask*) [static]

Returns true if the *mask* is one of allowed masks for wxLogTrace().

See also: AddTraceMask(), RemoveTraceMask()

static bool wxLog::IsEnabled ( ) [static]

Returns true if logging is enabled at all now.

See also

IsLevelEnabled(), EnableLogging()

static bool wxLog::IsLevelEnabled (wxLogLevel *level,* wxString *component*) [static]

Returns true if logging at this level is enabled for the current thread.

This function only returns true if logging is globally enabled and if *level* is less than or equal to the maximal log level enabled for the given *component*.

See also

IsEnabled(), SetLogLevel(), GetLogLevel(), SetComponentLevel()

Since

2.9.1

void wxLog::LogRecord (wxLogLevel *level,* const wxString & *msg,* const wxLogRecordInfo & *info*)

Log the given record.

This function should only be called from the DoLog() implementations in the derived classes if they need to call DoLogRecord() on another log object (they can, of course, just use wxLog::DoLogRecord() call syntax to call it on the object itself). It should not be used for logging new messages which can be only sent to the currently active logger using OnLog() which also checks if the logging (for this level) is enabled while this method just directly calls DoLog().

Example of use of this class from wxLogChain:

```
void wxLogChain::DoLogRecord(wxLogLevel level,
                             const wxString& msg,
                             const wxLogRecordInfo& info)
{
    // let the previous logger show it
    if ( m_logOld && IsPassingMessages() )
        m_logOld->LogRecord(level, msg, info);

    // and also send it to the new one
    if ( m_logNew && m_logNew != this )
        m_logNew->LogRecord(level, msg, info);
}
```

Since

2.9.1

static void wxLog::RemoveTraceMask (const wxString & *mask*) `[static]`

Remove the *mask* from the list of allowed masks for wxLogTrace().

See also

AddTraceMask()

static void wxLog::Resume ( ) `[static]`

Resumes logging previously suspended by a call to Suspend().

All messages logged in the meanwhile will be flushed soon.

static wxLog* wxLog::SetActiveTarget (wxLog * *logtarget*) `[static]`

Sets the specified log target as the active one.

Returns the pointer to the previous active log target (may be NULL). To suppress logging use a new instance of wxLogNull not NULL. If the active log target is set to NULL a new default log target will be created when logging occurs.

See also

SetThreadActiveTarget()

static void wxLog::SetComponentLevel (const wxString & *component,* wxLogLevel *level*) `[static]`

Sets the log level for the given component.

For example, to disable all but error messages from wxWidgets network classes you may use

```
wxLog::SetComponentLevel("wx/net", wxLOG_Error);
```

SetLogLevel() may be used to set the global log level.

Parameters

component	Non-empty component name, possibly using slashes (`/`) to separate it into several parts.
level	Maximal level of log messages from this component which will be handled instead of being simply discarded.

Since

2.9.1

wxLogFormatter* wxLog::SetFormatter (wxLogFormatter * *formatter*)

Sets the specified formatter as the active one.

Parameters

formatter	The new formatter. If NULL, reset to the default formatter.

Returns the pointer to the previous formatter. You must delete it if you don't plan to attach it again to a wxLog object later.

Since

2.9.4

static void wxLog::SetLogLevel (wxLogLevel *logLevel*) [static]

Specifies that log messages with level greater (numerically) than *logLevel* should be ignored and not sent to the active log target.

See also

SetComponentLevel()

static void wxLog::SetRepetitionCounting (bool *repetCounting* = `true`) [static]

Enables logging mode in which a log message is logged once, and in case exactly the same message successively repeats one or more times, only the number of repetitions is logged.

static wxLog* wxLog::SetThreadActiveTarget (wxLog * *logger*) [static]

Sets a thread-specific log target.

The log target passed to this function will be used for all messages logged by the current thread using the usual wxLog functions. This shouldn't be called from the main thread which never uses a thread- specific log target but can be used for the other threads to handle thread logging completely separately; instead of buffering thread log messages in the main thread logger.

Notice that unlike for SetActiveTarget(), wxWidgets does not destroy the thread-specific log targets when the thread terminates so doing this is your responsibility.

This method is only available if `wxUSE_THREADS` is 1, i.e. wxWidgets was compiled with threads support.

Parameters

logger	The new thread-specific log target, possibly NULL.

Returns

The previous thread-specific log target, initially NULL.

Since

2.9.1

static void wxLog::SetTimestamp (const wxString & *format*) `[static]`

Sets the timestamp format prepended by the default log targets to all messages.

The string may contain any normal characters as well as % prefixed format specifiers, see *strftime()* manual for details. Passing an empty string to this function disables message time stamping.

Notice that the current time stamp is only used by the default log formatter and custom formatters may ignore this format. You can also define a custom wxLogFormatter to customize the time stamp handling beyond changing its format.

static void wxLog::SetVerbose (bool *verbose* = `true`) `[static]`

Activates or deactivates verbose mode in which the verbose messages are logged as the normal ones instead of being silently dropped.

The verbose messages are the trace messages which are not disabled in the release mode and are generated by wxLogVerbose().

See also

Logging Overview

static void wxLog::Suspend ( ) `[static]`

Suspends the logging until Resume() is called.

Note that the latter must be called the same number of times as the former to undo it, i.e. if you call Suspend() twice you must call Resume() twice as well.

Note that suspending the logging means that the log sink won't be flushed periodically, it doesn't have any effect if the current log target does the logging immediately without waiting for Flush() to be called (the standard GUI log target only shows the log dialog when it is flushed, so Suspend() works as expected with it).

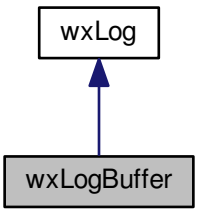
See also

Resume(), wxLogNull

21.431 wxLogBuffer Class Reference

`#include <wx/log.h>`

Inheritance diagram for wxLogBuffer:



21.431.1 Detailed Description

wxLogBuffer is a very simple implementation of log sink which simply collects all the logged messages in a string (except the debug messages which are output in the usual way immediately as we're presumably not interested in collecting them for later).

The messages from different log function calls are separated by the new lines.

All the messages collected so far can be shown to the user (and the current buffer cleared) by calling the overloaded wxLogBuffer::Flush method.

Library: wxBase

Category: Logging

Public Member Functions

- wxLogBuffer ()

  The default ctor does nothing.

- virtual void Flush ()

  Shows all the messages collected so far to the user (using a message box in the GUI applications or by printing them out to the console in text mode) and clears the internal buffer.

- const wxString & GetBuffer () const

  Returns the current buffer contains.

Additional Inherited Members

21.431.2 Constructor & Destructor Documentation

wxLogBuffer::wxLogBuffer ( )

The default ctor does nothing.

21.431.3 Member Function Documentation

virtual void wxLogBuffer::Flush ( ) [virtual]

Shows all the messages collected so far to the user (using a message box in the GUI applications or by printing them out to the console in text mode) and clears the internal buffer.

Reimplemented from wxLog.

const wxString& wxLogBuffer::GetBuffer ( ) const

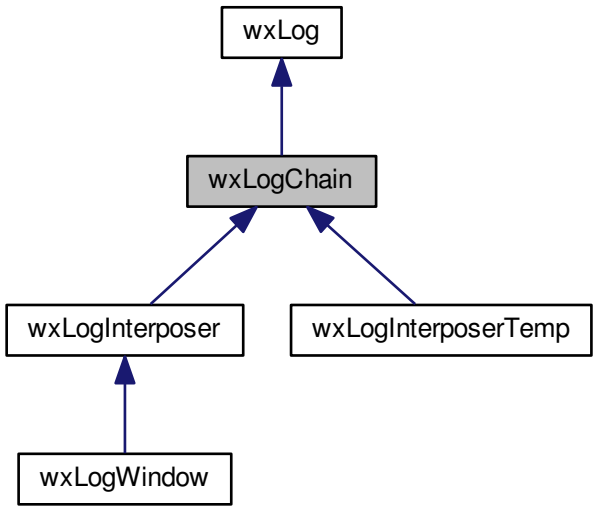
Returns the current buffer contains.

Messages from different log function calls are separated with the new lines in the buffer. The buffer can be cleared by Flush() which will also show the current contents to the user.

21.432 wxLogChain Class Reference

`#include <wx/log.h>`

Inheritance diagram for wxLogChain:



21.432.1 Detailed Description

This simple class allows you to chain log sinks, that is to install a new sink but keep passing log messages to the old one instead of replacing it completely as wxLog::SetActiveTarget does.

It is especially useful when you want to divert the logs somewhere (for example to a file or a log window) but also keep showing the error messages using the standard dialogs as wxLogGui does by default.

Example of usage:

```
wxLogChain *logChain = new wxLogChain(new wxLogStderr);
```

```
// all the log messages are sent to stderr and also processed as usually
...

// don't delete logChain directly as this would leave a dangling
// pointer as active log target, use SetActiveTarget() instead
delete wxLog::SetActiveTarget(...something else or NULL...);
```

Library: wxBase

Category: Logging

Public Member Functions

- wxLogChain (wxLog *logger)

  Sets the specified `logger` (which may be NULL) as the default log target but the log messages are also passed to the previous log target if any.
- virtual ~wxLogChain ()

  Destroys the previous log target.
- void DetachOldLog ()

  Detaches the old log target so it won't be destroyed when the wxLogChain object is destroyed.
- wxLog * GetOldLog () const

  Returns the pointer to the previously active log target (which may be NULL).
- bool IsPassingMessages () const

  Returns true if the messages are passed to the previously active log target (default) or false if PassMessages() had been called.
- void PassMessages (bool passMessages)

  By default, the log messages are passed to the previously active log target.
- void SetLog (wxLog *logger)

  Sets another log target to use (may be NULL).

Additional Inherited Members

21.432.2 Constructor & Destructor Documentation

wxLogChain::wxLogChain (wxLog * *logger*)

Sets the specified `logger` (which may be NULL) as the default log target but the log messages are also passed to the previous log target if any.

virtual wxLogChain::~wxLogChain ( ) [virtual]

Destroys the previous log target.

21.432.3 Member Function Documentation

void wxLogChain::DetachOldLog ( )

Detaches the old log target so it won't be destroyed when the wxLogChain object is destroyed.

wxLog* wxLogChain::GetOldLog ( ) const

Returns the pointer to the previously active log target (which may be NULL).

bool wxLogChain::IsPassingMessages ( ) const

Returns true if the messages are passed to the previously active log target (default) or false if PassMessages() had been called.

void wxLogChain::PassMessages (bool *passMessages*)

By default, the log messages are passed to the previously active log target.

Calling this function with false parameter disables this behaviour (presumably temporarily, as you shouldn't use wxLogChain at all otherwise) and it can be reenabled by calling it again with *passMessages* set to true.

void wxLogChain::SetLog (wxLog * *logger*)

Sets another log target to use (may be NULL).

The log target specified in the wxLogChain(wxLog*) constructor or in a previous call to this function is deleted. This doesn't change the old log target value (the one the messages are forwarded to) which still remains the same as was active when wxLogChain object was created.

21.433 wxLogFormatter Class Reference

`#include <wx/log.h>`

21.433.1 Detailed Description

wxLogFormatter class is used to format the log messages.

It implements the default formatting and can be derived from to create custom formatters.

The default implementation formats the message into a string containing the time stamp, level-dependent prefix and the message itself.

To change it, you can derive from it and override its Format() method. For example, to include the thread id in the log messages you can use

```
class LogFormatterWithThread : public wxLogFormatter
{
    virtual wxString Format(wxLogLevel level,
                            const wxString& msg,
                            const wxLogRecordInfo& info) const
    {
        return wxString::Format("[%d] %s(%d) : %s",
            info.threadId, info.filename, info.line, msg);
    }
};
```

And then associate it with wxLog instance using its SetFormatter(). Then, if you call:

```
wxLogMessage(_("*** Application started ***"));
```

the log output could be something like:

```
    [7872] d:\testApp\src\testApp.cpp(85) : *** Application started ***
```

Logging Overview

Since

2.9.4

Public Member Functions

- wxLogFormatter ()

  The default ctor does nothing.
- virtual wxString Format (wxLogLevel level, const wxString &msg, const wxLogRecordInfo &info) const

  This function creates the full log message string.

Protected Member Functions

- virtual wxString FormatTime (time_t time) const

  This function formats the time stamp part of the log message.

21.433.2 Constructor & Destructor Documentation

wxLogFormatter::wxLogFormatter ( )

The default ctor does nothing.

21.433.3 Member Function Documentation

virtual wxString wxLogFormatter::Format (wxLogLevel *level,* const wxString & *msg,* const wxLogRecordInfo & *info*) const `[virtual]`

This function creates the full log message string.

Override it to customize the output string format.

Parameters

level	The level of this log record, e.g. wxLOG_Error.
msg	The log message itself.
info	All the other information (such as time, component, location...) associated with this log record.

Returns

The formated message.

Note

Time stamping is disabled for Visual C++ users in debug builds by default because otherwise it would be impossible to directly go to the line from which the log message was generated by simply clicking in the debugger window on the corresponding error message. If you wish to enable it, override FormatTime().

virtual wxString wxLogFormatter::FormatTime (time_t *time*) const `[protected], [virtual]`

This function formats the time stamp part of the log message.

Override this function if you need to customize just the time stamp.

Parameters

time	Time to format.

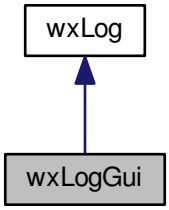
Returns

The formated time string, may be empty.

21.434 wxLogGui Class Reference

`#include <wx/log.h>`

Inheritance diagram for wxLogGui:



21.434.1 Detailed Description

This is the default log target for the GUI wxWidgets applications.

Please see Logging Customization for explanation of how to change the default log target.

An object of this class is used by default to show the log messages created by using wxLogMessage(), wxLogError() and other logging functions. It doesn't display the messages logged by them immediately however but accumulates all messages logged during an event handler execution and then shows them all at once when its Flush() method is called during the idle time processing. This has the important advantage of showing only a single dialog to the user even if several messages were logged because of a single error as it often happens (e.g. a low level function could log a message because it failed to open a file resulting in its caller logging another message due to the failure of higher level operation requiring the use of this file). If you need to force the display of all previously logged messages immediately you can use wxLog::FlushActive() to force the dialog display.

Also notice that if an error message is logged when several informative messages had been already logged before, the informative messages are discarded on the assumption that they are not useful – and may be confusing and hence harmful – any more after the error. The warning and error messages are never discarded however and any informational messages logged after the first error one are also kept (as they may contain information about the error recovery). You may override DoLog() method to change this behaviour.

At any rate, it is possible that that several messages were accumulated before this class Flush() method is called. If this is the case, Flush() uses a custom dialog which shows the last message directly and allows the user to view the previously logged ones by expanding the "Details" wxCollapsiblePane inside it. This custom dialog also provides the buttons for copying the log messages to the clipboard and saving them to a file.

However if only a single message is present when Flush() is called, just a wxMessageBox() is used to show it. This has the advantage of being closer to the native behaviour but it doesn't give the user any possibility to copy or save the message (except for the recent Windows versions where `Ctrl-C` may be pressed in the message box to copy its contents to the clipboard) so you may want to override DoShowSingleLogMessage() to customize wxLogGui – the dialogs sample shows how to do this.

Library: wxCore

Category: Logging

Public Member Functions

- wxLogGui ()

  Default constructor.
- virtual void Flush ()

  Presents the accumulated log messages, if any, to the user.

Protected Member Functions

- wxString GetTitle () const

  Returns the appropriate title for the dialog.
- int GetSeverityIcon () const

  Returns wxICON_ERROR, wxICON_WARNING or wxICON_INFORMATION depending on the current maximal severity.
- void Clear ()

  Forgets all the currently stored messages.

Protected Attributes

- wxArrayString m_aMessages

  All currently accumulated messages.
- wxArrayInt m_aSeverity

  The severities of each logged message.
- wxArrayLong m_aTimes

  The time stamps of each logged message.
- bool m_bErrors

  True if there any error messages.
- bool m_bWarnings

  True if there any warning messages.
- bool m_bHasMessages

  True if there any messages to be shown to the user.

Private Member Functions

- virtual void DoShowSingleLogMessage (const wxString &message, const wxString &title, int style)

  Method called by Flush() to show a single log message.
- virtual void DoShowMultipleLogMessages (const wxArrayString &messages, const wxArrayInt &severities, const wxArrayLong &times, const wxString &title, int style)

  Method called by Flush() to show multiple log messages.

Additional Inherited Members

21.434.2 Constructor & Destructor Documentation

wxLogGui::wxLogGui ( )

Default constructor.

21.434.3 Member Function Documentation

void wxLogGui::Clear ( ) `[protected]`

Forgets all the currently stored messages.

If you override Flush() (and don't call the base class version), you must call this method to avoid messages being logged over and over again.

virtual void wxLogGui::DoShowMultipleLogMessages (const wxArrayString & *messages*, const wxArrayInt & *severities*, const wxArrayLong & *times*, const wxString & *title*, int *style*) `[private], [virtual]`

Method called by Flush() to show multiple log messages.

This function can be overridden to show the messages in a different way. By default a special log dialog showing the most recent message and allowing the user to expand it to view the previously logged ones is used.

Parameters

messages	Array of messages to show; it contains more than one element.
severities	Array of message severities containing `wxLOG_XXX` values.
times	Array of time_t values indicating when each message was logged.
title	The suggested title for the dialog showing the message, see GetTitle().
style	One of `wxICON_XXX` constants, see GetSeverityIcon().

virtual void wxLogGui::DoShowSingleLogMessage (const wxString & *message*, const wxString & *title*, int *style*) `[private], [virtual]`

Method called by Flush() to show a single log message.

This function can be overridden to show the message in a different way. By default a simple wxMessageBox() call is used.

Parameters

message	The message to show (it can contain multiple lines).
title	The suggested title for the dialog showing the message, see GetTitle().
style	One of `wxICON_XXX` constants, see GetSeverityIcon().

virtual void wxLogGui::Flush ( ) `[virtual]`

Presents the accumulated log messages, if any, to the user.

This method is called during the idle time and should show any messages accumulated in wxLogGui::m_aMessages field to the user.

Reimplemented from wxLog.

int wxLogGui::GetSeverityIcon ( ) const [protected]

Returns wxICON_ERROR, wxICON_WARNING or wxICON_INFORMATION depending on the current maximal severity.

This value is suitable to be used in the style parameter of wxMessageBox() function.

wxString wxLogGui::GetTitle ( ) const [protected]

Returns the appropriate title for the dialog.

The title is constructed from wxApp::GetAppDisplayName() and the severity string (e.g. "error" or "warning") appropriate for the current wxLogGui::m_bErrors and wxLogGui::m_bWarnings values.

21.434.4 Member Data Documentation

wxArrayString wxLogGui::m_aMessages [protected]

All currently accumulated messages.

This array may be empty if no messages were logged.

See also

m_aSeverity, m_aTimes

wxArrayInt wxLogGui::m_aSeverity [protected]

The severities of each logged message.

This array is synchronized with wxLogGui::m_aMessages, i.e. the n-th element of this array corresponds to the severity of the n-th message. The possible severity values are wxLOG_XXX constants, e.g. wxLOG_Error, wxLOG_Warning, wxLOG_Message etc.

wxArrayLong wxLogGui::m_aTimes [protected]

The time stamps of each logged message.

The elements of this array are time_t values corresponding to the time when the message was logged.

bool wxLogGui::m_bErrors [protected]

True if there any error messages.

bool wxLogGui::m_bHasMessages [protected]

True if there any messages to be shown to the user.

This variable is used instead of simply checking whether wxLogGui::m_aMessages array is empty to allow blocking further calls to Flush() while a log dialog is already being shown, even if the messages array hasn't been emptied yet.

bool wxLogGui::m_bWarnings [protected]

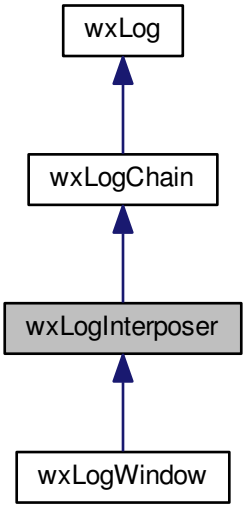
True if there any warning messages.

If both wxLogGui::m_bErrors and this member are false, there are only informational messages to be shown.

21.435 wxLogInterposer Class Reference

`#include <wx/log.h>`

Inheritance diagram for wxLogInterposer:



21.435.1 Detailed Description

A special version of wxLogChain which uses itself as the new log target.

It forwards log messages to the previously installed one in addition to processing them itself.

Unlike wxLogChain which is usually used directly as is, this class must be derived from to implement wxLog::DoLog and/or wxLog::DoLogString methods.

wxLogInterposer destroys the previous log target in its destructor. If you don't want this to happen, use wxLog↩ InterposerTemp instead.

Library: wxBase

Category: Logging

Public Member Functions

- wxLogInterposer ()

  The default constructor installs this object as the current active log target.

Additional Inherited Members

21.435.2 Constructor & Destructor Documentation

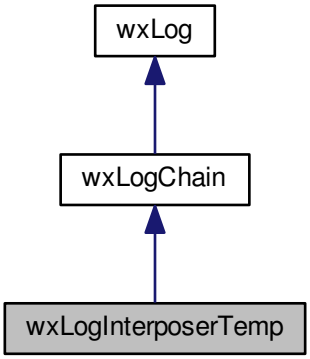
wxLogInterposer::wxLogInterposer ( )

The default constructor installs this object as the current active log target.

21.436 wxLogInterposerTemp Class Reference

`#include <wx/log.h>`

Inheritance diagram for wxLogInterposerTemp:



21.436.1 Detailed Description

A special version of wxLogChain which uses itself as the new log target.

It forwards log messages to the previously installed one in addition to processing them itself. Unlike wxLog↩ Interposer, it doesn't delete the old target which means it can be used to temporarily redirect log output.

As per wxLogInterposer, this class must be derived from to implement wxLog::DoLog and/or wxLog::DoLogString methods.

Library: wxBase

Category: Logging

Public Member Functions

- wxLogInterposerTemp ()

  The default constructor installs this object as the current active log target.

Additional Inherited Members

21.436.2 Constructor & Destructor Documentation

wxLogInterposerTemp::wxLogInterposerTemp ( )

The default constructor installs this object as the current active log target.

21.437 wxLogNull Class Reference

`#include <wx/log.h>`

21.437.1 Detailed Description

This class allows you to temporarily suspend logging.

All calls to the log functions during the life time of an object of this class are just ignored.

In particular, it can be used to suppress the log messages given by wxWidgets itself but it should be noted that it is rarely the best way to cope with this problem as **all** log messages are suppressed, even if they indicate a completely different error than the one the programmer wanted to suppress.

For instance, the example of the overview:

```
wxFile file;

// wxFile.Open() normally complains if file can't be opened, we don't want it
{
  wxLogNull logNo;
  if ( !file.Open("bar") )
    ... process error ourselves ...
} // ~wxLogNull called, old log sink restored

wxLogMessage("..."); // ok
```

would be better written as:

```
wxFile file;

// don't try to open file if it doesn't exist, we are prepared to deal with
// this ourselves - but all other errors are not expected
if ( wxFile::Exists("bar") )
{
    // gives an error message if the file couldn't be opened
    file.Open("bar");
}
else
{
    ...
}
```

Library: wxBase

Category: Logging

Public Member Functions

- wxLogNull ()

  Suspends logging.

- ~wxLogNull ()

  Resumes logging.

21.437.2 Constructor & Destructor Documentation

wxLogNull::wxLogNull ( )

Suspends logging.

wxLogNull::~wxLogNull ( )

Resumes logging.

21.438 wxLogRecordInfo Class Reference

`#include <wx/log.h>`

21.438.1 Detailed Description

Information about a log record (unit of the log output).

Public Attributes

- const char * filename

  The name of the file where this log message was generated.
- int line

  The line number at which this log message was generated.
- const char * func

  The name of the function where the log record was generated.
- time_t timestamp

  Time when the log message was generated.
- wxThreadIdType threadId

  Id of the thread in which the message was generated.

21.438.2 Member Data Documentation

const char* wxLogRecordInfo::filename

The name of the file where this log message was generated.

const char* wxLogRecordInfo::func

The name of the function where the log record was generated.

This field may be NULL if the compiler doesn't support **`__FUNCTION__`** (but most modern compilers do).

int wxLogRecordInfo::line

The line number at which this log message was generated.

wxThreadIdType wxLogRecordInfo::threadId

Id of the thread in which the message was generated.

This field is only available if wxWidgets was built with threads support (`wxUSE_THREADS == 1`).

See also

wxThread::GetCurrentId()

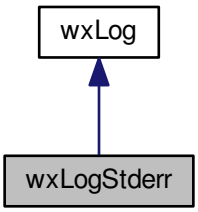
time_t wxLogRecordInfo::timestamp

Time when the log message was generated.

21.439 wxLogStderr Class Reference

`#include <wx/log.h>`

Inheritance diagram for wxLogStderr:



21.439.1 Detailed Description

This class can be used to redirect the log messages to a C file stream (not to be confused with C++ streams).

It is the default log target for the non-GUI wxWidgets applications which send all the output to `stderr`.

Library: wxBase

Category: Logging

See also

wxLogStream

Public Member Functions

- wxLogStderr (FILE *fp=NULL)

  Constructs a log target which sends all the log messages to the given `FILE`.

Additional Inherited Members

21.439.2 Constructor & Destructor Documentation

wxLogStderr::wxLogStderr (FILE * *fp* = NULL)

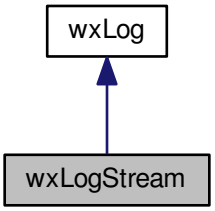
Constructs a log target which sends all the log messages to the given FILE.

If it is NULL, the messages are sent to stderr.

21.440 wxLogStream Class Reference

#include <wx/log.h>

Inheritance diagram for wxLogStream:



21.440.1 Detailed Description

This class can be used to redirect the log messages to a C++ stream.

Please note that this class is only available if wxWidgets was compiled with the standard iostream library support (wxUSE_STD_IOSTREAM must be on).

Library: wxBase

Category: Logging

See also

wxLogStderr, wxStreamToTextRedirector

Public Member Functions

- wxLogStream (std::ostream *ostr=NULL)

  Constructs a log target which sends all the log messages to the given output stream.

Additional Inherited Members

21.440.2 Constructor & Destructor Documentation

wxLogStream::wxLogStream (std::ostream * *ostr* = NULL)

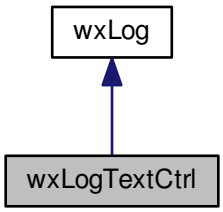
Constructs a log target which sends all the log messages to the given output stream.

If it is NULL, the messages are sent to `cerr`.

21.441 wxLogTextCtrl Class Reference

`#include <wx/log.h>`

Inheritance diagram for wxLogTextCtrl:



21.441.1 Detailed Description

Using these target all the log messages can be redirected to a text control.

The text control must have been created with `wxTE_MULTILINE` style by the caller previously.

Library: wxCore

Category: Logging

See also

wxTextCtrl, wxStreamToTextRedirector

Public Member Functions

- wxLogTextCtrl (wxTextCtrl *pTextCtrl)

  Constructs a log target which sends all the log messages to the given text control.

Additional Inherited Members

21.441.2 Constructor & Destructor Documentation

wxLogTextCtrl::wxLogTextCtrl (wxTextCtrl * *pTextCtrl*)

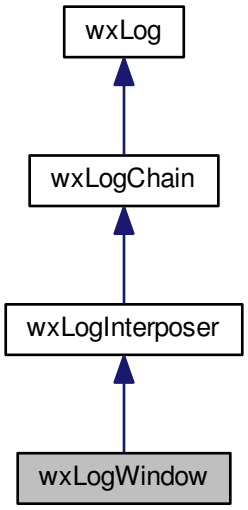
Constructs a log target which sends all the log messages to the given text control.

The *textctrl* parameter cannot be NULL.

21.442 wxLogWindow Class Reference

`#include <wx/log.h>`

Inheritance diagram for wxLogWindow:



21.442.1 Detailed Description

This class represents a background log window: to be precise, it collects all log messages in the log frame which it manages but also passes them on to the log target which was active at the moment of its creation.

This allows you, for example, to show all the log messages in a frame but still continue to process them normally by showing the standard log dialog.

Library: wxCore

Category: Logging

See also

wxLogTextCtrl

Public Member Functions

- wxLogWindow (wxWindow *pParent, const wxString &szTitle, bool show=true, bool passToOld=true)

Creates the log frame window and starts collecting the messages in it.

- wxFrame * GetFrame () const

  Returns the associated log frame window.

- virtual bool OnFrameClose (wxFrame *frame)

  Called if the user closes the window interactively, will not be called if it is destroyed for another reason (such as when program exits).

- virtual void OnFrameDelete (wxFrame *frame)

  Called right before the log frame is going to be deleted: will always be called unlike OnFrameClose().

- void Show (bool show=true)

  Shows or hides the frame.

Additional Inherited Members

21.442.2 Constructor & Destructor Documentation

wxLogWindow::wxLogWindow (wxWindow * *pParent*, const wxString & *szTitle*, bool *show* = `true`, bool *passToOld* = `true`)

Creates the log frame window and starts collecting the messages in it.

Parameters

pParent	The parent window for the log frame, may be NULL
szTitle	The title for the log frame
show	true to show the frame initially (default), otherwise Show() must be called later.
passToOld	true to process the log messages normally in addition to logging them in the log frame (default), false to only log them in the log frame. Note that if no targets were set using wxLog::SetActiveTarget() then wxLogWindow simply becomes the active one and messages won't be passed to other targets.

21.442.3 Member Function Documentation

wxFrame* wxLogWindow::GetFrame ( ) const

Returns the associated log frame window.

This may be used to position or resize it but use Show() to show or hide it.

virtual bool wxLogWindow::OnFrameClose (wxFrame * *frame*) `[virtual]`

Called if the user closes the window interactively, will not be called if it is destroyed for another reason (such as when program exits).

Return true from here to allow the frame to close, false to prevent this from happening.

See also

OnFrameDelete()

virtual void wxLogWindow::OnFrameDelete (wxFrame * *frame*) `[virtual]`

Called right before the log frame is going to be deleted: will always be called unlike OnFrameClose().

void wxLogWindow::Show (bool *show* = `true`)

Shows or hides the frame.

21.443 wxLongLong Class Reference

`#include <wx/longlong.h>`

21.443.1 Detailed Description

This class represents a signed 64 bit long number.

It is implemented using the native 64 bit type where available (machines with 64 bit longs or compilers which have (an analog of) *long* long type) and uses the emulation code in the other cases which ensures that it is the most efficient solution for working with 64 bit integers independently of the architecture.

wxLongLong defines all usual arithmetic operations such as addition, subtraction, bitwise shifts and logical operations as well as multiplication and division (not yet for the machines without native *long* long). It also has operators for implicit construction from and conversion to the native *long* long type if it exists and *long*.

You would usually use this type in exactly the same manner as any other (built-in) arithmetic type. Note that wxLongLong is a signed type, if you want unsigned values use wxULongLong which has exactly the same API as wxLongLong except when explicitly mentioned otherwise.

If a native (i.e. supported directly by the compiler) 64 bit integer type was found to exist, *wxLongLong_t* macro will be defined to correspond to it. Also, in this case only, two additional macros will be defined:

- wxLongLongFmtSpec() for printing 64 bit integers using the standard `printf()` function (but see also wxLongLong::ToString for a more portable solution);
- wxLL() for defining 64 bit integer compile-time constants.

Library: wxBase

Category: Data Structures

Public Member Functions

- wxLongLong ()

  Default constructor initializes the object to 0.
- wxLongLong (wxLongLong_t ll)

  Constructor from native long long (only for compilers supporting it).
- wxLongLong (long hi, unsigned long lo)

  Constructor from 2 longs: the high and low part are combined into one wxLongLong.
- wxLongLong Assign (double d)

  This allows to convert a double value to wxLongLong type.
- long GetHi () const

  Returns the high 32 bits of 64 bit integer.
- unsigned long GetLo () const

  Returns the low 32 bits of 64 bit integer.
- wxLongLong_t GetValue () const

  Convert to native long long (only for compilers supporting it).
- double ToDouble () const

Returns the value as `double`.

- long ToLong () const

  Truncate wxLongLong to long.
- wxString ToString () const

  Returns the string representation of a wxLongLong.
- wxLongLong operator+ (const wxLongLong &ll) const

  Adds 2 wxLongLongs together and returns the result.
- wxLongLong & operator+ (const wxLongLong &ll)

  Add another wxLongLong to this one.
- wxLongLong operator- (const wxLongLong &ll) const

  Subtracts 2 wxLongLongs and returns the result.
- wxLongLong & operator- (const wxLongLong &ll)

  Subtracts another wxLongLong from this one.
- wxLongLong operator- () const

  Returns the value of this wxLongLong with opposite sign.
- wxLongLong & operator= (const wxULongLong &ll)

  Assignment operator from unsigned long long.
- wxLongLong & operator= (wxLongLong_t ll)

  Assignment operator from native long long (only for compilers supporting it).
- wxLongLong & operator= (wxULongLong_t ll)

  Assignment operator from native unsigned long long (only for compilers supporting it).
- wxLongLong & operator= (long l)

  Assignment operator from long.
- wxLongLong & operator= (unsigned long l)

  Assignment operator from unsigned long.

- wxLongLong Abs () const

  Returns an absolute value of wxLongLong - either making a copy (const version) or modifying it in place (the second one).
- wxLongLong & Abs ()

  Returns an absolute value of wxLongLong - either making a copy (const version) or modifying it in place (the second one).

- wxLongLong operator++ ()

  Pre/post increment operator.
- wxLongLong operator++ (int)

  Pre/post increment operator.

- wxLongLong operator-- ()

  Pre/post decrement operator.
- wxLongLong operator-- (int)

  Pre/post decrement operator.

21.443.2 Constructor & Destructor Documentation

wxLongLong::wxLongLong ( )

Default constructor initializes the object to 0.

wxLongLong::wxLongLong (wxLongLong_t *ll*)

Constructor from native long long (only for compilers supporting it).

wxLongLong::wxLongLong (long *hi,* unsigned long *lo*)

Constructor from 2 longs: the high and low part are combined into one wxLongLong.

21.443.3 Member Function Documentation

wxLongLong wxLongLong::Abs ( ) const

Returns an absolute value of wxLongLong - either making a copy (const version) or modifying it in place (the second one).

Not in wxULongLong.

wxLongLong& wxLongLong::Abs ( )

Returns an absolute value of wxLongLong - either making a copy (const version) or modifying it in place (the second one).

Not in wxULongLong.

wxLongLong wxLongLong::Assign (double *d*)

This allows to convert a double value to wxLongLong type.

Such conversion is not always possible in which case the result will be silently truncated in a platform-dependent way. Not in wxULongLong.

long wxLongLong::GetHi ( ) const

Returns the high 32 bits of 64 bit integer.

unsigned long wxLongLong::GetLo ( ) const

Returns the low 32 bits of 64 bit integer.

wxLongLong_t wxLongLong::GetValue ( ) const

Convert to native long long (only for compilers supporting it).

wxLongLong wxLongLong::operator+ (const wxLongLong & *ll*) const

Adds 2 wxLongLongs together and returns the result.

wxLongLong& wxLongLong::operator+ (const wxLongLong & *ll*)

Add another wxLongLong to this one.

wxLongLong wxLongLong::operator++ ( )

Pre/post increment operator.

wxLongLong wxLongLong::operator++ (int)

Pre/post increment operator.

wxLongLong wxLongLong::operator- (const wxLongLong & //) const

Subtracts 2 wxLongLongs and returns the result.

wxLongLong& wxLongLong::operator- (const wxLongLong & //)

Subtracts another wxLongLong from this one.

wxLongLong wxLongLong::operator- ( ) const

Returns the value of this wxLongLong with opposite sign.

Not in wxULongLong.

wxLongLong wxLongLong::operator-- ( )

Pre/post decrement operator.

wxLongLong wxLongLong::operator-- (int)

Pre/post decrement operator.

wxLongLong& wxLongLong::operator= (const wxULongLong & //)

Assignment operator from unsigned long long.

The sign bit will be copied too.

Since

2.7.0

wxLongLong& wxLongLong::operator= (wxLongLong_t //)

Assignment operator from native long long (only for compilers supporting it).

wxLongLong& wxLongLong::operator= (wxULongLong_t //)

Assignment operator from native unsigned long long (only for compilers supporting it).

Since

2.7.0

wxLongLong& wxLongLong::operator= (long l)

Assignment operator from long.

Since

2.7.0

wxLongLong& wxLongLong::operator= (unsigned long l)

Assignment operator from unsigned long.

Since

2.7.0

double wxLongLong::ToDouble ( ) const

Returns the value as `double`.

long wxLongLong::ToLong ( ) const

Truncate wxLongLong to long.

If the conversion loses data (i.e. the wxLongLong value is outside the range of built-in long type), an assert will be triggered in debug mode.

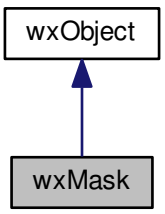
wxString wxLongLong::ToString ( ) const

Returns the string representation of a wxLongLong.

21.444 wxMask Class Reference

`#include <wx/bitmap.h>`

Inheritance diagram for wxMask:



21.444.1 Detailed Description

This class encapsulates a monochrome mask bitmap, where the masked area is black and the unmasked area is white.

When associated with a bitmap and drawn in a device context, the unmasked area of the bitmap will be drawn, and the masked area will not be drawn.

Library: wxCore

Category: Graphics Device Interface (GDI)

See also

wxBitmap, wxDC::Blit, wxMemoryDC

Public Member Functions

- wxMask ()

  Default constructor.
- wxMask (const wxBitmap &bitmap, int index)

  Constructs a mask from a bitmap and a palette index that indicates the background.
- wxMask (const wxBitmap &bitmap)

  Constructs a mask from a monochrome bitmap.
- wxMask (const wxBitmap &bitmap, const wxColour &colour)

  Constructs a mask from a bitmap and a colour that indicates the background.
- virtual ~wxMask ()

  Destroys the wxMask object and the underlying bitmap data.
- bool Create (const wxBitmap &bitmap, int index)

  Constructs a mask from a bitmap and a palette index that indicates the background.
- bool Create (const wxBitmap &bitmap)

  Constructs a mask from a monochrome bitmap.
- bool Create (const wxBitmap &bitmap, const wxColour &colour)

  Constructs a mask from a bitmap and a colour that indicates the background.
- wxBitmap GetBitmap () const

  Returns the mask as a monochrome bitmap.

Additional Inherited Members

21.444.2 Constructor & Destructor Documentation

wxMask::wxMask ( )

Default constructor.

wxMask::wxMask (const wxBitmap & *bitmap,* int *index*)

Constructs a mask from a bitmap and a palette index that indicates the background.

Not implemented for GTK.

Parameters

bitmap	A valid bitmap.
index	Index into a palette, specifying the transparency colour.

wxMask::wxMask (const wxBitmap & *bitmap*)

Constructs a mask from a monochrome bitmap.

wxMask::wxMask (const wxBitmap & *bitmap,* const wxColour & *colour*)

Constructs a mask from a bitmap and a colour that indicates the background.

virtual wxMask::~wxMask ( ) [virtual]

Destroys the wxMask object and the underlying bitmap data.

21.444.3 Member Function Documentation

bool wxMask::Create (const wxBitmap & *bitmap,* int *index*)

Constructs a mask from a bitmap and a palette index that indicates the background.

Not implemented for GTK.

Parameters

bitmap	A valid bitmap.
index	Index into a palette, specifying the transparency colour.

bool wxMask::Create (const wxBitmap & *bitmap*)

Constructs a mask from a monochrome bitmap.

bool wxMask::Create (const wxBitmap & *bitmap,* const wxColour & *colour*)

Constructs a mask from a bitmap and a colour that indicates the background.

wxBitmap wxMask::GetBitmap ( ) const

Returns the mask as a monochrome bitmap.

Currently this method is implemented in wxMSW, wxGTK and wxOSX.

Since

2.9.5

21.445 wxMatrix2D Class Reference

`#include <wx/affinematrix2dbase.h>`

21.445.1 Detailed Description

A simple container for 2x2 matrix.

This simple structure is used with wxAffineMatrix2D.

Library: wxCore

Category: Miscellaneous

Since

2.9.2

Public Member Functions

- wxMatrix2D (wxDouble v11=1, wxDouble v12=0, wxDouble v21=0, wxDouble v22=1)

  Default constructor.

Public Attributes

- wxDouble m_11

  The matrix elements in the usual mathematical notation.
- wxDouble m_12
- wxDouble m_21
- wxDouble m_22

21.445.2 Constructor & Destructor Documentation

wxMatrix2D::wxMatrix2D (wxDouble *v11* = `1`, wxDouble *v12* = `0`, wxDouble *v21* = `0`, wxDouble *v22* = `1`)

Default constructor.

Initializes the matrix elements to the identity.

21.445.3 Member Data Documentation

wxDouble wxMatrix2D::m_11

The matrix elements in the usual mathematical notation.

wxDouble wxMatrix2D::m_12

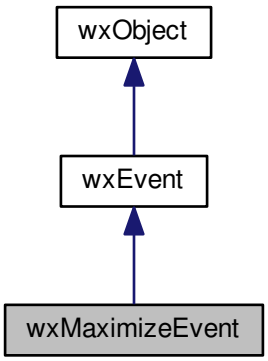
wxDouble wxMatrix2D::m_21

wxDouble wxMatrix2D::m_22

21.446 wxMaximizeEvent Class Reference

```
#include <wx/event.h>
```

Inheritance diagram for wxMaximizeEvent:



21.446.1 Detailed Description

An event being sent when a top level window is maximized.

Notice that it is not sent when the window is restored to its original size after it had been maximized, only a normal wxSizeEvent is generated in this case.

Currently this event is only generated in wxMSW, wxGTK and wxOSX/Cocoa ports so portable programs should only rely on receiving `wxEVT_SIZE` and not necessarily this event when the window is maximized.

Events using this class

The following event handler macros redirect the events to member function handlers '**func**' with prototypes like: void handlerFuncName(wxMaximizeEvent& event)

Event macros:

- EVT_MAXIMIZE(func): Process a `wxEVT_MAXIMIZE` event.

Library: wxCore

Category: Events

Public Member Functions

- wxMaximizeEvent (int id=0)

  Constructor.

Additional Inherited Members

21.446.2 Constructor & Destructor Documentation

wxMaximizeEvent::wxMaximizeEvent (int *id* = `0`)

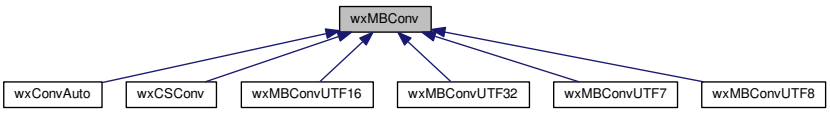
Constructor.

Only used by wxWidgets internally.

21.447 wxMBConv Class Reference

`#include <wx/strconv.h>`

Inheritance diagram for wxMBConv:



21.447.1 Detailed Description

This class is the base class of a hierarchy of classes capable of converting text strings between multibyte (SBCS or DBCS) encodings and Unicode.

This is an abstract base class which defines the operations implemented by all different conversion classes. The derived classes don't add any new operations of their own (except, possibly, some non-default constructors) and so you should simply use this class ToWChar() and FromWChar() (or cMB2WC() and cWC2MB()) methods with the objects of the derived class.

In the documentation for this and related classes please notice that length of the string refers to the number of characters in the string not counting the terminating `NUL`, if any. While the size of the string is the total number of bytes in the string, including any trailing `NUL`. Thus, length of wide character string `L"foo"` is 3 while its size can be either 8 or 16 depending on whether `wchar_t` is 2 bytes (as under Windows) or 4 (Unix).

Library: wxBase

Category: Text Conversion

Public Member Functions

- wxMBConv ()

  Trivial default constructor.
- virtual wxMBConv * Clone () const =0

  This pure virtual function is overridden in each of the derived classes to return a new copy of the object it is called on.
- virtual size_t GetMBNulLen () const

This function returns 1 for most of the multibyte encodings in which the string is terminated by a single NUL, 2 for UTF-16 and 4 for UTF-32 for which the string is terminated with 2 and 4 NUL characters respectively.

- virtual size_t ToWChar (wchar_t *dst, size_t dstLen, const char *src, size_t srcLen=wxNO_LEN) const

  Convert multibyte string to a wide character one.
- virtual size_t FromWChar (char *dst, size_t dstLen, const wchar_t *src, size_t srcLen=wxNO_LEN) const

  Converts wide character string to multibyte.
- const wxWCharBuffer cMB2WC (const char *in, size_t inLen, size_t *outLen) const
