Converts the strings contents to UTF-8 and returns it either as a temporary wxCharBuffer object or as a pointer to the internal string contents in UTF-8 build.

See also

wc_str(), c_str(), mb_str()

const wchar_t* wxString::wc_str ( ) const

Converts the strings contents to the wide character representation and returns it as a temporary wxWCharBuffer object (Unix and OS X) or returns a pointer to the internal string contents in wide character mode (Windows).

The macro wxWX2WCbuf is defined as the correct return type (without const).

See also

utf8_str(), c_str(), mb_str(), fn_str(), wchar_str()

const wxWCharBuffer wxString::wc_str ( ) const

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.

wxWritableWCharBuffer wxString::wchar_str ( ) const

Returns an object with string data that is implicitly convertible to `char*` pointer.

Note that changes to the returned buffer may or may not be lost (depending on the build) and so this function is only usable for passing strings to legacy libraries that don't have const-correct API. Use wxStringBuffer if you want to modify the string.

See also

mb_str(), wc_str(), fn_str(), c_str(), char_str()

const wxStringCharType* wxString::wx_str ( ) const

Explicit conversion to C string in the internal representation (either wchar_t* or UTF-8-encoded char*, depending on the build).

21.730.10 Member Data Documentation

const size_t wxString::npos `[static]`

An 'invalid' value for string index.

21.731 wxStringBuffer Class Reference

`#include <wx/string.h>`

21.731.1 Detailed Description

This tiny class allows you to conveniently access the wxString internal buffer as a writable pointer without any risk of forgetting to restore the string to the usable state later.

For example, assuming you have a low-level OS function called "`GetMeaningOfLifeAsString(char *)`" returning the value in the provided buffer (which must be writable, of course) you might call it like this:

```
wxString theAnswer;
GetMeaningOfLifeAsString(wxStringBuffer(theAnswer, 1024));
if ( theAnswer != "42" )
    wxLogError("Something is very wrong!");
```

Note that the exact usage of this depends on whether or not `wxUSE_STL` is enabled. If `wxUSE_STL` is enabled, wxStringBuffer creates a separate empty character buffer, and if `wxUSE_STL` is disabled, it uses GetWriteBuf() from wxString, keeping the same buffer wxString uses intact. In other words, relying on wxStringBuffer containing the old wxString data is not a good idea if you want to build your program both with and without `wxUSE_STL`.

Library: wxBase

Category: Data Structures

Public Member Functions

- wxStringBuffer (const wxString &str, size_t len)

  Constructs a writable string buffer object associated with the given string and containing enough space for at least len characters.
- ~wxStringBuffer ()

  Restores the string passed to the constructor to the usable state by calling wxString::UngetWriteBuf() on it.
- wxStringCharType * operator wxStringCharType * ()

  Returns the writable pointer to a buffer of the size at least equal to the length specified in the constructor.

21.731.2 Constructor & Destructor Documentation

wxStringBuffer::wxStringBuffer (const wxString & *str,* size_t *len*)

Constructs a writable string buffer object associated with the given string and containing enough space for at least *len* characters.

Basically, this is equivalent to calling wxString::GetWriteBuf() and saving the result.

wxStringBuffer::~wxStringBuffer ( )

Restores the string passed to the constructor to the usable state by calling wxString::UngetWriteBuf() on it.

21.731.3 Member Function Documentation

wxStringCharType* wxStringBuffer::operator wxStringCharType * ( )

Returns the writable pointer to a buffer of the size at least equal to the length specified in the constructor.

21.732 wxStringBufferLength Class Reference

`#include <wx/string.h>`

21.732.1 Detailed Description

This tiny class allows you to conveniently access the wxString internal buffer as a writable pointer without any risk of forgetting to restore the string to the usable state later, and allows the user to set the internal length of the string.

For example, assuming you have a low-level OS function called "`int GetMeaningOfLifeAsString(char *)`" copying the value in the provided buffer (which must be writable, of course), and returning the actual length of the string, you might call it like this:

```
wxString theAnswer;
wxStringBufferLength theAnswerBuffer(theAnswer, 1024);
int nLength = GetMeaningOfLifeAsString(theAnswerBuffer);
theAnswerBuffer.SetLength(nLength);
if ( theAnswer != "42" )
    wxLogError("Something is very wrong!");
```

Note that the exact usage of this depends on whether or not wxUSE_STL is enabled. If wxUSE_STL is enabled, wxStringBuffer creates a separate empty character buffer, and if wxUSE_STL is disabled, it uses GetWriteBuf() from wxString, keeping the same buffer wxString uses intact. In other words, relying on wxStringBuffer containing the old wxString data is not a good idea if you want to build your program both with and without wxUSE_STL.

Note that wxStringBuffer::SetLength **must** be called before wxStringBufferLength destructs.

Library: wxBase

Category: Data Structures

Public Member Functions

- wxStringBufferLength (const wxString &str, size_t len)

  Constructs a writable string buffer object associated with the given string and containing enough space for at least len characters.
- ~wxStringBufferLength ()

  Restores the string passed to the constructor to the usable state by calling wxString::UngetWriteBuf on it.
- void SetLength (size_t nLength)

  Sets the internal length of the string referred to by wxStringBufferLength to nLength characters.
- wxChar * operator wxChar * ()

  Returns the writable pointer to a buffer of the size at least equal to the length specified in the constructor.

21.732.2 Constructor & Destructor Documentation

wxStringBufferLength::wxStringBufferLength (const wxString & *str,* size_t *len*)

Constructs a writable string buffer object associated with the given string and containing enough space for at least *len* characters.

Basically, this is equivalent to calling wxString::GetWriteBuf and saving the result.

wxStringBufferLength::~wxStringBufferLength ( )

Restores the string passed to the constructor to the usable state by calling wxString::UngetWriteBuf on it.

21.732.3 Member Function Documentation

wxChar* wxStringBufferLength::operator wxChar * ( )

Returns the writable pointer to a buffer of the size at least equal to the length specified in the constructor.

void wxStringBufferLength::SetLength (size_t *nLength*)

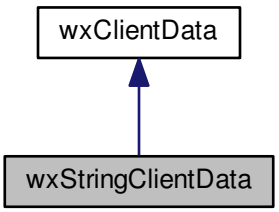
Sets the internal length of the string referred to by wxStringBufferLength to *nLength* characters.

Must be called before wxStringBufferLength destructs.

21.733 wxStringClientData Class Reference

`#include <wx/clntdata.h>`

Inheritance diagram for wxStringClientData:



21.733.1 Detailed Description

Predefined client data class for holding a string.

Library: wxBase

Category: Containers

Public Member Functions

- wxStringClientData ()

  Default constructor.

- wxStringClientData (const wxString &data)

  Create client data with string.

- const wxString & GetData () const

  Get string client data.

- void SetData (const wxString &data)

  Set string client data.

21.733.2 Constructor & Destructor Documentation

wxStringClientData::wxStringClientData ( )

Default constructor.

wxStringClientData::wxStringClientData (const wxString & *data*)

Create client data with string.

21.733.3 Member Function Documentation

const wxString& wxStringClientData::GetData ( ) const

Get string client data.

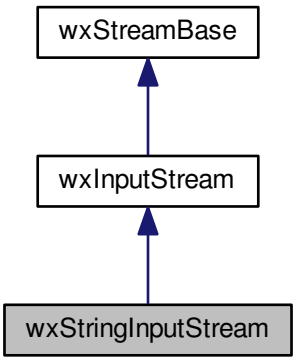
void wxStringClientData::SetData (const wxString & *data*)

Set string client data.

21.734 wxStringInputStream Class Reference

```
#include <wx/sstream.h>
```

Inheritance diagram for wxStringInputStream:



21.734.1 Detailed Description

This class implements an input stream which reads data from a string.

It supports seeking.

Library: wxBase

Category: Streams

Public Member Functions

- wxStringInputStream (const wxString &s)

  Creates a new read-only stream using the specified string.

Additional Inherited Members

21.734.2 Constructor & Destructor Documentation

wxStringInputStream::wxStringInputStream (const wxString & *s*)

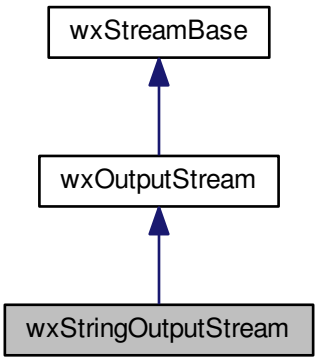
Creates a new read-only stream using the specified string.

Note that the string is copied by the stream so if the original string is modified after using this constructor, changes to it are not reflected when reading from stream.

21.735 wxStringOutputStream Class Reference

```
#include <wx/sstream.h>
```

Inheritance diagram for wxStringOutputStream:



21.735.1 Detailed Description

This class implements an output stream which writes data either to a user-provided or internally allocated string.

Note that currently this stream does not support seeking but can tell its current position.

Library: wxBase

Category: Streams

Public Member Functions

- wxStringOutputStream (wxString *pString=0, wxMBConv &conv=wxConvUTF8)

  Construct a new stream object writing the data to a string.
- const wxString & GetString () const

  Returns the string containing all the data written to the stream so far.

Additional Inherited Members

21.735.2 Constructor & Destructor Documentation

wxStringOutputStream::wxStringOutputStream (wxString * *pString* = `0`, wxMBConv & *conv* = `wxConvUTF8`)

Construct a new stream object writing the data to a string.

If the provided pointer is non-NULL, data will be written to it. Otherwise, an internal string is used for the data written to this stream, use GetString() to get access to it.

If *str* is used, data written to the stream is appended to the current contents of it, i.e. the string is not cleared here. However if it is not empty, the positions returned by wxOutputStream::TellO will be offset by the initial string length, i.e. initial stream position will be the initial length of the string and not 0.

Notice that the life time of *conv* must be greater than the life time of this object itself as it stores a reference to it. Also notice that with default value of this argument the data written to the stream must be valid UTF-8, pass `wxConvISO8859_1` to deal with arbitrary 8 bit data.

21.735.3 Member Function Documentation

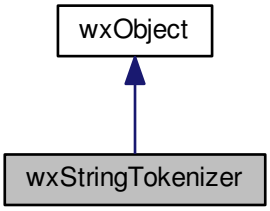
const wxString& wxStringOutputStream::GetString ( ) const

Returns the string containing all the data written to the stream so far.

21.736 wxStringTokenizer Class Reference

`#include <wx/tokenzr.h>`

Inheritance diagram for wxStringTokenizer:



21.736.1 Detailed Description

wxStringTokenizer helps you to break a string up into a number of tokens.

It replaces the standard C function `strtok()` and also extends it in a number of ways.

To use this class, you should create a wxStringTokenizer object, give it the string to tokenize and also the delimiters which separate tokens in the string (by default, white space characters will be used).

Then wxStringTokenizer::GetNextToken() may be called repeatedly until wxStringTokenizer::HasMoreTokens() returns false.

For example:

```
wxStringTokenizer tokenizer("first:second:third:fourth", ":");
while ( tokenizer.HasMoreTokens() )
{
    wxString token = tokenizer.GetNextToken();

    // process token here
}
```

Library: wxBase

Category: Data Structures

See also

wxStringTokenize()

Public Member Functions

- wxStringTokenizer ()

  Default constructor.
- wxStringTokenizer (const wxString &str, const wxString &delims=wxDEFAULT_DELIMITERS, wxStringTokenizerMode mode=wxTOKEN_DEFAULT)

  Constructor.
- size_t CountTokens () const

  Returns the number of tokens remaining in the input string.
- wxChar GetLastDelimiter () const

  Returns the delimiter which ended scan for the last token returned by GetNextToken() or `NUL` if there had been no calls to this function yet or if it returned the trailing empty token in wxTOKEN_RET_EMPTY_ALL mode.
- wxString GetNextToken ()

  Returns the next token or empty string if the end of string was reached.
- size_t GetPosition () const

  Returns the current position (i.e. one index after the last returned token or 0 if GetNextToken() has never been called) in the original string.
- wxString GetString () const

  Returns the part of the starting string without all token already extracted.
- bool HasMoreTokens () const

  Returns true if the tokenizer has further tokens, false if none are left.
- void SetString (const wxString &str, const wxString &delims=wxDEFAULT_DELIMITERS, wxStringTokenizerMode mode=wxTOKEN_DEFAULT)

  Initializes the tokenizer.

Additional Inherited Members

21.736.2 Constructor & Destructor Documentation

wxStringTokenizer::wxStringTokenizer ( )

Default constructor.

You must call SetString() before calling any other methods.

wxStringTokenizer::wxStringTokenizer (const wxString & *str*, const wxString & *delims* = wxDEFAULT_DELIMITERS, wxStringTokenizerMode *mode* = wxTOKEN_DEFAULT)

Constructor.

Pass the string to tokenize, a string containing delimiters, and the *mode* specifying how the string should be tokenized.

See also

SetString()

21.736.3 Member Function Documentation

size_t wxStringTokenizer::CountTokens ( ) const

Returns the number of tokens remaining in the input string.

The number of tokens returned by this function is decremented each time GetNextToken() is called and when it reaches 0, HasMoreTokens() returns false.

wxChar wxStringTokenizer::GetLastDelimiter ( ) const

Returns the delimiter which ended scan for the last token returned by GetNextToken() or `NUL` if there had been no calls to this function yet or if it returned the trailing empty token in wxTOKEN_RET_EMPTY_ALL mode.

Since

2.7.0

wxString wxStringTokenizer::GetNextToken ( )

Returns the next token or empty string if the end of string was reached.

size_t wxStringTokenizer::GetPosition ( ) const

Returns the current position (i.e. one index after the last returned token or 0 if GetNextToken() has never been called) in the original string.

wxString wxStringTokenizer::GetString ( ) const

Returns the part of the starting string without all token already extracted.

bool wxStringTokenizer::HasMoreTokens ( ) const

Returns true if the tokenizer has further tokens, false if none are left.

void wxStringTokenizer::SetString (const wxString & *str*, const wxString & *delims* = wxDEFAULT_DELIMITERS, wxStringTokenizerMode *mode* = wxTOKEN_DEFAULT)

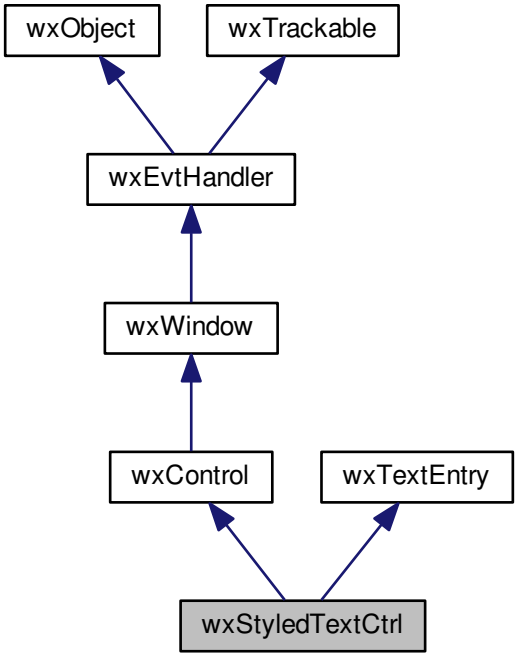
Initializes the tokenizer.

Pass the string to tokenize, a string containing delimiters, and the *mode* specifying how the string should be tokenized.

21.737 wxStyledTextCtrl Class Reference

`#include <wx/stc/stc.h>`

Inheritance diagram for wxStyledTextCtrl:



21.737.1 Detailed Description

A wxWidgets implementation of the Scintilla source code editing component.

As well as features found in standard text editing components, Scintilla includes features especially useful when editing and debugging source code. These include support for syntax styling, error indicators, code completion and call tips.

The selection margin can contain markers like those used in debuggers to indicate breakpoints and the current line. Styling choices are more open than with many editors, allowing the use of proportional fonts, bold and italics, multiple foreground and background colours and multiple fonts.

wxStyledTextCtrl is a 1 to 1 mapping of "raw" scintilla interface, whose documentation can be found in the Scintilla website (http://www.scintilla.org/).

Events emitted by this class

The following event handler macros redirect the events to member function handlers '**func**' with prototypes like: void handlerFuncName(wxStyledTextEvent& event)

Event macros for events emitted by this class:

- EVT_STC_CHANGE(id, fn): TOWRITE
- EVT_STC_STYLENEEDED(id, fn): TOWRITE
- EVT_STC_CHARADDED(id, fn): TOWRITE
- EVT_STC_SAVEPOINTREACHED(id, fn): TOWRITE

- EVT_STC_SAVEPOINTLEFT(id, fn): TOWRITE
- EVT_STC_ROMODIFYATTEMPT(id, fn): TOWRITE
- EVT_STC_KEY(id, fn): TOWRITE
- EVT_STC_DOUBLECLICK(id, fn): TOWRITE
- EVT_STC_UPDATEUI(id, fn): TOWRITE
- EVT_STC_MODIFIED(id, fn): TOWRITE
- EVT_STC_MACRORECORD(id, fn): TOWRITE
- EVT_STC_MARGINCLICK(id, fn): TOWRITE
- EVT_STC_NEEDSHOWN(id, fn): TOWRITE
- EVT_STC_PAINTED(id, fn): TOWRITE
- EVT_STC_USERLISTSELECTION(id, fn): TOWRITE
- EVT_STC_URIDROPPED(id, fn): TOWRITE
- EVT_STC_DWELLSTART(id, fn): TOWRITE
- EVT_STC_DWELLEND(id, fn): TOWRITE
- EVT_STC_START_DRAG(id, fn): Process a `wxEVT_STC_START_DRAG` event, generated when text is being dragged from the control. Details of the drag may be altered by changing the respective fields of the event; in particular, set an empty string to prohibit the drag entirely. Valid event functions: GetDragFlags, SetDragFlags, GetPosition, GetString, SetString.
- EVT_STC_DRAG_OVER(id, fn): TOWRITE
- EVT_STC_DO_DROP(id, fn): Process a `wxEVT_STC_DO_DROP` event, generated when text is being dropped into the control. Details of the drag may be altered by changing the respective fields of the event. Valid event functions: GetDragResult, SetDragResult, GetPosition, SetPosition, GetString, SetString, GetX, GetY.
- EVT_STC_ZOOM(id, fn): TOWRITE
- EVT_STC_HOTSPOT_CLICK(id, fn): TOWRITE
- EVT_STC_HOTSPOT_DCLICK(id, fn): TOWRITE
- EVT_STC_CALLTIP_CLICK(id, fn): TOWRITE
- EVT_STC_AUTOCOMP_SELECTION(id, fn): TOWRITE

wxStyledTextEvent

Public Member Functions

- wxStyledTextCtrl (wxWindow *parent, wxWindowID id=wxID_ANY, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, long style=0, const wxString &name=wxSTCNameStr)

  Ctor.
- wxStyledTextCtrl ()

  Default ctor.
- ~wxStyledTextCtrl ()

  Destructor.
- bool Create (wxWindow *parent, wxWindowID id=wxID_ANY, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, long style=0, const wxString &name=wxSTCNameStr)

  Create the UI elements for a STC that was created with the default ctor.
- void AddText (const wxString &text)

  Add text to the document at current position.
- void AddStyledText (const wxMemoryBuffer &data)

  Add array of cells to document.
- void InsertText (int pos, const wxString &text)

  Insert string at a position.
- void ClearAll ()

  Delete all text in the document.
- void DeleteRange (int pos, int deleteLength)

  Delete a range of text in the document.
- void ClearDocumentStyle ()

  Set all style bytes to 0, remove all folding information.
- int GetLength () const

  Returns the number of bytes in the document.
- int GetCharAt (int pos) const

  Returns the character byte at the position.
- int GetCurrentPos () const

  Returns the position of the caret.
- int GetAnchor () const

  Returns the position of the opposite end of the selection to the caret.
- int GetStyleAt (int pos) const

Returns the style byte at the position.

- void Redo ()

  Redoes the next action on the undo history.

- void SetUndoCollection (bool collectUndo)

  Choose between collecting actions into the undo history and discarding them.

- void SelectAll ()

  Select all the text in the document.

- void SetSavePoint ()

  Remember the current position in the undo history as the position at which the document was saved.

- wxMemoryBuffer GetStyledText (int startPos, int endPos)

  Retrieve a buffer of cells.

- bool CanRedo () const

  Are there any redoable actions in the undo history?

- int MarkerLineFromHandle (int handle)

  Retrieve the line number at which a particular marker is located.

- void MarkerDeleteHandle (int handle)

  Delete a marker.

- bool GetUndoCollection () const

  Is undo history being collected?

- int GetViewWhiteSpace () const

  Are white space characters currently visible? Returns one of SCWS_∗ constants.

- void SetViewWhiteSpace (int viewWS)

  Make white space characters invisible, always visible or visible outside indentation.

- int PositionFromPoint (wxPoint pt) const

  Find the position from a point within the window.

- int PositionFromPointClose (int x, int y)

  Find the position from a point within the window but return INVALID_POSITION if not close to text.

- void GotoLine (int line)

  Set caret to start of a line and ensure it is visible.

- void GotoPos (int pos)

  Set caret to a position and ensure it is visible.

- void SetAnchor (int posAnchor)

  Set the selection anchor to a position.

- wxString GetCurLine (int ∗linePos=NULL)

  Retrieve the text of the line containing the caret.

- int GetEndStyled () const

  Retrieve the position of the last correctly styled character.

- void ConvertEOLs (int eolMode)

  Convert all line endings in the document to one mode.

- int GetEOLMode () const

  Retrieve the current end of line mode - one of CRLF, CR, or LF.

- void SetEOLMode (int eolMode)

  Set the current end of line mode.

- void StartStyling (int pos, int mask)

  Set the current styling position to pos and the styling mask to mask.

- void SetStyling (int length, int style)

  Change style from current styling position for length characters to a style and move the current styling position to after this newly styled segment.

- bool GetBufferedDraw () const

  Is drawing done first into a buffer or direct to the screen?

- void SetBufferedDraw (bool buffered)

If drawing is buffered then each line of text is drawn into a bitmap buffer before drawing it to the screen to avoid flicker.

- void SetTabWidth (int tabWidth)

  Change the visible size of a tab to be a multiple of the width of a space character.
- int GetTabWidth () const

  Retrieve the visible size of a tab.
- void SetCodePage (int codePage)

  Set the code page used to interpret the bytes of the document as characters.
- void MarkerDefine (int markerNumber, int markerSymbol, const wxColour &foreground=wxNullColour, const wxColour &background=wxNullColour)

  Set the symbol used for a particular marker number, and optionally the fore and background colours.
- void MarkerSetForeground (int markerNumber, const wxColour &fore)

  Set the foreground colour used for a particular marker number.
- void MarkerSetBackground (int markerNumber, const wxColour &back)

  Set the background colour used for a particular marker number.
- void MarkerSetBackgroundSelected (int markerNumber, const wxColour &back)

  Set the background colour used for a particular marker number when its folding block is selected.
- void MarkerEnableHighlight (bool enabled)

  Enable/disable highlight for current folding bloc (smallest one that contains the caret)
- int MarkerAdd (int line, int markerNumber)

  Add a marker to a line, returning an ID which can be used to find or delete the marker.
- void MarkerDelete (int line, int markerNumber)

  Delete a marker from a line.
- void MarkerDeleteAll (int markerNumber)

  Delete all markers with a particular number from all lines.
- int MarkerGet (int line)

  Get a bit mask of all the markers set on a line.
- int MarkerNext (int lineStart, int markerMask)

  Find the next line at or after lineStart that includes a marker in mask.
- int MarkerPrevious (int lineStart, int markerMask)

  Find the previous line before lineStart that includes a marker in mask.
- void MarkerDefineBitmap (int markerNumber, const wxBitmap &bmp)

  Define a marker from a bitmap.
- void MarkerAddSet (int line, int set)

  Add a set of markers to a line.
- void MarkerSetAlpha (int markerNumber, int alpha)

  Set the alpha used for a marker that is drawn in the text area, not the margin.
- void SetMarginType (int margin, int marginType)

  Set a margin to be either numeric or symbolic.
- int GetMarginType (int margin) const

  Retrieve the type of a margin.
- void SetMarginWidth (int margin, int pixelWidth)

  Set the width of a margin to a width expressed in pixels.
- int GetMarginWidth (int margin) const

  Retrieve the width of a margin in pixels.
- void SetMarginMask (int margin, int mask)

  Set a mask that determines which markers are displayed in a margin.
- int GetMarginMask (int margin) const

  Retrieve the marker mask of a margin.
- void SetMarginSensitive (int margin, bool sensitive)

  Make a margin sensitive or insensitive to mouse clicks.
- bool GetMarginSensitive (int margin) const

Retrieve the mouse click sensitivity of a margin.

- void SetMarginCursor (int margin, int cursor)

  Set the cursor shown when the mouse is inside a margin.
- int GetMarginCursor (int margin) const

  Retrieve the cursor shown in a margin.
- void StyleClearAll ()

  Clear all the styles and make equivalent to the global default style.
- void StyleSetForeground (int style, const wxColour &fore)

  Set the foreground colour of a style.
- void StyleSetBackground (int style, const wxColour &back)

  Set the background colour of a style.
- void StyleSetBold (int style, bool bold)

  Set a style to be bold or not.
- void StyleSetItalic (int style, bool italic)

  Set a style to be italic or not.
- void StyleSetSize (int style, int sizePoints)

  Set the size of characters of a style.
- void StyleSetFaceName (int style, const wxString &fontName)

  Set the font of a style.
- void StyleSetEOLFilled (int style, bool filled)

  Set a style to have its end of line filled or not.
- void StyleResetDefault ()

  Reset the default style to its state at startup.
- void StyleSetUnderline (int style, bool underline)

  Set a style to be underlined or not.
- wxColour StyleGetForeground (int style) const

  Get the foreground colour of a style.
- wxColour StyleGetBackground (int style) const

  Get the background colour of a style.
- bool StyleGetBold (int style) const

  Get is a style bold or not.
- bool StyleGetItalic (int style) const

  Get is a style italic or not.
- int StyleGetSize (int style) const

  Get the size of characters of a style.
- wxString StyleGetFaceName (int style)

  Get the font facename of a style.
- bool StyleGetEOLFilled (int style) const

  Get is a style to have its end of line filled or not.
- bool StyleGetUnderline (int style) const

  Get is a style underlined or not.
- int StyleGetCase (int style) const

  Get is a style mixed case, or to force upper or lower case.
- int StyleGetCharacterSet (int style) const

  Get the character get of the font in a style.
- bool StyleGetVisible (int style) const

  Get is a style visible or not.
- bool StyleGetChangeable (int style) const

  Get is a style changeable or not (read only).
- bool StyleGetHotSpot (int style) const

  Get is a style a hotspot or not.

- void StyleSetCase (int style, int caseForce)

  Set a style to be mixed case, or to force upper or lower case.
- void StyleSetSizeFractional (int style, int caseForce)

  Set the size of characters of a style.
- int StyleGetSizeFractional (int style) const

  Get the size of characters of a style in points multiplied by 100.
- void StyleSetWeight (int style, int weight)

  Set the weight of characters of a style.
- int StyleGetWeight (int style) const

  Get the weight of characters of a style.
- void StyleSetHotSpot (int style, bool hotspot)

  Set a style to be a hotspot or not.
- void SetSelForeground (bool useSetting, const wxColour &fore)

  Set the foreground colour of the main and additional selections and whether to use this setting.
- void SetSelBackground (bool useSetting, const wxColour &back)

  Set the background colour of the main and additional selections and whether to use this setting.
- int GetSelAlpha () const

  Get the alpha of the selection.
- void SetSelAlpha (int alpha)

  Set the alpha of the selection.
- bool GetSelEOLFilled () const

  Is the selection end of line filled?
- void SetSelEOLFilled (bool filled)

  Set the selection to have its end of line filled or not.
- void SetCaretForeground (const wxColour &fore)

  Set the foreground colour of the caret.
- void CmdKeyAssign (int key, int modifiers, int cmd)

  When key+modifier combination km is pressed perform msg.
- void CmdKeyClear (int key, int modifiers)

  When key+modifier combination km is pressed do nothing.
- void CmdKeyClearAll ()

  Drop all key mappings.
- void SetStyleBytes (int length, char ∗styleBytes)

  Set the styles for a segment of the document.
- void StyleSetVisible (int style, bool visible)

  Set a style to be visible or not.
- int GetCaretPeriod () const

  Get the time in milliseconds that the caret is on and off.
- void SetCaretPeriod (int periodMilliseconds)

  Get the time in milliseconds that the caret is on and off.
- void SetWordChars (const wxString &characters)

  Set the set of characters making up words for when moving or selecting by word.
- wxString GetWordChars () const

  Get the set of characters making up words for when moving or selecting by word.
- void BeginUndoAction ()

  Start a sequence of actions that is undone and redone as a unit.
- void EndUndoAction ()

  End a sequence of actions that is undone and redone as a unit.
- void IndicatorSetStyle (int indic, int style)

  Set an indicator to plain, squiggle or TT.
- int IndicatorGetStyle (int indic) const

Retrieve the style of an indicator.

- void IndicatorSetForeground (int indic, const wxColour &fore)

  Set the foreground colour of an indicator.
- wxColour IndicatorGetForeground (int indic) const

  Retrieve the foreground colour of an indicator.
- void IndicatorSetUnder (int indic, bool under)

  Set an indicator to draw under text or over(default).
- bool IndicatorGetUnder (int indic) const

  Retrieve whether indicator drawn under or over text.
- void SetWhitespaceForeground (bool useSetting, const wxColour &fore)

  Set the foreground colour of all whitespace and whether to use this setting.
- void SetWhitespaceBackground (bool useSetting, const wxColour &back)

  Set the background colour of all whitespace and whether to use this setting.
- void SetWhitespaceSize (int size)

  Set the size of the dots used to mark space characters.
- int GetWhitespaceSize () const

  Get the size of the dots used to mark space characters.
- void SetStyleBits (int bits)

  Divide each styling byte into lexical class bits (default: 5) and indicator bits (default: 3).
- int GetStyleBits () const

  Retrieve number of bits in style bytes used to hold the lexical state.
- void SetLineState (int line, int state)

  Used to hold extra styling information for each line.
- int GetLineState (int line) const

  Retrieve the extra styling information for a line.
- int GetMaxLineState () const

  Retrieve the last line number that has line state.
- bool GetCaretLineVisible () const

  Is the background of the line containing the caret in a different colour?
- void SetCaretLineVisible (bool show)

  Display the background of the line containing the caret in a different colour.
- wxColour GetCaretLineBackground () const

  Get the colour of the background of the line containing the caret.
- void SetCaretLineBackground (const wxColour &back)

  Set the colour of the background of the line containing the caret.
- void StyleSetChangeable (int style, bool changeable)

  Set a style to be changeable or not (read only).
- void AutoCompShow (int lenEntered, const wxString &itemList)

  Display a auto-completion list.
- void AutoCompCancel ()

  Remove the auto-completion list from the screen.
- bool AutoCompActive ()

  Is there an auto-completion list visible?
- int AutoCompPosStart ()

  Retrieve the position of the caret when the auto-completion list was displayed.
- void AutoCompComplete ()

  User has selected an item so remove the list and insert the selection.
- void AutoCompStops (const wxString &characterSet)

  Define a set of character that when typed cancel the auto-completion list.
- void AutoCompSetSeparator (int separatorCharacter)

  Change the separator character in the string setting up an auto-completion list.

- int AutoCompGetSeparator () const

  Retrieve the auto-completion list separator character.
- void AutoCompSelect (const wxString &text)

  Select the item in the auto-completion list that starts with a string.
- void AutoCompSetCancelAtStart (bool cancel)

  Should the auto-completion list be cancelled if the user backspaces to a position before where the box was created.
- bool AutoCompGetCancelAtStart () const

  Retrieve whether auto-completion cancelled by backspacing before start.
- void AutoCompSetFillUps (const wxString &characterSet)

  Define a set of characters that when typed will cause the autocompletion to choose the selected item.
- void AutoCompSetChooseSingle (bool chooseSingle)

  Should a single item auto-completion list automatically choose the item.
- bool AutoCompGetChooseSingle () const

  Retrieve whether a single item auto-completion list automatically choose the item.
- void AutoCompSetIgnoreCase (bool ignoreCase)

  Set whether case is significant when performing auto-completion searches.
- bool AutoCompGetIgnoreCase () const

  Retrieve state of ignore case flag.
- void UserListShow (int listType, const wxString &itemList)

  Display a list of strings and send notification when user chooses one.
- void AutoCompSetAutoHide (bool autoHide)

  Set whether or not autocompletion is hidden automatically when nothing matches.
- bool AutoCompGetAutoHide () const

  Retrieve whether or not autocompletion is hidden automatically when nothing matches.
- void AutoCompSetDropRestOfWord (bool dropRestOfWord)

  Set whether or not autocompletion deletes any word characters after the inserted text upon completion.
- bool AutoCompGetDropRestOfWord () const

  Retrieve whether or not autocompletion deletes any word characters after the inserted text upon completion.
- void RegisterImage (int type, const wxBitmap &bmp)

  Register an image for use in autocompletion lists.
- void ClearRegisteredImages ()

  Clear all the registered images.
- int AutoCompGetTypeSeparator () const

  Retrieve the auto-completion list type-separator character.
- void AutoCompSetTypeSeparator (int separatorCharacter)

  Change the type-separator character in the string setting up an auto-completion list.
- void AutoCompSetMaxWidth (int characterCount)

  Set the maximum width, in characters, of auto-completion and user lists.
- int AutoCompGetMaxWidth () const

  Get the maximum width, in characters, of auto-completion and user lists.
- void AutoCompSetMaxHeight (int rowCount)

  Set the maximum height, in rows, of auto-completion and user lists.
- int AutoCompGetMaxHeight () const

  Set the maximum height, in rows, of auto-completion and user lists.
- void SetIndent (int indentSize)

  Set the number of spaces used for one level of indentation.
- int GetIndent () const

  Retrieve indentation size.
- void SetUseTabs (bool useTabs)

  Indentation will only use space characters if useTabs is false, otherwise it will use a combination of tabs and spaces.
- bool GetUseTabs () const

Retrieve whether tabs will be used in indentation.

- void SetLineIndentation (int line, int indentSize)

  Change the indentation of a line to a number of columns.
- int GetLineIndentation (int line) const

  Retrieve the number of columns that a line is indented.
- int GetLineIndentPosition (int line) const

  Retrieve the position before the first non indentation character on a line.
- int GetColumn (int pos) const

  Retrieve the column number of a position, taking tab width into account.
- int CountCharacters (int startPos, int endPos)

  Count characters between two positions.
- void SetUseHorizontalScrollBar (bool show)

  Show or hide the horizontal scroll bar.
- bool GetUseHorizontalScrollBar () const

  Is the horizontal scroll bar visible?
- void SetIndentationGuides (int indentView)

  Show or hide indentation guides.
- int GetIndentationGuides () const

  Are the indentation guides visible?
- void SetHighlightGuide (int column)

  Set the highlighted indentation guide column.
- int GetHighlightGuide () const

  Get the highlighted indentation guide column.
- int GetLineEndPosition (int line) const

  Get the position after the last visible characters on a line.
- int GetCodePage () const

  Get the code page used to interpret the bytes of the document as characters.
- wxColour GetCaretForeground () const

  Get the foreground colour of the caret.
- bool GetReadOnly () const

  In read-only mode?
- void SetCurrentPos (int pos)

  Sets the position of the caret.
- void SetSelectionStart (int pos)

  Sets the position that starts the selection - this becomes the anchor.
- int GetSelectionStart () const

  Returns the position at the start of the selection.
- void SetSelectionEnd (int pos)

  Sets the position that ends the selection - this becomes the currentPosition.
- int GetSelectionEnd () const

  Returns the position at the end of the selection.
- void SetEmptySelection (int pos)

  Set caret to a position, while removing any existing selection.
- void SetPrintMagnification (int magnification)

  Sets the print magnification added to the point size of each style for printing.
- int GetPrintMagnification () const

  Returns the print magnification.
- void SetPrintColourMode (int mode)

  Modify colours when printing for clearer printed text.
- int GetPrintColourMode () const

  Returns the print colour mode.

- int FindText (int minPos, int maxPos, const wxString &text, int flags=0)

  Find some text in the document.
- int FormatRange (bool doDraw, int startPos, int endPos, wxDC *draw, wxDC *target, wxRect renderRect, wxRect pageRect)

  On Windows, will draw the document into a display context such as a printer.
- int GetFirstVisibleLine () const

  Retrieve the display line at the top of the display.
- wxString GetLine (int line) const

  Retrieve the contents of a line.
- int GetLineCount () const

  Returns the number of lines in the document.
- void SetMarginLeft (int pixelWidth)

  Sets the size in pixels of the left margin.
- int GetMarginLeft () const

  Returns the size in pixels of the left margin.
- void SetMarginRight (int pixelWidth)

  Sets the size in pixels of the right margin.
- int GetMarginRight () const

  Returns the size in pixels of the right margin.
- bool GetModify () const

  Is the document different from when it was last saved?
- wxString GetSelectedText ()

  Retrieve the selected text.
- wxString GetTextRange (int startPos, int endPos)

  Retrieve a range of text.
- void HideSelection (bool normal)

  Draw the selection in normal style or with selection highlighted.
- int LineFromPosition (int pos) const

  Retrieve the line containing a position.
- int PositionFromLine (int line) const

  Retrieve the position at the start of a line.
- void LineScroll (int columns, int lines)

  Scroll horizontally and vertically.
- void EnsureCaretVisible ()

  Ensure the caret is visible.
- void ScrollRange (int secondary, int primary)

  Scroll the argument positions and the range between them into view giving priority to the primary position then the secondary position.
- void ReplaceSelection (const wxString &text)

  Replace the selected text with the argument text.
- void SetReadOnly (bool readOnly)

  Set to read only or read write.
- bool CanPaste () const

  Will a paste succeed?
- bool CanUndo () const

  Are there any undoable actions in the undo history?
- void EmptyUndoBuffer ()

  Delete the undo history.
- void Undo ()

  Undo one action in the undo history.
- void Cut ()

Cut the selection to the clipboard.

- void Copy ()

  Copy the selection to the clipboard.

- void Paste ()

  Paste the contents of the clipboard into the document replacing the selection.

- void Clear ()

  Clear the selection.

- void SetText (const wxString &text)

  Replace the contents of the document with the argument text.

- wxString GetText () const

  Retrieve all the text in the document.

- int GetTextLength () const

  Retrieve the number of characters in the document.

- void SetOvertype (bool overtype)

  Set to overtype (true) or insert mode.

- bool GetOvertype () const

  Returns true if overtype mode is active otherwise false is returned.

- void SetCaretWidth (int pixelWidth)

  Set the width of the insert mode caret.

- int GetCaretWidth () const

  Returns the width of the insert mode caret.

- void SetTargetStart (int pos)

  Sets the position that starts the target which is used for updating the document without affecting the scroll position.

- int GetTargetStart () const

  Get the position that starts the target.

- void SetTargetEnd (int pos)

  Sets the position that ends the target which is used for updating the document without affecting the scroll position.

- int GetTargetEnd () const

  Get the position that ends the target.

- int ReplaceTarget (const wxString &text)

  Replace the target text with the argument text.

- int ReplaceTargetRE (const wxString &text)

  Replace the target text with the argument text after \d processing.

- int SearchInTarget (const wxString &text)

  Search for a counted string in the target and set the target to the found range.

- void SetSearchFlags (int flags)

  Set the search flags used by SearchInTarget.

- int GetSearchFlags () const

  Get the search flags used by SearchInTarget.

- void CallTipShow (int pos, const wxString &definition)

  Show a call tip containing a definition near position pos.

- void CallTipCancel ()

  Remove the call tip from the screen.

- bool CallTipActive ()

  Is there an active call tip?

- int CallTipPosAtStart ()

  Retrieve the position where the caret was before displaying the call tip.

- void CallTipSetPosAtStart (int posStart)

  Set the start position in order to change when backspacing removes the calltip.

- void CallTipSetHighlight (int start, int end)

  Highlight a segment of the definition.

- void CallTipSetBackground (const wxColour &back)

  Set the background colour for the call tip.
- void CallTipSetForeground (const wxColour &fore)

  Set the foreground colour for the call tip.
- void CallTipSetForegroundHighlight (const wxColour &fore)

  Set the foreground colour for the highlighted part of the call tip.
- void CallTipUseStyle (int tabSize)

  Enable use of STYLE_CALLTIP and set call tip tab size in pixels.
- void CallTipSetPosition (bool above)

  Set position of calltip, above or below text.
- int VisibleFromDocLine (int line)

  Find the display line of a document line taking hidden lines into account.
- int DocLineFromVisible (int lineDisplay)

  Find the document line of a display line taking hidden lines into account.
- int WrapCount (int line)

  The number of display lines needed to wrap a document line.
- void SetFoldLevel (int line, int level)

  Set the fold level of a line.
- int GetFoldLevel (int line) const

  Retrieve the fold level of a line.
- int GetLastChild (int line, int level) const

  Find the last child line of a header line.
- int GetFoldParent (int line) const

  Find the parent line of a child line.
- void ShowLines (int lineStart, int lineEnd)

  Make a range of lines visible.
- void HideLines (int lineStart, int lineEnd)

  Make a range of lines invisible.
- bool GetLineVisible (int line) const

  Is a line visible?
- bool GetAllLinesVisible () const

  Are all lines visible?
- void SetFoldExpanded (int line, bool expanded)

  Show the children of a header line.
- bool GetFoldExpanded (int line) const

  Is a header line expanded?
- void ToggleFold (int line)

  Switch a header line between expanded and contracted.
- void FoldLine (int line, int action)

  Expand or contract a fold header.
- void FoldChildren (int line, int action)

  Expand or contract a fold header and its children.
- void ExpandChildren (int line, int level)

  Expand a fold header and all children.
- void FoldAll (int action)

  Expand or contract all fold headers.
- void EnsureVisible (int line)

  Ensure a particular line is visible by expanding any header line hiding it.
- void SetAutomaticFold (int automaticFold)

  Set automatic folding behaviours.
- int GetAutomaticFold () const

Get automatic folding behaviours.

- void SetFoldFlags (int flags)

  Set some style options for folding.
- void EnsureVisibleEnforcePolicy (int line)

  Ensure a particular line is visible by expanding any header line hiding it.
- void SetTabIndents (bool tabIndents)

  Sets whether a tab pressed when caret is within indentation indents.
- bool GetTabIndents () const

  Does a tab pressed when caret is within indentation indent?
- void SetBackSpaceUnIndents (bool bsUnIndents)

  Sets whether a backspace pressed when caret is within indentation unindents.
- bool GetBackSpaceUnIndents () const

  Does a backspace pressed when caret is within indentation unindent?
- void SetMouseDwellTime (int periodMilliseconds)

  Sets the time the mouse must sit still to generate a mouse dwell event.
- int GetMouseDwellTime () const

  Retrieve the time the mouse must sit still to generate a mouse dwell event.
- int WordStartPosition (int pos, bool onlyWordCharacters)

  Get position of start of word.
- int WordEndPosition (int pos, bool onlyWordCharacters)

  Get position of end of word.
- void SetWrapMode (int mode)

  Sets whether text is word wrapped.
- int GetWrapMode () const

  Retrieve whether text is word wrapped.
- void SetWrapVisualFlags (int wrapVisualFlags)

  Set the display mode of visual flags for wrapped lines.
- int GetWrapVisualFlags () const

  Retrive the display mode of visual flags for wrapped lines.
- void SetWrapVisualFlagsLocation (int wrapVisualFlagsLocation)

  Set the location of visual flags for wrapped lines.
- int GetWrapVisualFlagsLocation () const

  Retrive the location of visual flags for wrapped lines.
- void SetWrapStartIndent (int indent)

  Set the start indent for wrapped lines.
- int GetWrapStartIndent () const

  Retrive the start indent for wrapped lines.
- void SetWrapIndentMode (int mode)

  Sets how wrapped sublines are placed.
- int GetWrapIndentMode () const

  Retrieve how wrapped sublines are placed.
- void SetLayoutCache (int mode)

  Sets the degree of caching of layout information.
- int GetLayoutCache () const

  Retrieve the degree of caching of layout information.
- void SetScrollWidth (int pixelWidth)

  Sets the document width assumed for scrolling.
- int GetScrollWidth () const

  Retrieve the document width assumed for scrolling.
- void SetScrollWidthTracking (bool tracking)

  Sets whether the maximum width line displayed is used to set scroll width.

- bool GetScrollWidthTracking () const

  Retrieve whether the scroll width tracks wide lines.
- int TextWidth (int style, const wxString &text)

  Measure the pixel width of some text in a particular style.
- void SetEndAtLastLine (bool endAtLastLine)

  Sets the scroll range so that maximum scroll position has the last line at the bottom of the view (default).
- bool GetEndAtLastLine () const

  Retrieve whether the maximum scroll position has the last line at the bottom of the view.
- int TextHeight (int line)

  Retrieve the height of a particular line of text in pixels.
- void SetUseVerticalScrollBar (bool show)

  Show or hide the vertical scroll bar.
- bool GetUseVerticalScrollBar () const

  Is the vertical scroll bar visible?
- void AppendText (const wxString &text)

  Append a string to the end of the document without changing the selection.
- bool GetTwoPhaseDraw () const

  Is drawing done in two phases with backgrounds drawn before faoregrounds?
- void SetTwoPhaseDraw (bool twoPhase)

  In twoPhaseDraw mode, drawing is performed in two phases, first the background and then the foreground.
- void SetFirstVisibleLine (int lineDisplay)

  Scroll so that a display line is at the top of the display.
- void SetMultiPaste (int multiPaste)

  Change the effect of pasting when there are multiple selections.
- int GetMultiPaste () const

  Retrieve the effect of pasting when there are multiple selections.
- wxString GetTag (int tagNumber) const

  Retrieve the value of a tag from a regular expression search.
- void TargetFromSelection ()

  Make the target range start and end be the same as the selection range start and end.
- void LinesJoin ()

  Join the lines in the target.
- void LinesSplit (int pixelWidth)

  Split the lines in the target into lines that are less wide than pixelWidth where possible.
- void SetFoldMarginColour (bool useSetting, const wxColour &back)

  Set the colours used as a chequerboard pattern in the fold margin.
- void SetFoldMarginHiColour (bool useSetting, const wxColour &fore)
- void LineDown ()

  Move caret down one line.
- void LineDownExtend ()

  Move caret down one line extending selection to new caret position.
- void LineUp ()

  Move caret up one line.
- void LineUpExtend ()

  Move caret up one line extending selection to new caret position.
- void CharLeft ()

  Move caret left one character.
- void CharLeftExtend ()

  Move caret left one character extending selection to new caret position.
- void CharRight ()

  Move caret right one character.

- void CharRightExtend ()

  Move caret right one character extending selection to new caret position.
- void WordLeft ()

  Move caret left one word.
- void WordLeftExtend ()

  Move caret left one word extending selection to new caret position.
- void WordRight ()

  Move caret right one word.
- void WordRightExtend ()

  Move caret right one word extending selection to new caret position.
- void Home ()

  Move caret to first position on line.
- void HomeExtend ()

  Move caret to first position on line extending selection to new caret position.
- void LineEnd ()

  Move caret to last position on line.
- void LineEndExtend ()

  Move caret to last position on line extending selection to new caret position.
- void DocumentStart ()

  Move caret to first position in document.
- void DocumentStartExtend ()

  Move caret to first position in document extending selection to new caret position.
- void DocumentEnd ()

  Move caret to last position in document.
- void DocumentEndExtend ()

  Move caret to last position in document extending selection to new caret position.
- void PageUp ()

  Move caret one page up.
- void PageUpExtend ()

  Move caret one page up extending selection to new caret position.
- void PageDown ()

  Move caret one page down.
- void PageDownExtend ()

  Move caret one page down extending selection to new caret position.
- void EditToggleOvertype ()

  Switch from insert to overtype mode or the reverse.
- void Cancel ()

  Cancel any modes such as call tip or auto-completion list display.
- void DeleteBack ()

  Delete the selection or if no selection, the character before the caret.
- void Tab ()

  If selection is empty or all on one line replace the selection with a tab character.
- void BackTab ()

  Dedent the selected lines.
- void NewLine ()

  Insert a new line, may use a CRLF, CR or LF depending on EOL mode.
- void FormFeed ()

  Insert a Form Feed character.
- void VCHome ()

  Move caret to before first visible character on line.
- void VCHomeExtend ()

Like VCHome but extending selection to new caret position.

- void ZoomIn ()

  Magnify the displayed text by increasing the sizes by 1 point.
- void ZoomOut ()

  Make the displayed text smaller by decreasing the sizes by 1 point.
- void DelWordLeft ()

  Delete the word to the left of the caret.
- void DelWordRight ()

  Delete the word to the right of the caret.
- void DelWordRightEnd ()

  Delete the word to the right of the caret, but not the trailing non-word characters.
- void LineCut ()

  Cut the line containing the caret.
- void LineDelete ()

  Delete the line containing the caret.
- void LineTranspose ()

  Switch the current line with the previous.
- void LineDuplicate ()

  Duplicate the current line.
- void LowerCase ()

  Transform the selection to lower case.
- void UpperCase ()

  Transform the selection to upper case.
- void LineScrollDown ()

  Scroll the document down, keeping the caret visible.
- void LineScrollUp ()

  Scroll the document up, keeping the caret visible.
- void DeleteBackNotLine ()

  Delete the selection or if no selection, the character before the caret.
- void HomeDisplay ()

  Move caret to first position on display line.
- void HomeDisplayExtend ()

  Move caret to first position on display line extending selection to new caret position.
- void LineEndDisplay ()

  Move caret to last position on display line.
- void LineEndDisplayExtend ()

  Move caret to last position on display line extending selection to new caret position.
- void HomeWrap ()

  These are like their namesakes Home(Extend)?, LineEnd(Extend)?, VCHome(Extend)? except they behave differently when word-wrap is enabled: They go first to the start / end of the display line, like (Home|LineEnd)Display The difference is that, the cursor is already at the point, it goes on to the start or end of the document line, as appropriate for (Home|LineEnd|VCHome)(Extend)?.
- void HomeWrapExtend ()
- void LineEndWrap ()
- void LineEndWrapExtend ()
- void VCHomeWrap ()
- void VCHomeWrapExtend ()
- void LineCopy ()

  Copy the line containing the caret.
- void MoveCaretInsideView ()

  Move the caret inside current view if it's not there already.
- int LineLength (int line) const

How many characters are on a line, including end of line characters?

- void BraceHighlight (int pos1, int pos2)

  Highlight the characters at two positions.
- void BraceHighlightIndicator (bool useBraceHighlightIndicator, int indicator)

  Use specified indicator to highlight matching braces instead of changing their style.
- void BraceBadLight (int pos)

  Highlight the character at a position indicating there is no matching brace.
- void BraceBadLightIndicator (bool useBraceBadLightIndicator, int indicator)

  Use specified indicator to highlight non matching brace instead of changing its style.
- int BraceMatch (int pos)

  Find the position of a matching brace or INVALID_POSITION if no match.
- bool GetViewEOL () const

  Are the end of line characters visible?
- void SetViewEOL (bool visible)

  Make the end of line characters visible or invisible.
- void * GetDocPointer ()

  Retrieve a pointer to the document object.
- void SetDocPointer (void *docPointer)

  Change the document object used.
- void SetModEventMask (int mask)

  Set which document modification events are sent to the container.
- int GetEdgeColumn () const

  Retrieve the column number which text should be kept within.
- void SetEdgeColumn (int column)

  Set the column number of the edge.
- int GetEdgeMode () const

  Retrieve the edge highlight mode.
- void SetEdgeMode (int mode)

  The edge may be displayed by a line (EDGE_LINE) or by highlighting text that goes beyond it (EDGE_BACKGRO↩ UND) or not displayed at all (EDGE_NONE).
- wxColour GetEdgeColour () const

  Retrieve the colour used in edge indication.
- void SetEdgeColour (const wxColour &edgeColour)

  Change the colour used in edge indication.
- void SearchAnchor ()

  Sets the current caret position to be the search anchor.
- int SearchNext (int flags, const wxString &text)

  Find some text starting at the search anchor.
- int SearchPrev (int flags, const wxString &text)

  Find some text starting at the search anchor and moving backwards.
- int LinesOnScreen () const

  Retrieves the number of lines completely visible.
- void UsePopUp (bool allowPopUp)

  Set whether a pop up menu is displayed automatically when the user presses the wrong mouse button.
- bool SelectionIsRectangle () const

  Is the selection rectangular? The alternative is the more common stream selection.
- void SetZoom (int zoom)

  Set the zoom level.
- int GetZoom () const

  Retrieve the zoom level.
- void * CreateDocument ()

Create a new document object.

- void AddRefDocument (void *docPointer)

  Extend life of document.
- void ReleaseDocument (void *docPointer)

  Release a reference to the document, deleting document if it fades to black.
- int GetModEventMask () const

  Get which document modification events are sent to the container.
- void SetSTCFocus (bool focus)

  Change internal focus flag.
- bool GetSTCFocus () const

  Get internal focus flag.
- void SetStatus (int statusCode)

  Change error status - 0 = OK.
- int GetStatus () const

  Get error status.
- void SetMouseDownCaptures (bool captures)

  Set whether the mouse is captured when its button is pressed.
- bool GetMouseDownCaptures () const

  Get whether mouse gets captured.
- void SetSTCCursor (int cursorType)

  Sets the cursor to one of the SC_CURSOR values.*
- int GetSTCCursor () const

  Get cursor type.
- void SetControlCharSymbol (int symbol)

  Change the way control characters are displayed: If symbol is < 32, keep the drawn way, else, use the given character.
- int GetControlCharSymbol () const

  Get the way control characters are displayed.
- void WordPartLeft ()

  Move to the previous change in capitalisation.
- void WordPartLeftExtend ()

  Move to the previous change in capitalisation extending selection to new caret position.
- void WordPartRight ()

  Move to the change next in capitalisation.
- void WordPartRightExtend ()

  Move to the next change in capitalisation extending selection to new caret position.
- void SetVisiblePolicy (int visiblePolicy, int visibleSlop)

  Set the way the display area is determined when a particular line is to be moved to by Find, FindNext, GotoLine, etc.
- void DelLineLeft ()

  Delete back from the current position to the start of the line.
- void DelLineRight ()

  Delete forwards from the current position to the end of the line.
- void SetXOffset (int newOffset)

  Get and Set the xOffset (ie, horizontal scroll position).
- int GetXOffset () const
- void ChooseCaretX ()

  Set the last x chosen value to be the caret x position.
- void SetXCaretPolicy (int caretPolicy, int caretSlop)

  Set the way the caret is kept visible when going sideways.
- void SetYCaretPolicy (int caretPolicy, int caretSlop)

  Set the way the line the caret is on is kept visible.
- void SetPrintWrapMode (int mode)

Set printing to line wrapped (SC_WRAP_WORD) or not line wrapped (SC_WRAP_NONE).

- int GetPrintWrapMode () const

  Is printing line wrapped?

- void SetHotspotActiveForeground (bool useSetting, const wxColour &fore)

  Set a fore colour for active hotspots.

- wxColour GetHotspotActiveForeground () const

  Get the fore colour for active hotspots.

- void SetHotspotActiveBackground (bool useSetting, const wxColour &back)

  Set a back colour for active hotspots.

- wxColour GetHotspotActiveBackground () const

  Get the back colour for active hotspots.

- void SetHotspotActiveUnderline (bool underline)

  Enable / Disable underlining active hotspots.

- bool GetHotspotActiveUnderline () const

  Get whether underlining for active hotspots.

- void SetHotspotSingleLine (bool singleLine)

  Limit hotspots to single line so hotspots on two lines don't merge.

- bool GetHotspotSingleLine () const

  Get the HotspotSingleLine property.

- void ParaDown ()

  Move caret between paragraphs (delimited by empty lines).

- void ParaDownExtend ()
- void ParaUp ()
- void ParaUpExtend ()
- int PositionBefore (int pos)

  Given a valid document position, return the previous position taking code page into account.

- int PositionAfter (int pos)

  Given a valid document position, return the next position taking code page into account.

- int PositionRelative (int pos, int relative)

  Given a valid document position, return a position that differs in a number of characters.

- void CopyRange (int start, int end)

  Copy a range of text to the clipboard.

- void CopyText (int length, const wxString &text)

  Copy argument text to the clipboard.

- void SetSelectionMode (int mode)

  Set the selection mode to stream (SC_SEL_STREAM) or rectangular (SC_SEL_RECTANGLE/SC_SEL_THIN) or by lines (SC_SEL_LINES).

- int GetSelectionMode () const

  Get the mode of the current selection.

- int GetLineSelStartPosition (int line)

  Retrieve the position of the start of the selection at the given line (INVALID_POSITION if no selection on this line).

- int GetLineSelEndPosition (int line)

  Retrieve the position of the end of the selection at the given line (INVALID_POSITION if no selection on this line).

- void LineDownRectExtend ()

  Move caret down one line, extending rectangular selection to new caret position.

- void LineUpRectExtend ()

  Move caret up one line, extending rectangular selection to new caret position.

- void CharLeftRectExtend ()

  Move caret left one character, extending rectangular selection to new caret position.

- void CharRightRectExtend ()

  Move caret right one character, extending rectangular selection to new caret position.

- void HomeRectExtend ()

  Move caret to first position on line, extending rectangular selection to new caret position.
- void VCHomeRectExtend ()

  Move caret to before first visible character on line.
- void LineEndRectExtend ()

  Move caret to last position on line, extending rectangular selection to new caret position.
- void PageUpRectExtend ()

  Move caret one page up, extending rectangular selection to new caret position.
- void PageDownRectExtend ()

  Move caret one page down, extending rectangular selection to new caret position.
- void StutteredPageUp ()

  Move caret to top of page, or one page up if already at top of page.
- void StutteredPageUpExtend ()

  Move caret to top of page, or one page up if already at top of page, extending selection to new caret position.
- void StutteredPageDown ()

  Move caret to bottom of page, or one page down if already at bottom of page.
- void StutteredPageDownExtend ()

  Move caret to bottom of page, or one page down if already at bottom of page, extending selection to new caret position.
- void WordLeftEnd ()

  Move caret left one word, position cursor at end of word.
- void WordLeftEndExtend ()

  Move caret left one word, position cursor at end of word, extending selection to new caret position.
- void WordRightEnd ()

  Move caret right one word, position cursor at end of word.
- void WordRightEndExtend ()

  Move caret right one word, position cursor at end of word, extending selection to new caret position.
- void SetWhitespaceChars (const wxString &characters)

  Set the set of characters making up whitespace for when moving or selecting by word.
- wxString GetWhitespaceChars () const

  Get the set of characters making up whitespace for when moving or selecting by word.
- void SetPunctuationChars (const wxString &characters)

  Set the set of characters making up punctuation characters Should be called after SetWordChars.
- wxString GetPunctuationChars () const

  Get the set of characters making up punctuation characters.
- void SetCharsDefault ()

  Reset the set of characters for whitespace and word characters to the defaults.
- int AutoCompGetCurrent () const

  Get currently selected item position in the auto-completion list.
- void AutoCompSetCaseInsensitiveBehaviour (int behaviour)

  Set auto-completion case insensitive behaviour to either prefer case-sensitive matches or have no preference.
- int AutoCompGetCaseInsensitiveBehaviour () const

  Get auto-completion case insensitive behaviour.
- void AutoCompSetOrder (int order)

  Set the way autocompletion lists are ordered.
- int AutoCompGetOrder () const

  Get the way autocompletion lists are ordered.
- void Allocate (int bytes)

  Enlarge the document to a particular size of text bytes.
- int FindColumn (int line, int column)

  Find the position of a column on a line taking into account tabs and multi-byte characters.

- int GetCaretSticky () const

  Can the caret preferred x position only be changed by explicit movement commands?
- void SetCaretSticky (int useCaretStickyBehaviour)

  Stop the caret preferred x position changing when the user types.
- void ToggleCaretSticky ()

  Switch between sticky and non-sticky: meant to be bound to a key.
- void SetPasteConvertEndings (bool convert)

  Enable/Disable convert-on-paste for line endings.
- bool GetPasteConvertEndings () const

  Get convert-on-paste setting.
- void SelectionDuplicate ()

  Duplicate the selection.
- void SetCaretLineBackAlpha (int alpha)

  Set background alpha of the caret line.
- int GetCaretLineBackAlpha () const

  Get the background alpha of the caret line.
- void SetCaretStyle (int caretStyle)

  Set the style of the caret to be drawn.
- int GetCaretStyle () const

  Returns the current style of the caret.
- void SetIndicatorCurrent (int indicator)

  Set the indicator used for IndicatorFillRange and IndicatorClearRange.
- int GetIndicatorCurrent () const

  Get the current indicator.
- void SetIndicatorValue (int value)

  Set the value used for IndicatorFillRange.
- int GetIndicatorValue () const

  Get the current indicator value.
- void IndicatorFillRange (int position, int fillLength)

  Turn a indicator on over a range.
- void IndicatorClearRange (int position, int clearLength)

  Turn a indicator off over a range.
- int IndicatorAllOnFor (int position)

  Are any indicators present at position?
- int IndicatorValueAt (int indicator, int position)

  What value does a particular indicator have at at a position?
- int IndicatorStart (int indicator, int position)

  Where does a particular indicator start?
- int IndicatorEnd (int indicator, int position)

  Where does a particular indicator end?
- void SetPositionCacheSize (int size)

  Set number of entries in position cache.
- int GetPositionCacheSize () const

  How many entries are allocated to the position cache?
- void CopyAllowLine ()

  Copy the selection, if selection empty copy the line with the caret.
- const char * GetCharacterPointer () const

  Compact the document buffer and return a read-only pointer to the characters in the document.
- const char * GetRangePointer (int position, int rangeLength) const

  Return a read-only pointer to a range of characters in the document.
- int GetGapPosition () const

Return a position which, to avoid performance costs, should not be within the range of a call to GetRangePointer.

- void SetKeysUnicode (bool keysUnicode)

  Always interpret keyboard input as Unicode.
- bool GetKeysUnicode () const

  Are keys always interpreted as Unicode?
- void IndicatorSetAlpha (int indicator, int alpha)

  Set the alpha fill colour of the given indicator.
- int IndicatorGetAlpha (int indicator) const

  Get the alpha fill colour of the given indicator.
- void IndicatorSetOutlineAlpha (int indicator, int alpha)

  Set the alpha outline colour of the given indicator.
- int IndicatorGetOutlineAlpha (int indicator) const

  Get the alpha outline colour of the given indicator.
- void SetExtraAscent (int extraAscent)

  Set extra ascent for each line.
- int GetExtraAscent () const

  Get extra ascent for each line.
- void SetExtraDescent (int extraDescent)

  Set extra descent for each line.
- int GetExtraDescent () const

  Get extra descent for each line.
- int GetMarkerSymbolDefined (int markerNumber)

  Which symbol was defined for markerNumber with MarkerDefine.
- void MarginSetText (int line, const wxString &text)

  Set the text in the text margin for a line.
- wxString MarginGetText (int line) const

  Get the text in the text margin for a line.
- void MarginSetStyle (int line, int style)

  Set the style number for the text margin for a line.
- int MarginGetStyle (int line) const

  Get the style number for the text margin for a line.
- void MarginSetStyles (int line, const wxString &styles)

  Set the style in the text margin for a line.
- wxString MarginGetStyles (int line) const

  Get the styles in the text margin for a line.
- void MarginTextClearAll ()

  Clear the margin text on all lines.
- void MarginSetStyleOffset (int style)

  Get the start of the range of style numbers used for margin text.
- int MarginGetStyleOffset () const

  Get the start of the range of style numbers used for margin text.
- void SetMarginOptions (int marginOptions)

  Set the margin options.
- int GetMarginOptions () const

  Get the margin options.
- void AnnotationSetText (int line, const wxString &text)

  Set the annotation text for a line.
- wxString AnnotationGetText (int line) const

  Get the annotation text for a line.
- void AnnotationSetStyle (int line, int style)

  Set the style number for the annotations for a line.

- int AnnotationGetStyle (int line) const

  Get the style number for the annotations for a line.
- void AnnotationSetStyles (int line, const wxString &styles)

  Set the annotation styles for a line.
- wxString AnnotationGetStyles (int line) const

  Get the annotation styles for a line.
- int AnnotationGetLines (int line) const

  Get the number of annotation lines for a line.
- void AnnotationClearAll ()

  Clear the annotations from all lines.
- void AnnotationSetVisible (int visible)

  Set the visibility for the annotations for a view.
- int AnnotationGetVisible () const

  Get the visibility for the annotations for a view.
- void AnnotationSetStyleOffset (int style)

  Get the start of the range of style numbers used for annotations.
- int AnnotationGetStyleOffset () const

  Get the start of the range of style numbers used for annotations.
- void ReleaseAllExtendedStyles ()

  Release all extended (>255) style numbers.
- int AllocateExtendedStyles (int numberStyles)

  Allocate some extended (>255) style numbers and return the start of the range.
- void AddUndoAction (int token, int flags)

  Add a container action to the undo stack.
- int CharPositionFromPoint (int x, int y)

  Find the position of a character from a point within the window.
- int CharPositionFromPointClose (int x, int y)

  Find the position of a character from a point within the window.
- void SetMouseSelectionRectangularSwitch (bool mouseSelectionRectangularSwitch)

  Set whether switching to rectangular mode while selecting with the mouse is allowed.
- bool GetMouseSelectionRectangularSwitch () const

  Whether switching to rectangular mode while selecting with the mouse is allowed.
- void SetMultipleSelection (bool multipleSelection)

  Set whether multiple selections can be made.
- bool GetMultipleSelection () const

  Whether multiple selections can be made.
- void SetAdditionalSelectionTyping (bool additionalSelectionTyping)

  Set whether typing can be performed into multiple selections.
- bool GetAdditionalSelectionTyping () const

  Whether typing can be performed into multiple selections.
- void SetAdditionalCaretsBlink (bool additionalCaretsBlink)

  Set whether additional carets will blink.
- bool GetAdditionalCaretsBlink () const

  Whether additional carets will blink.
- void SetAdditionalCaretsVisible (bool additionalCaretsBlink)

  Set whether additional carets are visible.
- bool GetAdditionalCaretsVisible () const

  Whether additional carets are visible.
- int GetSelections () const

  How many selections are there?
- bool GetSelectionEmpty () const

Is every selected range empty?

- void ClearSelections ()

  Clear selections to a single empty stream selection.
- int AddSelection (int caret, int anchor)

  Add a selection.
- void DropSelectionN (int selection)

  Drop one selection.
- void SetMainSelection (int selection)

  Set the main selection.
- int GetMainSelection () const

  Which selection is the main selection.
- void SetSelectionNCaret (int selection, int pos)
- int GetSelectionNCaret (int selection) const
- void SetSelectionNAnchor (int selection, int posAnchor)
- int GetSelectionNAnchor (int selection) const
- void SetSelectionNCaretVirtualSpace (int selection, int space)
- int GetSelectionNCaretVirtualSpace (int selection) const
- void SetSelectionNAnchorVirtualSpace (int selection, int space)
- int GetSelectionNAnchorVirtualSpace (int selection) const
- void SetSelectionNStart (int selection, int pos)

  Sets the position that starts the selection - this becomes the anchor.
- int GetSelectionNStart (int selection) const

  Returns the position at the start of the selection.
- void SetSelectionNEnd (int selection, int pos)

  Sets the position that ends the selection - this becomes the currentPosition.
- int GetSelectionNEnd (int selection) const

  Returns the position at the end of the selection.
- void SetRectangularSelectionCaret (int pos)
- int GetRectangularSelectionCaret () const
- void SetRectangularSelectionAnchor (int posAnchor)
- int GetRectangularSelectionAnchor () const
- void SetRectangularSelectionCaretVirtualSpace (int space)
- int GetRectangularSelectionCaretVirtualSpace () const
- void SetRectangularSelectionAnchorVirtualSpace (int space)
- int GetRectangularSelectionAnchorVirtualSpace () const
- void SetVirtualSpaceOptions (int virtualSpaceOptions)
- int GetVirtualSpaceOptions () const
- void SetRectangularSelectionModifier (int modifier)

  On GTK+, allow selecting the modifier key to use for mouse-based rectangular selection.
- int GetRectangularSelectionModifier () const

  Get the modifier key used for rectangular selection.
- void SetAdditionalSelForeground (const wxColour &fore)

  Set the foreground colour of additional selections.
- void SetAdditionalSelBackground (const wxColour &back)

  Set the background colour of additional selections.
- void SetAdditionalSelAlpha (int alpha)

  Set the alpha of the selection.
- int GetAdditionalSelAlpha () const

  Get the alpha of the selection.
- void SetAdditionalCaretForeground (const wxColour &fore)

  Set the foreground colour of additional carets.
- wxColour GetAdditionalCaretForeground () const

Get the foreground colour of additional carets.

- void RotateSelection ()

  Set the main selection to the next selection.
- void SwapMainAnchorCaret ()

  Swap that caret and anchor of the main selection.
- int ChangeLexerState (int start, int end)

  Indicate that the internal state of a lexer has changed over a range and therefore there may be a need to redraw.
- int ContractedFoldNext (int lineStart)

  Find the next line at or after lineStart that is a contracted fold header line.
- void VerticalCentreCaret ()

  Centre current line in window.
- void MoveSelectedLinesUp ()

  Move the selected lines up one line, shifting the line above after the selection.
- void MoveSelectedLinesDown ()

  Move the selected lines down one line, shifting the line below before the selection.
- void SetIdentifier (int identifier)

  Set the identifier reported as idFrom in notification messages.
- int GetIdentifier () const

  Get the identifier.
- void RGBAImageSetWidth (int width)

  Set the width for future RGBA image data.
- void RGBAImageSetHeight (int height)

  Set the height for future RGBA image data.
- void RGBAImageSetScale (int scalePercent)

  Set the scale factor in percent for future RGBA image data.
- void MarkerDefineRGBAImage (int markerNumber, const unsigned char ∗pixels)

  Define a marker from RGBA data.
- void RegisterRGBAImage (int type, const unsigned char ∗pixels)

  Register an RGBA image for use in autocompletion lists.
- void ScrollToStart ()

  Scroll to start of document.
- void ScrollToEnd ()

  Scroll to end of document.
- void SetTechnology (int technology)

  Set the technology used.
- int GetTechnology () const

  Get the tech.
- void ∗ CreateLoader (int bytes) const

  Create an ILoader∗.
- void VCHomeDisplay ()

  Move caret to before first visible character on display line.
- void VCHomeDisplayExtend ()

  Like VCHomeDisplay but extending selection to new caret position.
- bool GetCaretLineVisibleAlways () const

  Is the caret line always visible?
- void SetCaretLineVisibleAlways (bool alwaysVisible)

  Sets the caret line to always visible.
- void SetLineEndTypesAllowed (int lineEndBitSet)

  Set the line end types that the application wants to use.
- int GetLineEndTypesAllowed () const

  Get the line end types currently allowed.

- int GetLineEndTypesActive () const

  Get the line end types currently recognised.
- void SetRepresentation (const wxString &encodedCharacter, const wxString &representation)

  Set the way a character is drawn.
- wxString GetRepresentation (const wxString &encodedCharacter) const

  Set the way a character is drawn.
- void ClearRepresentation (const wxString &encodedCharacter)

  Remove a character representation.
- void StartRecord ()

  Start notifying the container of all key presses and commands.
- void StopRecord ()

  Stop notifying the container of all key presses and commands.
- void SetLexer (int lexer)

  Set the lexing language of the document.
- int GetLexer () const

  Retrieve the lexing language of the document.
- void Colourise (int start, int end)

  Colourise a segment of the document using the current lexing language.
- void SetProperty (const wxString &key, const wxString &value)

  Set up a value that may be used by a lexer for some optional feature.
- void SetKeyWords (int keywordSet, const wxString &keyWords)

  Set up the key words used by the lexer.
- void SetLexerLanguage (const wxString &language)

  Set the lexing language of the document based on string name.
- wxString GetProperty (const wxString &key)

  Retrieve a 'property' value previously set with SetProperty.
- wxString GetPropertyExpanded (const wxString &key)

  Retrieve a 'property' value previously set with SetProperty, with '$()' variable replacement on returned buffer.
- int GetPropertyInt (const wxString &key) const

  Retrieve a 'property' value previously set with SetProperty, interpreted as an int AFTER any '$()' variable replacement.
- int GetStyleBitsNeeded () const

  Retrieve the number of bits the current lexer needs for styling.
- void * PrivateLexerCall (int operation, void *pointer)

  For private communication between an application and a known lexer.
- wxString PropertyNames () const

  Retrieve a '
  ' separated list of properties understood by the current lexer.
- int PropertyType (const wxString &name)

  Retrieve the type of a property.
- wxString DescribeProperty (const wxString &name) const

  Describe a property.
- wxString DescribeKeyWordSets () const

  Retrieve a '
  ' separated list of descriptions of the keyword sets understood by the current lexer.
- int GetLineEndTypesSupported () const

  Bit set of LineEndType enumertion for which line ends beyond the standard LF, CR, and CRLF are supported by the lexer.
- int AllocateSubStyles (int styleBase, int numberStyles)

  Allocate a set of sub styles for a particular base style, returning start of range.
- int GetSubStylesStart (int styleBase) const

  The starting style number for the sub styles associated with a base style.

- int GetSubStylesLength (int styleBase) const

  The number of sub styles associated with a base style.
- int GetStyleFromSubStyle (int subStyle) const

  For a sub style, return the base style, else return the argument.
- int GetPrimaryStyleFromStyle (int style) const

  For a secondary style, return the primary style, else return the argument.
- void FreeSubStyles ()

  Free allocated sub styles.
- void SetIdentifiers (int style, const wxString &identifiers)

  Set the identifiers that are shown in a particular style.
- int DistanceToSecondaryStyles () const

  Where styles are duplicated by a feature such as active/inactive code return the distance between the two types.
- wxString GetSubStyleBases () const

  Get the set of base styles that can be extended with sub styles.
- int GetCurrentLine ()

  Returns the line number of the line with the caret.
- void StyleSetSpec (int styleNum, const wxString &spec)

  Extract style settings from a spec-string which is composed of one or more of the following comma separated elements:
- wxFont StyleGetFont (int style)

  Get the font of a style.
- void StyleSetFont (int styleNum, wxFont &font)

  Set style size, face, bold, italic, and underline attributes from a wxFont's attributes.
- void StyleSetFontAttr (int styleNum, int size, const wxString &faceName, bool bold, bool italic, bool underline, wxFontEncoding encoding=wxFONTENCODING_DEFAULT)

  Set all font style attributes at once.
- void StyleSetCharacterSet (int style, int characterSet)

  Set the character set of the font in a style.
- void StyleSetFontEncoding (int style, wxFontEncoding encoding)

  Set the font encoding to be used by a style.
- void CmdKeyExecute (int cmd)

  Perform one of the operations defined by the wxSTC_CMD_∗ constants.
- void SetMargins (int left, int right)

  Set the left and right margin in the edit area, measured in pixels.
- wxPoint PointFromPosition (int pos)

  Retrieve the point in the window where a position is displayed.
- void ScrollToLine (int line)

  Scroll enough to make the given line visible.
- void ScrollToColumn (int column)

  Scroll enough to make the given column visible.
- wxIntPtr SendMsg (int msg, wxUIntPtr wp=0, wxIntPtr lp=0) const

  Send a message to Scintilla.
- void SetVScrollBar (wxScrollBar ∗bar)

  Set the vertical scrollbar to use instead of the ont that's built-in.
- void SetHScrollBar (wxScrollBar ∗bar)

  Set the horizontal scrollbar to use instead of the ont that's built-in.
- bool GetLastKeydownProcessed ()

  Can be used to prevent the EVT_CHAR handler from adding the char.
- void SetLastKeydownProcessed (bool val)
- bool SaveFile (const wxString &filename)

  Write the contents of the editor to filename.

- bool LoadFile (const wxString &filename)

  Load the contents of filename into the editor.
- wxDragResult DoDragEnter (wxCoord x, wxCoord y, wxDragResult defaultRes)

  Allow for simulating a DnD DragEnter.
- wxDragResult DoDragOver (wxCoord x, wxCoord y, wxDragResult defaultRes)

  Allow for simulating a DnD DragOver.
- void DoDragLeave ()

  Allow for simulating a DnD DragLeave.
- bool DoDropText (long x, long y, const wxString &data)

  Allow for simulating a DnD DropText.
- void AnnotationClearLine (int line)

  Clear annotations from the given line.
- void AddTextRaw (const char *text, int length=-1)

  Add text to the document at current position.
- void InsertTextRaw (int pos, const char *text)

  Insert string at a position.
- wxCharBuffer GetCurLineRaw (int *linePos=NULL)

  Retrieve the text of the line containing the caret.
- wxCharBuffer GetLineRaw (int line)

  Retrieve the contents of a line.
- wxCharBuffer GetSelectedTextRaw ()

  Retrieve the selected text.
- wxCharBuffer GetTextRangeRaw (int startPos, int endPos)

  Retrieve a range of text.
- void SetTextRaw (const char *text)

  Replace the contents of the document with the argument text.
- wxCharBuffer GetTextRaw ()

  Retrieve all the text in the document.
- void AppendTextRaw (const char *text, int length=-1)

  Append a string to the end of the document without changing the selection.
- virtual void WriteText (const wxString &text)

  Writes the text into the text control at the current insertion position.
- virtual void Remove (long from, long to)

  Removes the text starting at the first given position up to (but not including) the character at the last position.
- virtual void Replace (long from, long to, const wxString &text)

  Replaces the text starting at the first position up to (but not including) the character at the last position with the given text.
- virtual void SetInsertionPoint (long pos)

  Sets the insertion point at the given position.
- virtual long GetInsertionPoint () const

  Returns the insertion point, or cursor, position.
- virtual long GetLastPosition () const

  Returns the zero based index of the last position in the text control, which is equal to the number of characters in the control.
- virtual void SetSelection (long from, long to)

  Selects the text starting at the first position up to (but not including) the character at the last position.
- virtual void SelectNone ()

  Deselects selected text in the control.
- virtual void GetSelection (long *from, long *to) const

  Gets the current selection span.
- virtual bool IsEditable () const

Returns true if the controls contents may be edited by user (note that it always can be changed by the program).

- virtual void SetEditable (bool editable)

  *Makes the text item editable or read-only, overriding the **wxTE_READONLY** flag.*
- virtual int GetLineLength (long n) const
- virtual wxString GetLineText (long n) const
- virtual int GetNumberOfLines () const
- virtual bool IsModified () const
- virtual void MarkDirty ()
- virtual void DiscardEdits ()
- virtual bool SetStyle (long start, long end, const wxTextAttr &style)
- virtual bool GetStyle (long position, wxTextAttr &style)
- virtual bool SetDefaultStyle (const wxTextAttr &style)
- virtual long XYToPosition (long x, long y) const
- virtual bool PositionToXY (long pos, long *x, long *y) const
- virtual void ShowPosition (long pos)
- virtual wxTextCtrlHitTestResult HitTest (const wxPoint &pt, long *pos) const
- virtual wxTextCtrlHitTestResult HitTest (const wxPoint &pt, wxTextCoord *col, wxTextCoord *row) const

21.737.2 Constructor & Destructor Documentation

wxStyledTextCtrl::wxStyledTextCtrl (wxWindow * *parent*, wxWindowID *id* = wxID_ANY, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, long *style* = 0, const wxString & *name* = wxSTCNameStr)

Ctor.

wxStyledTextCtrl::wxStyledTextCtrl ( )

Default ctor.

wxStyledTextCtrl::~wxStyledTextCtrl ( )

Destructor.

21.737.3 Member Function Documentation

void wxStyledTextCtrl::AddRefDocument (void * *docPointer*)

Extend life of document.

int wxStyledTextCtrl::AddSelection (int *caret*, int *anchor*)

Add a selection.

void wxStyledTextCtrl::AddStyledText (const wxMemoryBuffer & *data*)

Add array of cells to document.

void wxStyledTextCtrl::AddText (const wxString & *text*)

Add text to the document at current position.

void wxStyledTextCtrl::AddTextRaw (const char * *text,* int *length* = -1)

Add text to the document at current position.

void wxStyledTextCtrl::AddUndoAction (int *token,* int *flags*)

Add a container action to the undo stack.

void wxStyledTextCtrl::Allocate (int *bytes*)

Enlarge the document to a particular size of text bytes.

int wxStyledTextCtrl::AllocateExtendedStyles (int *numberStyles*)

Allocate some extended (>255) style numbers and return the start of the range.

int wxStyledTextCtrl::AllocateSubStyles (int *styleBase,* int *numberStyles*)

Allocate a set of sub styles for a particular base style, returning start of range.

void wxStyledTextCtrl::AnnotationClearAll ( )

Clear the annotations from all lines.

void wxStyledTextCtrl::AnnotationClearLine (int *line*)

Clear annotations from the given line.

int wxStyledTextCtrl::AnnotationGetLines (int *line*) const

Get the number of annotation lines for a line.

int wxStyledTextCtrl::AnnotationGetStyle (int *line*) const

Get the style number for the annotations for a line.

int wxStyledTextCtrl::AnnotationGetStyleOffset ( ) const

Get the start of the range of style numbers used for annotations.

wxString wxStyledTextCtrl::AnnotationGetStyles (int *line*) const

Get the annotation styles for a line.

wxString wxStyledTextCtrl::AnnotationGetText (int *line*) const

Get the annotation text for a line.

int wxStyledTextCtrl::AnnotationGetVisible ( ) const

Get the visibility for the annotations for a view.

void wxStyledTextCtrl::AnnotationSetStyle (int *line,* int *style*)

Set the style number for the annotations for a line.

void wxStyledTextCtrl::AnnotationSetStyleOffset (int *style*)

Get the start of the range of style numbers used for annotations.

void wxStyledTextCtrl::AnnotationSetStyles (int *line,* const wxString & *styles*)

Set the annotation styles for a line.

void wxStyledTextCtrl::AnnotationSetText (int *line,* const wxString & *text*)

Set the annotation text for a line.

void wxStyledTextCtrl::AnnotationSetVisible (int *visible*)

Set the visibility for the annotations for a view.

void wxStyledTextCtrl::AppendText (const wxString & *text*) `[virtual]`

Append a string to the end of the document without changing the selection.

Reimplemented from wxTextEntry.

void wxStyledTextCtrl::AppendTextRaw (const char * *text,* int *length* = -1)

Append a string to the end of the document without changing the selection.

bool wxStyledTextCtrl::AutoCompActive ( )

Is there an auto-completion list visible?

void wxStyledTextCtrl::AutoCompCancel ( )

Remove the auto-completion list from the screen.

void wxStyledTextCtrl::AutoCompComplete ( )

User has selected an item so remove the list and insert the selection.

bool wxStyledTextCtrl::AutoCompGetAutoHide ( ) const

Retrieve whether or not autocompletion is hidden automatically when nothing matches.

bool wxStyledTextCtrl::AutoCompGetCancelAtStart ( ) const

Retrieve whether auto-completion cancelled by backspacing before start.

int wxStyledTextCtrl::AutoCompGetCaseInsensitiveBehaviour ( ) const

Get auto-completion case insensitive behaviour.

bool wxStyledTextCtrl::AutoCompGetChooseSingle ( ) const

Retrieve whether a single item auto-completion list automatically choose the item.

int wxStyledTextCtrl::AutoCompGetCurrent ( ) const

Get currently selected item position in the auto-completion list.

bool wxStyledTextCtrl::AutoCompGetDropRestOfWord ( ) const

Retrieve whether or not autocompletion deletes any word characters after the inserted text upon completion.

bool wxStyledTextCtrl::AutoCompGetIgnoreCase ( ) const

Retrieve state of ignore case flag.

int wxStyledTextCtrl::AutoCompGetMaxHeight ( ) const

Set the maximum height, in rows, of auto-completion and user lists.

int wxStyledTextCtrl::AutoCompGetMaxWidth ( ) const

Get the maximum width, in characters, of auto-completion and user lists.

int wxStyledTextCtrl::AutoCompGetOrder ( ) const

Get the way autocompletion lists are ordered.

int wxStyledTextCtrl::AutoCompGetSeparator ( ) const

Retrieve the auto-completion list separator character.

int wxStyledTextCtrl::AutoCompGetTypeSeparator ( ) const

Retrieve the auto-completion list type-separator character.

int wxStyledTextCtrl::AutoCompPosStart ( )

Retrieve the position of the caret when the auto-completion list was displayed.

void wxStyledTextCtrl::AutoCompSelect (const wxString & *text*)

Select the item in the auto-completion list that starts with a string.

void wxStyledTextCtrl::AutoCompSetAutoHide (bool *autoHide*)

Set whether or not autocompletion is hidden automatically when nothing matches.

void wxStyledTextCtrl::AutoCompSetCancelAtStart (bool *cancel*)

Should the auto-completion list be cancelled if the user backspaces to a position before where the box was created.

void wxStyledTextCtrl::AutoCompSetCaseInsensitiveBehaviour (int *behaviour*)

Set auto-completion case insensitive behaviour to either prefer case-sensitive matches or have no preference.

void wxStyledTextCtrl::AutoCompSetChooseSingle (bool *chooseSingle*)

Should a single item auto-completion list automatically choose the item.

void wxStyledTextCtrl::AutoCompSetDropRestOfWord (bool *dropRestOfWord*)

Set whether or not autocompletion deletes any word characters after the inserted text upon completion.

void wxStyledTextCtrl::AutoCompSetFillUps (const wxString & *characterSet*)

Define a set of characters that when typed will cause the autocompletion to choose the selected item.

void wxStyledTextCtrl::AutoCompSetIgnoreCase (bool *ignoreCase*)

Set whether case is significant when performing auto-completion searches.

void wxStyledTextCtrl::AutoCompSetMaxHeight (int *rowCount*)

Set the maximum height, in rows, of auto-completion and user lists.

The default is 5 rows.

void wxStyledTextCtrl::AutoCompSetMaxWidth (int *characterCount*)

Set the maximum width, in characters, of auto-completion and user lists.

Set to 0 to autosize to fit longest item, which is the default.

void wxStyledTextCtrl::AutoCompSetOrder (int *order*)

Set the way autocompletion lists are ordered.

void wxStyledTextCtrl::AutoCompSetSeparator (int *separatorCharacter*)

Change the separator character in the string setting up an auto-completion list.

Default is space but can be changed if items contain space.

void wxStyledTextCtrl::AutoCompSetTypeSeparator (int *separatorCharacter*)

Change the type-separator character in the string setting up an auto-completion list.

Default is '?' but can be changed if items contain '?'.

void wxStyledTextCtrl::AutoCompShow (int *lenEntered,* const wxString & *itemList*)

Display a auto-completion list.

The lenEntered parameter indicates how many characters before the caret should be used to provide context.

void wxStyledTextCtrl::AutoCompStops (const wxString & *characterSet*)

Define a set of character that when typed cancel the auto-completion list.

void wxStyledTextCtrl::BackTab ( )

Dedent the selected lines.

void wxStyledTextCtrl::BeginUndoAction ( )

Start a sequence of actions that is undone and redone as a unit.

May be nested.

void wxStyledTextCtrl::BraceBadLight (int *pos*)

Highlight the character at a position indicating there is no matching brace.

void wxStyledTextCtrl::BraceBadLightIndicator (bool *useBraceBadLightIndicator,* int *indicator*)

Use specified indicator to highlight non matching brace instead of changing its style.

void wxStyledTextCtrl::BraceHighlight (int *pos1,* int *pos2*)

Highlight the characters at two positions.

void wxStyledTextCtrl::BraceHighlightIndicator (bool *useBraceHighlightIndicator,* int *indicator*)

Use specified indicator to highlight matching braces instead of changing their style.

int wxStyledTextCtrl::BraceMatch (int *pos*)

Find the position of a matching brace or INVALID_POSITION if no match.

bool wxStyledTextCtrl::CallTipActive ( )

Is there an active call tip?

void wxStyledTextCtrl::CallTipCancel ( )

Remove the call tip from the screen.

int wxStyledTextCtrl::CallTipPosAtStart ( )

Retrieve the position where the caret was before displaying the call tip.

void wxStyledTextCtrl::CallTipSetBackground (const wxColour & *back*)

Set the background colour for the call tip.

void wxStyledTextCtrl::CallTipSetForeground (const wxColour & *fore*)

Set the foreground colour for the call tip.

void wxStyledTextCtrl::CallTipSetForegroundHighlight (const wxColour & *fore*)

Set the foreground colour for the highlighted part of the call tip.

void wxStyledTextCtrl::CallTipSetHighlight (int *start,* int *end*)

Highlight a segment of the definition.

void wxStyledTextCtrl::CallTipSetPosAtStart (int *posStart*)

Set the start position in order to change when backspacing removes the calltip.

void wxStyledTextCtrl::CallTipSetPosition (bool *above*)

Set position of calltip, above or below text.

void wxStyledTextCtrl::CallTipShow (int *pos,* const wxString & *definition*)

Show a call tip containing a definition near position pos.

void wxStyledTextCtrl::CallTipUseStyle (int *tabSize*)

Enable use of STYLE_CALLTIP and set call tip tab size in pixels.

void wxStyledTextCtrl::Cancel ( )

Cancel any modes such as call tip or auto-completion list display.

bool wxStyledTextCtrl::CanPaste ( ) const `[virtual]`

Will a paste succeed?

Reimplemented from wxTextEntry.

bool wxStyledTextCtrl::CanRedo ( ) const `[virtual]`

Are there any redoable actions in the undo history?

Reimplemented from wxTextEntry.

bool wxStyledTextCtrl::CanUndo ( ) const `[virtual]`

Are there any undoable actions in the undo history?

Reimplemented from wxTextEntry.

int wxStyledTextCtrl::ChangeLexerState (int *start*, int *end*)

Indicate that the internal state of a lexer has changed over a range and therefore there may be a need to redraw.

void wxStyledTextCtrl::CharLeft ( )

Move caret left one character.

void wxStyledTextCtrl::CharLeftExtend ( )

Move caret left one character extending selection to new caret position.

void wxStyledTextCtrl::CharLeftRectExtend ( )

Move caret left one character, extending rectangular selection to new caret position.

int wxStyledTextCtrl::CharPositionFromPoint (int *x*, int *y*)

Find the position of a character from a point within the window.

int wxStyledTextCtrl::CharPositionFromPointClose (int *x*, int *y*)

Find the position of a character from a point within the window.

Return INVALID_POSITION if not close to text.

void wxStyledTextCtrl::CharRight ( )

Move caret right one character.

void wxStyledTextCtrl::CharRightExtend ( )

Move caret right one character extending selection to new caret position.

void wxStyledTextCtrl::CharRightRectExtend ( )

Move caret right one character, extending rectangular selection to new caret position.

void wxStyledTextCtrl::ChooseCaretX ( )

Set the last x chosen value to be the caret x position.

void wxStyledTextCtrl::Clear ( ) `[virtual]`

Clear the selection.

Reimplemented from wxTextEntry.

void wxStyledTextCtrl::ClearAll ( )

Delete all text in the document.

void wxStyledTextCtrl::ClearDocumentStyle ( )

Set all style bytes to 0, remove all folding information.

void wxStyledTextCtrl::ClearRegisteredImages ( )

Clear all the registered images.

void wxStyledTextCtrl::ClearRepresentation (const wxString & *encodedCharacter*)

Remove a character representation.

void wxStyledTextCtrl::ClearSelections ( )

Clear selections to a single empty stream selection.

void wxStyledTextCtrl::CmdKeyAssign (int *key,* int *modifiers,* int *cmd*)

When key+modifier combination km is pressed perform msg.

void wxStyledTextCtrl::CmdKeyClear (int *key,* int *modifiers*)

When key+modifier combination km is pressed do nothing.

void wxStyledTextCtrl::CmdKeyClearAll ( )

Drop all key mappings.

void wxStyledTextCtrl::CmdKeyExecute (int *cmd*)

Perform one of the operations defined by the wxSTC_CMD_* constants.

void wxStyledTextCtrl::Colourise (int *start*, int *end*)

Colourise a segment of the document using the current lexing language.

int wxStyledTextCtrl::ContractedFoldNext (int *lineStart*)

Find the next line at or after lineStart that is a contracted fold header line.

Return -1 when no more lines.

void wxStyledTextCtrl::ConvertEOLs (int *eolMode*)

Convert all line endings in the document to one mode.

void wxStyledTextCtrl::Copy ( ) [virtual]

Copy the selection to the clipboard.

Reimplemented from wxTextEntry.

void wxStyledTextCtrl::CopyAllowLine ( )

Copy the selection, if selection empty copy the line with the caret.

void wxStyledTextCtrl::CopyRange (int *start*, int *end*)

Copy a range of text to the clipboard.

Positions are clipped into the document.

void wxStyledTextCtrl::CopyText (int *length*, const wxString & *text*)

Copy argument text to the clipboard.

int wxStyledTextCtrl::CountCharacters (int *startPos*, int *endPos*)

Count characters between two positions.

bool wxStyledTextCtrl::Create (wxWindow * *parent*, wxWindowID *id* = wxID_ANY, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, long *style* = 0, const wxString & *name* = wxSTCNameStr)

Create the UI elements for a STC that was created with the default ctor.

(For 2-phase create.)

void* wxStyledTextCtrl::CreateDocument ( )

Create a new document object.

Starts with reference count of 1 and not selected into editor.

void* wxStyledTextCtrl::CreateLoader (int *bytes*) const

Create an ILoader*.

void wxStyledTextCtrl::Cut ( ) [virtual]

Cut the selection to the clipboard.

Reimplemented from wxTextEntry.

void wxStyledTextCtrl::DeleteBack ( )

Delete the selection or if no selection, the character before the caret.

void wxStyledTextCtrl::DeleteBackNotLine ( )

Delete the selection or if no selection, the character before the caret.

Will not delete the character before at the start of a line.

void wxStyledTextCtrl::DeleteRange (int *pos,* int *deleteLength*)

Delete a range of text in the document.

void wxStyledTextCtrl::DelLineLeft ( )

Delete back from the current position to the start of the line.

void wxStyledTextCtrl::DelLineRight ( )

Delete forwards from the current position to the end of the line.

void wxStyledTextCtrl::DelWordLeft ( )

Delete the word to the left of the caret.

void wxStyledTextCtrl::DelWordRight ( )

Delete the word to the right of the caret.

void wxStyledTextCtrl::DelWordRightEnd ( )

Delete the word to the right of the caret, but not the trailing non-word characters.

wxString wxStyledTextCtrl::DescribeKeyWordSets ( ) const

Retrieve a '
' separated list of descriptions of the keyword sets understood by the current lexer.

wxString wxStyledTextCtrl::DescribeProperty (const wxString & *name*) const

Describe a property.

virtual void wxStyledTextCtrl::DiscardEdits ( ) [virtual]

int wxStyledTextCtrl::DistanceToSecondaryStyles ( ) const

Where styles are duplicated by a feature such as active/inactive code return the distance between the two types.

int wxStyledTextCtrl::DocLineFromVisible (int *lineDisplay*)

Find the document line of a display line taking hidden lines into account.

void wxStyledTextCtrl::DocumentEnd ( )

Move caret to last position in document.

void wxStyledTextCtrl::DocumentEndExtend ( )

Move caret to last position in document extending selection to new caret position.

void wxStyledTextCtrl::DocumentStart ( )

Move caret to first position in document.

void wxStyledTextCtrl::DocumentStartExtend ( )

Move caret to first position in document extending selection to new caret position.

wxDragResult wxStyledTextCtrl::DoDragEnter (wxCoord *x*, wxCoord *y*, wxDragResult *defaultRes*)

Allow for simulating a DnD DragEnter.

Since

3.1.0

void wxStyledTextCtrl::DoDragLeave ( )

Allow for simulating a DnD DragLeave.

Since

3.1.0

wxDragResult wxStyledTextCtrl::DoDragOver (wxCoord *x,* wxCoord *y,* wxDragResult *defaultRes*)

Allow for simulating a DnD DragOver.

bool wxStyledTextCtrl::DoDropText (long *x,* long *y,* const wxString & *data*)

Allow for simulating a DnD DropText.

void wxStyledTextCtrl::DropSelectionN (int *selection*)

Drop one selection.

void wxStyledTextCtrl::EditToggleOvertype ( )

Switch from insert to overtype mode or the reverse.

void wxStyledTextCtrl::EmptyUndoBuffer ( )

Delete the undo history.

void wxStyledTextCtrl::EndUndoAction ( )

End a sequence of actions that is undone and redone as a unit.

void wxStyledTextCtrl::EnsureCaretVisible ( )

Ensure the caret is visible.

void wxStyledTextCtrl::EnsureVisible (int *line*)

Ensure a particular line is visible by expanding any header line hiding it.

void wxStyledTextCtrl::EnsureVisibleEnforcePolicy (int *line*)

Ensure a particular line is visible by expanding any header line hiding it.
Use the currently set visibility policy to determine which range to display.

void wxStyledTextCtrl::ExpandChildren (int *line,* int *level*)

Expand a fold header and all children.
Use the level argument instead of the line's current level.

int wxStyledTextCtrl::FindColumn (int *line,* int *column*)

Find the position of a column on a line taking into account tabs and multi-byte characters.
If beyond end of line, return line end position.

int wxStyledTextCtrl::FindText (int *minPos,* int *maxPos,* const wxString & *text,* int *flags* = 0)

Find some text in the document.

void wxStyledTextCtrl::FoldAll (int *action*)

Expand or contract all fold headers.

void wxStyledTextCtrl::FoldChildren (int *line,* int *action*)

Expand or contract a fold header and its children.

void wxStyledTextCtrl::FoldLine (int *line,* int *action*)

Expand or contract a fold header.

int wxStyledTextCtrl::FormatRange (bool *doDraw,* int *startPos,* int *endPos,* wxDC * *draw,* wxDC * *target,* wxRect *renderRect,* wxRect *pageRect*)

On Windows, will draw the document into a display context such as a printer.

void wxStyledTextCtrl::FormFeed ( )

Insert a Form Feed character.

void wxStyledTextCtrl::FreeSubStyles ( )

Free allocated sub styles.

wxColour wxStyledTextCtrl::GetAdditionalCaretForeground ( ) const

Get the foreground colour of additional carets.

bool wxStyledTextCtrl::GetAdditionalCaretsBlink ( ) const

Whether additional carets will blink.

bool wxStyledTextCtrl::GetAdditionalCaretsVisible ( ) const

Whether additional carets are visible.

int wxStyledTextCtrl::GetAdditionalSelAlpha ( ) const

Get the alpha of the selection.

bool wxStyledTextCtrl::GetAdditionalSelectionTyping ( ) const

Whether typing can be performed into multiple selections.

bool wxStyledTextCtrl::GetAllLinesVisible ( ) const

Are all lines visible?

int wxStyledTextCtrl::GetAnchor ( ) const

Returns the position of the opposite end of the selection to the caret.

int wxStyledTextCtrl::GetAutomaticFold ( ) const

Get automatic folding behaviours.

bool wxStyledTextCtrl::GetBackSpaceUnIndents ( ) const

Does a backspace pressed when caret is within indentation unindent?

bool wxStyledTextCtrl::GetBufferedDraw ( ) const

Is drawing done first into a buffer or direct to the screen?

wxColour wxStyledTextCtrl::GetCaretForeground ( ) const

Get the foreground colour of the caret.

int wxStyledTextCtrl::GetCaretLineBackAlpha ( ) const

Get the background alpha of the caret line.

wxColour wxStyledTextCtrl::GetCaretLineBackground ( ) const

Get the colour of the background of the line containing the caret.

bool wxStyledTextCtrl::GetCaretLineVisible ( ) const

Is the background of the line containing the caret in a different colour?

bool wxStyledTextCtrl::GetCaretLineVisibleAlways ( ) const

Is the caret line always visible?

int wxStyledTextCtrl::GetCaretPeriod ( ) const

Get the time in milliseconds that the caret is on and off.

int wxStyledTextCtrl::GetCaretSticky ( ) const

Can the caret preferred x position only be changed by explicit movement commands?

int wxStyledTextCtrl::GetCaretStyle ( ) const

Returns the current style of the caret.

int wxStyledTextCtrl::GetCaretWidth ( ) const

Returns the width of the insert mode caret.

const char* wxStyledTextCtrl::GetCharacterPointer ( ) const

Compact the document buffer and return a read-only pointer to the characters in the document.

int wxStyledTextCtrl::GetCharAt (int *pos*) const

Returns the character byte at the position.

int wxStyledTextCtrl::GetCodePage ( ) const

Get the code page used to interpret the bytes of the document as characters.

int wxStyledTextCtrl::GetColumn (int *pos*) const

Retrieve the column number of a position, taking tab width into account.

int wxStyledTextCtrl::GetControlCharSymbol ( ) const

Get the way control characters are displayed.

wxString wxStyledTextCtrl::GetCurLine (int * *linePos* = NULL)

Retrieve the text of the line containing the caret.

Returns the index of the caret on the line.

wxCharBuffer wxStyledTextCtrl::GetCurLineRaw (int * *linePos* = NULL)

Retrieve the text of the line containing the caret.

Returns the index of the caret on the line.

int wxStyledTextCtrl::GetCurrentLine ( )

Returns the line number of the line with the caret.

int wxStyledTextCtrl::GetCurrentPos ( ) const

Returns the position of the caret.

void* wxStyledTextCtrl::GetDocPointer ( )

Retrieve a pointer to the document object.

wxColour wxStyledTextCtrl::GetEdgeColour ( ) const

Retrieve the colour used in edge indication.

int wxStyledTextCtrl::GetEdgeColumn ( ) const

Retrieve the column number which text should be kept within.

int wxStyledTextCtrl::GetEdgeMode ( ) const

Retrieve the edge highlight mode.

bool wxStyledTextCtrl::GetEndAtLastLine ( ) const

Retrieve whether the maximum scroll position has the last line at the bottom of the view.

int wxStyledTextCtrl::GetEndStyled ( ) const

Retrieve the position of the last correctly styled character.

int wxStyledTextCtrl::GetEOLMode ( ) const

Retrieve the current end of line mode - one of CRLF, CR, or LF.

int wxStyledTextCtrl::GetExtraAscent ( ) const

Get extra ascent for each line.

int wxStyledTextCtrl::GetExtraDescent ( ) const

Get extra descent for each line.

int wxStyledTextCtrl::GetFirstVisibleLine ( ) const

Retrieve the display line at the top of the display.

bool wxStyledTextCtrl::GetFoldExpanded (int *line*) const

Is a header line expanded?

int wxStyledTextCtrl::GetFoldLevel (int *line*) const

Retrieve the fold level of a line.

int wxStyledTextCtrl::GetFoldParent (int *line*) const

Find the parent line of a child line.

int wxStyledTextCtrl::GetGapPosition ( ) const

Return a position which, to avoid performance costs, should not be within the range of a call to GetRangePointer.

int wxStyledTextCtrl::GetHighlightGuide ( ) const

Get the highlighted indentation guide column.

wxColour wxStyledTextCtrl::GetHotspotActiveBackground ( ) const

Get the back colour for active hotspots.

wxColour wxStyledTextCtrl::GetHotspotActiveForeground ( ) const

Get the fore colour for active hotspots.

bool wxStyledTextCtrl::GetHotspotActiveUnderline ( ) const

Get whether underlining for active hotspots.

bool wxStyledTextCtrl::GetHotspotSingleLine ( ) const

Get the HotspotSingleLine property.

int wxStyledTextCtrl::GetIdentifier ( ) const

Get the identifier.

int wxStyledTextCtrl::GetIndent ( ) const

Retrieve indentation size.

int wxStyledTextCtrl::GetIndentationGuides ( ) const

Are the indentation guides visible?

int wxStyledTextCtrl::GetIndicatorCurrent ( ) const

Get the current indicator.

int wxStyledTextCtrl::GetIndicatorValue ( ) const

Get the current indicator value.

virtual long wxStyledTextCtrl::GetInsertionPoint ( ) const `[virtual]`

Returns the insertion point, or cursor, position.

This is defined as the zero based index of the character position to the right of the insertion point. For example, if the insertion point is at the end of the single-line text control, it is equal to GetLastPosition().

Notice that insertion position is, in general, different from the index of the character the cursor position at in the string returned by GetValue(). While this is always the case for the single line controls, multi-line controls can use two characters "\\r\\n" as line separator (this is notably the case under MSW) meaning that indices in the control and its string value are offset by 1 for every line.

Hence to correctly get the character at the current cursor position, taking into account that there can be none if the cursor is at the end of the string, you could do the following:

```
wxString GetCurrentChar(wxTextCtrl *tc)
{
    long pos = tc->GetInsertionPoint();
    if ( pos == tc->GetLastPosition() )
        return wxString();

    return tc->GetRange(pos, pos + 1);
}
```

Reimplemented from wxTextEntry.

bool wxStyledTextCtrl::GetKeysUnicode ( ) const

Are keys always interpreted as Unicode?

int wxStyledTextCtrl::GetLastChild (int *line,* int *level*) const

Find the last child line of a header line.

bool wxStyledTextCtrl::GetLastKeydownProcessed ( )

Can be used to prevent the EVT_CHAR handler from adding the char.

virtual long wxStyledTextCtrl::GetLastPosition ( ) const [virtual]

Returns the zero based index of the last position in the text control, which is equal to the number of characters in the control.

Reimplemented from wxTextEntry.

int wxStyledTextCtrl::GetLayoutCache ( ) const

Retrieve the degree of caching of layout information.

int wxStyledTextCtrl::GetLength ( ) const

Returns the number of bytes in the document.

int wxStyledTextCtrl::GetLexer ( ) const

Retrieve the lexing language of the document.

static wxVersionInfo wxStyledTextCtrl::GetLibraryVersionInfo ( ) [static]

wxString wxStyledTextCtrl::GetLine (int *line*) const

Retrieve the contents of a line.

int wxStyledTextCtrl::GetLineCount ( ) const

Returns the number of lines in the document.

There is always at least one.

int wxStyledTextCtrl::GetLineEndPosition (int *line*) const

Get the position after the last visible characters on a line.

int wxStyledTextCtrl::GetLineEndTypesActive ( ) const

Get the line end types currently recognised.

May be a subset of the allowed types due to lexer limitation.

int wxStyledTextCtrl::GetLineEndTypesAllowed ( ) const

Get the line end types currently allowed.

int wxStyledTextCtrl::GetLineEndTypesSupported ( ) const

Bit set of LineEndType enumertion for which line ends beyond the standard LF, CR, and CRLF are supported by the lexer.

int wxStyledTextCtrl::GetLineIndentation (int *line*) const

Retrieve the number of columns that a line is indented.

int wxStyledTextCtrl::GetLineIndentPosition (int *line*) const

Retrieve the position before the first non indentation character on a line.

virtual int wxStyledTextCtrl::GetLineLength (long *n*) const `[virtual]`

wxCharBuffer wxStyledTextCtrl::GetLineRaw (int *line*)

Retrieve the contents of a line.

int wxStyledTextCtrl::GetLineSelEndPosition (int *line*)

Retrieve the position of the end of the selection at the given line (INVALID_POSITION if no selection on this line).

int wxStyledTextCtrl::GetLineSelStartPosition (int *line*)

Retrieve the position of the start of the selection at the given line (INVALID_POSITION if no selection on this line).

int wxStyledTextCtrl::GetLineState (int *line*) const

Retrieve the extra styling information for a line.

virtual wxString wxStyledTextCtrl::GetLineText (long *n*) const `[virtual]`

bool wxStyledTextCtrl::GetLineVisible (int *line*) const

Is a line visible?

int wxStyledTextCtrl::GetMainSelection ( ) const

Which selection is the main selection.

int wxStyledTextCtrl::GetMarginCursor (int *margin*) const

Retrieve the cursor shown in a margin.

int wxStyledTextCtrl::GetMarginLeft ( ) const

Returns the size in pixels of the left margin.

int wxStyledTextCtrl::GetMarginMask (int *margin*) const

Retrieve the marker mask of a margin.

int wxStyledTextCtrl::GetMarginOptions ( ) const

Get the margin options.

int wxStyledTextCtrl::GetMarginRight ( ) const

Returns the size in pixels of the right margin.

bool wxStyledTextCtrl::GetMarginSensitive (int *margin*) const

Retrieve the mouse click sensitivity of a margin.

int wxStyledTextCtrl::GetMarginType (int *margin*) const

Retrieve the type of a margin.

int wxStyledTextCtrl::GetMarginWidth (int *margin*) const

Retrieve the width of a margin in pixels.

int wxStyledTextCtrl::GetMarkerSymbolDefined (int *markerNumber*)

Which symbol was defined for markerNumber with MarkerDefine.

int wxStyledTextCtrl::GetMaxLineState ( ) const

Retrieve the last line number that has line state.

int wxStyledTextCtrl::GetModEventMask ( ) const

Get which document modification events are sent to the container.

bool wxStyledTextCtrl::GetModify ( ) const

Is the document different from when it was last saved?

bool wxStyledTextCtrl::GetMouseDownCaptures ( ) const

Get whether mouse gets captured.

int wxStyledTextCtrl::GetMouseDwellTime ( ) const

Retrieve the time the mouse must sit still to generate a mouse dwell event.

bool wxStyledTextCtrl::GetMouseSelectionRectangularSwitch ( ) const

Whether switching to rectangular mode while selecting with the mouse is allowed.

int wxStyledTextCtrl::GetMultiPaste ( ) const

Retrieve the effect of pasting when there are multiple selections.

bool wxStyledTextCtrl::GetMultipleSelection ( ) const

Whether multiple selections can be made.

virtual int wxStyledTextCtrl::GetNumberOfLines ( ) const `[virtual]`

bool wxStyledTextCtrl::GetOvertype ( ) const

Returns true if overtype mode is active otherwise false is returned.

bool wxStyledTextCtrl::GetPasteConvertEndings ( ) const

Get convert-on-paste setting.

int wxStyledTextCtrl::GetPositionCacheSize ( ) const

How many entries are allocated to the position cache?

int wxStyledTextCtrl::GetPrimaryStyleFromStyle (int *style*) const

For a secondary style, return the primary style, else return the argument.

int wxStyledTextCtrl::GetPrintColourMode ( ) const

Returns the print colour mode.

int wxStyledTextCtrl::GetPrintMagnification ( ) const

Returns the print magnification.

int wxStyledTextCtrl::GetPrintWrapMode ( ) const

Is printing line wrapped?

wxString wxStyledTextCtrl::GetProperty (const wxString & *key*)

Retrieve a 'property' value previously set with SetProperty.

wxString wxStyledTextCtrl::GetPropertyExpanded (const wxString & *key*)

Retrieve a 'property' value previously set with SetProperty, with '$()' variable replacement on returned buffer.

int wxStyledTextCtrl::GetPropertyInt (const wxString & *key*) const

Retrieve a 'property' value previously set with SetProperty, interpreted as an int AFTER any '$()' variable replacement.

wxString wxStyledTextCtrl::GetPunctuationChars ( ) const

Get the set of characters making up punctuation characters.

const char* wxStyledTextCtrl::GetRangePointer (int *position,* int *rangeLength*) const

Return a read-only pointer to a range of characters in the document.

May move the gap so that the range is contiguous, but will only move up to rangeLength bytes.

bool wxStyledTextCtrl::GetReadOnly ( ) const

In read-only mode?

int wxStyledTextCtrl::GetRectangularSelectionAnchor ( ) const

int wxStyledTextCtrl::GetRectangularSelectionAnchorVirtualSpace ( ) const

int wxStyledTextCtrl::GetRectangularSelectionCaret ( ) const

int wxStyledTextCtrl::GetRectangularSelectionCaretVirtualSpace ( ) const

int wxStyledTextCtrl::GetRectangularSelectionModifier ( ) const

Get the modifier key used for rectangular selection.

wxString wxStyledTextCtrl::GetRepresentation (const wxString & *encodedCharacter*) const

Set the way a character is drawn.

int wxStyledTextCtrl::GetScrollWidth ( ) const

Retrieve the document width assumed for scrolling.

bool wxStyledTextCtrl::GetScrollWidthTracking ( ) const

Retrieve whether the scroll width tracks wide lines.

int wxStyledTextCtrl::GetSearchFlags ( ) const

Get the search flags used by SearchInTarget.

int wxStyledTextCtrl::GetSelAlpha ( ) const

Get the alpha of the selection.

wxString wxStyledTextCtrl::GetSelectedText ( )

Retrieve the selected text.

wxCharBuffer wxStyledTextCtrl::GetSelectedTextRaw ( )

Retrieve the selected text.

virtual void wxStyledTextCtrl::GetSelection (long * *from,* long * *to*) const `[virtual]`

Gets the current selection span.

If the returned values are equal, there was no selection. Please note that the indices returned may be used with the other wxTextCtrl methods but don't necessarily represent the correct indices into the string returned by GetValue() for multiline controls under Windows (at least,) you should use GetStringSelection() to get the selected text.

Parameters

from	The returned first position.
to	The returned last position.

wxPerl Note: In wxPerl this method takes no parameters and returns a 2-element list (from, to).

Reimplemented from wxTextEntry.

bool wxStyledTextCtrl::GetSelectionEmpty ( ) const

Is every selected range empty?

int wxStyledTextCtrl::GetSelectionEnd ( ) const

Returns the position at the end of the selection.

int wxStyledTextCtrl::GetSelectionMode ( ) const

Get the mode of the current selection.

int wxStyledTextCtrl::GetSelectionNAnchor (int *selection*) const

int wxStyledTextCtrl::GetSelectionNAnchorVirtualSpace (int *selection*) const

int wxStyledTextCtrl::GetSelectionNCaret (int *selection*) const

int wxStyledTextCtrl::GetSelectionNCaretVirtualSpace (int *selection*) const

int wxStyledTextCtrl::GetSelectionNEnd (int *selection*) const

Returns the position at the end of the selection.

int wxStyledTextCtrl::GetSelectionNStart (int *selection*) const

Returns the position at the start of the selection.

int wxStyledTextCtrl::GetSelections ( ) const

How many selections are there?

int wxStyledTextCtrl::GetSelectionStart ( ) const

Returns the position at the start of the selection.

bool wxStyledTextCtrl::GetSelEOLFilled ( ) const

Is the selection end of line filled?

int wxStyledTextCtrl::GetStatus ( ) const

Get error status.

int wxStyledTextCtrl::GetSTCCursor ( ) const

Get cursor type.

bool wxStyledTextCtrl::GetSTCFocus ( ) const

Get internal focus flag.

virtual bool wxStyledTextCtrl::GetStyle (long *position,* wxTextAttr & *style*) `[virtual]`

int wxStyledTextCtrl::GetStyleAt (int *pos*) const

Returns the style byte at the position.

int wxStyledTextCtrl::GetStyleBits ( ) const

Retrieve number of bits in style bytes used to hold the lexical state.

int wxStyledTextCtrl::GetStyleBitsNeeded ( ) const

Retrieve the number of bits the current lexer needs for styling.

wxMemoryBuffer wxStyledTextCtrl::GetStyledText (int *startPos,* int *endPos*)

Retrieve a buffer of cells.

int wxStyledTextCtrl::GetStyleFromSubStyle (int *subStyle*) const

For a sub style, return the base style, else return the argument.

wxString wxStyledTextCtrl::GetSubStyleBases ( ) const

Get the set of base styles that can be extended with sub styles.

int wxStyledTextCtrl::GetSubStylesLength (int *styleBase*) const

The number of sub styles associated with a base style.

int wxStyledTextCtrl::GetSubStylesStart (int *styleBase*) const

The starting style number for the sub styles associated with a base style.

bool wxStyledTextCtrl::GetTabIndents ( ) const

Does a tab pressed when caret is within indentation indent?

int wxStyledTextCtrl::GetTabWidth ( ) const

Retrieve the visible size of a tab.

wxString wxStyledTextCtrl::GetTag (int *tagNumber*) const

Retrieve the value of a tag from a regular expression search.

int wxStyledTextCtrl::GetTargetEnd ( ) const

Get the position that ends the target.

int wxStyledTextCtrl::GetTargetStart ( ) const

Get the position that starts the target.

int wxStyledTextCtrl::GetTechnology ( ) const

Get the tech.

wxString wxStyledTextCtrl::GetText ( ) const

Retrieve all the text in the document.

int wxStyledTextCtrl::GetTextLength ( ) const

Retrieve the number of characters in the document.

wxString wxStyledTextCtrl::GetTextRange (int *startPos,* int *endPos*)

Retrieve a range of text.

wxCharBuffer wxStyledTextCtrl::GetTextRangeRaw (int *startPos,* int *endPos*)

Retrieve a range of text.

wxCharBuffer wxStyledTextCtrl::GetTextRaw ( )

Retrieve all the text in the document.

bool wxStyledTextCtrl::GetTwoPhaseDraw ( ) const

Is drawing done in two phases with backgrounds drawn before faoregrounds?

bool wxStyledTextCtrl::GetUndoCollection ( ) const

Is undo history being collected?

bool wxStyledTextCtrl::GetUseHorizontalScrollBar ( ) const

Is the horizontal scroll bar visible?

bool wxStyledTextCtrl::GetUseTabs ( ) const

Retrieve whether tabs will be used in indentation.

bool wxStyledTextCtrl::GetUseVerticalScrollBar ( ) const

Is the vertical scroll bar visible?

bool wxStyledTextCtrl::GetViewEOL ( ) const

Are the end of line characters visible?

int wxStyledTextCtrl::GetViewWhiteSpace ( ) const

Are white space characters currently visible? Returns one of SCWS_∗ constants.

int wxStyledTextCtrl::GetVirtualSpaceOptions ( ) const

wxString wxStyledTextCtrl::GetWhitespaceChars ( ) const

Get the set of characters making up whitespace for when moving or selecting by word.

int wxStyledTextCtrl::GetWhitespaceSize ( ) const

Get the size of the dots used to mark space characters.

wxString wxStyledTextCtrl::GetWordChars ( ) const

Get the set of characters making up words for when moving or selecting by word.

int wxStyledTextCtrl::GetWrapIndentMode ( ) const

Retrieve how wrapped sublines are placed.
Default is fixed.

int wxStyledTextCtrl::GetWrapMode ( ) const

Retrieve whether text is word wrapped.

int wxStyledTextCtrl::GetWrapStartIndent ( ) const

Retrive the start indent for wrapped lines.

int wxStyledTextCtrl::GetWrapVisualFlags ( ) const

Retrive the display mode of visual flags for wrapped lines.

int wxStyledTextCtrl::GetWrapVisualFlagsLocation ( ) const

Retrive the location of visual flags for wrapped lines.

int wxStyledTextCtrl::GetXOffset ( ) const

int wxStyledTextCtrl::GetZoom ( ) const

Retrieve the zoom level.

void wxStyledTextCtrl::GotoLine (int *line*)

Set caret to start of a line and ensure it is visible.

void wxStyledTextCtrl::GotoPos (int *pos*)

Set caret to a position and ensure it is visible.

void wxStyledTextCtrl::HideLines (int *lineStart,* int *lineEnd*)

Make a range of lines invisible.

void wxStyledTextCtrl::HideSelection (bool *normal*)

Draw the selection in normal style or with selection highlighted.

virtual wxTextCtrlHitTestResult wxStyledTextCtrl::HitTest (const wxPoint & *pt,* long * *pos*) const `[virtual]`

virtual wxTextCtrlHitTestResult wxStyledTextCtrl::HitTest (const wxPoint & *pt,* wxTextCoord * *col,* wxTextCoord * *row*) const `[virtual]`

void wxStyledTextCtrl::Home ( )

Move caret to first position on line.

void wxStyledTextCtrl::HomeDisplay ( )

Move caret to first position on display line.

void wxStyledTextCtrl::HomeDisplayExtend ( )

Move caret to first position on display line extending selection to new caret position.

void wxStyledTextCtrl::HomeExtend ( )

Move caret to first position on line extending selection to new caret position.

void wxStyledTextCtrl::HomeRectExtend ( )

Move caret to first position on line, extending rectangular selection to new caret position.

void wxStyledTextCtrl::HomeWrap ( )

These are like their namesakes Home(Extend)?, LineEnd(Extend)?, VCHome(Extend)? except they behave differently when word-wrap is enabled: They go first to the start / end of the display line, like (Home|LineEnd)Display The difference is that, the cursor is already at the point, it goes on to the start or end of the document line, as appropriate for (Home|LineEnd|VCHome)(Extend)?.

void wxStyledTextCtrl::HomeWrapExtend ( )

int wxStyledTextCtrl::IndicatorAllOnFor (int *position*)

Are any indicators present at position?

void wxStyledTextCtrl::IndicatorClearRange (int *position,* int *clearLength*)

Turn a indicator off over a range.

int wxStyledTextCtrl::IndicatorEnd (int *indicator,* int *position*)

Where does a particular indicator end?

void wxStyledTextCtrl::IndicatorFillRange (int *position,* int *fillLength*)

Turn a indicator on over a range.

int wxStyledTextCtrl::IndicatorGetAlpha (int *indicator*) const

Get the alpha fill colour of the given indicator.

wxColour wxStyledTextCtrl::IndicatorGetForeground (int *indic*) const

Retrieve the foreground colour of an indicator.

int wxStyledTextCtrl::IndicatorGetOutlineAlpha (int *indicator*) const

Get the alpha outline colour of the given indicator.

int wxStyledTextCtrl::IndicatorGetStyle (int *indic*) const

Retrieve the style of an indicator.

bool wxStyledTextCtrl::IndicatorGetUnder (int *indic*) const

Retrieve whether indicator drawn under or over text.

void wxStyledTextCtrl::IndicatorSetAlpha (int *indicator,* int *alpha*)

Set the alpha fill colour of the given indicator.

void wxStyledTextCtrl::IndicatorSetForeground (int *indic,* const wxColour & *fore*)

Set the foreground colour of an indicator.

void wxStyledTextCtrl::IndicatorSetOutlineAlpha (int *indicator,* int *alpha*)

Set the alpha outline colour of the given indicator.

void wxStyledTextCtrl::IndicatorSetStyle (int *indic,* int *style*)

Set an indicator to plain, squiggle or TT.

void wxStyledTextCtrl::IndicatorSetUnder (int *indic,* bool *under*)

Set an indicator to draw under text or over(default).

int wxStyledTextCtrl::IndicatorStart (int *indicator,* int *position*)

Where does a particular indicator start?

int wxStyledTextCtrl::IndicatorValueAt (int *indicator,* int *position*)

What value does a particular indicator have at at a position?

void wxStyledTextCtrl::InsertText (int *pos,* const wxString & *text*)

Insert string at a position.

void wxStyledTextCtrl::InsertTextRaw (int *pos,* const char * *text*)

Insert string at a position.

virtual bool wxStyledTextCtrl::IsEditable ( ) const `[virtual]`

Returns true if the controls contents may be edited by user (note that it always can be changed by the program).

In other words, this functions returns true if the control hasn't been put in read-only mode by a previous call to SetEditable().

Reimplemented from wxTextEntry.

virtual bool wxStyledTextCtrl::IsModified ( ) const `[virtual]`

void wxStyledTextCtrl::LineCopy ( )

Copy the line containing the caret.

void wxStyledTextCtrl::LineCut ( )

Cut the line containing the caret.

void wxStyledTextCtrl::LineDelete ( )

Delete the line containing the caret.

void wxStyledTextCtrl::LineDown ( )

Move caret down one line.

void wxStyledTextCtrl::LineDownExtend ( )

Move caret down one line extending selection to new caret position.

void wxStyledTextCtrl::LineDownRectExtend ( )

Move caret down one line, extending rectangular selection to new caret position.

void wxStyledTextCtrl::LineDuplicate ( )

Duplicate the current line.

void wxStyledTextCtrl::LineEnd ( )

Move caret to last position on line.

void wxStyledTextCtrl::LineEndDisplay ( )

Move caret to last position on display line.

void wxStyledTextCtrl::LineEndDisplayExtend ( )

Move caret to last position on display line extending selection to new caret position.

void wxStyledTextCtrl::LineEndExtend ( )

Move caret to last position on line extending selection to new caret position.

void wxStyledTextCtrl::LineEndRectExtend ( )

Move caret to last position on line, extending rectangular selection to new caret position.

void wxStyledTextCtrl::LineEndWrap ( )

void wxStyledTextCtrl::LineEndWrapExtend ( )

int wxStyledTextCtrl::LineFromPosition (int *pos*) const

Retrieve the line containing a position.

int wxStyledTextCtrl::LineLength (int *line*) const

How many characters are on a line, including end of line characters?

void wxStyledTextCtrl::LineScroll (int *columns,* int *lines*)

Scroll horizontally and vertically.

void wxStyledTextCtrl::LineScrollDown ( )

Scroll the document down, keeping the caret visible.

void wxStyledTextCtrl::LineScrollUp ( )

Scroll the document up, keeping the caret visible.

void wxStyledTextCtrl::LinesJoin ( )

Join the lines in the target.

int wxStyledTextCtrl::LinesOnScreen ( ) const

Retrieves the number of lines completely visible.

void wxStyledTextCtrl::LinesSplit (int *pixelWidth*)

Split the lines in the target into lines that are less wide than pixelWidth where possible.

void wxStyledTextCtrl::LineTranspose ( )

Switch the current line with the previous.

void wxStyledTextCtrl::LineUp ( )

Move caret up one line.

void wxStyledTextCtrl::LineUpExtend ( )

Move caret up one line extending selection to new caret position.

void wxStyledTextCtrl::LineUpRectExtend ( )

Move caret up one line, extending rectangular selection to new caret position.

bool wxStyledTextCtrl::LoadFile (const wxString & *filename*)

Load the contents of filename into the editor.

void wxStyledTextCtrl::LowerCase ( )

Transform the selection to lower case.

int wxStyledTextCtrl::MarginGetStyle (int *line*) const

Get the style number for the text margin for a line.

int wxStyledTextCtrl::MarginGetStyleOffset ( ) const

Get the start of the range of style numbers used for margin text.

wxString wxStyledTextCtrl::MarginGetStyles (int *line*) const

Get the styles in the text margin for a line.

wxString wxStyledTextCtrl::MarginGetText (int *line*) const

Get the text in the text margin for a line.

void wxStyledTextCtrl::MarginSetStyle (int *line,* int *style*)

Set the style number for the text margin for a line.

void wxStyledTextCtrl::MarginSetStyleOffset (int *style*)

Get the start of the range of style numbers used for margin text.

void wxStyledTextCtrl::MarginSetStyles (int *line,* const wxString & *styles*)

Set the style in the text margin for a line.

void wxStyledTextCtrl::MarginSetText (int *line,* const wxString & *text*)

Set the text in the text margin for a line.

void wxStyledTextCtrl::MarginTextClearAll ( )

Clear the margin text on all lines.

virtual void wxStyledTextCtrl::MarkDirty ( ) [virtual]

int wxStyledTextCtrl::MarkerAdd (int *line,* int *markerNumber*)

Add a marker to a line, returning an ID which can be used to find or delete the marker.

void wxStyledTextCtrl::MarkerAddSet (int *line,* int *set*)

Add a set of markers to a line.

void wxStyledTextCtrl::MarkerDefine (int *markerNumber,* int *markerSymbol,* const wxColour & *foreground* = wxNullColour, const wxColour & *background* = wxNullColour)

Set the symbol used for a particular marker number, and optionally the fore and background colours.

void wxStyledTextCtrl::MarkerDefineBitmap (int *markerNumber,* const wxBitmap & *bmp*)

Define a marker from a bitmap.

void wxStyledTextCtrl::MarkerDefineRGBAImage (int *markerNumber,* const unsigned char * *pixels*)

Define a marker from RGBA data.

It has the width and height from RGBAImageSetWidth/Height

void wxStyledTextCtrl::MarkerDelete (int *line,* int *markerNumber*)

Delete a marker from a line.

void wxStyledTextCtrl::MarkerDeleteAll (int *markerNumber*)

Delete all markers with a particular number from all lines.

void wxStyledTextCtrl::MarkerDeleteHandle (int *handle*)

Delete a marker.

void wxStyledTextCtrl::MarkerEnableHighlight (bool *enabled*)

Enable/disable highlight for current folding bloc (smallest one that contains the caret)

int wxStyledTextCtrl::MarkerGet (int *line*)

Get a bit mask of all the markers set on a line.

int wxStyledTextCtrl::MarkerLineFromHandle (int *handle*)

Retrieve the line number at which a particular marker is located.

int wxStyledTextCtrl::MarkerNext (int *lineStart,* int *markerMask*)

Find the next line at or after lineStart that includes a marker in mask.
Return -1 when no more lines.

int wxStyledTextCtrl::MarkerPrevious (int *lineStart,* int *markerMask*)

Find the previous line before lineStart that includes a marker in mask.

void wxStyledTextCtrl::MarkerSetAlpha (int *markerNumber,* int *alpha*)

Set the alpha used for a marker that is drawn in the text area, not the margin.

void wxStyledTextCtrl::MarkerSetBackground (int *markerNumber,* const wxColour & *back*)

Set the background colour used for a particular marker number.

void wxStyledTextCtrl::MarkerSetBackgroundSelected (int *markerNumber,* const wxColour & *back*)

Set the background colour used for a particular marker number when its folding block is selected.

void wxStyledTextCtrl::MarkerSetForeground (int *markerNumber,* const wxColour & *fore*)

Set the foreground colour used for a particular marker number.

void wxStyledTextCtrl::MoveCaretInsideView ( )

Move the caret inside current view if it's not there already.

void wxStyledTextCtrl::MoveSelectedLinesDown ( )

Move the selected lines down one line, shifting the line below before the selection.

void wxStyledTextCtrl::MoveSelectedLinesUp ( )

Move the selected lines up one line, shifting the line above after the selection.

void wxStyledTextCtrl::NewLine ( )

Insert a new line, may use a CRLF, CR or LF depending on EOL mode.

void wxStyledTextCtrl::PageDown ( )

Move caret one page down.

void wxStyledTextCtrl::PageDownExtend ( )

Move caret one page down extending selection to new caret position.

void wxStyledTextCtrl::PageDownRectExtend ( )

Move caret one page down, extending rectangular selection to new caret position.

void wxStyledTextCtrl::PageUp ( )

Move caret one page up.

void wxStyledTextCtrl::PageUpExtend ( )

Move caret one page up extending selection to new caret position.

void wxStyledTextCtrl::PageUpRectExtend ( )

Move caret one page up, extending rectangular selection to new caret position.

void wxStyledTextCtrl::ParaDown ( )

Move caret between paragraphs (delimited by empty lines).

void wxStyledTextCtrl::ParaDownExtend ( )

void wxStyledTextCtrl::ParaUp ( )

void wxStyledTextCtrl::ParaUpExtend ( )

void wxStyledTextCtrl::Paste ( ) [virtual]

Paste the contents of the clipboard into the document replacing the selection.

Reimplemented from wxTextEntry.

wxPoint wxStyledTextCtrl::PointFromPosition (int *pos*)

Retrieve the point in the window where a position is displayed.

int wxStyledTextCtrl::PositionAfter (int *pos*)

Given a valid document position, return the next position taking code page into account.

Maximum value returned is the last position in the document.

int wxStyledTextCtrl::PositionBefore (int *pos*)

Given a valid document position, return the previous position taking code page into account.

Returns 0 if passed 0.

int wxStyledTextCtrl::PositionFromLine (int *line*) const

Retrieve the position at the start of a line.

int wxStyledTextCtrl::PositionFromPoint (wxPoint *pt*) const

Find the position from a point within the window.

int wxStyledTextCtrl::PositionFromPointClose (int *x*, int *y*)

Find the position from a point within the window but return INVALID_POSITION if not close to text.

int wxStyledTextCtrl::PositionRelative (int *pos*, int *relative*)

Given a valid document position, return a position that differs in a number of characters.

Returned value is always between 0 and last position in document.

virtual bool wxStyledTextCtrl::PositionToXY (long *pos*, long * *x*, long * *y*) const [virtual]

void* wxStyledTextCtrl::PrivateLexerCall (int *operation*, void * *pointer*)

For private communication between an application and a known lexer.

wxString wxStyledTextCtrl::PropertyNames ( ) const

Retrieve a '
' separated list of properties understood by the current lexer.

int wxStyledTextCtrl::PropertyType (const wxString & *name*)

Retrieve the type of a property.

void wxStyledTextCtrl::Redo ( ) [virtual]

Redoes the next action on the undo history.

Reimplemented from wxTextEntry.

void wxStyledTextCtrl::RegisterImage (int *type*, const wxBitmap & *bmp*)

Register an image for use in autocompletion lists.

void wxStyledTextCtrl::RegisterRGBAImage (int *type*, const unsigned char * *pixels*)

Register an RGBA image for use in autocompletion lists.

It has the width and height from RGBAImageSetWidth/Height

void wxStyledTextCtrl::ReleaseAllExtendedStyles ( )

Release all extended (>255) style numbers.

void wxStyledTextCtrl::ReleaseDocument (void * *docPointer*)

Release a reference to the document, deleting document if it fades to black.

virtual void wxStyledTextCtrl::Remove (long *from*, long *to*) [virtual]

Removes the text starting at the first given position up to (but not including) the character at the last position.

This function puts the current insertion point position at *to* as a side effect.

Parameters

from	The first position.
to	The last position.

Reimplemented from wxTextEntry.

virtual void wxStyledTextCtrl::Replace (long *from*, long *to*, const wxString & *value*) [virtual]

Replaces the text starting at the first position up to (but not including) the character at the last position with the given text.

This function puts the current insertion point position at *to* as a side effect.

Parameters

from	The first position.
to	The last position.

value	The value to replace the existing text with.

Reimplemented from wxTextEntry.

void wxStyledTextCtrl::ReplaceSelection (const wxString & *text*)

Replace the selected text with the argument text.

int wxStyledTextCtrl::ReplaceTarget (const wxString & *text*)

Replace the target text with the argument text.

Text is counted so it can contain NULs. Returns the length of the replacement text.

int wxStyledTextCtrl::ReplaceTargetRE (const wxString & *text*)

Replace the target text with the argument text after \d processing.

Text is counted so it can contain NULs. Looks for \d where d is between 1 and 9 and replaces these with the strings matched in the last search operation which were surrounded by (and). Returns the length of the replacement text including any change caused by processing the \d patterns.

void wxStyledTextCtrl::RGBAImageSetHeight (int *height*)

Set the height for future RGBA image data.

void wxStyledTextCtrl::RGBAImageSetScale (int *scalePercent*)

Set the scale factor in percent for future RGBA image data.

void wxStyledTextCtrl::RGBAImageSetWidth (int *width*)

Set the width for future RGBA image data.

void wxStyledTextCtrl::RotateSelection ( )

Set the main selection to the next selection.

bool wxStyledTextCtrl::SaveFile (const wxString & *filename*)

Write the contents of the editor to filename.

void wxStyledTextCtrl::ScrollRange (int *secondary*, int *primary*)

Scroll the argument positions and the range between them into view giving priority to the primary position then the secondary position.

This may be used to make a search match visible.

void wxStyledTextCtrl::ScrollToColumn (int *column*)

Scroll enough to make the given column visible.

void wxStyledTextCtrl::ScrollToEnd ( )

Scroll to end of document.

void wxStyledTextCtrl::ScrollToLine (int *line*)

Scroll enough to make the given line visible.

void wxStyledTextCtrl::ScrollToStart ( )

Scroll to start of document.

void wxStyledTextCtrl::SearchAnchor ( )

Sets the current caret position to be the search anchor.

int wxStyledTextCtrl::SearchInTarget (const wxString & *text*)

Search for a counted string in the target and set the target to the found range.

Text is counted so it can contain NULs. Returns length of range or -1 for failure in which case target is not moved.

int wxStyledTextCtrl::SearchNext (int *flags,* const wxString & *text*)

Find some text starting at the search anchor.

Does not ensure the selection is visible.

int wxStyledTextCtrl::SearchPrev (int *flags,* const wxString & *text*)

Find some text starting at the search anchor and moving backwards.

Does not ensure the selection is visible.

void wxStyledTextCtrl::SelectAll ( ) [virtual]

Select all the text in the document.

Reimplemented from wxTextEntry.

void wxStyledTextCtrl::SelectionDuplicate ( )

Duplicate the selection.

If selection empty duplicate the line containing the caret.

bool wxStyledTextCtrl::SelectionIsRectangle ( ) const

Is the selection rectangular? The alternative is the more common stream selection.

virtual void wxStyledTextCtrl::SelectNone ( ) [virtual]

Deselects selected text in the control.

Since

2.9.5

Reimplemented from wxTextEntry.

wxIntPtr wxStyledTextCtrl::SendMsg (int *msg*, wxUIntPtr *wp* = 0, wxIntPtr *lp* = 0) const

Send a message to Scintilla.

void wxStyledTextCtrl::SetAdditionalCaretForeground (const wxColour & *fore*)

Set the foreground colour of additional carets.

void wxStyledTextCtrl::SetAdditionalCaretsBlink (bool *additionalCaretsBlink*)

Set whether additional carets will blink.

void wxStyledTextCtrl::SetAdditionalCaretsVisible (bool *additionalCaretsBlink*)

Set whether additional carets are visible.

void wxStyledTextCtrl::SetAdditionalSelAlpha (int *alpha*)

Set the alpha of the selection.

void wxStyledTextCtrl::SetAdditionalSelBackground (const wxColour & *back*)

Set the background colour of additional selections.

Must have previously called SetSelBack with non-zero first argument for this to have an effect.

void wxStyledTextCtrl::SetAdditionalSelectionTyping (bool *additionalSelectionTyping*)

Set whether typing can be performed into multiple selections.

void wxStyledTextCtrl::SetAdditionalSelForeground (const wxColour & *fore*)

Set the foreground colour of additional selections.

Must have previously called SetSelFore with non-zero first argument for this to have an effect.

void wxStyledTextCtrl::SetAnchor (int *posAnchor*)

Set the selection anchor to a position.

The anchor is the opposite end of the selection from the caret.

void wxStyledTextCtrl::SetAutomaticFold (int *automaticFold*)

Set automatic folding behaviours.

void wxStyledTextCtrl::SetBackSpaceUnIndents (bool *bsUnIndents*)

Sets whether a backspace pressed when caret is within indentation unindents.

void wxStyledTextCtrl::SetBufferedDraw (bool *buffered*)

If drawing is buffered then each line of text is drawn into a bitmap buffer before drawing it to the screen to avoid flicker.

void wxStyledTextCtrl::SetCaretForeground (const wxColour & *fore*)

Set the foreground colour of the caret.

void wxStyledTextCtrl::SetCaretLineBackAlpha (int *alpha*)

Set background alpha of the caret line.

void wxStyledTextCtrl::SetCaretLineBackground (const wxColour & *back*)

Set the colour of the background of the line containing the caret.

void wxStyledTextCtrl::SetCaretLineVisible (bool *show*)

Display the background of the line containing the caret in a different colour.

void wxStyledTextCtrl::SetCaretLineVisibleAlways (bool *alwaysVisible*)

Sets the caret line to always visible.

void wxStyledTextCtrl::SetCaretPeriod (int *periodMilliseconds*)

Get the time in milliseconds that the caret is on and off.

0 = steady on.

void wxStyledTextCtrl::SetCaretSticky (int *useCaretStickyBehaviour*)

Stop the caret preferred x position changing when the user types.

void wxStyledTextCtrl::SetCaretStyle (int *caretStyle*)

Set the style of the caret to be drawn.

void wxStyledTextCtrl::SetCaretWidth (int *pixelWidth*)

Set the width of the insert mode caret.

void wxStyledTextCtrl::SetCharsDefault ( )

Reset the set of characters for whitespace and word characters to the defaults.

void wxStyledTextCtrl::SetCodePage (int *codePage*)

Set the code page used to interpret the bytes of the document as characters.

void wxStyledTextCtrl::SetControlCharSymbol (int *symbol*)

Change the way control characters are displayed: If symbol is $<$ 32, keep the drawn way, else, use the given character.

void wxStyledTextCtrl::SetCurrentPos (int *pos*)

Sets the position of the caret.

virtual bool wxStyledTextCtrl::SetDefaultStyle (const wxTextAttr & *style*) `[virtual]`

void wxStyledTextCtrl::SetDocPointer (void * *docPointer*)

Change the document object used.

void wxStyledTextCtrl::SetEdgeColour (const wxColour & *edgeColour*)

Change the colour used in edge indication.

void wxStyledTextCtrl::SetEdgeColumn (int *column*)

Set the column number of the edge.

If text goes past the edge then it is highlighted.

void wxStyledTextCtrl::SetEdgeMode (int *mode*)

The edge may be displayed by a line (EDGE_LINE) or by highlighting text that goes beyond it (EDGE_BACKGR↩OUND) or not displayed at all (EDGE_NONE).

virtual void wxStyledTextCtrl::SetEditable (bool *editable*) `[virtual]`

Makes the text item editable or read-only, overriding the **wxTE_READONLY** flag.

Parameters

editable	If true, the control is editable. If false, the control is read-only.

See also

IsEditable()

Reimplemented from wxTextEntry.

void wxStyledTextCtrl::SetEmptySelection (int *pos*)

Set caret to a position, while removing any existing selection.

void wxStyledTextCtrl::SetEndAtLastLine (bool *endAtLastLine*)

Sets the scroll range so that maximum scroll position has the last line at the bottom of the view (default).

Setting this to false allows scrolling one page below the last line.

void wxStyledTextCtrl::SetEOLMode (int *eolMode*)

Set the current end of line mode.

void wxStyledTextCtrl::SetExtraAscent (int *extraAscent*)

Set extra ascent for each line.

void wxStyledTextCtrl::SetExtraDescent (int *extraDescent*)

Set extra descent for each line.

void wxStyledTextCtrl::SetFirstVisibleLine (int *lineDisplay*)

Scroll so that a display line is at the top of the display.

void wxStyledTextCtrl::SetFoldExpanded (int *line,* bool *expanded*)

Show the children of a header line.

void wxStyledTextCtrl::SetFoldFlags (int *flags*)

Set some style options for folding.

void wxStyledTextCtrl::SetFoldLevel (int *line,* int *level*)

Set the fold level of a line.

This encodes an integer level along with flags indicating whether the line is a header and whether it is effectively white space.

void wxStyledTextCtrl::SetFoldMarginColour (bool *useSetting,* const wxColour & *back*)

Set the colours used as a chequerboard pattern in the fold margin.

void wxStyledTextCtrl::SetFoldMarginHiColour (bool *useSetting,* const wxColour & *fore*)

void wxStyledTextCtrl::SetHighlightGuide (int *column*)

Set the highlighted indentation guide column.

0 = no highlighted guide.

void wxStyledTextCtrl::SetHotspotActiveBackground (bool *useSetting,* const wxColour & *back*)

Set a back colour for active hotspots.

void wxStyledTextCtrl::SetHotspotActiveForeground (bool *useSetting,* const wxColour & *fore*)

Set a fore colour for active hotspots.

void wxStyledTextCtrl::SetHotspotActiveUnderline (bool *underline*)

Enable / Disable underlining active hotspots.

void wxStyledTextCtrl::SetHotspotSingleLine (bool *singleLine*)

Limit hotspots to single line so hotspots on two lines don't merge.

void wxStyledTextCtrl::SetHScrollBar (wxScrollBar * *bar*)

Set the horizontal scrollbar to use instead of the ont that's built-in.

void wxStyledTextCtrl::SetIdentifier (int *identifier*)

Set the identifier reported as idFrom in notification messages.

void wxStyledTextCtrl::SetIdentifiers (int *style,* const wxString & *identifiers*)

Set the identifiers that are shown in a particular style.

void wxStyledTextCtrl::SetIndent (int *indentSize*)

Set the number of spaces used for one level of indentation.

void wxStyledTextCtrl::SetIndentationGuides (int *indentView*)

Show or hide indentation guides.

void wxStyledTextCtrl::SetIndicatorCurrent (int *indicator*)

Set the indicator used for IndicatorFillRange and IndicatorClearRange.

void wxStyledTextCtrl::SetIndicatorValue (int *value*)

Set the value used for IndicatorFillRange.

virtual void wxStyledTextCtrl::SetInsertionPoint (long *pos*) `[virtual]`

Sets the insertion point at the given position.

Parameters

pos	Position to set, in the range from 0 to GetLastPosition() inclusive.

Reimplemented from wxTextEntry.

void wxStyledTextCtrl::SetKeysUnicode (bool *keysUnicode*)

Always interpret keyboard input as Unicode.

void wxStyledTextCtrl::SetKeyWords (int *keywordSet,* const wxString & *keyWords*)

Set up the key words used by the lexer.

void wxStyledTextCtrl::SetLastKeydownProcessed (bool *val*)

void wxStyledTextCtrl::SetLayoutCache (int *mode*)

Sets the degree of caching of layout information.

void wxStyledTextCtrl::SetLexer (int *lexer*)

Set the lexing language of the document.

void wxStyledTextCtrl::SetLexerLanguage (const wxString & *language*)

Set the lexing language of the document based on string name.

void wxStyledTextCtrl::SetLineEndTypesAllowed (int *lineEndBitSet*)

Set the line end types that the application wants to use.
May not be used if incompatible with lexer or encoding.

void wxStyledTextCtrl::SetLineIndentation (int *line,* int *indentSize*)

Change the indentation of a line to a number of columns.

void wxStyledTextCtrl::SetLineState (int *line,* int *state*)

Used to hold extra styling information for each line.

void wxStyledTextCtrl::SetMainSelection (int *selection*)

Set the main selection.

void wxStyledTextCtrl::SetMarginCursor (int *margin,* int *cursor*)

Set the cursor shown when the mouse is inside a margin.

void wxStyledTextCtrl::SetMarginLeft (int *pixelWidth*)

Sets the size in pixels of the left margin.

void wxStyledTextCtrl::SetMarginMask (int *margin,* int *mask*)

Set a mask that determines which markers are displayed in a margin.

void wxStyledTextCtrl::SetMarginOptions (int *marginOptions*)

Set the margin options.

void wxStyledTextCtrl::SetMarginRight (int *pixelWidth*)

Sets the size in pixels of the right margin.

void wxStyledTextCtrl::SetMargins (int *left,* int *right*)

Set the left and right margin in the edit area, measured in pixels.

void wxStyledTextCtrl::SetMarginSensitive (int *margin,* bool *sensitive*)

Make a margin sensitive or insensitive to mouse clicks.

void wxStyledTextCtrl::SetMarginType (int *margin,* int *marginType*)

Set a margin to be either numeric or symbolic.

void wxStyledTextCtrl::SetMarginWidth (int *margin,* int *pixelWidth*)

Set the width of a margin to a width expressed in pixels.

void wxStyledTextCtrl::SetModEventMask (int *mask*)

Set which document modification events are sent to the container.

void wxStyledTextCtrl::SetMouseDownCaptures (bool *captures*)

Set whether the mouse is captured when its button is pressed.

void wxStyledTextCtrl::SetMouseDwellTime (int *periodMilliseconds*)

Sets the time the mouse must sit still to generate a mouse dwell event.

void wxStyledTextCtrl::SetMouseSelectionRectangularSwitch (bool *mouseSelectionRectangularSwitch*)

Set whether switching to rectangular mode while selecting with the mouse is allowed.

void wxStyledTextCtrl::SetMultiPaste (int *multiPaste*)

Change the effect of pasting when there are multiple selections.

void wxStyledTextCtrl::SetMultipleSelection (bool *multipleSelection*)

Set whether multiple selections can be made.

void wxStyledTextCtrl::SetOvertype (bool *overtype*)

Set to overtype (true) or insert mode.

void wxStyledTextCtrl::SetPasteConvertEndings (bool *convert*)

Enable/Disable convert-on-paste for line endings.

void wxStyledTextCtrl::SetPositionCacheSize (int *size*)

Set number of entries in position cache.

void wxStyledTextCtrl::SetPrintColourMode (int *mode*)

Modify colours when printing for clearer printed text.

void wxStyledTextCtrl::SetPrintMagnification (int *magnification*)

Sets the print magnification added to the point size of each style for printing.

void wxStyledTextCtrl::SetPrintWrapMode (int *mode*)

Set printing to line wrapped (SC_WRAP_WORD) or not line wrapped (SC_WRAP_NONE).

void wxStyledTextCtrl::SetProperty (const wxString & *key,* const wxString & *value*)

Set up a value that may be used by a lexer for some optional feature.

void wxStyledTextCtrl::SetPunctuationChars (const wxString & *characters*)

Set the set of characters making up punctuation characters Should be called after SetWordChars.

void wxStyledTextCtrl::SetReadOnly (bool *readOnly*)

Set to read only or read write.

void wxStyledTextCtrl::SetRectangularSelectionAnchor (int *posAnchor*)

void wxStyledTextCtrl::SetRectangularSelectionAnchorVirtualSpace (int *space*)

void wxStyledTextCtrl::SetRectangularSelectionCaret (int *pos*)

void wxStyledTextCtrl::SetRectangularSelectionCaretVirtualSpace (int *space*)

void wxStyledTextCtrl::SetRectangularSelectionModifier (int *modifier*)

On GTK+, allow selecting the modifier key to use for mouse-based rectangular selection.

Often the window manager requires Alt+Mouse Drag for moving windows. Valid values are SCMOD_CTRL(default), SCMOD_ALT, or SCMOD_SUPER.

void wxStyledTextCtrl::SetRepresentation (const wxString & *encodedCharacter,* const wxString & *representation*)

Set the way a character is drawn.

void wxStyledTextCtrl::SetSavePoint ( )

Remember the current position in the undo history as the position at which the document was saved.

void wxStyledTextCtrl::SetScrollWidth (int *pixelWidth*)

Sets the document width assumed for scrolling.

void wxStyledTextCtrl::SetScrollWidthTracking (bool *tracking*)

Sets whether the maximum width line displayed is used to set scroll width.

void wxStyledTextCtrl::SetSearchFlags (int *flags*)

Set the search flags used by SearchInTarget.

void wxStyledTextCtrl::SetSelAlpha (int *alpha*)

Set the alpha of the selection.

void wxStyledTextCtrl::SetSelBackground (bool *useSetting,* const wxColour & *back*)

Set the background colour of the main and additional selections and whether to use this setting.

virtual void wxStyledTextCtrl::SetSelection (long *from,* long *to*) `[virtual]`

Selects the text starting at the first position up to (but not including) the character at the last position.

If both parameters are equal to -1 all text in the control is selected.

Notice that the insertion point will be moved to *from* by this function.

Parameters

from	The first position.
to	The last position.

See also

SelectAll()

Reimplemented from wxTextEntry.

void wxStyledTextCtrl::SetSelectionEnd (int *pos*)

Sets the position that ends the selection - this becomes the currentPosition.

void wxStyledTextCtrl::SetSelectionMode (int *mode*)

Set the selection mode to stream (SC_SEL_STREAM) or rectangular (SC_SEL_RECTANGLE/SC_SEL_THIN) or by lines (SC_SEL_LINES).

void wxStyledTextCtrl::SetSelectionNAnchor (int *selection,* int *posAnchor*)

void wxStyledTextCtrl::SetSelectionNAnchorVirtualSpace (int *selection,* int *space*)

void wxStyledTextCtrl::SetSelectionNCaret (int *selection,* int *pos*)

void wxStyledTextCtrl::SetSelectionNCaretVirtualSpace (int *selection,* int *space*)

void wxStyledTextCtrl::SetSelectionNEnd (int *selection,* int *pos*)

Sets the position that ends the selection - this becomes the currentPosition.

void wxStyledTextCtrl::SetSelectionNStart (int *selection,* int *pos*)

Sets the position that starts the selection - this becomes the anchor.

void wxStyledTextCtrl::SetSelectionStart (int *pos*)

Sets the position that starts the selection - this becomes the anchor.

void wxStyledTextCtrl::SetSelEOLFilled (bool *filled*)

Set the selection to have its end of line filled or not.

void wxStyledTextCtrl::SetSelForeground (bool *useSetting,* const wxColour & *fore*)

Set the foreground colour of the main and additional selections and whether to use this setting.

void wxStyledTextCtrl::SetStatus (int *statusCode*)

Change error status - 0 = OK.

void wxStyledTextCtrl::SetSTCCursor (int *cursorType*)

Sets the cursor to one of the SC_CURSOR∗ values.

void wxStyledTextCtrl::SetSTCFocus (bool *focus*)

Change internal focus flag.

virtual bool wxStyledTextCtrl::SetStyle (long *start,* long *end,* const wxTextAttr & *style*) [virtual]

void wxStyledTextCtrl::SetStyleBits (int *bits*)

Divide each styling byte into lexical class bits (default: 5) and indicator bits (default: 3).

If a lexer requires more than 32 lexical states, then this is used to expand the possible states.

void wxStyledTextCtrl::SetStyleBytes (int *length,* char * *styleBytes*)

Set the styles for a segment of the document.

void wxStyledTextCtrl::SetStyling (int *length,* int *style*)

Change style from current styling position for length characters to a style and move the current styling position to after this newly styled segment.

void wxStyledTextCtrl::SetTabIndents (bool *tabIndents*)

Sets whether a tab pressed when caret is within indentation indents.

void wxStyledTextCtrl::SetTabWidth (int *tabWidth*)

Change the visible size of a tab to be a multiple of the width of a space character.

void wxStyledTextCtrl::SetTargetEnd (int *pos*)

Sets the position that ends the target which is used for updating the document without affecting the scroll position.

void wxStyledTextCtrl::SetTargetStart (int *pos*)

Sets the position that starts the target which is used for updating the document without affecting the scroll position.

void wxStyledTextCtrl::SetTechnology (int *technology*)

Set the technology used.

void wxStyledTextCtrl::SetText (const wxString & *text*)

Replace the contents of the document with the argument text.

void wxStyledTextCtrl::SetTextRaw (const char * *text*)

Replace the contents of the document with the argument text.

void wxStyledTextCtrl::SetTwoPhaseDraw (bool *twoPhase*)

In twoPhaseDraw mode, drawing is performed in two phases, first the background and then the foreground.

This avoids chopping off characters that overlap the next run.

void wxStyledTextCtrl::SetUndoCollection (bool *collectUndo*)

Choose between collecting actions into the undo history and discarding them.

void wxStyledTextCtrl::SetUseHorizontalScrollBar (bool *show*)

Show or hide the horizontal scroll bar.

void wxStyledTextCtrl::SetUseTabs (bool *useTabs*)

Indentation will only use space characters if useTabs is false, otherwise it will use a combination of tabs and spaces.

void wxStyledTextCtrl::SetUseVerticalScrollBar (bool *show*)

Show or hide the vertical scroll bar.

void wxStyledTextCtrl::SetViewEOL (bool *visible*)

Make the end of line characters visible or invisible.

void wxStyledTextCtrl::SetViewWhiteSpace (int *viewWS*)

Make white space characters invisible, always visible or visible outside indentation.

void wxStyledTextCtrl::SetVirtualSpaceOptions (int *virtualSpaceOptions*)

void wxStyledTextCtrl::SetVisiblePolicy (int *visiblePolicy,* int *visibleSlop*)

Set the way the display area is determined when a particular line is to be moved to by Find, FindNext, GotoLine, etc.

void wxStyledTextCtrl::SetVScrollBar (wxScrollBar * *bar*)

Set the vertical scrollbar to use instead of the ont that's built-in.

void wxStyledTextCtrl::SetWhitespaceBackground (bool *useSetting,* const wxColour & *back*)

Set the background colour of all whitespace and whether to use this setting.

void wxStyledTextCtrl::SetWhitespaceChars (const wxString & *characters*)

Set the set of characters making up whitespace for when moving or selecting by word.

Should be called after SetWordChars.

void wxStyledTextCtrl::SetWhitespaceForeground (bool *useSetting,* const wxColour & *fore*)

Set the foreground colour of all whitespace and whether to use this setting.

void wxStyledTextCtrl::SetWhitespaceSize (int *size*)

Set the size of the dots used to mark space characters.

void wxStyledTextCtrl::SetWordChars (const wxString & *characters*)

Set the set of characters making up words for when moving or selecting by word.

First sets defaults like SetCharsDefault.

void wxStyledTextCtrl::SetWrapIndentMode (int *mode*)

Sets how wrapped sublines are placed.

Default is fixed.

void wxStyledTextCtrl::SetWrapMode (int *mode*)

Sets whether text is word wrapped.

void wxStyledTextCtrl::SetWrapStartIndent (int *indent*)

Set the start indent for wrapped lines.

void wxStyledTextCtrl::SetWrapVisualFlags (int *wrapVisualFlags*)

Set the display mode of visual flags for wrapped lines.

void wxStyledTextCtrl::SetWrapVisualFlagsLocation (int *wrapVisualFlagsLocation*)

Set the location of visual flags for wrapped lines.

void wxStyledTextCtrl::SetXCaretPolicy (int *caretPolicy,* int *caretSlop*)

Set the way the caret is kept visible when going sideways.

The exclusion zone is given in pixels.

void wxStyledTextCtrl::SetXOffset (int *newOffset*)

Get and Set the xOffset (ie, horizontal scroll position).

void wxStyledTextCtrl::SetYCaretPolicy (int *caretPolicy,* int *caretSlop*)

Set the way the line the caret is on is kept visible.

The exclusion zone is given in lines.

void wxStyledTextCtrl::SetZoom (int *zoom*)

Set the zoom level.

This number of points is added to the size of all fonts. It may be positive to magnify or negative to reduce.

void wxStyledTextCtrl::ShowLines (int *lineStart,* int *lineEnd*)

Make a range of lines visible.

virtual void wxStyledTextCtrl::ShowPosition (long *pos*) `[virtual]`

void wxStyledTextCtrl::StartRecord ( )

Start notifying the container of all key presses and commands.

void wxStyledTextCtrl::StartStyling (int *pos,* int *mask*)

Set the current styling position to pos and the styling mask to mask.

The styling mask can be used to protect some bits in each styling byte from modification.

void wxStyledTextCtrl::StopRecord ( )

Stop notifying the container of all key presses and commands.

void wxStyledTextCtrl::StutteredPageDown ( )

Move caret to bottom of page, or one page down if already at bottom of page.

void wxStyledTextCtrl::StutteredPageDownExtend ( )

Move caret to bottom of page, or one page down if already at bottom of page, extending selection to new caret position.

void wxStyledTextCtrl::StutteredPageUp ( )

Move caret to top of page, or one page up if already at top of page.

void wxStyledTextCtrl::StutteredPageUpExtend ( )

Move caret to top of page, or one page up if already at top of page, extending selection to new caret position.

void wxStyledTextCtrl::StyleClearAll ( )

Clear all the styles and make equivalent to the global default style.

wxColour wxStyledTextCtrl::StyleGetBackground (int *style*) const

Get the background colour of a style.

bool wxStyledTextCtrl::StyleGetBold (int *style*) const

Get is a style bold or not.

int wxStyledTextCtrl::StyleGetCase (int *style*) const

Get is a style mixed case, or to force upper or lower case.

bool wxStyledTextCtrl::StyleGetChangeable (int *style*) const

Get is a style changeable or not (read only).
Experimental feature, currently buggy.

int wxStyledTextCtrl::StyleGetCharacterSet (int *style*) const

Get the character get of the font in a style.

bool wxStyledTextCtrl::StyleGetEOLFilled (int *style*) const

Get is a style to have its end of line filled or not.

wxString wxStyledTextCtrl::StyleGetFaceName (int *style*)

Get the font facename of a style.

wxFont wxStyledTextCtrl::StyleGetFont (int *style*)

Get the font of a style.

wxColour wxStyledTextCtrl::StyleGetForeground (int *style*) const

Get the foreground colour of a style.

bool wxStyledTextCtrl::StyleGetHotSpot (int *style*) const

Get is a style a hotspot or not.

bool wxStyledTextCtrl::StyleGetItalic (int *style*) const

Get is a style italic or not.

int wxStyledTextCtrl::StyleGetSize (int *style*) const

Get the size of characters of a style.

int wxStyledTextCtrl::StyleGetSizeFractional (int *style*) const

Get the size of characters of a style in points multiplied by 100.

bool wxStyledTextCtrl::StyleGetUnderline (int *style*) const

Get is a style underlined or not.

bool wxStyledTextCtrl::StyleGetVisible (int *style*) const

Get is a style visible or not.

int wxStyledTextCtrl::StyleGetWeight (int *style*) const

Get the weight of characters of a style.

void wxStyledTextCtrl::StyleResetDefault ( )

Reset the default style to its state at startup.

void wxStyledTextCtrl::StyleSetBackground (int *style,* const wxColour & *back*)

Set the background colour of a style.

void wxStyledTextCtrl::StyleSetBold (int *style,* bool *bold*)

Set a style to be bold or not.

void wxStyledTextCtrl::StyleSetCase (int *style,* int *caseForce*)

Set a style to be mixed case, or to force upper or lower case.

void wxStyledTextCtrl::StyleSetChangeable (int *style,* bool *changeable*)

Set a style to be changeable or not (read only).

Experimental feature, currently buggy.

void wxStyledTextCtrl::StyleSetCharacterSet (int *style,* int *characterSet*)

Set the character set of the font in a style.

Converts the Scintilla character set values to a wxFontEncoding.

void wxStyledTextCtrl::StyleSetEOLFilled (int *style,* bool *filled*)

Set a style to have its end of line filled or not.

void wxStyledTextCtrl::StyleSetFaceName (int *style,* const wxString & *fontName*)

Set the font of a style.

void wxStyledTextCtrl::StyleSetFont (int *styleNum,* wxFont & *font*)

Set style size, face, bold, italic, and underline attributes from a wxFont's attributes.

void wxStyledTextCtrl::StyleSetFontAttr (int *styleNum,* int *size,* const wxString & *faceName,* bool *bold,* bool *italic,* bool *underline,* wxFontEncoding *encoding* = wxFONTENCODING_DEFAULT)

Set all font style attributes at once.

void wxStyledTextCtrl::StyleSetFontEncoding (int *style,* wxFontEncoding *encoding*)

Set the font encoding to be used by a style.

void wxStyledTextCtrl::StyleSetForeground (int *style,* const wxColour & *fore*)

Set the foreground colour of a style.

void wxStyledTextCtrl::StyleSetHotSpot (int *style,* bool *hotspot*)

Set a style to be a hotspot or not.

void wxStyledTextCtrl::StyleSetItalic (int *style,* bool *italic*)

Set a style to be italic or not.

void wxStyledTextCtrl::StyleSetSize (int *style,* int *sizePoints*)

Set the size of characters of a style.

void wxStyledTextCtrl::StyleSetSizeFractional (int *style,* int *caseForce*)

Set the size of characters of a style.

Size is in points multiplied by 100.

void wxStyledTextCtrl::StyleSetSpec (int *styleNum,* const wxString & *spec*)

Extract style settings from a spec-string which is composed of one or more of the following comma separated elements:

bold turns on bold italic turns on italics fore:[name or #RRGGBB] sets the foreground colour back:[name or #RR↩ GGBB] sets the background colour face:[facename] sets the font face name to use size:[num] sets the font size in points eol turns on eol filling underline turns on underlining

void wxStyledTextCtrl::StyleSetUnderline (int *style,* bool *underline*)

Set a style to be underlined or not.

void wxStyledTextCtrl::StyleSetVisible (int *style,* bool *visible*)

Set a style to be visible or not.

void wxStyledTextCtrl::StyleSetWeight (int *style,* int *weight*)

Set the weight of characters of a style.

void wxStyledTextCtrl::SwapMainAnchorCaret ( )

Swap that caret and anchor of the main selection.

void wxStyledTextCtrl::Tab ( )

If selection is empty or all on one line replace the selection with a tab character.

If more than one line selected, indent the lines.

void wxStyledTextCtrl::TargetFromSelection ( )

Make the target range start and end be the same as the selection range start and end.

int wxStyledTextCtrl::TextHeight (int *line*)

Retrieve the height of a particular line of text in pixels.

int wxStyledTextCtrl::TextWidth (int *style,* const wxString & *text*)

Measure the pixel width of some text in a particular style.

NUL terminated text argument. Does not handle tab or control characters.

void wxStyledTextCtrl::ToggleCaretSticky ( )

Switch between sticky and non-sticky: meant to be bound to a key.

void wxStyledTextCtrl::ToggleFold (int *line*)

Switch a header line between expanded and contracted.

void wxStyledTextCtrl::Undo ( ) [virtual]

Undo one action in the undo history.

Reimplemented from wxTextEntry.

void wxStyledTextCtrl::UpperCase ( )

Transform the selection to upper case.

void wxStyledTextCtrl::UsePopUp (bool *allowPopUp*)

Set whether a pop up menu is displayed automatically when the user presses the wrong mouse button.

void wxStyledTextCtrl::UserListShow (int *listType,* const wxString & *itemList*)

Display a list of strings and send notification when user chooses one.

void wxStyledTextCtrl::VCHome ( )

Move caret to before first visible character on line.

If already there move to first character on line.

void wxStyledTextCtrl::VCHomeDisplay ( )

Move caret to before first visible character on display line.

If already there move to first character on display line.

void wxStyledTextCtrl::VCHomeDisplayExtend ( )

Like VCHomeDisplay but extending selection to new caret position.

void wxStyledTextCtrl::VCHomeExtend ( )

Like VCHome but extending selection to new caret position.

void wxStyledTextCtrl::VCHomeRectExtend ( )

Move caret to before first visible character on line.

If already there move to first character on line. In either case, extend rectangular selection to new caret position.

void wxStyledTextCtrl::VCHomeWrap ( )

void wxStyledTextCtrl::VCHomeWrapExtend ( )

void wxStyledTextCtrl::VerticalCentreCaret ( )

Centre current line in window.

int wxStyledTextCtrl::VisibleFromDocLine (int *line*)

Find the display line of a document line taking hidden lines into account.

int wxStyledTextCtrl::WordEndPosition (int *pos,* bool *onlyWordCharacters*)

Get position of end of word.

void wxStyledTextCtrl::WordLeft ( )

Move caret left one word.

void wxStyledTextCtrl::WordLeftEnd ( )

Move caret left one word, position cursor at end of word.

void wxStyledTextCtrl::WordLeftEndExtend ( )

Move caret left one word, position cursor at end of word, extending selection to new caret position.

void wxStyledTextCtrl::WordLeftExtend ( )

Move caret left one word extending selection to new caret position.

void wxStyledTextCtrl::WordPartLeft ( )

Move to the previous change in capitalisation.

void wxStyledTextCtrl::WordPartLeftExtend ( )

Move to the previous change in capitalisation extending selection to new caret position.

void wxStyledTextCtrl::WordPartRight ( )

Move to the change next in capitalisation.

void wxStyledTextCtrl::WordPartRightExtend ( )

Move to the next change in capitalisation extending selection to new caret position.

void wxStyledTextCtrl::WordRight ( )

Move caret right one word.

void wxStyledTextCtrl::WordRightEnd ( )

Move caret right one word, position cursor at end of word.

void wxStyledTextCtrl::WordRightEndExtend ( )

Move caret right one word, position cursor at end of word, extending selection to new caret position.

void wxStyledTextCtrl::WordRightExtend ( )

Move caret right one word extending selection to new caret position.

int wxStyledTextCtrl::WordStartPosition (int *pos,* bool *onlyWordCharacters*)

Get position of start of word.

int wxStyledTextCtrl::WrapCount (int *line*)

The number of display lines needed to wrap a document line.

virtual void wxStyledTextCtrl::WriteText (const wxString & *text*) `[virtual]`

Writes the text into the text control at the current insertion position.

Parameters

text	Text to write to the text control.

Remarks

Newlines in the text string are the only control characters allowed, and they will cause appropriate line breaks. See operator<<() and AppendText() for more convenient ways of writing to the window. After the write operation, the insertion point will be at the end of the inserted text, so subsequent write operations will be appended. To append text after the user may have interacted with the control, call wxTextCtrl::SetInsertionPointEnd() before writing.

Reimplemented from wxTextEntry.

virtual long wxStyledTextCtrl::XYToPosition (long *x*, long *y*) const `[virtual]`

void wxStyledTextCtrl::ZoomIn ( )

Magnify the displayed text by increasing the sizes by 1 point.

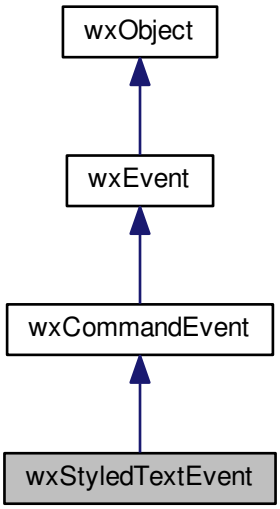
void wxStyledTextCtrl::ZoomOut ( )

Make the displayed text smaller by decreasing the sizes by 1 point.

21.738 wxStyledTextEvent Class Reference

`#include <wx/stc/stc.h>`

Inheritance diagram for wxStyledTextEvent:



21.738.1 Detailed Description

The type of events sent from wxStyledTextCtrl.

Todo list styled text ctrl events.

Library: wxSTC

Category: Events, Scintilla Text Editor

Public Member Functions

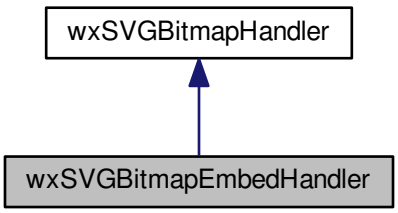
21.739 wxSVGBitmapEmbedHandler Class Reference

`#include <wx/dcsvg.h>`

Inheritance diagram for wxSVGBitmapEmbedHandler:



21.739.1 Detailed Description

Handler embedding bitmaps as base64-encoded PNGs into the SVG.

See also

wxSVGFileDC::SetBitmapHandler().

Library: wxCore

Category: Device Contexts

Since

3.1.0

Public Member Functions

- virtual bool ProcessBitmap (const wxBitmap &bitmap, wxCoord x, wxCoord y, wxOutputStream &stream) const

  Writes the bitmap representation as SVG to the given stream.

21.739.2 Member Function Documentation

virtual bool wxSVGBitmapEmbedHandler::ProcessBitmap (const wxBitmap & *bitmap*, wxCoord *x*, wxCoord *y*, wxOutputStream & *stream*) const `[virtual]`

Writes the bitmap representation as SVG to the given stream.

The XML generated by this function will be inserted into the SVG file inline with the XML generated by the main wxSVGFileDC class so it is important that the XML is properly formed.

Parameters

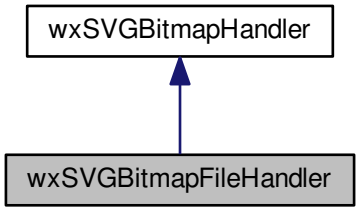
bitmap	A valid bitmap to add to SVG.
x	Horizontal position of the bitmap.
y	Vertical position of the bitmap.
stream	The stream to write SVG contents to.

Implements wxSVGBitmapHandler.

21.740 wxSVGBitmapFileHandler Class Reference

`#include <wx/dcsvg.h>`

Inheritance diagram for wxSVGBitmapFileHandler:



21.740.1 Detailed Description

Handler saving a bitmap to an external file and linking to it from the SVG.

This handler is used by default by wxSVGFileDC.

See also

wxSVGFileDC::SetBitmapHandler().

Library: wxCore

Category: Device Contexts

Since

3.1.0

Public Member Functions

- virtual bool ProcessBitmap (const wxBitmap &bitmap, wxCoord x, wxCoord y, wxOutputStream &stream) const

  Writes the bitmap representation as SVG to the given stream.

21.740.2 Member Function Documentation

virtual bool wxSVGBitmapFileHandler::ProcessBitmap (const wxBitmap & *bitmap*, wxCoord *x*, wxCoord *y*, wxOutputStream & *stream*) const `[virtual]`

Writes the bitmap representation as SVG to the given stream.

The XML generated by this function will be inserted into the SVG file inline with the XML generated by the main wxSVGFileDC class so it is important that the XML is properly formed.

Parameters

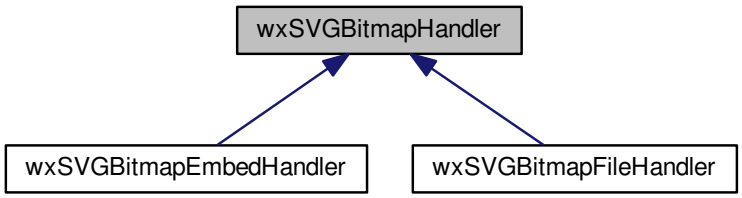
bitmap	A valid bitmap to add to SVG.
x	Horizontal position of the bitmap.
y	Vertical position of the bitmap.
stream	The stream to write SVG contents to.

Implements wxSVGBitmapHandler.

21.741 wxSVGBitmapHandler Class Reference

`#include <wx/dcsvg.h>`

Inheritance diagram for wxSVGBitmapHandler:



21.741.1 Detailed Description

Abstract base class for handling bitmaps inside a wxSVGFileDC.

To use it you need to derive a new class from it and override ProcessBitmap() to generate a properly a formed SVG image element (see http://www.w3.org/TR/SVG/struct.html#ImageElement).

Two example bitmap handlers are provided in wx/dcsvg.h. The first (default) handler will create PNG files in the same folder as the SVG file and uses links to them in the SVG. The second handler (wxSVGBitmapEmbedHandler) will embed the PNG image in the SVG file using base 64 encoding.

The handler can be changed by calling wxSVGFileDC::SetBitmapHandler().

Library: wxCore

Category: Device Contexts

Since

3.1.0

Public Member Functions

- virtual bool ProcessBitmap (const wxBitmap &bitmap, wxCoord x, wxCoord y, wxOutputStream &stream) const =0

  Writes the bitmap representation as SVG to the given stream.

21.741.2 Member Function Documentation

virtual bool wxSVGBitmapHandler::ProcessBitmap (const wxBitmap & *bitmap,* wxCoord *x,* wxCoord *y,* wxOutputStream & *stream*) const [pure virtual]

Writes the bitmap representation as SVG to the given stream.

The XML generated by this function will be inserted into the SVG file inline with the XML generated by the main wxSVGFileDC class so it is important that the XML is properly formed.

Parameters

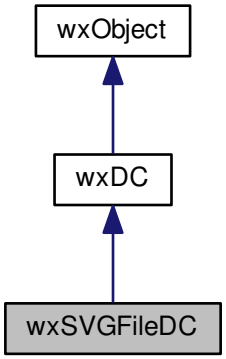
bitmap	A valid bitmap to add to SVG.
x	Horizontal position of the bitmap.
y	Vertical position of the bitmap.
stream	The stream to write SVG contents to.

Implemented in wxSVGBitmapFileHandler, and wxSVGBitmapEmbedHandler.

21.742 wxSVGFileDC Class Reference

```
#include <wx/dcsvg.h>
```

Inheritance diagram for wxSVGFileDC:



21.742.1 Detailed Description

A wxSVGFileDC is a device context onto which graphics and text can be drawn, and the output produced as a vector file, in SVG format.

This format can be read by a range of programs, including a Netscape plugin (Adobe) and the open source Inkscape program (http://inkscape.org/). Full details are given in the W3C SVG recommendation (http://www.w3.org/TR/SVG/).

The intention behind wxSVGFileDC is that it can be used to produce a file corresponding to the screen display context, wxSVGFileDC, by passing the wxSVGFileDC as a parameter instead of a wxDC. Thus the wxSVGFileDC is a write-only class.

As the wxSVGFileDC is a vector format, raster operations like GetPixel() are unlikely to be supported. However, the SVG specification allows for raster files to be embedded in the SVG, and so bitmaps, icons and blit operations in wxSVGFileDC are supported. By default only PNG format bitmaps are supported and these are saved as separate files in the same folder as the SVG file, however it is possible to change this behaviour by replacing the built in bitmap handler using wxSVGFileDC::SetBitmapHandler().

A more substantial SVG library (for reading and writing) is available at the wxArt2D website http://wxart2d.↩ sourceforge.net/.

Library: wxCore

Category: Device Contexts

Public Member Functions

- wxSVGFileDC (const wxString &filename, int width=320, int height=240, double dpi=72)

  Initializes a wxSVGFileDC with the given f filename with the given Width and Height at dpi resolution.
- virtual ~wxSVGFileDC ()

  Destructor.
- void EndDoc ()

  Does nothing.

- void EndPage ()

  Does nothing.
- void Clear ()

  This makes no sense in wxSVGFileDC and does nothing.
- void SetBitmapHandler (wxSVGBitmapHandler *handler)

  Replaces the default bitmap handler with handler.
- void SetLogicalFunction (wxRasterOperationMode function)

  Does the same as wxDC::SetLogicalFunction(), except that only wxCOPY is available.
- void SetClippingRegion (wxCoord x, wxCoord y, wxCoord width, wxCoord height)

  Sets the clipping region for this device context to the intersection of the given region described by the parameters of this method and the previously set clipping region.
- void SetClippingRegion (const wxPoint &pt, const wxSize &sz)

  This is an overloaded member function, provided for convenience.
- void SetClippingRegion (const wxRect &rect)

  This is an overloaded member function, provided for convenience.
- void SetClippingRegion (const wxRegion &region)

  This function is not implemented in this DC class.
- void DestroyClippingRegion ()

  Destroys the current clipping region so that none of the DC is clipped.

- void CrossHair (wxCoord x, wxCoord y)

  Functions not implemented in this DC class.
- bool FloodFill (wxCoord x, wxCoord y, const wxColour &colour, wxFloodFillStyle style=wxFLOOD_SURFACE)

  Functions not implemented in this DC class.
- void GetClippingBox (wxCoord *x, wxCoord *y, wxCoord *width, wxCoord *height) const

  Functions not implemented in this DC class.
- bool GetPixel (wxCoord x, wxCoord y, wxColour *colour) const

  Functions not implemented in this DC class.
- void SetPalette (const wxPalette &palette)

  Functions not implemented in this DC class.
- bool StartDoc (const wxString &message)

  Functions not implemented in this DC class.

Additional Inherited Members

21.742.2 Constructor & Destructor Documentation

wxSVGFileDC::wxSVGFileDC (const wxString & *filename*, int *width* = 320, int *height* = 240, double *dpi* = 72)

Initializes a wxSVGFileDC with the given *f* filename with the given *Width* and *Height* at *dpi* resolution.

virtual wxSVGFileDC::~wxSVGFileDC ( ) [virtual]

Destructor.

21.742.3 Member Function Documentation

void wxSVGFileDC::Clear ( )

This makes no sense in wxSVGFileDC and does nothing.

void wxSVGFileDC::CrossHair (wxCoord *x,* wxCoord *y*)

Functions not implemented in this DC class.

void wxSVGFileDC::DestroyClippingRegion ( )

Destroys the current clipping region so that none of the DC is clipped.

Since intersections arising from sequential calls to SetClippingRegion are represented with nested SVG group elements (<g>), all such groups are closed when DestroyClippingRegion is called.

void wxSVGFileDC::EndDoc ( )

Does nothing.

void wxSVGFileDC::EndPage ( )

Does nothing.

bool wxSVGFileDC::FloodFill (wxCoord *x,* wxCoord *y,* const wxColour & *colour,* wxFloodFillStyle *style* = wxFLOOD_SURFACE)

Functions not implemented in this DC class.

void wxSVGFileDC::GetClippingBox (wxCoord * *x,* wxCoord * *y,* wxCoord * *width,* wxCoord * *height*) const

Functions not implemented in this DC class.

bool wxSVGFileDC::GetPixel (wxCoord *x,* wxCoord *y,* wxColour * *colour*) const

Functions not implemented in this DC class.

void wxSVGFileDC::SetBitmapHandler (wxSVGBitmapHandler * *handler*)

Replaces the default bitmap handler with *handler*.

By default, an object of wxSVGBitmapFileHandler class is used as bitmap handler. You may want to replace it with an object of predefined wxSVGBitmapEmbedHandler class to embed the bitmaps in the generated SVG instead of storing them in separate files like this:

```
mySVGFileDC->SetBitmapHandler(new wxSVGBitmapEmbedHandler());
```

or derive your own bitmap handler class and use it if you need to customize the bitmap handling further.

Parameters

handler	The new bitmap handler. If non-NULL, this object takes ownership of this handler and will delete it when it is not needed any more.

Since

3.1.0

void wxSVGFileDC::SetClippingRegion (wxCoord *x,* wxCoord *y,* wxCoord *width,* wxCoord *height*)

Sets the clipping region for this device context to the intersection of the given region described by the parameters of this method and the previously set clipping region.

Clipping is implemented in the SVG output using SVG group elements (<g>), with nested group elements being used to represent clipping region intersections when two or more calls are made to SetClippingRegion().

void wxSVGFileDC::SetClippingRegion (const wxPoint & *pt,* const wxSize & *sz*)

This is an overloaded member function, provided for convenience.

It differs from the above function only in what argument(s) it accepts.

void wxSVGFileDC::SetClippingRegion (const wxRect & *rect*)

This is an overloaded member function, provided for convenience.

It differs from the above function only in what argument(s) it accepts.

void wxSVGFileDC::SetClippingRegion (const wxRegion & *region*)

This function is not implemented in this DC class.

It could be implemented in future if a GetPoints() function were made available on wxRegion.

void wxSVGFileDC::SetLogicalFunction (wxRasterOperationMode *function*)

Does the same as wxDC::SetLogicalFunction(), except that only wxCOPY is available.

Trying to set one of the other values will fail.

void wxSVGFileDC::SetPalette (const wxPalette & *palette*)

Functions not implemented in this DC class.

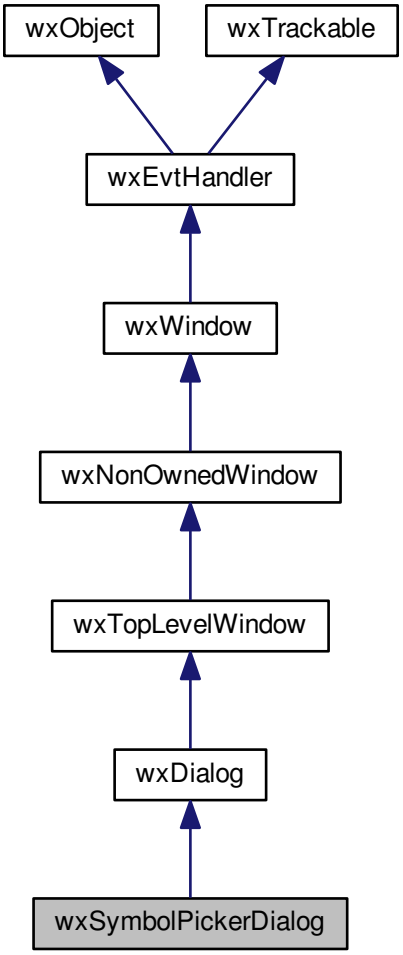
bool wxSVGFileDC::StartDoc (const wxString & *message*)

Functions not implemented in this DC class.

21.743 wxSymbolPickerDialog Class Reference

`#include <wx/richtext/richtextsymboldlg.h>`

Inheritance diagram for wxSymbolPickerDialog:



21.743.1 Detailed Description

wxSymbolPickerDialog presents the user with a choice of fonts and a grid of available characters.

This modal dialog provides the application with a selected symbol and optional font selection.

Although this dialog is contained in the rich text library, the dialog is generic and can be used in other contexts.

To use the dialog, pass a default symbol specified as a string, an initial font name, and a current font name. The difference between the initial font and current font is that the initial font determines what the font control will be set to when the dialog shows - an empty string will show the selection *normal* text. The current font, on the other hand, is used by the dialog to determine what font to display the characters in, even when no initial font is selected. This allows the user (and application) to distinguish between inserting a symbol in the current font, and inserting it with a specified font.

When the dialog is dismissed, the application can get the selected symbol with wxSymbolPickerDialog::GetSymbol and test whether a font was specified with wxSymbolPickerDialog::UseNormalFont,fetching the specified font with wxSymbolPickerDialog::GetFontName.

Here's a realistic example, inserting the supplied symbol into a rich text control in either the current font or specified

font.

```
wxRichTextCtrl* ctrl = (wxRichTextCtrl*) FindWindow(ID_RICHTEXT_CTRL)
      ;

wxTextAttr attr;
attr.SetFlags(wxTEXT_ATTR_FONT);
ctrl->GetStyle(ctrl->GetInsertionPoint(), attr);

wxString currentFontName;
if (attr.HasFont() && attr.GetFont().IsOk())
    currentFontName = attr.GetFont().GetFaceName();

// Don't set the initial font in the dialog (so the user is choosing
// 'normal text', i.e. the current font) but do tell the dialog
// what 'normal text' is.

wxSymbolPickerDialog dlg("*", wxEmptyString, currentFontName, this);

if (dlg.ShowModal() == wxID_OK)
{
    if (dlg.HasSelection())
    {
        long insertionPoint = ctrl->GetInsertionPoint();

        ctrl->WriteText(dlg.GetSymbol());

        if (!dlg.UseNormalFont())
        {
            wxFont font(attr.GetFont());
            font.SetFaceName(dlg.GetFontName());
            attr.SetFont(font);
            ctrl->SetStyle(insertionPoint, insertionPoint+1, attr);
        }
    }
}
```

Library: wxRichText

Category: Common Dialogs

Public Member Functions

- wxSymbolPickerDialog ()

  Default ctor.

- wxSymbolPickerDialog (const wxString &symbol, const wxString &initialFont, const wxString &normalTextFont, wxWindow *parent, wxWindowID id=wxID_ANY, const wxString &title=_("Symbols"), const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, long style=wxDEFAULT_DIALOG_STYLE|wxRESIZE_BORDER|wxCLOSE_BOX)

  Constructor.

- bool Create (const wxString &symbol, const wxString &initialFont, const wxString &normalTextFont, wxWindow *parent, wxWindowID id=wxID_ANY, const wxString &caption=wxGetTranslation("Symbols"), const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxSize(400, 300), long style=wxDEFAULT_DIALOG_STYLE|wxRESIZE_BORDER|wxCLOSE_BOX)

  Creation: see the constructor for details about the parameters.

- wxString GetFontName () const

  Returns the font name (the font reflected in the font list).

- bool GetFromUnicode () const

  Returns true if the dialog is showing the full range of Unicode characters.

- wxString GetNormalTextFontName () const

  Gets the font name used for displaying symbols in the absence of a selected font.

- wxString GetSymbol () const

  Gets the current or initial symbol as a string.

- int GetSymbolChar () const

Gets the selected symbol character as an integer.

- bool HasSelection () const

  Returns true if a symbol is selected.

- void SetFontName (wxString value)

  Sets the initial/selected font name.

- void SetFromUnicode (bool value)

  Sets the internal flag indicating that the full Unicode range should be displayed.

- void SetNormalTextFontName (wxString value)

  Sets the name of the font to be used in the absence of a selected font.

- void SetSymbol (wxString value)

  Sets the symbol as a one or zero character string.

- void SetUnicodeMode (bool unicodeMode)

  Sets Unicode display mode.

- bool UseNormalFont () const

  Returns true if the has specified normal text - that is, there is no selected font.

Additional Inherited Members

21.743.2 Constructor & Destructor Documentation

wxSymbolPickerDialog::wxSymbolPickerDialog ( )

Default ctor.

wxSymbolPickerDialog::wxSymbolPickerDialog (const wxString & *symbol*, const wxString & *initialFont*, const wxString & *normalTextFont*, wxWindow * *parent*, wxWindowID *id* = wxID_ANY, const wxString & *title* = _("Symbols"), const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, long *style* = wxDEFAULT_DIALOG_STYLE|wxRESIZE_BORDER|wxCLOSE_BOX)

Constructor.

Parameters

symbol	The initial symbol to show. Specify a single character in a string, or an empty string.
initialFont	The initial font to be displayed in the font list. If empty, the item normal text will be selected.
normalTextFont	The font the dialog will use to display the symbols if the initial font is empty.
parent	The dialog's parent.
id	The dialog's identifier.
title	The dialog's caption.
pos	The dialog's position.
size	The dialog's size.
style	The dialog's window style.

21.743.3 Member Function Documentation

bool wxSymbolPickerDialog::Create (const wxString & *symbol*, const wxString & *initialFont*, const wxString & *normalTextFont*, wxWindow * *parent*, wxWindowID *id* = wxID_ANY, const wxString & *caption* = wxGetTranslation("Symbols"), const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxSize(400, 300), long *style* = wxDEFAULT_DIALOG_STYLE|wxRESIZE_BORDER|wxCLOSE_BOX)

Creation: see the constructor for details about the parameters.

wxString wxSymbolPickerDialog::GetFontName ( ) const

Returns the font name (the font reflected in the font list).

bool wxSymbolPickerDialog::GetFromUnicode ( ) const

Returns true if the dialog is showing the full range of Unicode characters.

wxString wxSymbolPickerDialog::GetNormalTextFontName ( ) const

Gets the font name used for displaying symbols in the absence of a selected font.

wxString wxSymbolPickerDialog::GetSymbol ( ) const

Gets the current or initial symbol as a string.

int wxSymbolPickerDialog::GetSymbolChar ( ) const

Gets the selected symbol character as an integer.

bool wxSymbolPickerDialog::HasSelection ( ) const

Returns true if a symbol is selected.

void wxSymbolPickerDialog::SetFontName (wxString *value*)

Sets the initial/selected font name.

void wxSymbolPickerDialog::SetFromUnicode (bool *value*)

Sets the internal flag indicating that the full Unicode range should be displayed.

void wxSymbolPickerDialog::SetNormalTextFontName (wxString *value*)

Sets the name of the font to be used in the absence of a selected font.

void wxSymbolPickerDialog::SetSymbol (wxString *value*)

Sets the symbol as a one or zero character string.

void wxSymbolPickerDialog::SetUnicodeMode (bool *unicodeMode*)

Sets Unicode display mode.

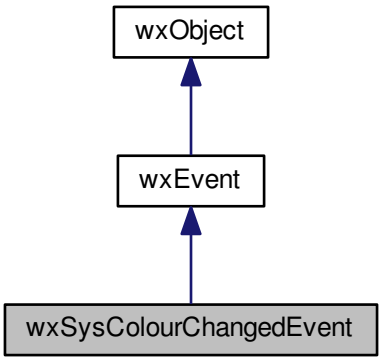
bool wxSymbolPickerDialog::UseNormalFont ( ) const

Returns true if the has specified normal text - that is, there is no selected font.

21.744 wxSysColourChangedEvent Class Reference

`#include <wx/event.h>`

Inheritance diagram for wxSysColourChangedEvent:



21.744.1 Detailed Description

This class is used for system colour change events, which are generated when the user changes the colour settings using the control panel.

This is only appropriate under Windows.

Remarks

The default event handler for this event propagates the event to child windows, since Windows only sends the events to top-level windows. If intercepting this event for a top-level window, remember to call the base class handler, or to pass the event on to the window's children explicitly.

Events using this class

The following event handler macros redirect the events to member function handlers '**func**' with prototypes like: void handlerFuncName(wxSysColourChangedEvent& event)

Event macros:

- EVT_SYS_COLOUR_CHANGED(func): Process a `wxEVT_SYS_COLOUR_CHANGED` event.

Library: wxCore

Category: Events

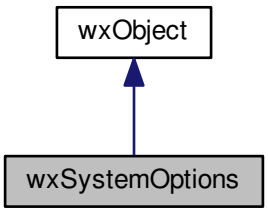
wxSysColourChangedEvent::wxSysColourChangedEvent ( )

Constructor.

21.745 wxSystemOptions Class Reference

`#include <wx/sysopt.h>`

Inheritance diagram for wxSystemOptions:



21.745.1 Detailed Description

wxSystemOptions stores option/value pairs that wxWidgets itself or applications can use to alter behaviour at run-time.

It can be used to optimize behaviour that doesn't deserve a distinct API, but is still important to be able to configure.

System options can be set by the program itself using SetOption() method and they also can be set from the program environment by defining an environment variable `wx_option` to set the given option for all wxWidgets applications or `wx_appname_option` to set it just for the application with the given name (as returned by wxApp::GetAppName()). Notice that any characters not allowed in the environment variables names, such as periods and dashes, should be replaced with underscores. E.g. to define a system option "foo-bar" you need to define the environment variable "wx_foo_bar".

The program may use system options for its own needs but they are mostly used to control the behaviour of wxWidgets library itself.

These options are currently recognised by wxWidgets:

21.745.2 All platforms

- exit-on-assert: If set to non-zero value, abort the program if an assertion fails. The default behaviour in case of assertion failure depends on the build mode and can be changed by overriding wxApp::OnAssertFailure() but setting this option allows to change it without modifying the program code and also applies to asserts which may happen before the wxApp object creation or after its destruction.

21.745.3 Windows

- no-maskblt: 1 to never use WIN32's MaskBlt function, 0 to allow it to be used where possible. Default: 0. In some circumstances the MaskBlt function can be slower than using the fallback code, especially if using DC caching. By default, MaskBlt will be used where it is implemented by the operating system and driver.

- msw.remap: If 1 (the default), wxToolBar bitmap colours will be remapped to the current theme's values. Set this to 0 to disable this functionality, for example if you're using more than 16 colours in your tool bitmaps.

- msw.window.no-clip-children: If 1, windows will not automatically get the WS_CLIPCHILDREN style. This restores the way windows are refreshed back to the method used in versions of wxWidgets earlier than 2.5.4, and for some complex window hierarchies it can reduce apparent refresh delays. You may still specify wxCLIP_CHILDREN for individual windows.

- msw.notebook.themed-background: If set to 0, globally disables themed backgrounds on notebook pages. Note that this won't disable the theme on the actual notebook background (noticeable only if there are no pages).

- msw.staticbox.optimized-paint: If set to 0, switches off optimized wxStaticBox painting. Setting this to 0 causes more flicker, but allows applications to paint graphics on the parent of a static box (the optimized refresh causes any such drawing to disappear).

- msw.display.directdraw: If set to 1, use DirectDraw-based implementation of wxDisplay. By default the standard Win32 functions are used.

- msw.font.no-proof-quality: If set to 1, use default fonts quality instead of proof quality when creating fonts. With proof quality the fonts have slightly better appearance but not all fonts are available in this quality, e.g. the Terminal font in small sizes is not and this option may be used if wider fonts selection is more important than higher quality.

- wince.dialog.real-ok-cancel: The PocketPC guidelines recommend for Ok/Cancel dialogs to use an OK button located inside the caption bar and implement Cancel functionality through Undo outside the dialog. wxDialog::CreateButtonSizer will follow the native behaviour on WinCE but it can be overridden with real wxButtons by setting the option below to 1.

21.745.4 GTK+

- gtk.tlw.can-set-transparent: wxTopLevelWindow::CanSetTransparent() method normally tries to detect automatically whether transparency for top level windows is currently supported, however this may sometimes fail and this option allows to override the automatic detection. Setting it to 1 makes the transparency be always available (setting it can still fail, of course) and setting it to 0 makes it always unavailable.

- gtk.desktop: This option can be set to override the default desktop environment determination. Supported values are GNOME and KDE.

- gtk.window.force-background-colour: If 1, the backgrounds of windows with the wxBG_STYLE_COLOUR background style are cleared forcibly instead of relying on the underlying GTK+ window colour. This works around a display problem when running applications under KDE with the gtk-qt theme installed (0.6 and below).

21.745.5 Mac

- mac.window-plain-transition: If 1, uses a plainer transition when showing a window. You can also use the symbol wxMAC_WINDOW_PLAIN_TRANSITION.
- window-default-variant: The default variant used by windows (cast to integer from the wxWindowVariant enum). Also known as wxWINDOW_DEFAULT_VARIANT.
- mac.listctrl.always_use_generic: Tells wxListCtrl to use the generic control even when it is capable of using the native control instead. Also known as wxMAC_ALWAYS_USE_GENERIC_LISTCTRL.
- mac.textcontrol-use-spell-checker: This option only has effect for Mac OS X 10.4 and higher. If 1 activates the spell checking in wxTextCtrl.
- osx.openfiledialog.always-show-types: Per default a wxFileDialog with wxFD_OPEN does not show a types-popup on OSX but allows the selection of files from any of the supported types. Setting this to 1 shows a wxChoice for selection (if there is more than one supported filetype).

21.745.6 Motif

- motif.largebuttons: If 1, uses a bigger default size for wxButtons.

The compile-time option to include or exclude this functionality is wxUSE_SYSTEM_OPTIONS.

Library: wxBase

Category: Application and System configuration

wxSystemSettings

Public Member Functions

- wxSystemOptions ()

  Default constructor.

Static Public Member Functions

- static wxString GetOption (const wxString &name)

  Gets an option.
- static int GetOptionInt (const wxString &name)

  Gets an option as an integer.
- static bool HasOption (const wxString &name)

  Returns true if the given option is present.
- static bool IsFalse (const wxString &name)

  Returns true if the option with the given name had been set to 0 value.
- static void SetOption (const wxString &name, const wxString &value)

  Sets an option.
- static void SetOption (const wxString &name, int value)

  Sets an option.

Additional Inherited Members

21.745.7 Constructor & Destructor Documentation

wxSystemOptions::wxSystemOptions ( )

Default constructor.

You don't need to create an instance of wxSystemOptions since all of its functions are static.

21.745.8 Member Function Documentation

static wxString wxSystemOptions::GetOption (const wxString & *name*) `[static]`

Gets an option.

The function is case-insensitive to *name*. Returns empty string if the option hasn't been set.

See also

SetOption(), GetOptionInt(), HasOption()

static int wxSystemOptions::GetOptionInt (const wxString & *name*) `[static]`

Gets an option as an integer.

The function is case-insensitive to *name*. If the option hasn't been set, this function returns 0.

See also

SetOption(), GetOption(), HasOption()

static bool wxSystemOptions::HasOption (const wxString & *name*) `[static]`

Returns true if the given option is present.

The function is case-insensitive to *name*.

See also

SetOption(), GetOption(), GetOptionInt()

static bool wxSystemOptions::IsFalse (const wxString & *name*) `[static]`

Returns true if the option with the given *name* had been set to 0 value.

This is mostly useful for boolean options for which you can't use `GetOptionInt(name) == 0` as this would also be true if the option hadn't been set at all.

static void wxSystemOptions::SetOption (const wxString & *name*, const wxString & *value*) `[static]`

Sets an option.

The function is case-insensitive to *name*.

static void wxSystemOptions::SetOption (const wxString & *name,* int *value*) `[static]`

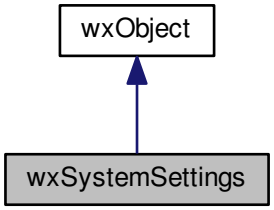
Sets an option.

The function is case-insensitive to *name*.

21.746 wxSystemSettings Class Reference

`#include <wx/settings.h>`

Inheritance diagram for wxSystemSettings:



21.746.1 Detailed Description

wxSystemSettings allows the application to ask for details about the system.

This can include settings such as standard colours, fonts, and user interface element sizes.

Library: wxCore

Category: Application and System configuration

See also

wxFont, wxColour, wxSystemOptions

Public Member Functions

- wxSystemSettings ()
  Default constructor.

Static Public Member Functions

- static wxColour GetColour (wxSystemColour index)
  Returns a system colour.
- static wxFont GetFont (wxSystemFont index)
  Returns a system font.
- static int GetMetric (wxSystemMetric index, wxWindow *win=NULL)

Returns the value of a system metric, or -1 if the metric is not supported on the current system.

- static wxSystemScreenType GetScreenType ()

  Returns the screen type.

- static bool HasFeature (wxSystemFeature index)

  Returns true if the port has certain feature.

Additional Inherited Members

21.746.2 Constructor & Destructor Documentation

wxSystemSettings::wxSystemSettings ( )

Default constructor.

You don't need to create an instance of wxSystemSettings since all of its functions are static.

21.746.3 Member Function Documentation

static wxColour wxSystemSettings::GetColour (wxSystemColour *index*) `[static]`

Returns a system colour.

Parameters

index	Can be one of the wxSystemColour enum values.

Returns

The returned colour is always valid.

static wxFont wxSystemSettings::GetFont (wxSystemFont *index*) `[static]`

Returns a system font.

Parameters

index	Can be one of the wxSystemFont enum values.

Returns

The returned font is always valid.

static int wxSystemSettings::GetMetric (wxSystemMetric *index*, wxWindow * *win* = NULL) `[static]`

Returns the value of a system metric, or -1 if the metric is not supported on the current system.

The value of *win* determines if the metric returned is a global value or a wxWindow based value, in which case it might determine the widget, the display the window is on, or something similar. The window given should be as close to the metric as possible (e.g. a wxTopLevelWindow in case of the wxSYS_CAPTION_Y metric).

index can be one of the wxSystemMetric enum values.

win is a pointer to the window for which the metric is requested. Specifying the *win* parameter is encouraged, because some metrics on some ports are not supported without one,or they might be capable of reporting better values if given one. If a window does not make sense for a metric, one should still be given, as for example it might determine which displays cursor width is requested with wxSYS_CURSOR_X.

static wxSystemScreenType wxSystemSettings::GetScreenType ( ) [static]

Returns the screen type.

The return value is one of the wxSystemScreenType enum values.

static bool wxSystemSettings::HasFeature (wxSystemFeature *index*) [static]

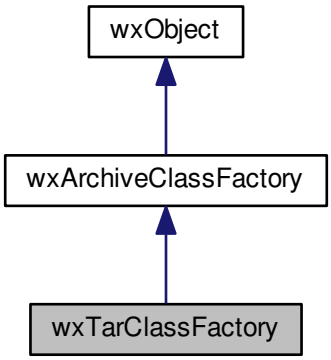
Returns true if the port has certain feature.

See the wxSystemFeature enum values.

21.747 wxTarClassFactory Class Reference

`#include <wx/tarstrm.h>`

Inheritance diagram for wxTarClassFactory:



21.747.1 Detailed Description

Class factory for the tar archive format.

See the base class for details.

Library: wxBase

Category: Archive support, Streams

wxDateTime wxTarEntry::GetCreateTime ( ) const

The entry's creation time stamp.

See also wxArchiveEntry::GetDateTime() and wxArchiveEntry::SetDateTime().

int wxTarEntry::GetDevMajor ( ) const

OS specific IDs defining a device; these are only meaningful when wxTarEntry::GetTypeFlag() is *wxTAR_CHRTYPE* or *wxTAR_BLKTYPE*.

int wxTarEntry::GetDevMinor ( ) const

OS specific IDs defining a device; these are only meaningful when wxTarEntry::GetTypeFlag() is *wxTAR_CHRTYPE* or *wxTAR_BLKTYPE*.

int wxTarEntry::GetGroupId ( ) const

The user ID and group ID that has permissions (see wxTarEntry::GetMode()) over this entry.

These values aren't usually useful unless the file will only be restored to the same system it originated from. wxTarEntry::GetGroupName() and wxTarEntry::GetUserName() can be used instead.

wxString wxTarEntry::GetGroupName ( ) const

The names of the user and group that has permissions (see wxTarEntry::GetMode()) over this entry.

These are not present in very old tars.

wxString wxTarEntry::GetInternalName ( ) const [virtual]

Returns the entry's filename in the internal format used within the archive.

The name can include directory components, i.e. it can be a full path. The names of directory entries are returned without any trailing path separator. This gives a canonical name that can be used in comparisons.

Implements wxArchiveEntry.

static wxString wxTarEntry::GetInternalName (const wxString & *name*, wxPathFormat *format* = wxPATH_NATIVE, bool * *pIsDir* = NULL) [static]

A static member that translates a filename into the internal format used within the archive.

If the third parameter is provided, the bool pointed to is set to indicate whether the name looks like a directory name (i.e. has a trailing path separator).

wxString wxTarEntry::GetLinkName ( ) const

The filename of a previous entry in the tar that this entry is a link to.

Only meaningful when wxTarEntry::GetTypeFlag() is set to *wxTAR_LNKTYPE* or *wxTAR_SYMTYPE*.

int wxTarEntry::GetMode ( ) const

UNIX permission bits for this entry.

Giving read, write and execute permissions to the file's user and group (see GetGroupName() and GetUserName()) and to others.

The integer is one or more wxPosixPermissions flags OR-combined.

wxFileOffset wxTarEntry::GetSize ( ) const [virtual]

The size of the entry's data in bytes.

The tar archive format stores the entry's size ahead of the entry's data. Therefore when creating an archive on a non-seekable stream it is necessary to supply the correct size when each entry is created.

For seekable streams this is not necessary as wxTarOutputStream will attempt to seek back and fix the entry's header when the entry is closed, though it is still more efficient if the size is given beforehand.

Implements wxArchiveEntry.

int wxTarEntry::GetTypeFlag ( ) const

Returns/Sets the type of the entry as a wxTarType value.

When creating archives use only one of wxTarType values. When reading archives, GetTypeFlag() may return a value which does not match any value of wxTarType; in this case the returned value should be treated as *wxTAR_REGTYPE*.

int wxTarEntry::GetUserId ( ) const

The user ID and group ID that has permissions (see wxTarEntry::GetMode()) over this entry.

These values aren't usually useful unless the file will only be restored to the same system it originated from. wxTarEntry::GetGroupName() and wxTarEntry::GetUserName() can be used instead.

wxString wxTarEntry::GetUserName ( ) const

The names of the user and group that has permissions (see wxTarEntry::GetMode()) over this entry.

These are not present in very old tars.

wxTarEntry& wxTarEntry::operator operator= (const wxTarEntry & *entry*)

Assignment operator.

void wxTarEntry::SetAccessTime (const wxDateTime & *dt*)

Gets/sets the entry's access time stamp.

See also wxArchiveEntry::GetDateTime() and wxArchiveEntry::SetDateTime().

void wxTarEntry::SetCreateTime (const wxDateTime & *dt*)

The entry's creation time stamp.

See also wxArchiveEntry::GetDateTime() and wxArchiveEntry::SetDateTime().

void wxTarEntry::SetDevMajor (int *dev*)

OS specific IDs defining a device; these are only meaningful when wxTarEntry::GetTypeFlag() is *wxTAR_CHRTYPE* or *wxTAR_BLKTYPE*.

void wxTarEntry::SetDevMinor (int *dev*)

OS specific IDs defining a device; these are only meaningful when wxTarEntry::GetTypeFlag() is *wxTAR_CHRTYPE* or *wxTAR_BLKTYPE*.

void wxTarEntry::SetGroupId (int *id*)

The user ID and group ID that has permissions (see wxTarEntry::GetMode()) over this entry.

These values aren't usually useful unless the file will only be restored to the same system it originated from. wxTarEntry::GetGroupName() and wxTarEntry::GetUserName() can be used instead.

void wxTarEntry::SetGroupName (const wxString & *group*)

The names of the user and group that has permissions (see wxTarEntry::GetMode()) over this entry.

These are not present in very old tars.

void wxTarEntry::SetLinkName (const wxString & *link*)

The filename of a previous entry in the tar that this entry is a link to.

Only meaningful when wxTarEntry::GetTypeFlag() is set to *wxTAR_LNKTYPE* or *wxTAR_SYMTYPE*.

void wxTarEntry::SetMode (int *mode*)

UNIX permission bits for this entry.

Giving read, write and execute permissions to the file's user and group (see GetGroupName() and GetUserName()) and to others.

The integer is one or more wxPosixPermissions flags OR-combined.

void wxTarEntry::SetSize (wxFileOffset *size*) `[virtual]`

The size of the entry's data in bytes.

The tar archive format stores the entry's size ahead of the entry's data. Therefore when creating an archive on a non-seekable stream it is necessary to supply the correct size when each entry is created.

For seekable streams this is not necessary as wxTarOutputStream will attempt to seek back and fix the entry's header when the entry is closed, though it is still more efficient if the size is given beforehand.

Implements wxArchiveEntry.

void wxTarEntry::SetTypeFlag (int *type*)

Returns/Sets the type of the entry as a wxTarType value.

When creating archives use only one of wxTarType values. When reading archives, GetTypeFlag() may return a value which does not match any value of wxTarType; in this case the returned value should be treated as *wxTAR_REGTYPE*.

void wxTarEntry::SetUserId (int *id*)

The user ID and group ID that has permissions (see wxTarEntry::GetMode()) over this entry.

These values aren't usually useful unless the file will only be restored to the same system it originated from. wxTarEntry::GetGroupName() and wxTarEntry::GetUserName() can be used instead.

void wxTarEntry::SetUserName (const wxString & *user*)

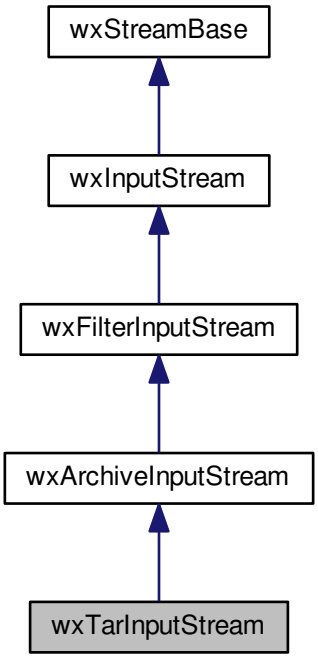
The names of the user and group that has permissions (see wxTarEntry::GetMode()) over this entry.

These are not present in very old tars.

21.749 wxTarInputStream Class Reference

`#include <wx/tarstrm.h>`

Inheritance diagram for wxTarInputStream:



21.749.1 Detailed Description

Input stream for reading tar files.

wxTarInputStream::GetNextEntry() returns a wxTarEntry object containing the meta-data for the next entry in the tar (and gives away ownership). Reading from the wxTarInputStream then returns the entry's data. wxTarInputStream::Eof() becomes true after an attempt has been made to read past the end of the entry's data.

When there are no more entries, wxTarInputStream::GetNextEntry() returns NULL and sets wxTarInputStream::Eof().

Tar entries are seekable if the parent stream is seekable. In practice this usually means they are only seekable if the tar is stored as a local file and is not compressed.

Library: wxBase

Category: Archive support, Streams

Looking Up an Archive Entry by Name

Public Member Functions

- bool CloseEntry ()

  Closes the current entry.
- wxTarEntry * GetNextEntry ()

  Closes the current entry if one is open, then reads the meta-data for the next entry and returns it in a wxTarEntry object, giving away ownership.
- bool OpenEntry (wxTarEntry &entry)

  Closes the current entry if one is open, then opens the entry specified by the entry object.

- wxTarInputStream (wxInputStream &stream, wxMBConv &conv=wxConvLocal)

  Constructor.
- wxTarInputStream (wxInputStream *stream, wxMBConv &conv=wxConvLocal)

  Constructor.

Additional Inherited Members

21.749.2 Constructor & Destructor Documentation

wxTarInputStream::wxTarInputStream (wxInputStream & *stream*, wxMBConv & *conv* = `wxConvLocal`)

Constructor.

In a Unicode build the second parameter *conv* is used to translate fields from the standard tar header into Unicode.

It has no effect on the stream's data. *conv* is only used for the standard tar headers, any pax extended headers are always UTF-8 encoded.

If the parent stream is passed as a pointer then the new filter stream takes ownership of it. If it is passed by reference then it does not.

wxTarInputStream::wxTarInputStream (wxInputStream * *stream*, wxMBConv & *conv* = `wxConvLocal`)

Constructor.

In a Unicode build the second parameter *conv* is used to translate fields from the standard tar header into Unicode.

It has no effect on the stream's data. *conv* is only used for the standard tar headers, any pax extended headers are always UTF-8 encoded.

If the parent stream is passed as a pointer then the new filter stream takes ownership of it. If it is passed by reference then it does not.

21.749.3 Member Function Documentation

bool wxTarInputStream::CloseEntry ( ) `[virtual]`

Closes the current entry.

On a non-seekable stream reads to the end of the current entry first.

Implements wxArchiveInputStream.

wxTarEntry* wxTarInputStream::GetNextEntry ( )

Closes the current entry if one is open, then reads the meta-data for the next entry and returns it in a wxTarEntry object, giving away ownership.

The stream is then open and can be read.

bool wxTarInputStream::OpenEntry (wxTarEntry & *entry*)

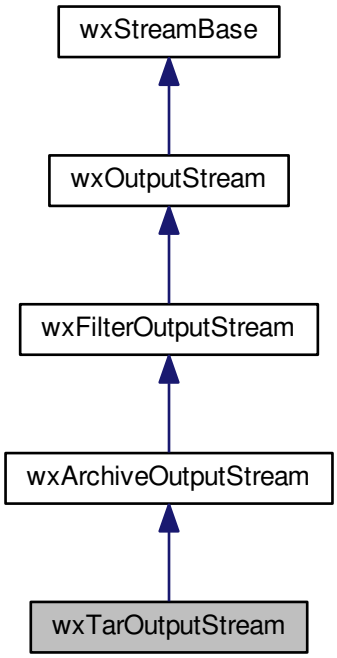
Closes the current entry if one is open, then opens the entry specified by the *entry* object.

entry should be from the same tar file, and the tar should be on a seekable stream.

21.750 wxTarOutputStream Class Reference

`#include <wx/tarstrm.h>`

Inheritance diagram for wxTarOutputStream:



21.750.1 Detailed Description

Output stream for writing tar files.

wxTarOutputStream::PutNextEntry() is used to create a new entry in the output tar, then the entry's data is written to the wxTarOutputStream. Another call to wxTarOutputStream::PutNextEntry() closes the current entry and begins the next.

Library: wxBase

Category: Streams

See also

Archive Formats, wxTarEntry, wxTarInputStream

Public Member Functions

- virtual ~wxTarOutputStream ()

  The destructor calls Close() to finish writing the tar if it has not been called already.
- bool Close ()

  Finishes writing the tar, returning true if successful.
- bool CloseEntry ()

  Close the current entry.
- bool CopyArchiveMetaData (wxTarInputStream &s)

  See wxArchiveOutputStream::CopyArchiveMetaData().
- bool CopyEntry (wxTarEntry *entry, wxTarInputStream &inputStream)

  Takes ownership of entry and uses it to create a new entry in the tar.
- bool PutNextDirEntry (const wxString &name, const wxDateTime &dt=wxDateTime::Now())

  Create a new directory entry (see wxArchiveEntry::IsDir()) with the given name and timestamp.
- bool PutNextEntry (wxTarEntry *entry)

  Takes ownership of entry and uses it to create a new entry in the tar.
- bool PutNextEntry (const wxString &name, const wxDateTime &dt=wxDateTime::Now(), wxFileOffset size=wxInvalidOffset)

  Create a new entry with the given name, timestamp and size.

- wxTarOutputStream (wxOutputStream &stream, wxTarFormat format=wxTAR_PAX, wxMBConv &conv=wxConvLocal)

  If the parent stream is passed as a pointer then the new filter stream takes ownership of it.
- wxTarOutputStream (wxOutputStream *stream, wxTarFormat format=wxTAR_PAX, wxMBConv &conv=wxConvLocal)

  If the parent stream is passed as a pointer then the new filter stream takes ownership of it.

- int GetBlockingFactor () const

  *The tar is zero padded to round its size up to BlockingFactor * 512 bytes.*
- void SetBlockingFactor (int factor)

  *The tar is zero padded to round its size up to BlockingFactor * 512 bytes.*

Additional Inherited Members

21.750.2 Constructor & Destructor Documentation

wxTarOutputStream::wxTarOutputStream (wxOutputStream & *stream*, wxTarFormat *format* = wxTAR_PAX, wxMBConv & *conv* = `wxConvLocal`)

If the parent stream is passed as a pointer then the new filter stream takes ownership of it.

If it is passed by reference then it does not.

In a Unicode build the third parameter *conv* is used to translate the headers fields into an 8-bit encoding. It has no effect on the stream's data.

When the *format* is *wxTAR_PAX*, pax extended headers are generated when any header field will not fit the standard tar header block or if it uses any non-ascii characters.

Extended headers are stored as extra 'files' within the tar, and will be extracted as such by any other tar program that does not understand them. The *conv* parameter only affect the standard tar headers, the extended headers are always UTF-8 encoded.

When the *format* is *wxTAR_USTAR*, no extended headers are generated, and instead a warning message is logged if any header field overflows.

wxTarOutputStream::wxTarOutputStream (wxOutputStream * *stream*, wxTarFormat *format* = wxTAR_PAX, wxMBConv & *conv* = `wxConvLocal`)

If the parent stream is passed as a pointer then the new filter stream takes ownership of it.

If it is passed by reference then it does not.

In a Unicode build the third parameter *conv* is used to translate the headers fields into an 8-bit encoding. It has no effect on the stream's data.

When the *format* is *wxTAR_PAX*, pax extended headers are generated when any header field will not fit the standard tar header block or if it uses any non-ascii characters.

Extended headers are stored as extra 'files' within the tar, and will be extracted as such by any other tar program that does not understand them. The *conv* parameter only affect the standard tar headers, the extended headers are always UTF-8 encoded.

When the *format* is *wxTAR_USTAR*, no extended headers are generated, and instead a warning message is logged if any header field overflows.

virtual wxTarOutputStream::~wxTarOutputStream ( ) `[virtual]`

The destructor calls Close() to finish writing the tar if it has not been called already.

21.750.3 Member Function Documentation

bool wxTarOutputStream::Close ( ) `[virtual]`

Finishes writing the tar, returning true if successful.

Called by the destructor if not called explicitly.

Reimplemented from wxArchiveOutputStream.

bool wxTarOutputStream::CloseEntry ( ) `[virtual]`

Close the current entry.

It is called implicitly whenever another new entry is created with CopyEntry() or PutNextEntry(), or when the tar is closed.

Implements wxArchiveOutputStream.

bool wxTarOutputStream::CopyArchiveMetaData (wxTarInputStream & *s*)

See wxArchiveOutputStream::CopyArchiveMetaData().

For the tar format this function does nothing.

bool wxTarOutputStream::CopyEntry (wxTarEntry * *entry*, wxTarInputStream & *inputStream*)

Takes ownership of *entry* and uses it to create a new entry in the tar.

entry is then opened in *inputStream* and its contents copied to this stream.

For some other archive formats CopyEntry() is much more efficient than transferring the data using Read() and Write() since it will copy them without decompressing and recompressing them. For tar however it makes no difference.

For tars on seekable streams, *entry* must be from the same tar file as *inputStream*. For non-seekable streams, *entry* must also be the last thing read from *inputStream*.

int wxTarOutputStream::GetBlockingFactor ( ) const

The tar is zero padded to round its size up to *BlockingFactor* * 512 bytes.

The blocking factor defaults to 10 for *wxTAR_PAX* and 20 for *wxTAR_USTAR* (see wxTarOutputStream()), as specified in the POSIX standards.

bool wxTarOutputStream::PutNextDirEntry (const wxString & *name*, const wxDateTime & *dt* = wxDateTime::Now ()) [virtual]

Create a new directory entry (see wxArchiveEntry::IsDir()) with the given name and timestamp.

PutNextEntry() can also be used to create directory entries, by supplying a name with a trailing path separator.

Implements wxArchiveOutputStream.

bool wxTarOutputStream::PutNextEntry (wxTarEntry * *entry*)

Takes ownership of entry and uses it to create a new entry in the tar.

bool wxTarOutputStream::PutNextEntry (const wxString & *name*, const wxDateTime & *dt* = wxDateTime::Now (), wxFileOffset *size* = wxInvalidOffset) [virtual]

Create a new entry with the given name, timestamp and size.

Implements wxArchiveOutputStream.

void wxTarOutputStream::SetBlockingFactor (int *factor*)

The tar is zero padded to round its size up to *BlockingFactor* * 512 bytes.

The blocking factor defaults to 10 for *wxTAR_PAX* and 20 for *wxTAR_USTAR* (see wxTarOutputStream()), as specified in the POSIX standards.

21.751 wxTaskBarButton Class Reference

`#include <wx/taskbarbutton.h>`

21.751.1 Detailed Description

A taskbar button that associated with the window under Windows 7 or later.

It is used to access the functionality including thumbnail representations, thumbnail toolbars, notification and status overlays, and progress indicators.

Note

This class is only created and initialized in the internal implementation of wxFrame by design. You can only get the pointer of the instance which associated with the frame by calling wxFrame::MSWGetTaskBarButton().

Library: wxCore

Category: Miscellaneous

Implementations: native under wxMSW port; a generic implementation is used elsewhere. Availability: only available for the wxMSW port.

See also

wxFrame::MSWGetTaskBarButton()

Since

3.1.0

Public Member Functions

- virtual void SetProgressRange (int range)

  Starts showing a determinate progress indicator.
- virtual void SetProgressValue (int value)

  Update the progress indicator, setting the progress to the new value .
- virtual void PulseProgress ()

  Makes the progress indicator run in indeterminate mode.
- virtual void Show (bool show=true)

  Show in the taskbar.
- virtual void Hide ()

  Hide in the taskbar.
- virtual void SetThumbnailTooltip (const wxString &tooltip)

  Specifies or updates the text of the tooltip that is displayed when the mouse pointer rests on an individual preview thumbnail in a taskbar button flyout.
- virtual void SetProgressState (wxTaskBarButtonState state)

  Set the state of the progress indicator displayed on a taskbar button.
- virtual void SetOverlayIcon (const wxIcon &icon, const wxString &description=wxString())

  Set an overlay icon to indicate application status or a notification top the user.
- virtual void SetThumbnailClip (const wxRect &rect)

  Selects a portion of a window's client area to display as that window's thumbnail in the taskbar.
- virtual void SetThumbnailContents (const wxWindow *child)

  Selects the child window area to display as that window's thumbnail in the taskbar.
- virtual bool InsertThumbBarButton (size_t pos, wxThumbBarButton *button)

  Inserts the given button before the position pos to the taskbar thumbnail toolbar.
- virtual bool AppendThumbBarButton (wxThumbBarButton *button)

  Appends a button to the taskbar thumbnail toolbar.
- virtual bool AppendSeparatorInThumbBar ()

  Appends a separator to the taskbar thumbnail toolbar.
- virtual wxThumbBarButton * RemoveThumbBarButton (wxThumbBarButton *button)

  Removes the thumbnail toolbar button from the taskbar button but doesn't delete the associated c++ object.
- virtual wxThumbBarButton * RemoveThumbBarButton (int id)

  Removes the thumbnail toolbar button from the taskbar button but doesn't delete the associated c++ object.

21.751.2 Member Function Documentation

virtual bool wxTaskBarButton::AppendSeparatorInThumbBar ( ) [virtual]

Appends a separator to the taskbar thumbnail toolbar.

Note

The number of buttons and separators is limited to 7.

See also

AppendThumbBarButton(), InsertThumbBarButton()

virtual bool wxTaskBarButton::AppendThumbBarButton (wxThumbBarButton * *button*) [virtual]

Appends a button to the taskbar thumbnail toolbar.

Note

The number of buttons and separators is limited to 7.

See also

InsertThumbBarButton(), AppendSeparatorInThumbBar()

virtual void wxTaskBarButton::Hide ( ) [virtual]

Hide in the taskbar.

virtual bool wxTaskBarButton::InsertThumbBarButton (size_t *pos,* wxThumbBarButton * *button*) [virtual]

Inserts the given button before the position pos to the taskbar thumbnail toolbar.

Note

The number of buttons and separators is limited to 7.

See also

AppendThumbBarButton(), AppendSeparatorInThumbBar()

virtual wxThumbBarButton* wxTaskBarButton::RemoveThumbBarButton (wxThumbBarButton * *button*) [virtual]

Removes the thumbnail toolbar button from the taskbar button but doesn't delete the associated c++ object.

Parameters

button	The thumbnail toolbar button to remove.

Returns

A pointer to the button which was detached from the taskbar button.

virtual wxThumbBarButton* wxTaskBarButton::RemoveThumbBarButton (int *id*) [virtual]

Removes the thumbnail toolbar button from the taskbar button but doesn't delete the associated c++ object.

Parameters

id	The identifier of the thumbnail toolbar button to remove.

Returns

A pointer to the button which was detached from the taskbar button.

virtual void wxTaskBarButton::SetOverlayIcon (const wxIcon & *icon*, const wxString & *description* = wxString()) [virtual]

Set an overlay icon to indicate application status or a notification top the user.

Parameters

icon	This should be a small icon, measuring 16x16 pixels at 96 dpi. If an overlay icon is already applied to the taskbar button, that existing overlay is replaced. Setting with wxNullIcon to remove.
description	The property holds the description of the overlay for accessibility purposes.

virtual void wxTaskBarButton::SetProgressRange (int *range*) [virtual]

Starts showing a determinate progress indicator.

Call SetProgressValue() after this call to update the progress indicator.

If *range* is 0, the progress indicator is dismissed.

virtual void wxTaskBarButton::SetProgressState (wxTaskBarButtonState *state*) [virtual]

Set the state of the progress indicator displayed on a taskbar button.

See also

wxTaskBarButtonState

virtual void wxTaskBarButton::SetProgressValue (int *value*) [virtual]

Update the progress indicator, setting the progress to the new value .

Parameters

value	Must be in the range from 0 to the argument to the last SetProgressRange() call. When it is equal to the range, the progress bar is dismissed.

virtual void wxTaskBarButton::SetThumbnailClip (const wxRect & *rect*) [virtual]

Selects a portion of a window's client area to display as that window's thumbnail in the taskbar.

Parameters

rect	The portion inside of the window. Setting with an empty wxRect will restore the default diaplay of the thumbnail.

virtual void wxTaskBarButton::SetThumbnailContents (const wxWindow * *child*) [virtual]

Selects the child window area to display as that window's thumbnail in the taskbar.

virtual void wxTaskBarButton::SetThumbnailTooltip (const wxString & *tooltip*) [virtual]

Specifies or updates the text of the tooltip that is displayed when the mouse pointer rests on an individual preview thumbnail in a taskbar button flyout.

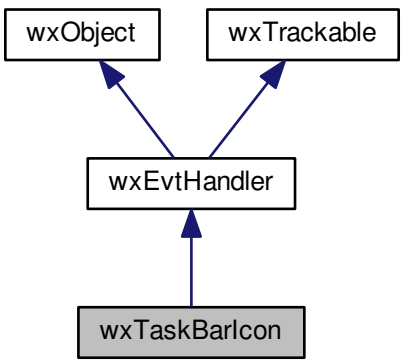
virtual void wxTaskBarButton::Show (bool *show* = true) [virtual]

Show in the taskbar.

21.752 wxTaskBarIcon Class Reference

`#include <wx/taskbar.h>`

Inheritance diagram for wxTaskBarIcon:



21.752.1 Detailed Description

This class represents a taskbar icon.

A taskbar icon is an icon that appears in the 'system tray' and responds to mouse clicks, optionally with a tooltip above it to help provide information.

21.752.2 X Window System Note

Under X Window System, the window manager must support either the "System Tray Protocol" (see http://freedesktop.org/wiki/Specifications/systemtray-spec) by freedesktop.org (WMs used by modern desktop environments such as GNOME >= 2, KDE >= 3 and XFCE >= 4 all do) or the older methods used in GNOME 1.2 and KDE 1 and 2.

If it doesn't, the icon will appear as a toplevel window on user's desktop. Because not all window managers have system tray, there's no guarantee that wxTaskBarIcon will work correctly under X Window System and so the applications should use it only as an optional component of their user interface. The user should be required to explicitly enable the taskbar icon on Unix, it shouldn't be on by default.

Events emitted by this class

The following event handler macros redirect the events to member function handlers '**func**' with prototypes like: void handlerFuncName(wxTaskBarIconEvent& event)

Event macros for events emitted by this class: Note that not all ports are required to send these events and so it's better to override wxTaskBarIcon::CreatePopupMenu() if all that the application does is that it shows a popup menu in reaction to mouse click.

- EVT_TASKBAR_MOVE(func): Process a `wxEVT_TASKBAR_MOVE` event.
- EVT_TASKBAR_LEFT_DOWN(func): Process a `wxEVT_TASKBAR_LEFT_DOWN` event.
- EVT_TASKBAR_LEFT_UP(func): Process a `wxEVT_TASKBAR_LEFT_UP` event.
- EVT_TASKBAR_RIGHT_DOWN(func): Process a `wxEVT_TASKBAR_RIGHT_DOWN` event.
- EVT_TASKBAR_RIGHT_UP(func): Process a `wxEVT_TASKBAR_RIGHT_UP` event.
- EVT_TASKBAR_LEFT_DCLICK(func): Process a `wxEVT_TASKBAR_LEFT_DCLICK` event.
- EVT_TASKBAR_RIGHT_DCLICK(func): Process a `wxEVT_TASKBAR_RIGHT_DCLICK` event.
- EVT_TASKBAR_CLICK(func): This is a synonym for either EVT_TASKBAR_RIGHT_DOWN or UP depending on the platform, use this event macro to catch the event which should result in the menu being displayed on the current platform.

Library: wxAdvanced

Category: Miscellaneous

Public Member Functions

- wxTaskBarIcon (wxTaskBarIconType iconType=wxTBI_DEFAULT_TYPE)

  Default constructor.
- virtual ~wxTaskBarIcon ()

  Destroys the wxTaskBarIcon object, removing the icon if not already removed.
- void Destroy ()

This method is similar to wxWindow::Destroy and can be used to schedule the task bar icon object for the delayed destruction: it will be deleted during the next event loop iteration, which allows the task bar icon to process any pending events for it before being destroyed.

- bool IsIconInstalled () const

  Returns true if SetIcon() was called with no subsequent RemoveIcon().

- bool IsOk () const

  Returns true if the object initialized successfully.

- virtual bool PopupMenu (wxMenu *menu)

  Pops up a menu at the current mouse position.

- virtual bool RemoveIcon ()

  Removes the icon previously set with SetIcon().

- virtual bool SetIcon (const wxIcon &icon, const wxString &tooltip=wxEmptyString)

  Sets the icon, and optional tooltip text.

Static Public Member Functions

- static bool IsAvailable ()

  Returns true if system tray is available in the desktop environment the app runs under.

Protected Member Functions

- virtual wxMenu * CreatePopupMenu ()

  This method is called by the library when the user requests popup menu (on Windows and Unix platforms, this is when the user right-clicks the icon).

Additional Inherited Members

21.752.3 Constructor & Destructor Documentation

wxTaskBarIcon::wxTaskBarIcon (wxTaskBarIconType *iconType* = wxTBI_DEFAULT_TYPE)

Default constructor.

The iconType is only applicable on wxOSX_Cocoa.

virtual wxTaskBarIcon::~wxTaskBarIcon ( ) [virtual]

Destroys the wxTaskBarIcon object, removing the icon if not already removed.

21.752.4 Member Function Documentation

virtual wxMenu* wxTaskBarIcon::CreatePopupMenu ( ) [protected], [virtual]

This method is called by the library when the user requests popup menu (on Windows and Unix platforms, this is when the user right-clicks the icon).

Override this function in order to provide popup menu associated with the icon. If CreatePopupMenu() returns NULL (this happens by default), no menu is shown, otherwise the menu is displayed and then deleted by the library as soon as the user dismisses it.

The events can be handled by a class derived from wxTaskBarIcon.

void wxTaskBarIcon::Destroy ( )

This method is similar to wxWindow::Destroy and can be used to schedule the task bar icon object for the delayed destruction: it will be deleted during the next event loop iteration, which allows the task bar icon to process any pending events for it before being destroyed.

static bool wxTaskBarIcon::IsAvailable ( ) [static]

Returns true if system tray is available in the desktop environment the app runs under.

On Windows and Mac OS X, the tray is always available and this function simply returns true.

On Unix, X11 environment may or may not provide the tray, depending on user's desktop environment. Most modern desktops support the tray via the System Tray Protocol by freedesktop.org (http://freedesktop.org/wiki/Specifications/systemtray-spec).

Note

Tray availability may change during application's lifetime under X11 and so applications shouldn't cache the result.
wxTaskBarIcon supports older GNOME 1.2 and KDE 1/2 methods of adding icons to tray, but they are unreliable and this method doesn't detect them.

Since

2.9.0

bool wxTaskBarIcon::IsIconInstalled ( ) const

Returns true if SetIcon() was called with no subsequent RemoveIcon().

bool wxTaskBarIcon::IsOk ( ) const

Returns true if the object initialized successfully.

virtual bool wxTaskBarIcon::PopupMenu (wxMenu * *menu*) [virtual]

Pops up a menu at the current mouse position.

The events can be handled by a class derived from wxTaskBarIcon.

Note

It is recommended to override CreatePopupMenu() callback instead of calling this method from event handler, because some ports (e.g. wxCocoa) may not implement PopupMenu() and mouse click events at all.

virtual bool wxTaskBarIcon::RemoveIcon ( ) [virtual]

Removes the icon previously set with SetIcon().

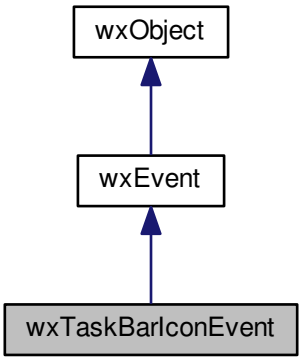
virtual bool wxTaskBarIcon::SetIcon (const wxIcon & *icon*, const wxString & *tooltip* = wxEmptyString) [virtual]

Sets the icon, and optional tooltip text.

21.753 wxTaskBarIconEvent Class Reference

`#include <wx/taskbar.h>`

Inheritance diagram for wxTaskBarIconEvent:



21.753.1 Detailed Description

The event class used by wxTaskBarIcon.

Constructor.

21.754 wxTaskBarJumpList Class Reference

`#include <wx/taskbarbutton.h>`

21.754.1 Detailed Description

This class is an transparent wrapper around Windows Jump Lists.

Jump Lists, as an new feature since Windows 7, are lists of recently opened items, such as files, folders, or websites, which are organized by the program that the user use to open them. Jump Lists don't just show shortcuts to files. Sometimes they can also provide quick access to tasks. With this class, you can access the recent and frequent category in the jump lists. You can also set the tasks category of the Jump Lists of your application. What's more, you can add custom category to them.

Library: wxCore

Category: Miscellaneous

Availability: only available for the wxMSW port.

Public Member Functions

- wxTaskBarJumpList (const wxString &appID=wxEmptyString)

  Constructs the jump list.
- virtual ~wxTaskBarJumpList ()
- void ShowRecentCategory (bool shown=true)

  Shows or hides the recent category.
- void HideRecentCategory ()

  Hides the recent category.
- void ShowFrequentCategory (bool shown=true)

  Shows or hides the frequent category.
- void HideFrequentCategory ()

  Hides the frequent category.
- wxTaskBarJumpListCategory & GetTasks () const

  Accesses the built in tasks category.
- const wxTaskBarJumpListCategory & GetFrequentCategory () const

  Gets the built in frequent category.
- const wxTaskBarJumpListCategory & GetRecentCategory () const

  Gets the built in recent category.
- const wxTaskBarJumpListCategories & GetCustomCategories () const

  Gets the custom categories.
- void AddCustomCategory (wxTaskBarJumpListCategory *category)

  Add an new custom category.
- wxTaskBarJumpListCategory * RemoveCustomCategory (const wxString &title)

  Removes the custom category from the jump lists but doesn't delete the associated C++ object.
- void DeleteCustomCategory (const wxString &title)

  Deletes the custom category from the jump lists.

21.754.2 Constructor & Destructor Documentation

wxTaskBarJumpList::wxTaskBarJumpList (const wxString & *appID* = wxEmptyString)

Constructs the jump list.

Parameters

appID	Specifies a unique identifier for the application jump list, can be empty by default.

See Application User Model IDs on MSDN for further details.

virtual wxTaskBarJumpList::~wxTaskBarJumpList ( ) [virtual]

21.754.3 Member Function Documentation

void wxTaskBarJumpList::AddCustomCategory (wxTaskBarJumpListCategory * *category*)

Add an new custom category.

Parameters

category	A wxTaskBarJumpListCategory object. It will be owned by the wxTaskBarJumpList object after this function is called, so do not delete it yourself.

void wxTaskBarJumpList::DeleteCustomCategory (const wxString & *title*)

Deletes the custom category from the jump lists.

Parameters

title	The title of the custom category.

const wxTaskBarJumpListCategories& wxTaskBarJumpList::GetCustomCategories ( ) const

Gets the custom categories.

const wxTaskBarJumpListCategory& wxTaskBarJumpList::GetFrequentCategory ( ) const

Gets the built in frequent category.

Note that the returned category is read-only.

const wxTaskBarJumpListCategory& wxTaskBarJumpList::GetRecentCategory ( ) const

Gets the built in recent category.

Note that the returned category is read-only.

wxTaskBarJumpListCategory& wxTaskBarJumpList::GetTasks ( ) const

Accesses the built in tasks category.

With the returned tasks category, you can append an new task, remove an existing task, modify the task item etc.

void wxTaskBarJumpList::HideFrequentCategory ( )

Hides the frequent category.

Equivalent to calling wxTaskBarJumpList::ShowFrequentCategory(false).

void wxTaskBarJumpList::HideRecentCategory ( )

Hides the recent category.

Equivalent to calling wxTaskBarJumpList::ShowFrequentCategory(false).

wxTaskBarJumpListCategory* wxTaskBarJumpList::RemoveCustomCategory (const wxString & *title*)

Removes the custom category from the jump lists but doesn't delete the associated C++ object.

Parameters

title	The title of the custom category.

void wxTaskBarJumpList::ShowFrequentCategory (bool *shown* = `true`)

Shows or hides the frequent category.

void wxTaskBarJumpList::ShowRecentCategory (bool *shown* = `true`)

Shows or hides the recent category.

21.755 wxTaskBarJumpListCategory Class Reference

`#include <wx/taskbarbutton.h>`

21.755.1 Detailed Description

This class represents a category of jump list in the taskbar button.

There are four kinds of categories in Windows: Recent, Frequent, Tasks and custom.

Library: wxCore

Category: Miscellaneous

Availability: only available for the wxMSW port.

Public Member Functions

- wxTaskBarJumpListCategory (wxTaskBarJumpList *parent=NULL, const wxString &title=wxEmptyString)

  Constructs the jump list category.
- virtual ~wxTaskBarJumpListCategory ()
- wxTaskBarJumpListItem * Append (wxTaskBarJumpListItem *item)

Appends a jump list item.

- void Delete (wxTaskBarJumpListItem *item)

  Deletes the jump list item from the category.
- wxTaskBarJumpListItem * Remove (wxTaskBarJumpListItem *item)

  Removes the jump list item from the category but doesn't delete the associated C++ object.
- wxTaskBarJumpListItem * FindItemByPosition (size_t pos) const

  Returns the wxTaskBarJumpListItem given a position in the category.
- wxTaskBarJumpListItem * Insert (size_t pos, wxTaskBarJumpListItem *item)

  Inserts the given item before the position pos.
- wxTaskBarJumpListItem * Prepend (wxTaskBarJumpListItem *item)

  Inserts the given item at position 0, i.e.
- void SetTitle (const wxString &title)

  Sets the title of the category.
- const wxString & GetTitle () const

  Gets the title of the category.
- const wxTaskBarJumpListItems & GetItems () const

  Gets the jump list items of the category.

21.755.2 Constructor & Destructor Documentation

wxTaskBarJumpListCategory::wxTaskBarJumpListCategory (wxTaskBarJumpList * *parent* = NULL, const wxString & *title* = wxEmptyString)

Constructs the jump list category.

Parameters

parent	Jump list that the jump list category belongs to. Can be NULL if the category is going to be added to the jump list later.
title	The title of the category.

virtual wxTaskBarJumpListCategory::~wxTaskBarJumpListCategory ( ) [virtual]

21.755.3 Member Function Documentation

wxTaskBarJumpListItem* wxTaskBarJumpListCategory::Append (wxTaskBarJumpListItem * *item*)

Appends a jump list item.

Parameters

item	The jump list item to be appended. It will be owned by the wxTaskBarJumpListCategory object after this function is called, so do not delete it yourself.

See also

Insert(), Prepend()

void wxTaskBarJumpListCategory::Delete (wxTaskBarJumpListItem * *item*)

Deletes the jump list item from the category.

Parameters

item	The jump list item to be deleted.

See also

Remove()

wxTaskBarJumpListItem* wxTaskBarJumpListCategory::FindItemByPosition (size_t *pos*) const

Returns the wxTaskBarJumpListItem given a position in the category.

const wxTaskBarJumpListItems& wxTaskBarJumpListCategory::GetItems ( ) const

Gets the jump list items of the category.

const wxString& wxTaskBarJumpListCategory::GetTitle ( ) const

Gets the title of the category.

wxTaskBarJumpListItem* wxTaskBarJumpListCategory::Insert (size_t *pos,* wxTaskBarJumpListItem * *item*)

Inserts the given item before the position pos.

See also

Append(), Prepend()

wxTaskBarJumpListItem* wxTaskBarJumpListCategory::Prepend (wxTaskBarJumpListItem * *item*)

Inserts the given item at position 0, i.e.

before all the other existing items.

See also

Append(), Insert();

wxTaskBarJumpListItem* wxTaskBarJumpListCategory::Remove (wxTaskBarJumpListItem * *item*)

Removes the jump list item from the category but doesn't delete the associated C++ object.

Parameters

item	The jump list item to be removed.

void wxTaskBarJumpListCategory::SetTitle (const wxString & *title*)

Sets the title of the category.

21.756 wxTaskBarJumpListItem Class Reference

`#include <wx/taskbarbutton.h>`

21.756.1 Detailed Description

A wxTaskBarJumpListItem represents an item in a jump list category.

Library: wxCore

Category: Miscellaneous

Availability: only available for the wxMSW port.

Since

3.1.0

Public Member Functions

- wxTaskBarJumpListItem (wxTaskBarJumpListCategory *parentCategory=NULL, wxTaskBarJumpListItemType type=wxTASKBAR_JUMP_LIST_SEPARATOR, const wxString &title=wxEmptyString, const wxString &filePath=wxEmptyString, const wxString &arguments=wxEmptyString, const wxString &tooltip=wxEmptyString, const wxString &iconPath=wxEmptyString, int iconIndex=0)

  Constructs a jump list item.
- wxTaskBarJumpListItemType GetType () const

  Returns the type of this item.
- void SetType (wxTaskBarJumpListItemType type)

  Sets the type of this item.
- const wxString & GetTitle () const

  Returns the title of this item.
- void SetTitle (const wxString &title)

  Sets the title of this item.
- const wxString & GetFilePath () const

  Returns the file path of this item.
- void SetFilePath (const wxString &filePath)

  Sets the file path of this item.
- const wxString & GetArguments () const

  Returns the command-line arguments of this item.
- void SetArguments (const wxString &arguments)

  Sets the command-line arguments of this item.
- const wxString & GetTooltip () const

  Returns the description tooltip of this item.
- void SetTooltip (const wxString &tooltip)

  Sets the description tooltip of this item.
- const wxString & GetIconPath () const

  Returns the icon path of this item.
- void SetIconPath (const wxString &iconPath)

  Sets the icon path of this item.
- int GetIconIndex () const

  Returns the icon index of icon in this item.

- void SetIconIndex (int iconIndex)

  Sets the icon index of icon in this item.
- wxTaskBarJumpListCategory * GetCategory () const

  Returns the category this jump list item is in, or NULL if this jump list item is not attached.
- void SetCategory (wxTaskBarJumpListCategory *category)

  Sets the parent category which will contain this jump list item.

21.756.2 Constructor & Destructor Documentation

wxTaskBarJumpListItem::wxTaskBarJumpListItem (wxTaskBarJumpListCategory * *parentCategory* = NULL, wxTaskBarJumpListItemType *type* = wxTASKBAR_JUMP_LIST_SEPARATOR, const wxString & *title* = wxEmptyString, const wxString & *filePath* = wxEmptyString, const wxString & *arguments* = wxEmptyString, const wxString & *tooltip* = wxEmptyString, const wxString & *iconPath* = wxEmptyString, int *iconIndex* = 0)

Constructs a jump list item.

Parameters

parentCategory	Category that the jump list item belongs to. Can be NULL if the item is going to be added to the category later.
type	The type for this item.
title	The title of this item.
filePath	The filePath of this item, the meaning of which depends on the type of this item: If the item type is wxTASKBAR_JUMP_LIST_DESTIONATION, filePath is the path to a file that can be opened by an application. If the item type is wxTASKBAR_JUMP_LIST_TASK, filePath is the path to an executable that is executed when this item is clicked by the user.
arguments	The command-line arguments of this item.
tooltip	The description tooltip of this item.
iconPath	The path to the file containing the icon.
iconIndex	The index of the icon, which is specified by iconPath.

21.756.3 Member Function Documentation

const wxString& wxTaskBarJumpListItem::GetArguments ( ) const

Returns the command-line arguments of this item.

wxTaskBarJumpListCategory* wxTaskBarJumpListItem::GetCategory ( ) const

Returns the category this jump list item is in, or NULL if this jump list item is not attached.

const wxString& wxTaskBarJumpListItem::GetFilePath ( ) const

Returns the file path of this item.

int wxTaskBarJumpListItem::GetIconIndex ( ) const

Returns the icon index of icon in this item.

const wxString& wxTaskBarJumpListItem::GetIconPath ( ) const

Returns the icon path of this item.

const wxString& wxTaskBarJumpListItem::GetTitle ( ) const

Returns the title of this item.

const wxString& wxTaskBarJumpListItem::GetTooltip ( ) const

Returns the description tooltip of this item.

wxTaskBarJumpListItemType wxTaskBarJumpListItem::GetType ( ) const

Returns the type of this item.

void wxTaskBarJumpListItem::SetArguments (const wxString & *arguments*)

Sets the command-line arguments of this item.

void wxTaskBarJumpListItem::SetCategory (wxTaskBarJumpListCategory * *category*)

Sets the parent category which will contain this jump list item.

void wxTaskBarJumpListItem::SetFilePath (const wxString & *filePath*)

Sets the file path of this item.

void wxTaskBarJumpListItem::SetIconIndex (int *iconIndex*)

Sets the icon index of icon in this item.

void wxTaskBarJumpListItem::SetIconPath (const wxString & *iconPath*)

Sets the icon path of this item.

void wxTaskBarJumpListItem::SetTitle (const wxString & *title*)

Sets the title of this item.

void wxTaskBarJumpListItem::SetTooltip (const wxString & *tooltip*)

Sets the description tooltip of this item.

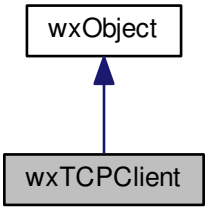
void wxTaskBarJumpListItem::SetType (wxTaskBarJumpListItemType *type*)

Sets the type of this item.

21.757 wxTCPClient Class Reference

```
#include <wx/sckipc.h>
```

Inheritance diagram for wxTCPClient:



21.757.1 Detailed Description

A wxTCPClient object represents the client part of a client-server conversation.

It emulates a DDE-style protocol, but uses TCP/IP which is available on most platforms.

A DDE-based implementation for Windows is available using wxDDEClient.

To create a client which can communicate with a suitable server, you need to derive a class from wxTCPConnection and another from wxTCPClient. The custom wxTCPConnection class will intercept communications in a 'conversation' with a server, and the custom wxTCPServer is required so that a user-overridden wxTCPClient::OnMake↩Connection() member can return a wxTCPConnection of the required class, when a connection is made.

Library: wxNet

Category: Networking

See also

wxTCPServer, wxTCPConnection, Interprocess Communication

Public Member Functions

- wxTCPClient ()

  Constructs a client object.

- virtual wxConnectionBase * MakeConnection (const wxString &host, const wxString &service, const wxString &topic)

  Tries to make a connection with a server specified by the host (a machine name under Unix), service name (must contain an integer port number under Unix), and a topic string.

- virtual wxConnectionBase * OnMakeConnection ()

  *The type of wxTCPConnection returned from a MakeConnection() call can be altered by deriving the **OnMake↩Connection** member to return your own derived connection object.*

- virtual bool ValidHost (const wxString &host)

  Returns true if this is a valid host name, false otherwise.

Additional Inherited Members

21.757.2 Constructor & Destructor Documentation

wxTCPClient::wxTCPClient ( )

Constructs a client object.

21.757.3 Member Function Documentation

virtual wxConnectionBase* wxTCPClient::MakeConnection (const wxString & *host*, const wxString & *service*, const wxString & *topic*) `[virtual]`

Tries to make a connection with a server specified by the host (a machine name under Unix), service name (must contain an integer port number under Unix), and a topic string.

If the server allows a connection, a wxTCPConnection object will be returned.

The type of wxTCPConnection returned can be altered by overriding the OnMakeConnection() member to return your own derived connection object.

virtual wxConnectionBase* wxTCPClient::OnMakeConnection ( ) `[virtual]`

The type of wxTCPConnection returned from a MakeConnection() call can be altered by deriving the **OnMake↩ Connection** member to return your own derived connection object.

By default, a wxTCPConnection object is returned.

The advantage of deriving your own connection class is that it will enable you to intercept messages initiated by the server, such as wxTCPConnection::OnAdvise(). You may also want to store application-specific data in instances of the new class.

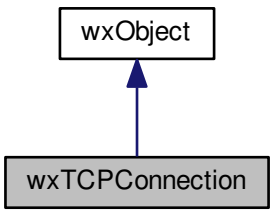
virtual bool wxTCPClient::ValidHost (const wxString & *host*) `[virtual]`

Returns true if this is a valid host name, false otherwise.

21.758 wxTCPConnection Class Reference

`#include <wx/sckipc.h>`

Inheritance diagram for wxTCPConnection:



21.758.1 Detailed Description

A wxTCPClient object represents the connection between a client and a server.

It emulates a DDE-style protocol, but uses TCP/IP which is available on most platforms.

A DDE-based implementation for Windows is available using wxDDEConnection.

A wxTCPConnection object can be created by making a connection using a wxTCPClient object, or by the acceptance of a connection by a wxTCPServer object. The bulk of a conversation is controlled by calling members in a **wxTCPConnection** object or by overriding its members.

An application should normally derive a new connection class from wxTCPConnection, in order to override the communication event handlers to do something interesting.

Library: wxNet

Category: Networking

wxTCPClient, wxTCPServer, Interprocess Communication

Public Member Functions

- virtual bool Disconnect ()

  Called by the client or server application to disconnect from the other program; it causes the OnDisconnect() message to be sent to the corresponding connection object in the other program.
- virtual bool OnAdvise (const wxString &topic, const wxString &item, const void ∗data, size_t size, wxIPC↩ Format format)

  Message sent to the client application when the server notifies it of a change in the data associated with the given item.
- virtual bool OnDisconnect ()

  Message sent to the client or server application when the other application notifies it to delete the connection.
- virtual bool OnExecute (const wxString &topic, const void ∗data, size_t size, wxIPCFormat format)

  Message sent to the server application when the client notifies it to execute the given data.
- virtual bool OnPoke (const wxString &topic, const wxString &item, const void ∗data, size_t size, wxIPCFormat format)

  Message sent to the server application when the client notifies it to accept the given data.
- virtual const void ∗ OnRequest (const wxString &topic, const wxString &item, size_t ∗size, wxIPCFormat format)

  Message sent to the server application when the client calls Request().
- virtual bool OnStartAdvise (const wxString &topic, const wxString &item)

  Message sent to the server application by the client, when the client wishes to start an 'advise loop' for the given topic and item.
- virtual bool OnStopAdvise (const wxString &topic, const wxString &item)

  Message sent to the server application by the client, when the client wishes to stop an 'advise loop' for the given topic and item.
- virtual const void ∗ Request (const wxString &item, size_t ∗size=0, wxIPCFormat format=wxIPC_TEXT)

  Called by the client application to request data from the server.
- virtual bool StartAdvise (const wxString &item)

  Called by the client application to ask if an advise loop can be started with the server.
- virtual bool StopAdvise (const wxString &item)

  Called by the client application to ask if an advise loop can be stopped.

- wxTCPConnection ()

  Constructs a connection object.
- wxTCPConnection (void ∗buffer, size_t size)

  Constructs a connection object.

- bool Advise (const wxString &item, const void ∗data, size_t size, wxIPCFormat format=wxIPC_PRIVATE)

  Called by the server application to advise the client of a change in the data associated with the given item.
- bool Advise (const wxString &item, const char ∗data)

  Called by the server application to advise the client of a change in the data associated with the given item.
- bool Advise (const wxString &item, const wchar_t ∗data)

  Called by the server application to advise the client of a change in the data associated with the given item.
- bool Advise (const wxString &item, const wxString data)

  Called by the server application to advise the client of a change in the data associated with the given item.

- bool Execute (const void ∗data, size_t size, wxIPCFormat format=wxIPC_PRIVATE)

  Called by the client application to execute a command on the server.
- bool Execute (const char ∗data)

  Called by the client application to execute a command on the server.
- bool Execute (const wchar_t ∗data)

  Called by the client application to execute a command on the server.
- bool Execute (const wxString data)

  Called by the client application to execute a command on the server.

- bool Poke (const wxString &item, const void ∗data, size_t size, wxIPCFormat format=wxIPC_PRIVATE)

  Called by the client application to poke data into the server.
- bool Poke (const wxString &item, const char ∗data)

  Called by the client application to poke data into the server.
- bool Poke (const wxString &item, const wchar_t ∗data)

  Called by the client application to poke data into the server.
- bool Poke (const wxString &item, const wxString data)

  Called by the client application to poke data into the server.

Additional Inherited Members

21.758.2 Constructor & Destructor Documentation

wxTCPConnection::wxTCPConnection ( )

Constructs a connection object.

If no user-defined connection object is to be derived from wxTCPConnection, then the constructor should not be called directly, since the default connection object will be provided on requesting (or accepting) a connection.

However, if the user defines his or her own derived connection object, the wxTCPServer::OnAcceptConnection and/or wxTCPClient::OnMakeConnection members should be replaced by functions which construct the new connection object.

If the arguments of the wxTCPConnection constructor are void, then a default buffer is associated with the connection. Otherwise, the programmer must provide a buffer and size of the buffer for the connection object to use in transactions.

wxTCPConnection::wxTCPConnection (void * *buffer,* size_t *size*)

Constructs a connection object.

If no user-defined connection object is to be derived from wxTCPConnection, then the constructor should not be called directly, since the default connection object will be provided on requesting (or accepting) a connection.

However, if the user defines his or her own derived connection object, the wxTCPServer::OnAcceptConnection and/or wxTCPClient::OnMakeConnection members should be replaced by functions which construct the new connection object.

If the arguments of the wxTCPConnection constructor are void, then a default buffer is associated with the connection. Otherwise, the programmer must provide a buffer and size of the buffer for the connection object to use in transactions.

21.758.3 Member Function Documentation

bool wxTCPConnection::Advise (const wxString & *item,* const void * *data,* size_t *size,* wxIPCFormat *format* = wxIPC_PRIVATE)

Called by the server application to advise the client of a change in the data associated with the given item.

Causes the client connection's OnAdvise() member to be called.

Returns true if successful.

bool wxTCPConnection::Advise (const wxString & *item,* const char * *data*)

Called by the server application to advise the client of a change in the data associated with the given item.

Causes the client connection's OnAdvise() member to be called.

Returns true if successful.

bool wxTCPConnection::Advise (const wxString & *item,* const wchar_t * *data*)

Called by the server application to advise the client of a change in the data associated with the given item.

Causes the client connection's OnAdvise() member to be called.

Returns true if successful.

bool wxTCPConnection::Advise (const wxString & *item,* const wxString *data*)

Called by the server application to advise the client of a change in the data associated with the given item.

Causes the client connection's OnAdvise() member to be called.

Returns true if successful.

virtual bool wxTCPConnection::Disconnect ( ) [virtual]

Called by the client or server application to disconnect from the other program; it causes the OnDisconnect() message to be sent to the corresponding connection object in the other program.

The default behaviour of **OnDisconnect** is to delete the connection, but the calling application must explicitly delete its side of the connection having called **Disconnect**.

Returns true if successful.

bool wxTCPConnection::Execute (const void * *data*, size_t *size*, wxIPCFormat *format* = wxIPC_PRIVATE)

Called by the client application to execute a command on the server.

Can also be used to transfer arbitrary data to the server (similar to Poke() in that respect). Causes the server connection's OnExecute() member to be called.

Returns true if successful.

bool wxTCPConnection::Execute (const char * *data*)

Called by the client application to execute a command on the server.

Can also be used to transfer arbitrary data to the server (similar to Poke() in that respect). Causes the server connection's OnExecute() member to be called.

Returns true if successful.

bool wxTCPConnection::Execute (const wchar_t * *data*)

Called by the client application to execute a command on the server.

Can also be used to transfer arbitrary data to the server (similar to Poke() in that respect). Causes the server connection's OnExecute() member to be called.

Returns true if successful.

bool wxTCPConnection::Execute (const wxString *data*)

Called by the client application to execute a command on the server.

Can also be used to transfer arbitrary data to the server (similar to Poke() in that respect). Causes the server connection's OnExecute() member to be called.

Returns true if successful.

virtual bool wxTCPConnection::OnAdvise (const wxString & *topic*, const wxString & *item*, const void * *data*, size_t *size*, wxIPCFormat *format*) `[virtual]`

Message sent to the client application when the server notifies it of a change in the data associated with the given item.

virtual bool wxTCPConnection::OnDisconnect ( ) `[virtual]`

Message sent to the client or server application when the other application notifies it to delete the connection.

Default behaviour is to delete the connection object.

virtual bool wxTCPConnection::OnExecute (const wxString & *topic*, const void * *data*, size_t *size*, wxIPCFormat *format*) `[virtual]`

Message sent to the server application when the client notifies it to execute the given data.

Note that there is no item associated with this message.

virtual bool wxTCPConnection::OnPoke (const wxString & *topic,* const wxString & *item,* const void * *data,* size_t *size,* wxIPCFormat *format*) [virtual]

Message sent to the server application when the client notifies it to accept the given data.

virtual const void* wxTCPConnection::OnRequest (const wxString & *topic,* const wxString & *item,* size_t * *size,* wxIPCFormat *format*) [virtual]

Message sent to the server application when the client calls Request().

The server should respond by returning a character string from **OnRequest**, or NULL to indicate no data.

virtual bool wxTCPConnection::OnStartAdvise (const wxString & *topic,* const wxString & *item*) [virtual]

Message sent to the server application by the client, when the client wishes to start an 'advise loop' for the given topic and item.

The server can refuse to participate by returning false.

virtual bool wxTCPConnection::OnStopAdvise (const wxString & *topic,* const wxString & *item*) [virtual]

Message sent to the server application by the client, when the client wishes to stop an 'advise loop' for the given topic and item.

The server can refuse to stop the advise loop by returning false, although this doesn't have much meaning in practice.

bool wxTCPConnection::Poke (const wxString & *item,* const void * *data,* size_t *size,* wxIPCFormat *format =* wxIPC_PRIVATE)

Called by the client application to poke data into the server.

Can be used to transfer arbitrary data to the server. Causes the server connection's OnPoke() member to be called. Returns true if successful.

bool wxTCPConnection::Poke (const wxString & *item,* const char * *data*)

Called by the client application to poke data into the server.

Can be used to transfer arbitrary data to the server. Causes the server connection's OnPoke() member to be called. Returns true if successful.

bool wxTCPConnection::Poke (const wxString & *item,* const wchar_t * *data*)

Called by the client application to poke data into the server.

Can be used to transfer arbitrary data to the server. Causes the server connection's OnPoke() member to be called. Returns true if successful.

bool wxTCPConnection::Poke (const wxString & *item,* const wxString *data*)

Called by the client application to poke data into the server.

Can be used to transfer arbitrary data to the server. Causes the server connection's OnPoke() member to be called. Returns true if successful.

virtual const void* wxTCPConnection::Request (const wxString & *item*, size_t * *size* = 0, wxIPCFormat *format* = wxIPC_TEXT) [virtual]

Called by the client application to request data from the server.

Causes the server connection's OnRequest() member to be called.

Returns a character string (actually a pointer to the connection's buffer) if successful, NULL otherwise.

virtual bool wxTCPConnection::StartAdvise (const wxString & *item*) [virtual]

Called by the client application to ask if an advise loop can be started with the server.

Causes the server connection's OnStartAdvise() member to be called. Returns true if the server okays it, false otherwise.

virtual bool wxTCPConnection::StopAdvise (const wxString & *item*) [virtual]

Called by the client application to ask if an advise loop can be stopped.

Causes the server connection's OnStopAdvise() member to be called. Returns true if the server okays it, false otherwise.

Public Member Functions

- wxTCPServer ()

  Constructs a server object.
- virtual bool Create (const wxString &service)

  Registers the server using the given service name.
- virtual wxConnectionBase * OnAcceptConnection (const wxString &topic)

  *When a client calls **MakeConnection**, the server receives the message and this member is called.*

Additional Inherited Members

21.759.2 Constructor & Destructor Documentation

wxTCPServer::wxTCPServer ( )

Constructs a server object.

21.759.3 Member Function Documentation

virtual bool wxTCPServer::Create (const wxString & *service*) `[virtual]`

Registers the server using the given service name.

Under Unix, the string must contain an integer id which is used as an Internet port number. false is returned if the call failed (for example, the port number is already in use).

virtual wxConnectionBase* wxTCPServer::OnAcceptConnection (const wxString & *topic*) `[virtual]`

When a client calls **MakeConnection**, the server receives the message and this member is called.

The application should derive a member to intercept this message and return a connection object of either the standard wxTCPConnection type, or of a user-derived type. If the topic is "STDIO", the application may wish to refuse the connection. Under Unix, when a server is created the OnAcceptConnection message is always sent for standard input and output.

21.760 wxTempFile Class Reference

`#include <wx/file.h>`

21.760.1 Detailed Description

wxTempFile provides a relatively safe way to replace the contents of the existing file.

The name is explained by the fact that it may be also used as just a temporary file if you don't replace the old file contents.

Usually, when a program replaces the contents of some file it first opens it for writing, thus losing all of the old data and then starts recreating it. This approach is not very safe because during the regeneration of the file bad things may happen: the program may find that there is an internal error preventing it from completing file generation, the

user may interrupt it (especially if file generation takes long time) and, finally, any other external interrupts (power supply failure or a disk error) will leave you without either the original file or the new one.

wxTempFile addresses this problem by creating a temporary file which is meant to replace the original file - but only after it is fully written. So, if the user interrupts the program during the file generation, the old file won't be lost. Also, if the program discovers itself that it doesn't want to replace the old file there is no problem - in fact, wxTempFile will **not** replace the old file by default, you should explicitly call wxTempFile::Commit() to do it. Calling wxTempFile::Discard() explicitly discards any modifications: it closes and deletes the temporary file and leaves the original file unchanged. If you call neither Commit() nor Discard(), the destructor will call Discard() automatically.

To summarize: if you want to replace another file, create an instance of wxTempFile passing the name of the file to be replaced to the constructor. (You may also use default constructor and pass the file name to wxTempFile::Open.) Then you can write to wxTempFile using wxFile-like functions and later call wxTempFile::Commit() to replace the old file (and close this one) or call wxTempFile::Discard() to cancel the modifications.

Library: wxBase

Category: File Handling

Public Member Functions

- wxTempFile (const wxString &strName)

  Associates wxTempFile with the file to be replaced and opens it.
- ~wxTempFile ()

  Destructor calls Discard() if temporary file is still open.
- bool Commit ()

  Validate changes: deletes the old file of name m_strName and renames the new file to the old name.
- void Discard ()

  Discard changes: the old file contents are not changed, the temporary file is deleted.
- bool Flush ()

  Flush the data written to the file to disk.
- bool IsOpened () const

  Returns true if the file was successfully opened.
- wxFileOffset Length () const

  Returns the length of the file.
- bool Open (const wxString &strName)

  Open the temporary file, returns true on success, false if an error occurred.
- wxFileOffset Seek (wxFileOffset ofs, wxSeekMode mode=wxFromStart)

  Seeks to the specified position.
- wxFileOffset Tell () const

  Returns the current position or wxInvalidOffset if file is not opened or if another error occurred.
- bool Write (const wxString &str, const wxMBConv &conv=wxConvUTF8)

  Write to the file, return true on success, false on failure.

21.760.2 Constructor & Destructor Documentation

wxTempFile::wxTempFile (const wxString & *strName*)

Associates wxTempFile with the file to be replaced and opens it.

Warning

You should use IsOpened() to verify that the constructor succeeded.

wxTempFile::~wxTempFile ( )

Destructor calls Discard() if temporary file is still open.

21.760.3 Member Function Documentation

bool wxTempFile::Commit ( )

Validate changes: deletes the old file of name m_strName and renames the new file to the old name.

Returns true if both actions succeeded.

If false is returned it may unfortunately mean two quite different things: either that the old file couldn't be deleted or that the new file couldn't be renamed to the old name.

void wxTempFile::Discard ( )

Discard changes: the old file contents are not changed, the temporary file is deleted.

bool wxTempFile::Flush ( )

Flush the data written to the file to disk.

This simply calls wxFile::Flush() for the underlying file and may be necessary with file systems such as XFS and Ext4 under Linux. Calling this function may however have serious performance implications and also is not necessary with many other file systems so it is not done by default – but you can call it before calling Commit() to absolutely ensure that the data was indeed written to the disk correctly.

bool wxTempFile::IsOpened ( ) const

Returns true if the file was successfully opened.

wxFileOffset wxTempFile::Length ( ) const

Returns the length of the file.

This method may return wxInvalidOffset if the length couldn't be determined or 0 even for non-empty files if the file is not seekable.

In general, the only way to determine if the file for which this function returns 0 is really empty or not is to try reading from it.

bool wxTempFile::Open (const wxString & *strName*)

Open the temporary file, returns true on success, false if an error occurred.

strName is the name of file to be replaced. The temporary file is always created in the directory where *strName* is. In particular, if *strName* doesn't include the path, it is created in the current directory and the program should have write access to it for the function to succeed.

wxFileOffset wxTempFile::Seek (wxFileOffset *ofs*, wxSeekMode *mode* = wxFromStart)

Seeks to the specified position.

wxFileOffset wxTempFile::Tell ( ) const

Returns the current position or wxInvalidOffset if file is not opened or if another error occurred.

bool wxTempFile::Write (const wxString & *str,* const wxMBConv & *conv* = `wxConvUTF8`)

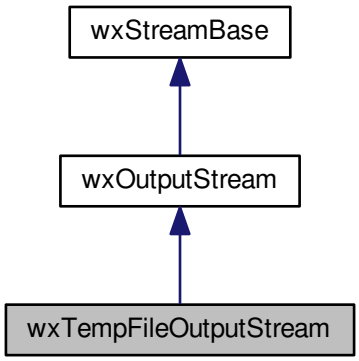
Write to the file, return true on success, false on failure.

The second argument is only meaningful in Unicode build of wxWidgets when *conv* is used to convert *str* to multibyte representation.

21.761 wxTempFileOutputStream Class Reference

`#include <wx/wfstream.h>`

Inheritance diagram for wxTempFileOutputStream:



21.761.1 Detailed Description

wxTempFileOutputStream is an output stream based on wxTempFile.

It provides a relatively safe way to replace the contents of the existing file.

Library: wxBase

Category: Streams

wxTempFile

Public Member Functions

- wxTempFileOutputStream (const wxString &fileName)

Associates wxTempFileOutputStream with the file to be replaced and opens it.

- virtual bool Commit ()

  Validate changes: deletes the old file of the given name and renames the new file to the old name.

- virtual void Discard ()

  Discard changes: the old file contents are not changed, the temporary file is deleted.

Additional Inherited Members

21.761.2 Constructor & Destructor Documentation

wxTempFileOutputStream::wxTempFileOutputStream (const wxString & *fileName*)

Associates wxTempFileOutputStream with the file to be replaced and opens it.

Warning

You should use wxStreamBase::IsOk() to verify if the constructor succeeded.

Call Commit() or wxOutputStream::Close() to replace the old file and close this one. Calling Discard() (or allowing the destructor to do it) will discard the changes.

21.761.3 Member Function Documentation

virtual bool wxTempFileOutputStream::Commit ( ) [virtual]

Validate changes: deletes the old file of the given name and renames the new file to the old name.

Returns true if both actions succeeded.

If false is returned it may unfortunately mean two quite different things: either that either the old file couldn't be deleted or that the new file couldn't be renamed to the old name.

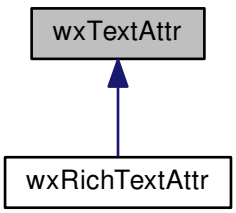
virtual void wxTempFileOutputStream::Discard ( ) [virtual]

Discard changes: the old file contents are not changed, the temporary file is deleted.

21.762 wxTextAttr Class Reference

`#include <wx/textctrl.h>`

Inheritance diagram for wxTextAttr:



21.762.1 Detailed Description

wxTextAttr represents the character and paragraph attributes, or style, for a range of text in a wxTextCtrl or wxRichTextCtrl.

When setting up a wxTextAttr object, pass a bitlist mask to wxTextAttr::SetFlags() to indicate which style elements should be changed. As a convenience, when you call a setter such as SetFont, the relevant bit will be set.

Library: wxCore

Category: Rich Text

wxTextCtrl, wxRichTextCtrl

Public Member Functions

- bool Apply (const wxTextAttr &style, const wxTextAttr *compareWith=NULL)

  Applies the attributes in style to the original object, but not those attributes from style that are the same as those in compareWith (if passed).
- void Merge (const wxTextAttr &overlay)

  Copies all defined/valid properties from overlay to current object.
- bool EqPartial (const wxTextAttr &attr, bool weakTest=true) const

  Partial equality test.
- void operator= (const wxTextAttr &attr)

  Assignment from a wxTextAttr object.

- wxTextAttr ()

  Constructors.
- wxTextAttr (const wxColour &colText, const wxColour &colBack=wxNullColour, const wxFont &font=wxNullFont, wxTextAttrAlignment alignment=wxTEXT_ALIGNMENT_DEFAULT)

  Constructors.
- wxTextAttr (const wxTextAttr &attr)

  Constructors.

GetXXX functions

- wxTextAttrAlignment GetAlignment () const

  Returns the alignment flags.
- const wxColour & GetBackgroundColour () const

  Returns the background colour.
- const wxString & GetBulletFont () const

  Returns a string containing the name of the font associated with the bullet symbol.
- const wxString & GetBulletName () const

  Returns the standard bullet name, applicable if the bullet style is wxTEXT_ATTR_BULLET_STYLE_STANDARD.
- int GetBulletNumber () const

  Returns the bullet number.
- int GetBulletStyle () const

  Returns the bullet style.
- const wxString & GetBulletText () const

  Returns the bullet text, which could be a symbol, or (for example) cached outline text.
- const wxString & GetCharacterStyleName () const

  Returns the name of the character style.

- long GetFlags () const
  Returns flags indicating which attributes are applicable.
- wxFont GetFont () const
  Creates and returns a font specified by the font attributes in the wxTextAttr object.
- bool GetFontAttributes (const wxFont &font, int flags=wxTEXT_ATTR_FONT)
  Gets the font attributes from the given font, using only the attributes specified by flags.
- wxFontEncoding GetFontEncoding () const
  Returns the font encoding.
- const wxString & GetFontFaceName () const
  Returns the font face name.
- wxFontFamily GetFontFamily () const
  Returns the font family.
- int GetFontSize () const
  Returns the font size in points.
- wxFontStyle GetFontStyle () const
  Returns the font style.
- bool GetFontUnderlined () const
  Returns true if the font is underlined.
- wxFontWeight GetFontWeight () const
  Returns the font weight.
- long GetLeftIndent () const
  Returns the left indent in tenths of a millimetre.
- long GetLeftSubIndent () const
  Returns the left sub-indent in tenths of a millimetre.
- int GetLineSpacing () const
  Returns the line spacing value, one of wxTextAttrLineSpacing values.
- const wxString & GetListStyleName () const
  Returns the name of the list style.
- int GetOutlineLevel () const
  Returns the outline level.
- int GetParagraphSpacingAfter () const
  Returns the space in tenths of a millimeter after the paragraph.
- int GetParagraphSpacingBefore () const
  Returns the space in tenths of a millimeter before the paragraph.
- const wxString & GetParagraphStyleName () const
  Returns the name of the paragraph style.
- long GetRightIndent () const
  Returns the right indent in tenths of a millimeter.
- const wxArrayInt & GetTabs () const
  Returns an array of tab stops, each expressed in tenths of a millimeter.
- const wxColour & GetTextColour () const
  Returns the text foreground colour.
- int GetTextEffectFlags () const
  Returns the text effect bits of interest.
- int GetTextEffects () const
  Returns the text effects, a bit list of styles.
- const wxString & GetURL () const
  Returns the URL for the content.

HasXXX and IsXXX functions

- bool HasAlignment () const
  Returns true if the attribute object specifies alignment.
- bool HasBackgroundColour () const
  Returns true if the attribute object specifies a background colour.
- bool HasBulletName () const
  Returns true if the attribute object specifies a standard bullet name.
- bool HasBulletNumber () const
  Returns true if the attribute object specifies a bullet number.

- bool HasBulletStyle () const

  Returns true if the attribute object specifies a bullet style.
- bool HasBulletText () const

  Returns true if the attribute object specifies bullet text (usually specifying a symbol).
- bool HasCharacterStyleName () const

  Returns true if the attribute object specifies a character style name.
- bool HasFlag (long flag) const

  Returns true if the flag is present in the attribute object's flag bitlist.
- bool HasFont () const

  Returns true if the attribute object specifies any font attributes.
- bool HasFontEncoding () const

  Returns true if the attribute object specifies an encoding.
- bool HasFontFaceName () const

  Returns true if the attribute object specifies a font face name.
- bool HasFontFamily () const

  Returns true if the attribute object specifies a font family.
- bool HasFontItalic () const

  Returns true if the attribute object specifies italic style.
- bool HasFontSize () const

  Returns true if the attribute object specifies a font point or pixel size.
- bool HasFontPointSize () const

  Returns true if the attribute object specifies a font point size.
- bool HasFontPixelSize () const

  Returns true if the attribute object specifies a font pixel size.
- bool HasFontUnderlined () const

  Returns true if the attribute object specifies either underlining or no underlining.
- bool HasFontWeight () const

  Returns true if the attribute object specifies font weight (bold, light or normal).
- bool HasLeftIndent () const

  Returns true if the attribute object specifies a left indent.
- bool HasLineSpacing () const

  Returns true if the attribute object specifies line spacing.
- bool HasListStyleName () const

  Returns true if the attribute object specifies a list style name.
- bool HasOutlineLevel () const

  Returns true if the attribute object specifies an outline level.
- bool HasPageBreak () const

  Returns true if the attribute object specifies a page break before this paragraph.
- bool HasParagraphSpacingAfter () const

  Returns true if the attribute object specifies spacing after a paragraph.
- bool HasParagraphSpacingBefore () const

  Returns true if the attribute object specifies spacing before a paragraph.
- bool HasParagraphStyleName () const

  Returns true if the attribute object specifies a paragraph style name.
- bool HasRightIndent () const

  Returns true if the attribute object specifies a right indent.
- bool HasTabs () const

  Returns true if the attribute object specifies tab stops.
- bool HasTextColour () const

  Returns true if the attribute object specifies a text foreground colour.
- bool HasTextEffects () const

  Returns true if the attribute object specifies text effects.
- bool HasURL () const

  Returns true if the attribute object specifies a URL.
- bool IsCharacterStyle () const

  Returns true if the object represents a character style, that is, the flags specify a font or a text background or foreground colour.
- bool IsDefault () const

  Returns false if we have any attributes set, true otherwise.

- bool IsParagraphStyle () const

  Returns true if the object represents a paragraph style, that is, the flags specify alignment, indentation, tabs, paragraph spacing, or bullet style.

SetXXX functions

- void SetAlignment (wxTextAttrAlignment alignment)

  Sets the paragraph alignment.
- void SetBackgroundColour (const wxColour &colBack)

  Sets the background colour.
- void SetBulletFont (const wxString &font)

  Sets the name of the font associated with the bullet symbol.
- void SetBulletName (const wxString &name)

  Sets the standard bullet name, applicable if the bullet style is wxTEXT_ATTR_BULLET_STYLE_STANDARD.
- void SetBulletNumber (int n)

  Sets the bullet number.
- void SetBulletStyle (int style)

  Sets the bullet style.
- void SetBulletText (const wxString &text)

  Sets the bullet text, which could be a symbol, or (for example) cached outline text.
- void SetCharacterStyleName (const wxString &name)

  Sets the character style name.
- void SetFlags (long flags)

  Sets the flags determining which styles are being specified.
- void SetFont (const wxFont &font, int flags=wxTEXT_ATTR_FONT &∼wxTEXT_ATTR_FONT_PIXEL_↩ SIZE)

  Sets the attributes for the given font.
- void SetFontEncoding (wxFontEncoding encoding)

  Sets the font encoding.
- void SetFontFaceName (const wxString &faceName)

  Sets the font face name.
- void SetFontFamily (wxFontFamily family)

  Sets the font family.
- void SetFontSize (int pointSize)

  Sets the font size in points.
- void SetFontPointSize (int pointSize)

  Sets the font size in points.
- void SetFontPixelSize (int pixelSize)

  Sets the font size in pixels.
- void SetFontStyle (wxFontStyle fontStyle)

  Sets the font style (normal, italic or slanted).
- void SetFontUnderlined (bool underlined)

  Sets the font underlining.
- void SetFontWeight (wxFontWeight fontWeight)

  Sets the font weight.
- void SetLeftIndent (int indent, int subIndent=0)

  Sets the left indent and left subindent in tenths of a millimetre.
- void SetLineSpacing (int spacing)

  Sets the line spacing.
- void SetListStyleName (const wxString &name)

  Sets the list style name.
- void SetOutlineLevel (int level)

  Specifies the outline level.
- void SetPageBreak (bool pageBreak=true)

  Specifies a page break before this paragraph.
- void SetParagraphSpacingAfter (int spacing)

  Sets the spacing after a paragraph, in tenths of a millimetre.
- void SetParagraphSpacingBefore (int spacing)

  Sets the spacing before a paragraph, in tenths of a millimetre.

- void SetParagraphStyleName (const wxString &name)
  Sets the name of the paragraph style.
- void SetRightIndent (int indent)
  Sets the right indent in tenths of a millimetre.
- void SetTabs (const wxArrayInt &tabs)
  Sets the tab stops, expressed in tenths of a millimetre.
- void SetTextColour (const wxColour &colText)
  Sets the text foreground colour.
- void SetTextEffectFlags (int flags)
  Sets the text effect bits of interest.
- void SetTextEffects (int effects)
  Sets the text effects, a bit list of styles.
- void SetURL (const wxString &url)
  Sets the URL for the content.

Static Public Member Functions

- static wxTextAttr Merge (const wxTextAttr &base, const wxTextAttr &overlay)
  Creates a new `wxTextAttr` which is a merge of base and overlay.

21.762.2 Constructor & Destructor Documentation

wxTextAttr::wxTextAttr ( )

Constructors.

wxTextAttr::wxTextAttr (const wxColour & *colText*, const wxColour & *colBack* = wxNullColour, const wxFont & *font* = wxNullFont, wxTextAttrAlignment *alignment* = wxTEXT_ALIGNMENT_DEFAULT)

Constructors.

wxTextAttr::wxTextAttr (const wxTextAttr & *attr*)

Constructors.

21.762.3 Member Function Documentation

bool wxTextAttr::Apply (const wxTextAttr & *style*, const wxTextAttr * *compareWith* = `NULL`)

Applies the attributes in *style* to the original object, but not those attributes from *style* that are the same as those in *compareWith* (if passed).

bool wxTextAttr::EqPartial (const wxTextAttr & *attr*, bool *weakTest* = `true`) const

Partial equality test.

If *weakTest* is true, attributes of this object do not have to be present if those attributes of *attr* are present. If *weakTest* is false, the function will fail if an attribute is present in *attr* but not in this object.

wxTextAttrAlignment wxTextAttr::GetAlignment ( ) const

Returns the alignment flags.

See wxTextAttrAlignment for a list of available styles.

const wxColour& wxTextAttr::GetBackgroundColour ( ) const

Returns the background colour.

const wxString& wxTextAttr::GetBulletFont ( ) const

Returns a string containing the name of the font associated with the bullet symbol.

Only valid for attributes with wxTEXT_ATTR_BULLET_SYMBOL.

const wxString& wxTextAttr::GetBulletName ( ) const

Returns the standard bullet name, applicable if the bullet style is wxTEXT_ATTR_BULLET_STYLE_STANDARD.

Currently the following standard bullet names are supported:

- `standard/circle`
- `standard/square`
- `standard/diamond`
- `standard/triangle`

Note

For wxRichTextCtrl users only: if you wish your rich text controls to support further bullet graphics, you can derive a class from wxRichTextRenderer or wxRichTextStdRenderer, override `DrawStandardBullet` and `EnumerateStandardBulletNames`, and set an instance of the class using wxRichTextBuffer::SetRenderer.

int wxTextAttr::GetBulletNumber ( ) const

Returns the bullet number.

int wxTextAttr::GetBulletStyle ( ) const

Returns the bullet style.

See wxTextAttrBulletStyle for a list of available styles.

const wxString& wxTextAttr::GetBulletText ( ) const

Returns the bullet text, which could be a symbol, or (for example) cached outline text.

const wxString& wxTextAttr::GetCharacterStyleName ( ) const

Returns the name of the character style.

long wxTextAttr::GetFlags ( ) const

Returns flags indicating which attributes are applicable.

See SetFlags() for a list of available flags.

wxFont wxTextAttr::GetFont ( ) const

Creates and returns a font specified by the font attributes in the wxTextAttr object.

Note that wxTextAttr does not store a wxFont object, so this is only a temporary font.

For greater efficiency, access the font attributes directly.

bool wxTextAttr::GetFontAttributes (const wxFont & *font,* int *flags* = wxTEXT_ATTR_FONT)

Gets the font attributes from the given font, using only the attributes specified by *flags*.

wxFontEncoding wxTextAttr::GetFontEncoding ( ) const

Returns the font encoding.

const wxString& wxTextAttr::GetFontFaceName ( ) const

Returns the font face name.

wxFontFamily wxTextAttr::GetFontFamily ( ) const

Returns the font family.

int wxTextAttr::GetFontSize ( ) const

Returns the font size in points.

wxFontStyle wxTextAttr::GetFontStyle ( ) const

Returns the font style.

bool wxTextAttr::GetFontUnderlined ( ) const

Returns true if the font is underlined.

wxFontWeight wxTextAttr::GetFontWeight ( ) const

Returns the font weight.

long wxTextAttr::GetLeftIndent ( ) const

Returns the left indent in tenths of a millimetre.

long wxTextAttr::GetLeftSubIndent ( ) const

Returns the left sub-indent in tenths of a millimetre.

int wxTextAttr::GetLineSpacing ( ) const

Returns the line spacing value, one of wxTextAttrLineSpacing values.

const wxString& wxTextAttr::GetListStyleName ( ) const

Returns the name of the list style.

int wxTextAttr::GetOutlineLevel ( ) const

Returns the outline level.

int wxTextAttr::GetParagraphSpacingAfter ( ) const

Returns the space in tenths of a millimeter after the paragraph.

int wxTextAttr::GetParagraphSpacingBefore ( ) const

Returns the space in tenths of a millimeter before the paragraph.

const wxString& wxTextAttr::GetParagraphStyleName ( ) const

Returns the name of the paragraph style.

long wxTextAttr::GetRightIndent ( ) const

Returns the right indent in tenths of a millimeter.

const wxArrayInt& wxTextAttr::GetTabs ( ) const

Returns an array of tab stops, each expressed in tenths of a millimeter.

Each stop is measured from the left margin and therefore each value must be larger than the last.

const wxColour& wxTextAttr::GetTextColour ( ) const

Returns the text foreground colour.

int wxTextAttr::GetTextEffectFlags ( ) const

Returns the text effect bits of interest.

See SetFlags() for further information.

int wxTextAttr::GetTextEffects ( ) const

Returns the text effects, a bit list of styles.

See SetTextEffects() for details.

const wxString& wxTextAttr::GetURL ( ) const

Returns the URL for the content.

Content with *wxTEXT_ATTR_URL* style causes wxRichTextCtrl to show a hand cursor over it, and wxRichTextCtrl generates a wxTextUrlEvent when the content is clicked.

bool wxTextAttr::HasAlignment ( ) const

Returns true if the attribute object specifies alignment.

bool wxTextAttr::HasBackgroundColour ( ) const

Returns true if the attribute object specifies a background colour.

bool wxTextAttr::HasBulletName ( ) const

Returns true if the attribute object specifies a standard bullet name.

bool wxTextAttr::HasBulletNumber ( ) const

Returns true if the attribute object specifies a bullet number.

bool wxTextAttr::HasBulletStyle ( ) const

Returns true if the attribute object specifies a bullet style.

bool wxTextAttr::HasBulletText ( ) const

Returns true if the attribute object specifies bullet text (usually specifying a symbol).

bool wxTextAttr::HasCharacterStyleName ( ) const

Returns true if the attribute object specifies a character style name.

bool wxTextAttr::HasFlag (long *flag*) const

Returns true if the *flag* is present in the attribute object's flag bitlist.

bool wxTextAttr::HasFont ( ) const

Returns true if the attribute object specifies any font attributes.

bool wxTextAttr::HasFontEncoding ( ) const

Returns true if the attribute object specifies an encoding.

bool wxTextAttr::HasFontFaceName ( ) const

Returns true if the attribute object specifies a font face name.

bool wxTextAttr::HasFontFamily ( ) const

Returns true if the attribute object specifies a font family.

bool wxTextAttr::HasFontItalic ( ) const

Returns true if the attribute object specifies italic style.

bool wxTextAttr::HasFontPixelSize ( ) const

Returns true if the attribute object specifies a font pixel size.

bool wxTextAttr::HasFontPointSize ( ) const

Returns true if the attribute object specifies a font point size.

bool wxTextAttr::HasFontSize ( ) const

Returns true if the attribute object specifies a font point or pixel size.

bool wxTextAttr::HasFontUnderlined ( ) const

Returns true if the attribute object specifies either underlining or no underlining.

bool wxTextAttr::HasFontWeight ( ) const

Returns true if the attribute object specifies font weight (bold, light or normal).

bool wxTextAttr::HasLeftIndent ( ) const

Returns true if the attribute object specifies a left indent.

bool wxTextAttr::HasLineSpacing ( ) const

Returns true if the attribute object specifies line spacing.

bool wxTextAttr::HasListStyleName ( ) const

Returns true if the attribute object specifies a list style name.

bool wxTextAttr::HasOutlineLevel ( ) const

Returns true if the attribute object specifies an outline level.

bool wxTextAttr::HasPageBreak ( ) const

Returns true if the attribute object specifies a page break before this paragraph.

bool wxTextAttr::HasParagraphSpacingAfter ( ) const

Returns true if the attribute object specifies spacing after a paragraph.

bool wxTextAttr::HasParagraphSpacingBefore ( ) const

Returns true if the attribute object specifies spacing before a paragraph.

bool wxTextAttr::HasParagraphStyleName ( ) const

Returns true if the attribute object specifies a paragraph style name.

bool wxTextAttr::HasRightIndent ( ) const

Returns true if the attribute object specifies a right indent.

bool wxTextAttr::HasTabs ( ) const

Returns true if the attribute object specifies tab stops.

bool wxTextAttr::HasTextColour ( ) const

Returns true if the attribute object specifies a text foreground colour.

bool wxTextAttr::HasTextEffects ( ) const

Returns true if the attribute object specifies text effects.

bool wxTextAttr::HasURL ( ) const

Returns true if the attribute object specifies a URL.

bool wxTextAttr::IsCharacterStyle ( ) const

Returns true if the object represents a character style, that is, the flags specify a font or a text background or foreground colour.

bool wxTextAttr::IsDefault ( ) const

Returns false if we have any attributes set, true otherwise.

bool wxTextAttr::IsParagraphStyle ( ) const

Returns true if the object represents a paragraph style, that is, the flags specify alignment, indentation, tabs, paragraph spacing, or bullet style.

void wxTextAttr::Merge (const wxTextAttr & *overlay*)

Copies all defined/valid properties from overlay to current object.

static wxTextAttr wxTextAttr::Merge (const wxTextAttr & *base*, const wxTextAttr & *overlay*) [static]

Creates a new `wxTextAttr` which is a merge of *base* and *overlay*.

Properties defined in *overlay* take precedence over those in *base*. Properties undefined/invalid in both are undefined in the result.

void wxTextAttr::operator= (const wxTextAttr & *attr*)

Assignment from a wxTextAttr object.

void wxTextAttr::SetAlignment (wxTextAttrAlignment *alignment*)

Sets the paragraph alignment.

See wxTextAttrAlignment enumeration values.

Of these, wxTEXT_ALIGNMENT_JUSTIFIED is unimplemented. In future justification may be supported when printing or previewing, only.

void wxTextAttr::SetBackgroundColour (const wxColour & *colBack*)

Sets the background colour.

void wxTextAttr::SetBulletFont (const wxString & *font*)

Sets the name of the font associated with the bullet symbol.

Only valid for attributes with wxTEXT_ATTR_BULLET_SYMBOL.

void wxTextAttr::SetBulletName (const wxString & *name*)

Sets the standard bullet name, applicable if the bullet style is wxTEXT_ATTR_BULLET_STYLE_STANDARD.

See GetBulletName() for a list of supported names, and how to expand the range of supported types.

void wxTextAttr::SetBulletNumber (int *n*)

Sets the bullet number.

void wxTextAttr::SetBulletStyle (int *style*)

Sets the bullet style.

The wxTextAttrBulletStyle enumeration values are all supported, except for wxTEXT_ATTR_BULLET_STYLE_BI↩TMAP.

void wxTextAttr::SetBulletText (const wxString & *text*)

Sets the bullet text, which could be a symbol, or (for example) cached outline text.

void wxTextAttr::SetCharacterStyleName (const wxString & *name*)

Sets the character style name.

void wxTextAttr::SetFlags (long *flags*)

Sets the flags determining which styles are being specified.

The wxTextAttrFlags values can be passed in a bitlist.

void wxTextAttr::SetFont (const wxFont & *font*, int *flags* = wxTEXT_ATTR_FONT &~wxTEXT_ATTR_FONT_PIXEL_SIZE)

Sets the attributes for the given font.

Note that wxTextAttr does not store an actual wxFont object.

void wxTextAttr::SetFontEncoding (wxFontEncoding *encoding*)

Sets the font encoding.

void wxTextAttr::SetFontFaceName (const wxString & *faceName*)

Sets the font face name.

void wxTextAttr::SetFontFamily (wxFontFamily *family*)

Sets the font family.

void wxTextAttr::SetFontPixelSize (int *pixelSize*)

Sets the font size in pixels.

void wxTextAttr::SetFontPointSize (int *pointSize*)

Sets the font size in points.

void wxTextAttr::SetFontSize (int *pointSize*)

Sets the font size in points.

void wxTextAttr::SetFontStyle (wxFontStyle *fontStyle*)

Sets the font style (normal, italic or slanted).

void wxTextAttr::SetFontUnderlined (bool *underlined*)

Sets the font underlining.

void wxTextAttr::SetFontWeight (wxFontWeight *fontWeight*)

Sets the font weight.

void wxTextAttr::SetLeftIndent (int *indent,* int *subIndent* = `0`)

Sets the left indent and left subindent in tenths of a millimetre.

The sub-indent is an offset from the left of the paragraph, and is used for all but the first line in a paragraph.

A positive value will cause the first line to appear to the left of the subsequent lines, and a negative value will cause the first line to be indented relative to the subsequent lines.

wxRichTextBuffer uses indentation to render a bulleted item. The left indent is the distance between the margin and the bullet. The content of the paragraph, including the first line, starts at leftMargin + leftSubIndent. So the distance between the left edge of the bullet and the left of the actual paragraph is leftSubIndent.

void wxTextAttr::SetLineSpacing (int *spacing*)

Sets the line spacing.

spacing is a multiple, where 10 means single-spacing, 15 means 1.5 spacing, and 20 means double spacing. The wxTextAttrLineSpacing values are defined for convenience.

void wxTextAttr::SetListStyleName (const wxString & *name*)

Sets the list style name.

void wxTextAttr::SetOutlineLevel (int *level*)

Specifies the outline level.

Zero represents normal text. At present, the outline level is not used, but may be used in future for determining list levels and for applications that need to store document structure information.

void wxTextAttr::SetPageBreak (bool *pageBreak* = `true`)

Specifies a page break before this paragraph.

void wxTextAttr::SetParagraphSpacingAfter (int *spacing*)

Sets the spacing after a paragraph, in tenths of a millimetre.

void wxTextAttr::SetParagraphSpacingBefore (int *spacing*)

Sets the spacing before a paragraph, in tenths of a millimetre.

void wxTextAttr::SetParagraphStyleName (const wxString & *name*)

Sets the name of the paragraph style.

void wxTextAttr::SetRightIndent (int *indent*)

Sets the right indent in tenths of a millimetre.

void wxTextAttr::SetTabs (const wxArrayInt & *tabs*)

Sets the tab stops, expressed in tenths of a millimetre.

Each stop is measured from the left margin and therefore each value must be larger than the last.

void wxTextAttr::SetTextColour (const wxColour & *colText*)

Sets the text foreground colour.

void wxTextAttr::SetTextEffectFlags (int *flags*)

Sets the text effect bits of interest.

You should also pass wxTEXT_ATTR_EFFECTS to SetFlags(). See SetFlags() for further information.

void wxTextAttr::SetTextEffects (int *effects*)

Sets the text effects, a bit list of styles.

The wxTextAttrEffects enumeration values can be used.

Of these, only wxTEXT_ATTR_EFFECT_CAPITALS, wxTEXT_ATTR_EFFECT_STRIKETHROUGH, wxTEXT_↩ ATTR_EFFECT_SUPERSCRIPT and wxTEXT_ATTR_EFFECT_SUBSCRIPT are implemented.

wxTEXT_ATTR_EFFECT_CAPITALS capitalises text when displayed (leaving the case of the actual buffer text unchanged), and wxTEXT_ATTR_EFFECT_STRIKETHROUGH draws a line through text.

To set effects, you should also pass wxTEXT_ATTR_EFFECTS to SetFlags(), and call SetTextEffectFlags() with the styles (taken from the above set) that you are interested in setting.

void wxTextAttr::SetURL (const wxString & *url*)

Sets the URL for the content.

Sets the wxTEXT_ATTR_URL style; content with this style causes wxRichTextCtrl to show a hand cursor over it, and wxRichTextCtrl generates a wxTextUrlEvent when the content is clicked.

21.763 wxTextAttrBorder Class Reference

`#include <wx/richtext/richtextbuffer.h>`

21.763.1 Detailed Description

A class representing a rich text object border.

Library: wxRichText

Category: Rich Text

wxRichTextAttr, wxRichTextCtrl, wxRichTextAttrBorders

Public Member Functions

- wxTextAttrBorder ()

  Default constructor.
- bool operator== (const wxTextAttrBorder &border) const

  Equality operator.
- void Reset ()

  Resets the border style, colour, width and flags.
- bool EqPartial (const wxTextAttrBorder &border, bool weakTest=true) const

  Partial equality test.
- bool Apply (const wxTextAttrBorder &border, const wxTextAttrBorder *compareWith=NULL)

  Applies the border to this object, but not if the same as compareWith.
- bool RemoveStyle (const wxTextAttrBorder &attr)

  Removes the specified attributes from this object.
- void CollectCommonAttributes (const wxTextAttrBorder &attr, wxTextAttrBorder &clashingAttr, wxTextAttrBorder &absentAttr)

  Collects the attributes that are common to a range of content, building up a note of which attributes are absent in some objects and which clash in some objects.
- void SetStyle (int style)

  Sets the border style.
- int GetStyle () const

  Gets the border style.
- void SetColour (unsigned long colour)

  Sets the border colour.
- void SetColour (const wxColour &colour)

  Sets the border colour.
- unsigned long GetColourLong () const

  Gets the colour as a long.
- wxColour GetColour () const

  Gets the colour.
- wxTextAttrDimension & GetWidth ()

  Gets the border width.
- const wxTextAttrDimension & GetWidth () const
- void SetWidth (const wxTextAttrDimension &width)

  Sets the border width.
- void SetWidth (int value, wxTextAttrUnits units=wxTEXT_ATTR_UNITS_TENTHS_MM)

  Sets the border width.
- bool HasStyle () const

  True if the border has a valid style.
- bool HasColour () const

  True if the border has a valid colour.
- bool HasWidth () const

  True if the border has a valid width.
- bool IsValid () const

  True if the border is valid.
- bool IsDefault () const

  True if the border has no attributes set.
- void MakeValid ()

  Set the valid flag for this border.
- int GetFlags () const

  Returns the border flags.

- void SetFlags (int flags)

  Sets the border flags.
- void AddFlag (int flag)

  Adds a border flag.
- void RemoveFlag (int flag)

  Removes a border flag.

Public Attributes

- int m_borderStyle
- unsigned long m_borderColour
- wxTextAttrDimension m_borderWidth
- int m_flags

21.763.2 Constructor & Destructor Documentation

wxTextAttrBorder::wxTextAttrBorder ( ) [inline]

Default constructor.

21.763.3 Member Function Documentation

void wxTextAttrBorder::AddFlag (int *flag*) [inline]

Adds a border flag.

bool wxTextAttrBorder::Apply (const wxTextAttrBorder & *border,* const wxTextAttrBorder * *compareWith* = NULL)

Applies the border to this object, but not if the same as *compareWith*.

void wxTextAttrBorder::CollectCommonAttributes (const wxTextAttrBorder & *attr,* wxTextAttrBorder & *clashingAttr,* wxTextAttrBorder & *absentAttr*)

Collects the attributes that are common to a range of content, building up a note of which attributes are absent in some objects and which clash in some objects.

bool wxTextAttrBorder::EqPartial (const wxTextAttrBorder & *border,* bool *weakTest* = true) const

Partial equality test.

If *weakTest* is true, attributes of this object do not have to be present if those attributes of *border* are present. If *weakTest* is false, the function will fail if an attribute is present in *border* but not in this object.

wxColour wxTextAttrBorder::GetColour ( ) const [inline]

Gets the colour.

unsigned long wxTextAttrBorder::GetColourLong ( ) const [inline]

Gets the colour as a long.

int wxTextAttrBorder::GetFlags ( ) const [inline]

Returns the border flags.

int wxTextAttrBorder::GetStyle ( ) const [inline]

Gets the border style.

wxTextAttrDimension& wxTextAttrBorder::GetWidth ( ) [inline]

Gets the border width.

const wxTextAttrDimension& wxTextAttrBorder::GetWidth ( ) const [inline]

bool wxTextAttrBorder::HasColour ( ) const [inline]

True if the border has a valid colour.

bool wxTextAttrBorder::HasStyle ( ) const [inline]

True if the border has a valid style.

bool wxTextAttrBorder::HasWidth ( ) const [inline]

True if the border has a valid width.

bool wxTextAttrBorder::IsDefault ( ) const [inline]

True if the border has no attributes set.

bool wxTextAttrBorder::IsValid ( ) const [inline]

True if the border is valid.

void wxTextAttrBorder::MakeValid ( ) [inline]

Set the valid flag for this border.

bool wxTextAttrBorder::operator== (const wxTextAttrBorder & *border*) const [inline]

Equality operator.

void wxTextAttrBorder::RemoveFlag (int *flag*) [inline]

Removes a border flag.

bool wxTextAttrBorder::RemoveStyle (const wxTextAttrBorder & *attr*)

Removes the specified attributes from this object.

void wxTextAttrBorder::Reset ( ) [inline]

Resets the border style, colour, width and flags.

void wxTextAttrBorder::SetColour (unsigned long *colour*) [inline]

Sets the border colour.

void wxTextAttrBorder::SetColour (const wxColour & *colour*) [inline]

Sets the border colour.

void wxTextAttrBorder::SetFlags (int *flags*) [inline]

Sets the border flags.

void wxTextAttrBorder::SetStyle (int *style*) [inline]

Sets the border style.

void wxTextAttrBorder::SetWidth (const wxTextAttrDimension & *width*) [inline]

Sets the border width.

void wxTextAttrBorder::SetWidth (int *value,* wxTextAttrUnits *units* = wxTEXT_ATTR_UNITS_TENTHS_MM) [inline]

Sets the border width.

  Collects the attributes that are common to a range of content, building up a note of which attributes are absent in some objects and which clash in some objects.
- bool IsValid () const

  Returns true if at least one border is valid.
- const wxTextAttrBorder & GetLeft () const

  Returns the left border.
- wxTextAttrBorder & GetLeft ()
- const wxTextAttrBorder & GetRight () const

  Returns the right border.
- wxTextAttrBorder & GetRight ()
- const wxTextAttrBorder & GetTop () const

  Returns the top border.
- wxTextAttrBorder & GetTop ()
- const wxTextAttrBorder & GetBottom () const

  Returns the bottom border.
- wxTextAttrBorder & GetBottom ()

Public Attributes

- wxTextAttrBorder m_left
- wxTextAttrBorder m_right
- wxTextAttrBorder m_top
- wxTextAttrBorder m_bottom

21.764.2 Constructor & Destructor Documentation

wxTextAttrBorders::wxTextAttrBorders ( ) [inline]

Default constructor.

21.764.3 Member Function Documentation

bool wxTextAttrBorders::Apply (const wxTextAttrBorders & *borders,* const wxTextAttrBorders * *compareWith* = NULL)

Applies border to this object, but not if the same as *compareWith*.

void wxTextAttrBorders::CollectCommonAttributes (const wxTextAttrBorders & *attr,* wxTextAttrBorders & *clashingAttr,* wxTextAttrBorders & *absentAttr*)

Collects the attributes that are common to a range of content, building up a note of which attributes are absent in some objects and which clash in some objects.

bool wxTextAttrBorders::EqPartial (const wxTextAttrBorders & *borders,* bool *weakTest* = true) const

Partial equality test.

If *weakTest* is true, attributes of this object do not have to be present if those attributes of *borders* are present. If *weakTest* is false, the function will fail if an attribute is present in *borders* but not in this object.

const wxTextAttrBorder& wxTextAttrBorders::GetBottom ( ) const [inline]

Returns the bottom border.

wxTextAttrBorder& wxTextAttrBorders::GetBottom ( ) [inline]

const wxTextAttrBorder& wxTextAttrBorders::GetLeft ( ) const [inline]

Returns the left border.

wxTextAttrBorder& wxTextAttrBorders::GetLeft ( ) [inline]

const wxTextAttrBorder& wxTextAttrBorders::GetRight ( ) const [inline]

Returns the right border.

wxTextAttrBorder& wxTextAttrBorders::GetRight ( ) [inline]

const wxTextAttrBorder& wxTextAttrBorders::GetTop ( ) const [inline]

Returns the top border.

wxTextAttrBorder& wxTextAttrBorders::GetTop ( ) [inline]

bool wxTextAttrBorders::IsValid ( ) const [inline]

Returns true if at least one border is valid.

bool wxTextAttrBorders::operator== (const wxTextAttrBorders & *borders*) const [inline]

Equality operator.

bool wxTextAttrBorders::RemoveStyle (const wxTextAttrBorders & *attr*)

Removes the specified attributes from this object.

void wxTextAttrBorders::Reset ( ) [inline]

Resets all borders.

void wxTextAttrBorders::SetColour (unsigned long *colour*)

Sets colour of all borders.

void wxTextAttrBorders::SetColour (const wxColour & *colour*)

Sets the colour for all borders.

void wxTextAttrBorders::SetStyle (int *style*)

Sets the style of all borders.

void wxTextAttrBorders::SetWidth (const wxTextAttrDimension & *width*)

Sets the width of all borders.

void wxTextAttrBorders::SetWidth (int *value,* wxTextAttrUnits *units* = wxTEXT_ATTR_UNITS_TENTHS_MM) [inline]

Sets the width of all borders.

21.765 wxTextAttrDimension Class Reference

`#include <wx/richtext/richtextbuffer.h>`

21.765.1 Detailed Description

A class representing a rich text dimension, including units and position.

Library: wxRichText

Category: Rich Text

See also

wxRichTextAttr, wxRichTextCtrl, wxTextAttrDimensions

Public Member Functions

- wxTextAttrDimension ()

  Default constructor.
- wxTextAttrDimension (int value, wxTextAttrUnits units=wxTEXT_ATTR_UNITS_TENTHS_MM)

  Constructor taking value and units flag.
- void Reset ()

  Resets the dimension value and flags.
- bool EqPartial (const wxTextAttrDimension &dim, bool weakTest=true) const

  Partial equality test.
- bool Apply (const wxTextAttrDimension &dim, const wxTextAttrDimension *compareWith=NULL)

  Apply the dimension, but not those identical to compareWith if present.
- void CollectCommonAttributes (const wxTextAttrDimension &attr, wxTextAttrDimension &clashingAttr, wxTextAttrDimension &absentAttr)

  Collects the attributes that are common to a range of content, building up a note of which attributes are absent in some objects and which clash in some objects.
- bool operator== (const wxTextAttrDimension &dim) const

  Equality operator.
- int GetValue () const

  Returns the integer value of the dimension.
- float GetValueMM () const

  Returns the floating-pointing value of the dimension in mm.
- void SetValueMM (float value)

  Sets the value of the dimension in mm.
- void SetValue (int value)

  Sets the integer value of the dimension.
- void SetValue (int value, wxTextAttrDimensionFlags flags)

  Sets the integer value of the dimension, passing dimension flags.

- void SetValue (int value, wxTextAttrUnits units)

  Sets the integer value and units.
- void SetValue (const wxTextAttrDimension &dim)

  Sets the dimension.
- wxTextAttrUnits GetUnits () const

  Gets the units of the dimension.
- void SetUnits (wxTextAttrUnits units)

  Sets the units of the dimension.
- wxTextBoxAttrPosition GetPosition () const

  Gets the position flags.
- void SetPosition (wxTextBoxAttrPosition pos)

  Sets the position flags.
- bool IsValid () const

  Returns true if the dimension is valid.
- void SetValid (bool b)

  Sets the valid flag.
- wxTextAttrDimensionFlags GetFlags () const

  Gets the dimension flags.
- void SetFlags (wxTextAttrDimensionFlags flags)

  Sets the dimension flags.

Public Attributes

- int m_value
- wxTextAttrDimensionFlags m_flags

21.765.2 Constructor & Destructor Documentation

wxTextAttrDimension::wxTextAttrDimension ( ) [inline]

Default constructor.

wxTextAttrDimension::wxTextAttrDimension (int *value,* wxTextAttrUnits *units* = wxTEXT_ATTR_UNITS_TENTHS_MM) [inline]

Constructor taking value and units flag.

21.765.3 Member Function Documentation

bool wxTextAttrDimension::Apply (const wxTextAttrDimension & *dim,* const wxTextAttrDimension * *compareWith* = NULL)

Apply the dimension, but not those identical to *compareWith* if present.

void wxTextAttrDimension::CollectCommonAttributes (const wxTextAttrDimension & *attr,* wxTextAttrDimension & *clashingAttr,* wxTextAttrDimension & *absentAttr*)

Collects the attributes that are common to a range of content, building up a note of which attributes are absent in some objects and which clash in some objects.

bool wxTextAttrDimension::EqPartial (const wxTextAttrDimension & *dim,* bool *weakTest* = `true`) const

Partial equality test.

If *weakTest* is true, attributes of this object do not have to be present if those attributes of *dim* are present. If *weakTest* is false, the function will fail if an attribute is present in *dim* but not in this object.

wxTextAttrDimensionFlags wxTextAttrDimension::GetFlags ( ) const `[inline]`

Gets the dimension flags.

wxTextBoxAttrPosition wxTextAttrDimension::GetPosition ( ) const `[inline]`

Gets the position flags.

wxTextAttrUnits wxTextAttrDimension::GetUnits ( ) const `[inline]`

Gets the units of the dimension.

int wxTextAttrDimension::GetValue ( ) const `[inline]`

Returns the integer value of the dimension.

float wxTextAttrDimension::GetValueMM ( ) const `[inline]`

Returns the floating-pointing value of the dimension in mm.

bool wxTextAttrDimension::IsValid ( ) const `[inline]`

Returns true if the dimension is valid.

bool wxTextAttrDimension::operator== (const wxTextAttrDimension & *dim*) const `[inline]`

Equality operator.

void wxTextAttrDimension::Reset ( ) `[inline]`

Resets the dimension value and flags.

void wxTextAttrDimension::SetFlags (wxTextAttrDimensionFlags *flags*) `[inline]`

Sets the dimension flags.

void wxTextAttrDimension::SetPosition (wxTextBoxAttrPosition *pos*) `[inline]`

Sets the position flags.

void wxTextAttrDimension::SetUnits (wxTextAttrUnits *units*) `[inline]`

Sets the units of the dimension.

void wxTextAttrDimension::SetValid (bool *b*) `[inline]`

Sets the valid flag.

void wxTextAttrDimension::SetValue (int *value*) `[inline]`

Sets the integer value of the dimension.

void wxTextAttrDimension::SetValue (int *value,* wxTextAttrDimensionFlags *flags*) `[inline]`

Sets the integer value of the dimension, passing dimension flags.

void wxTextAttrDimension::SetValue (int *value,* wxTextAttrUnits *units*) `[inline]`

Sets the integer value and units.

void wxTextAttrDimension::SetValue (const wxTextAttrDimension & *dim*) `[inline]`

Sets the dimension.

void wxTextAttrDimension::SetValueMM (float *value*) `[inline]`

Sets the value of the dimension in mm.

21.768 wxTextAttrShadow Class Reference

`#include <wx/richtext/richtextbuffer.h>`

21.768.1 Detailed Description

A class representing a shadow.

Library: wxRichText

Category: Rich Text

See also

wxRichTextAttr, wxRichTextCtrl

Public Member Functions

- wxTextAttrShadow ()

  Default constructor.
- bool operator== (const wxTextAttrShadow &shadow) const

  Equality operator.
- void Reset ()

  Resets the shadow.
- bool EqPartial (const wxTextAttrShadow &shadow, bool weakTest=true) const

  Partial equality test.
- bool Apply (const wxTextAttrShadow &shadow, const wxTextAttrShadow *compareWith=NULL)

  Applies the border to this object, but not if the same as compareWith.
- bool RemoveStyle (const wxTextAttrShadow &attr)

  Removes the specified attributes from this object.
- void CollectCommonAttributes (const wxTextAttrShadow &attr, wxTextAttrShadow &clashingAttr, wxTextAttrShadow &absentAttr)

  Collects the attributes that are common to a range of content, building up a note of which attributes are absent in some objects and which clash in some objects.
- void SetColour (unsigned long colour)

  Sets the shadow colour.
- void SetColour (const wxColour &colour)

  Sets the shadow colour.
- unsigned long GetColourLong () const

  Gets the colour as a long.
- wxColour GetColour () const

  Gets the colour.
- bool HasColour () const

  True if the shadow has a valid colour.
- wxTextAttrDimension & GetOffsetX ()

  Gets the shadow horizontal offset.
- const wxTextAttrDimension & GetOffsetX () const
- void SetOffsetX (const wxTextAttrDimension &offset)

  Sets the shadow horizontal offset.
- wxTextAttrDimension & GetOffsetY ()

  Gets the shadow vertical offset.
- const wxTextAttrDimension & GetOffsetY () const
- void SetOffsetY (const wxTextAttrDimension &offset)

  Sets the shadow vertical offset.
- wxTextAttrDimension & GetSpread ()

  Gets the shadow spread size.
- const wxTextAttrDimension & GetSpread () const
- void SetSpread (const wxTextAttrDimension &spread)

  Sets the shadow spread size.

- wxTextAttrDimension & GetBlurDistance ()

  Gets the shadow blur distance.
- const wxTextAttrDimension & GetBlurDistance () const
- void SetBlurDistance (const wxTextAttrDimension &blur)

  Sets the shadow blur distance.
- wxTextAttrDimension & GetOpacity ()

  Gets the shadow opacity.
- const wxTextAttrDimension & GetOpacity () const
- bool IsValid () const

  Returns true if the dimension is valid.
- void SetValid (bool b)

  Sets the valid flag.
- int GetFlags () const

  Returns the border flags.
- void SetFlags (int flags)

  Sets the border flags.
- void AddFlag (int flag)

  Adds a border flag.
- void RemoveFlag (int flag)

  Removes a border flag.
- void SetOpacity (const wxTextAttrDimension &opacity)

  Sets the shadow opacity.
- bool IsDefault () const

  True if the shadow has no attributes set.

Public Attributes

- int m_flags
- unsigned long m_shadowColour
- wxTextAttrDimension m_offsetX
- wxTextAttrDimension m_offsetY
- wxTextAttrDimension m_spread
- wxTextAttrDimension m_blurDistance
- wxTextAttrDimension m_opacity

21.768.2 Constructor & Destructor Documentation

wxTextAttrShadow::wxTextAttrShadow ( ) [inline]

Default constructor.

21.768.3 Member Function Documentation

void wxTextAttrShadow::AddFlag (int *flag*) [inline]

Adds a border flag.

bool wxTextAttrShadow::Apply (const wxTextAttrShadow & *shadow*, const wxTextAttrShadow * *compareWith* = NULL)

Applies the border to this object, but not if the same as *compareWith*.

void wxTextAttrShadow::CollectCommonAttributes (const wxTextAttrShadow & *attr,* wxTextAttrShadow & *clashingAttr,* wxTextAttrShadow & *absentAttr*)

Collects the attributes that are common to a range of content, building up a note of which attributes are absent in some objects and which clash in some objects.

bool wxTextAttrShadow::EqPartial (const wxTextAttrShadow & *shadow,* bool *weakTest* = `true`) const

Partial equality test.

If *weakTest* is true, attributes of this object do not have to be present if those attributes of *border* are present. If *weakTest* is false, the function will fail if an attribute is present in *border* but not in this object.

wxTextAttrDimension& wxTextAttrShadow::GetBlurDistance ( ) `[inline]`

Gets the shadow blur distance.

const wxTextAttrDimension& wxTextAttrShadow::GetBlurDistance ( ) const `[inline]`

wxColour wxTextAttrShadow::GetColour ( ) const `[inline]`

Gets the colour.

unsigned long wxTextAttrShadow::GetColourLong ( ) const `[inline]`

Gets the colour as a long.

int wxTextAttrShadow::GetFlags ( ) const `[inline]`

Returns the border flags.

wxTextAttrDimension& wxTextAttrShadow::GetOffsetX ( ) `[inline]`

Gets the shadow horizontal offset.

const wxTextAttrDimension& wxTextAttrShadow::GetOffsetX ( ) const `[inline]`

wxTextAttrDimension& wxTextAttrShadow::GetOffsetY ( ) `[inline]`

Gets the shadow vertical offset.

const wxTextAttrDimension& wxTextAttrShadow::GetOffsetY ( ) const `[inline]`

wxTextAttrDimension& wxTextAttrShadow::GetOpacity ( ) `[inline]`

Gets the shadow opacity.

const wxTextAttrDimension& wxTextAttrShadow::GetOpacity ( ) const `[inline]`

wxTextAttrDimension& wxTextAttrShadow::GetSpread ( ) `[inline]`

Gets the shadow spread size.

const wxTextAttrDimension& wxTextAttrShadow::GetSpread ( ) const `[inline]`

bool wxTextAttrShadow::HasColour ( ) const `[inline]`

True if the shadow has a valid colour.

bool wxTextAttrShadow::IsDefault ( ) const `[inline]`

True if the shadow has no attributes set.

bool wxTextAttrShadow::IsValid ( ) const `[inline]`

Returns true if the dimension is valid.

bool wxTextAttrShadow::operator== (const wxTextAttrShadow & *shadow*) const

Equality operator.

void wxTextAttrShadow::RemoveFlag (int *flag*) `[inline]`

Removes a border flag.

bool wxTextAttrShadow::RemoveStyle (const wxTextAttrShadow & *attr*)

Removes the specified attributes from this object.

void wxTextAttrShadow::Reset ( )

Resets the shadow.

void wxTextAttrShadow::SetBlurDistance (const wxTextAttrDimension & *blur*) `[inline]`

Sets the shadow blur distance.

void wxTextAttrShadow::SetColour (unsigned long *colour*) `[inline]`

Sets the shadow colour.

void wxTextAttrShadow::SetColour (const wxColour & *colour*) `[inline]`

Sets the shadow colour.

void wxTextAttrShadow::SetFlags (int *flags*) `[inline]`

Sets the border flags.

void wxTextAttrShadow::SetOffsetX (const wxTextAttrDimension & *offset*) `[inline]`

Sets the shadow horizontal offset.

void wxTextAttrShadow::SetOffsetY (const wxTextAttrDimension & *offset*) `[inline]`

Sets the shadow vertical offset.

void wxTextAttrShadow::SetOpacity (const wxTextAttrDimension & *opacity*) `[inline]`

Sets the shadow opacity.

void wxTextAttrShadow::SetSpread (const wxTextAttrDimension & *spread*) `[inline]`

Sets the shadow spread size.

void wxTextAttrShadow::SetValid (bool *b*) `[inline]`

Sets the valid flag.

21.769 wxTextAttrSize Class Reference

`#include <wx/richtext/richtextbuffer.h>`

21.769.1 Detailed Description

A class for representing width and height.

Library: wxRichText

Category: Rich Text

See also

wxRichTextAttr, wxRichTextCtrl, wxTextAttrDimension

Public Member Functions

- wxTextAttrSize ()

  Default constructor.
- void Reset ()

  Resets the width and height dimensions.
- bool operator== (const wxTextAttrSize &size) const

  Equality operator.
- bool EqPartial (const wxTextAttrSize &size, bool weakTest=true) const

  Partial equality test.
- bool Apply (const wxTextAttrSize &dims, const wxTextAttrSize *compareWith=NULL)

  Apply to this object, but not if the same as compareWith.
- void CollectCommonAttributes (const wxTextAttrSize &attr, wxTextAttrSize &clashingAttr, wxTextAttrSize &absentAttr)

  Collects the attributes that are common to a range of content, building up a note of which attributes are absent in some objects and which clash in some objects.
- bool RemoveStyle (const wxTextAttrSize &attr)

  Removes the specified attributes from this object.
- wxTextAttrDimension & GetWidth ()

  Returns the width.
- const wxTextAttrDimension & GetWidth () const
- void SetWidth (int value, wxTextAttrDimensionFlags flags)

  Sets the width.
- void SetWidth (int value, wxTextAttrUnits units)

  Sets the width.
- void SetWidth (const wxTextAttrDimension &dim)

  Sets the width.
- wxTextAttrDimension & GetHeight ()

  Gets the height.
- const wxTextAttrDimension & GetHeight () const
- void SetHeight (int value, wxTextAttrDimensionFlags flags)

  Sets the height.
- void SetHeight (int value, wxTextAttrUnits units)

  Sets the height.
- void SetHeight (const wxTextAttrDimension &dim)

  Sets the height.
- bool IsValid () const

  Is the size valid?

Public Attributes

- wxTextAttrDimension m_width
- wxTextAttrDimension m_height

21.769.2 Constructor & Destructor Documentation

wxTextAttrSize::wxTextAttrSize ( ) [inline]

Default constructor.

21.769.3 Member Function Documentation

bool wxTextAttrSize::Apply (const wxTextAttrSize & *dims,* const wxTextAttrSize * *compareWith* = NULL)

Apply to this object, but not if the same as *compareWith*.

void wxTextAttrSize::CollectCommonAttributes (const wxTextAttrSize & *attr,* wxTextAttrSize & *clashingAttr,* wxTextAttrSize & *absentAttr*)

Collects the attributes that are common to a range of content, building up a note of which attributes are absent in some objects and which clash in some objects.

bool wxTextAttrSize::EqPartial (const wxTextAttrSize & *size,* bool *weakTest* = true) const

Partial equality test.

If *weakTest* is true, attributes of this object do not have to be present if those attributes of *size* are present. If *weakTest* is false, the function will fail if an attribute is present in *size* but not in this object.

wxTextAttrDimension& wxTextAttrSize::GetHeight ( ) [inline]

Gets the height.

const wxTextAttrDimension& wxTextAttrSize::GetHeight ( ) const [inline]

wxTextAttrDimension& wxTextAttrSize::GetWidth ( ) [inline]

Returns the width.

const wxTextAttrDimension& wxTextAttrSize::GetWidth ( ) const [inline]

bool wxTextAttrSize::IsValid ( ) const [inline]

Is the size valid?

21.770 wxTextBoxAttr Class Reference

`#include <wx/richtext/richtextbuffer.h>`

21.770.1 Detailed Description

A class representing the box attributes of a rich text object.

Library: wxRichText

Category: Rich Text

See also

wxRichTextAttr, wxRichTextCtrl

Public Member Functions

- wxTextBoxAttr ()

  Default constructor.
- wxTextBoxAttr (const wxTextBoxAttr &attr)

  Copy constructor.
- void Init ()

Initialises this object.

- void Reset ()

  Resets this object.

- bool operator== (const wxTextBoxAttr &attr) const

  Equality test.

- bool EqPartial (const wxTextBoxAttr &attr, bool weakTest=true) const

  Partial equality test, ignoring unset attributes.

- bool Apply (const wxTextBoxAttr &style, const wxTextBoxAttr *compareWith=NULL)

  Merges the given attributes.

- void CollectCommonAttributes (const wxTextBoxAttr &attr, wxTextBoxAttr &clashingAttr, wxTextBoxAttr &absentAttr)

  Collects the attributes that are common to a range of content, building up a note of which attributes are absent in some objects and which clash in some objects.

- bool RemoveStyle (const wxTextBoxAttr &attr)

  Removes the specified attributes from this object.

- void SetFlags (int flags)

  Sets the flags.

- int GetFlags () const

  Returns the flags.

- bool HasFlag (wxTextBoxAttrFlags flag) const

  Is this flag present?

- void RemoveFlag (wxTextBoxAttrFlags flag)

  Removes this flag.

- void AddFlag (wxTextBoxAttrFlags flag)

  Adds this flag.

- bool IsDefault () const

  Returns true if no attributes are set.

- wxTextBoxAttrFloatStyle GetFloatMode () const

  Returns the float mode.

- void SetFloatMode (wxTextBoxAttrFloatStyle mode)

  Sets the float mode.

- bool HasFloatMode () const

  Returns true if float mode is active.

- bool IsFloating () const

  Returns true if this object is floating.

- wxTextBoxAttrClearStyle GetClearMode () const

  Returns the clear mode - whether to wrap text after object.

- void SetClearMode (wxTextBoxAttrClearStyle mode)

  Set the clear mode.

- bool HasClearMode () const

  Returns true if we have a clear flag.

- wxTextBoxAttrCollapseMode GetCollapseBorders () const

  Returns the collapse mode - whether to collapse borders.

- void SetCollapseBorders (wxTextBoxAttrCollapseMode collapse)

  Sets the collapse mode - whether to collapse borders.

- bool HasCollapseBorders () const

  Returns true if the collapse borders flag is present.

- wxTextBoxAttrWhitespaceMode GetWhitespaceMode () const

  Returns the whitespace mode.

- void SetWhitespaceMode (wxTextBoxAttrWhitespaceMode whitespace)

  Sets the whitespace mode.

- bool HasWhitespaceMode () const

  Returns true if the whitespace flag is present.
- bool HasCornerRadius () const

  Returns true if the corner radius flag is present.
- const wxTextAttrDimension & GetCornerRadius () const

  Returns the corner radius value.
- wxTextAttrDimension & GetCornerRadius ()
- void SetCornerRadius (const wxTextAttrDimension &dim)

  Sets the corner radius value.
- wxTextBoxAttrVerticalAlignment GetVerticalAlignment () const

  Returns the vertical alignment.
- void SetVerticalAlignment (wxTextBoxAttrVerticalAlignment verticalAlignment)

  Sets the vertical alignment.
- bool HasVerticalAlignment () const

  Returns true if a vertical alignment flag is present.
- wxTextAttrDimensions & GetMargins ()

  Returns the margin values.
- const wxTextAttrDimensions & GetMargins () const
- wxTextAttrDimension & GetLeftMargin ()

  Returns the left margin.
- const wxTextAttrDimension & GetLeftMargin () const
- wxTextAttrDimension & GetRightMargin ()

  Returns the right margin.
- const wxTextAttrDimension & GetRightMargin () const
- wxTextAttrDimension & GetTopMargin ()

  Returns the top margin.
- const wxTextAttrDimension & GetTopMargin () const
- wxTextAttrDimension & GetBottomMargin ()

  Returns the bottom margin.
- const wxTextAttrDimension & GetBottomMargin () const
- wxTextAttrDimensions & GetPosition ()

  Returns the position.
- const wxTextAttrDimensions & GetPosition () const
- wxTextAttrDimension & GetLeft ()

  Returns the left position.
- const wxTextAttrDimension & GetLeft () const
- wxTextAttrDimension & GetRight ()

  Returns the right position.
- const wxTextAttrDimension & GetRight () const
- wxTextAttrDimension & GetTop ()

  Returns the top position.
- const wxTextAttrDimension & GetTop () const
- wxTextAttrDimension & GetBottom ()

  Returns the bottom position.
- const wxTextAttrDimension & GetBottom () const
- wxTextAttrDimensions & GetPadding ()

  Returns the padding values.
- const wxTextAttrDimensions & GetPadding () const
- wxTextAttrDimension & GetLeftPadding ()

  Returns the left padding value.
- const wxTextAttrDimension & GetLeftPadding () const
- wxTextAttrDimension & GetRightPadding ()

Returns the right padding value.

- const wxTextAttrDimension & GetRightPadding () const
- wxTextAttrDimension & GetTopPadding ()

Returns the top padding value.

- const wxTextAttrDimension & GetTopPadding () const
- wxTextAttrDimension & GetBottomPadding ()

Returns the bottom padding value.

- const wxTextAttrDimension & GetBottomPadding () const
- wxTextAttrBorders & GetBorder ()

Returns the borders.

- const wxTextAttrBorders & GetBorder () const
- wxTextAttrBorder & GetLeftBorder ()

Returns the left border.

- const wxTextAttrBorder & GetLeftBorder () const
- wxTextAttrBorder & GetTopBorder ()

Returns the top border.

- const wxTextAttrBorder & GetTopBorder () const
- wxTextAttrBorder & GetRightBorder ()

Returns the right border.

- const wxTextAttrBorder & GetRightBorder () const
- wxTextAttrBorder & GetBottomBorder ()

Returns the bottom border.

- const wxTextAttrBorder & GetBottomBorder () const
- wxTextAttrBorders & GetOutline ()

Returns the outline.

- const wxTextAttrBorders & GetOutline () const
- wxTextAttrBorder & GetLeftOutline ()

Returns the left outline.

- const wxTextAttrBorder & GetLeftOutline () const
- wxTextAttrBorder & GetTopOutline ()

Returns the top outline.

- const wxTextAttrBorder & GetTopOutline () const
- wxTextAttrBorder & GetRightOutline ()

Returns the right outline.

- const wxTextAttrBorder & GetRightOutline () const
- wxTextAttrBorder & GetBottomOutline ()

Returns the bottom outline.

- const wxTextAttrBorder & GetBottomOutline () const
- wxTextAttrSize & GetSize ()

Returns the object size.

- const wxTextAttrSize & GetSize () const
- wxTextAttrSize & GetMinSize ()

Returns the object minimum size.

- const wxTextAttrSize & GetMinSize () const
- wxTextAttrSize & GetMaxSize ()

Returns the object maximum size.

- const wxTextAttrSize & GetMaxSize () const
- void SetSize (const wxTextAttrSize &sz)

Sets the object size.

- void SetMinSize (const wxTextAttrSize &sz)

Sets the object minimum size.

- void SetMaxSize (const wxTextAttrSize &sz)

Sets the object maximum size.

- wxTextAttrDimension & GetWidth ()

  Returns the object width.
- const wxTextAttrDimension & GetWidth () const
- wxTextAttrDimension & GetHeight ()

  Returns the object height.
- const wxTextAttrDimension & GetHeight () const
- const wxString & GetBoxStyleName () const

  Returns the box style name.
- void SetBoxStyleName (const wxString &name)

  Sets the box style name.
- bool HasBoxStyleName () const

  Returns true if the box style name is present.
- wxTextAttrShadow & GetShadow ()

  Returns the box shadow attributes.
- const wxTextAttrShadow & GetShadow () const

21.770.2 Constructor & Destructor Documentation

wxTextBoxAttr::wxTextBoxAttr ( ) [inline]

Default constructor.

wxTextBoxAttr::wxTextBoxAttr (const wxTextBoxAttr & *attr*) [inline]

Copy constructor.

21.770.3 Member Function Documentation

void wxTextBoxAttr::AddFlag (wxTextBoxAttrFlags *flag*) [inline]

Adds this flag.

bool wxTextBoxAttr::Apply (const wxTextBoxAttr & *style,* const wxTextBoxAttr * *compareWith* = NULL)

Merges the given attributes.

If *compareWith* is non-NULL, then it will be used to mask out those attributes that are the same in style and *compareWith*, for situations where we don't want to explicitly set inherited attributes.

void wxTextBoxAttr::CollectCommonAttributes (const wxTextBoxAttr & *attr,* wxTextBoxAttr & *clashingAttr,* wxTextBoxAttr & *absentAttr*)

Collects the attributes that are common to a range of content, building up a note of which attributes are absent in some objects and which clash in some objects.

bool wxTextBoxAttr::EqPartial (const wxTextBoxAttr & *attr,* bool *weakTest* = true) const

Partial equality test, ignoring unset attributes.

If *weakTest* is true, attributes of this object do not have to be present if those attributes of *attr* are present. If *weakTest* is false, the function will fail if an attribute is present in *attr* but not in this object.

wxTextAttrBorders& wxTextBoxAttr::GetBorder ( ) [inline]

Returns the borders.

const wxTextAttrBorders& wxTextBoxAttr::GetBorder ( ) const [inline]

wxTextAttrDimension& wxTextBoxAttr::GetBottom ( ) [inline]

Returns the bottom position.

const wxTextAttrDimension& wxTextBoxAttr::GetBottom ( ) const [inline]

wxTextAttrBorder& wxTextBoxAttr::GetBottomBorder ( ) [inline]

Returns the bottom border.

const wxTextAttrBorder& wxTextBoxAttr::GetBottomBorder ( ) const [inline]

wxTextAttrDimension& wxTextBoxAttr::GetBottomMargin ( ) [inline]

Returns the bottom margin.

const wxTextAttrDimension& wxTextBoxAttr::GetBottomMargin ( ) const [inline]

wxTextAttrBorder& wxTextBoxAttr::GetBottomOutline ( ) [inline]

Returns the bottom outline.

const wxTextAttrBorder& wxTextBoxAttr::GetBottomOutline ( ) const [inline]

wxTextAttrDimension& wxTextBoxAttr::GetBottomPadding ( ) [inline]

Returns the bottom padding value.

const wxTextAttrDimension& wxTextBoxAttr::GetBottomPadding ( ) const `[inline]`

const wxString& wxTextBoxAttr::GetBoxStyleName ( ) const `[inline]`

Returns the box style name.

wxTextBoxAttrClearStyle wxTextBoxAttr::GetClearMode ( ) const `[inline]`

Returns the clear mode - whether to wrap text after object.
Currently unimplemented.

wxTextBoxAttrCollapseMode wxTextBoxAttr::GetCollapseBorders ( ) const `[inline]`

Returns the collapse mode - whether to collapse borders.

const wxTextAttrDimension& wxTextBoxAttr::GetCornerRadius ( ) const `[inline]`

Returns the corner radius value.

wxTextAttrDimension& wxTextBoxAttr::GetCornerRadius ( ) `[inline]`

int wxTextBoxAttr::GetFlags ( ) const `[inline]`

Returns the flags.

wxTextBoxAttrFloatStyle wxTextBoxAttr::GetFloatMode ( ) const `[inline]`

Returns the float mode.

wxTextAttrDimension& wxTextBoxAttr::GetHeight ( ) `[inline]`

Returns the object height.

const wxTextAttrDimension& wxTextBoxAttr::GetHeight ( ) const `[inline]`

wxTextAttrDimension& wxTextBoxAttr::GetLeft ( ) `[inline]`

Returns the left position.

const wxTextAttrDimension& wxTextBoxAttr::GetLeft ( ) const `[inline]`

wxTextAttrBorder& wxTextBoxAttr::GetLeftBorder ( ) `[inline]`

Returns the left border.

const wxTextAttrBorder& wxTextBoxAttr::GetLeftBorder ( ) const `[inline]`

wxTextAttrDimension& wxTextBoxAttr::GetLeftMargin ( ) `[inline]`

Returns the left margin.

const wxTextAttrDimension& wxTextBoxAttr::GetLeftMargin ( ) const `[inline]`

wxTextAttrBorder& wxTextBoxAttr::GetLeftOutline ( ) `[inline]`

Returns the left outline.

const wxTextAttrBorder& wxTextBoxAttr::GetLeftOutline ( ) const `[inline]`

wxTextAttrDimension& wxTextBoxAttr::GetLeftPadding ( ) `[inline]`

Returns the left padding value.

const wxTextAttrDimension& wxTextBoxAttr::GetLeftPadding ( ) const `[inline]`

wxTextAttrDimensions& wxTextBoxAttr::GetMargins ( ) `[inline]`

Returns the margin values.

const wxTextAttrDimensions& wxTextBoxAttr::GetMargins ( ) const `[inline]`

wxTextAttrSize& wxTextBoxAttr::GetMaxSize ( ) `[inline]`

Returns the object maximum size.

const wxTextAttrSize& wxTextBoxAttr::GetMaxSize ( ) const `[inline]`

wxTextAttrSize& wxTextBoxAttr::GetMinSize ( ) `[inline]`

Returns the object minimum size.

const wxTextAttrSize& wxTextBoxAttr::GetMinSize ( ) const `[inline]`

wxTextAttrBorders& wxTextBoxAttr::GetOutline ( ) `[inline]`

Returns the outline.

const wxTextAttrBorders& wxTextBoxAttr::GetOutline ( ) const `[inline]`

wxTextAttrDimensions& wxTextBoxAttr::GetPadding ( ) `[inline]`

Returns the padding values.

const wxTextAttrDimensions& wxTextBoxAttr::GetPadding ( ) const `[inline]`

wxTextAttrDimensions& wxTextBoxAttr::GetPosition ( ) `[inline]`

Returns the position.

const wxTextAttrDimensions& wxTextBoxAttr::GetPosition ( ) const `[inline]`

wxTextAttrDimension& wxTextBoxAttr::GetRight ( ) `[inline]`

Returns the right position.

const wxTextAttrDimension& wxTextBoxAttr::GetRight ( ) const `[inline]`

wxTextAttrBorder& wxTextBoxAttr::GetRightBorder ( ) `[inline]`

Returns the right border.

const wxTextAttrBorder& wxTextBoxAttr::GetRightBorder ( ) const `[inline]`

wxTextAttrDimension& wxTextBoxAttr::GetRightMargin ( ) `[inline]`

Returns the right margin.

const wxTextAttrDimension& wxTextBoxAttr::GetRightMargin ( ) const `[inline]`

wxTextAttrBorder& wxTextBoxAttr::GetRightOutline ( ) `[inline]`

Returns the right outline.

const wxTextAttrBorder& wxTextBoxAttr::GetRightOutline ( ) const `[inline]`

wxTextAttrDimension& wxTextBoxAttr::GetRightPadding ( ) `[inline]`

Returns the right padding value.

const wxTextAttrDimension& wxTextBoxAttr::GetRightPadding ( ) const `[inline]`

wxTextAttrShadow& wxTextBoxAttr::GetShadow ( ) `[inline]`

Returns the box shadow attributes.

const wxTextAttrShadow& wxTextBoxAttr::GetShadow ( ) const `[inline]`

wxTextAttrSize& wxTextBoxAttr::GetSize ( ) `[inline]`

Returns the object size.

const wxTextAttrSize& wxTextBoxAttr::GetSize ( ) const `[inline]`

wxTextAttrDimension& wxTextBoxAttr::GetTop ( ) `[inline]`

Returns the top position.

const wxTextAttrDimension& wxTextBoxAttr::GetTop ( ) const `[inline]`

wxTextAttrBorder& wxTextBoxAttr::GetTopBorder ( ) `[inline]`

Returns the top border.

const wxTextAttrBorder& wxTextBoxAttr::GetTopBorder ( ) const `[inline]`

wxTextAttrDimension& wxTextBoxAttr::GetTopMargin ( ) `[inline]`

Returns the top margin.

const wxTextAttrDimension& wxTextBoxAttr::GetTopMargin ( ) const `[inline]`

wxTextAttrBorder& wxTextBoxAttr::GetTopOutline ( ) `[inline]`

Returns the top outline.

const wxTextAttrBorder& wxTextBoxAttr::GetTopOutline ( ) const `[inline]`

wxTextAttrDimension& wxTextBoxAttr::GetTopPadding ( ) `[inline]`

Returns the top padding value.

const wxTextAttrDimension& wxTextBoxAttr::GetTopPadding ( ) const `[inline]`

wxTextBoxAttrVerticalAlignment wxTextBoxAttr::GetVerticalAlignment ( ) const `[inline]`

Returns the vertical alignment.

wxTextBoxAttrWhitespaceMode wxTextBoxAttr::GetWhitespaceMode ( ) const `[inline]`

Returns the whitespace mode.

wxTextAttrDimension& wxTextBoxAttr::GetWidth ( ) `[inline]`

Returns the object width.

const wxTextAttrDimension& wxTextBoxAttr::GetWidth ( ) const `[inline]`

bool wxTextBoxAttr::HasBoxStyleName ( ) const `[inline]`

Returns true if the box style name is present.

bool wxTextBoxAttr::HasClearMode ( ) const `[inline]`

Returns true if we have a clear flag.

bool wxTextBoxAttr::HasCollapseBorders ( ) const `[inline]`

Returns true if the collapse borders flag is present.

bool wxTextBoxAttr::HasCornerRadius ( ) const `[inline]`

Returns true if the corner radius flag is present.

bool wxTextBoxAttr::HasFlag (wxTextBoxAttrFlags *flag*) const `[inline]`

Is this flag present?

bool wxTextBoxAttr::HasFloatMode ( ) const `[inline]`

Returns true if float mode is active.

bool wxTextBoxAttr::HasVerticalAlignment ( ) const `[inline]`

Returns true if a vertical alignment flag is present.

bool wxTextBoxAttr::HasWhitespaceMode ( ) const `[inline]`

Returns true if the whitespace flag is present.

void wxTextBoxAttr::Init ( ) `[inline]`

Initialises this object.

bool wxTextBoxAttr::IsDefault ( ) const

Returns true if no attributes are set.

bool wxTextBoxAttr::IsFloating ( ) const `[inline]`

Returns true if this object is floating.

bool wxTextBoxAttr::operator== (const wxTextBoxAttr & *attr*) const

Equality test.

void wxTextBoxAttr::RemoveFlag (wxTextBoxAttrFlags *flag*) `[inline]`

Removes this flag.

bool wxTextBoxAttr::RemoveStyle (const wxTextBoxAttr & *attr*)

Removes the specified attributes from this object.

void wxTextBoxAttr::Reset ( )

Resets this object.

void wxTextBoxAttr::SetBoxStyleName (const wxString & *name*) `[inline]`

Sets the box style name.

void wxTextBoxAttr::SetClearMode (wxTextBoxAttrClearStyle *mode*) `[inline]`

Set the clear mode.

Currently unimplemented.

void wxTextBoxAttr::SetCollapseBorders (wxTextBoxAttrCollapseMode *collapse*) `[inline]`

Sets the collapse mode - whether to collapse borders.

void wxTextBoxAttr::SetCornerRadius (const wxTextAttrDimension & *dim*) `[inline]`

Sets the corner radius value.

void wxTextBoxAttr::SetFlags (int *flags*) `[inline]`

Sets the flags.

void wxTextBoxAttr::SetFloatMode (wxTextBoxAttrFloatStyle *mode*) `[inline]`

Sets the float mode.

void wxTextBoxAttr::SetMaxSize (const wxTextAttrSize & *sz*) `[inline]`

Sets the object maximum size.

void wxTextBoxAttr::SetMinSize (const wxTextAttrSize & *sz*) `[inline]`

Sets the object minimum size.

void wxTextBoxAttr::SetSize (const wxTextAttrSize & *sz*) `[inline]`

Sets the object size.

void wxTextBoxAttr::SetVerticalAlignment (wxTextBoxAttrVerticalAlignment *verticalAlignment*) `[inline]`

Sets the vertical alignment.

void wxTextBoxAttr::SetWhitespaceMode (wxTextBoxAttrWhitespaceMode *whitespace*) `[inline]`

Sets the whitespace mode.

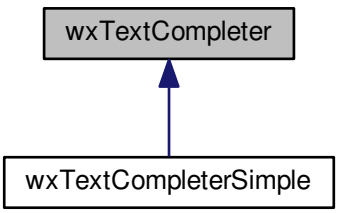
21.771 wxTextCompleter Class Reference

`#include <wx/textcompleter.h>`

Inheritance diagram for wxTextCompleter:



21.771.1 Detailed Description

Base class for custom text completer objects.

Custom completer objects used with wxTextEntry::AutoComplete() must derive from this class and implement its pure virtual method returning the completions. You would typically use a custom completer when the total number of completions is too big for performance to be acceptable if all of them need to be returned at once but if they can be generated hierarchically, i.e. only the first component initially, then the second one after the user finished entering the first one and so on.

When inheriting from this class you need to implement its two pure virtual methods. This allows to return the results incrementally and may or not be convenient depending on where do they come from. If you prefer to return all the completions at once, you should inherit from wxTextCompleterSimple instead.

Since

2.9.2

Public Member Functions

- virtual bool Start (const wxString &prefix)=0

  Function called to start iteration over the completions for the given prefix.
- virtual wxString GetNext ()=0

  Called to retrieve the next completion.

21.771.2 Member Function Documentation

virtual wxString wxTextCompleter::GetNext ( ) [pure virtual]

Called to retrieve the next completion.

All completions returned by this function should start with the prefix passed to the last call to Start().

Notice that, as Start(), this method is called from a worker thread context under MSW.

Returns

The next completion or an empty string to indicate that there are no more of them.

virtual bool wxTextCompleter::Start (const wxString & *prefix*) [pure virtual]

Function called to start iteration over the completions for the given prefix.

This function could start a database query, for example, if the results are read from a database.

Notice that under some platforms (currently MSW only) it is called from another thread context and so the appropriate synchronization mechanism should be used to access any data also used by the main UI thread.

Parameters

prefix	The prefix for which completions are to be generated.

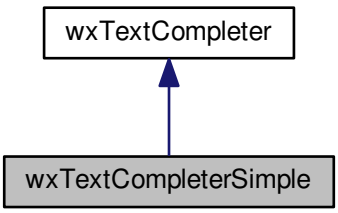
Returns

true to continue with calling GetNext() or false to indicate that there are no matches and GetNext() shouldn't be called at all.

21.772 wxTextCompleterSimple Class Reference

`#include <wx/textcompleter.h>`

Inheritance diagram for wxTextCompleterSimple:



21.772.1 Detailed Description

A simpler base class for custom completer objects.

This class may be simpler to use than the base wxTextCompleter as it allows to implement only a single virtual method instead of two of them (at the price of storing all completions in a temporary array).

Here is a simple example of a custom completer that completes the names of some chess pieces. Of course, as the total list here has only four items it would have been much simpler to just specify the array containing all the completions in this example but the same approach could be used when the total number of completions is much higher provided the number of possibilities for each word is still relatively small:

```
class MyTextCompleter : public wxTextCompleterSimple
{
public:
    virtual void GetCompletions(const wxString& prefix,
      wxArrayString& res)
    {
        const wxString firstWord = prefix.BeforeFirst(' ');
        if ( firstWord == "white" )
        {
            res.push_back("white pawn");
            res.push_back("white rook");
        }
        else if ( firstWord == "black" )
        {
            res.push_back("black king");
            res.push_back("black queen");
        }
        else
        {
            res.push_back("white");
            res.push_back("black");
        }
    }
};
...
wxTextCtrl *text = ...;
text->AutoComplete(new MyTextCompleter);
```

Library: wxCore

Since

2.9.2

Public Member Functions

- virtual void GetCompletions (const wxString &prefix, wxArrayString &res)=0

Pure virtual method returning all possible completions for the given prefix.

21.772.2 Member Function Documentation

virtual void wxTextCompleterSimple::GetCompletions (const wxString & *prefix,* wxArrayString & *res*) `[pure virtual]`

Pure virtual method returning all possible completions for the given prefix.

The custom completer should examine the provided prefix and return all the possible completions for it in the output array *res*.

Please notice that the returned values should start with the prefix, otherwise they will be simply ignored, making adding them to the array in the first place useless.

Notice that this function may be called from thread other than main one (this is currently always the case under MSW) so the appropriate synchronization mechanism should be used to protect the shared data.

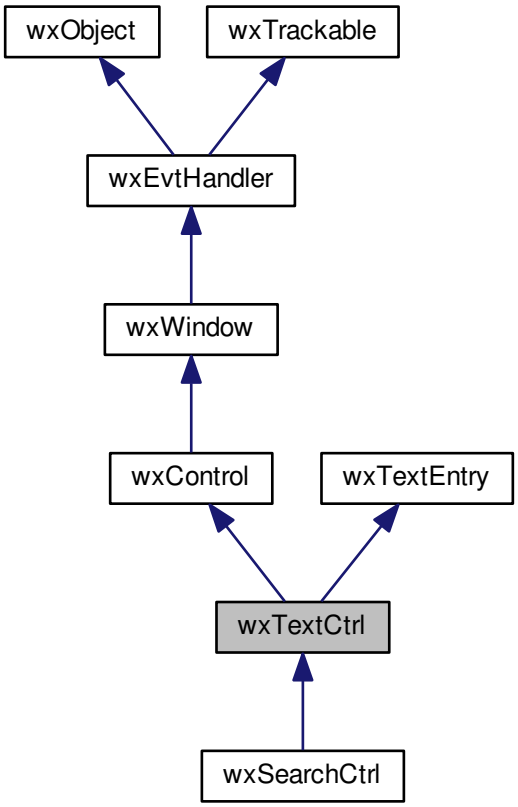
Parameters

prefix	The possibly empty prefix that the user had already entered.
res	Initially empty array that should be filled with all possible completions (possibly none if there are no valid possibilities starting with the given prefix).

21.773 wxTextCtrl Class Reference

`#include <wx/textctrl.h>`

Inheritance diagram for wxTextCtrl:



21.773.1 Detailed Description

A text control allows text to be displayed and edited.

It may be single line or multi-line. Notice that a lot of methods of the text controls are found in the base wxTextEntry class which is a common base class for wxTextCtrl and other controls using a single line text entry field (e.g. wxComboBox).

Styles

This class supports the following styles:

- wxTE_PROCESS_ENTER: The control will generate the event `wxEVT_TEXT_ENTER` (otherwise pressing Enter key is either processed internally by the control or used for navigation between dialog controls).
- wxTE_PROCESS_TAB: The control will receive `wxEVT_CHAR` events for TAB pressed - normally, TAB is used for passing to the next control in a dialog instead. For the control created with this style, you can still use Ctrl-Enter to pass to the next control from the keyboard.
- wxTE_MULTILINE: The text control allows multiple lines. If this style is not specified, line break characters should not be used in the controls value.
- wxTE_PASSWORD: The text will be echoed as asterisks.

- wxTE_READONLY: The text will not be user-editable.
- wxTE_RICH: Use rich text control under Win32, this allows to have more than 64KB of text in the control even under Win9x. This style is ignored under other platforms.
- wxTE_RICH2: Use rich text control version 2.0 or 3.0 under Win32, this style is ignored under other platforms
- wxTE_AUTO_URL: Highlight the URLs and generate the wxTextUrlEvents when mouse events occur over them. This style is only supported for wxTE_RICH Win32 and multi-line wxGTK2 text controls.
- wxTE_NOHIDESEL: By default, the Windows text control doesn't show the selection when it doesn't have focus - use this style to force it to always show it. It doesn't do anything under other platforms.
- wxHSCROLL: A horizontal scrollbar will be created and used, so that text won't be wrapped. No effect under wxGTK1.
- wxTE_NO_VSCROLL: For multiline controls only: vertical scrollbar will never be created. This limits the amount of text which can be entered into the control to what can be displayed in it under MSW but not under GTK2. Currently not implemented for the other platforms.
- wxTE_LEFT: The text in the control will be left-justified (default).
- wxTE_CENTRE: The text in the control will be centered (currently wxMSW and wxGTK2 only).
- wxTE_RIGHT: The text in the control will be right-justified (currently wxMSW and wxGTK2 only).
- wxTE_DONTWRAP: Same as wxHSCROLL style: don't wrap at all, show horizontal scrollbar instead.
- wxTE_CHARWRAP: Wrap the lines too long to be shown entirely at any position (wxUniv and wxGTK2 only).
- wxTE_WORDWRAP: Wrap the lines too long to be shown entirely at word boundaries (wxUniv and wxGTK2 only).
- wxTE_BESTWRAP: Wrap the lines at word boundaries or at any other character if there are words longer than the window width (this is the default).
- wxTE_CAPITALIZE: On PocketPC and Smartphone, causes the first letter to be capitalized.

Note that alignment styles (wxTE_LEFT, wxTE_CENTRE and wxTE_RIGHT) can be changed dynamically after control creation on wxMSW and wxGTK. wxTE_READONLY, wxTE_PASSWORD and wrapping styles can be dynamically changed under wxGTK but not wxMSW. The other styles can be only set during control creation.

21.773.2 wxTextCtrl Text Format

The multiline text controls always store the text as a sequence of lines separated by `'\n'` characters, i.e. in the Unix text format even on non-Unix platforms. This allows the user code to ignore the differences between the platforms but at a price: the indices in the control such as those returned by GetInsertionPoint() or GetSelection() can **not** be used as indices into the string returned by GetValue() as they're going to be slightly off for platforms using `"\\r\\n"` as separator (as Windows does).

Instead, if you need to obtain a substring between the 2 indices obtained from the control with the help of the functions mentioned above, you should use GetRange(). And the indices themselves can only be passed to other methods, for example SetInsertionPoint() or SetSelection().

To summarize: never use the indices returned by (multiline) wxTextCtrl as indices into the string it contains, but only as arguments to be passed back to the other wxTextCtrl methods. This problem doesn't arise for single-line platforms however where the indices in the control do correspond to the positions in the value string.

21.773.3 wxTextCtrl Styles.

Multi-line text controls support styling, i.e. provide a possibility to set colours and font for individual characters in it (note that under Windows `wxTE_RICH` style is required for style support). To use the styles you can either call SetDefaultStyle() before inserting the text or call SetStyle() later to change the style of the text already in the control (the first solution is much more efficient).

In either case, if the style doesn't specify some of the attributes (for example you only want to set the text colour but without changing the font nor the text background), the values of the default style will be used for them. If there is no default style, the attributes of the text control itself are used.

So the following code correctly describes what it does: the second call to SetDefaultStyle() doesn't change the text foreground colour (which stays red) while the last one doesn't change the background colour (which stays grey):

```
text->SetDefaultStyle(wxTextAttr(*wxRED));
text->AppendText("Red text\n");
text->SetDefaultStyle(wxTextAttr(wxNullColour, *
      wxLIGHT_GREY));
text->AppendText("Red on grey text\n");
text->SetDefaultStyle(wxTextAttr(*wxBLUE);
text->AppendText("Blue on grey text\n");
```

21.773.4 wxTextCtrl and C++ Streams

This class multiply-inherits from `std::streambuf` (except for some really old compilers using non-standard iostream library), allowing code such as the following:

```
wxTextCtrl *control = new wxTextCtrl(...);

ostream stream(control)

stream << 123.456 << " some text\n";
stream.flush();
```

Note that even if your build of wxWidgets doesn't support this (the symbol `wxHAS_TEXT_WINDOW_STREAM` has value of 0 then) you can still use wxTextCtrl itself in a stream-like manner:

```
wxTextCtrl *control = new wxTextCtrl(...);

*control << 123.456 << " some text\n";
```

However the possibility to create an ostream associated with wxTextCtrl may be useful if you need to redirect the output of a function taking an ostream as parameter to a text control.

Another commonly requested need is to redirect `std::cout` to the text control. This may be done in the following way:

```
#include <iostream>

wxTextCtrl *control = new wxTextCtrl(...);

std::streambuf *sbOld = std::cout.rdbuf();
std::cout.rdbuf(control);

// use cout as usual, the output appears in the text control
...

std::cout.rdbuf(sbOld);
```

But wxWidgets provides a convenient class to make it even simpler so instead you may just do

```
#include <iostream>

wxTextCtrl *control = new wxTextCtrl(...);

wxStreamToTextRedirector redirect(control);

// all output to cout goes into the text control until the exit from
// current scope
```

See wxStreamToTextRedirector for more details.

21.773.5 Event Handling.

The following commands are processed by default event handlers in wxTextCtrl: `wxID_CUT`, `wxID_COPY`, `wxID_PASTE`, `wxID_UNDO`, `wxID_REDO`. The associated UI update events are also processed automatically, when the control has the focus.

Events emitted by this class

The following event handler macros redirect the events to member function handlers '**func**' with prototypes like: void handlerFuncName(wxCommandEvent& event)

Event macros for events emitted by this class:

- EVT_TEXT(id, func): Respond to a `wxEVT_TEXT` event, generated when the text changes. Notice that this event will be sent when the text controls contents changes – whether this is due to user input or comes from the program itself (for example, if wxTextCtrl::SetValue() is called); see wxTextCtrl::ChangeValue() for a function which does not send this event. This event is however not sent during the control creation.
- EVT_TEXT_ENTER(id, func): Respond to a `wxEVT_TEXT_ENTER` event, generated when enter is pressed in a text control which must have wxTE_PROCESS_ENTER style for this event to be generated.
- EVT_TEXT_URL(id, func): A mouse event occurred over an URL in the text control (wxMSW and wxGTK2 only currently).
- EVT_TEXT_MAXLEN(id, func): This event is generated when the user tries to enter more text into the control than the limit set by wxTextCtrl::SetMaxLength(), see its description.

wxTextCtrl::Create, wxValidator

Public Member Functions

- wxTextCtrl ()

  Default ctor.
- wxTextCtrl (wxWindow *parent, wxWindowID id, const wxString &value=wxEmptyString, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, long style=0, const wxValidator &validator=wxDefaultValidator, const wxString &name=wxTextCtrlNameStr)

  Constructor, creating and showing a text control.
- virtual ~wxTextCtrl ()

  Destructor, destroying the text control.
- bool Create (wxWindow *parent, wxWindowID id, const wxString &value=wxEmptyString, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, long style=0, const wxValidator &validator=wxDefaultValidator, const wxString &name=wxTextCtrlNameStr)

  Creates the text control for two-step construction.
- virtual void DiscardEdits ()

  Resets the internal modified flag as if the current changes had been saved.
- virtual bool EmulateKeyPress (const wxKeyEvent &event)

  This function inserts into the control the character which would have been inserted if the given key event had occurred in the text control.
- virtual const wxTextAttr & GetDefaultStyle () const

Returns the style currently used for the new text.

- virtual int GetLineLength (long lineNo) const

  Gets the length of the specified line, not including any trailing newline character(s).
- virtual wxString GetLineText (long lineNo) const

  Returns the contents of a given line in the text control, not including any trailing newline character(s).
- virtual int GetNumberOfLines () const

  Returns the number of lines in the text control buffer.
- virtual bool GetStyle (long position, wxTextAttr &style)

  Returns the style at this position in the text control.
- wxTextCtrlHitTestResult HitTest (const wxPoint &pt, long ∗pos) const

  Finds the position of the character at the specified point.
- wxTextCtrlHitTestResult HitTest (const wxPoint &pt, wxTextCoord ∗col, wxTextCoord ∗row) const

  Finds the row and column of the character at the specified point.
- virtual bool IsModified () const

  Returns true if the text has been modified by user.
- bool IsMultiLine () const

  Returns true if this is a multi line edit control and false otherwise.
- bool IsSingleLine () const

  Returns true if this is a single line edit control and false otherwise.
- bool LoadFile (const wxString &filename, int fileType=wxTEXT_TYPE_ANY)

  Loads and displays the named file, if it exists.
- virtual void MarkDirty ()

  Mark text as modified (dirty).
- void OnDropFiles (wxDropFilesEvent &event)

  This event handler function implements default drag and drop behaviour, which is to load the first dropped file into the control.
- virtual bool PositionToXY (long pos, long ∗x, long ∗y) const

  Converts given position to a zero-based column, line number pair.
- wxPoint PositionToCoords (long pos) const

  Converts given text position to client coordinates in pixels.
- bool SaveFile (const wxString &filename=wxEmptyString, int fileType=wxTEXT_TYPE_ANY)

  Saves the contents of the control in a text file.
- virtual bool SetDefaultStyle (const wxTextAttr &style)

  Changes the default style to use for the new text which is going to be added to the control using WriteText() or AppendText().
- void SetModified (bool modified)

  Marks the control as being modified by the user or not.
- virtual bool SetStyle (long start, long end, const wxTextAttr &style)

  Changes the style of the given range.
- virtual void ShowPosition (long pos)

  Makes the line containing the given position visible.
- virtual long XYToPosition (long x, long y) const

  Converts the given zero based column and line number to a position.

- wxTextCtrl & operator<< (const wxString &s)

  Operator definitions for appending to a text control.
- wxTextCtrl & operator<< (int i)

  Operator definitions for appending to a text control.
- wxTextCtrl & operator<< (long i)

  Operator definitions for appending to a text control.
- wxTextCtrl & operator<< (float f)

Operator definitions for appending to a text control.

- wxTextCtrl & operator<< (double d)

  Operator definitions for appending to a text control.
- wxTextCtrl & operator<< (char c)

  Operator definitions for appending to a text control.
- wxTextCtrl & operator<< (wchar_t c)

  Operator definitions for appending to a text control.

Additional Inherited Members

21.773.6 Constructor & Destructor Documentation

wxTextCtrl::wxTextCtrl ( )

Default ctor.

wxTextCtrl::wxTextCtrl (wxWindow * *parent*, wxWindowID *id*, const wxString & *value* = wxEmptyString, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, long *style* = 0, const wxValidator & *validator* = wxDefaultValidator, const wxString & *name* = wxTextCtrlNameStr)

Constructor, creating and showing a text control.

Parameters

parent	Parent window. Should not be NULL.
id	Control identifier. A value of -1 denotes a default value.
value	Default text value.
pos	Text control position.
size	Text control size.
style	Window style. See wxTextCtrl.
validator	Window validator.
name	Window name.

Remarks

The horizontal scrollbar (wxHSCROLL style flag) will only be created for multi-line text controls. Without a horizontal scrollbar, text lines that don't fit in the control's size will be wrapped (but no newline character is inserted). Single line controls don't have a horizontal scrollbar, the text is automatically scrolled so that the insertion point is always visible.

See also

Create(), wxValidator

virtual wxTextCtrl::~wxTextCtrl ( ) [virtual]

Destructor, destroying the text control.

21.773.7 Member Function Documentation

bool wxTextCtrl::Create (wxWindow * *parent*, wxWindowID *id*, const wxString & *value* = wxEmptyString, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, long *style* = 0, const wxValidator & *validator* = wxDefaultValidator, const wxString & *name* = wxTextCtrlNameStr)

Creates the text control for two-step construction.

This method should be called if the default constructor was used for the control creation. Its parameters have the same meaning as for the non-default constructor.

virtual void wxTextCtrl::DiscardEdits ( ) [virtual]

Resets the internal modified flag as if the current changes had been saved.

virtual bool wxTextCtrl::EmulateKeyPress (const wxKeyEvent & *event*) [virtual]

This function inserts into the control the character which would have been inserted if the given key event had occurred in the text control.

The *event* object should be the same as the one passed to `EVT_KEY_DOWN` handler previously by wxWidgets. Please note that this function doesn't currently work correctly for all keys under any platform but MSW.

Returns

true if the event resulted in a change to the control, false otherwise.

virtual const wxTextAttr& wxTextCtrl::GetDefaultStyle ( ) const [virtual]

Returns the style currently used for the new text.

See also

SetDefaultStyle()

virtual int wxTextCtrl::GetLineLength (long *lineNo*) const [virtual]

Gets the length of the specified line, not including any trailing newline character(s).

Parameters

lineNo	Line number (starting from zero).

Returns

The length of the line, or -1 if *lineNo* was invalid.

virtual wxString wxTextCtrl::GetLineText (long *lineNo*) const [virtual]

Returns the contents of a given line in the text control, not including any trailing newline character(s).

Parameters

lineNo	The line number, starting from zero.

Returns

The contents of the line.

virtual int wxTextCtrl::GetNumberOfLines ( ) const [virtual]

Returns the number of lines in the text control buffer.

The returned number is the number of logical lines, i.e. just the count of the number of newline characters in the control + 1, for wxGTK and wxOSX/Cocoa ports while it is the number of physical lines, i.e. the count of lines actually shown in the control, in wxMSW and wxOSX/Carbon. Because of this discrepancy, it is not recommended to use this function.

Remarks

Note that even empty text controls have one line (where the insertion point is), so GetNumberOfLines() never returns 0.

virtual bool wxTextCtrl::GetStyle (long *position,* wxTextAttr & *style*) [virtual]

Returns the style at this position in the text control.

Not all platforms support this function.

Returns

true on success, false if an error occurred (this may also mean that the styles are not supported under this platform).

See also

SetStyle(), wxTextAttr

wxTextCtrlHitTestResult wxTextCtrl::HitTest (const wxPoint & *pt,* long * *pos*) const

Finds the position of the character at the specified point.

If the return code is not wxTE_HT_UNKNOWN the row and column of the character closest to this position are returned, otherwise the output parameters are not modified.

Please note that this function is currently only implemented in wxUniv, wxMSW and wxGTK2 ports and always returns wxTE_HT_UNKNOWN in the other ports.

wxPerl Note: In wxPerl this function takes only the *pt* argument and returns a 3-element list (result, col, row).

Parameters

pt	The position of the point to check, in window device coordinates.
pos	Receives the position of the character at the given position. May be NULL.

See also

PositionToXY(), XYToPosition()

wxTextCtrlHitTestResult wxTextCtrl::HitTest (const wxPoint & *pt,* wxTextCoord * *col,* wxTextCoord * *row*) const

Finds the row and column of the character at the specified point.

If the return code is not wxTE_HT_UNKNOWN the row and column of the character closest to this position are returned, otherwise the output parameters are not modified.

Please note that this function is currently only implemented in wxUniv, wxMSW and wxGTK2 ports and always returns wxTE_HT_UNKNOWN in the other ports.

wxPerl Note: In wxPerl this function takes only the *pt* argument and returns a 3-element list (result, col, row).

Parameters

pt	The position of the point to check, in window device coordinates.
col	Receives the column of the character at the given position. May be NULL.
row	Receives the row of the character at the given position. May be NULL.

See also

PositionToXY(), XYToPosition()

virtual bool wxTextCtrl::IsModified ( ) const `[virtual]`

Returns true if the text has been modified by user.

Note that calling SetValue() doesn't make the control modified.

See also

MarkDirty()

bool wxTextCtrl::IsMultiLine ( ) const

Returns true if this is a multi line edit control and false otherwise.

See also

IsSingleLine()

bool wxTextCtrl::IsSingleLine ( ) const

Returns true if this is a single line edit control and false otherwise.

See also

IsSingleLine(), IsMultiLine()

bool wxTextCtrl::LoadFile (const wxString & *filename*, int *fileType* = wxTEXT_TYPE_ANY)

Loads and displays the named file, if it exists.

Parameters

filename	The filename of the file to load.
fileType	The type of file to load. This is currently ignored in wxTextCtrl.

Returns

true if successful, false otherwise.

virtual void wxTextCtrl::MarkDirty ( ) `[virtual]`

Mark text as modified (dirty).

See also

IsModified()

void wxTextCtrl::OnDropFiles (wxDropFilesEvent & *event*)

This event handler function implements default drag and drop behaviour, which is to load the first dropped file into the control.

Parameters

event	The drop files event.

Remarks

This is not implemented on non-Windows platforms.

See also

wxDropFilesEvent

wxTextCtrl& wxTextCtrl::operator<< (const wxString & *s*)

Operator definitions for appending to a text control.

These operators can be used as with the standard C++ streams, for example:

```
wxTextCtrl *wnd = new wxTextCtrl(my_frame);
(*wnd) << "Welcome to text control number " << 1 << ".\n";
```

wxTextCtrl& wxTextCtrl::operator<< (int *i*)

Operator definitions for appending to a text control.

These operators can be used as with the standard C++ streams, for example:

```
wxTextCtrl *wnd = new wxTextCtrl(my_frame);
(*wnd) << "Welcome to text control number " << 1 << ".\n";
```

wxTextCtrl& wxTextCtrl::operator<< (long *i*)

Operator definitions for appending to a text control.

These operators can be used as with the standard C++ streams, for example:

```
wxTextCtrl *wnd = new wxTextCtrl(my_frame);
(*wnd) << "Welcome to text control number " << 1 << ".\n";
```

wxTextCtrl& wxTextCtrl::operator<< (float *f*)

Operator definitions for appending to a text control.

These operators can be used as with the standard C++ streams, for example:

```
wxTextCtrl *wnd = new wxTextCtrl(my_frame);
(*wnd) << "Welcome to text control number " << 1 << ".\n";
```

wxTextCtrl& wxTextCtrl::operator<< (double *d*)

Operator definitions for appending to a text control.

These operators can be used as with the standard C++ streams, for example:

```
wxTextCtrl *wnd = new wxTextCtrl(my_frame);
(*wnd) << "Welcome to text control number " << 1 << ".\n";
```

wxTextCtrl& wxTextCtrl::operator<< (char *c*)

Operator definitions for appending to a text control.

These operators can be used as with the standard C++ streams, for example:

```
wxTextCtrl *wnd = new wxTextCtrl(my_frame);

(*wnd) << "Welcome to text control number " << 1 << ".\n";
```

wxTextCtrl& wxTextCtrl::operator<< (wchar_t *c*)

Operator definitions for appending to a text control.

These operators can be used as with the standard C++ streams, for example:

```
wxTextCtrl *wnd = new wxTextCtrl(my_frame);

(*wnd) << "Welcome to text control number " << 1 << ".\n";
```

wxPoint wxTextCtrl::PositionToCoords (long *pos*) const

Converts given text position to client coordinates in pixels.

This function allows to find where is the character at the given position displayed in the text control.

Availability: only available for the wxMSW, wxGTK ports.. Additionally, wxGTK only implements this method for multiline controls and wxDefaultPosition is always returned for the single line ones.

Parameters

pos	Text position in 0 to GetLastPosition() range (inclusive).

Returns

On success returns a wxPoint which contains client coordinates for the given position in pixels, otherwise returns wxDefaultPosition.

Since

2.9.3

See also

XYToPosition(), PositionToXY()

virtual bool wxTextCtrl::PositionToXY (long *pos*, long * *x*, long * *y*) const [virtual]

Converts given position to a zero-based column, line number pair.

Parameters

pos	Position.
x	Receives zero based column number.

y	Receives zero based line number.

Returns

true on success, false on failure (most likely due to a too large position parameter).

wxPerl Note: In wxPerl this function takes only the *pos* argument and returns a 2-element list (x, y).

See also

XYToPosition()

bool wxTextCtrl::SaveFile (const wxString & *filename* = wxEmptyString, int *fileType* = wxTEXT_TYPE_ANY)

Saves the contents of the control in a text file.

Parameters

filename	The name of the file in which to save the text.
fileType	The type of file to save. This is currently ignored in wxTextCtrl.

Returns

true if the operation was successful, false otherwise.

virtual bool wxTextCtrl::SetDefaultStyle (const wxTextAttr & *style*) [virtual]

Changes the default style to use for the new text which is going to be added to the control using WriteText() or AppendText().

If either of the font, foreground, or background colour is not set in *style*, the values of the previous default style are used for them. If the previous default style didn't set them neither, the global font or colours of the text control itself are used as fall back.

However if the *style* parameter is the default wxTextAttr, then the default style is just reset (instead of being combined with the new style which wouldn't change it at all).

Parameters

style	The style for the new text.

Returns

true on success, false if an error occurred (this may also mean that the styles are not supported under this platform).

See also

GetDefaultStyle()

void wxTextCtrl::SetModified (bool *modified*)

Marks the control as being modified by the user or not.

See also

MarkDirty(), DiscardEdits()

virtual bool wxTextCtrl::SetStyle (long *start,* long *end,* const wxTextAttr & *style*) `[virtual]`

Changes the style of the given range.

If any attribute within *style* is not set, the corresponding attribute from GetDefaultStyle() is used.

Parameters

start	The start of the range to change.
end	The end of the range to change.
style	The new style for the range.

Returns

true on success, false if an error occurred (this may also mean that the styles are not supported under this platform).

See also

GetStyle(), wxTextAttr

virtual void wxTextCtrl::ShowPosition (long *pos*) `[virtual]`

Makes the line containing the given position visible.

Parameters

pos	The position that should be visible.

virtual long wxTextCtrl::XYToPosition (long *x,* long *y*) const `[virtual]`

Converts the given zero based column and line number to a position.

Parameters

x	The column number.
y	The line number.

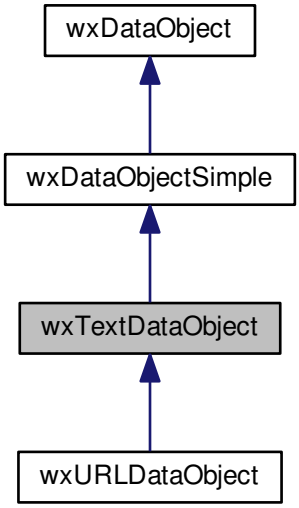
Returns

The position value, or -1 if x or y was invalid.

21.774 wxTextDataObject Class Reference

`#include <wx/dataobj.h>`

Inheritance diagram for wxTextDataObject:



21.774.1 Detailed Description

wxTextDataObject is a specialization of wxDataObjectSimple for text data.

It can be used without change to paste data into the wxClipboard or a wxDropSource. A user may wish to derive a new class from this class for providing text on-demand in order to minimize memory consumption when offering data in several formats, such as plain text and RTF because by default the text is stored in a string in this class, but it might as well be generated when requested. For this, GetTextLength() and GetText() will have to be overridden.

Note that if you already have the text inside a string, you will not achieve any efficiency gain by overriding these functions because copying wxStrings is already a very efficient operation (data is not actually copied because wx↩ Strings are reference counted).

Library: wxCore

Category: Clipboard and Drag & Drop

See also

Drag and Drop Overview, wxDataObject, wxDataObjectSimple, wxFileDataObject, wxBitmapDataObject

Public Member Functions

- wxTextDataObject (const wxString &text=wxEmptyString)

  Constructor, may be used to initialise the text (otherwise SetText() should be used later).
- virtual wxString GetText () const

  Returns the text associated with the data object.
- virtual size_t GetTextLength () const

  Returns the data size.
- virtual size_t GetFormatCount (wxDataObject::Direction dir=wxDataObject::Get) const

  Returns 2 under wxMac and wxGTK, where text data coming from the clipboard may be provided as ANSI (wxDF_TEXT) or as Unicode text (wxDF_UNICODETEXT, but only when wxUSE_UNICODE==1).
- const wxDataFormat & GetFormat () const

  Returns the preferred format supported by this object.
- virtual void GetAllFormats (wxDataFormat *formats, wxDataObject::Direction dir=wxDataObject::Get) const

  Returns all the formats supported by wxTextDataObject.
- virtual void SetText (const wxString &strText)

  Sets the text associated with the data object.

Additional Inherited Members

21.774.2 Constructor & Destructor Documentation

wxTextDataObject::wxTextDataObject (const wxString & *text* = wxEmptyString)

Constructor, may be used to initialise the text (otherwise SetText() should be used later).

21.774.3 Member Function Documentation

virtual void wxTextDataObject::GetAllFormats (wxDataFormat * *formats*, wxDataObject::Direction *dir* = wxDataObject::Get) const `[virtual]`

Returns all the formats supported by wxTextDataObject.

Under wxMac and wxGTK they are `wxDF_TEXT` and `wxDF_UNICODETEXT`, under other ports returns only one of the two, depending on the build mode.

Implements wxDataObject.

const wxDataFormat& wxTextDataObject::GetFormat ( ) const

Returns the preferred format supported by this object.

This is `wxDF_TEXT` or `wxDF_UNICODETEXT` depending on the platform and from the build mode (i.e. from `wxUSE_UNICODE`).

virtual size_t wxTextDataObject::GetFormatCount (wxDataObject::Direction *dir* = wxDataObject::Get) const `[virtual]`

Returns 2 under wxMac and wxGTK, where text data coming from the clipboard may be provided as ANSI (`wxDF_TEXT`) or as Unicode text (`wxDF_UNICODETEXT`, but only when `wxUSE_UNICODE==1`).

Returns 1 under other platforms (e.g. wxMSW) or when building in ANSI mode (`wxUSE_UNICODE==0`).

Implements wxDataObject.

virtual wxString wxTextDataObject::GetText ( ) const `[virtual]`

Returns the text associated with the data object.

You may wish to override this method when offering data on-demand, but this is not required by wxWidgets' internals. Use this method to get data in text form from the wxClipboard.

virtual size_t wxTextDataObject::GetTextLength ( ) const `[virtual]`

Returns the data size.

By default, returns the size of the text data set in the constructor or using SetText(). This can be overridden to provide text size data on-demand. It is recommended to return the text length plus 1 for a trailing zero, but this is not strictly required.

virtual void wxTextDataObject::SetText (const wxString & *strText*) `[virtual]`

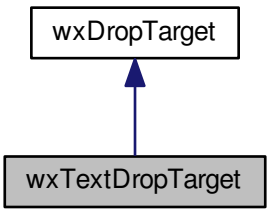
Sets the text associated with the data object.

This method is called when the data object receives the data and, by default, copies the text into the member variable. If you want to process the text on the fly you may wish to override this function.

21.775 wxTextDropTarget Class Reference

`#include <wx/dnd.h>`

Inheritance diagram for wxTextDropTarget:



21.775.1 Detailed Description

A predefined drop target for dealing with text data.

Library: wxCore

Category: Clipboard and Drag & Drop

See also

Drag and Drop Overview, wxDropSource, wxDropTarget, wxFileDropTarget

Public Member Functions

- wxTextDropTarget ()

  Constructor.
- virtual bool OnDrop (wxCoord x, wxCoord y)

  See wxDropTarget::OnDrop().
- virtual bool OnDropText (wxCoord x, wxCoord y, const wxString &data)=0

  Override this function to receive dropped text.

21.775.2 Constructor & Destructor Documentation

wxTextDropTarget::wxTextDropTarget ( )

Constructor.

21.775.3 Member Function Documentation

virtual bool wxTextDropTarget::OnDrop (wxCoord *x*, wxCoord *y*) `[virtual]`

See wxDropTarget::OnDrop().

This function is implemented appropriately for text, and calls OnDropText().

Reimplemented from wxDropTarget.

virtual bool wxTextDropTarget::OnDropText (wxCoord *x*, wxCoord *y*, const wxString & *data*) `[pure virtual]`

Override this function to receive dropped text.

Parameters

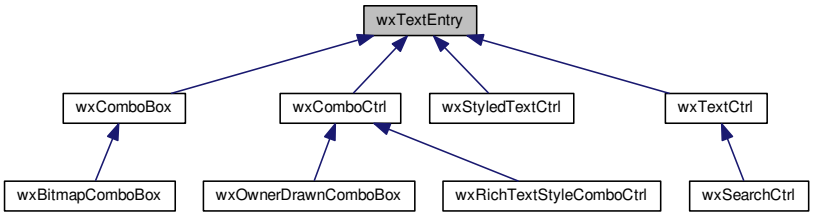
x	The x coordinate of the mouse.
y	The y coordinate of the mouse.
data	The data being dropped: a wxString.

Return true to accept the data, or false to veto the operation.

21.776 wxTextEntry Class Reference

`#include <wx/textentry.h>`

Inheritance diagram for wxTextEntry:



21.776.1 Detailed Description

Common base class for single line text entry fields.

This class is not a control itself, as it doesn't derive from wxWindow. Instead it is used as a base class by other controls, notably wxTextCtrl and wxComboBox and gathers the methods common to both of them.

Library: wxCore

Category: Controls

See also

wxTextCtrl, wxComboBox

Since

2.9.0

Public Member Functions

- virtual void AppendText (const wxString &text)

  Appends the text to the end of the text control.
- bool AutoComplete (const wxArrayString &choices)

  Call this function to enable auto-completion of the text typed in a single-line text control using the given choices.
- bool AutoComplete (wxTextCompleter *completer)

  Enable auto-completion using the provided completer object.
- bool AutoCompleteFileNames ()

  Call this function to enable auto-completion of the text typed in a single-line text control using all valid file system paths.
- bool AutoCompleteDirectories ()

  Call this function to enable auto-completion of the text using the file system directories.
- virtual bool CanCopy () const

  Returns true if the selection can be copied to the clipboard.
- virtual bool CanCut () const

  Returns true if the selection can be cut to the clipboard.
- virtual bool CanPaste () const

  Returns true if the contents of the clipboard can be pasted into the text control.
- virtual bool CanRedo () const

  Returns true if there is a redo facility available and the last operation can be redone.
- virtual bool CanUndo () const

  Returns true if there is an undo facility available and the last operation can be undone.
- virtual void ChangeValue (const wxString &value)

  Sets the new text control value.
- virtual void Clear ()

  Clears the text in the control.
- virtual void Copy ()

  Copies the selected text to the clipboard.
- virtual void Cut ()

  Copies the selected text to the clipboard and removes it from the control.
- virtual long GetInsertionPoint () const

Returns the insertion point, or cursor, position.

- virtual wxTextPos GetLastPosition () const

  Returns the zero based index of the last position in the text control, which is equal to the number of characters in the control.

- virtual wxString GetRange (long from, long to) const

  Returns the string containing the text starting in the positions from and up to to in the control.

- virtual void GetSelection (long *from, long *to) const

  Gets the current selection span.

- virtual wxString GetStringSelection () const

  Gets the text currently selected in the control.

- virtual wxString GetValue () const

  Gets the contents of the control.

- virtual bool IsEditable () const

  Returns true if the controls contents may be edited by user (note that it always can be changed by the program).

- virtual bool IsEmpty () const

  Returns true if the control is currently empty.

- virtual void Paste ()

  Pastes text from the clipboard to the text item.

- virtual void Redo ()

  If there is a redo facility and the last operation can be redone, redoes the last operation.

- virtual void Remove (long from, long to)

  Removes the text starting at the first given position up to (but not including) the character at the last position.

- virtual void Replace (long from, long to, const wxString &value)

  Replaces the text starting at the first position up to (but not including) the character at the last position with the given text.

- virtual void SetEditable (bool editable)

  *Makes the text item editable or read-only, overriding the **wxTE_READONLY** flag.*

- virtual void SetInsertionPoint (long pos)

  Sets the insertion point at the given position.

- virtual void SetInsertionPointEnd ()

  Sets the insertion point at the end of the text control.

- virtual void SetMaxLength (unsigned long len)

  This function sets the maximum number of characters the user can enter into the control.

- virtual void SetSelection (long from, long to)

  Selects the text starting at the first position up to (but not including) the character at the last position.

- virtual void SelectAll ()

  Selects all text in the control.

- virtual void SelectNone ()

  Deselects selected text in the control.

- virtual bool SetHint (const wxString &hint)

  Sets a hint shown in an empty unfocused text control.

- virtual wxString GetHint () const

  Returns the current hint string.

- wxPoint GetMargins () const

  Returns the margins used by the control.

- virtual void SetValue (const wxString &value)

  Sets the new text control value.

- virtual void Undo ()

  If there is an undo facility and the last operation can be undone, undoes the last operation.

- virtual void WriteText (const wxString &text)

  Writes the text into the text control at the current insertion position.

- bool SetMargins (const wxPoint &pt)

  Attempts to set the control margins.
- bool SetMargins (wxCoord left, wxCoord top=-1)

  Attempts to set the control margins.

21.776.2 Member Function Documentation

virtual void wxTextEntry::AppendText (const wxString & *text*) `[virtual]`

Appends the text to the end of the text control.

Parameters

text	Text to write to the text control.

Remarks

After the text is appended, the insertion point will be at the end of the text control. If this behaviour is not desired, the programmer should use GetInsertionPoint() and SetInsertionPoint().

See also

WriteText()

Reimplemented in wxStyledTextCtrl.

bool wxTextEntry::AutoComplete (const wxArrayString & *choices*)

Call this function to enable auto-completion of the text typed in a single-line text control using the given *choices*.

Notice that currently this function is only implemented in wxGTK2, wxMSW and wxOSX/Cocoa (for wxTextCtrl only, but not for wxComboBox) ports and does nothing under the other platforms.

Since

2.9.0

Returns

true if the auto-completion was enabled or false if the operation failed, typically because auto-completion is not supported by the current platform.

See also

AutoCompleteFileNames()

bool wxTextEntry::AutoComplete (wxTextCompleter * *completer*)

Enable auto-completion using the provided completer object.

This method should be used instead of AutoComplete() overload taking the array of possible completions if the total number of strings is too big as it allows to return the completions dynamically, depending on the text already entered by user and so is more efficient.

The specified *completer* object will be used to retrieve the list of possible completions for the already entered text and will be deleted by wxTextEntry itself when it's not needed any longer.

Notice that you need to include wx/textcompleter.h in order to define your class inheriting from wxTextCompleter.

Currently this method is only implemented in wxMSW and wxOSX/Cocoa (for wxTextCtrl only, but not for wxComboBox).

Since

2.9.2

Parameters

completer	The object to be used for generating completions if non-NULL. If it is NULL, auto-completion is disabled. The wxTextEntry object takes ownership of this pointer and will delete it in any case (i.e. even if this method returns false).

Returns

true if the auto-completion was enabled or false if the operation failed, typically because auto-completion is not supported by the current platform.

See also

wxTextCompleter

bool wxTextEntry::AutoCompleteDirectories ( )

Call this function to enable auto-completion of the text using the file system directories.

Unlike AutoCompleteFileNames() which completes both file names and directories, this function only completes the directory names.

Notice that currently this function is only implemented in wxMSW port and does nothing under the other platforms.

Since

2.9.3

Returns

true if the auto-completion was enabled or false if the operation failed, typically because auto-completion is not supported by the current platform.

See also

AutoComplete()

bool wxTextEntry::AutoCompleteFileNames ( )

Call this function to enable auto-completion of the text typed in a single-line text control using all valid file system paths.

Notice that currently this function is only implemented in wxMSW port and does nothing under the other platforms.

Since

2.9.0

Returns

true if the auto-completion was enabled or false if the operation failed, typically because auto-completion is not supported by the current platform.

See also

AutoComplete()

virtual bool wxTextEntry::CanCopy ( ) const `[virtual]`

Returns true if the selection can be copied to the clipboard.

virtual bool wxTextEntry::CanCut ( ) const `[virtual]`

Returns true if the selection can be cut to the clipboard.

virtual bool wxTextEntry::CanPaste ( ) const `[virtual]`

Returns true if the contents of the clipboard can be pasted into the text control.

On some platforms (Motif, GTK) this is an approximation and returns true if the control is editable, false otherwise.

Reimplemented in wxStyledTextCtrl.

virtual bool wxTextEntry::CanRedo ( ) const `[virtual]`

Returns true if there is a redo facility available and the last operation can be redone.

Reimplemented in wxStyledTextCtrl.

virtual bool wxTextEntry::CanUndo ( ) const `[virtual]`

Returns true if there is an undo facility available and the last operation can be undone.

Reimplemented in wxStyledTextCtrl.

virtual void wxTextEntry::ChangeValue (const wxString & *value*) `[virtual]`

Sets the new text control value.

It also marks the control as not-modified which means that IsModified() would return false immediately after the call to ChangeValue().

The insertion point is set to the start of the control (i.e. position 0) by this function.

This functions does not generate the `wxEVT_TEXT` event but otherwise is identical to SetValue().

See User Generated Events vs Programmatically Generated Events for more information.

Since

2.7.1

Parameters

value	The new value to set. It may contain newline characters if the text control is multi-line.

virtual void wxTextEntry::Clear ( ) [virtual]

Clears the text in the control.

Note that this function will generate a `wxEVT_TEXT` event, i.e. its effect is identical to calling `SetValue("")`.

Reimplemented in wxStyledTextCtrl.

virtual void wxTextEntry::Copy ( ) [virtual]

Copies the selected text to the clipboard.

Reimplemented in wxStyledTextCtrl, and wxComboCtrl.

virtual void wxTextEntry::Cut ( ) [virtual]

Copies the selected text to the clipboard and removes it from the control.

Reimplemented in wxStyledTextCtrl, and wxComboCtrl.

virtual wxString wxTextEntry::GetHint ( ) const [virtual]

Returns the current hint string.

See SetHint() for more information about hints.

Since

2.9.0

Reimplemented in wxComboCtrl.

virtual long wxTextEntry::GetInsertionPoint ( ) const [virtual]

Returns the insertion point, or cursor, position.

This is defined as the zero based index of the character position to the right of the insertion point. For example, if the insertion point is at the end of the single-line text control, it is equal to GetLastPosition().

Notice that insertion position is, in general, different from the index of the character the cursor position at in the string returned by GetValue(). While this is always the case for the single line controls, multi-line controls can use two characters `"\\r\\n"` as line separator (this is notably the case under MSW) meaning that indices in the control and its string value are offset by 1 for every line.

Hence to correctly get the character at the current cursor position, taking into account that there can be none if the cursor is at the end of the string, you could do the following:

```
wxString GetCurrentChar(wxTextCtrl *tc)
{
    long pos = tc->GetInsertionPoint();
    if ( pos == tc->GetLastPosition() )
        return wxString();

    return tc->GetRange(pos, pos + 1);
}
```

Reimplemented in wxStyledTextCtrl, wxComboCtrl, and wxComboBox.

virtual **wxTextPos** **wxTextEntry::GetLastPosition** ( ) const [virtual]

Returns the zero based index of the last position in the text control, which is equal to the number of characters in the control.

Reimplemented in wxStyledTextCtrl, and wxComboCtrl.

wxPoint **wxTextEntry::GetMargins** ( ) const

Returns the margins used by the control.

The `x` field of the returned point is the horizontal margin and the `y` field is the vertical one.

Remarks

If given margin cannot be accurately determined, its value will be set to -1. On some platforms you cannot obtain valid margin values until you have called SetMargins().

See also

SetMargins()

Since

2.9.1

virtual **wxString** **wxTextEntry::GetRange** (long *from*, long *to*) const [virtual]

Returns the string containing the text starting in the positions *from* and up to *to* in the control.

The positions must have been returned by another wxTextCtrl method. Please note that the positions in a multiline wxTextCtrl do **not** correspond to the indices in the string returned by GetValue() because of the different new line representations (`CR` or `CR` LF) and so this method should be used to obtain the correct results instead of extracting parts of the entire value. It may also be more efficient, especially if the control contains a lot of data.

virtual void **wxTextEntry::GetSelection** (long * *from*, long * *to*) const [virtual]

Gets the current selection span.

If the returned values are equal, there was no selection. Please note that the indices returned may be used with the other wxTextCtrl methods but don't necessarily represent the correct indices into the string returned by GetValue() for multiline controls under Windows (at least,) you should use GetStringSelection() to get the selected text.

Parameters

from	The returned first position.
to	The returned last position.

wxPerl Note: In wxPerl this method takes no parameters and returns a 2-element list (from, to).

Reimplemented in wxStyledTextCtrl, and wxComboBox.

virtual **wxString** **wxTextEntry::GetStringSelection** ( ) const [virtual]

Gets the text currently selected in the control.

If there is no selection, the returned string is empty.

Reimplemented in wxComboBox.

virtual wxString wxTextEntry::GetValue ( ) const [virtual]

Gets the contents of the control.

Notice that for a multiline text control, the lines will be separated by (Unix-style) \n characters, even under Windows where they are separated by a \r\n sequence in the native control.

Reimplemented in wxComboCtrl.

virtual bool wxTextEntry::IsEditable ( ) const [virtual]

Returns true if the controls contents may be edited by user (note that it always can be changed by the program).

In other words, this functions returns true if the control hasn't been put in read-only mode by a previous call to SetEditable().

Reimplemented in wxStyledTextCtrl.

virtual bool wxTextEntry::IsEmpty ( ) const [virtual]

Returns true if the control is currently empty.

This is the same as GetValue().empty() but can be much more efficient for the multiline controls containing big amounts of text.

Since

2.7.1

Reimplemented in wxComboBox, and wxOwnerDrawnComboBox.

virtual void wxTextEntry::Paste ( ) [virtual]

Pastes text from the clipboard to the text item.

Reimplemented in wxStyledTextCtrl, and wxComboCtrl.

virtual void wxTextEntry::Redo ( ) [virtual]

If there is a redo facility and the last operation can be redone, redoes the last operation.

Does nothing if there is no redo facility.

Reimplemented in wxStyledTextCtrl.

virtual void wxTextEntry::Remove (long *from*, long *to*) [virtual]

Removes the text starting at the first given position up to (but not including) the character at the last position.

This function puts the current insertion point position at *to* as a side effect.

Parameters

from	The first position.
to	The last position.

Reimplemented in wxStyledTextCtrl, and wxComboCtrl.

virtual void wxTextEntry::Replace (long *from,* long *to,* const wxString & *value*) `[virtual]`

Replaces the text starting at the first position up to (but not including) the character at the last position with the given text.

This function puts the current insertion point position at *to* as a side effect.

Parameters

from	The first position.
to	The last position.
value	The value to replace the existing text with.

Reimplemented in wxStyledTextCtrl, and wxComboCtrl.

virtual void wxTextEntry::SelectAll ( ) `[virtual]`

Selects all text in the control.

See also

SetSelection()

Reimplemented in wxStyledTextCtrl.

virtual void wxTextEntry::SelectNone ( ) `[virtual]`

Deselects selected text in the control.

Since

2.9.5

Reimplemented in wxStyledTextCtrl.

virtual void wxTextEntry::SetEditable (bool *editable*) `[virtual]`

Makes the text item editable or read-only, overriding the **wxTE_READONLY** flag.

Parameters

editable	If true, the control is editable. If false, the control is read-only.

See also

IsEditable()

Reimplemented in wxStyledTextCtrl.

virtual bool wxTextEntry::SetHint (const wxString & *hint*) `[virtual]`

Sets a hint shown in an empty unfocused text control.

The hints are usually used to indicate to the user what is supposed to be entered into the given entry field, e.g. a common use of them is to show an explanation of what can be entered in a wxSearchCtrl.

The hint is shown (usually greyed out) for an empty control until it gets focus and is shown again if the control loses it and remains empty. It won't be shown once the control has a non-empty value, although it will be shown again if the control contents is cleared. Because of this, it generally only makes sense to use hints with the controls which are initially empty.

Notice that hints are known as *cue banners* under MSW or *placeholder strings* under OS X.

Remarks

Currently implemented natively on Windows (Vista and later only), OS X and GTK+ (3.2 and later).

For the platforms without native hints support, the implementation has several known limitations. Notably, the hint display will not be properly updated if you change wxTextEntry contents programmatically when the hint is displayed using methods other than SetValue() or ChangeValue() or others which use them internally (e.g. Clear()). In other words, currently you should avoid calling methods such as WriteText() or Replace() when using hints and the text control is empty. If you bind to the control's focus and wxEVT_TEXT events, you must call wxEvent::Skip() on them so that the generic implementation works correctly.

Remarks

Hints can be used for single line text controls under all platforms, but only MSW and GTK+ 2 support them for multi-line text controls, they are ignored for them under the other platforms.

Since

2.9.0

Reimplemented in wxComboCtrl.

virtual void wxTextEntry::SetInsertionPoint (long *pos*) [virtual]

Sets the insertion point at the given position.

Parameters

pos	Position to set, in the range from 0 to GetLastPosition() inclusive.

Reimplemented in wxStyledTextCtrl, and wxComboCtrl.

virtual void wxTextEntry::SetInsertionPointEnd ( ) [virtual]

Sets the insertion point at the end of the text control.

This is equivalent to calling wxTextCtrl::SetInsertionPoint() with wxTextCtrl::GetLastPosition() argument.

Reimplemented in wxComboCtrl.

bool wxTextEntry::SetMargins (const wxPoint & *pt*)

Attempts to set the control margins.

When margins are given as wxPoint, x indicates the left and y the top margin. Use -1 to indicate that an existing value should be used.

Returns

true if setting of all requested margins was successful.

Since

2.9.1

bool wxTextEntry::SetMargins (wxCoord *left,* wxCoord *top* = -1)

Attempts to set the control margins.

When margins are given as wxPoint, x indicates the left and y the top margin. Use -1 to indicate that an existing value should be used.

Returns

true if setting of all requested margins was successful.

Since

2.9.1

virtual void wxTextEntry::SetMaxLength (unsigned long *len*) [virtual]

This function sets the maximum number of characters the user can enter into the control.

In other words, it allows to limit the text value length to *len* not counting the terminating `NUL` character.

If *len* is 0, the previously set max length limit, if any, is discarded and the user may enter as much text as the underlying native text control widget supports (typically at least 32Kb). If the user tries to enter more characters into the text control when it already is filled up to the maximal length, a `wxEVT_TEXT_MAXLEN` event is sent to notify the program about it (giving it the possibility to show an explanatory message, for example) and the extra input is discarded.

Note that in wxGTK this function may only be used with single line text controls.

virtual void wxTextEntry::SetSelection (long *from,* long *to*) [virtual]

Selects the text starting at the first position up to (but not including) the character at the last position.

If both parameters are equal to -1 all text in the control is selected.

Notice that the insertion point will be moved to *from* by this function.

Parameters

from	The first position.
to	The last position.

See also

SelectAll()

Reimplemented in wxStyledTextCtrl, wxComboCtrl, and wxComboBox.

virtual void wxTextEntry::SetValue (const wxString & *value*) [virtual]

Sets the new text control value.

It also marks the control as not-modified which means that IsModified() would return false immediately after the call to SetValue().

The insertion point is set to the start of the control (i.e. position 0) by this function.

Note that, unlike most other functions changing the controls values, this function generates a `wxEVT_TEXT` event. To avoid this you can use ChangeValue() instead.

Parameters

value	The new value to set. It may contain newline characters if the text control is multi-line.

Reimplemented in wxComboCtrl, and wxComboBox.

virtual void wxTextEntry::Undo ( ) [virtual]

If there is an undo facility and the last operation can be undone, undoes the last operation.

Does nothing if there is no undo facility.

Reimplemented in wxStyledTextCtrl, and wxComboCtrl.

virtual void wxTextEntry::WriteText (const wxString & *text*) [virtual]

Writes the text into the text control at the current insertion position.

Parameters

text	Text to write to the text control.

Remarks

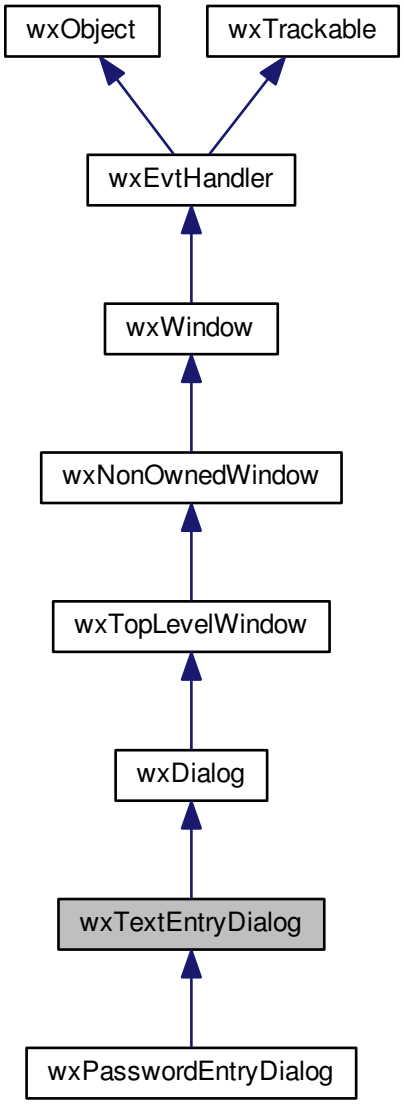
Newlines in the text string are the only control characters allowed, and they will cause appropriate line breaks. See operator<<() and AppendText() for more convenient ways of writing to the window. After the write operation, the insertion point will be at the end of the inserted text, so subsequent write operations will be appended. To append text after the user may have interacted with the control, call wxTextCtrl::SetInsertionPointEnd() before writing.

Reimplemented in wxStyledTextCtrl.

21.777 wxTextEntryDialog Class Reference

```
#include <wx/textdlg.h>
```

Inheritance diagram for wxTextEntryDialog:



21.777.1 Detailed Description

This class represents a dialog that requests a one-line text string from the user.

It is implemented as a generic wxWidgets dialog.

Library: wxCore

Category: Common Dialogs

See also

wxTextEntryDialog Overview

Public Member Functions

- wxTextEntryDialog ()

  Default constructor.
- wxTextEntryDialog (wxWindow *parent, const wxString &message, const wxString &caption=wxGetTextFromUserPromptStr, const wxString &value=wxEmptyString, long style=wxTextEntryDialogStyle, const wxPoint &pos=wxDefaultPosition)

  Constructor.
- bool Create (wxWindow *parent, const wxString &message, const wxString &caption=wxGetTextFromUserPromptStr, const wxString &value=wxEmptyString, long style=wxTextEntryDialogStyle, const wxPoint &pos=wxDefaultPosition)
- virtual ~wxTextEntryDialog ()

  Destructor.
- wxString GetValue () const

  Returns the text that the user has entered if the user has pressed OK, or the original value if the user has pressed Cancel.
- void SetMaxLength (unsigned long len)

  This function sets the maximum number of characters the user can enter into this dialog.
- void SetValue (const wxString &value)

  Sets the default text value.
- int ShowModal ()

  Shows the dialog, returning wxID_OK if the user pressed OK, and wxID_CANCEL otherwise.

- void SetTextValidator (const wxTextValidator &validator)

  Associate a validator with the text control used by the dialog.
- void SetTextValidator (wxTextValidatorStyle style=wxFILTER_NONE)

  Associate a validator with the text control used by the dialog.

Additional Inherited Members

21.777.2 Constructor & Destructor Documentation

wxTextEntryDialog::wxTextEntryDialog ( )

Default constructor.

Call Create() to really create the dialog later.

Since

2.9.5

wxTextEntryDialog::wxTextEntryDialog (wxWindow * *parent*, const wxString & *message*, const wxString & *caption* = wxGetTextFromUserPromptStr, const wxString & *value* = wxEmptyString, long *style* = wxTextEntryDialogStyle, const wxPoint & *pos* = wxDefaultPosition)

Constructor.

Use ShowModal() to show the dialog.

See Create() method for parameter description.

virtual wxTextEntryDialog::~wxTextEntryDialog ( ) [virtual]

Destructor.

21.777.3 Member Function Documentation

bool wxTextEntryDialog::Create (wxWindow * *parent*, const wxString & *message*, const wxString & *caption* = wxGetTextFromUserPromptStr, const wxString & *value* = wxEmptyString, long *style* = wxTextEntryDialogStyle, const wxPoint & *pos* = wxDefaultPosition)

Parameters

parent	Parent window.
message	Message to show on the dialog.
caption	The caption of the dialog.
value	The default value, which may be the empty string.
style	A dialog style, specifying the buttons (wxOK, wxCANCEL) and an optional wxCENTRE style. Additionally, wxTextCtrl styles (such as `wxTE_PASSWORD` or `wxTE_MULTILINE`) may be specified here.
pos	Dialog position.

Since

2.9.5

wxString wxTextEntryDialog::GetValue ( ) const

Returns the text that the user has entered if the user has pressed OK, or the original value if the user has pressed Cancel.

void wxTextEntryDialog::SetMaxLength (unsigned long *len*)

This function sets the maximum number of characters the user can enter into this dialog.

See also

wxTextEntry::SetMaxLength()

Since

2.9.5

void wxTextEntryDialog::SetTextValidator (const wxTextValidator & *validator*)

Associate a validator with the text control used by the dialog.

These methods can be used to limit the user entry to only some characters, e.g.

```
wxTextEntryDialog dlg(this, ...);
dlg.SetTextValidator(wxFILTER_ALPHA);
if ( dlg.ShowModal() == wxID_OK )
{
    // We can be certain that this string contains letters only.
    wxString value = dlg.GetValue();
}
```

The first overload uses the provided *validator* which can be of a custom class derived from wxTextValidator while the second one creates a wxTextValidator with the specified *style*.

void wxTextEntryDialog::SetTextValidator (wxTextValidatorStyle *style* = wxFILTER_NONE)

Associate a validator with the text control used by the dialog.

These methods can be used to limit the user entry to only some characters, e.g.

```
wxTextEntryDialog dlg(this, ...);
dlg.SetTextValidator(wxFILTER_ALPHA);
if ( dlg.ShowModal() == wxID_OK )
{
    // We can be certain that this string contains letters only.
    wxString value = dlg.GetValue();
}
```

The first overload uses the provided *validator* which can be of a custom class derived from wxTextValidator while the second one creates a wxTextValidator with the specified *style*.

void wxTextEntryDialog::SetValue (const wxString & *value*)

Sets the default text value.

int wxTextEntryDialog::ShowModal ( ) [virtual]

Shows the dialog, returning wxID_OK if the user pressed OK, and wxID_CANCEL otherwise.

Call GetValue() to retrieve the values of the string entered by the user after showing the dialog.

Reimplemented from wxDialog.

21.778 wxTextFile Class Reference

`#include <wx/textfile.h>`

21.778.1 Detailed Description

The wxTextFile is a simple class which allows to work with text files on line by line basis.

It also understands the differences in line termination characters under different platforms and will not do anything bad to files with "non native" line termination sequences - in fact, it can be also used to modify the text files and change the line termination characters from one type (say DOS) to another (say Unix).

One word of warning: the class is not at all optimized for big files and thus it will load the file entirely into memory when opened. Of course, you should not work in this way with large files (as an estimation, anything over 1 Megabyte is surely too big for this class). On the other hand, it is not a serious limitation for small files like configuration files or program sources which are well handled by wxTextFile.

The typical things you may do with wxTextFile in order are:

- Create and open it: this is done with either wxTextFile::Create or wxTextFile::Open function which opens the file (name may be specified either as the argument to these functions or in the constructor), reads its contents in memory (in the case of wxTextFile::Open()) and closes it.
- Work with the lines in the file: this may be done either with "direct access" functions like wxTextFile::GetLineCount and wxTextFile::GetLine (*operator*[] does exactly the same but looks more like array addressing) or with "sequential access" functions which include wxTextFile::GetFirstLine, wxTextFile::GetNextLine and also wxTextFile::GetLastLine, wxTextFile::GetPrevLine. For the sequential access functions the current line number is maintained: it is returned by wxTextFile::GetCurrentLine and may be changed with wxTextFile::GoToLine.
- Add/remove lines to the file: wxTextFile::AddLine and wxTextFile::InsertLine add new lines while wxTextFile::RemoveLine deletes the existing ones. wxTextFile::Clear resets the file to empty.

- Save your changes: notice that the changes you make to the file will **not** be saved automatically; calling wxTextFile::Close or doing nothing discards them! To save the changes you must explicitly call wxTextFile::Write - here, you may also change the line termination type if you wish.

Library: wxBase

Category: File Handling

See also

wxFile

Public Member Functions

- wxTextFile ()

  Default constructor, use Create() or Open() with a file name parameter to initialize the object.
- wxTextFile (const wxString &strFile)

  Constructor does not load the file into memory, use Open() to do it.
- virtual ~wxTextFile ()

  Destructor does nothing.
- void AddLine (const wxString &str, wxTextFileType type=typeDefault)

  Adds a line to the end of file.
- void Clear ()

  Delete all lines from the file, set current line number to 0.
- bool Close ()

  *Closes the file and frees memory, **"losing all changes"**.*
- bool Create ()

  Creates the file with the name which was given in the wxTextFile(const wxString&) constructor.
- bool Create (const wxString &strFile)

  Creates the file with the given name.
- bool Eof () const

  Returns true if the current line is the last one.
- bool Exists () const

  Return true if file exists - the name of the file should have been specified in the constructor before calling Exists().
- size_t GetCurrentLine () const

  Returns the current line: it has meaning only when you're using GetFirstLine()/GetNextLine() functions, it doesn't get updated when you're using "direct access" functions like GetLine().
- wxString & GetFirstLine ()

  This method together with GetNextLine() allows more "iterator-like" traversal of the list of lines, i.e.
- wxString & GetLastLine ()

  Gets the last line of the file.
- size_t GetLineCount () const

  Get the number of lines in the file.
- wxTextFileType GetLineType (size_t n) const

  Get the type of the line (see also wxTextFile::GetEOL).
- const wxString & GetName () const

  Get the name of the file.
- wxString & GetNextLine ()

  Gets the next line (see GetFirstLine() for the example).
- wxString & GetPrevLine ()

Gets the previous line in the file.

- void GoToLine (size_t n)

  Changes the value returned by GetCurrentLine() and used by GetFirstLine() and GetNextLine().
- wxTextFileType GuessType () const

  Guess the type of file (which is supposed to be opened).
- void InsertLine (const wxString &str, size_t n, wxTextFileType type=typeDefault)

  Insert a line before the line number n.
- bool IsOpened () const

  Returns true if the file is currently opened.
- bool Open (const wxMBConv &conv=wxConvAuto())

  Opens the file with the name which was given in the wxTextFile(const wxString&) constructor and also loads file in memory on success.
- bool Open (const wxString &strFile, const wxMBConv &conv=wxConvAuto())

  Opens the file with the given name and also loads file in memory on success.
- void RemoveLine (size_t n)

  Delete line number n from the file.
- bool Write (wxTextFileType typeNew=wxTextFileType_None, const wxMBConv &conv=wxConvAuto())

  Change the file on disk.
- wxString & operator[] (size_t n) const

  The same as GetLine().

- wxString & GetLine (size_t n)

  Retrieves the line number n from the file.
- const wxString & GetLine (size_t n) const

  Retrieves the line number n from the file.

Static Public Member Functions

- static const wxChar * GetEOL (wxTextFileType type=typeDefault)

  Get the line termination string corresponding to given constant.

Static Public Attributes

- static const wxTextFileType typeDefault

  Default type for current platform determined at compile time.

21.778.2 Constructor & Destructor Documentation

wxTextFile::wxTextFile ( )

Default constructor, use Create() or Open() with a file name parameter to initialize the object.

wxTextFile::wxTextFile (const wxString & *strFile*)

Constructor does not load the file into memory, use Open() to do it.

virtual wxTextFile::~wxTextFile ( ) `[virtual]`

Destructor does nothing.

21.778.3 Member Function Documentation

void wxTextFile::AddLine (const wxString & *str,* wxTextFileType *type* = typeDefault)

Adds a line to the end of file.

void wxTextFile::Clear ( )

Delete all lines from the file, set current line number to 0.

bool wxTextFile::Close ( )

Closes the file and frees memory, **"losing all changes"**.

Use Write() if you want to save them.

bool wxTextFile::Create ( )

Creates the file with the name which was given in the wxTextFile(const wxString&) constructor.

The array of file lines is initially empty.

It will fail if the file already exists, Open() should be used in this case.

bool wxTextFile::Create (const wxString & *strFile*)

Creates the file with the given name.

The array of file lines is initially empty.

It will fail if the file already exists, Open() should be used in this case.

bool wxTextFile::Eof ( ) const

Returns true if the current line is the last one.

bool wxTextFile::Exists ( ) const

Return true if file exists - the name of the file should have been specified in the constructor before calling Exists().

size_t wxTextFile::GetCurrentLine ( ) const

Returns the current line: it has meaning only when you're using GetFirstLine()/GetNextLine() functions, it doesn't get updated when you're using "direct access" functions like GetLine().

GetFirstLine() and GetLastLine() also change the value of the current line, as well as GoToLine().

static const wxChar* wxTextFile::GetEOL (wxTextFileType *type* = typeDefault) [static]

Get the line termination string corresponding to given constant.

typeDefault is the value defined during the compilation and corresponds to the native format of the platform, i.e. it will be `wxTextFileType_Dos` under Windows and `wxTextFileType_Unix` under Unix (including Mac OS X, the value `wxTextFileType_Mac` was only used for classic Mac OS versions).

wxString& wxTextFile::GetFirstLine ( )

This method together with GetNextLine() allows more "iterator-like" traversal of the list of lines, i.e.

you may write something like:

```
wxTextFile file;
...
for ( str = file.GetFirstLine(); !file.Eof(); str = file.
      GetNextLine() )
{
    // do something with the current line in str
}
// do something with the last line in str
```

wxString& wxTextFile::GetLastLine ( )

Gets the last line of the file.

Together with GetPrevLine() it allows to enumerate the lines in the file from the end to the beginning like this:

```
wxTextFile file;
...
for ( str = file.GetLastLine();
    file.GetCurrentLine() > 0;
    str = file.GetPrevLine() )
{
    // do something with the current line in str
}
// do something with the first line in str
```

wxString& wxTextFile::GetLine (size_t *n*)

Retrieves the line number *n* from the file.

The returned line may be modified when non-const method is used but you shouldn't add line terminator at the end – this will be done by wxTextFile itself.

const wxString& wxTextFile::GetLine (size_t *n*) const

Retrieves the line number *n* from the file.

The returned line may be modified when non-const method is used but you shouldn't add line terminator at the end – this will be done by wxTextFile itself.

size_t wxTextFile::GetLineCount ( ) const

Get the number of lines in the file.

wxTextFileType wxTextFile::GetLineType (size_t *n*) const

Get the type of the line (see also wxTextFile::GetEOL).

const wxString& wxTextFile::GetName ( ) const

Get the name of the file.

wxString& wxTextFile::GetNextLine ( )

Gets the next line (see GetFirstLine() for the example).

wxString& wxTextFile::GetPrevLine ( )

Gets the previous line in the file.

void wxTextFile::GoToLine (size_t *n*)

Changes the value returned by GetCurrentLine() and used by GetFirstLine() and GetNextLine().

wxTextFileType wxTextFile::GuessType ( ) const

Guess the type of file (which is supposed to be opened).

If sufficiently many lines of the file are in DOS/Unix/Mac format, the corresponding value will be returned. If the detection mechanism fails `wxTextFileType_None` is returned.

void wxTextFile::InsertLine (const wxString & *str,* size_t *n,* wxTextFileType *type* = typeDefault)

Insert a line before the line number *n*.

bool wxTextFile::IsOpened ( ) const

Returns true if the file is currently opened.

bool wxTextFile::Open (const wxMBConv & *conv* = wxConvAuto())

Opens the file with the name which was given in the wxTextFile(const wxString&) constructor and also loads file in memory on success.

It will fail if the file does not exist, Create() should be used in this case.

The *conv* argument is only meaningful in Unicode build of wxWidgets when it is used to convert the file to wide character representation.

bool wxTextFile::Open (const wxString & *strFile,* const wxMBConv & *conv* = wxConvAuto())

Opens the file with the given name and also loads file in memory on success.

It will fail if the file does not exist, Create() should be used in this case.

The *conv* argument is only meaningful in Unicode build of wxWidgets when it is used to convert the file to wide character representation.

wxString& wxTextFile::operator[] (size_t *n*) const

The same as GetLine().

void wxTextFile::RemoveLine (size_t *n*)

Delete line number *n* from the file.

bool wxTextFile::Write (wxTextFileType *typeNew* = wxTextFileType_None, const wxMBConv & *conv* = wxConvAuto())

Change the file on disk.

The *typeNew* parameter allows you to change the file format (default argument means "don't change type") and may be used to convert, for example, DOS files to Unix.

The *conv* argument is only meaningful in Unicode build of wxWidgets when it is used to convert all lines to multibyte representation before writing them to physical file.

Returns

true if operation succeeded, false if it failed.

21.778.4 Member Data Documentation

const wxTextFileType wxTextFile::typeDefault `[static]`

Default type for current platform determined at compile time.

21.779 wxTextInputStream Class Reference

`#include <wx/txtstrm.h>`

21.779.1 Detailed Description

This class provides functions that reads text data using an input stream, allowing you to read text, floats, and integers.

The wxTextInputStream correctly reads text files (or streams) in DOS, Macintosh and Unix formats and reports a single newline char as a line ending.

wxTextInputStream::operator>>() is overloaded and you can use this class like a standard C++ iostream. Note, however, that the arguments are the fixed size types wxUint32, wxInt32 etc and on a typical 32-bit computer, none of these match to the "long" type (wxInt32 is defined as int on 32-bit architectures) so that you cannot use long. To avoid problems (here and elsewhere), make use of wxInt32, wxUint32 and similar types.

If you're scanning through a file using wxTextInputStream, you should check for `EOF` **before** reading the next item (word / number), because otherwise the last item may get lost. You should however be prepared to receive an empty item (empty string / zero number) at the end of file, especially on Windows systems. This is unavoidable because most (but not all) files end with whitespace (i.e. usually a newline).

For example:

```
wxFileInputStream input( "mytext.txt" );
wxTextInputStream text( input );
wxUint8 i1;
float f2;
wxString line;

text >> i1;       // read a 8 bit integer.
text >> i1 >> f2; // read a 8 bit integer followed by float.
text >> line;     // read a text line
```

Library: wxBase

Category: Streams

See also

wxTextOutputStream

Public Member Functions

- wxTextInputStream (wxInputStream &stream, const wxString &sep=" \t", const wxMBConv &conv=wxConvAuto())

  Constructs a text stream associated to the given input stream.
- ~wxTextInputStream ()

  Destructor.
- const wxInputStream & GetInputStream () const

  Returns a pointer to the underlying input stream object.
- wxChar GetChar ()

  Reads a character, returns 0 if there are no more characters in the stream.
- wxUint16 Read16 (int base=10)

  Reads a unsigned 16 bit integer from the stream.
- wxInt16 Read16S (int base=10)

  Reads a signed 16 bit integer from the stream.
- wxUint32 Read32 (int base=10)

  Reads a 32 bit unsigned integer from the stream.
- wxInt32 Read32S (int base=10)

  Reads a 32 bit signed integer from the stream.
- wxUint64 Read64 (int base=10)

  Reads a 64 bit unsigned integer from the stream.
- wxInt64 Read64S (int base=10)

  Reads a 64 bit signed integer from the stream.
- wxUint8 Read8 (int base=10)

  Reads a single unsigned byte from the stream, given in base base.
- wxInt8 Read8S (int base=10)

  Reads a single signed byte from the stream.
- double ReadDouble ()

  Reads a double (IEEE encoded) from the stream.
- wxString ReadLine ()

  Reads a line from the input stream and returns it (without the end of line character).
- wxString ReadString ()
- wxString ReadWord ()

  Reads a word (a sequence of characters until the next separator) from the input stream.
- void SetStringSeparators (const wxString &sep)

  Sets the characters which are used to define the word boundaries in ReadWord().

21.779.2 Constructor & Destructor Documentation

wxTextInputStream::wxTextInputStream (wxInputStream & *stream*, const wxString & *sep* = " \t", const wxMBConv & *conv* = wxConvAuto())

Constructs a text stream associated to the given input stream.

Parameters

stream	The underlying input stream.
sep	The initial string separator characters.
conv	**In Unicode build only:** The encoding converter used to convert the bytes in the underlying input stream to characters.

wxTextInputStream::~wxTextInputStream ( )

Destructor.

21.779.3 Member Function Documentation

wxChar wxTextInputStream::GetChar ( )

Reads a character, returns 0 if there are no more characters in the stream.

const wxInputStream& wxTextInputStream::GetInputStream ( ) const

Returns a pointer to the underlying input stream object.

Since

2.9.2

wxUint16 wxTextInputStream::Read16 (int *base* = 10)

Reads a unsigned 16 bit integer from the stream.

See Read8() for the description of the *base* parameter.

wxInt16 wxTextInputStream::Read16S (int *base* = 10)

Reads a signed 16 bit integer from the stream.

See Read8() for the description of the *base* parameter.

wxUint32 wxTextInputStream::Read32 (int *base* = 10)

Reads a 32 bit unsigned integer from the stream.

See Read8() for the description of the *base* parameter.

wxInt32 wxTextInputStream::Read32S (int *base* = 10)

Reads a 32 bit signed integer from the stream.

See Read8() for the description of the *base* parameter.

wxUint64 wxTextInputStream::Read64 (int *base* = 10)

Reads a 64 bit unsigned integer from the stream.

See Read8() for the description of the *base* parameter.

Since

3.1.0

wxInt64 wxTextInputStream::Read64S (int *base* = `10`)

Reads a 64 bit signed integer from the stream.

See Read8() for the description of the *base* parameter.

Since

3.1.0

wxUint8 wxTextInputStream::Read8 (int *base* = `10`)

Reads a single unsigned byte from the stream, given in base *base*.

The value of *base* must be comprised between 2 and 36, inclusive, or be a special value 0 which means that the usual rules of C numbers are applied: if the number starts with `0x` it is considered to be in base 16, if it starts with 0 - in base 8 and in base 10 otherwise. Note that you may not want to specify the base 0 if you are parsing the numbers which may have leading zeroes as they can yield unexpected (to the user not familiar with C) results.

wxInt8 wxTextInputStream::Read8S (int *base* = `10`)

Reads a single signed byte from the stream.

See Read8() for the description of the *base* parameter.

double wxTextInputStream::ReadDouble ( )

Reads a double (IEEE encoded) from the stream.

wxString wxTextInputStream::ReadLine ( )

Reads a line from the input stream and returns it (without the end of line character).

wxString wxTextInputStream::ReadString ( )

Deprecated Use ReadLine() or ReadWord() instead.

Same as ReadLine().

wxString wxTextInputStream::ReadWord ( )

Reads a word (a sequence of characters until the next separator) from the input stream.

See also

SetStringSeparators()

void wxTextInputStream::SetStringSeparators (const wxString & *sep*)

Sets the characters which are used to define the word boundaries in ReadWord().

The default separators are the `space` and `TAB` characters.

21.780 wxTextOutputStream Class Reference

```
#include <wx/txtstrm.h>
```

21.780.1 Detailed Description

This class provides functions that write text data using an output stream, allowing you to write text, floats, and integers.

You can also simulate the C++ `std::cout` class:

```
wxFFileOutputStream output( stderr );
wxTextOutputStream cout( output );

cout << "This is a text line" << endl;
cout << 1234;
cout << 1.23456;
```

The wxTextOutputStream writes text files (or streams) on DOS, Macintosh and Unix in their native formats (concerning the line ending).

Library: wxBase

Category: Streams

See also

wxTextInputStream

Public Member Functions

- wxTextOutputStream (wxOutputStream &stream, wxEOL mode=wxEOL_NATIVE, const wxMBConv &conv=wxConvAuto())

  Constructs a text stream object associated to the given output stream.
- virtual ~wxTextOutputStream ()

  Destroys the wxTextOutputStream object.
- void Flush ()

  Flushes the stream.
- const wxOutputStream & GetOutputStream () const

  Returns a pointer to the underlying output stream object.
- wxEOL GetMode ()

  Returns the end-of-line mode.
- wxTextOutputStream & PutChar (wxChar c)

  Writes a character to the stream.
- void SetMode (wxEOL mode=wxEOL_NATIVE)

  Set the end-of-line mode.
- void Write64 (wxUint64 i64)

  Writes the 64 bit integer i64 to the stream.
- void Write32 (wxUint32 i32)

  Writes the 32 bit integer i32 to the stream.
- void Write16 (wxUint16 i16)

  Writes the 16 bit integer i16 to the stream.
- void Write8 (wxUint8 i8)

Writes the single byte i8 to the stream.

- virtual void WriteDouble (double f)

  Writes the double f to the stream using the IEEE format.

- virtual void WriteString (const wxString &string)

  Writes string as a line.

21.780.2 Constructor & Destructor Documentation

wxTextOutputStream::wxTextOutputStream (wxOutputStream & *stream*, wxEOL *mode* = wxEOL_NATIVE, const wxMBConv & *conv* = wxConvAuto ())

Constructs a text stream object associated to the given output stream.

Parameters

stream	The output stream.
mode	The end-of-line mode. One of wxEOL_NATIVE, wxEOL_DOS, wxEOL_MAC and wxEOL_UNIX.
conv	**In Unicode build only:** The object used to convert Unicode text into ASCII characters written to the output stream.

virtual wxTextOutputStream::~wxTextOutputStream ( ) [virtual]

Destroys the wxTextOutputStream object.

Also calls Flush().

21.780.3 Member Function Documentation

void wxTextOutputStream::Flush ( )

Flushes the stream.

This method should be called when using stateful encodings (currently the only example of such encoding in wxWidgets is wxMBConvUTF7) to write the end of the encoded data to the stream.

Since

2.9.0

wxEOL wxTextOutputStream::GetMode ( )

Returns the end-of-line mode.

One of wxEOL_DOS, wxEOL_MAC and wxEOL_UNIX.

const wxOutputStream& wxTextOutputStream::GetOutputStream ( ) const

Returns a pointer to the underlying output stream object.

Since

2.9.2

wxTextOutputStream& wxTextOutputStream::PutChar (wxChar *c*)

Writes a character to the stream.

void wxTextOutputStream::SetMode (wxEOL *mode* = wxEOL_NATIVE)

Set the end-of-line mode.

One of wxEOL_NATIVE, wxEOL_DOS, wxEOL_MAC and wxEOL_UNIX.

void wxTextOutputStream::Write16 (wxUint16 *i16*)

Writes the 16 bit integer *i16* to the stream.

void wxTextOutputStream::Write32 (wxUint32 *i32*)

Writes the 32 bit integer *i32* to the stream.

void wxTextOutputStream::Write64 (wxUint64 *i64*)

Writes the 64 bit integer *i64* to the stream.

Since

3.1.0

void wxTextOutputStream::Write8 (wxUint8 *i8*)

Writes the single byte *i8* to the stream.

virtual void wxTextOutputStream::WriteDouble (double *f*) [virtual]

Writes the double *f* to the stream using the IEEE format.

virtual void wxTextOutputStream::WriteString (const wxString & *string*) [virtual]

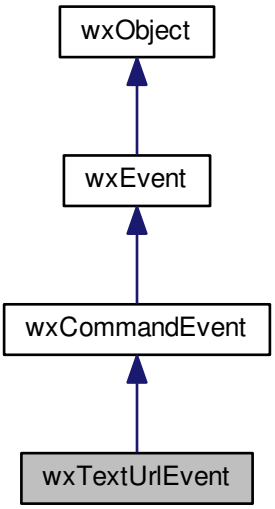
Writes *string* as a line.

Depending on the end-of-line mode the end of line ('\n') characters in the string are converted to the correct line ending terminator.

21.781 wxTextUrlEvent Class Reference

```
#include <wx/textctrl.h>
```

Inheritance diagram for wxTextUrlEvent:



Public Member Functions

- wxTextUrlEvent (int winid, const wxMouseEvent &evtMouse, long start, long end)
- wxTextUrlEvent (const wxTextUrlEvent &event)
- const wxMouseEvent & GetMouseEvent () const
- long GetURLStart () const
- long GetURLEnd () const
- virtual wxEvent * Clone () const

  Returns a copy of the event.

Additional Inherited Members

21.781.1 Constructor & Destructor Documentation

wxTextUrlEvent::wxTextUrlEvent (int *winid,* const wxMouseEvent & *evtMouse,* long *start,* long *end*)

wxTextUrlEvent::wxTextUrlEvent (const wxTextUrlEvent & *event*)

21.781.2 Member Function Documentation

virtual wxEvent* wxTextUrlEvent::Clone ( ) const `[virtual]`

Returns a copy of the event.

Any event that is posted to the wxWidgets event system for later action (via wxEvtHandler::AddPendingEvent, wxEvtHandler::QueueEvent or wxPostEvent()) must implement this method.

All wxWidgets events fully implement this method, but any derived events implemented by the user should also implement this method just in case they (or some event derived from them) are ever posted.

All wxWidgets events implement a copy constructor, so the easiest way of implementing the Clone function is to implement a copy constructor for a new event (call it MyEvent) and then define the Clone function like this:

```
wxEvent *Clone() const { return new MyEvent(*this); }
```

Implements wxEvent.

const wxMouseEvent& wxTextUrlEvent::GetMouseEvent ( ) const

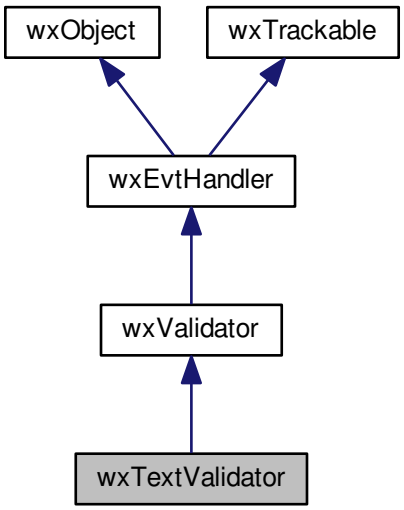
long wxTextUrlEvent::GetURLEnd ( ) const

long wxTextUrlEvent::GetURLStart ( ) const

21.782 wxTextValidator Class Reference

`#include <wx/valtext.h>`

Inheritance diagram for wxTextValidator:



21.782.1 Detailed Description

wxTextValidator validates text controls, providing a variety of filtering behaviours.

For more information, please see wxValidator Overview.

Library: wxCore

Category: Validators

See also

wxValidator Overview, wxValidator, wxGenericValidator, wxIntegerValidator, wxFloatingPointValidator

Public Member Functions

- wxTextValidator (const wxTextValidator &validator)

  Default constructor.
- wxTextValidator (long style=wxFILTER_NONE, wxString *valPtr=NULL)

  Constructor taking a style and optional pointer to a wxString variable.
- virtual wxObject * Clone () const

  Clones the text validator using the copy constructor.
- wxArrayString & GetExcludes ()

  Returns a reference to the exclude list (the list of invalid values).
- wxArrayString & GetIncludes ()

  Returns a reference to the include list (the list of valid values).
- long GetStyle () const

  Returns the validator style.
- bool HasFlag (wxTextValidatorStyle style) const

  Returns true if the given style bit is set in the current style.
- void OnChar (wxKeyEvent &event)

  Receives character input from the window and filters it according to the current validator style.
- void SetExcludes (const wxArrayString &stringList)

  Sets the exclude list (invalid values for the user input).
- void SetCharExcludes (const wxString &chars)

  Breaks the given chars strings in single characters and sets the internal wxArrayString used to store the "excluded" characters (see SetExcludes()).
- void SetIncludes (const wxArrayString &stringList)

  Sets the include list (valid values for the user input).
- void SetCharIncludes (const wxString &chars)

  Breaks the given chars strings in single characters and sets the internal wxArrayString used to store the "included" characters (see SetIncludes()).
- void SetStyle (long style)

  Sets the validator style which must be a combination of one or more of the wxTextValidatorStyle values.
- virtual bool TransferFromWindow ()

  Transfers the value in the text control to the string.
- virtual bool TransferToWindow ()

  Transfers the string value to the text control.
- virtual bool Validate (wxWindow *parent)

  Validates the window contents against the include or exclude lists, depending on the validator style.

Protected Member Functions

- bool ContainsOnlyIncludedCharacters (const wxString &val) const

  Returns true if all the characters of the given val string are present in the include list (set by SetIncludes() or SetCharIncludes()).
- bool ContainsExcludedCharacters (const wxString &val) const

  Returns true if at least one character of the given val string is present in the exclude list (set by SetExcludes() or SetCharExcludes()).
- virtual wxString IsValid (const wxString &val) const

  Returns the error message if the contents of val are invalid or the empty string if val is valid.

Additional Inherited Members

21.782.2 Constructor & Destructor Documentation

wxTextValidator::wxTextValidator (const wxTextValidator & *validator*)

Default constructor.

wxTextValidator::wxTextValidator (long *style* = wxFILTER_NONE, wxString * *valPtr* = NULL)

Constructor taking a style and optional pointer to a wxString variable.

Parameters

style	One or more of the wxTextValidatorStyle styles. See SetStyle().
valPtr	A pointer to a wxString variable that contains the value. This variable should have a lifetime equal to or longer than the validator lifetime (which is usually determined by the lifetime of the window).

21.782.3 Member Function Documentation

virtual wxObject* wxTextValidator::Clone ( ) const [virtual]

Clones the text validator using the copy constructor.

Reimplemented from wxValidator.

bool wxTextValidator::ContainsExcludedCharacters (const wxString & *val*) const [protected]

Returns true if at least one character of the given *val* string is present in the exclude list (set by SetExcludes() or SetCharExcludes()).

bool wxTextValidator::ContainsOnlyIncludedCharacters (const wxString & *val*) const [protected]

Returns true if all the characters of the given *val* string are present in the include list (set by SetIncludes() or SetCharIncludes()).

wxArrayString& wxTextValidator::GetExcludes ( )

Returns a reference to the exclude list (the list of invalid values).

wxArrayString& wxTextValidator::GetIncludes ( )

Returns a reference to the include list (the list of valid values).

long wxTextValidator::GetStyle ( ) const

Returns the validator style.

See also

HasFlag()

bool wxTextValidator::HasFlag (wxTextValidatorStyle *style*) const

Returns true if the given *style* bit is set in the current style.

virtual wxString wxTextValidator::IsValid (const wxString & *val*) const `[protected], [virtual]`

Returns the error message if the contents of *val* are invalid or the empty string if *val* is valid.

void wxTextValidator::OnChar (wxKeyEvent & *event*)

Receives character input from the window and filters it according to the current validator style.

void wxTextValidator::SetCharExcludes (const wxString & *chars*)

Breaks the given *chars* strings in single characters and sets the internal wxArrayString used to store the "excluded" characters (see SetExcludes()).

This function is mostly useful when `wxFILTER_EXCLUDE_CHAR_LIST` was used.

void wxTextValidator::SetCharIncludes (const wxString & *chars*)

Breaks the given *chars* strings in single characters and sets the internal wxArrayString used to store the "included" characters (see SetIncludes()).

This function is mostly useful when `wxFILTER_INCLUDE_CHAR_LIST` was used.

void wxTextValidator::SetExcludes (const wxArrayString & *stringList*)

Sets the exclude list (invalid values for the user input).

void wxTextValidator::SetIncludes (const wxArrayString & *stringList*)

Sets the include list (valid values for the user input).

void wxTextValidator::SetStyle (long *style*)

Sets the validator style which must be a combination of one or more of the wxTextValidatorStyle values.

Note that not all possible combinations make sense! Also note that the order in which the checks are performed is important, in case you specify more than a single style. wxTextValidator will perform the checks in the same definition order used in the wxTextValidatorStyle enumeration.

virtual bool wxTextValidator::TransferFromWindow ( ) `[virtual]`

Transfers the value in the text control to the string.

Reimplemented from wxValidator.

virtual bool wxTextValidator::TransferToWindow ( ) `[virtual]`

Transfers the string value to the text control.

Reimplemented from wxValidator.

virtual bool wxTextValidator::Validate (**wxWindow** * *parent*) [virtual]

Validates the window contents against the include or exclude lists, depending on the validator style.

Reimplemented from wxValidator.

21.783 wxTextWrapper Class Reference

`#include <wx/textwrapper.h>`

21.783.1 Detailed Description

Helps wrap lines of text to given width.

This is a generic purpose class which can be used to wrap lines of text to the specified width. It doesn't do anything by itself but simply calls its virtual OnOutputLine() and OnNewLine() methods for each wrapped line of text, you need to implement them in your derived class to actually do something useful.

Here is an example function using this class which inserts hard line breaks into a string of text at the positions where it would be wrapped:

```
wxString WrapText(wxWindow *win, const wxString& text, int widthMax)
{
    class HardBreakWrapper : public wxTextWrapper
    {
    public:
        HardBreakWrapper(wxWindow *win, const wxString& text, int widthMax)
        {
            Wrap(win, text, widthMax);
        }

        wxString const& GetWrapped() const { return m_wrapped; }

    protected:
        virtual void OnOutputLine(const wxString& line)
        {
            m_wrapped += line;
        }

        virtual void OnNewLine()
        {
            m_wrapped += '\n';
        }

    private:
        wxString m_wrapped;
    };

    HardBreakWrapper wrapper(win, text, widthMax);
    return wrapper.GetWrapped();
}
```

Library: None; this class implementation is entirely header-based.

Category: Graphics Device Interface (GDI)

Public Member Functions

- wxTextWrapper ()

  Trivial default constructor.

- void Wrap (wxWindow *win, const wxString &text, int widthMax)

  Wrap the given text.

Protected Member Functions

- virtual void OnOutputLine (const wxString &line)=0

  Called by Wrap() for each wrapped line of text.
- virtual void OnNewLine ()

  Called at the start of each subsequent line of text by Wrap().

21.783.2 Constructor & Destructor Documentation

wxTextWrapper::wxTextWrapper ( )

Trivial default constructor.

21.783.3 Member Function Documentation

virtual void wxTextWrapper::OnNewLine ( ) `[protected],[virtual]`

Called at the start of each subsequent line of text by Wrap().

This method may not be called at all if the entire text passed to Wrap() fits into the specified width.

virtual void wxTextWrapper::OnOutputLine (const wxString & *line*) `[protected],[pure virtual]`

Called by Wrap() for each wrapped line of text.

This method will always be called at least once by Wrap(). Notice that *line* may be empty if the text passed to Wrap() was empty itself.

void wxTextWrapper::Wrap (wxWindow * *win,* const wxString & *text,* int *widthMax*)

Wrap the given text.

This method will call OnOutputLine() for every line of wrapped text and OnNewLine() before the beginning of every new line after the first one (so it might be never called at all if the width of entire *text* is less than *widthMax*).

Parameters

win	A non-NULL window used for measuring the text extents.
text	The text to wrap.
widthMax	Maximal width of each line of text or `-1` to disable wrapping.

21.784 wxThread Class Reference

`#include <wx/thread.h>`

21.784.1 Detailed Description

A thread is basically a path of execution through a program.

Threads are sometimes called *light-weight* processes, but the fundamental difference between threads and processes is that memory spaces of different processes are separated while all threads share the same address space.

While it makes it much easier to share common data between several threads, it also makes it much easier to shoot oneself in the foot, so careful use of synchronization objects such as mutexes (see wxMutex) or critical sections (see

wxCriticalSection) is recommended. In addition, don't create global thread objects because they allocate memory in their constructor, which will cause problems for the memory checking system.

21.784.2 Types of wxThreads

There are two types of threads in wxWidgets: *detached* and *joinable*, modeled after the POSIX thread API. This is different from the Win32 API where all threads are joinable.

By default wxThreads in wxWidgets use the **detached** behaviour. Detached threads delete themselves once they have completed, either by themselves when they complete processing or through a call to Delete(), and thus **must** be created on the heap (through the new operator, for example).

Typically you'll want to store the instances of the detached wxThreads you allocate, so that you can call functions on them. Because of their nature however you'll need to always use a critical section when accessing them:

```
// declare a new type of event, to be used by our MyThread class:
wxDECLARE_EVENT(wxEVT_COMMAND_MYTHREAD_COMPLETED, wxThreadEvent);
wxDECLARE_EVENT(wxEVT_COMMAND_MYTHREAD_UPDATE, wxThreadEvent);
class MyFrame;

class MyThread : public wxThread
{
public:
    MyThread(MyFrame *handler)
        : wxThread(wxTHREAD_DETACHED)
        { m_pHandler = handler }
    ~MyThread();

protected:
    virtual ExitCode Entry();
    MyFrame *m_pHandler;
};

class MyFrame : public wxFrame
{
public:
    ...
    ~MyFrame()
    {
        // it's better to do any thread cleanup in the OnClose()
        // event handler, rather than in the destructor.
        // This is because the event loop for a top-level window is not
        // active anymore when its destructor is called and if the thread
        // sends events when ending, they won't be processed unless
        // you ended the thread from OnClose.
        // See @ref overview_windowdeletion for more info.
    }
    ...
    void DoStartThread();
    void DoPauseThread();

    // a resume routine would be nearly identic to DoPauseThread()
    void DoResumeThread() { ... }

    void OnThreadUpdate(wxThreadEvent&);
    void OnThreadCompletion(wxThreadEvent&);
    void OnClose(wxCloseEvent&);

protected:
    MyThread *m_pThread;
    wxCriticalSection m_pThreadCS;    // protects the m_pThread pointer

    friend class MyThread;            // allow it to access our m_pThread

    wxDECLARE_EVENT_TABLE();
};

wxBEGIN_EVENT_TABLE(MyFrame, wxFrame)
    EVT_CLOSE(MyFrame::OnClose)
    EVT_MENU(Minimal_Start,  MyFrame::DoStartThread)
    EVT_COMMAND(wxID_ANY, wxEVT_COMMAND_MYTHREAD_UPDATE, MyFrame::OnThreadUpdate)
    EVT_COMMAND(wxID_ANY, wxEVT_COMMAND_MYTHREAD_COMPLETED, MyFrame::OnThreadCompletion)
wxEND_EVENT_TABLE()

wxDEFINE_EVENT(wxEVT_COMMAND_MYTHREAD_COMPLETED, wxThreadEvent);
wxDEFINE_EVENT(wxEVT_COMMAND_MYTHREAD_UPDATE, wxThreadEvent);

void MyFrame::DoStartThread()
{
    m_pThread = new MyThread(this);
```

```
    if ( m_pThread->Run() != wxTHREAD_NO_ERROR )
    {
        wxLogError("Can't create the thread!");
        delete m_pThread;
        m_pThread = NULL;
    }

    // after the call to wxThread::Run(), the m_pThread pointer is "unsafe":
    // at any moment the thread may cease to exist (because it completes its work).
    // To avoid dangling pointers OnThreadExit() will set m_pThread
    // to NULL when the thread dies.
}

wxThread::ExitCode MyThread::Entry()
{
    while (!TestDestroy())
    {
        // ... do a bit of work...

        wxQueueEvent(m_pHandler, new wxThreadEvent(wxEVT_COMMAND_MYTHREAD_UPDATE));
    }

    // signal the event handler that this thread is going to be destroyed
    // NOTE: here we assume that using the m_pHandler pointer is safe,
    //       (in this case this is assured by the MyFrame destructor)
    wxQueueEvent(m_pHandler, new wxThreadEvent(wxEVT_COMMAND_MYTHREAD_COMPLETED));

    return (wxThread::ExitCode)0;     // success
}

MyThread::~MyThread()
{
    wxCriticalSectionLocker enter(m_pHandler->m_pThreadCS);

    // the thread is being destroyed; make sure not to leave dangling pointers around
    m_pHandler->m_pThread = NULL;
}

void MyFrame::OnThreadCompletion(wxThreadEvent&)
{
    wxMessageOutputDebug().Printf("MYFRAME: MyThread exited!\n");
}

void MyFrame::OnThreadUpdate(wxThreadEvent&)
{
    wxMessageOutputDebug().Printf("MYFRAME: MyThread update...\n");
}

void MyFrame::DoPauseThread()
{
    // anytime we access the m_pThread pointer we must ensure that it won't
    // be modified in the meanwhile; since only a single thread may be
    // inside a given critical section at a given time, the following code
    // is safe:
    wxCriticalSectionLocker enter(m_pThreadCS);

    if (m_pThread)         // does the thread still exist?
    {
        // without a critical section, once reached this point it may happen
        // that the OS scheduler gives control to the MyThread::Entry() function,
        // which in turn may return (because it completes its work) making
        // invalid the m_pThread pointer

        if (m_pThread->Pause() != wxTHREAD_NO_ERROR )
            wxLogError("Can't pause the thread!");
    }
}

void MyFrame::OnClose(wxCloseEvent&)
{
    {
        wxCriticalSectionLocker enter(m_pThreadCS);

        if (m_pThread)         // does the thread still exist?
        {
            wxMessageOutputDebug().Printf("MYFRAME: deleting thread");

            if (m_pThread->Delete() != wxTHREAD_NO_ERROR )
                wxLogError("Can't delete the thread!");
        }
    }       // exit from the critical section to give the thread
            // the possibility to enter its destructor
            // (which is guarded with m_pThreadCS critical section!)

    while (1)
    {
```

```
        { // was the ~MyThread() function executed?
            wxCriticalSectionLocker enter(m_pThreadCS);
            if (!m_pThread) break;
        }

        // wait for thread completion
        wxThread::This()->Sleep(1);
    }

    Destroy();
}
```

For a more detailed and comprehensive example, see Thread Sample. For a simpler way to share data and synchronization objects between the main and the secondary thread see wxThreadHelper.

Conversely, **joinable** threads do not delete themselves when they are done processing and as such are safe to create on the stack. Joinable threads also provide the ability for one to get value it returned from Entry() through Wait(). You shouldn't hurry to create all the threads joinable, however, because this has a disadvantage as well: you **must** Wait() for a joinable thread or the system resources used by it will never be freed, and you also must delete the corresponding wxThread object yourself if you did not create it on the stack. In contrast, detached threads are of the "fire-and-forget" kind: you only have to start a detached thread and it will terminate and destroy itself.

21.784.3 wxThread Deletion

Regardless of whether it has terminated or not, you should call Wait() on a **joinable** thread to release its memory, as outlined in Types of wxThreads. If you created a joinable thread on the heap, remember to delete it manually with the `delete` operator or similar means as only detached threads handle this type of memory management.

Since **detached** threads delete themselves when they are finished processing, you should take care when calling a routine on one. If you are certain the thread is still running and would like to end it, you may call Delete() to gracefully end it (which implies that the thread will be deleted after that call to Delete()). It should be implied that you should **never** attempt to delete a detached thread with the `delete` operator or similar means.

As mentioned, Wait() or Delete() functions attempt to gracefully terminate a joinable and a detached thread, respectively. They do this by waiting until the thread in question calls TestDestroy() or ends processing (i.e. returns from wxThread::Entry).

Obviously, if the thread does call TestDestroy() and does not end, the thread which called Wait() or Delete() will come to halt. This is why it's important to call TestDestroy() in the Entry() routine of your threads as often as possible and immediately exit when it returns true.

As a last resort you can end the thread immediately through Kill(). It is strongly recommended that you do not do this, however, as it does not free the resources associated with the object (although the wxThread object of detached threads will still be deleted) and could leave the C runtime library in an undefined state.

21.784.4 wxWidgets Calls in Secondary Threads

All threads other than the "main application thread" (the one running wxApp::OnInit() or the one your main function runs in, for example) are considered "secondary threads".

GUI calls, such as those to a wxWindow or wxBitmap are explicitly not safe at all in secondary threads and could end your application prematurely. This is due to several reasons, including the underlying native API and the fact that wxThread does not run a GUI event loop similar to other APIs as MFC.

A workaround for some wxWidgets ports is calling wxMutexGUIEnter() before any GUI calls and then calling wx↩MutexGUILeave() afterwords. However, the recommended way is to simply process the GUI calls in the main thread through an event that is posted by wxQueueEvent(). This does not imply that calls to these classes are thread-safe, however, as most wxWidgets classes are not thread-safe, including wxString.

21.784.5 Don't Poll a wxThread

A common problem users experience with wxThread is that in their main thread they will check the thread every now and then to see if it has ended through IsRunning(), only to find that their application has run into problems

because the thread is using the default behaviour (i.e. it's **detached**) and has already deleted itself. Naturally, they instead attempt to use joinable threads in place of the previous behaviour. However, polling a wxThread for when it has ended is in general a bad idea - in fact calling a routine on any running wxThread should be avoided if possible. Instead, find a way to notify yourself when the thread has ended.

Usually you only need to notify the main thread, in which case you can post an event to it via wxQueueEvent(). In the case of secondary threads you can call a routine of another class when the thread is about to complete processing and/or set the value of a variable, possibly using mutexes (see wxMutex) and/or other synchronization means if necessary.

Library: wxBase

Category: Threading

See also

wxThreadHelper, wxMutex, wxCondition, wxCriticalSection, Multithreading Overview

Public Types

- typedef void * ExitCode

  The return type for the thread functions.

Public Member Functions

- wxThread (wxThreadKind kind=wxTHREAD_DETACHED)

  This constructor creates a new detached (default) or joinable C++ thread object.
- virtual ~wxThread ()

  The destructor frees the resources associated with the thread.
- wxThreadError Create (unsigned int stackSize=0)

  Creates a new thread.
- wxThreadError Delete (ExitCode *rc=NULL, wxThreadWait waitMode=wxTHREAD_WAIT_BLOCK)

  *Calling Delete() gracefully terminates a **detached** thread, either when the thread calls TestDestroy() or when it finishes processing.*
- wxThreadIdType GetId () const

  Gets the thread identifier: this is a platform dependent number that uniquely identifies the thread throughout the system during its existence (i.e. the thread identifiers may be reused).
- WXHANDLE MSWGetHandle () const

  Gets the native thread handle.
- wxThreadKind GetKind () const

  Returns the thread kind as it was given in the ctor.
- unsigned int GetPriority () const

  Gets the priority of the thread, between 0 (lowest) and 100 (highest).
- bool IsAlive () const

  Returns true if the thread is alive (i.e. started and not terminating).
- bool IsDetached () const

  Returns true if the thread is of the detached kind, false if it is a joinable one.
- bool IsPaused () const

  Returns true if the thread is paused.
- bool IsRunning () const

  Returns true if the thread is running.
- wxThreadError Kill ()

Immediately terminates the target thread.

- wxThreadError Pause ()

  Suspends the thread.

- wxThreadError Resume ()

  Resumes a thread suspended by the call to Pause().

- wxThreadError Run ()

  Starts the thread execution.

- void SetPriority (unsigned int priority)

  Sets the priority of the thread, between 0 (lowest) and 100 (highest).

- virtual bool TestDestroy ()

  This function should be called periodically by the thread to ensure that calls to Pause() and Delete() will work.

- ExitCode Wait (wxThreadWait flags=wxTHREAD_WAIT_BLOCK)

  *Waits for a **joinable** thread to terminate and returns the value the thread returned from Entry() or "`(ExitCode)-1`" on error.*

Static Public Member Functions

- static int GetCPUCount ()

  Returns the number of system CPUs or -1 if the value is unknown.

- static wxThreadIdType GetCurrentId ()

  Returns the platform specific thread ID of the current thread as a long.

- static wxThreadIdType GetMainId ()

  Returns the thread ID of the main thread.

- static bool IsMain ()

  Returns true if the calling thread is the main application thread.

- static bool SetConcurrency (size_t level)

  Sets the thread concurrency level for this process.

- static void Sleep (unsigned long milliseconds)

  Pauses the thread execution for the given amount of time.

- static wxThread * This ()

  Return the thread object for the calling thread.

- static void Yield ()

  Give the rest of the thread's time-slice to the system allowing the other threads to run.

Protected Member Functions

- virtual ExitCode Entry ()=0

  This is the entry point of the thread.

- void Exit (ExitCode exitcode=0)

  This is a protected function of the wxThread class and thus can only be called from a derived class.

Private Member Functions

- virtual void OnExit ()

  Called when the thread exits.

21.784.6 Member Typedef Documentation

typedef void* wxThread::ExitCode

The return type for the thread functions.

21.784.7 Constructor & Destructor Documentation

wxThread::wxThread (wxThreadKind *kind* = wxTHREAD_DETACHED)

This constructor creates a new detached (default) or joinable C++ thread object.

It does not create or start execution of the real thread - for this you should use the Run() method.

The possible values for *kind* parameters are:

- **wxTHREAD_DETACHED** - Creates a detached thread.
- **wxTHREAD_JOINABLE** - Creates a joinable thread.

virtual wxThread::~wxThread ( ) [virtual]

The destructor frees the resources associated with the thread.

Notice that you should never delete a detached thread – you may only call Delete() on it or wait until it terminates (and auto destructs) itself.

Because the detached threads delete themselves, they can only be allocated on the heap. Joinable threads should be deleted explicitly. The Delete() and Kill() functions will not delete the C++ thread object. It is also safe to allocate them on stack.

21.784.8 Member Function Documentation

wxThreadError wxThread::Create (unsigned int *stackSize* = 0)

Creates a new thread.

The thread object is created in the suspended state, and you should call Run() to start running it. You may optionally specify the stack size to be allocated to it (Ignored on platforms that don't support setting it explicitly, eg. Unix system without `pthread_attr_setstacksize`).

If you do not specify the stack size, the system's default value is used.

Note

It is not necessary to call this method since 2.9.5, Run() will create the thread internally. You only need to call Create() if you need to do something with the thread (e.g. pass its ID to an external library) before it starts.

Warning

It is a good idea to explicitly specify a value as systems' default values vary from just a couple of KB on some systems (BSD and OS/2 systems) to one or several MB (Windows, Solaris, Linux). So, if you have a thread that requires more than just a few KB of memory, you will have mysterious problems on some platforms but not on the common ones. On the other hand, just indicating a large stack size by default will give you performance issues on those systems with small default stack since those typically use fully committed memory for the stack. On the contrary, if you use a lot of threads (say several hundred), virtual address space can get tight unless you explicitly specify a smaller amount of thread stack space for each thread.

Returns

One of:

- **wxTHREAD_NO_ERROR** - No error.
- **wxTHREAD_NO_RESOURCE** - There were insufficient resources to create the thread.
- **wxTHREAD_NO_RUNNING** - The thread is already running

wxThreadError wxThread::Delete (ExitCode * *rc* = NULL, wxThreadWait *waitMode* = wxTHREAD_WAIT_BLOCK)

Calling Delete() gracefully terminates a **detached** thread, either when the thread calls TestDestroy() or when it finishes processing.

Parameters

rc	The thread exit code, if rc is not NULL.
waitMode	As described in wxThreadWait documentation, wxTHREAD_WAIT_BLOCK should be used as the wait mode even although currently wxTHREAD_WAIT_YIELD is for compatibility reasons. This parameter is new in wxWidgets 2.9.2.

Note

This function works on a joinable thread but in that case makes the TestDestroy() function of the thread return true and then waits for its completion (i.e. it differs from Wait() because it asks the thread to terminate before waiting).

See wxThread Deletion for a broader explanation of this routine.

virtual ExitCode wxThread::Entry ( ) [protected], [pure virtual]

This is the entry point of the thread.

This function is pure virtual and must be implemented by any derived class. The thread execution will start here.

The returned value is the thread exit code which is only useful for joinable threads and is the value returned by Wait(). This function is called by wxWidgets itself and should never be called directly.

void wxThread::Exit (ExitCode *exitcode* = 0) [protected]

This is a protected function of the wxThread class and thus can only be called from a derived class.

It also can only be called in the context of this thread, i.e. a thread can only exit from itself, not from another thread.

This function will terminate the OS thread (i.e. stop the associated path of execution) and also delete the associated C++ object for detached threads. OnExit() will be called just before exiting.

static int wxThread::GetCPUCount ( ) [static]

Returns the number of system CPUs or -1 if the value is unknown.

For multi-core systems the returned value is typically the total number of *cores*, since the OS usually abstract a single N-core CPU as N different cores.

See also

SetConcurrency()

static wxThreadIdType wxThread::GetCurrentId ( ) [static]

Returns the platform specific thread ID of the current thread as a long.

This can be used to uniquely identify threads, even if they are not wxThreads.

See also

GetMainId()

wxThreadIdType wxThread::GetId ( ) const

Gets the thread identifier: this is a platform dependent number that uniquely identifies the thread throughout the system during its existence (i.e. the thread identifiers may be reused).

wxThreadKind wxThread::GetKind ( ) const

Returns the thread kind as it was given in the ctor.

Since

2.9.0

static wxThreadIdType wxThread::GetMainId ( ) [static]

Returns the thread ID of the main thread.

See also

IsMain()

Since

2.9.1

unsigned int wxThread::GetPriority ( ) const

Gets the priority of the thread, between 0 (lowest) and 100 (highest).

See also

SetPriority()

bool wxThread::IsAlive ( ) const

Returns true if the thread is alive (i.e. started and not terminating).

Note that this function can only safely be used with joinable threads, not detached ones as the latter delete themselves and so when the real thread is no longer alive, it is not possible to call this function because the wxThread object no longer exists.

bool wxThread::IsDetached ( ) const

Returns true if the thread is of the detached kind, false if it is a joinable one.

static bool wxThread::IsMain ( ) [static]

Returns true if the calling thread is the main application thread.

Main thread in the context of wxWidgets is the one which initialized the library.

See also

GetMainId(), GetCurrentId()

bool wxThread::IsPaused ( ) const

Returns true if the thread is paused.

bool wxThread::IsRunning ( ) const

Returns true if the thread is running.

This method may only be safely used for joinable threads, see the remark in IsAlive().

wxThreadError wxThread::Kill ( )

Immediately terminates the target thread.

"This function is dangerous and should be used with extreme care" (and not used at all whenever possible)! The resources allocated to the thread will not be freed and the state of the C runtime library may become inconsistent. Use Delete() for detached threads or Wait() for joinable threads instead.

For detached threads Kill() will also delete the associated C++ object. However this will not happen for joinable threads and this means that you will still have to delete the wxThread object yourself to avoid memory leaks.

In neither case OnExit() of the dying thread will be called, so no thread-specific cleanup will be performed. This function can only be called from another thread context, i.e. a thread cannot kill itself.

It is also an error to call this function for a thread which is not running or paused (in the latter case, the thread will be resumed first) – if you do it, a **wxTHREAD_NOT_RUNNING** error will be returned.

WXHANDLE wxThread::MSWGetHandle ( ) const

Gets the native thread handle.

This method only exists in wxMSW, use GetId() in portable code.

Since

3.1.0

virtual void wxThread::OnExit ( ) [private], [virtual]

Called when the thread exits.

This function is called in the context of the thread associated with the wxThread object, not in the context of the main thread. This function will not be called if the thread was Kill() killed.

This function should never be called directly.

wxThreadError wxThread::Pause ( )

Suspends the thread.

Under some implementations (Win32), the thread is suspended immediately, under others it will only be suspended when it calls TestDestroy() for the next time (hence, if the thread doesn't call it at all, it won't be suspended).

This function can only be called from another thread context.

wxThreadError wxThread::Resume ( )

Resumes a thread suspended by the call to Pause().

This function can only be called from another thread context.

wxThreadError wxThread::Run ( )

Starts the thread execution.

Note that once you Run() a **detached** thread, *any* function call you do on the thread pointer (you must allocate it on the heap) is *"unsafe"*; i.e. the thread may have terminated at any moment after Run() and your pointer may be dangling. See Types of wxThreads for an example of safe manipulation of detached threads.

This function can only be called from another thread context.

Finally, note that once a thread has completed and its Entry() function returns, you cannot call Run() on it again (an assert will fail in debug builds or `wxTHREAD_RUNNING` will be returned in release builds).

static bool wxThread::SetConcurrency (size_t *level*) [static]

Sets the thread concurrency level for this process.

This is, roughly, the number of threads that the system tries to schedule to run in parallel. The value of 0 for *level* may be used to set the default one.

Returns

true on success or false otherwise (for example, if this function is not implemented for this platform – currently everything except Solaris).

void wxThread::SetPriority (unsigned int *priority*)

Sets the priority of the thread, between 0 (lowest) and 100 (highest).

The following symbolic constants can be used in addition to raw values in 0..100 range:

- `wxPRIORITY_MIN`: 0
- `wxPRIORITY_DEFAULT`: 50
- `wxPRIORITY_MAX`: 100

Notice that in the MSW implementation the thread priority can currently be only set after creating the thread with CreateThread(). But under all platforms this method can be called either before launching the thread using Run() or after doing it.

static void wxThread::Sleep (unsigned long *milliseconds*) [static]

Pauses the thread execution for the given amount of time.

This is the same as wxMilliSleep().

virtual bool wxThread::TestDestroy ( ) [virtual]

This function should be called periodically by the thread to ensure that calls to Pause() and Delete() will work.

If it returns true, the thread should exit as soon as possible. Notice that under some platforms (POSIX), implementation of Pause() also relies on this function being called, so not calling it would prevent both stopping and suspending thread from working.

static wxThread* wxThread::This ( ) [static]

Return the thread object for the calling thread.

NULL is returned if the calling thread is the main (GUI) thread, but IsMain() should be used to test whether the thread is really the main one because NULL may also be returned for the thread not created with wxThread class. Generally speaking, the return value for such a thread is undefined.

ExitCode wxThread::Wait (wxThreadWait *flags* = wxTHREAD_WAIT_BLOCK)

Waits for a **joinable** thread to terminate and returns the value the thread returned from Entry() or "`(ExitCode)-1`" on error.

Notice that, unlike Delete(), this function doesn't cancel the thread in any way so the caller waits for as long as it takes to the thread to exit.

You can only Wait() for **joinable** (not detached) threads.

This function can only be called from another thread context.

Parameters

flags	As described in wxThreadWait documentation, wxTHREAD_WAIT_BLOCK should be used as the wait mode even although currently wxTHREAD_WAIT_YIELD is for compatibility reasons. This parameter is new in wxWidgets 2.9.2.

See wxThread Deletion for a broader explanation of this routine.

static void wxThread::Yield ( ) `[static]`

Give the rest of the thread's time-slice to the system allowing the other threads to run.

Note that using this function is **strongly** discouraged, since in many cases it indicates a design weakness of your threading model (as does using Sleep() functions).

Threads should use the CPU in an efficient manner, i.e. they should do their current work efficiently, then as soon as the work is done block on a wakeup event (wxCondition, wxMutex, select(), poll(), ...) which will get signalled e.g. by other threads or a user device once further thread work is available. Using Yield() or Sleep() indicates polling-type behaviour, since we're fuzzily giving up our timeslice and wait until sometime later we'll get reactivated, at which time we realize that there isn't really much to do and Yield() again...

The most critical characteristic of Yield() is that it's operating system specific: there may be scheduler changes which cause your thread to not wake up relatively soon again, but instead many seconds later, causing huge performance issues for your application.

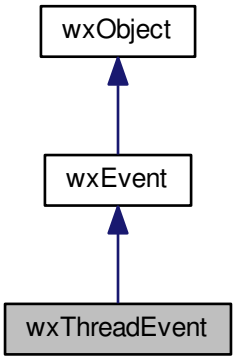
With a well-behaving, CPU-efficient thread the operating system is likely to properly care for its reactivation the moment it needs it, whereas with non-deterministic, Yield-using threads all bets are off and the system scheduler is free to penalize them drastically, and this effect gets worse with increasing system load due to less free CPU resources available. You may refer to various Linux kernel `sched_yield` discussions for more information.

See also Sleep().

21.785 wxThreadEvent Class Reference

`#include <wx/event.h>`

Inheritance diagram for wxThreadEvent:



21.785.1 Detailed Description

This class adds some simple functionality to wxEvent to facilitate inter-thread communication.

This event is not natively emitted by any control/class: it is just a helper class for the user. Its most important feature is the GetEventCategory() implementation which allows thread events **NOT** to be processed by wxEventLoop↩ Base::YieldFor calls (unless the `wxEVT_CATEGORY_THREAD` is specified - which is never in wx code).

Library: wxCore

Category: Events, Threading

See also

Multithreading Overview, wxEventLoopBase::YieldFor

Since

2.9.0

Public Member Functions

- wxThreadEvent (wxEventType eventType=wxEVT_THREAD, int id=wxID_ANY)

  Constructor.
- virtual wxEvent * Clone () const

  Clones this event making sure that all internal members which use COW (only `m_commandString` for now; see Reference Counting) are unshared (see wxObject::UnShare).
- virtual wxEventCategory GetEventCategory () const

  Returns `wxEVT_CATEGORY_THREAD`.
- template<typename T >
  void SetPayload (const T &payload)

  Sets custom data payload.

- template<typename T >
  T GetPayload () const

  Get custom data payload.
- long GetExtraLong () const

  Returns extra information integer value.
- int GetInt () const

  Returns stored integer value.
- wxString GetString () const

  Returns stored string value.
- void SetExtraLong (long extraLong)

  Sets the extra information value.
- void SetInt (int intCommand)

  Sets the integer value.
- void SetString (const wxString &string)

  Sets the string value.

Additional Inherited Members

21.785.2 Constructor & Destructor Documentation

wxThreadEvent::wxThreadEvent (wxEventType *eventType* = wxEVT_THREAD, int *id* = wxID_ANY)

Constructor.

21.785.3 Member Function Documentation

virtual wxEvent* wxThreadEvent::Clone ( ) const `[virtual]`

Clones this event making sure that all internal members which use COW (only `m_commandString` for now; see Reference Counting) are unshared (see wxObject::UnShare).

Implements wxEvent.

virtual wxEventCategory wxThreadEvent::GetEventCategory ( ) const `[virtual]`

Returns `wxEVT_CATEGORY_THREAD`.

This is important to avoid unwanted processing of thread events when calling wxEventLoopBase::YieldFor().

Reimplemented from wxEvent.

long wxThreadEvent::GetExtraLong ( ) const

Returns extra information integer value.

int wxThreadEvent::GetInt ( ) const

Returns stored integer value.

template<typename T > T wxThreadEvent::GetPayload ( ) const

Get custom data payload.

Correct type is checked in debug builds.

Note

This method is not available with Visual C++ 6.

Since

2.9.1

See also

SetPayload(), wxAny

wxString wxThreadEvent::GetString ( ) const

Returns stored string value.

void wxThreadEvent::SetExtraLong (long *extraLong*)

Sets the extra information value.

void wxThreadEvent::SetInt (int *intCommand*)

Sets the integer value.

template<typename T > void wxThreadEvent::SetPayload (const T & *payload*)

Sets custom data payload.

The *payload* argument may be of any type that wxAny can handle (i.e. pretty much anything). Note that T's copy constructor must be thread-safe, i.e. create a copy that doesn't share anything with the original (see Clone()).

Note

This method is not available with Visual C++ 6.

Since

2.9.1

See also

GetPayload(), wxAny

void wxThreadEvent::SetString (const wxString & *string*)

Sets the string value.

21.786 wxThreadHelper Class Reference

`#include <wx/thread.h>`

21.786.1 Detailed Description

The wxThreadHelper class is a mix-in class that manages a single background thread, either detached or joinable (see wxThread for the differences).

By deriving from wxThreadHelper, a class can implement the thread code in its own wxThreadHelper::Entry() method and easily share data and synchronization objects between the main thread and the worker thread.

Doing this prevents the awkward passing of pointers that is needed when the original object in the main thread needs to synchronize with its worker thread in its own wxThread derived object.

For example, wxFrame may need to make some calculations in a background thread and then display the results of those calculations in the main window.

Ordinarily, a wxThread derived object would be created with the calculation code implemented in wxThread::Entry. To access the inputs to the calculation, the frame object would often need to pass a pointer to itself to the thread object. Similarly, the frame object would hold a pointer to the thread object.

Shared data and synchronization objects could be stored in either object though the object without the data would have to access the data through a pointer. However with wxThreadHelper the frame object and the thread object are treated as the same object. Shared data and synchronization variables are stored in the single object, eliminating a layer of indirection and the associated pointers.

Example:

```
wxDECLARE_EVENT(myEVT_THREAD_UPDATE, wxThreadEvent);

class MyFrame : public wxFrame, public wxThreadHelper
{
public:
    MyFrame(...) { ... }
    ~MyFrame()
    {
        // it's better to do any thread cleanup in the OnClose()
        // event handler, rather than in the destructor.
        // This is because the event loop for a top-level window is not
        // active anymore when its destructor is called and if the thread
        // sends events when ending, they won't be processed unless
        // you ended the thread from OnClose.
        // See @ref overview_windowdeletion for more info.
    }

    ...
    void DoStartALongTask();
    void OnThreadUpdate(wxThreadEvent& evt);
    void OnClose(wxCloseEvent& evt);
    ...

protected:
    virtual wxThread::ExitCode Entry();

    // the output data of the Entry() routine:
    char m_data[1024];
    wxCriticalSection m_dataCS; // protects field above

    wxDECLARE_EVENT_TABLE();
};

wxDEFINE_EVENT(myEVT_THREAD_UPDATE, wxThreadEvent);
wxBEGIN_EVENT_TABLE(MyFrame, wxFrame)
    EVT_THREAD(wxID_ANY, myEVT_THREAD_UPDATE, MyFrame::OnThreadUpdate)
    EVT_CLOSE(MyFrame::OnClose)
wxEND_EVENT_TABLE()

void MyFrame::DoStartALongTask()
{
    // we want to start a long task, but we don't want our GUI to block
    // while it's executed, so we use a thread to do it.
    if (CreateThread(wxTHREAD_JOINABLE) !=
      wxTHREAD_NO_ERROR)
    {
        wxLogError("Could not create the worker thread!");
```

```
        return;
    }

    // go!
    if (GetThread()->Run() != wxTHREAD_NO_ERROR)
    {
        wxLogError("Could not run the worker thread!");
        return;
    }
}

wxThread::ExitCode MyFrame::Entry()
{
    // IMPORTANT:
    // this function gets executed in the secondary thread context!

    int offset = 0;

    // here we do our long task, periodically calling TestDestroy():
    while (!GetThread()->TestDestroy())
    {
        // since this Entry() is implemented in MyFrame context we don't
        // need any pointer to access the m_data, m_processedData, m_dataCS
        // variables... very nice!

        // this is an example of the generic structure of a download thread:
        char buffer[1024];
        download_chunk(buffer, 1024);     // this takes time...

        {
            // ensure no one reads m_data while we write it
            wxCriticalSectionLocker lock(m_dataCS);
            memcpy(m_data+offset, buffer, 1024);
            offset += 1024;
        }

        // VERY IMPORTANT: do not call any GUI function inside this
        //                 function; rather use wxQueueEvent():
        wxQueueEvent(this, new wxThreadEvent(wxEVT_COMMAND_MYTHREAD_UPDATE));
            // we used pointer 'this' assuming it's safe; see OnClose()
    }

    // TestDestroy() returned true (which means the main thread asked us
    // to terminate as soon as possible) or we ended the long task...
    return (wxThread::ExitCode)0;
}

void MyFrame::OnClose(wxCloseEvent&)
{
    // important: before terminating, we _must_ wait for our joinable
    // thread to end, if it's running; in fact it uses variables of this
    // instance and posts events to *this event handler

    if (GetThread() &&      // DoStartALongTask() may have not been called
        GetThread()->IsRunning())
        GetThread()->Wait();

    Destroy();
}

void MyFrame::OnThreadUpdate(wxThreadEvent& evt)
{
    // ...do something... e.g. m_pGauge->Pulse();

    // read some parts of m_data just for fun:
    wxCriticalSectionLocker lock(m_dataCS);
    wxPrintf("%c", m_data[100]);
}
```

Library: wxBase

Category: Threading

wxThread, wxThreadEvent

Public Member Functions

- wxThreadHelper (wxThreadKind kind=wxTHREAD_JOINABLE)

  This constructor simply initializes internal member variables and tells wxThreadHelper which type the thread internally managed should be.
- virtual ~wxThreadHelper ()

  The destructor frees the resources associated with the thread, forcing it to terminate (it uses wxThread::Kill function).
- virtual ExitCode Entry ()=0

  This is the entry point of the thread.
- virtual void OnDelete ()

  Callback called by Delete() before actually deleting the thread.
- virtual void OnKill ()

  Callback called by Kill() before actually killing the thread.
- wxThreadError Create (unsigned int stackSize=0)
- wxThreadError CreateThread (wxThreadKind kind=wxTHREAD_JOINABLE, unsigned int stackSize=0)

  Creates a new thread of the given kind.
- wxThread * GetThread () const

  This is a public function that returns the wxThread object associated with the thread.
- wxThreadKind GetThreadKind () const

  Returns the last type of thread given to the CreateThread() function or to the constructor.

21.786.2 Constructor & Destructor Documentation

wxThreadHelper::wxThreadHelper (wxThreadKind *kind* = wxTHREAD_JOINABLE)

This constructor simply initializes internal member variables and tells wxThreadHelper which type the thread internally managed should be.

virtual wxThreadHelper::~wxThreadHelper ( ) [virtual]

The destructor frees the resources associated with the thread, forcing it to terminate (it uses wxThread::Kill function).

Because of the wxThread::Kill unsafety, you should always wait (with wxThread::Wait) for joinable threads to end or call wxThread::Delete on detached threads, instead of relying on this destructor for stopping the thread.

21.786.3 Member Function Documentation

wxThreadError wxThreadHelper::Create (unsigned int *stackSize* = 0)

Deprecated Use CreateThread() instead.

wxThreadError wxThreadHelper::CreateThread (wxThreadKind *kind* = wxTHREAD_JOINABLE, unsigned int *stackSize* = 0)

Creates a new thread of the given *kind*.

The thread object is created in the suspended state, and you should call GetThread()->Run() to start running it.

You may optionally specify the stack size to be allocated to it (ignored on platforms that don't support setting it explicitly, e.g. Unix).

Returns

One of the wxThreadError enum values.

virtual ExitCode wxThreadHelper::Entry ( ) [pure virtual]

This is the entry point of the thread.

This function is pure virtual and must be implemented by any derived class. The thread execution will start here.

You'll typically want your Entry() to look like:

```
wxThread::ExitCode Entry()
{
    while (!GetThread()->TestDestroy())
    {
        // ... do some work ...

        if (IsWorkCompleted)
            break;

        if (HappenedStoppingError)
            return (wxThread::ExitCode)1;   // failure
    }

    return (wxThread::ExitCode)0;           // success
}
```

The returned value is the thread exit code which is only useful for joinable threads and is the value returned by `"GetThread()->Wait()"`.

This function is called by wxWidgets itself and should never be called directly.

wxThread* wxThreadHelper::GetThread ( ) const

This is a public function that returns the wxThread object associated with the thread.

wxThreadKind wxThreadHelper::GetThreadKind ( ) const

Returns the last type of thread given to the CreateThread() function or to the constructor.

virtual void wxThreadHelper::OnDelete ( ) [virtual]

Callback called by Delete() before actually deleting the thread.

This function can be overridden by the derived class to perform some specific task when the thread is gracefully destroyed. Notice that it will be executed in the context of the thread that called Delete() and **not** in this thread's context.

TestDestroy() will be true for the thread before OnDelete() gets executed.

Since

2.9.2

See also

OnKill()

virtual void wxThreadHelper::OnKill ( ) [virtual]

Callback called by Kill() before actually killing the thread.

This function can be overridden by the derived class to perform some specific task when the thread is terminated. Notice that it will be executed in the context of the thread that called Kill() and **not** in this thread's context.

Since

2.9.2

wxTaskBarButton

Since

3.1.0

Public Member Functions

- wxThumbBarButton ()

  Default constructor to allow 2-phase creation.
- wxThumbBarButton (int id, const wxIcon &icon, const wxString &tooltip=wxString(), bool enable=true, bool dismissOnClick=false, bool hasBackground=true, bool shown=true, bool interactive=true)

  Constructs the thumbnail toolbar button.
- bool Create (int id, const wxIcon &icon, const wxString &tooltip=wxString(), bool enable=true, bool dismiss↩ OnClick=false, bool hasBackground=true, bool shown=true, bool interactive=true)
- virtual ~wxThumbBarButton ()
- int GetID () const

  Returns the identifier associated with this control.
- const wxIcon & GetIcon () const

  Returns the icon associated with this control.
- const wxString & GetTooltip () const

  Returns the tooltip.
- bool IsEnable () const

  Returns true if the button is enabled, false if it has been disabled.
- void Enable (bool enable=true)

  Enables or disables the thumbnail toolbar button.
- void Disable ()

Equivalent to calling wxThumbBarButton::Enable(false).

- bool IsDismissOnClick () const

  Returns true if the button will dismiss on click.

- void EnableDismissOnClick (bool enable=true)

  Whether the window thumbnail is dismissed after a button click.

- void DisableDimissOnClick ()

  Equivalent to calling wxThumbBarButton::DisableDimissOnClick(false).

- bool HasBackground () const

  Returns true if the button has button border.

- void SetHasBackground (bool has=true)

  Set the property that whether the button has background.

- bool IsShown () const

  Returns true if the button is shown, false if it has been hidden.

- void Show (bool shown=true)

  Show or hide the thumbnail toolbar button.

- void Hide ()

  Hide the thumbnail toolbar button.

- bool IsInteractive () const

  Returns true if the button is interactive.

- void SetInteractive (bool interactive=true)

  Set the property which holds whether the button is interactive.

21.787.2 Constructor & Destructor Documentation

wxThumbBarButton::wxThumbBarButton ( )

Default constructor to allow 2-phase creation.

wxThumbBarButton::wxThumbBarButton (int *id*, const wxIcon & *icon*, const wxString & *tooltip* = wxString(), bool *enable* = `true`, bool *dismissOnClick* = `false`, bool *hasBackground* = `true`, bool *shown* = `true`, bool *interactive* = `true`)

Constructs the thumbnail toolbar button.

Parameters

id	The identifier for the control.
icon	The icon used as the button image.
tooltip	The text of the button's tooltip, displayed when the mouse pointer hovers over the button.
enable	If true (default), the button is active and available to the user. If false, the button is disabled. It is present, but has a visual state that indicates that it will not respond to user action.
dismissOnClick	If true, when the button is clicked, the taskbar button's flyout closes immediately. false by default.
hasBackground	If false, the button border is not drawn. true by default.
shown	If false, the button is not shown to the user. true by default.
interactive	If false, the button is enabled but not interactive; no pressed button state is drawn. This flag is intended for instances where the button is used in a notification. true by default.

virtual wxThumbBarButton::~wxThumbBarButton ( ) `[virtual]`

21.787.3 Member Function Documentation

bool wxThumbBarButton::Create (int *id,* const wxIcon & *icon,* const wxString & *tooltip* = wxString (), bool *enable* = true, bool *dismissOnClick* = false, bool *hasBackground* = true, bool *shown* = true, bool *interactive* = true)

void wxThumbBarButton::Disable ( )

Equivalent to calling wxThumbBarButton::Enable(false).

void wxThumbBarButton::DisableDimissOnClick ( )

Equivalent to calling wxThumbBarButton::DisableDimissOnClick(false).

void wxThumbBarButton::Enable (bool *enable* = true)

Enables or disables the thumbnail toolbar button.

void wxThumbBarButton::EnableDismissOnClick (bool *enable* = true)

Whether the window thumbnail is dismissed after a button click.

const wxIcon& wxThumbBarButton::GetIcon ( ) const

Returns the icon associated with this control.

int wxThumbBarButton::GetID ( ) const

Returns the identifier associated with this control.

const wxString& wxThumbBarButton::GetTooltip ( ) const

Returns the tooltip.

bool wxThumbBarButton::HasBackground ( ) const

Returns true if the button has button border.

void wxThumbBarButton::Hide ( )

Hide the thumbnail toolbar button.

Equivalent to calling wxThumbBarButton::Show(false).

bool wxThumbBarButton::IsDismissOnClick ( ) const

Returns true if the button will dismiss on click.

bool wxThumbBarButton::IsEnable ( ) const

Returns true if the button is enabled, false if it has been disabled.

bool wxThumbBarButton::IsInteractive ( ) const

Returns true if the button is interactive.

bool wxThumbBarButton::IsShown ( ) const

Returns true if the button is shown, false if it has been hidden.

void wxThumbBarButton::SetHasBackground (bool *has* = `true`)

Set the property that whether the button has background.

void wxThumbBarButton::SetInteractive (bool *interactive* = `true`)

Set the property which holds whether the button is interactive.

A non-interactive thumbnail toolbar button does not react to user interaction, but is still visually enabled.

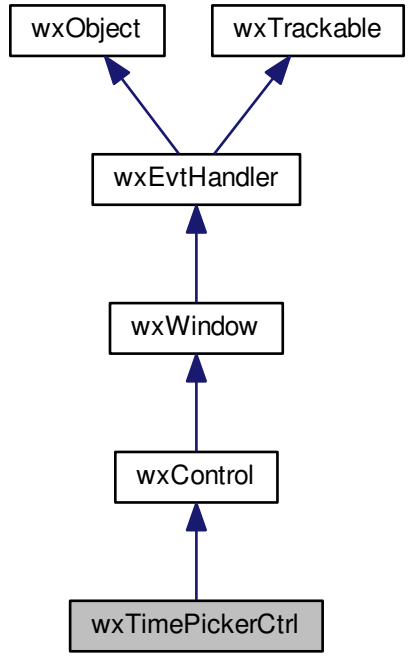
void wxThumbBarButton::Show (bool *shown* = `true`)

Show or hide the thumbnail toolbar button.

21.788 wxTimePickerCtrl Class Reference

```
#include <wx/timectrl.h>
```

Inheritance diagram for wxTimePickerCtrl:



21.788.1 Detailed Description

This control allows the user to enter time.

It is similar to wxDatePickerCtrl but is used for time, and not date, selection. While GetValue() and SetValue() still work with values of type wxDateTime (because wxWidgets doesn't provide a time-only class), their date part is ignored by this control.

It is only available if `wxUSE_TIMEPICKCTRL` is set to 1.

This control currently doesn't have any specific flags.

Events emitted by this class

The following event handler macros redirect the events to member function handlers '**func**' with prototypes like: void handlerFuncName(wxDateEvent& event)

Event macros for events emitted by this class:

- EVT_TIME_CHANGED(id, func): This event fires when the user changes the current selection in the control.

Library: wxAdvanced

Category: Picker Controls

2.9.3

Public Member Functions

- wxTimePickerCtrl ()

  Default constructor.
- wxTimePickerCtrl (wxWindow *parent, wxWindowID id, const wxDateTime &dt=wxDefaultDateTime, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, long style=wxTP_DEFAULT, const wxValidator &validator=wxDefaultValidator, const wxString &name="timectrl")

  Initializes the object and calls Create() with all the parameters.
- bool Create (wxWindow *parent, wxWindowID id, const wxDateTime &dt=wxDefaultDateTime, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, long style=wxDP_DEFAULT|wxDP_SHOWCENTURY, const wxValidator &validator=wxDefaultValidator, const wxString &name="timectrl")

  Create the control window.
- bool GetTime (int *hour, int *min, int *sec) const

  Returns the currently entered time as hours, minutes and seconds.
- virtual wxDateTime GetValue () const

  Returns the currently entered time.
- bool SetTime (int hour, int min, int sec)

  Changes the current time of the control.
- virtual void SetValue (const wxDateTime &dt)

  Changes the current value of the control.

Additional Inherited Members

21.788.2 Constructor & Destructor Documentation

wxTimePickerCtrl::wxTimePickerCtrl ( )

Default constructor.

wxTimePickerCtrl::wxTimePickerCtrl (wxWindow * *parent*, wxWindowID *id*, const wxDateTime & *dt* = wxDefaultDateTime, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, long *style* = wxTP_DEFAULT, const wxValidator & *validator* = wxDefaultValidator, const wxString & *name* = "timectrl")

Initializes the object and calls Create() with all the parameters.

21.788.3 Member Function Documentation

bool wxTimePickerCtrl::Create (wxWindow * *parent*, wxWindowID *id*, const wxDateTime & *dt* = wxDefaultDateTime, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, long *style* = wxDP_DEFAULT|wxDP_SHOWCENTURY, const wxValidator & *validator* = wxDefaultValidator, const wxString & *name* = "timectrl")

Create the control window.

This method should only be used for objects created using default constructor.

Parameters

parent	Parent window, must not be non-NULL.
id	The identifier for the control.
dt	The initial value of the control, if an invalid date (such as the default value) is used, the control is set to current time.
pos	Initial position.
size	Initial size. If left at default value, the control chooses its own best size by using the height approximately equal to a text control and width large enough to show the time fully.
style	The window style, should be left at 0 as there are no special styles for this control in this version.
validator	Validator which can be used for additional checks.
name	Control name.

Returns

true if the control was successfully created or false if creation failed.

bool wxTimePickerCtrl::GetTime (int * *hour*, int * *min*, int * *sec*) const

Returns the currently entered time as hours, minutes and seconds.

All the arguments must be non-NULL, false is returned otherwise and none of them is modified.

See also

SetTime()

Since

2.9.4

virtual wxDateTime wxTimePickerCtrl::GetValue ( ) const [virtual]

Returns the currently entered time.

The date part of the returned wxDateTime object is always set to today and should be ignored, only the time part is relevant.

bool wxTimePickerCtrl::SetTime (int *hour*, int *min*, int *sec*)

Changes the current time of the control.

Calling this method does not result in a time change event.

Parameters

hour	The new hour value in 0..23 interval.
min	The new minute value in 0..59 interval.
sec	The new second value in 0..59 interval.

Returns

true if the time was changed or false on failure, e.g. if the time components were invalid.

See also

GetTime()

Since

2.9.4

virtual void wxTimePickerCtrl::SetValue (const wxDateTime & *dt*) [virtual]

Changes the current value of the control.

The date part of *dt* is ignored, only the time part is displayed in the control. The *dt* object must however be valid.

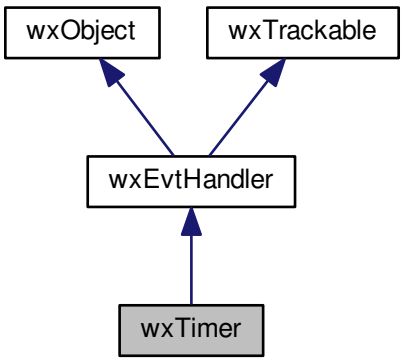
In particular notice that it is a bad idea to use default wxDateTime constructor from hour, minute and second values as it uses the today date for the date part which means that some times can be invalid if today happens to be the day of DST change. For example, when switching to summer time the time 2:00 typically doesn't exist as the clocks jump directly to 3:00. To avoid this problem, use a fixed date on which DST is known not to change (e.g. Jan 1, 2012) for the date part of the argument or use SetTime().

Calling this method does not result in a time change event.

21.789 wxTimer Class Reference

`#include <wx/timer.h>`

Inheritance diagram for wxTimer:



21.789.1 Detailed Description

The wxTimer class allows you to execute code at specified intervals.

Its precision is platform-dependent, but in general will not be better than `1ms` nor worse than `1s`.

There are three different ways to use this class:

- You may derive a new class from wxTimer and override the wxTimer::Notify member to perform the required action.

- You may redirect the notifications to any wxEvtHandler derived object by using the non-default constructor or wxTimer::SetOwner. Then use the `EVT_TIMER` macro to connect it to the event handler which will receive wxTimerEvent notifications.
- You may use a derived class and the `EVT_TIMER` macro to connect it to an event handler defined in the derived class. If the default constructor is used, the timer object will be its own owner object, since it is derived from wxEvtHandler.

In any case, you must start the timer with wxTimer::Start() after constructing it before it actually starts sending notifications. It can be stopped later with wxTimer::Stop().

Note

A timer can only be used from the main thread.

Library: wxBase

Category: Miscellaneous

See also

wxStopWatch

Public Member Functions

- wxTimer ()

  Default constructor.
- wxTimer (wxEvtHandler *owner, int id=-1)

  Creates a timer and associates it with owner.
- virtual ~wxTimer ()

  Destructor.
- int GetId () const

  Returns the ID of the events generated by this timer.
- int GetInterval () const

  Returns the current interval for the timer (in milliseconds).
- wxEvtHandler * GetOwner () const

  Returns the current owner of the timer.
- bool IsOneShot () const

  Returns true if the timer is one shot, i.e. if it will stop after firing the first notification automatically.
- bool IsRunning () const

  Returns true if the timer is running, false if it is stopped.
- virtual void Notify ()

  This member should be overridden by the user if the default constructor was used and SetOwner() wasn't called.
- void SetOwner (wxEvtHandler *owner, int id=-1)

  Associates the timer with the given owner object.
- virtual bool Start (int milliseconds=-1, bool oneShot=wxTIMER_CONTINUOUS)

  (Re)starts the timer.
- bool StartOnce (int milliseconds=-1)

  Starts the timer for a once-only notification.
- virtual void Stop ()

  Stops the timer.

Additional Inherited Members

21.789.2 Constructor & Destructor Documentation

wxTimer::wxTimer ( )

Default constructor.

If you use it to construct the object and don't call SetOwner() later, you must override Notify() method to process the notifications.

wxTimer::wxTimer (wxEvtHandler * *owner*, int *id* = -1)

Creates a timer and associates it with *owner*.

Please see SetOwner() for the description of parameters.

virtual wxTimer::~wxTimer ( ) [virtual]

Destructor.

Stops the timer if it is running.

21.789.3 Member Function Documentation

int wxTimer::GetId ( ) const

Returns the ID of the events generated by this timer.

int wxTimer::GetInterval ( ) const

Returns the current interval for the timer (in milliseconds).

wxEvtHandler* wxTimer::GetOwner ( ) const

Returns the current *owner* of the timer.

If non-NULL this is the event handler which will receive the timer events (see wxTimerEvent) when the timer is running.

bool wxTimer::IsOneShot ( ) const

Returns true if the timer is one shot, i.e. if it will stop after firing the first notification automatically.

bool wxTimer::IsRunning ( ) const

Returns true if the timer is running, false if it is stopped.

virtual void wxTimer::Notify ( ) [virtual]

This member should be overridden by the user if the default constructor was used and SetOwner() wasn't called.

Perform whatever action which is to be taken periodically here.

Notice that throwing exceptions from this method is currently not supported, use event-based timer handling approach if an exception can be thrown while handling timer notifications.

void wxTimer::SetOwner (wxEvtHandler * *owner*, int *id* = -1)

Associates the timer with the given *owner* object.

When the timer is running, the owner will receive timer events (see wxTimerEvent) with *id* equal to *id* specified here.

virtual bool wxTimer::Start (int *milliseconds* = -1, bool *oneShot* = wxTIMER_CONTINUOUS) [virtual]

(Re)starts the timer.

If *milliseconds* parameter is -1 (value by default), the previous value is used. Returns false if the timer could not be started, true otherwise (in MS Windows timers are a limited resource).

If *oneShot* is false (the default), the Notify() function will be called repeatedly until the timer is stopped. If true, it will be called only once and the timer will stop automatically.

To make your code more readable you may also use the following symbolic constants:

- wxTIMER_CONTINUOUS: Start a normal, continuously running, timer
- wxTIMER_ONE_SHOT: Start a one shot timer Alternatively, use StartOnce().

If the timer was already running, it will be stopped by this method before restarting it.

bool wxTimer::StartOnce (int *milliseconds* = -1)

Starts the timer for a once-only notification.

This is a simple wrapper for Start() with `wxTIMER_ONE_SHOT` parameter.

Since

2.9.5

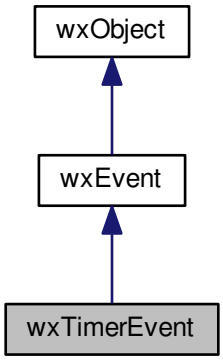
virtual void wxTimer::Stop ( ) [virtual]

Stops the timer.

21.790 wxTimerEvent Class Reference

`#include <wx/timer.h>`

Inheritance diagram for wxTimerEvent:



21.790.1 Detailed Description

wxTimerEvent object is passed to the event handler of timer events (see wxTimer::SetOwner).

For example:

```
class MyFrame : public wxFrame
{
public:
    ...
    void OnTimer(wxTimerEvent& event);

private:
    wxTimer m_timer;
    wxDECLARE_EVENT_TABLE();
};

wxBEGIN_EVENT_TABLE(MyFrame, wxFrame)
    EVT_TIMER(TIMER_ID, MyFrame::OnTimer)
wxEND_EVENT_TABLE()

MyFrame::MyFrame()
       : m_timer(this, TIMER_ID)
{
    m_timer.Start(1000);    // 1 second interval
}

void MyFrame::OnTimer(wxTimerEvent& event)
{
    // do whatever you want to do every second here
}
```

Library: wxBase

void wxTimerRunner::Start (int *milli,* bool *oneShot* = `false`)

21.792 wxTimeSpan Class Reference

```
#include <wx/datetime.h>
```

21.792.1 Detailed Description

wxTimeSpan class represents a time interval.

Library: wxBase

Category: Data Structures

See also

Date and Time, wxDateTime

Public Member Functions

- wxTimeSpan ()

  Default constructor, constructs a zero timespan.
- wxTimeSpan (long hours, long min=0, wxLongLong sec=0, wxLongLong msec=0)

  Constructs timespan from separate values for each component, with the date set to 0.
- wxTimeSpan Abs () const

  Returns the absolute value of the timespan: does not modify the object.
- wxTimeSpan Add (const wxTimeSpan &diff) const

  Returns the sum of two time spans.
- wxTimeSpan & Add (const wxTimeSpan &diff)

  Adds the given wxTimeSpan to this wxTimeSpan and returns a reference to itself.
- wxString Format (const wxString &format=wxDefaultTimeSpanFormat) const

  Returns the string containing the formatted representation of the time span.
- int GetDays () const

  Returns the difference in number of days.
- int GetHours () const

  Returns the difference in number of hours.
- wxLongLong GetMilliseconds () const

  Returns the difference in number of milliseconds.
- int GetMinutes () const

  Returns the difference in number of minutes.
- wxLongLong GetSeconds () const

  Returns the difference in number of seconds.
- wxLongLong GetValue () const

  Returns the internal representation of timespan.
- int GetWeeks () const

  Returns the difference in number of weeks.
- bool IsEqualTo (const wxTimeSpan &ts) const

  Returns true if two timespans are equal.
- bool IsLongerThan (const wxTimeSpan &ts) const

  Compares two timespans: works with the absolute values, i.e. -2 hours is longer than 1 hour.
- bool IsNegative () const

Returns true if the timespan is negative.

- bool IsNull () const

  Returns true if the timespan is empty.

- bool IsPositive () const

  Returns true if the timespan is positive.

- bool IsShorterThan (const wxTimeSpan &ts) const

  Compares two timespans: works with the absolute values, i.e. 1 hour is shorter than -2 hours.

- wxTimeSpan Multiply (int n) const

  Returns the product of this time span by n.

- wxTimeSpan & Multiply (int n)

  Multiplies this time span by n.

- wxTimeSpan & Neg ()

  Negate the value of the timespan.

- wxTimeSpan Negate () const

  Returns timespan with inverted sign.

- wxTimeSpan Subtract (const wxTimeSpan &diff) const

  Returns the difference of two time spans.

- wxTimeSpan & Subtract (const wxTimeSpan &diff)

  Subtracts the given wxTimeSpan to this wxTimeSpan and returns a reference to itself.

- wxTimeSpan & operator+= (const wxTimeSpan &diff)

  Adds the given wxTimeSpan to this wxTimeSpan and returns the result.

- wxTimeSpan & operator*= (int n)

  Multiplies this time span by n.

- wxTimeSpan & operator- ()

  Negate the value of the timespan.

- wxTimeSpan & operator-= (const wxTimeSpan &diff)

  Subtracts the given wxTimeSpan to this wxTimeSpan and returns the result.

Static Public Member Functions

- static wxTimeSpan Day ()

  Returns the timespan for one day.

- static wxTimeSpan Days (long days)

  Returns the timespan for the given number of days.

- static wxTimeSpan Hour ()

  Returns the timespan for one hour.

- static wxTimeSpan Hours (long hours)

  Returns the timespan for the given number of hours.

- static wxTimeSpan Millisecond ()

  Returns the timespan for one millisecond.

- static wxTimeSpan Milliseconds (wxLongLong ms)

  Returns the timespan for the given number of milliseconds.

- static wxTimeSpan Minute ()

  Returns the timespan for one minute.

- static wxTimeSpan Minutes (long min)

  Returns the timespan for the given number of minutes.

- static wxTimeSpan Second ()

  Returns the timespan for one second.

- static wxTimeSpan Seconds (wxLongLong sec)

  Returns the timespan for the given number of seconds.

- static wxTimeSpan Week ()

  Returns the timespan for one week.
- static wxTimeSpan Weeks (long weeks)

  Returns the timespan for the given number of weeks.

21.792.2 Constructor & Destructor Documentation

wxTimeSpan::wxTimeSpan ( )

Default constructor, constructs a zero timespan.

wxTimeSpan::wxTimeSpan (long *hours*, long *min* = `0`, wxLongLong *sec* = `0`, wxLongLong *msec* = `0`)

Constructs timespan from separate values for each component, with the date set to 0.

Hours are not restricted to 0-24 range, neither are minutes, seconds or milliseconds.

21.792.3 Member Function Documentation

wxTimeSpan wxTimeSpan::Abs ( ) const

Returns the absolute value of the timespan: does not modify the object.

wxTimeSpan wxTimeSpan::Add (const wxTimeSpan & *diff*) const

Returns the sum of two time spans.

Returns

A new wxDateSpan object with the result.

wxTimeSpan& wxTimeSpan::Add (const wxTimeSpan & *diff*)

Adds the given wxTimeSpan to this wxTimeSpan and returns a reference to itself.

static wxTimeSpan wxTimeSpan::Day ( ) `[static]`

Returns the timespan for one day.

static wxTimeSpan wxTimeSpan::Days (long *days*) `[static]`

Returns the timespan for the given number of days.

wxString wxTimeSpan::Format (const wxString & *format* = `wxDefaultTimeSpanFormat`) const

Returns the string containing the formatted representation of the time span.

The following format specifiers are allowed after %:

- `H` - Number of Hours
- `M` - Number of Minutes

- `S` - Number of Seconds
- `l` - Number of Milliseconds
- `D` - Number of Days
- `E` - Number of Weeks
- `%` - The percent character

Note that, for example, the number of hours in the description above is not well defined: it can be either the total number of hours (for example, for a time span of 50 hours this would be 50) or just the hour part of the time span, which would be 2 in this case as 50 hours is equal to 2 days and 2 hours.

wxTimeSpan resolves this ambiguity in the following way: if there had been, indeed, the `D` format specified preceding the `H`, then it is interpreted as 2. Otherwise, it is 50.

The same applies to all other format specifiers: if they follow a specifier of larger unit, only the rest part is taken, otherwise the full value is used.

int wxTimeSpan::GetDays ( ) const

Returns the difference in number of days.

int wxTimeSpan::GetHours ( ) const

Returns the difference in number of hours.

wxLongLong wxTimeSpan::GetMilliseconds ( ) const

Returns the difference in number of milliseconds.

int wxTimeSpan::GetMinutes ( ) const

Returns the difference in number of minutes.

wxLongLong wxTimeSpan::GetSeconds ( ) const

Returns the difference in number of seconds.

wxLongLong wxTimeSpan::GetValue ( ) const

Returns the internal representation of timespan.

int wxTimeSpan::GetWeeks ( ) const

Returns the difference in number of weeks.

static wxTimeSpan wxTimeSpan::Hour ( ) [static]

Returns the timespan for one hour.

static wxTimeSpan wxTimeSpan::Hours (long *hours*) `[static]`

Returns the timespan for the given number of hours.

bool wxTimeSpan::IsEqualTo (const wxTimeSpan & *ts*) const

Returns true if two timespans are equal.

bool wxTimeSpan::IsLongerThan (const wxTimeSpan & *ts*) const

Compares two timespans: works with the absolute values, i.e. -2 hours is longer than 1 hour.
Also, it will return false if the timespans are equal in absolute value.

bool wxTimeSpan::IsNegative ( ) const

Returns true if the timespan is negative.

bool wxTimeSpan::IsNull ( ) const

Returns true if the timespan is empty.

bool wxTimeSpan::IsPositive ( ) const

Returns true if the timespan is positive.

bool wxTimeSpan::IsShorterThan (const wxTimeSpan & *ts*) const

Compares two timespans: works with the absolute values, i.e. 1 hour is shorter than -2 hours.
Also, it will return false if the timespans are equal in absolute value.

static wxTimeSpan wxTimeSpan::Millisecond ( ) `[static]`

Returns the timespan for one millisecond.

static wxTimeSpan wxTimeSpan::Milliseconds (wxLongLong *ms*) `[static]`

Returns the timespan for the given number of milliseconds.

static wxTimeSpan wxTimeSpan::Minute ( ) `[static]`

Returns the timespan for one minute.

static wxTimeSpan wxTimeSpan::Minutes (long *min*) `[static]`

Returns the timespan for the given number of minutes.

wxTimeSpan wxTimeSpan::Multiply (int *n*) const

Returns the product of this time span by *n*.

Returns

A new wxTimeSpan object with the result.

wxTimeSpan& wxTimeSpan::Multiply (int *n*)

Multiplies this time span by *n*.

Returns

A reference to this wxTimeSpan object modified in place.

wxTimeSpan& wxTimeSpan::Neg ( )

Negate the value of the timespan.

See also

Negate()

wxTimeSpan wxTimeSpan::Negate ( ) const

Returns timespan with inverted sign.

See also

Neg()

wxTimeSpan& wxTimeSpan::operator*= (int *n*)

Multiplies this time span by *n*.

Returns

A reference to this wxTimeSpan object modified in place.

wxTimeSpan& wxTimeSpan::operator+= (const wxTimeSpan & *diff*)

Adds the given wxTimeSpan to this wxTimeSpan and returns the result.

wxTimeSpan& wxTimeSpan::operator- ( )

Negate the value of the timespan.

See also

Negate()

wxTimeSpan& wxTimeSpan::operator-= (const wxTimeSpan & *diff*)

Subtracts the given wxTimeSpan to this wxTimeSpan and returns the result.

static wxTimeSpan wxTimeSpan::Second ( ) [static]

Returns the timespan for one second.

static wxTimeSpan wxTimeSpan::Seconds (wxLongLong *sec*) [static]

Returns the timespan for the given number of seconds.

wxTimeSpan wxTimeSpan::Subtract (const wxTimeSpan & *diff*) const

Returns the difference of two time spans.

Returns

A new wxDateSpan object with the result.

wxTimeSpan& wxTimeSpan::Subtract (const wxTimeSpan & *diff*)

Subtracts the given wxTimeSpan to this wxTimeSpan and returns a reference to itself.

static wxTimeSpan wxTimeSpan::Week ( ) [static]

Returns the timespan for one week.

static wxTimeSpan wxTimeSpan::Weeks (long *weeks*) [static]

Returns the timespan for the given number of weeks.

21.793 wxTipProvider Class Reference

```
#include <wx/tipdlg.h>
```

21.793.1 Detailed Description

This is the class used together with wxShowTip() function.

It must implement wxTipProvider::GetTip function and return the current tip from it (different tip each time it is called).

You will never use this class yourself, but you need it to show startup tips with wxShowTip. Also, if you want to get the tips text from elsewhere than a simple text file, you will want to derive a new class from wxTipProvider and use it instead of the one returned by wxCreateFileTipProvider().

Library: wxAdvanced

Category: Miscellaneous

See also

wxTipProvider Overview, wxShowTip

Public Member Functions

- wxTipProvider (size_t currentTip)

  Constructor.

- virtual ~wxTipProvider ()
- size_t GetCurrentTip () const

  Returns the index of the current tip (i.e. the one which would be returned by GetTip()).

- virtual wxString GetTip ()=0

  Return the text of the current tip and pass to the next one.

21.793.2 Constructor & Destructor Documentation

wxTipProvider::wxTipProvider (size_t *currentTip*)

Constructor.

Parameters

currentTip	The starting tip index.

virtual wxTipProvider::~wxTipProvider ( ) [virtual]

21.793.3 Member Function Documentation

size_t wxTipProvider::GetCurrentTip ( ) const

Returns the index of the current tip (i.e. the one which would be returned by GetTip()).

The program usually remembers the value returned by this function after calling wxShowTip(). Note that it is not the same as the value which was passed to wxShowTip + 1 because the user might have pressed the "Next" button in the tip dialog.

virtual wxString wxTipProvider::GetTip ( ) [pure virtual]

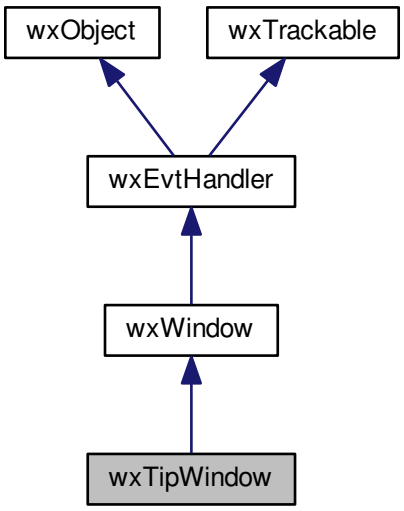
Return the text of the current tip and pass to the next one.

This function is pure virtual, it should be implemented in the derived classes.

21.794 wxTipWindow Class Reference

```
#include <wx/tipwin.h>
```

Inheritance diagram for wxTipWindow:



21.794.1 Detailed Description

Shows simple text in a popup tip window on creation.

This is used by wxSimpleHelpProvider to show popup help. The window automatically destroys itself when the user clicks on it or it loses the focus.

You may also use this class to emulate the tooltips when you need finer control over them than what the standard tooltips provide.

Library: wxCore

Category: Managed Windows

Public Member Functions

- wxTipWindow (wxWindow *parent, const wxString &text, wxCoord maxLength=100, wxTipWindow **windowPtr=NULL, wxRect *rectBounds=NULL)

  Constructor.

- void SetBoundingRect (const wxRect &rectBound)

  By default, the tip window disappears when the user clicks the mouse or presses a keyboard key or if it loses focus in any other way - for example because the user switched to another application window.

- void SetTipWindowPtr (wxTipWindow **windowPtr)

  When the tip window closes itself (which may happen at any moment and unexpectedly to the caller) it may NULL out the pointer pointed to by windowPtr.

Additional Inherited Members

21.794.2 Constructor & Destructor Documentation

wxTipWindow::wxTipWindow (wxWindow * *parent,* const wxString & *text,* wxCoord *maxLength* = 100, wxTipWindow ** *windowPtr* = NULL, wxRect * *rectBounds* = NULL)

Constructor.

The tip is shown immediately after the window is constructed.

Parameters

parent	The parent window, must be non-NULL
text	The text to show, may contain the new line characters
maxLength	The length of each line, in pixels. Set to a very large value to avoid wrapping lines
windowPtr	Simply passed to SetTipWindowPtr() below, please see its documentation for the description of this parameter
rectBounds	If non-NULL, passed to SetBoundingRect() below, please see its documentation for the description of this parameter

21.794.3 Member Function Documentation

void wxTipWindow::SetBoundingRect (const wxRect & *rectBound*)

By default, the tip window disappears when the user clicks the mouse or presses a keyboard key or if it loses focus in any other way - for example because the user switched to another application window.

Additionally, if a non-empty *rectBound* is provided, the tip window will also automatically close if the mouse leaves this area. This is useful to dismiss the tip mouse when the mouse leaves the object it is associated with.

Parameters

rectBound	The bounding rectangle for the mouse in the screen coordinates

void wxTipWindow::SetTipWindowPtr (wxTipWindow ** *windowPtr*)

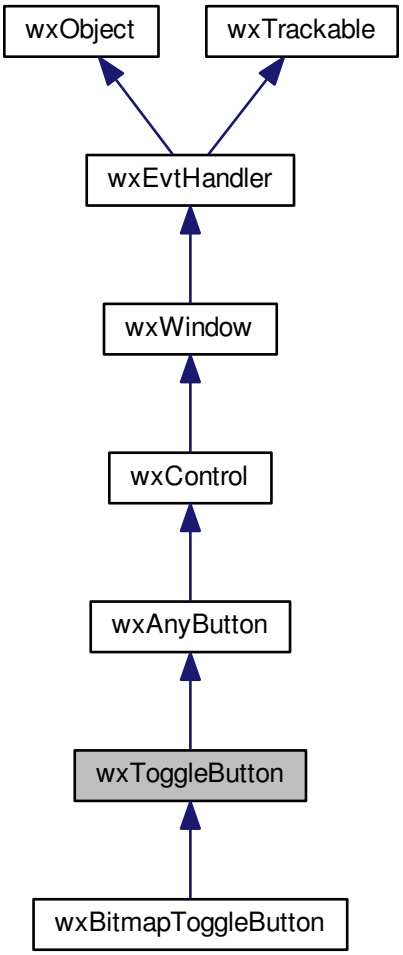
When the tip window closes itself (which may happen at any moment and unexpectedly to the caller) it may NULL out the pointer pointed to by *windowPtr*.

This is helpful to avoid dereferencing the tip window which had been already closed and deleted.

21.795 wxToggleButton Class Reference

`#include <wx/tglbtn.h>`

Inheritance diagram for wxToggleButton:



21.795.1 Detailed Description

wxToggleButton is a button that stays pressed when clicked by the user.

In other words, it is similar to wxCheckBox in functionality but looks like a wxButton.

Since wxWidgets version 2.9.0 this control emits an update UI event.

You can see wxToggleButton in action in Controls Sample.

Events emitted by this class

The following event handler macros redirect the events to member function handlers '**func**' with prototypes like: void handlerFuncName(wxCommandEvent& event)

Event macros for events emitted by this class:

- EVT_TOGGLEBUTTON(id, func): Handles a wxEVT_TOGGLEBUTTON event.

Library: wxCore

Category: Controls

See also

wxCheckBox, wxButton, wxBitmapToggleButton

Public Member Functions

- wxToggleButton ()

  Default constructor.
- wxToggleButton (wxWindow *parent, wxWindowID id, const wxString &label, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, long style=0, const wxValidator &val=wxDefaultValidator, const wxString &name=wxCheckBoxNameStr)

  Constructor, creating and showing a toggle button.
- virtual ~wxToggleButton ()

  Destructor, destroying the toggle button.
- bool Create (wxWindow *parent, wxWindowID id, const wxString &label, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, long style=0, const wxValidator &val=wxDefaultValidator, const wxString &name=wxCheckBoxNameStr)

  Creates the toggle button for two-step construction.
- virtual bool GetValue () const

  Gets the state of the toggle button.
- virtual void SetValue (bool state)

  Sets the toggle button to the given state.

Additional Inherited Members

21.795.2 Constructor & Destructor Documentation

wxToggleButton::wxToggleButton ( )

Default constructor.

wxToggleButton::wxToggleButton (wxWindow * *parent*, wxWindowID *id*, const wxString & *label*, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, long *style* = `0`, const wxValidator & *val* = wxDefaultValidator, const wxString & *name* = `wxCheckBoxNameStr`)

Constructor, creating and showing a toggle button.

Parameters

parent	Parent window. Must not be NULL.
id	Toggle button identifier. The value wxID_ANY indicates a default value.
label	Text to be displayed next to the toggle button.
pos	Toggle button position. If wxDefaultPosition is specified then a default position is chosen.
size	Toggle button size. If wxDefaultSize is specified then a default size is chosen.

style	Window style. See wxToggleButton.
val	Window validator.
name	Window name.

See also

Create(), wxValidator

virtual wxToggleButton::~wxToggleButton ( ) [virtual]

Destructor, destroying the toggle button.

21.795.3 Member Function Documentation

bool wxToggleButton::Create (wxWindow * *parent*, wxWindowID *id*, const wxString & *label*, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, long *style* = 0, const wxValidator & *val* = wxDefaultValidator, const wxString & *name* = wxCheckBoxNameStr)

Creates the toggle button for two-step construction.

See wxToggleButton() for details.

virtual bool wxToggleButton::GetValue ( ) const [virtual]

Gets the state of the toggle button.

Returns

Returns true if it is pressed, false otherwise.

Reimplemented in wxBitmapToggleButton.

virtual void wxToggleButton::SetValue (bool *state*) [virtual]

Sets the toggle button to the given state.

This does not cause a EVT_TOGGLEBUTTON event to be emitted.

Parameters

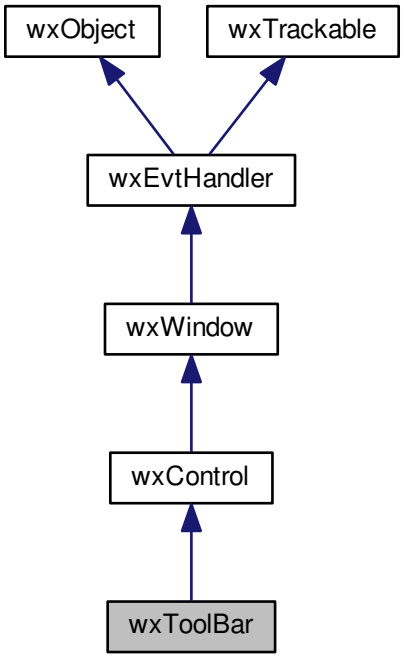
state	If true, the button is pressed.

Reimplemented in wxBitmapToggleButton.

21.796 wxToolBar Class Reference

```
#include <wx/toolbar.h>
```

Inheritance diagram for wxToolBar:



21.796.1 Detailed Description

A toolbar is a bar of buttons and/or other controls usually placed below the menu bar in a wxFrame.

You may create a toolbar that is managed by a frame calling wxFrame::CreateToolBar(). Under Pocket PC, you should always use this function for creating the toolbar to be managed by the frame, so that wxWidgets can use a combined menubar and toolbar. Where you manage your own toolbars, create wxToolBar as usual.

There are several different types of tools you can add to a toolbar. These types are controlled by the wxItemKind enumeration.

Note that many methods in wxToolBar such as wxToolBar::AddTool return a `wxToolBarToolBase*` object. This should be regarded as an opaque handle representing the newly added toolbar item, providing access to its id and position within the toolbar. Changes to the item's state should be made through calls to wxToolBar methods, for example wxToolBar::EnableTool. Calls to `wxToolBarToolBase` methods (undocumented by purpose) will not change the visible state of the item within the tool bar.

wxMSW note: Note that under wxMSW toolbar paints tools to reflect system-wide colours. If you use more than 16 colours in your tool bitmaps, you may wish to suppress this behaviour, otherwise system colours in your bitmaps will inadvertently be mapped to system colours. To do this, set the msw.remap system option before creating the toolbar:

```
wxSystemOptions::SetOption("msw.remap", 0);
```

If you wish to use 32-bit images (which include an alpha channel for transparency) use:

```
wxSystemOptions::SetOption("msw.remap", 2);
```

Then colour remapping is switched off, and a transparent background used. But only use this option under Windows XP with true colour:

```
if (wxTheApp->GetComCtl32Version() >= 600 && ::wxDisplayDepth() >= 32)
```

Styles

This class supports the following styles:

- wxTB_FLAT: Gives the toolbar a flat look (Windows and GTK only).
- wxTB_DOCKABLE: Makes the toolbar floatable and dockable (GTK only).
- wxTB_HORIZONTAL: Specifies horizontal layout (default).
- wxTB_VERTICAL: Specifies vertical layout.
- wxTB_TEXT: Shows the text in the toolbar buttons; by default only icons are shown.
- wxTB_NOICONS: Specifies no icons in the toolbar buttons; by default they are shown.
- wxTB_NODIVIDER: Specifies no divider (border) above the toolbar (Windows only)
- wxTB_NOALIGN: Specifies no alignment with the parent window (Windows only, not very useful).
- wxTB_HORZ_LAYOUT: Shows the text and the icons alongside, not vertically stacked (Windows and GTK 2 only). This style must be used with `wxTB_TEXT`.
- wxTB_HORZ_TEXT: Combination of `wxTB_HORZ_LAYOUT` and `wxTB_TEXT`.
- wxTB_NO_TOOLTIPS: Don't show the short help tooltips for the tools when the mouse hovers over them.
- wxTB_BOTTOM: Align the toolbar at the bottom of parent window.
- wxTB_RIGHT: Align the toolbar at the right side of parent window.
- wxTB_DEFAULT_STYLE: Combination of `wxTB_HORIZONTAL` and `wxTB_FLAT`. This style is new since wxWidgets 2.9.5.

See also Window Styles. Note that the wxMSW native toolbar ignores `wxTB_NOICONS` style. Also, toggling the `wxTB_TEXT` works only if the style was initially on.

Events emitted by this class

The following event handler macros redirect the events to member function handlers '**func**' with prototypes like: void handlerFuncName(wxCommandEvent& event)

Event macros for events emitted by this class:

- EVT_TOOL(id, func): Process a `wxEVT_TOOL` event (a synonym for `wxEVT_MENU`). Pass the id of the tool.
- EVT_MENU(id, func): The same as EVT_TOOL().
- EVT_TOOL_RANGE(id1, id2, func): Process a `wxEVT_TOOL` event for a range of identifiers. Pass the ids of the tools.
- EVT_MENU_RANGE(id1, id2, func): The same as EVT_TOOL_RANGE().
- EVT_TOOL_RCLICKED(id, func): Process a `wxEVT_TOOL_RCLICKED` event. Pass the id of the tool. (Not available on wxOSX.)
- EVT_TOOL_RCLICKED_RANGE(id1, id2, func): Process a `wxEVT_TOOL_RCLICKED` event for a range of ids. Pass the ids of the tools. (Not available on wxOSX.)
- EVT_TOOL_ENTER(id, func): Process a `wxEVT_TOOL_ENTER` event. Pass the id of the toolbar itself. The value of wxCommandEvent::GetSelection() is the tool id, or -1 if the mouse cursor has moved off a tool. (Not available on wxOSX.)

- EVT_TOOL_DROPDOWN(id, func): Process a `wxEVT_TOOL_DROPDOWN` event. If unhandled, displays the default dropdown menu set using wxToolBar::SetDropdownMenu().

The toolbar class emits menu commands in the same way that a frame menubar does, so you can use one EVT_MENU() macro for both a menu item and a toolbar button. The event handler functions take a wxCommandEvent argument. For most event macros, the identifier of the tool is passed, but for EVT_TOOL_ENTER() the toolbar window identifier is passed and the tool identifier is retrieved from the wxCommandEvent. This is because the identifier may be `wxID_ANY` when the mouse moves off a tool, and `wxID_ANY` is not allowed as an identifier in the event system.

Library: wxCore

Category: Miscellaneous Windows

Toolbar Overview

Public Member Functions

- wxToolBar ()

  Default constructor.
- wxToolBar (wxWindow *parent, wxWindowID id, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, long style=wxTB_HORIZONTAL, const wxString &name=wxToolBarNameStr)

  Constructs a toolbar.
- virtual ~wxToolBar ()

  Toolbar destructor.
- wxToolBarToolBase * AddCheckTool (int toolId, const wxString &label, const wxBitmap &bitmap1, const wxBitmap &bmpDisabled=wxNullBitmap, const wxString &shortHelp=wxEmptyString, const wxString &longHelp=wxEmptyString, wxObject *clientData=NULL)

  Adds a new check (or toggle) tool to the toolbar.
- virtual wxToolBarToolBase * AddControl (wxControl *control, const wxString &label=wxEmptyString)

  Adds any control to the toolbar, typically e.g. a wxComboBox.
- wxToolBarToolBase * AddRadioTool (int toolId, const wxString &label, const wxBitmap &bitmap1, const wxBitmap &bmpDisabled=wxNullBitmap, const wxString &shortHelp=wxEmptyString, const wxString &longHelp=wxEmptyString, wxObject *clientData=NULL)

  Adds a new radio tool to the toolbar.
- virtual wxToolBarToolBase * AddSeparator ()

  Adds a separator for spacing groups of tools.
- wxToolBarToolBase * AddStretchableSpace ()

  Adds a stretchable space to the toolbar.
- virtual void ClearTools ()

  Deletes all the tools in the toolbar.
- virtual bool DeleteTool (int toolId)

  Removes the specified tool from the toolbar and deletes it.
- virtual bool DeleteToolByPos (size_t pos)

  This function behaves like DeleteTool() but it deletes the tool at the specified position and not the one with the given id.
- virtual void EnableTool (int toolId, bool enable)

  Enables or disables the tool.
- wxToolBarToolBase * FindById (int id) const

  Returns a pointer to the tool identified by id or NULL if no corresponding tool is found.

- virtual wxControl * FindControl (int id)

  Returns a pointer to the control identified by id or NULL if no corresponding control is found.
- virtual wxToolBarToolBase * FindToolForPosition (wxCoord x, wxCoord y) const

  Finds a tool for the given mouse position.
- wxSize GetMargins () const

  Returns the left/right and top/bottom margins, which are also used for inter-toolspacing.
- virtual wxSize GetToolBitmapSize () const

  Returns the size of bitmap that the toolbar expects to have.
- const wxToolBarToolBase * GetToolByPos (int pos) const

  Returns a pointer to the tool at ordinal position pos.
- virtual wxObject * GetToolClientData (int toolId) const

  Get any client data associated with the tool.
- virtual bool GetToolEnabled (int toolId) const

  Called to determine whether a tool is enabled (responds to user input).
- virtual wxString GetToolLongHelp (int toolId) const

  Returns the long help for the given tool.
- virtual int GetToolPacking () const

  Returns the value used for packing tools.
- virtual int GetToolPos (int toolId) const

  Returns the tool position in the toolbar, or `wxNOT_FOUND` if the tool is not found.
- virtual int GetToolSeparation () const

  Returns the default separator size.
- virtual wxString GetToolShortHelp (int toolId) const

  Returns the short help for the given tool.
- virtual wxSize GetToolSize () const

  Returns the size of a whole button, which is usually larger than a tool bitmap because of added 3D effects.
- virtual bool GetToolState (int toolId) const

  Gets the on/off state of a toggle tool.
- size_t GetToolsCount () const

  Returns the number of tools in the toolbar.
- virtual wxToolBarToolBase * InsertControl (size_t pos, wxControl *control, const wxString &label=wxEmptyString)

  Inserts the control into the toolbar at the given position.
- virtual wxToolBarToolBase * InsertSeparator (size_t pos)

  Inserts the separator into the toolbar at the given position.
- wxToolBarToolBase * InsertStretchableSpace (size_t pos)

  Inserts a stretchable space at the given position.
- virtual bool OnLeftClick (int toolId, bool toggleDown)

  Called when the user clicks on a tool with the left mouse button.
- virtual void OnMouseEnter (int toolId)

  This is called when the mouse cursor moves into a tool or out of the toolbar.
- virtual void OnRightClick (int toolId, long x, long y)
- virtual bool Realize ()

  This function should be called after you have added tools.
- virtual wxToolBarToolBase * RemoveTool (int id)

  Removes the given tool from the toolbar but doesn't delete it.
- void SetBitmapResource (int resourceId)

  Sets the bitmap resource identifier for specifying tool bitmaps as indices into a custom bitmap.
- bool SetDropdownMenu (int id, wxMenu *menu)

  Sets the dropdown menu for the tool given by its id.
- virtual void SetToolBitmapSize (const wxSize &size)

Sets the default size of each tool bitmap.

- virtual void SetToolClientData (int id, wxObject *clientData)

  Sets the client data associated with the tool.
- virtual void SetToolDisabledBitmap (int id, const wxBitmap &bitmap)

  Sets the bitmap to be used by the tool with the given ID when the tool is in a disabled state.
- virtual void SetToolLongHelp (int toolId, const wxString &helpString)

  Sets the long help for the given tool.
- virtual void SetToolNormalBitmap (int id, const wxBitmap &bitmap)

  Sets the bitmap to be used by the tool with the given ID.
- virtual void SetToolPacking (int packing)

  Sets the value used for spacing tools.
- virtual void SetToolSeparation (int separation)

  Sets the default separator size.
- virtual void SetToolShortHelp (int toolId, const wxString &helpString)

  Sets the short help for the given tool.
- virtual void ToggleTool (int toolId, bool toggle)

  Toggles a tool on or off.
- virtual wxToolBarToolBase * CreateTool (int toolId, const wxString &label, const wxBitmap &bmpNormal, const wxBitmap &bmpDisabled=wxNullBitmap, wxItemKind kind=wxITEM_NORMAL, wxObject *clientData=NULL, const wxString &shortHelp=wxEmptyString, const wxString &longHelp=wxEmptyString)

  Factory function to create a new toolbar tool.
- virtual wxToolBarToolBase * CreateTool (wxControl *control, const wxString &label)

  Factory function to create a new control toolbar tool.

- virtual wxToolBarToolBase * AddTool (wxToolBarToolBase *tool)

  Adds a tool to the toolbar.
- wxToolBarToolBase * AddTool (int toolId, const wxString &label, const wxBitmap &bitmap, const wxString &shortHelp=wxEmptyString, wxItemKind kind=wxITEM_NORMAL)

  Adds a tool to the toolbar.
- wxToolBarToolBase * AddTool (int toolId, const wxString &label, const wxBitmap &bitmap, const wxBitmap &bmpDisabled, wxItemKind kind=wxITEM_NORMAL, const wxString &shortHelpString=wxEmptyString, const wxString &longHelpString=wxEmptyString, wxObject *clientData=NULL)

  Adds a tool to the toolbar.

- wxToolBarToolBase * InsertTool (size_t pos, int toolId, const wxString &label, const wxBitmap &bitmap, const wxBitmap &bmpDisabled=wxNullBitmap, wxItemKind kind=wxITEM_NORMAL, const wxString &shortHelp=wxEmptyString, const wxString &longHelp=wxEmptyString, wxObject *clientData=NULL)

  Inserts the tool with the specified attributes into the toolbar at the given position.
- wxToolBarToolBase * InsertTool (size_t pos, wxToolBarToolBase *tool)

  Inserts the tool with the specified attributes into the toolbar at the given position.

- virtual void SetMargins (int x, int y)

  Set the values to be used as margins for the toolbar.
- void SetMargins (const wxSize &size)

  Set the margins for the toolbar.

Additional Inherited Members

21.796.2 Constructor & Destructor Documentation

wxToolBar::wxToolBar ( )

Default constructor.

wxToolBar::wxToolBar (wxWindow * *parent*, wxWindowID *id*, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, long *style* = wxTB_HORIZONTAL, const wxString & *name* = `wxToolBarNameStr`)

Constructs a toolbar.

Parameters

parent	Pointer to a parent window.
id	Window identifier. If -1, will automatically create an identifier.
pos	Window position. wxDefaultPosition indicates that wxWidgets should generate a default position for the window. If using the wxWindow class directly, supply an actual position.
size	Window size. wxDefaultSize indicates that wxWidgets should generate a default size for the window.
style	Window style. See wxToolBar initial description for details.
name	Window name.

Remarks

After a toolbar is created, you use AddTool() and perhaps AddSeparator(), and then you must call Realize() to construct and display the toolbar tools.

virtual wxToolBar::~wxToolBar ( ) [virtual]

Toolbar destructor.

21.796.3 Member Function Documentation

wxToolBarToolBase* wxToolBar::AddCheckTool (int *toolId*, const wxString & *label*, const wxBitmap & *bitmap1*, const wxBitmap & *bmpDisabled* = wxNullBitmap, const wxString & *shortHelp* = wxEmptyString, const wxString & *longHelp* = wxEmptyString, wxObject * *clientData* = NULL)

Adds a new check (or toggle) tool to the toolbar.

The parameters are the same as in AddTool().

See also

AddTool()

virtual wxToolBarToolBase* wxToolBar::AddControl (wxControl * *control*, const wxString & *label* = wxEmptyString) [virtual]

Adds any control to the toolbar, typically e.g. a wxComboBox.

Parameters

control	The control to be added.
label	Text to be displayed near the control.

Remarks

wxMSW: the label is only displayed if there is enough space available below the embedded control.
wxMac: labels are only displayed if wxWidgets is built with wxMAC_USE_NATIVE_TOOLBAR set to 1

wxToolBarToolBase* wxToolBar::AddRadioTool (int *toolId*, const wxString & *label*, const wxBitmap & *bitmap1*, const wxBitmap & *bmpDisabled* = wxNullBitmap, const wxString & *shortHelp* = wxEmptyString, const wxString & *longHelp* = wxEmptyString, wxObject * *clientData* = NULL)

Adds a new radio tool to the toolbar.

Consecutive radio tools form a radio group such that exactly one button in the group is pressed at any moment, in other words whenever a button in the group is pressed the previously pressed button is automatically released. You should avoid having the radio groups of only one element as it would be impossible for the user to use such button.

By default, the first button in the radio group is initially pressed, the others are not.

See also

AddTool()

virtual wxToolBarToolBase* wxToolBar::AddSeparator ( ) [virtual]

Adds a separator for spacing groups of tools.

Notice that the separator uses the look appropriate for the current platform so it can be a vertical line (MSW, some versions of GTK) or just an empty space or something else.

See also

AddTool(), SetToolSeparation(), AddStretchableSpace()

wxToolBarToolBase* wxToolBar::AddStretchableSpace ( )

Adds a stretchable space to the toolbar.

Any space not taken up by the fixed items (all items except for stretchable spaces) is distributed in equal measure between the stretchable spaces in the toolbar. The most common use for this method is to add a single stretchable space before the items which should be right-aligned in the toolbar, but more exotic possibilities are possible, e.g. a stretchable space may be added in the beginning and the end of the toolbar to centre all toolbar items.

See also

AddTool(), AddSeparator(), InsertStretchableSpace()

Since

2.9.1

virtual wxToolBarToolBase* wxToolBar::AddTool (wxToolBarToolBase * *tool*) [virtual]

Adds a tool to the toolbar.

Parameters

tool	The tool to be added.

Remarks

After you have added tools to a toolbar, you must call Realize() in order to have the tools appear.

See also

AddSeparator(), AddCheckTool(), AddRadioTool(), InsertTool(), DeleteTool(), Realize(), SetDropdownMenu()

wxToolBarToolBase* **wxToolBar::AddTool** (**int** *toolId*, **const wxString &** *label*, **const wxBitmap &** *bitmap*, **const wxString &** *shortHelp* = **wxEmptyString**, **wxItemKind** *kind* = **wxITEM_NORMAL**)

Adds a tool to the toolbar.

This most commonly used version has fewer parameters than the full version below which specifies the more rarely used button features.

Parameters

toolId	An integer by which the tool may be identified in subsequent operations.
label	The string to be displayed with the tool.
bitmap	The primary tool bitmap.
shortHelp	This string is used for the tools tooltip.
kind	May be wxITEM_NORMAL for a normal button (default), wxITEM_CHECK for a checkable tool (such tool stays pressed after it had been toggled) or wxITEM_RADIO for a checkable tool which makes part of a radio group of tools each of which is automatically unchecked whenever another button in the group is checked. wxITEM_DROPDOWN specifies that a drop-down menu button will appear next to the tool button (only GTK+ and MSW). Call SetDropdownMenu() afterwards.

Remarks

After you have added tools to a toolbar, you must call Realize() in order to have the tools appear.

See also

AddSeparator(), AddCheckTool(), AddRadioTool(), InsertTool(), DeleteTool(), Realize(), SetDropdownMenu()

wxToolBarToolBase* wxToolBar::AddTool (int *toolId*, const wxString & *label*, const wxBitmap & *bitmap*, const wxBitmap & *bmpDisabled*, wxItemKind *kind* = wxITEM_NORMAL, const wxString & *shortHelpString* = wxEmptyString, const wxString & *longHelpString* = wxEmptyString, wxObject * *clientData* = NULL)

Adds a tool to the toolbar.

Parameters

toolId	An integer by which the tool may be identified in subsequent operations.
label	The string to be displayed with the tool.
bitmap	The primary tool bitmap.
bmpDisabled	The bitmap used when the tool is disabled. If it is equal to wxNullBitmap (default), the disabled bitmap is automatically generated by greying the normal one.
kind	May be wxITEM_NORMAL for a normal button (default), wxITEM_CHECK for a checkable tool (such tool stays pressed after it had been toggled) or wxITEM_RADIO for a checkable tool which makes part of a radio group of tools each of which is automatically unchecked whenever another button in the group is checked. wxITEM_DROPDOWN specifies that a drop-down menu button will appear next to the tool button (only GTK+ and MSW). Call SetDropdownMenu() afterwards.
shortHelpString	This string is used for the tools tooltip.
longHelpString	This string is shown in the statusbar (if any) of the parent frame when the mouse pointer is inside the tool.
clientData	An optional pointer to client data which can be retrieved later using GetToolClientData().

Remarks

After you have added tools to a toolbar, you must call Realize() in order to have the tools appear.

See also

AddSeparator(), AddCheckTool(), AddRadioTool(), InsertTool(), DeleteTool(), Realize(), SetDropdownMenu()

virtual void wxToolBar::ClearTools ( ) [virtual]

Deletes all the tools in the toolbar.

virtual **wxToolBarToolBase**∗ wxToolBar::CreateTool (int *toolId,* const **wxString** & *label,* const **wxBitmap** & *bmpNormal,* const **wxBitmap** & *bmpDisabled* = **wxNullBitmap**, **wxItemKind** *kind* = **wxITEM_NORMAL**, **wxObject** ∗ *clientData* = NULL, const **wxString** & *shortHelp* = **wxEmptyString**, const **wxString** & *longHelp* = **wxEmptyString**) [virtual]

Factory function to create a new toolbar tool.

virtual **wxToolBarToolBase**∗ wxToolBar::CreateTool (**wxControl** ∗ *control,* const **wxString** & *label*) [virtual]

Factory function to create a new control toolbar tool.

virtual bool wxToolBar::DeleteTool (int *toolId*) [virtual]

Removes the specified tool from the toolbar and deletes it.

If you don't want to delete the tool, but just to remove it from the toolbar (to possibly add it back later), you may use RemoveTool() instead.

Note

It is unnecessary to call Realize() for the change to take place, it will happen immediately.

Returns

true if the tool was deleted, false otherwise.

See also

DeleteToolByPos()

virtual bool wxToolBar::DeleteToolByPos (size_t *pos*) [virtual]

This function behaves like DeleteTool() but it deletes the tool at the specified position and not the one with the given id.

virtual void wxToolBar::EnableTool (int *toolId,* bool *enable*) [virtual]

Enables or disables the tool.

Parameters

toolId	ID of the tool to enable or disable, as passed to AddTool().
enable	If true, enables the tool, otherwise disables it.

Remarks

Some implementations will change the visible state of the tool to indicate that it is disabled.

See also

GetToolEnabled(), ToggleTool()

wxToolBarToolBase∗ wxToolBar::FindById (int *id*) const

Returns a pointer to the tool identified by *id* or NULL if no corresponding tool is found.

virtual wxControl* wxToolBar::FindControl (int *id*) [virtual]

Returns a pointer to the control identified by *id* or NULL if no corresponding control is found.

virtual wxToolBarToolBase* wxToolBar::FindToolForPosition (wxCoord *x*, wxCoord *y*) const [virtual]

Finds a tool for the given mouse position.

Parameters

x	X position.
y	Y position.

Returns

A pointer to a tool if a tool is found, or NULL otherwise.

Remarks

Currently not implemented in wxGTK (always returns NULL there).

wxSize wxToolBar::GetMargins ( ) const

Returns the left/right and top/bottom margins, which are also used for inter-toolspacing.

See also

SetMargins()

virtual wxSize wxToolBar::GetToolBitmapSize ( ) const [virtual]

Returns the size of bitmap that the toolbar expects to have.

The default bitmap size is platform-dependent: for example, it is 16*15 for MSW and 24*24 for GTK. This size does *not* necessarily indicate the best size to use for the toolbars on the given platform, for this you should use `wx↩ ArtProvider::GetNativeSizeHint(wxART_TOOLBAR)` but in any case, as the bitmap size is deduced automatically from the size of the bitmaps associated with the tools added to the toolbar, it is usually unnecessary to call SetToolBitmapSize() explicitly.

Remarks

Note that this is the size of the bitmap you pass to AddTool(), and not the eventual size of the tool button.

See also

SetToolBitmapSize(), GetToolSize()

const wxToolBarToolBase* wxToolBar::GetToolByPos (int *pos*) const

Returns a pointer to the tool at ordinal position *pos*.

Don't confuse this with FindToolForPosition().

Since

2.9.1

See also

GetToolsCount()

virtual wxObject* wxToolBar::GetToolClientData (int *toolId*) const `[virtual]`

Get any client data associated with the tool.

Parameters

toolId	ID of the tool in question, as passed to AddTool().

Returns

Client data, or NULL if there is none.

virtual bool wxToolBar::GetToolEnabled (int *toolId*) const `[virtual]`

Called to determine whether a tool is enabled (responds to user input).

Parameters

toolId	ID of the tool in question, as passed to AddTool().

Returns

true if the tool is enabled, false otherwise.

See also

EnableTool()

virtual wxString wxToolBar::GetToolLongHelp (int *toolId*) const `[virtual]`

Returns the long help for the given tool.

Parameters

toolId	ID of the tool in question, as passed to AddTool().

See also

SetToolLongHelp(), SetToolShortHelp()

virtual int wxToolBar::GetToolPacking ( ) const `[virtual]`

Returns the value used for packing tools.

See also

SetToolPacking()

virtual int wxToolBar::GetToolPos (int *toolId*) const `[virtual]`

Returns the tool position in the toolbar, or `wxNOT_FOUND` if the tool is not found.

Parameters

toolId	ID of the tool in question, as passed to AddTool().

size_t wxToolBar::GetToolsCount ( ) const

Returns the number of tools in the toolbar.

virtual int wxToolBar::GetToolSeparation ( ) const `[virtual]`

Returns the default separator size.

See also

SetToolSeparation()

virtual wxString wxToolBar::GetToolShortHelp (int *toolId*) const `[virtual]`

Returns the short help for the given tool.

Parameters

toolId	ID of the tool in question, as passed to AddTool().

See also

GetToolLongHelp(), SetToolShortHelp()

virtual wxSize wxToolBar::GetToolSize ( ) const `[virtual]`

Returns the size of a whole button, which is usually larger than a tool bitmap because of added 3D effects.

See also

SetToolBitmapSize(), GetToolBitmapSize()

virtual bool wxToolBar::GetToolState (int *toolId*) const `[virtual]`

Gets the on/off state of a toggle tool.

Parameters

toolId	ID of the tool in question, as passed to AddTool().

Returns

true if the tool is toggled on, false otherwise.

See also

ToggleTool()

virtual **wxToolBarToolBase**∗ **wxToolBar::InsertControl** (**size_t** *pos*, **wxControl** ∗ *control*, **const wxString &** *label* = **wxEmptyString**) [virtual]

Inserts the control into the toolbar at the given position.

You must call Realize() for the change to take place.

See also

AddControl(), InsertTool()

virtual **wxToolBarToolBase**∗ **wxToolBar::InsertSeparator** (**size_t** *pos*) [virtual]

Inserts the separator into the toolbar at the given position.

You must call Realize() for the change to take place.

See also

AddSeparator(), InsertTool()

wxToolBarToolBase∗ **wxToolBar::InsertStretchableSpace** (**size_t** *pos*)

Inserts a stretchable space at the given position.

See AddStretchableSpace() for details about stretchable spaces.

See also

InsertTool(), InsertSeparator()

Since

2.9.1

wxToolBarToolBase∗ **wxToolBar::InsertTool** (**size_t** *pos*, **int** *toolId*, **const wxString &** *label*, **const wxBitmap &** *bitmap*, **const wxBitmap &** *bmpDisabled* = **wxNullBitmap**, **wxItemKind** *kind* = **wxITEM_NORMAL**, **const wxString &** *shortHelp* = **wxEmptyString**, **const wxString &** *longHelp* = **wxEmptyString**, **wxObject** ∗ *clientData* = NULL)

Inserts the tool with the specified attributes into the toolbar at the given position.

You must call Realize() for the change to take place.

See also

AddTool(), InsertControl(), InsertSeparator()

Returns

The newly inserted tool or NULL on failure. Notice that with the overload taking *tool* parameter the caller is responsible for deleting the tool in the latter case.

wxToolBarToolBase* **wxToolBar::InsertTool (size_t *pos,* wxToolBarToolBase * *tool*)**

Inserts the tool with the specified attributes into the toolbar at the given position.

You must call Realize() for the change to take place.

See also

AddTool(), InsertControl(), InsertSeparator()

Returns

The newly inserted tool or NULL on failure. Notice that with the overload taking *tool* parameter the caller is responsible for deleting the tool in the latter case.

virtual bool wxToolBar::OnLeftClick (int *toolId,* bool *toggleDown*) `[virtual]`

Called when the user clicks on a tool with the left mouse button.

This is the old way of detecting tool clicks; although it will still work, you should use the EVT_MENU() or EVT_TOOL() macro instead.

Parameters

toolId	The identifier passed to AddTool().
toggleDown	true if the tool is a toggle and the toggle is down, otherwise is false.

Returns

If the tool is a toggle and this function returns false, the toggle state (internal and visual) will not be changed. This provides a way of specifying that toggle operations are not permitted in some circumstances.

See also

OnMouseEnter(), OnRightClick()

virtual void wxToolBar::OnMouseEnter (int *toolId*) `[virtual]`

This is called when the mouse cursor moves into a tool or out of the toolbar.

This is the old way of detecting mouse enter events; although it will still work, you should use the EVT_TOOL_ENTER() macro instead.

Parameters

toolId	Greater than -1 if the mouse cursor has moved into the tool, or -1 if the mouse cursor has moved. The programmer can override this to provide extra information about the tool, such as a short description on the status line.

Remarks

With some derived toolbar classes, if the mouse moves quickly out of the toolbar, wxWidgets may not be able to detect it. Therefore this function may not always be called when expected.

virtual void wxToolBar::OnRightClick (int *toolId,* long *x,* long *y*) `[virtual]`

Deprecated This is the old way of detecting tool right clicks; although it will still work, you should use the EVT_T↩ OOL_RCLICKED() macro instead.

Called when the user clicks on a tool with the right mouse button. The programmer should override this function to detect right tool clicks.

Parameters

toolId	The identifier passed to AddTool().
x	The x position of the mouse cursor.
y	The y position of the mouse cursor.

Remarks

A typical use of this member might be to pop up a menu.

See also

OnMouseEnter(), OnLeftClick()

virtual bool wxToolBar::Realize ( ) [virtual]

This function should be called after you have added tools.

virtual wxToolBarToolBase* wxToolBar::RemoveTool (int *id*) [virtual]

Removes the given tool from the toolbar but doesn't delete it.

This allows to insert/add this tool back to this (or another) toolbar later.

Note

It is unnecessary to call Realize() for the change to take place, it will happen immediately.

See also

DeleteTool()

void wxToolBar::SetBitmapResource (int *resourceId*)

Sets the bitmap resource identifier for specifying tool bitmaps as indices into a custom bitmap.

This is a Windows CE-specific method not available in the other ports.

Availability: only available for the wxWinCE port.

bool wxToolBar::SetDropdownMenu (int *id,* wxMenu * *menu*)

Sets the dropdown menu for the tool given by its *id*.

The tool itself will delete the menu when it's no longer needed. Only supported under GTK+ und MSW.

If you define a EVT_TOOL_DROPDOWN() handler in your program, you must call wxEvent::Skip() from it or the menu won't be displayed.

virtual void wxToolBar::SetMargins (int *x,* int *y*) [virtual]

Set the values to be used as margins for the toolbar.

Parameters

x	Left margin, right margin and inter-tool separation value.
y	Top margin, bottom margin and inter-tool separation value.

Remarks

This must be called before the tools are added if absolute positioning is to be used, and the default (zero-size) margins are to be overridden.

See also

GetMargins()

void wxToolBar::SetMargins (const wxSize & *size*)

Set the margins for the toolbar.

Parameters

size	Margin size.

Remarks

This must be called before the tools are added if absolute positioning is to be used, and the default (zero-size) margins are to be overridden.

See also

GetMargins(), wxSize

virtual void wxToolBar::SetToolBitmapSize (const wxSize & *size*) [virtual]

Sets the default size of each tool bitmap.

The default bitmap size is 16 by 15 pixels.

Parameters

size	The size of the bitmaps in the toolbar.

Remarks

This should be called to tell the toolbar what the tool bitmap size is. Call it before you add tools.

See also

GetToolBitmapSize(), GetToolSize()

virtual void wxToolBar::SetToolClientData (int *id,* wxObject * *clientData*) [virtual]

Sets the client data associated with the tool.

Parameters

id	ID of the tool in question, as passed to AddTool().
clientData	The client data to use.

virtual void wxToolBar::SetToolDisabledBitmap (int *id,* const wxBitmap & *bitmap*) [virtual]

Sets the bitmap to be used by the tool with the given ID when the tool is in a disabled state.

This can only be used on Button tools, not controls.

Parameters

id	ID of the tool in question, as passed to AddTool().
bitmap	Bitmap to use for disabled tools.

Note

The native toolbar classes on the main platforms all synthesize the disabled bitmap from the normal bitmap, so this function will have no effect on those platforms.

virtual void wxToolBar::SetToolLongHelp (int *toolId,* const wxString & *helpString*) [virtual]

Sets the long help for the given tool.

Parameters

toolId	ID of the tool in question, as passed to AddTool().
helpString	A string for the long help.

Remarks

You might use the long help for displaying the tool purpose on the status line.

See also

GetToolLongHelp(), SetToolShortHelp(),

virtual void wxToolBar::SetToolNormalBitmap (int *id,* const wxBitmap & *bitmap*) [virtual]

Sets the bitmap to be used by the tool with the given ID.

This can only be used on Button tools, not controls.

Parameters

id	ID of the tool in question, as passed to AddTool().
bitmap	Bitmap to use for normals tools.

virtual void wxToolBar::SetToolPacking (int *packing*) [virtual]

Sets the value used for spacing tools.

The default value is 1.

Parameters

packing	The value for packing.

Remarks

The packing is used for spacing in the vertical direction if the toolbar is horizontal, and for spacing in the horizontal direction if the toolbar is vertical.

See also

GetToolPacking()

virtual void wxToolBar::SetToolSeparation (int *separation*) [virtual]

Sets the default separator size.

The default value is 5.

Parameters

separation	The separator size.

See also

AddSeparator()

virtual void wxToolBar::SetToolShortHelp (int *toolId,* const wxString & *helpString*) [virtual]

Sets the short help for the given tool.

Parameters

toolId	ID of the tool in question, as passed to AddTool().
helpString	The string for the short help.

Remarks

An application might use short help for identifying the tool purpose in a tooltip.

See also

GetToolShortHelp(), SetToolLongHelp()

virtual void wxToolBar::ToggleTool (int *toolId,* bool *toggle*) [virtual]

Toggles a tool on or off.

This does not cause any event to get emitted.

Parameters

toolId	ID of the tool in question, as passed to AddTool().

toggle	If true, toggles the tool on, otherwise toggles it off.

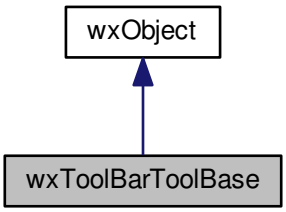
Remarks

Only applies to a tool that has been specified as a toggle tool.

21.797 wxToolBarToolBase Class Reference

`#include <wx/toolbar.h>`

Inheritance diagram for wxToolBarToolBase:



21.797.1 Detailed Description

A toolbar tool represents one item on the toolbar.

It has a unique id (except for the separators), the style (telling whether it is a normal button, separator or a control), the state (toggled or not, enabled or not) and short and long help strings. The default implementations use the short help string for the tooltip text which is popped up when the mouse pointer enters the tool and the long help string for the applications status bar.

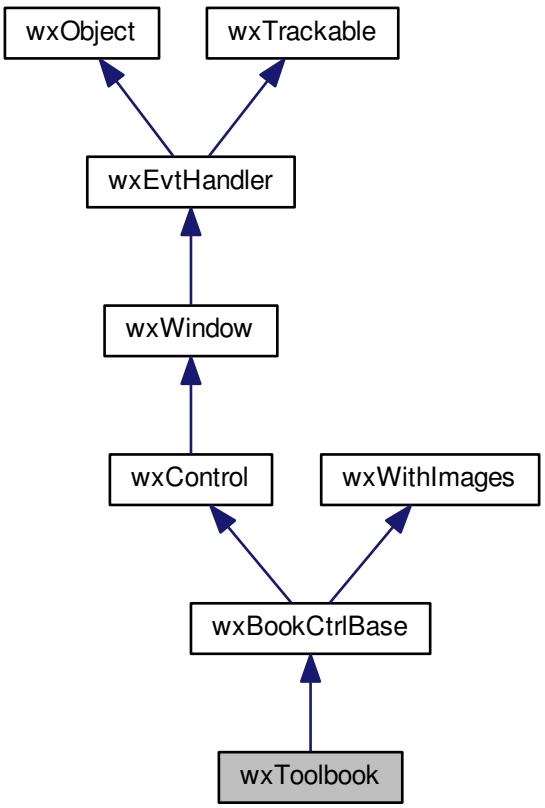
21.798 wxToolbook Class Reference

`#include <wx/toolbook.h>`

Inheritance diagram for wxToolbook:



21.798.1 Detailed Description

wxToolbook is a class similar to wxNotebook but which uses a wxToolBar to show the labels instead of the tabs.

There is no documentation for this class yet but its usage is identical to wxNotebook (except for the features clearly related to tabs only), so please refer to that class documentation for now. You can also use the Notebook Sample to see wxToolbook in action.

Styles

This class supports the following styles:

- wxTBK_BUTTONBAR: Use wxButtonToolBar-based implementation under Mac OS (ignored under other platforms).
- wxTBK_HORZ_LAYOUT: Shows the text and the icons alongside, not vertically stacked (only implement under Windows and GTK 2 platforms as it relies on `wxTB_HORZ_LAYOUT` flag support).

The common wxBookCtrl styles described in the wxBookCtrl Overview are also supported.

Events emitted by this class

The following event handler macros redirect the events to member function handlers '**func**' with prototypes like: void handlerFuncName(wxBookCtrlEvent& event)

Event macros for events emitted by this class:

- EVT_TOOLBOOK_PAGE_CHANGED(id, func): The page selection was changed. Processes a `wxEVT_TOOLBOOK_PAGE_CHANGED` event.
- EVT_TOOLBOOK_PAGE_CHANGING(id, func): The page selection is about to be changed. Processes a `wxEVT_TOOLBOOK_PAGE_CHANGING` event. This event can be vetoed (using wxNotifyEvent::Veto()).

Library: wxCore

Category: Book Controls

Public Member Functions

- bool Create (wxWindow *parent, wxWindowID id, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, long style=0, const wxString &name=wxEmptyString)

  Create the tool book control that has already been constructed with the default constructor.
- wxToolBarBase * GetToolBar () const

  Returns the wxToolBarBase associated with the control.
- wxToolbook ()

  Constructs a choicebook control.
- wxToolbook (wxWindow *parent, wxWindowID id, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, long style=0, const wxString &name=wxEmptyString)

  Constructs a choicebook control.

Additional Inherited Members

21.798.2 Constructor & Destructor Documentation

wxToolbook::wxToolbook ( )

Constructs a choicebook control.

wxToolbook::wxToolbook (wxWindow * *parent*, wxWindowID *id*, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, long *style* = 0, const wxString & *name* = wxEmptyString)

Constructs a choicebook control.

21.798.3 Member Function Documentation

bool wxToolbook::Create (wxWindow * *parent*, wxWindowID *id*, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, long *style* = 0, const wxString & *name* = wxEmptyString)

Create the tool book control that has already been constructed with the default constructor.

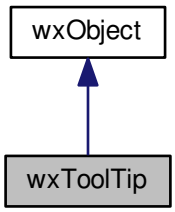
wxToolBarBase* wxToolbook::GetToolBar ( ) const

Returns the wxToolBarBase associated with the control.

21.799 wxToolTip Class Reference

`#include <wx/tooltip.h>`

Inheritance diagram for wxToolTip:



21.799.1 Detailed Description

This class holds information about a tooltip associated with a window (see wxWindow::SetToolTip()).

The four static methods, wxToolTip::Enable(), wxToolTip::SetDelay() wxToolTip::SetAutoPop() and wxToolTip::SetReshow() can be used to globally alter tooltips behaviour.

Library: wxCore

Category: Help

Public Member Functions

- wxToolTip (const wxString &tip)
  Constructor.
- wxString GetTip () const
  Get the tooltip text.
- wxWindow * GetWindow () const
  Get the associated window.
- void SetTip (const wxString &tip)

Set the tooltip text.

Static Public Member Functions

- static void Enable (bool flag)

  Enable or disable tooltips globally.
- static void SetAutoPop (long msecs)

  Set the delay after which the tooltip disappears or how long a tooltip remains visible.
- static void SetDelay (long msecs)

  Set the delay after which the tooltip appears.
- static void SetMaxWidth (int width)

  Set tooltip maximal width in pixels.
- static void SetReshow (long msecs)

  Set the delay between subsequent tooltips to appear.

Additional Inherited Members

21.799.2 Constructor & Destructor Documentation

wxToolTip::wxToolTip (const wxString & *tip*)

Constructor.

21.799.3 Member Function Documentation

static void wxToolTip::Enable (bool *flag*) `[static]`

Enable or disable tooltips globally.

Note

May not be supported on all platforms (eg. wxCocoa).

wxString wxToolTip::GetTip ( ) const

Get the tooltip text.

wxWindow* wxToolTip::GetWindow ( ) const

Get the associated window.

static void wxToolTip::SetAutoPop (long *msecs*) `[static]`

Set the delay after which the tooltip disappears or how long a tooltip remains visible.

Note

May not be supported on all platforms (eg. wxCocoa, GTK).

static void wxToolTip::SetDelay (long *msecs*) `[static]`

Set the delay after which the tooltip appears.

Note

May not be supported on all platforms (eg. wxCocoa).

static void wxToolTip::SetMaxWidth (int *width*) `[static]`

Set tooltip maximal width in pixels.

By default, tooltips are wrapped at a suitably chosen width. You can pass -1 as *width* to disable wrapping them completely, 0 to restore the default behaviour or an arbitrary positive value to wrap them at the given width.

Notice that this function does not change the width of the tooltips created before calling it.

Note

Currently this function is wxMSW-only.

static void wxToolTip::SetReshow (long *msecs*) `[static]`

Set the delay between subsequent tooltips to appear.

Note

May not be supported on all platforms (eg. wxCocoa, GTK).

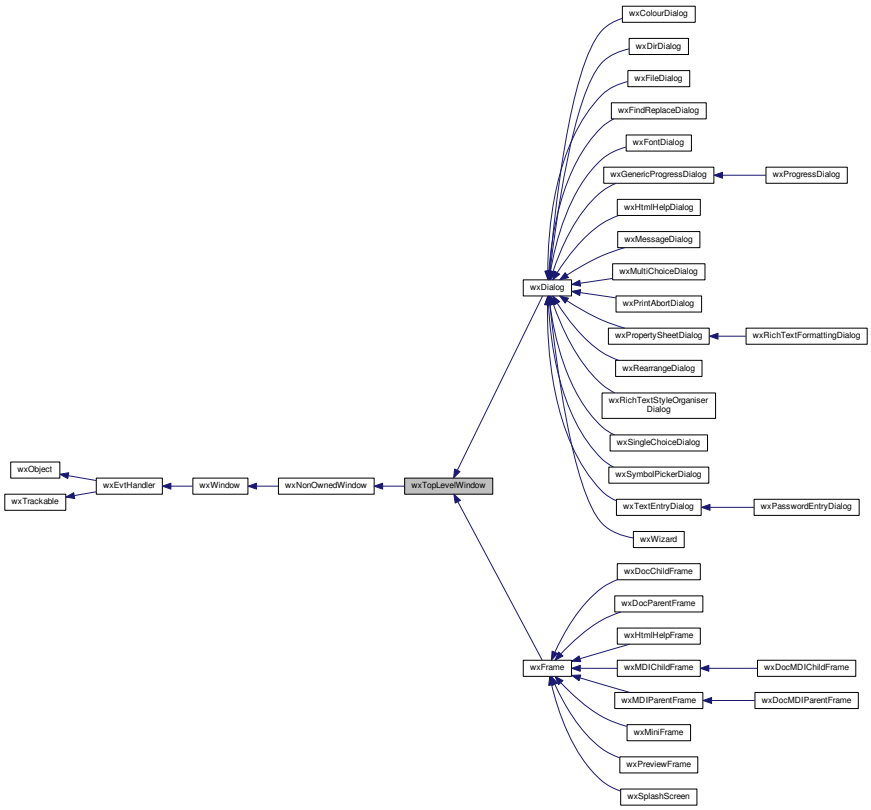
void wxToolTip::SetTip (const wxString & *tip*)

Set the tooltip text.

21.800 wxTopLevelWindow Class Reference

`#include <wx/toplevel.h>`

Inheritance diagram for wxTopLevelWindow:



21.800.1 Detailed Description

wxTopLevelWindow is a common base class for wxDialog and wxFrame.

It is an abstract base class meaning that you never work with objects of this class directly, but all of its methods are also applicable for the two classes above.

Note that the instances of wxTopLevelWindow are managed by wxWidgets in the internal top level window list.

Events emitted by this class

Event macros for events emitted by this class:

- EVT_MAXIMIZE(id, func): Process a `wxEVT_MAXIMIZE` event. See wxMaximizeEvent.
- EVT_MOVE(func): Process a `wxEVT_MOVE` event, which is generated when a window is moved. See wxMoveEvent.
- EVT_MOVE_START(func): Process a `wxEVT_MOVE_START` event, which is generated when the user starts to move or size a window. wxMSW only. See wxMoveEvent.
- EVT_MOVE_END(func): Process a `wxEVT_MOVE_END` event, which is generated when the user stops moving or sizing a window. wxMSW only. See wxMoveEvent.
- EVT_SHOW(func): Process a `wxEVT_SHOW` event. See wxShowEvent.

Library: wxCore

Category: Managed Windows

wxDialog, wxFrame

Public Member Functions

- wxTopLevelWindow ()

  Default ctor.
- wxTopLevelWindow (wxWindow *parent, wxWindowID id, const wxString &title, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, long style=wxDEFAULT_FRAME_STYLE, const wxString &name=wxFrameNameStr)

  Constructor creating the top level window.
- virtual ~wxTopLevelWindow ()

  Destructor.
- bool Create (wxWindow *parent, wxWindowID id, const wxString &title, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, long style=wxDEFAULT_FRAME_STYLE, const wxString &name=wxFrameNameStr)

  Creates the top level window.
- virtual bool CanSetTransparent ()

  Returns true if the platform supports making the window translucent.
- void CenterOnScreen (int direction=wxBOTH)

  A synonym for CentreOnScreen().
- void CentreOnScreen (int direction=wxBOTH)

  Centres the window on screen.
- virtual bool EnableCloseButton (bool enable=true)

  Enables or disables the Close button (most often in the right upper corner of a dialog) and the Close entry of the system menu (most often in the left upper corner of the dialog).
- wxWindow * GetDefaultItem () const

  Returns a pointer to the button which is the default for this window, or NULL.
- wxIcon GetIcon () const

  Returns the standard icon of the window.
- const wxIconBundle & GetIcons () const

  Returns all icons associated with the window, there will be none of them if neither SetIcon() nor SetIcons() had been called before.
- virtual wxString GetTitle () const

  Gets a string containing the window title.
- virtual bool HandleSettingChange (WXWPARAM wParam, WXLPARAM lParam)

  Unique to the wxWinCE port.
- virtual void Iconize (bool iconize=true)

  Iconizes or restores the window.
- virtual bool IsActive ()

  Returns true if this window is currently active, i.e. if the user is currently working with it.
- virtual bool IsAlwaysMaximized () const

  Returns true if this window is expected to be always maximized, either due to platform policy or due to local policy regarding particular class.
- virtual bool IsFullScreen () const

  Returns true if the window is in fullscreen mode.

- virtual bool IsIconized () const

  Returns true if the window is iconized.
- virtual bool IsMaximized () const

  Returns true if the window is maximized.
- bool IsUsingNativeDecorations () const

  This method is specific to wxUniversal port.
- virtual bool Layout ()

  See wxWindow::SetAutoLayout(): when auto layout is on, this function gets called automatically when the window is resized.
- virtual void Maximize (bool maximize=true)

  Maximizes or restores the window.
- wxMenu * MSWGetSystemMenu () const

  MSW-specific function for accessing the system menu.
- virtual void RequestUserAttention (int flags=wxUSER_ATTENTION_INFO)

  Use a system-dependent way to attract users attention to the window when it is in background.
- void Restore ()

  Restore a previously iconized or maximized window to its normal state.
- wxWindow * SetDefaultItem (wxWindow *win)

  Changes the default item for the panel, usually win is a button.
- wxWindow * SetTmpDefaultItem (wxWindow *win)
- wxWindow * GetTmpDefaultItem () const
- void SetIcon (const wxIcon &icon)

  Sets the icon for this window.
- virtual void SetIcons (const wxIconBundle &icons)

  Sets several icons of different sizes for this window: this allows to use different icons for different situations (e.g.
- void SetLeftMenu (int id=wxID_ANY, const wxString &label=wxEmptyString, wxMenu *subMenu=NULL)

  Sets action or menu activated by pressing left hardware button on the smart phones.
- virtual void SetMaxSize (const wxSize &size)

  A simpler interface for setting the size hints than SetSizeHints().
- virtual void SetMinSize (const wxSize &size)

  A simpler interface for setting the size hints than SetSizeHints().
- void SetRightMenu (int id=wxID_ANY, const wxString &label=wxEmptyString, wxMenu *subMenu=NULL)

  Sets action or menu activated by pressing right hardware button on the smart phones.
- virtual void SetSizeHints (int minW, int minH, int maxW=-1, int maxH=-1, int incW=-1, int incH=-1)

  Allows specification of minimum and maximum window sizes, and window size increments.
- void SetSizeHints (const wxSize &minSize, const wxSize &maxSize=wxDefaultSize, const wxSize &incSize=wxDefaultSize)

  Allows specification of minimum and maximum window sizes, and window size increments.
- virtual void SetTitle (const wxString &title)

  Sets the window title.
- virtual bool SetTransparent (wxByte alpha)

  If the platform supports it will set the window to be translucent.
- virtual bool ShouldPreventAppExit () const

  This virtual function is not meant to be called directly but can be overridden to return false (it returns true by default) to allow the application to close even if this, presumably not very important, window is still opened.
- virtual void OSXSetModified (bool modified)

  This function sets the wxTopLevelWindow's modified state on OS X, which currently draws a black dot in the wxTopLevelWindow's close button.
- virtual bool OSXIsModified () const

  Returns the current modified state of the wxTopLevelWindow on OS X.
- virtual void SetRepresentedFilename (const wxString &filename)

Sets the file name represented by this wxTopLevelWindow.

- virtual void ShowWithoutActivating ()

  Show the wxTopLevelWindow, but do not give it keyboard focus.

- virtual bool EnableFullScreenView (bool enable=true)

  Adds or removes a full screen button to the right upper corner of a window's title bar under OS X 10.7 and later.

- virtual bool ShowFullScreen (bool show, long style=wxFULLSCREEN_ALL)

  Depending on the value of show parameter the window is either shown full screen or restored to its normal state.

- void UseNativeDecorations (bool native=true)

  This method is specific to wxUniversal port.

- void UseNativeDecorationsByDefault (bool native=true)

  This method is specific to wxUniversal port.

Static Public Member Functions

- static wxSize GetDefaultSize ()

  Get the default size for a new top level window.

Additional Inherited Members

21.800.2 Constructor & Destructor Documentation

wxTopLevelWindow::wxTopLevelWindow ( )

Default ctor.

wxTopLevelWindow::wxTopLevelWindow (wxWindow * *parent*, wxWindowID *id*, const wxString & *title*, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, long *style* = wxDEFAULT_FRAME_STYLE, const wxString & *name* = `wxFrameNameStr`)

Constructor creating the top level window.

virtual wxTopLevelWindow::~wxTopLevelWindow ( ) `[virtual]`

Destructor.

Remember that wxTopLevelWindows do not get immediately destroyed when the user (or the app) closes them; they have a **delayed** destruction.

See Window Deletion for more info.

21.800.3 Member Function Documentation

virtual bool wxTopLevelWindow::CanSetTransparent ( ) `[virtual]`

Returns true if the platform supports making the window translucent.

See also

SetTransparent()

Reimplemented from wxWindow.

void wxTopLevelWindow::CenterOnScreen (int *direction* = wxBOTH)

A synonym for CentreOnScreen().

void wxTopLevelWindow::CentreOnScreen (int *direction* = wxBOTH)

Centres the window on screen.

Parameters

direction	Specifies the direction for the centering. May be `wxHORIZONTAL`, `wxVERTICAL` or `wxBOTH`.

See also

wxWindow::CentreOnParent()

bool wxTopLevelWindow::Create (wxWindow * *parent*, wxWindowID *id*, const wxString & *title*, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, long *style* = wxDEFAULT_FRAME_STYLE, const wxString & *name* = `wxFrameNameStr`)

Creates the top level window.

virtual bool wxTopLevelWindow::EnableCloseButton (bool *enable* = `true`) [virtual]

Enables or disables the Close button (most often in the right upper corner of a dialog) and the Close entry of the system menu (most often in the left upper corner of the dialog).

Currently only implemented for wxMSW and wxGTK.

Returns true if operation was successful. This may be wrong on X11 (including GTK+) where the window manager may not support this operation and there is no way to find out.

virtual bool wxTopLevelWindow::EnableFullScreenView (bool *enable* = `true`) [virtual]

Adds or removes a full screen button to the right upper corner of a window's title bar under OS X 10.7 and later.

Currently only available for wxOSX/Cocoa.

Parameters

enable	If true (default) adds the full screen button in the title bar; if false the button is removed.

Returns

true if the button was added or removed, false if running under a pre-OS X 10.7 system or another OS.

Note

Having the button is also required to let ShowFullScreen() make use of the full screen API available since OS X 10.7: a full screen window gets its own space and entering and exiting the mode is animated. If the button is not present the old way of switching to full screen is used.

Availability: only available for the wxOSX port.

See also

ShowFullScreen()

Since

3.1.0

wxWindow* wxTopLevelWindow::GetDefaultItem ( ) const

Returns a pointer to the button which is the default for this window, or NULL.

The default button is the one activated by pressing the Enter key.

static wxSize wxTopLevelWindow::GetDefaultSize ( ) [static]

Get the default size for a new top level window.

This is used internally by wxWidgets on some platforms to determine the default size for a window created using wxDefaultSize so it is not necessary to use it when creating a wxTopLevelWindow, however it may be useful if a rough estimation of the window size is needed for some other reason.

Since

2.9.2

wxIcon wxTopLevelWindow::GetIcon ( ) const

Returns the standard icon of the window.

The icon will be invalid if it hadn't been previously set by SetIcon().

See also

GetIcons()

const wxIconBundle& wxTopLevelWindow::GetIcons ( ) const

Returns all icons associated with the window, there will be none of them if neither SetIcon() nor SetIcons() had been called before.

Use GetIcon() to get the main icon of the window.

See also

wxIconBundle

virtual wxString wxTopLevelWindow::GetTitle ( ) const [virtual]

Gets a string containing the window title.

See also

SetTitle()

wxWindow* wxTopLevelWindow::GetTmpDefaultItem ( ) const

virtual bool wxTopLevelWindow::HandleSettingChange (WXWPARAM *wParam*, WXLPARAM *lParam*) [virtual]

Unique to the wxWinCE port.

Responds to showing/hiding SIP (soft input panel) area and resize window accordingly. Override this if you want to avoid resizing or do additional operations.

virtual void wxTopLevelWindow::Iconize (bool *iconize* = true) [virtual]

Iconizes or restores the window.

Parameters

iconize	If true, iconizes the window; if false, shows and restores it.

See also

IsIconized(), Restore()(), wxIconizeEvent.

Reimplemented in wxDialog.

virtual bool wxTopLevelWindow::IsActive ( ) [virtual]

Returns true if this window is currently active, i.e. if the user is currently working with it.

virtual bool wxTopLevelWindow::IsAlwaysMaximized ( ) const [virtual]

Returns true if this window is expected to be always maximized, either due to platform policy or due to local policy regarding particular class.

Reimplemented in wxMDIChildFrame.

virtual bool wxTopLevelWindow::IsFullScreen ( ) const [virtual]

Returns true if the window is in fullscreen mode.

See also

ShowFullScreen()

virtual bool wxTopLevelWindow::IsIconized ( ) const [virtual]

Returns true if the window is iconized.

Reimplemented in wxDialog.

virtual bool wxTopLevelWindow::IsMaximized ( ) const [virtual]

Returns true if the window is maximized.

bool wxTopLevelWindow::IsUsingNativeDecorations ( ) const

This method is specific to wxUniversal port.

Returns true if this window is using native decorations, false if we draw them ourselves.

See also

UseNativeDecorations(), UseNativeDecorationsByDefault()

virtual bool wxTopLevelWindow::Layout ( ) [virtual]

See wxWindow::SetAutoLayout(): when auto layout is on, this function gets called automatically when the window is resized.

Reimplemented from wxWindow.

virtual void wxTopLevelWindow::Maximize (bool *maximize* = true) [virtual]

Maximizes or restores the window.

Parameters

maximize	If true, maximizes the window, otherwise it restores it.

See also

Restore(), Iconize()

Reimplemented in wxMDIChildFrame.

wxMenu* wxTopLevelWindow::MSWGetSystemMenu ( ) const

MSW-specific function for accessing the system menu.

Returns a wxMenu pointer representing the system menu of the window under MSW. The returned wxMenu may be used, if non-NULL, to add extra items to the system menu. The usual wxEVT_MENU events (that can be processed using EVT_MENU event table macro) will then be generated for them. All the other wxMenu methods may be used as well but notice that they won't allow you to access any standard system menu items (e.g. they can't be deleted or modified in any way currently).

Notice that because of the native system limitations the identifiers of the items added to the system menu must be multiples of 16, otherwise no events will be generated for them.

The returned pointer must *not* be deleted, it is owned by the window and will be only deleted when the window itself is destroyed.

This function is not available in the other ports by design, any occurrences of it in the portable code must be guarded by

```
#ifdef __WXMSW__
```

preprocessor guards.

Since

2.9.3

virtual bool wxTopLevelWindow::OSXIsModified ( ) const `[virtual]`

Returns the current modified state of the wxTopLevelWindow on OS X.

On other platforms, this method does nothing.

See also

OSXSetModified()

virtual void wxTopLevelWindow::OSXSetModified (bool *modified*) `[virtual]`

This function sets the wxTopLevelWindow's modified state on OS X, which currently draws a black dot in the wxTopLevelWindow's close button.

On other platforms, this method does nothing.

See also

OSXIsModified()

virtual void wxTopLevelWindow::RequestUserAttention (int *flags* = wxUSER_ATTENTION_INFO) `[virtual]`

Use a system-dependent way to attract users attention to the window when it is in background.

flags may have the value of either `wxUSER_ATTENTION_INFO` (default) or `wxUSER_ATTENTION_ERROR` which results in a more drastic action. When in doubt, use the default value.

Note

This function should normally be only used when the application is not already in foreground.

This function is currently implemented for Win32 where it flashes the window icon in the taskbar, and for wxGTK with task bars supporting it.

void wxTopLevelWindow::Restore ( )

Restore a previously iconized or maximized window to its normal state.

In wxGTK this method currently doesn't return the maximized window to its normal state and you must use Maximize() with false argument explicitly for this. In the other ports, it both unmaximizes the maximized windows and uniconizes the iconized ones.

See also

Iconize(), Maximize()

wxWindow* wxTopLevelWindow::SetDefaultItem (wxWindow * *win*)

Changes the default item for the panel, usually *win* is a button.

See also

GetDefaultItem()

void wxTopLevelWindow::SetIcon (const wxIcon & *icon*)

Sets the icon for this window.

Parameters

icon	The wxIcon to associate with this window.

Remarks

The window takes a 'copy' of *icon*, but since it uses reference counting, the copy is very quick. It is safe to delete *icon* after calling this function.

Note

In wxMSW, *icon* must be either 16x16 or 32x32 icon.

See also

wxIcon, SetIcons()

virtual void wxTopLevelWindow::SetIcons (const wxIconBundle & *icons*) [virtual]

Sets several icons of different sizes for this window: this allows to use different icons for different situations (e.g.

task switching bar, taskbar, window title bar) instead of scaling, with possibly bad looking results, the only icon set by SetIcon().

Parameters

icons	The icons to associate with this window.

Note

In wxMSW, *icons* must contain a 16x16 or 32x32 icon, preferably both.

See also

wxIconBundle

Reimplemented in wxDialog.

void wxTopLevelWindow::SetLeftMenu (int *id* = wxID_ANY, const wxString & *label* = wxEmptyString, wxMenu * *subMenu* = NULL)

Sets action or menu activated by pressing left hardware button on the smart phones.

Unavailable on full keyboard machines.

Parameters

id	Identifier for this button.
label	Text to be displayed on the screen area dedicated to this hardware button.
subMenu	The menu to be opened after pressing this hardware button.

See also

SetRightMenu().

virtual void wxTopLevelWindow::SetMaxSize (const wxSize & *size*) [virtual]

A simpler interface for setting the size hints than SetSizeHints().

Reimplemented from wxWindow.

virtual void wxTopLevelWindow::SetMinSize (const wxSize & *size*) [virtual]

A simpler interface for setting the size hints than SetSizeHints().

Reimplemented from wxWindow.

virtual void wxTopLevelWindow::SetRepresentedFilename (const wxString & *filename*) [virtual]

Sets the file name represented by this wxTopLevelWindow.

Under OS X, this file name is used to set the "proxy icon", which appears in the window title bar near its title, corresponding to this file name. Under other platforms it currently doesn't do anything but it is harmless to call it now and it might be implemented to do something useful in the future so you're encouraged to use it for any window representing a file-based document.

Since

2.9.4

void wxTopLevelWindow::SetRightMenu (int *id* = wxID_ANY, const wxString & *label* = wxEmptyString, wxMenu * *subMenu* = NULL)

Sets action or menu activated by pressing right hardware button on the smart phones.

Unavailable on full keyboard machines.

Parameters

id	Identifier for this button.
label	Text to be displayed on the screen area dedicated to this hardware button.
subMenu	The menu to be opened after pressing this hardware button.

See also

SetLeftMenu().

virtual void wxTopLevelWindow::SetSizeHints (int *minW*, int *minH*, int *maxW* = -1, int *maxH* = -1, int *incW* = -1, int *incH* = -1) [virtual]

Allows specification of minimum and maximum window sizes, and window size increments.

If a pair of values is not set (or set to -1), no constraints will be used.

Parameters

minW	The minimum width.
minH	The minimum height.
maxW	The maximum width.
maxH	The maximum height.
incW	Specifies the increment for sizing the width (GTK/Motif/Xt only).
incH	Specifies the increment for sizing the height (GTK/Motif/Xt only).

Remarks

Notice that this function not only prevents the user from resizing the window outside the given bounds but it also prevents the program itself from doing it using wxWindow::SetSize().

Reimplemented from wxWindow.

void wxTopLevelWindow::SetSizeHints (const wxSize & *minSize*, const wxSize & *maxSize* = wxDefaultSize, const wxSize & *incSize* = wxDefaultSize) [virtual]

Allows specification of minimum and maximum window sizes, and window size increments.

If a pair of values is not set (or set to -1), no constraints will be used.

Parameters

minSize	The minimum size of the window.
maxSize	The maximum size of the window.
incSize	Increment size (only taken into account under X11-based ports such as wxGTK/wxMotif/wx↩ X11).

Remarks

Notice that this function not only prevents the user from resizing the window outside the given bounds but it also prevents the program itself from doing it using wxWindow::SetSize().

Reimplemented from wxWindow.

virtual void wxTopLevelWindow::SetTitle (const wxString & *title*) [virtual]

Sets the window title.

Parameters

title	The window title.

See also

GetTitle()

wxWindow* wxTopLevelWindow::SetTmpDefaultItem (wxWindow * *win*)

virtual bool wxTopLevelWindow::SetTransparent (wxByte *alpha*) [virtual]

If the platform supports it will set the window to be translucent.

Parameters

alpha	Determines how opaque or transparent the window will be, if the platform supports the operation. A value of 0 sets the window to be fully transparent, and a value of 255 sets the window to be fully opaque.

Reimplemented from wxWindow.

virtual bool wxTopLevelWindow::ShouldPreventAppExit ( ) const [virtual]

This virtual function is not meant to be called directly but can be overridden to return false (it returns true by default) to allow the application to close even if this, presumably not very important, window is still opened.

By default, the application stays alive as long as there are any open top level windows.

virtual bool wxTopLevelWindow::ShowFullScreen (bool *show*, long *style* = wxFULLSCREEN_ALL) [virtual]

Depending on the value of *show* parameter the window is either shown full screen or restored to its normal state.

style is a bit list containing some or all of the following values, which indicate what elements of the window to hide in full-screen mode:

- wxFULLSCREEN_NOMENUBAR
- wxFULLSCREEN_NOTOOLBAR
- wxFULLSCREEN_NOSTATUSBAR
- wxFULLSCREEN_NOBORDER
- wxFULLSCREEN_NOCAPTION
- wxFULLSCREEN_ALL (all of the above)

This function has not been tested with MDI frames.

Note

Showing a window full screen also actually Show()s the window if it isn't shown.

See also

EnableFullScreenView(), IsFullScreen()

virtual void wxTopLevelWindow::ShowWithoutActivating ( ) [virtual]

Show the wxTopLevelWindow, but do not give it keyboard focus.

This can be used for pop up or notification windows that should not steal the current focus.

void wxTopLevelWindow::UseNativeDecorations (bool *native* = true)

This method is specific to wxUniversal port.

Use native or custom-drawn decorations for this window only. Notice that to have any effect this method must be called before really creating the window, i.e. two step creation must be used:

```
MyFrame *frame = new MyFrame;       // use default ctor
frame->UseNativeDecorations(false); // change from default "true"
frame->Create(parent, title, ...);  // really create the frame
```

See also

UseNativeDecorationsByDefault(), IsUsingNativeDecorations()

void wxTopLevelWindow::UseNativeDecorationsByDefault (bool *native* = true)

This method is specific to wxUniversal port.

Top level windows in wxUniversal port can use either system-provided window decorations (i.e. title bar and various icons, buttons and menus in it) or draw the decorations themselves. By default the system decorations are used if they are available, but this method can be called with *native* set to false to change this for all windows created after this point.

Also note that if WXDECOR environment variable is set, then custom decorations are used by default and so it may make sense to call this method with default argument if the application can't use custom decorations at all for some reason.

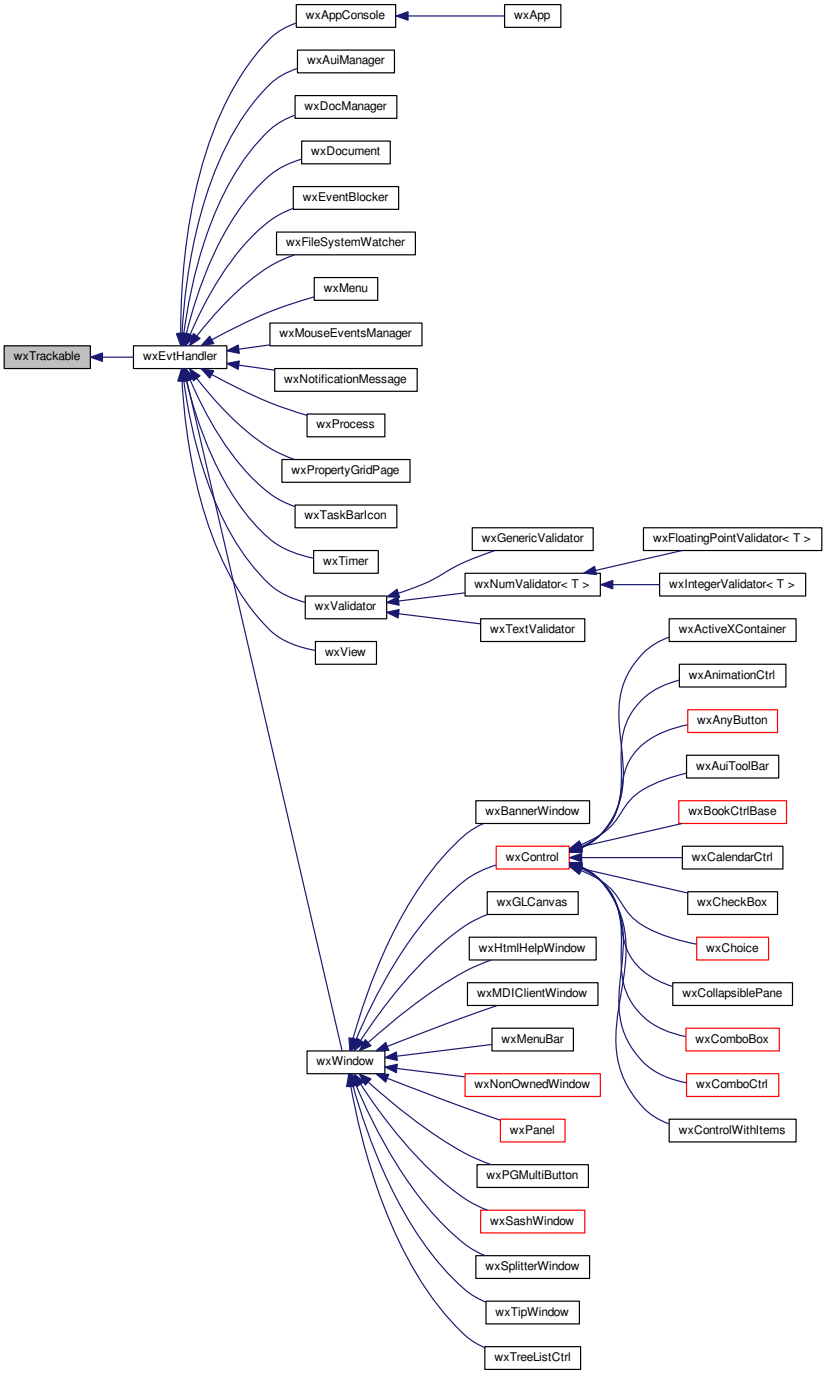
See also

UseNativeDecorations()

21.801 wxTrackable Class Reference

`#include <wx/tracker.h>`

Inheritance diagram for wxTrackable:



21.801.1 Detailed Description

Add-on base class for a trackable object.

This class maintains an internal linked list of classes of type wxTrackerNode and calls OnObjectDestroy() on them if this object is destroyed. The most common usage is by using the wxWeakRef<T> class template which automates this. This class has no public API. Its only use is by deriving another class from it to make it trackable.

```
class MyClass: public Foo, public wxTrackable
{
    // whatever
}

typedef wxWeakRef<MyClass> MyClassRef;
```

Library: wxBase

Category: Smart Pointers

21.803 wxTranslations Class Reference

```
#include <wx/translation.h>
```

21.803.1 Detailed Description

This class allows to get translations for strings.

In wxWidgets this class manages message catalogs which contain the translations of the strings used to the current language. Unlike wxLocale, it isn't bound to locale. It can be used either independently of, or in conjunction with wxLocale. In the latter case, you should initialize wxLocale (which creates wxTranslations instance) first; in the former, you need to create a wxTranslations object and Set() it manually.

Only one wxTranslations instance is active at a time; it is set with the Set() method and obtained using Get().

Unlike wxLocale, wxTranslations' primary mean of identifying language is by its "canonical name", i.e. ISO 639 code, possibly combined with ISO 3166 country code and additional modifiers (examples include "fr", "en_GB" or "ca@valencia"; see wxLocale::GetCanonicalName() for more information). This allows apps using wxTranslations API to use even languages not recognized by the operating system or not listed in wxLanguage enum.

Since

2.9.1

wxLocale, wxTranslationsLoader, wxFileTranslationsLoader

Public Member Functions

- wxTranslations ()

  Constructor.
- void SetLoader (wxTranslationsLoader *loader)

  Changes loader use to read catalogs to a non-default one.
- void SetLanguage (wxLanguage lang)

  Sets translations language to use.
- void SetLanguage (const wxString &lang)

  Sets translations language to use.
- wxArrayString GetAvailableTranslations (const wxString &domain) const

  Returns list of all translations of domain that were found.
- wxString GetBestTranslation (const wxString &domain, wxLanguage msgIdLanguage)

  Returns the best UI language for the domain.
- wxString GetBestTranslation (const wxString &domain, const wxString &msgIdLanguage="en")

  Returns the best UI language for the domain.
- bool AddStdCatalog ()

  Add standard wxWidgets catalogs ("wxstd" and possible port-specific catalogs).
- bool AddCatalog (const wxString &domain)

  Add a catalog for use with the current locale.
- bool AddCatalog (const wxString &domain, wxLanguage msgIdLanguage)

  Same as AddCatalog(const wxString&), but takes an additional argument, msgIdLanguage.
- bool AddCatalog (const wxString &domain, wxLanguage msgIdLanguage, const wxString &msgIdCharset)

  Same as AddCatalog(const wxString&, wxLanguage), but takes two additional arguments, msgIdLanguage and msgIdCharset.
- bool IsLoaded (const wxString &domain) const

Check if the given catalog is loaded, and returns true if it is.

- const wxString * GetTranslatedString (const wxString &origString, const wxString &domain=wxEmptyString) const

  Retrieves the translation for a string in all loaded domains unless the domain parameter is specified (and then only this catalog/domain is searched).

- const wxString * GetTranslatedString (const wxString &origString, unsigned n, const wxString &domain=wxEmptyString) const

  Retrieves the translation for a string in all loaded domains unless the domain parameter is specified (and then only this catalog/domain is searched).

- wxString GetHeaderValue (const wxString &header, const wxString &domain=wxEmptyString) const

  Returns the header value for header header.

Static Public Member Functions

- static wxTranslations * Get ()

  Returns current translations object, may return NULL.

- static void Set (wxTranslations *t)

  Sets current translations object.

21.803.2 Constructor & Destructor Documentation

wxTranslations::wxTranslations ( )

Constructor.

21.803.3 Member Function Documentation

bool wxTranslations::AddCatalog (const wxString & *domain*)

Add a catalog for use with the current locale.

By default, it is searched for in standard places (see wxFileTranslationsLoader), but you may also prepend additional directories to the search path with wxFileTranslationsLoader::AddCatalogLookupPathPrefix().

All loaded catalogs will be used for message lookup by GetString() for the current locale.

In this overload, `msgid` strings are assumed to be in English and written only using 7-bit ASCII characters. If you have to deal with non-English strings or 8-bit characters in the source code, see the instructions in Writing Non-English Applications.

Returns

true if catalog was successfully loaded, false otherwise (which might mean that the catalog is not found or that it isn't in the correct format).

bool wxTranslations::AddCatalog (const wxString & *domain*, wxLanguage *msgIdLanguage*)

Same as AddCatalog(const wxString&), but takes an additional argument, *msgIdLanguage*.

Parameters

domain	The catalog domain to add.
msgIdLanguage	Specifies the language of "msgid" strings in source code (i.e. arguments to GetString(), wxGetTranslation() and the _() macro). It is used if AddCatalog() cannot find any catalog for current language: if the language is same as source code language, then strings from source code are used instead.

Returns

true if catalog was successfully loaded, false otherwise (which might mean that the catalog is not found or that it isn't in the correct format).

bool wxTranslations::AddCatalog (const wxString & *domain*, wxLanguage *msgIdLanguage*, const wxString & *msgIdCharset*)

Same as AddCatalog(const wxString&, wxLanguage), but takes two additional arguments, *msgIdLanguage* and *msgIdCharset*.

This overload is only available in non-Unicode build.

Parameters

domain	The catalog domain to add.
msgIdLanguage	Specifies the language of "msgid" strings in source code (i.e. arguments to GetString(), wxGetTranslation() and the _() macro). It is used if AddCatalog() cannot find any catalog for current language: if the language is same as source code language, then strings from source code are used instead.
msgIdCharset	Lets you specify the charset used for msgids in sources in case they use 8-bit characters (e.g. German or French strings).

Returns

true if catalog was successfully loaded, false otherwise (which might mean that the catalog is not found or that it isn't in the correct format).

bool wxTranslations::AddStdCatalog ( )

Add standard wxWidgets catalogs ("wxstd" and possible port-specific catalogs).

Returns

true if a suitable catalog was found, false otherwise

See also

AddCatalog()

static wxTranslations* wxTranslations::Get ( ) [static]

Returns current translations object, may return NULL.

You must either call this early in app initialization code, or let wxLocale do it for you.

wxArrayString wxTranslations::GetAvailableTranslations (const wxString & *domain*) const

Returns list of all translations of *domain* that were found.

This method can be used e.g. to populate list of application's translations offered to the user. To do this, pass the app's main catalog as *domain*.

See also

GetBestTranslation()

wxString wxTranslations::GetBestTranslation (const wxString & *domain*, wxLanguage *msgIdLanguage*)

Returns the best UI language for the *domain*.

The language is determined from the preferred UI language or languages list the user configured in the OS. Notice that this may or may not correspond to the default *locale* as obtained from wxLocale::GetSystemLanguage(); modern operation systems (Windows Vista+, OS X) have separate language and regional (= locale) settings.

Parameters

domain	The catalog domain to look for.
msgIdLanguage	Specifies the language of "msgid" strings in source code (i.e. arguments to GetString(), wxGetTranslation() and the _() macro).

Returns

Language code if a suitable match was found, empty string otherwise.

Since

2.9.5

wxString wxTranslations::GetBestTranslation (const wxString & *domain*, const wxString & *msgIdLanguage* = "en")

Returns the best UI language for the *domain*.

The language is determined from the preferred UI language or languages list the user configured in the OS. Notice that this may or may not correspond to the default *locale* as obtained from wxLocale::GetSystemLanguage(); modern operation systems (Windows Vista+, OS X) have separate language and regional (= locale) settings.

Parameters

domain	The catalog domain to look for.
msgIdLanguage	Specifies the language of "msgid" strings in source code (i.e. arguments to GetString(), wxGetTranslation() and the _() macro).

Returns

Language code if a suitable match was found, empty string otherwise.

Since

2.9.5

wxString wxTranslations::GetHeaderValue (const wxString & *header,* const wxString & *domain* = wxEmptyString) const

Returns the header value for header *header*.

The search for *header* is case sensitive. If an *domain* is passed, this domain is searched. Else all domains will be searched until a header has been found.

The return value is the value of the header if found. Else this will be empty.

const wxString* wxTranslations::GetTranslatedString (const wxString & *origString,* const wxString & *domain* = wxEmptyString) const

Retrieves the translation for a string in all loaded domains unless the *domain* parameter is specified (and then only this catalog/domain is searched).

Returns NULL if translation is not available.

This function is thread-safe.

Remarks

Domains are searched in the last to first order, i.e. catalogs added later override those added before.

Since

3.0

const wxString* wxTranslations::GetTranslatedString (const wxString & *origString,* unsigned *n,* const wxString & *domain* = wxEmptyString) const

Retrieves the translation for a string in all loaded domains unless the *domain* parameter is specified (and then only this catalog/domain is searched).

Returns NULL if translation is not available.

This form is used when retrieving translation of string that has different singular and plural form in English or different plural forms in some other language.

Parameters

origString	The singular form of the string to be converted.
n	The number on which the plural form choice depends on. (In some languages, there are different plural forms for e.g. n=2 and n=3 etc., in addition to the singular form (n=1) being different.)
domain	The only domain (i.e. message catalog) to search if specified. By default this parameter is empty, indicating that all loaded catalogs should be searched.

See GNU gettext manual for additional information on plural forms handling. This method is called by the wxGet↩Translation() function and _() macro.

This function is thread-safe.

Remarks

Domains are searched in the last to first order, i.e. catalogs added later override those added before.

Since

3.0

bool wxTranslations::IsLoaded (const wxString & *domain*) const

Check if the given catalog is loaded, and returns true if it is.

According to GNU gettext tradition, each catalog normally corresponds to 'domain' which is more or less the application name.

See also

AddCatalog()

static void wxTranslations::Set (wxTranslations * *t*) [static]

Sets current translations object.

Deletes previous translation object and takes ownership of *t*.

void wxTranslations::SetLanguage (wxLanguage *lang*)

Sets translations language to use.

wxLANGUAGE_DEFAULT has special meaning: best suitable translation, given user's preference and available translations, will be used.

void wxTranslations::SetLanguage (const wxString & *lang*)

Sets translations language to use.

Empty *lang* string has the same meaning as wxLANGUAGE_DEFAULT in SetLanguage(wxLanguage): best suitable translation, given user's preference and available translations, will be used.

void wxTranslations::SetLoader (wxTranslationsLoader * *loader*)

Changes loader use to read catalogs to a non-default one.

Deletes previous loader and takes ownership of *loader*.

wxFileTranslationsLoader, wxResourceTranslationsLoader

Since

2.9.1

Public Member Functions

- wxTranslationsLoader ()

  Trivial default constructor.
- virtual wxMsgCatalog * LoadCatalog (const wxString &domain, const wxString &lang)=0

  Called to load requested catalog.
- virtual wxArrayString GetAvailableTranslations (const wxString &domain) const =0

  Implements wxTranslations::GetAvailableTranslations().

21.804.2 Constructor & Destructor Documentation

wxTranslationsLoader::wxTranslationsLoader ( )

Trivial default constructor.

21.804.3 Member Function Documentation

virtual wxArrayString wxTranslationsLoader::GetAvailableTranslations (const wxString & *domain*) const `[pure virtual]`

Implements wxTranslations::GetAvailableTranslations().

virtual wxMsgCatalog* wxTranslationsLoader::LoadCatalog (const wxString & *domain,* const wxString & *lang*) `[pure virtual]`

Called to load requested catalog.

If the catalog is found, LoadCatalog() should create wxMsgCatalog instance with its data and return it. The caller will take ownership of the catalog.

Parameters

domain	Domain to load.
lang	Language to look for. This is "canonical name" (see wxLocale::GetCanonicalName()), i.e. ISO 639 code, possibly combined with country code or additional modifiers (e.g. "fr", "en_GB" or "ca@valencia").

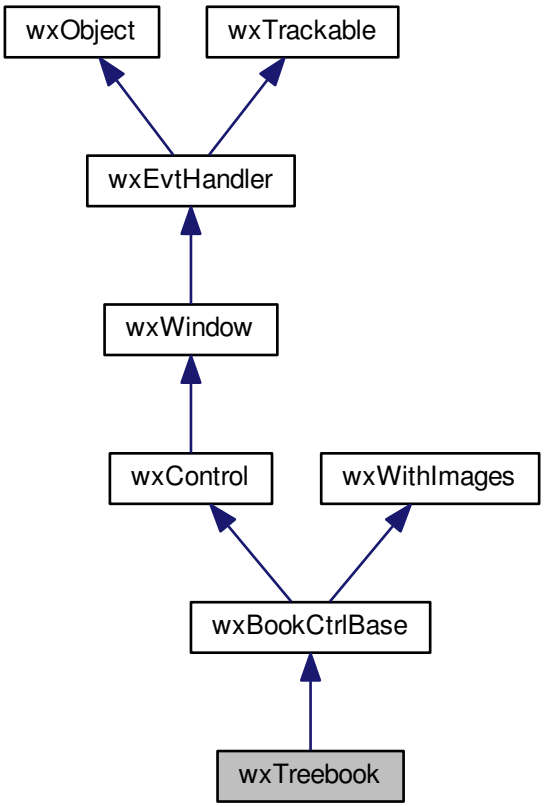
Returns

Loaded catalog or NULL on failure.

21.805 wxTreebook Class Reference

`#include <wx/treebook.h>`

Inheritance diagram for wxTreebook:



21.805.1 Detailed Description

This class is an extension of the wxNotebook class that allows a tree structured set of pages to be shown in a control.

A classic example is a netscape preferences dialog that shows a tree of preference sections on the left and select section page on the right.

To use the class simply create it and populate with pages using InsertPage(), InsertSubPage(), AddPage(), AddSubPage().

If your tree is no more than 1 level in depth then you could simply use AddPage() and AddSubPage() to sequentially populate your tree by adding at every step a page or a subpage to the end of the tree.

Events emitted by this class

The following event handler macros redirect the events to member function handlers '**func**' with prototypes like: void handlerFuncName(wxBookCtrlEvent& event)

Event macros for events emitted by this class:

- EVT_TREEBOOK_PAGE_CHANGED(id, func): The page selection was changed. Processes a `wxEVT_TREEBOOK_PAGE_CHANGED` event.

- EVT_TREEBOOK_PAGE_CHANGING(id, func): The page selection is about to be changed. Processes a `wxEVT_TREEBOOK_PAGE_CHANGING` event. This event can be vetoed.
- EVT_TREEBOOK_NODE_COLLAPSED(id, func): The page node is going to be collapsed. Processes a `wxEVT_TREEBOOK_NODE_COLLAPSED` event.
- EVT_TREEBOOK_NODE_EXPANDED(id, func): The page node is going to be expanded. Processes a `wxEVT_TREEBOOK_NODE_EXPANDED` event.

Library: wxCore

Category: Book Controls

Public Member Functions

- wxTreebook ()

  Default constructor.
- wxTreebook (wxWindow *parent, wxWindowID id, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, long style=wxBK_DEFAULT, const wxString &name=wxEmptyString)

  Creates an empty wxTreebook.
- virtual ~wxTreebook ()

  Destroys the wxTreebook object.
- virtual bool AddPage (wxWindow *page, const wxString &text, bool bSelect=false, int imageId=wxNOT_FOUND)

  Adds a new page.
- virtual bool AddSubPage (wxWindow *page, const wxString &text, bool bSelect=false, int imageId=wxNOT_FOUND)

  Adds a new child-page to the last top-level page.
- bool CollapseNode (size_t pageId)

  Shortcut for ExpandNode(pageId, false).
- bool Create (wxWindow *parent, wxWindowID id, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, long style=wxBK_DEFAULT, const wxString &name=wxEmptyString)

  Creates a treebook control.
- virtual bool DeletePage (size_t pagePos)

  Deletes the page at the specified position and all its children.
- virtual bool ExpandNode (size_t pageId, bool expand=true)

  Expands (collapses) the pageId node.
- int GetPageParent (size_t page) const

  Returns the parent page of the given one or `wxNOT_FOUND` if this is a top-level page.
- virtual int GetSelection () const

  Returns the currently selected page, or `wxNOT_FOUND` if none was selected.
- virtual bool InsertPage (size_t pagePos, wxWindow *page, const wxString &text, bool bSelect=false, int imageId=wxNOT_FOUND)

  Inserts a new page just before the page indicated by pagePos.
- virtual bool InsertSubPage (size_t pagePos, wxWindow *page, const wxString &text, bool bSelect=false, int imageId=wxNOT_FOUND)

  Inserts a sub page under the specified page.
- virtual bool IsNodeExpanded (size_t pageId) const

  Returns true if the page represented by pageId is expanded.

Additional Inherited Members

21.805.2 Constructor & Destructor Documentation

wxTreebook::wxTreebook ( )

Default constructor.

wxTreebook::wxTreebook (wxWindow * *parent*, wxWindowID *id*, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, long *style* = wxBK_DEFAULT, const wxString & *name* = wxEmptyString)

Creates an empty wxTreebook.

Parameters

parent	The parent window. Must be non-NULL.
id	The window identifier.
pos	The window position.
size	The window size.
style	The window style. See wxNotebook.
name	The name of the control (used only under Motif).

virtual wxTreebook::~wxTreebook ( ) [virtual]

Destroys the wxTreebook object.

Also deletes all the pages owned by the control (inserted previously into it).

21.805.3 Member Function Documentation

virtual bool wxTreebook::AddPage (wxWindow * *page*, const wxString & *text*, bool *bSelect* = false, int *imageId* = wxNOT_FOUND) [virtual]

Adds a new page.

The page is placed at the topmost level after all other pages. NULL could be specified for page to create an empty page.

Reimplemented from wxBookCtrlBase.

virtual bool wxTreebook::AddSubPage (wxWindow * *page*, const wxString & *text*, bool *bSelect* = false, int *imageId* = wxNOT_FOUND) [virtual]

Adds a new child-page to the last top-level page.

NULL could be specified for page to create an empty page.

bool wxTreebook::CollapseNode (size_t *pageId*)

Shortcut for ExpandNode(*pageId*, false).

bool wxTreebook::Create (wxWindow * *parent*, wxWindowID *id*, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, long *style* = wxBK_DEFAULT, const wxString & *name* = wxEmptyString)

Creates a treebook control.

See wxTreebook::wxTreebook() for the description of the parameters.

virtual bool wxTreebook::DeletePage (size_t *pagePos*) [virtual]

Deletes the page at the specified position and all its children.

Could trigger page selection change in a case when selected page is removed. In that case its parent is selected (or the next page if no parent).

Reimplemented from wxBookCtrlBase.

virtual bool wxTreebook::ExpandNode (size_t *pageId*, bool *expand* = true) [virtual]

Expands (collapses) the *pageId* node.

Returns the previous state. May generate page changing events (if selected page is under the collapsed branch, then its parent is autoselected).

int wxTreebook::GetPageParent (size_t *page*) const

Returns the parent page of the given one or wxNOT_FOUND if this is a top-level page.

virtual int wxTreebook::GetSelection ( ) const [virtual]

Returns the currently selected page, or wxNOT_FOUND if none was selected.

Note

This method may return either the previously or newly selected page when called from the EVT_TREEBOOK_PAGE_CHANGED() handler depending on the platform and so wxBookCtrlEvent::GetSelection() should be used instead in this case.

Implements wxBookCtrlBase.

virtual bool wxTreebook::InsertPage (size_t *pagePos*, wxWindow * *page*, const wxString & *text*, bool *bSelect* = false, int *imageId* = wxNOT_FOUND) [virtual]

Inserts a new page just before the page indicated by *pagePos*.

The new page is placed before *pagePos* page and on the same level. NULL could be specified for page to create an empty page.

Implements wxBookCtrlBase.

virtual bool wxTreebook::InsertSubPage (size_t *pagePos*, wxWindow * *page*, const wxString & *text*, bool *bSelect* = false, int *imageId* = wxNOT_FOUND) [virtual]

Inserts a sub page under the specified page.

NULL could be specified for page to create an empty page.

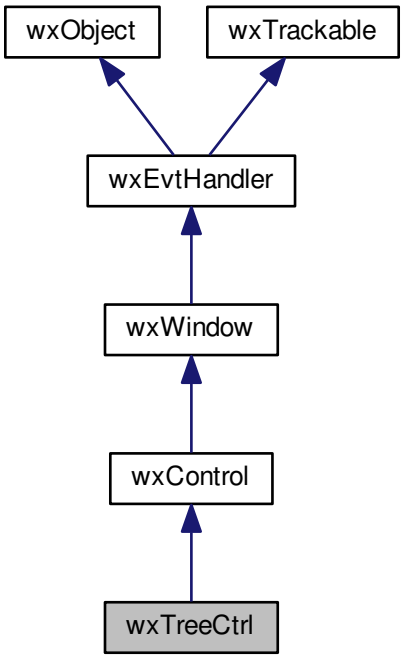
virtual bool wxTreebook::IsNodeExpanded (size_t *pageId*) const [virtual]

Returns true if the page represented by *pageId* is expanded.

21.806 wxTreeCtrl Class Reference

`#include <wx/treectrl.h>`

Inheritance diagram for wxTreeCtrl:



21.806.1 Detailed Description

A tree control presents information as a hierarchy, with items that may be expanded to show further items.

Items in a tree control are referenced by wxTreeItemId handles, which may be tested for validity by calling wxTreeItemId::IsOk().

A similar control with a fully native implementation for GTK+ and OS X as well is wxDataViewTreeCtrl.

To intercept events from a tree control, use the event table macros described in wxTreeEvent.

Styles

This class supports the following styles:

- wxTR_EDIT_LABELS: Use this style if you wish the user to be able to edit labels in the tree control.
- wxTR_NO_BUTTONS: For convenience to document that no buttons are to be drawn.
- wxTR_HAS_BUTTONS: Use this style to show + and - buttons to the left of parent items.
- wxTR_TWIST_BUTTONS: Selects alternative style of `+/- buttons` and shows rotating ("twisting") arrows instead. Currently this style is only implemented under Microsoft Windows Vista and later Windows versions and is ignored under the other platforms. Notice that under Vista this style results in the same appearance

as used by the tree control in Explorer and other built-in programs and so using it may be preferable to the default style.

- wxTR_NO_LINES: Use this style to hide vertical level connectors.
- wxTR_FULL_ROW_HIGHLIGHT: Use this style to have the background colour and the selection highlight extend over the entire horizontal row of the tree control window. (This flag is ignored under Windows unless you specify `wxTR_NO_LINES` as well.)
- wxTR_LINES_AT_ROOT: Use this style to show lines between root nodes. Only applicable if `wxTR_HIDE_ROOT` is set and `wxTR_NO_LINES` is not set.
- wxTR_HIDE_ROOT: Use this style to suppress the display of the root node, effectively causing the first-level nodes to appear as a series of root nodes.
- wxTR_ROW_LINES: Use this style to draw a contrasting border between displayed rows.
- wxTR_HAS_VARIABLE_ROW_HEIGHT: Use this style to cause row heights to be just big enough to fit the content. If not set, all rows use the largest row height. The default is that this flag is unset. Generic only.
- wxTR_SINGLE: For convenience to document that only one item may be selected at a time. Selecting another item causes the current selection, if any, to be deselected. This is the default.
- wxTR_MULTIPLE: Use this style to allow a range of items to be selected. If a second range is selected, the current range, if any, is deselected.
- wxTR_DEFAULT_STYLE: The set of flags that are closest to the defaults for the native control for a particular toolkit.

Events emitted by this class

The following event handler macros redirect the events to member function handlers '**func**' with prototypes like: void handlerFuncName(wxTreeEvent& event)

Event macros for events emitted by this class:

- EVT_TREE_BEGIN_DRAG(id, func): Begin dragging with the left mouse button. If you want to enable left-dragging you need to intercept this event and explicitly call wxTreeEvent::Allow(), as it's vetoed by default. Processes a `wxEVT_TREE_BEGIN_DRAG` event type.
- EVT_TREE_BEGIN_RDRAG(id, func): Begin dragging with the right mouse button. If you want to enable right-dragging you need to intercept this event and explicitly call wxTreeEvent::Allow(), as it's vetoed by default. Processes a `wxEVT_TREE_BEGIN_RDRAG` event type.
- EVT_TREE_END_DRAG(id, func): End dragging with the left or right mouse button. Processes a `wxEVT_TREE_END_DRAG` event type.
- EVT_TREE_BEGIN_LABEL_EDIT(id, func): Begin editing a label. This can be prevented by calling Veto(). Processes a `wxEVT_TREE_BEGIN_LABEL_EDIT` event type.
- EVT_TREE_END_LABEL_EDIT(id, func): Finish editing a label. This can be prevented by calling Veto(). Processes a `wxEVT_TREE_END_LABEL_EDIT` event type.
- EVT_TREE_DELETE_ITEM(id, func): An item was deleted. Processes a `wxEVT_TREE_DELETE_ITEM` event type.
- EVT_TREE_GET_INFO(id, func): Request information from the application. Processes a `wxEVT_TREE_GET_INFO` event type.
- EVT_TREE_SET_INFO(id, func): Information is being supplied. Processes a `wxEVT_TREE_SET_INFO` event type.
- EVT_TREE_ITEM_ACTIVATED(id, func): The item has been activated, i.e. chosen by double clicking it with mouse or from keyboard. Processes a `wxEVT_TREE_ITEM_ACTIVATED` event type.

- EVT_TREE_ITEM_COLLAPSED(id, func): The item has been collapsed. Processes a wxEVT_TREE_ITEM_COLLAPSED event type.
- EVT_TREE_ITEM_COLLAPSING(id, func): The item is being collapsed. This can be prevented by calling Veto(). Processes a wxEVT_TREE_ITEM_COLLAPSING event type.
- EVT_TREE_ITEM_EXPANDED(id, func): The item has been expanded. Processes a wxEVT_TREE_ITEM_EXPANDED event type.
- EVT_TREE_ITEM_EXPANDING(id, func): The item is being expanded. This can be prevented by calling Veto(). Processes a wxEVT_TREE_ITEM_EXPANDING event type.
- EVT_TREE_ITEM_RIGHT_CLICK(id, func): The user has clicked the item with the right mouse button. Processes a wxEVT_TREE_ITEM_RIGHT_CLICK event type.
- EVT_TREE_ITEM_MIDDLE_CLICK(id, func): The user has clicked the item with the middle mouse button. This is only supported by the generic control. Processes a wxEVT_TREE_ITEM_MIDDLE_CLICK event type.
- EVT_TREE_SEL_CHANGED(id, func): Selection has changed. Processes a wxEVT_TREE_SEL_CHANGED event type.
- EVT_TREE_SEL_CHANGING(id, func): Selection is changing. This can be prevented by calling Veto(). Processes a wxEVT_TREE_SEL_CHANGING event type.
- EVT_TREE_KEY_DOWN(id, func): A key has been pressed. Processes a wxEVT_TREE_KEY_DOWN event type.
- EVT_TREE_ITEM_GETTOOLTIP(id, func): The opportunity to set the item tooltip is being given to the application (call wxTreeEvent::SetToolTip). Windows only. Processes a wxEVT_TREE_ITEM_GETTOOLTIP event type.
- EVT_TREE_ITEM_MENU(id, func): The context menu for the selected item has been requested, either by a right click or by using the menu key. Processes a wxEVT_TREE_ITEM_MENU event type.
- EVT_TREE_STATE_IMAGE_CLICK(id, func): The state image has been clicked. Processes a wxEVT_TREE_STATE_IMAGE_CLICK event type.

See also Window Styles.

Win32 notes:

wxTreeCtrl class uses the standard common treeview control under Win32 implemented in the system library comctl32.dll. Some versions of this library are known to have bugs with handling the tree control colours: the usual symptom is that the expanded items leave black (or otherwise incorrectly coloured) background behind them, especially for the controls using non-default background colour. The recommended solution is to upgrade the comctl32.dll to a newer version: see http://www.microsoft.com/downloads/details.aspx?familyid=cb2cf3a2-8025-4e8f-8511-9b476a8d35d2

Library: wxCore

Public Member Functions

- wxTreeCtrl ()

  Default Constructor.
- wxTreeCtrl (wxWindow *parent, wxWindowID id=wxID_ANY, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, long style=wxTR_DEFAULT_STYLE, const wxValidator &validator=wxDefaultValidator, const wxString &name=wxTreeCtrlNameStr)

  Constructor, creating and showing a tree control.
- virtual ~wxTreeCtrl ()

  Destructor, destroying the tree control.
- virtual wxTreeItemId AddRoot (const wxString &text, int image=-1, int selImage=-1, wxTreeItemData *data=NULL)

  Adds the root node to the tree, returning the new item.
- wxTreeItemId AppendItem (const wxTreeItemId &parent, const wxString &text, int image=-1, int selImage=-1, wxTreeItemData *data=NULL)

  Appends an item to the end of the branch identified by parent, return a new item id.
- void AssignButtonsImageList (wxImageList *imageList)

  Sets the buttons image list.
- void AssignImageList (wxImageList *imageList)

  Sets the normal image list.
- void AssignStateImageList (wxImageList *imageList)

  Sets the state image list.
- virtual void Collapse (const wxTreeItemId &item)

  Collapses the given item.
- void CollapseAll ()

  Collapses the root item.
- void CollapseAllChildren (const wxTreeItemId &item)

  Collapses this item and all of its children, recursively.
- virtual void CollapseAndReset (const wxTreeItemId &item)

  Collapses the given item and removes all children.
- bool Create (wxWindow *parent, wxWindowID id=wxID_ANY, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, long style=wxTR_DEFAULT_STYLE, const wxValidator &validator=wxDefaultValidator, const wxString &name=wxTreeCtrlNameStr)

  Creates the tree control.
- virtual void Delete (const wxTreeItemId &item)

  Deletes the specified item.
- virtual void DeleteAllItems ()

  Deletes all items in the control.
- virtual void DeleteChildren (const wxTreeItemId &item)

  Deletes all children of the given item (but not the item itself).
- virtual wxTextCtrl * EditLabel (const wxTreeItemId &item, wxClassInfo *textCtrlClass=wxCLASSINFO(wxTextCtrl))

  Starts editing the label of the given item.
- void EnableBellOnNoMatch (bool on=true)

  Enable or disable a beep if there is no match for the currently entered text when searching for the item from keyboard.
- virtual void EndEditLabel (const wxTreeItemId &item, bool discardChanges=false)

  Ends label editing.
- virtual void EnsureVisible (const wxTreeItemId &item)

  Scrolls and/or expands items to ensure that the given item is visible.
- virtual void Expand (const wxTreeItemId &item)

  Expands the given item.
- void ExpandAll ()

Expands all items in the tree.

- void ExpandAllChildren (const wxTreeItemId &item)

  Expands the given item and all its children recursively.
- virtual bool GetBoundingRect (const wxTreeItemId &item, wxRect &rect, bool textOnly=false) const

  Retrieves the rectangle bounding the item.
- wxImageList * GetButtonsImageList () const

  Returns the buttons image list (from which application-defined button images are taken).
- virtual size_t GetChildrenCount (const wxTreeItemId &item, bool recursively=true) const

  Returns the number of items in the branch.
- virtual unsigned int GetCount () const

  Returns the number of items in the control.
- virtual wxTextCtrl * GetEditControl () const

  Returns the edit control being currently used to edit a label.
- virtual wxTreeItemId GetFirstChild (const wxTreeItemId &item, wxTreeItemIdValue &cookie) const

  Returns the first child; call GetNextChild() for the next child.
- virtual wxTreeItemId GetFirstVisibleItem () const

  Returns the first visible item.
- virtual wxTreeItemId GetFocusedItem () const

  Returns the item last clicked or otherwise selected.
- virtual void ClearFocusedItem ()

  Clears the currently focused item.
- virtual void SetFocusedItem (const wxTreeItemId &item)

  Sets the currently focused item.
- wxImageList * GetImageList () const

  Returns the normal image list.
- virtual unsigned int GetIndent () const

  Returns the current tree control indentation.
- virtual wxColour GetItemBackgroundColour (const wxTreeItemId &item) const

  Returns the background colour of the item.
- virtual wxTreeItemData * GetItemData (const wxTreeItemId &item) const

  Returns the tree item data associated with the item.
- virtual wxFont GetItemFont (const wxTreeItemId &item) const

  Returns the font of the item label.
- virtual int GetItemImage (const wxTreeItemId &item, wxTreeItemIcon which=wxTreeItemIcon_Normal) const

  Gets the specified item image.
- virtual wxTreeItemId GetItemParent (const wxTreeItemId &item) const

  Returns the item's parent.
- int GetItemState (const wxTreeItemId &item) const

  Gets the specified item state.
- virtual wxString GetItemText (const wxTreeItemId &item) const

  Returns the item label.
- virtual wxColour GetItemTextColour (const wxTreeItemId &item) const

  Returns the colour of the item label.
- virtual wxTreeItemId GetLastChild (const wxTreeItemId &item) const

  Returns the last child of the item (or an invalid tree item if this item has no children).
- virtual wxTreeItemId GetNextChild (const wxTreeItemId &item, wxTreeItemIdValue &cookie) const

  Returns the next child; call GetFirstChild() for the first child.
- virtual wxTreeItemId GetNextSibling (const wxTreeItemId &item) const

  Returns the next sibling of the specified item; call GetPrevSibling() for the previous sibling.
- virtual wxTreeItemId GetNextVisible (const wxTreeItemId &item) const

  Returns the next visible item or an invalid item if this item is the last visible one.

- virtual wxTreeItemId GetPrevSibling (const wxTreeItemId &item) const

  Returns the previous sibling of the specified item; call GetNextSibling() for the next sibling.
- virtual wxTreeItemId GetPrevVisible (const wxTreeItemId &item) const

  Returns the previous visible item or an invalid item if this item is the first visible one.
- bool GetQuickBestSize () const

  Returns true if the control will use a quick calculation for the best size, looking only at the first and last items.
- virtual wxTreeItemId GetRootItem () const

  Returns the root item for the tree control.
- virtual wxTreeItemId GetSelection () const

  Returns the selection, or an invalid item if there is no selection.
- virtual size_t GetSelections (wxArrayTreeItemIds &selection) const

  Fills the array of tree items passed in with the currently selected items.
- wxImageList * GetStateImageList () const

  Returns the state image list (from which application-defined state images are taken).
- wxTreeItemId HitTest (const wxPoint &point, int &flags) const

  Calculates which (if any) item is under the given point, returning the tree item id at this point plus extra information flags.
- wxTreeItemId InsertItem (const wxTreeItemId &parent, const wxTreeItemId &previous, const wxString &text, int image=-1, int selImage=-1, wxTreeItemData *data=NULL)

  Inserts an item after a given one (previous).
- wxTreeItemId InsertItem (const wxTreeItemId &parent, size_t pos, const wxString &text, int image=-1, int selImage=-1, wxTreeItemData *data=NULL)

  Inserts an item before one identified by its position (pos).
- virtual bool IsBold (const wxTreeItemId &item) const

  Returns true if the given item is in bold state.
- bool IsEmpty () const

  Returns true if the control is empty (i.e. has no items, even no root one).
- virtual bool IsExpanded (const wxTreeItemId &item) const

  Returns true if the item is expanded (only makes sense if it has children).
- virtual bool IsSelected (const wxTreeItemId &item) const

  Returns true if the item is selected.
- virtual bool IsVisible (const wxTreeItemId &item) const

  Returns true if the item is visible on the screen.
- virtual bool ItemHasChildren (const wxTreeItemId &item) const

  Returns true if the item has children.
- virtual int OnCompareItems (const wxTreeItemId &item1, const wxTreeItemId &item2)

  Override this function in the derived class to change the sort order of the items in the tree control.
- wxTreeItemId PrependItem (const wxTreeItemId &parent, const wxString &text, int image=-1, int selImage=-1, wxTreeItemData *data=NULL)

  Appends an item as the first child of parent, return a new item id.
- virtual void ScrollTo (const wxTreeItemId &item)

  Scrolls the specified item into view.
- virtual void SelectItem (const wxTreeItemId &item, bool select=true)

  Selects the given item.
- void SetButtonsImageList (wxImageList *imageList)

  Sets the buttons image list (from which application-defined button images are taken).
- virtual void SetImageList (wxImageList *imageList)

  Sets the normal image list.
- virtual void SetIndent (unsigned int indent)

  Sets the indentation for the tree control.
- virtual void SetItemBackgroundColour (const wxTreeItemId &item, const wxColour &col)

Sets the colour of the item's background.

- virtual void SetItemBold (const wxTreeItemId &item, bool bold=true)

  Makes item appear in bold font if bold parameter is true or resets it to the normal state.
- virtual void SetItemData (const wxTreeItemId &item, wxTreeItemData *data)

  Sets the item client data.
- virtual void SetItemDropHighlight (const wxTreeItemId &item, bool highlight=true)

  Gives the item the visual feedback for Drag'n'Drop actions, which is useful if something is dragged from the outside onto the tree control (as opposed to a DnD operation within the tree control, which already is implemented internally).
- virtual void SetItemFont (const wxTreeItemId &item, const wxFont &font)

  Sets the item's font.
- virtual void SetItemHasChildren (const wxTreeItemId &item, bool hasChildren=true)

  Force appearance of the button next to the item.
- virtual void SetItemImage (const wxTreeItemId &item, int image, wxTreeItemIcon which=wxTreeItemIcon_Normal)

  Sets the specified item's image.
- void SetItemState (const wxTreeItemId &item, int state)

  Sets the specified item state.
- virtual void SetItemText (const wxTreeItemId &item, const wxString &text)

  Sets the item label.
- virtual void SetItemTextColour (const wxTreeItemId &item, const wxColour &col)

  Sets the colour of the item's text.
- void SetQuickBestSize (bool quickBestSize)

  If true is passed, specifies that the control will use a quick calculation for the best size, looking only at the first and last items.
- virtual void SetStateImageList (wxImageList *imageList)

  Sets the state image list (from which application-defined state images are taken).
- void SetWindowStyle (long styles)

  Sets the mode flags associated with the display of the tree control.
- virtual void SortChildren (const wxTreeItemId &item)

  Sorts the children of the given item using OnCompareItems().
- virtual void Toggle (const wxTreeItemId &item)

  Toggles the given item between collapsed and expanded states.
- void ToggleItemSelection (const wxTreeItemId &item)

  Toggles the given item between selected and unselected states.
- virtual void Unselect ()

  Removes the selection from the currently selected item (if any).
- virtual void UnselectAll ()

  This function either behaves the same as Unselect() if the control doesn't have `wxTR_MULTIPLE` style, or removes the selection from all items if it does have this style.
- void UnselectItem (const wxTreeItemId &item)

  Unselects the given item.
- virtual void SelectChildren (const wxTreeItemId &parent)

  Select all the immediate children of the given parent.

Additional Inherited Members

21.806.2 Constructor & Destructor Documentation

wxTreeCtrl::wxTreeCtrl ( )

Default Constructor.

wxTreeCtrl::wxTreeCtrl (wxWindow * *parent*, wxWindowID *id* = wxID_ANY, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, long *style* = wxTR_DEFAULT_STYLE, const wxValidator & *validator* = wxDefaultValidator, const wxString & *name* = `wxTreeCtrlNameStr`)

Constructor, creating and showing a tree control.

Parameters

parent	Parent window. Must not be NULL.
id	Window identifier. The value `wxID_ANY` indicates a default value.
pos	Window position. If wxDefaultPosition is specified then a default position is chosen.
size	Window size. If wxDefaultSize is specified then the window is sized appropriately.
style	Window style. See wxTreeCtrl.
validator	Window validator.
name	Window name.

See also

Create(), wxValidator

virtual wxTreeCtrl::~wxTreeCtrl ( ) [virtual]

Destructor, destroying the tree control.

21.806.3 Member Function Documentation

virtual wxTreeItemId wxTreeCtrl::AddRoot (const wxString & *text*, int *image* = −1, int *selImage* = −1, wxTreeItemData * *data* = NULL) [virtual]

Adds the root node to the tree, returning the new item.

The *image* and *selImage* parameters are an index within the normal image list specifying the image to use for unselected and selected items, respectively. If *image* -1 and *selImage* is -1, the same image is used for both selected and unselected items.

wxTreeItemId wxTreeCtrl::AppendItem (const wxTreeItemId & *parent*, const wxString & *text*, int *image* = −1, int *selImage* = −1, wxTreeItemData * *data* = NULL)

Appends an item to the end of the branch identified by *parent*, return a new item id.

The *image* and *selImage* parameters are an index within the normal image list specifying the image to use for unselected and selected items, respectively. If *image* > -1 and *selImage* is -1, the same image is used for both selected and unselected items.

void wxTreeCtrl::AssignButtonsImageList (wxImageList * *imageList*)

Sets the buttons image list.

The button images assigned with this method will be automatically deleted by wxTreeCtrl as appropriate (i.e. it takes ownership of the list).

Setting or assigning the button image list enables the display of image buttons. Once enabled, the only way to disable the display of button images is to set the button image list to NULL.

This function is only available in the generic version.

See also

SetButtonsImageList().

void wxTreeCtrl::AssignImageList (wxImageList * *imageList*)

Sets the normal image list.

The image list assigned with this method will be automatically deleted by wxTreeCtrl as appropriate (i.e. it takes ownership of the list).

See also

SetImageList().

void wxTreeCtrl::AssignStateImageList (wxImageList * *imageList*)

Sets the state image list.

Image list assigned with this method will be automatically deleted by wxTreeCtrl as appropriate (i.e. it takes ownership of the list).

See also

SetStateImageList().

virtual void wxTreeCtrl::ClearFocusedItem ( ) [virtual]

Clears the currently focused item.

Since

2.9.1

virtual void wxTreeCtrl::Collapse (const wxTreeItemId & *item*) [virtual]

Collapses the given item.

void wxTreeCtrl::CollapseAll ( )

Collapses the root item.

See also

ExpandAll()

void wxTreeCtrl::CollapseAllChildren (const wxTreeItemId & *item*)

Collapses this item and all of its children, recursively.

See also

ExpandAllChildren()

virtual void wxTreeCtrl::CollapseAndReset (const wxTreeItemId & *item*) [virtual]

Collapses the given item and removes all children.

bool wxTreeCtrl::Create (wxWindow * *parent*, wxWindowID *id* = wxID_ANY, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, long *style* = wxTR_DEFAULT_STYLE, const wxValidator & *validator* = wxDefaultValidator, const wxString & *name* = wxTreeCtrlNameStr)

Creates the tree control.

See wxTreeCtrl::wxTreeCtrl() for further details.

virtual void wxTreeCtrl::Delete (const wxTreeItemId & *item*) [virtual]

Deletes the specified item.

A EVT_TREE_DELETE_ITEM event will be generated.

This function may cause a subsequent call to GetNextChild() to fail.

virtual void wxTreeCtrl::DeleteAllItems ( ) [virtual]

Deletes all items in the control.

Note that this may not generate EVT_TREE_DELETE_ITEM events under some Windows versions although normally such event is generated for each removed item.

virtual void wxTreeCtrl::DeleteChildren (const wxTreeItemId & *item*) [virtual]

Deletes all children of the given item (but not the item itself).

Note that this will **not** generate any events unlike Delete() method.

If you have called SetItemHasChildren(), you may need to call it again since DeleteChildren() does not automatically clear the setting.

virtual wxTextCtrl* wxTreeCtrl::EditLabel (const wxTreeItemId & *item*, wxClassInfo * *textCtrlClass* = wxCLASSINFO(wxTextCtrl)) [virtual]

Starts editing the label of the given *item*.

This function generates a EVT_TREE_BEGIN_LABEL_EDIT event which can be vetoed so that no text control will appear for in-place editing.

If the user changed the label (i.e. s/he does not press ESC or leave the text control without changes, a EVT_TREE_END_LABEL_EDIT event will be sent which can be vetoed as well.

See also

EndEditLabel(), wxTreeEvent

void wxTreeCtrl::EnableBellOnNoMatch (bool *on* = true)

Enable or disable a beep if there is no match for the currently entered text when searching for the item from keyboard.

The default is to not beep in this case except in wxMSW where the beep is always generated by the native control and cannot be disabled, i.e. calls to this function do nothing there.

Since

2.9.5

virtual void wxTreeCtrl::EndEditLabel (const wxTreeItemId & *item,* bool *discardChanges* = `false`) `[virtual]`

Ends label editing.

If *cancelEdit* is true, the edit will be cancelled.

Note

This function is currently supported under Windows only.

See also

EditLabel()

virtual void wxTreeCtrl::EnsureVisible (const wxTreeItemId & *item*) `[virtual]`

Scrolls and/or expands items to ensure that the given item is visible.

virtual void wxTreeCtrl::Expand (const wxTreeItemId & *item*) `[virtual]`

Expands the given item.

void wxTreeCtrl::ExpandAll ( )

Expands all items in the tree.

void wxTreeCtrl::ExpandAllChildren (const wxTreeItemId & *item*)

Expands the given item and all its children recursively.

virtual bool wxTreeCtrl::GetBoundingRect (const wxTreeItemId & *item,* wxRect & *rect,* bool *textOnly* = `false`) const `[virtual]`

Retrieves the rectangle bounding the *item*.

If *textOnly* is true, only the rectangle around the item's label will be returned, otherwise the item's image is also taken into account.

The return value is true if the rectangle was successfully retrieved or false if it was not (in this case *rect* is not changed) – for example, if the item is currently invisible.

Notice that the rectangle coordinates are logical, not physical ones. So, for example, the x coordinate may be negative if the tree has a horizontal scrollbar and its position is not 0.

wxPerl Note: In wxPerl this method only takes the *item* and *textOnly* parameters and returns a `Wx::Rect` (or `undef`).

wxImageList* wxTreeCtrl::GetButtonsImageList ( ) const

Returns the buttons image list (from which application-defined button images are taken).

This function is only available in the generic version.

virtual size_t wxTreeCtrl::GetChildrenCount (const wxTreeItemId & *item,* bool *recursively* = `true`) const `[virtual]`

Returns the number of items in the branch.

If *recursively* is true, returns the total number of descendants, otherwise only one level of children is counted.

virtual unsigned int wxTreeCtrl::GetCount ( ) const `[virtual]`

Returns the number of items in the control.

virtual wxTextCtrl* wxTreeCtrl::GetEditControl ( ) const `[virtual]`

Returns the edit control being currently used to edit a label.

Returns NULL if no label is being edited.

Note

This is currently only implemented for wxMSW.

virtual wxTreeItemId wxTreeCtrl::GetFirstChild (const wxTreeItemId & *item*, wxTreeItemIdValue & *cookie*) const `[virtual]`

Returns the first child; call GetNextChild() for the next child.

For this enumeration function you must pass in a 'cookie' parameter which is opaque for the application but is necessary for the library to make these functions reentrant (i.e. allow more than one enumeration on one and the same object simultaneously). The cookie passed to GetFirstChild() and GetNextChild() should be the same variable.

Returns an invalid tree item (i.e. wxTreeItemId::IsOk() returns false) if there are no further children.

wxPerl Note: In wxPerl this method only takes the *item* parameter, and returns a 2-element list (item, cookie).

See also

GetNextChild(), GetNextSibling()

virtual wxTreeItemId wxTreeCtrl::GetFirstVisibleItem ( ) const `[virtual]`

Returns the first visible item.

virtual wxTreeItemId wxTreeCtrl::GetFocusedItem ( ) const `[virtual]`

Returns the item last clicked or otherwise selected.

Unlike GetSelection(), it can be used whether or not the control has the `wxTR_MULTIPLE` style.

Since

2.9.1

wxImageList* wxTreeCtrl::GetImageList ( ) const

Returns the normal image list.

virtual unsigned int wxTreeCtrl::GetIndent ( ) const `[virtual]`

Returns the current tree control indentation.

virtual **wxColour** wxTreeCtrl::GetItemBackgroundColour (const **wxTreeItemId** & *item*) const [virtual]

Returns the background colour of the item.

virtual **wxTreeItemData**∗ wxTreeCtrl::GetItemData (const **wxTreeItemId** & *item*) const [virtual]

Returns the tree item data associated with the item.

See also

wxTreeItemData

wxPerl Note: wxPerl provides the following shortcut method:

- GetPlData(item): returns the Perl data associated with the Wx::TreeItemData. It is just the same as tree->GetItemData(item)->GetData().

virtual **wxFont** wxTreeCtrl::GetItemFont (const **wxTreeItemId** & *item*) const [virtual]

Returns the font of the item label.

If the font hadn't been explicitly set for the specified *item* with SetItemFont(), returns an invalid wxNullFont font. GetFont() can be used to retrieve the global tree control font used for the items without any specific font.

virtual int wxTreeCtrl::GetItemImage (const **wxTreeItemId** & *item,* **wxTreeItemIcon** *which* = **wxTreeItemIcon_Normal**) const [virtual]

Gets the specified item image.

The value of *which* may be:

- wxTreeItemIcon_Normal: to get the normal item image.
- wxTreeItemIcon_Selected: to get the selected item image (i.e. the image which is shown when the item is currently selected).
- wxTreeItemIcon_Expanded: to get the expanded image (this only makes sense for items which have children - then this image is shown when the item is expanded and the normal image is shown when it is collapsed).
- wxTreeItemIcon_SelectedExpanded: to get the selected expanded image (which is shown when an expanded item is currently selected).

virtual **wxTreeItemId** wxTreeCtrl::GetItemParent (const **wxTreeItemId** & *item*) const [virtual]

Returns the item's parent.

int wxTreeCtrl::GetItemState (const **wxTreeItemId** & *item*) const

Gets the specified item state.

virtual **wxString** wxTreeCtrl::GetItemText (const **wxTreeItemId** & *item*) const [virtual]

Returns the item label.

virtual **wxColour** wxTreeCtrl::GetItemTextColour (const **wxTreeItemId** & *item*) const [virtual]

Returns the colour of the item label.

virtual **wxTreeItemId** wxTreeCtrl::GetLastChild (const **wxTreeItemId** & *item*) const [virtual]

Returns the last child of the item (or an invalid tree item if this item has no children).

See also

GetFirstChild(), GetNextSibling(), GetLastChild()

virtual **wxTreeItemId** wxTreeCtrl::GetNextChild (const **wxTreeItemId** & *item,* wxTreeItemIdValue & *cookie*) const [virtual]

Returns the next child; call GetFirstChild() for the first child.

For this enumeration function you must pass in a 'cookie' parameter which is opaque for the application but is necessary for the library to make these functions reentrant (i.e. allow more than one enumeration on one and the same object simultaneously). The cookie passed to GetFirstChild() and GetNextChild() should be the same.

Returns an invalid tree item if there are no further children.

wxPerl Note: In wxPerl this method returns a 2-element list (item, cookie) instead of modifying its parameters.

See also

GetFirstChild()

virtual **wxTreeItemId** wxTreeCtrl::GetNextSibling (const **wxTreeItemId** & *item*) const [virtual]

Returns the next sibling of the specified item; call GetPrevSibling() for the previous sibling.

Returns an invalid tree item if there are no further siblings.

See also

GetPrevSibling()

virtual **wxTreeItemId** wxTreeCtrl::GetNextVisible (const **wxTreeItemId** & *item*) const [virtual]

Returns the next visible item or an invalid item if this item is the last visible one.

Note

The *item* itself must be visible.

virtual **wxTreeItemId** wxTreeCtrl::GetPrevSibling (const **wxTreeItemId** & *item*) const [virtual]

Returns the previous sibling of the specified item; call GetNextSibling() for the next sibling.

Returns an invalid tree item if there are no further children.

See also

GetNextSibling()

virtual **wxTreeItemId** **wxTreeCtrl::GetPrevVisible** (const **wxTreeItemId** & *item*) const [virtual]

Returns the previous visible item or an invalid item if this item is the first visible one.

Note

The *item* itself must be visible.

bool wxTreeCtrl::GetQuickBestSize ( ) const

Returns true if the control will use a quick calculation for the best size, looking only at the first and last items.

The default is false.

See also

SetQuickBestSize()

virtual **wxTreeItemId** **wxTreeCtrl::GetRootItem** ( ) const [virtual]

Returns the root item for the tree control.

virtual **wxTreeItemId** **wxTreeCtrl::GetSelection** ( ) const [virtual]

Returns the selection, or an invalid item if there is no selection.

This function only works with the controls without `wxTR_MULTIPLE` style, use GetSelections() for the controls which do have this style or, if a single item is wanted, use GetFocusedItem().

virtual **size_t** **wxTreeCtrl::GetSelections** (**wxArrayTreeItemIds** & *selection*) const [virtual]

Fills the array of tree items passed in with the currently selected items.

This function can be called only if the control has the `wxTR_MULTIPLE` style.

Returns the number of selected items.

wxPerl Note: In wxPerl this method takes no parameters and returns a list of `Wx::TreeItemId`.

wxImageList* **wxTreeCtrl::GetStateImageList** ( ) const

Returns the state image list (from which application-defined state images are taken).

wxTreeItemId **wxTreeCtrl::HitTest** (const **wxPoint** & *point,* int & *flags*) const

Calculates which (if any) item is under the given *point*, returning the tree item id at this point plus extra information *flags*.

flags is a bitlist of the following:

- `wxTREE_HITTEST_ABOVE`: Above the client area.
- `wxTREE_HITTEST_BELOW`: Below the client area.
- `wxTREE_HITTEST_NOWHERE`: In the client area but below the last item.
- `wxTREE_HITTEST_ONITEMBUTTON`: On the button associated with an item.

- `wxTREE_HITTEST_ONITEMICON`: On the bitmap associated with an item.
- `wxTREE_HITTEST_ONITEMINDENT`: In the indentation associated with an item.
- `wxTREE_HITTEST_ONITEMLABEL`: On the label (string) associated with an item.
- `wxTREE_HITTEST_ONITEMRIGHT`: In the area to the right of an item.
- `wxTREE_HITTEST_ONITEMSTATEICON`: On the state icon for a tree view item that is in a user-defined state.
- `wxTREE_HITTEST_TOLEFT`: To the right of the client area.
- `wxTREE_HITTEST_TORIGHT`: To the left of the client area.

wxPerl Note: In wxPerl this method only takes the *point* parameter and returns a 2-element list (item, flags).

wxTreeItemId wxTreeCtrl::InsertItem (const wxTreeItemId & *parent,* const wxTreeItemId & *previous,* const wxString & *text,* int *image* = −1, int *selImage* = −1, wxTreeItemData * *data* = NULL)

Inserts an item after a given one (*previous*).

The *image* and *selImage* parameters are an index within the normal image list specifying the image to use for unselected and selected items, respectively. If *image* -1 and *selImage* is -1, the same image is used for both selected and unselected items.

wxTreeItemId wxTreeCtrl::InsertItem (const wxTreeItemId & *parent,* size_t *pos,* const wxString & *text,* int *image* = −1, int *selImage* = −1, wxTreeItemData * *data* = NULL)

Inserts an item before one identified by its position (*pos*).

pos must be less than or equal to the number of children.

The *image* and *selImage* parameters are an index within the normal image list specifying the image to use for unselected and selected items, respectively. If *image* -1 and *selImage* is -1, the same image is used for both selected and unselected items.

virtual bool wxTreeCtrl::IsBold (const wxTreeItemId & *item*) const [virtual]

Returns true if the given item is in bold state.

See also

SetItemBold()

bool wxTreeCtrl::IsEmpty ( ) const

Returns true if the control is empty (i.e. has no items, even no root one).

virtual bool wxTreeCtrl::IsExpanded (const wxTreeItemId & *item*) const [virtual]

Returns true if the item is expanded (only makes sense if it has children).

virtual bool wxTreeCtrl::IsSelected (const wxTreeItemId & *item*) const [virtual]

Returns true if the item is selected.

virtual bool wxTreeCtrl::IsVisible (const wxTreeItemId & *item*) const [virtual]

Returns true if the item is visible on the screen.

virtual bool wxTreeCtrl::ItemHasChildren (const wxTreeItemId & *item*) const [virtual]

Returns true if the item has children.

virtual int wxTreeCtrl::OnCompareItems (const wxTreeItemId & *item1*, const wxTreeItemId & *item2*) [virtual]

Override this function in the derived class to change the sort order of the items in the tree control.

The function should return a negative, zero or positive value if the first item is less than, equal to or greater than the second one.

Please note that you **must** use wxRTTI macros wxDECLARE_DYNAMIC_CLASS() and wxIMPLEMENT_DYNAMIC_CLASS() if you override this function because otherwise the base class considers that it is not overridden and uses the default comparison, i.e. sorts the items alphabetically, which allows it optimize away the calls to the virtual function completely.

See also

SortChildren()

wxTreeItemId wxTreeCtrl::PrependItem (const wxTreeItemId & *parent*, const wxString & *text*, int *image* = -1, int *selImage* = -1, wxTreeItemData * *data* = NULL)

Appends an item as the first child of *parent*, return a new item id.

The *image* and *selImage* parameters are an index within the normal image list specifying the image to use for unselected and selected items, respectively. If *image* -1 and *selImage* is -1, the same image is used for both selected and unselected items.

virtual void wxTreeCtrl::ScrollTo (const wxTreeItemId & *item*) [virtual]

Scrolls the specified item into view.

virtual void wxTreeCtrl::SelectChildren (const wxTreeItemId & *parent*) [virtual]

Select all the immediate children of the given parent.

This function can be used with multiselection controls only.

Since

2.9.1

virtual void wxTreeCtrl::SelectItem (const wxTreeItemId & *item*, bool *select* = true) [virtual]

Selects the given item.

In multiple selection controls, can be also used to deselect a currently selected item if the value of *select* is false.

Notice that calling this method will generate wxEVT_TREE_SEL_CHANGING and wxEVT_TREE_SEL_CHANGED events and that the change could be vetoed by the former event handler.

void wxTreeCtrl::SetButtonsImageList (wxImageList * *imageList*)

Sets the buttons image list (from which application-defined button images are taken).

The button images assigned with this method will **not** be deleted by wxTreeCtrl's destructor, you must delete it yourself. Setting or assigning the button image list enables the display of image buttons. Once enabled, the only way to disable the display of button images is to set the button image list to NULL.

Note

This function is only available in the generic version.

See also

AssignButtonsImageList().

virtual void wxTreeCtrl::SetFocusedItem (const wxTreeItemId & *item*) [virtual]

Sets the currently focused item.

Parameters

item	The item to make the current one. It must be valid.

Since

2.9.1

virtual void wxTreeCtrl::SetImageList (wxImageList * *imageList*) [virtual]

Sets the normal image list.

The image list assigned with this method will **not** be deleted by wxTreeCtrl's destructor, you must delete it yourself.

See also

AssignImageList().

virtual void wxTreeCtrl::SetIndent (unsigned int *indent*) [virtual]

Sets the indentation for the tree control.

virtual void wxTreeCtrl::SetItemBackgroundColour (const wxTreeItemId & *item*, const wxColour & *col*) [virtual]

Sets the colour of the item's background.

virtual void wxTreeCtrl::SetItemBold (const wxTreeItemId & *item*, bool *bold* = true) [virtual]

Makes item appear in bold font if *bold* parameter is true or resets it to the normal state.

See also

IsBold()

virtual void wxTreeCtrl::SetItemData (const wxTreeItemId & *item,* wxTreeItemData * *data*) [virtual]

Sets the item client data.

Notice that the client data previously associated with the *item* (if any) is *not* freed by this function and so calling this function multiple times for the same item will result in memory leaks unless you delete the old item data pointer yourself.

wxPerl Note: wxPerl provides the following shortcut method:

- SetPlData(item, data): sets the Perl data associated with the `Wx::TreeItemData`. It is just the same as tree->GetItemData(item)->SetData(data).

virtual void wxTreeCtrl::SetItemDropHighlight (const wxTreeItemId & *item,* bool *highlight* = `true`) [virtual]

Gives the item the visual feedback for Drag'n'Drop actions, which is useful if something is dragged from the outside onto the tree control (as opposed to a DnD operation within the tree control, which already is implemented internally).

virtual void wxTreeCtrl::SetItemFont (const wxTreeItemId & *item,* const wxFont & *font*) [virtual]

Sets the item's font.

All items in the tree should have the same height to avoid text clipping, so the fonts height should be the same for all of them, although font attributes may vary.

See also

SetItemBold()

virtual void wxTreeCtrl::SetItemHasChildren (const wxTreeItemId & *item,* bool *hasChildren* = `true`) [virtual]

Force appearance of the button next to the item.

This is useful to allow the user to expand the items which don't have any children now, but instead adding them only when needed, thus minimizing memory usage and loading time.

virtual void wxTreeCtrl::SetItemImage (const wxTreeItemId & *item,* int *image,* wxTreeItemIcon *which* = wxTreeItemIcon_Normal) [virtual]

Sets the specified item's image.

See GetItemImage() for the description of the *which* parameter.

void wxTreeCtrl::SetItemState (const wxTreeItemId & *item,* int *state*)

Sets the specified item state.

The value of *state* may be:

- `wxTREE_ITEMSTATE_NONE`: to disable the item state (the state image will be not displayed).
- `wxTREE_ITEMSTATE_NEXT`: to set the next item state.
- `wxTREE_ITEMSTATE_PREV`: to set the previous item state.

virtual void wxTreeCtrl::SetItemText (const wxTreeItemId & *item,* const wxString & *text*) [virtual]

Sets the item label.

virtual void wxTreeCtrl::SetItemTextColour (const wxTreeItemId & *item,* const wxColour & *col*) [virtual]

Sets the colour of the item's text.

void wxTreeCtrl::SetQuickBestSize (bool *quickBestSize*)

If true is passed, specifies that the control will use a quick calculation for the best size, looking only at the first and last items.

Otherwise, it will look at all items. The default is false.

See also

GetQuickBestSize()

virtual void wxTreeCtrl::SetStateImageList (wxImageList * *imageList*) [virtual]

Sets the state image list (from which application-defined state images are taken).

Image list assigned with this method will **not** be deleted by wxTreeCtrl's destructor, you must delete it yourself.

See also

AssignStateImageList().

void wxTreeCtrl::SetWindowStyle (long *styles*)

Sets the mode flags associated with the display of the tree control.

The new mode takes effect immediately.

Note

Generic only; MSW ignores changes.

virtual void wxTreeCtrl::SortChildren (const wxTreeItemId & *item*) [virtual]

Sorts the children of the given item using OnCompareItems().

You should override that method to change the sort order (the default is ascending case-sensitive alphabetical order).

See also

wxTreeItemData, OnCompareItems()

virtual void wxTreeCtrl::Toggle (const wxTreeItemId & *item*) [virtual]

Toggles the given item between collapsed and expanded states.

void wxTreeCtrl::ToggleItemSelection (const wxTreeItemId & *item*)

Toggles the given item between selected and unselected states.

For multiselection controls only.

virtual void wxTreeCtrl::Unselect ( ) [virtual]

Removes the selection from the currently selected item (if any).

virtual void wxTreeCtrl::UnselectAll ( ) [virtual]

This function either behaves the same as Unselect() if the control doesn't have `wxTR_MULTIPLE` style, or removes the selection from all items if it does have this style.

void wxTreeCtrl::UnselectItem (const wxTreeItemId & *item*)

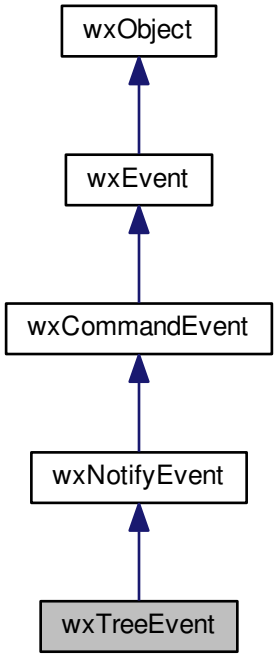
Unselects the given item.

This works in multiselection controls only.

21.807 wxTreeEvent Class Reference

`#include <wx/treectrl.h>`

Inheritance diagram for wxTreeEvent:



21.807.1 Detailed Description

A tree event holds information about events associated with wxTreeCtrl objects.

To process input from a tree control, use these event handler macros to direct input to member functions that take a wxTreeEvent argument.

Events using this class

The following event handler macros redirect the events to member function handlers '**func**' with prototypes like: void handlerFuncName(wxTreeEvent& event)

Event macros:

- EVT_TREE_BEGIN_DRAG(id, func): Begin dragging with the left mouse button. If you want to enable left-dragging you need to intercept this event and explicitly call wxTreeEvent::Allow(), as it's vetoed by default. Also notice that the control must have an associated image list (see SetImageList()) to drag its items under MSW.
- EVT_TREE_BEGIN_RDRAG(id, func): Begin dragging with the right mouse button. If you want to enable right-dragging you need to intercept this event and explicitly call wxTreeEvent::Allow(), as it's vetoed by default.
- EVT_TREE_END_DRAG(id, func): End dragging with the left or right mouse button.
- EVT_TREE_BEGIN_LABEL_EDIT(id, func): Begin editing a label. This can be prevented by calling Veto().
- EVT_TREE_END_LABEL_EDIT(id, func): Finish editing a label. This can be prevented by calling Veto().
- EVT_TREE_DELETE_ITEM(id, func): Delete an item.
- EVT_TREE_GET_INFO(id, func): Request information from the application.
- EVT_TREE_SET_INFO(id, func): Information is being supplied.
- EVT_TREE_ITEM_ACTIVATED(id, func): The item has been activated, i.e. chosen by double clicking it with mouse or from keyboard.
- EVT_TREE_ITEM_COLLAPSED(id, func): The item has been collapsed.
- EVT_TREE_ITEM_COLLAPSING(id, func): The item is being collapsed. This can be prevented by calling Veto().
- EVT_TREE_ITEM_EXPANDED(id, func): The item has been expanded.
- EVT_TREE_ITEM_EXPANDING(id, func): The item is being expanded. This can be prevented by calling Veto().
- EVT_TREE_ITEM_RIGHT_CLICK(id, func): The user has clicked the item with the right mouse button.
- EVT_TREE_ITEM_MIDDLE_CLICK(id, func): The user has clicked the item with the middle mouse button.
- EVT_TREE_SEL_CHANGED(id, func): Selection has changed.
- EVT_TREE_SEL_CHANGING(id, func): Selection is changing. This can be prevented by calling Veto().
- EVT_TREE_KEY_DOWN(id, func): A key has been pressed.
- EVT_TREE_ITEM_GETTOOLTIP(id, func): The opportunity to set the item tooltip is being given to the application (call SetToolTip()). Windows only.
- EVT_TREE_ITEM_MENU(id, func): The context menu for the selected item has been requested, either by a right click or by using the menu key.
- EVT_TREE_STATE_IMAGE_CLICK(id, func): The state image has been clicked.

wxTreeCtrl

Public Member Functions

- wxTreeEvent (wxEventType commandType, wxTreeCtrl *tree, const wxTreeItemId &item=wxTreeItemId())

  Constructor, used by wxWidgets itself only.
- wxTreeItemId GetItem () const

  Returns the item (valid for all events).
- int GetKeyCode () const

  Returns the key code if the event is a key event.
- const wxKeyEvent & GetKeyEvent () const

  Returns the key event for `EVT_TREE_KEY_DOWN` events.
- const wxString & GetLabel () const

  Returns the label if the event is a begin or end edit label event.
- wxTreeItemId GetOldItem () const

  Returns the old item index (valid for `EVT_TREE_ITEM_CHANGING` and `EVT_TREE_ITEM_CHANGED` events).
- wxPoint GetPoint () const

  Returns the position of the mouse pointer if the event is a drag or menu-context event.
- bool IsEditCancelled () const

  Returns true if the label edit was cancelled.
- void SetToolTip (const wxString &tooltip)

  Set the tooltip for the item (valid for `EVT_TREE_ITEM_GETTOOLTIP` events).

Additional Inherited Members

21.807.2 Constructor & Destructor Documentation

wxTreeEvent::wxTreeEvent (wxEventType *commandType,* wxTreeCtrl * *tree,* const wxTreeItemId & *item =* wxTreeItemId ())

Constructor, used by wxWidgets itself only.

21.807.3 Member Function Documentation

wxTreeItemId wxTreeEvent::GetItem ( ) const

Returns the item (valid for all events).

int wxTreeEvent::GetKeyCode ( ) const

Returns the key code if the event is a key event.

Use GetKeyEvent() to get the values of the modifier keys for this event (i.e. Shift or Ctrl).

const wxKeyEvent& wxTreeEvent::GetKeyEvent ( ) const

Returns the key event for `EVT_TREE_KEY_DOWN` events.

const wxString& wxTreeEvent::GetLabel ( ) const

Returns the label if the event is a begin or end edit label event.

wxTreeItemId wxTreeEvent::GetOldItem ( ) const

Returns the old item index (valid for `EVT_TREE_ITEM_CHANGING` and `EVT_TREE_ITEM_CHANGED` events).

wxPoint wxTreeEvent::GetPoint ( ) const

Returns the position of the mouse pointer if the event is a drag or menu-context event.

In both cases the position is in client coordinates - i.e. relative to the wxTreeCtrl window (so that you can pass it directly to e.g. wxWindow::PopupMenu()).

bool wxTreeEvent::IsEditCancelled ( ) const

Returns true if the label edit was cancelled.

This should be called from within an `EVT_TREE_END_LABEL_EDIT` handler.

void wxTreeEvent::SetToolTip (const wxString & *tooltip*)

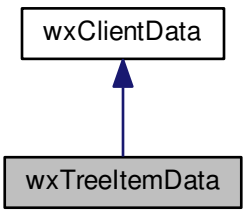
Set the tooltip for the item (valid for `EVT_TREE_ITEM_GETTOOLTIP` events).

Windows only.

21.808 wxTreeItemData Class Reference

`#include <wx/treebase.h>`

Inheritance diagram for wxTreeItemData:



21.808.1 Detailed Description

wxTreeItemData is some (arbitrary) user class associated with some item.

The main advantage of having this class is that wxTreeItemData objects are destroyed automatically by the tree and, as this class has virtual destructor, it means that the memory and any other resources associated with a tree item will be automatically freed when it is deleted. Note that we don't use wxObject as the base class for wxTreeItemData because the size of this class is critical: in many applications, each tree leaf will have wxTreeItemData associated with it and the number of leaves may be quite big.

Also please note that because the objects of this class are deleted by the tree using the operator `delete`, they must always be allocated on the heap using `new`.

Library: wxCore

Category: Containers

wxTreeCtrl

Public Member Functions

- wxTreeItemData ()

  Default constructor.
- virtual ~wxTreeItemData ()

  Virtual destructor.
- const wxTreeItemId & GetId () const

  Returns the item associated with this node.
- void SetId (const wxTreeItemId &id)

  Sets the item associated with this node.

21.808.2 Constructor & Destructor Documentation

wxTreeItemData::wxTreeItemData ( )

Default constructor.

wxPerl Note: In wxPerl the constructor accepts a scalar as an optional parameter and stores it as client data; use

- GetData() to retrieve the value.
- SetData(data) to set it.

virtual wxTreeItemData::~wxTreeItemData ( ) [virtual]

Virtual destructor.

21.808.3 Member Function Documentation

const wxTreeItemId& wxTreeItemData::GetId ( ) const

Returns the item associated with this node.

void wxTreeItemData::SetId (const wxTreeItemId & *id*)

Sets the item associated with this node.

Notice that this function is automatically called by wxTreeCtrl methods associating an object of this class with a tree control item such as wxTreeCtrl::AppendItem(), wxTreeCtrl::InsertItem() and wxTreeCtrl::SetItemData() so there is usually no need to call it yourself.

21.809 wxTreeItemId Class Reference

`#include <wx/treebase.h>`

21.809.1 Detailed Description

An opaque reference to a tree item.

21.809.2 Constructor & Destructor Documentation

wxTreeItemId::wxTreeItemId ( )

Default constructor.

A wxTreeItemId is not meant to be constructed explicitly by the user; only those returned by the wxTreeCtrl functions should be used.

21.809.3 Member Function Documentation

void* wxTreeItemId::GetID ( ) const

bool wxTreeItemId::IsOk ( ) const

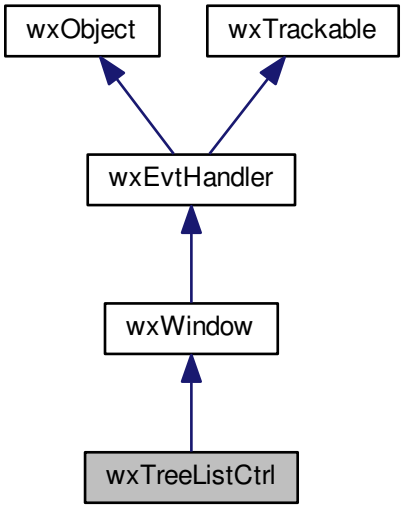
Returns true if this instance is referencing a valid tree item.

void wxTreeItemId::Unset ( )

21.810 wxTreeListCtrl Class Reference

`#include <wx/treelist.h>`

Inheritance diagram for wxTreeListCtrl:



21.810.1 Detailed Description

A control combining wxTreeCtrl and wxListCtrl features.

This is a multi-column tree control optionally supporting images and checkboxes for the items in the first column.

It is currently implemented using wxDataViewCtrl internally but provides a much simpler interface for the common use case it addresses. Thus, one of the design principles for this control is simplicity and intentionally doesn't provide all the features of wxDataViewCtrl. Most importantly, this class stores all its data internally and doesn't require you to define a custom model for it.

Instead, this controls works like wxTreeCtrl or non-virtual wxListCtrl and allows you to simply add items to it using wxTreeListCtrl::AppendItem() and related methods. Typically, you start by setting up the columns (you must have at least one) by calling wxTreeListCtrl::AppendColumn() and then add the items. While only the text of the first column can be specified when adding them, you can use wxTreeListCtrl::SetItemText() to set the text of the other columns.

Unlike wxTreeCtrl or wxListCtrl this control can sort its items on its own. To allow user to sort the control contents by clicking on some column you should use wxCOL_SORTABLE flag when adding that column to the control. When a column with this flag is clicked, the control resorts itself using the values in this column. By default the sort is done using alphabetical order comparison of the items text, which is not always correct (e.g. this doesn't work for the numeric columns). To change this you may use SetItemComparator() method to provide a custom comparator, i.e. simply an object that implements comparison between the two items. The treelist sample shows an example of doing this. And if you need to sort the control programmatically, you can call SetSortColumn() method.

Here are the styles supported by this control. Notice that using wxTL_USER_3STATE implies wxTL_3STATE and wxTL_3STATE in turn implies wxTL_CHECKBOX.

Styles

This class supports the following styles:

- wxTL_SINGLE: Single selection, this is the default.
- wxTL_MULTIPLE: Allow multiple selection, see GetSelections().
- wxTL_CHECKBOX: Show the usual, 2 state, checkboxes for the items in the first column.
- wxTL_3STATE: Show the checkboxes that can possibly be set by the program, but not the user, to a third, undetermined, state, for the items in the first column. Implies wxTL_CHECKBOX.
- wxTL_USER_3STATE: Same as wxTL_3STATE but the user can also set the checkboxes to the undetermined state. Implies wxTL_3STATE.
- wxTL_DEFAULT_STYLE: Style used by the control by default, just wxTL_SINGLE currently.

Events using this class

The following event handler macros redirect the events to member function handlers '**func**' with prototypes like: void handlerFuncName(wxTreeListEvent& event)

Event macros:

- EVT_TREELIST_SELECTION_CHANGED(id, func): Process `wxEVT_TREELIST_SELECTION_CHANGED` event and notifies about the selection change in the control. In the single selection case the item indicated by the event has been selected and previously selected item, if any, was deselected. In multiple selection case, the selection of this item has just changed (it may have been either selected or deselected) but notice that the selection of other items could have changed as well, use wxTreeListCtrl::GetSelections() to retrieve the new selection if necessary.
- EVT_TREELIST_ITEM_EXPANDING(id, func): Process `wxEVT_TREELIST_ITEM_EXPANDING` event notifying about the given branch being expanded. This event is sent before the expansion occurs and can be vetoed to prevent it from happening.
- EVT_TREELIST_ITEM_EXPANDED(id, func): Process `wxEVT_TREELIST_ITEM_EXPANDED` event notifying about the expansion of the given branch. This event is sent after the expansion occurs and can't be vetoed.
- EVT_TREELIST_ITEM_CHECKED(id, func): Process `wxEVT_TREELIST_ITEM_CHECKED` event notifying about the user checking or unchecking the item. You can use wxTreeListCtrl::GetCheckedState() to retrieve the new item state and wxTreeListEvent::GetOldCheckedState() to get the previous one.
- EVT_TREELIST_ITEM_ACTIVATED(id, func): Process `wxEVT_TREELIST_ITEM_ACTIVATED` event notifying about the user double clicking the item or activating it from keyboard.
- EVT_TREELIST_ITEM_CONTEXT_MENU(id, func): Process `wxEVT_TREELIST_ITEM_CONTEXT_MENU` event indicating that the popup menu for the given item should be displayed.
- EVT_TREELIST_COLUMN_SORTED(id, func): Process `wxEVT_TREELIST_COLUMN_SORTED` event indicating that the control contents has just been resorted using the specified column. The event doesn't carry the sort direction, use GetSortColumn() method if you need to know it.

Library: wxAdvanced

Category: Controls

Since

2.9.3

wxTreeCtrl, wxDataViewCtrl

- static const int NO_IMAGE = -1

  Image list methods.
- void AssignImageList (wxImageList *imageList)

  Sets the image list and gives its ownership to the control.
- void SetImageList (wxImageList *imageList)

  Sets the image list.

Public Member Functions

- wxTreeListCtrl ()

  Default constructor, call Create() later.
- wxTreeListCtrl (wxWindow *parent, wxWindowID id, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, long style=wxTL_DEFAULT_STYLE, const wxString &name=wxTreeListCtrlNameStr)

  Full constructing, creating the object and its window.
- bool Create (wxWindow *parent, wxWindowID id, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, long style=wxTL_DEFAULT_STYLE, const wxString &name=wxTreeListCtrlNameStr)

  Create the control window.

- int AppendColumn (const wxString &title, int width=wxCOL_WIDTH_AUTOSIZE, wxAlignment align=wxALIGN_LEFT, int flags=wxCOL_RESIZABLE)

  Column methods.
- unsigned GetColumnCount () const

  Return the total number of columns.
- bool DeleteColumn (unsigned col)

  Delete the column with the given index.
- void ClearColumns ()

  Delete all columns.
- void SetColumnWidth (unsigned col, int width)

  Change the width of the given column.
- int GetColumnWidth (unsigned col) const

  Get the current width of the given column in pixels.
- int WidthFor (const wxString &text) const

  Get the width appropriate for showing the given text.

- wxTreeListItem AppendItem (wxTreeListItem parent, const wxString &text, int imageClosed=NO_IMAGE, int imageOpened=NO_IMAGE, wxClientData *data=NULL)

  Adding and removing items.
- wxTreeListItem InsertItem (wxTreeListItem parent, wxTreeListItem previous, const wxString &text, int imageClosed=NO_IMAGE, int imageOpened=NO_IMAGE, wxClientData *data=NULL)

  Insert a new item into the tree.
- wxTreeListItem PrependItem (wxTreeListItem parent, const wxString &text, int imageClosed=NO_IMAGE, int imageOpened=NO_IMAGE, wxClientData *data=NULL)

  Same as InsertItem() with wxTLI_FIRST.
- void DeleteItem (wxTreeListItem item)

Delete the specified item.

- void DeleteAllItems ()

  Delete all tree items.

- wxTreeListItem GetRootItem () const

  Methods for the tree navigation.
- wxTreeListItem GetItemParent (wxTreeListItem item) const

  Return the parent of the given item.
- wxTreeListItem GetFirstChild (wxTreeListItem item) const

  Return the first child of the given item.
- wxTreeListItem GetNextSibling (wxTreeListItem item) const

  Return the next sibling of the given item.
- wxTreeListItem GetFirstItem () const

  Return the first item in the tree.
- wxTreeListItem GetNextItem (wxTreeListItem item) const

  Get item after the given one in the depth-first tree-traversal order.

- const wxString & GetItemText (wxTreeListItem item, unsigned col=0) const

  Items attributes.
- void SetItemText (wxTreeListItem item, unsigned col, const wxString &text)

  Set the text of the specified column of the given item.
- void SetItemText (wxTreeListItem item, const wxString &text)

  Set the text of the first column of the given item.
- void SetItemImage (wxTreeListItem item, int closed, int opened=NO_IMAGE)

  Set the images for the given item.
- wxClientData * GetItemData (wxTreeListItem item) const

  Get the data associated with the given item.
- void SetItemData (wxTreeListItem item, wxClientData *data)

  Set the data associated with the given item.

- void Expand (wxTreeListItem item)

  Expanding and collapsing tree branches.
- void Collapse (wxTreeListItem item)

  Collapse the given tree branch.
- bool IsExpanded (wxTreeListItem item) const

  Return whether the given item is expanded.

- wxTreeListItem GetSelection () const

  Selection methods.
- unsigned GetSelections (wxTreeListItems &selections) const

  Fill in the provided array with all the selected items.
- void Select (wxTreeListItem item)

  Select the given item.
- void Unselect (wxTreeListItem item)

  Deselect the given item.
- bool IsSelected (wxTreeListItem item) const

  Return true if the item is selected.
- void SelectAll ()

  Select all the control items.
- void UnselectAll ()

  Deselect all the control items.

- void CheckItem (wxTreeListItem item, wxCheckBoxState state=wxCHK_CHECKED)

  Checkbox handling.
- void CheckItemRecursively (wxTreeListItem item, wxCheckBoxState state=wxCHK_CHECKED)

  Change the checked state of the given item and all its children.
- void UncheckItem (wxTreeListItem item)

  Uncheck the given item.
- void UpdateItemParentStateRecursively (wxTreeListItem item)

  Update the state of the parent item to reflect the checked state of its children.
- wxCheckBoxState GetCheckedState (wxTreeListItem item) const

  Return the checked state of the item.
- bool AreAllChildrenInState (wxTreeListItem item, wxCheckBoxState state) const

  Return true if all children of the given item are in the specified state.

- void SetSortColumn (unsigned col, bool ascendingOrder=true)

  Sorting.
- bool GetSortColumn (unsigned *col, bool *ascendingOrder=NULL)

  Return the column currently used for sorting, if any.
- void SetItemComparator (wxTreeListItemComparator *comparator)

  Set the object to use for comparing the items.

- wxWindow * GetView () const

  View window.
- wxDataViewCtrl * GetDataView () const

  Return the view part of this control as wxDataViewCtrl.

Additional Inherited Members

21.810.2 Constructor & Destructor Documentation

wxTreeListCtrl::wxTreeListCtrl ( )

Default constructor, call Create() later.

This constructor is used during two-part construction process when it is impossible or undesirable to create the window when constructing the object.

wxTreeListCtrl::wxTreeListCtrl (wxWindow * *parent*, wxWindowID *id*, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, long *style* = wxTL_DEFAULT_STYLE, const wxString & *name* = `wxTreeListCtrlNameStr`)

Full constructing, creating the object and its window.

See Create() for the parameters description.

21.810.3 Member Function Documentation

int wxTreeListCtrl::AppendColumn (const wxString & *title*, int *width* = wxCOL_WIDTH_AUTOSIZE, wxAlignment *align* = wxALIGN_LEFT, int *flags* = wxCOL_RESIZABLE)

Column methods.

Add a column with the given title and attributes.

Parameters

title	The column label.
width	The width of the column in pixels or the special wxCOL_WIDTH_AUTOSIZE value indicating that the column should adjust to its contents. Notice that the first column is special and will be always resized to fill all the space not taken by the other columns, i.e. the width specified here is ignored for it.
align	Alignment of both the column header and its items.
flags	Column flags, currently can include wxCOL_RESIZABLE to allow the user to resize the column and wxCOL_SORTABLE to allow the user to resort the control contents by clicking on this column.

Returns

Index of the new column or -1 on failure.

wxTreeListItem wxTreeListCtrl::AppendItem (wxTreeListItem *parent,* const wxString & *text,* int *imageClosed* = NO_IMAGE, int *imageOpened* = NO_IMAGE, wxClientData * *data* = NULL)

Adding and removing items.

When adding items, the parent and text of the first column of the new item must always be specified, the rest is optional.

Each item can have two images: one used for closed state and another for opened one. Only the first one is ever used for the items that don't have children. And both are not set by default.

It is also possible to associate arbitrary client data pointer with the new item. It will be deleted by the control when the item is deleted (either by an explicit DeleteItem() call or because the entire control is destroyed).Same as InsertItem() with wxTLI_LAST.

bool wxTreeListCtrl::AreAllChildrenInState (wxTreeListItem *item,* wxCheckBoxState *state*) const

Return true if all children of the given item are in the specified state.

This is especially useful for the controls with wxTL_3STATE style to allow to decide whether the parent effective state should be the same *state*, if all its children are in it, or wxCHK_UNDETERMINED.

See also

UpdateItemParentStateRecursively()

void wxTreeListCtrl::AssignImageList (wxImageList * *imageList*)

Sets the image list and gives its ownership to the control.

The image list assigned with this method will be automatically deleted by wxTreeCtrl as appropriate (i.e. it takes ownership of the list).

See also

SetImageList().

void wxTreeListCtrl::CheckItem (wxTreeListItem *item,* wxCheckBoxState *state* = wxCHK_CHECKED)

Checkbox handling.

Methods in this section can only be used with the controls created with wxTL_CHECKBOX style. Change the item checked state.

Parameters

item	Valid non-root tree item.
state	One of wxCHK_CHECKED, wxCHK_UNCHECKED or, for the controls with wxTL_3STATE or wxTL_USER_3STATE styles, wxCHK_UNDETERMINED.

void wxTreeListCtrl::CheckItemRecursively (wxTreeListItem *item*, wxCheckBoxState *state* = wxCHK_CHECKED)

Change the checked state of the given item and all its children.

This is the same as CheckItem() but checks or unchecks not only this item itself but all its children recursively as well.

void wxTreeListCtrl::ClearColumns ( )

Delete all columns.

See also

DeleteAllItems()

void wxTreeListCtrl::Collapse (wxTreeListItem *item*)

Collapse the given tree branch.

bool wxTreeListCtrl::Create (wxWindow * *parent*, wxWindowID *id*, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, long *style* = wxTL_DEFAULT_STYLE, const wxString & *name* = `wxTreeListCtrlNameStr`)

Create the control window.

Can be only called for the objects created using the default constructor and exactly once.

Parameters

parent	The parent window, must be non-NULL.
id	The window identifier, may be wxID_ANY.
pos	The initial window position, usually unused.
size	The initial window size, usually unused.
style	The window style, see their description in the class documentation.
name	The name of the window.

void wxTreeListCtrl::DeleteAllItems ( )

Delete all tree items.

bool wxTreeListCtrl::DeleteColumn (unsigned *col*)

Delete the column with the given index.

Parameters

col	Column index in 0 to GetColumnCount() (exclusive) range.

Returns

True if the column was deleted, false if index is invalid or deleting the column failed for some other reason.

void wxTreeListCtrl::DeleteItem (wxTreeListItem *item*)

Delete the specified item.

void wxTreeListCtrl::Expand (wxTreeListItem *item*)

Expanding and collapsing tree branches.

Notice that calling neither Expand() nor Collapse() method generates any events. Expand the given tree branch.

wxCheckBoxState wxTreeListCtrl::GetCheckedState (wxTreeListItem *item*) const

Return the checked state of the item.

The return value can be wxCHK_CHECKED, wxCHK_UNCHECKED or wxCHK_UNDETERMINED.

unsigned wxTreeListCtrl::GetColumnCount ( ) const

Return the total number of columns.

int wxTreeListCtrl::GetColumnWidth (unsigned *col*) const

Get the current width of the given column in pixels.

wxDataViewCtrl* wxTreeListCtrl::GetDataView ( ) const

Return the view part of this control as wxDataViewCtrl.

This method may return NULL in the future, non wxDataViewCtrl-based, versions of this class, use GetView() unless you really need to use wxDataViewCtrl methods on the returned object.

wxTreeListItem wxTreeListCtrl::GetFirstChild (wxTreeListItem *item*) const

Return the first child of the given item.

Item may be the root item.

Return value may be invalid if the item doesn't have any children.

wxTreeListItem wxTreeListCtrl::GetFirstItem ( ) const

Return the first item in the tree.

This is the first child of the root item.

See also

GetNextItem()

wxClientData* wxTreeListCtrl::GetItemData (wxTreeListItem *item*) const

Get the data associated with the given item.

The returned pointer may be NULL.

It must not be deleted by the caller as this will be done by the control itself.

wxTreeListItem wxTreeListCtrl::GetItemParent (wxTreeListItem *item*) const

Return the parent of the given item.

All the tree items visible in the tree have valid parent items, only the never shown root item has no parent.

const wxString& wxTreeListCtrl::GetItemText (wxTreeListItem *item*, unsigned *col* = 0) const

Items attributes.

Return the text of the given item.

By default, returns the text of the first column but any other one can be specified using *col* argument.

wxTreeListItem wxTreeListCtrl::GetNextItem (wxTreeListItem *item*) const

Get item after the given one in the depth-first tree-traversal order.

Calling this function starting with the result of GetFirstItem() allows iterating over all items in the tree.

The iteration stops when this function returns an invalid item, i.e.

```
for ( wxTreeListItem item = tree->GetFirstItem();
      item.IsOk();
      item = tree->GetNextItem(item) )
{
    ... Do something with every tree item ...
}
```

wxTreeListItem wxTreeListCtrl::GetNextSibling (wxTreeListItem *item*) const

Return the next sibling of the given item.

Return value may be invalid if there are no more siblings.

wxTreeListItem wxTreeListCtrl::GetRootItem ( ) const

Methods for the tree navigation.

The tree has an invisible root item which is the hidden parent of all top-level items in the tree. Starting from it it is possible to iterate over all tree items using GetNextItem().

It is also possible to iterate over just the children of the given item by using GetFirstChild() to get the first of them and then calling GetNextSibling() to retrieve all the others.Return the (never shown) root item.

wxTreeListItem wxTreeListCtrl::GetSelection ( ) const

Selection methods.

The behaviour of the control is different in single selection mode (the default) and multi-selection mode (if wxTL↩_MULTIPLE was specified when creating it). Not all methods can be used in both modes and some of those that can don't behave in the same way in two cases. Return the currently selected item.

This method can't be used with multi-selection controls, use GetSelections() instead.

The return value may be invalid if no item has been selected yet. Once an item in a single selection control was selected, it will keep a valid selection.

unsigned wxTreeListCtrl::GetSelections (wxTreeListItems & *selections*) const

Fill in the provided array with all the selected items.

This method can be used in both single and multi-selection case.

The previous array contents is destroyed.

Returns the number of selected items.

bool wxTreeListCtrl::GetSortColumn (unsigned * *col*, bool * *ascendingOrder* = NULL)

Return the column currently used for sorting, if any.

If the control is currently unsorted, the function simply returns false and doesn't modify any of its output parameters.

Parameters

col	Receives the index of the column used for sorting if non-NULL.
ascendingOrder	Receives true or false depending on whether the items are sorted in ascending or descending order.

Returns

true if the control is sorted or false if it isn't sorted at all.

wxWindow* wxTreeListCtrl::GetView ( ) const

View window.

This control itself is entirely covered by the "view window" which is currently a wxDataViewCtrl but if you want to avoid relying on this to allow your code to work with later versions which might not be wxDataViewCtrl-based, use GetView() function only and only use GetDataView() if you really need to call wxDataViewCtrl methods on it. Return the view part of this control as a wxWindow.

This method always returns non-NULL pointer once the window was created.

wxTreeListItem wxTreeListCtrl::InsertItem (wxTreeListItem *parent*, wxTreeListItem *previous*, const wxString & *text*, int *imageClosed* = NO_IMAGE, int *imageOpened* = NO_IMAGE, wxClientData * *data* = NULL)

Insert a new item into the tree.

Parameters

parent	The item parent. Must be valid, may be GetRootItem().
previous	The previous item that this one should be inserted immediately after. It must be valid but may be one of the special values wxTLI_FIRST or wxTLI_LAST indicating that the item should be either inserted before the first child of its parent (if any) or after the last one.

text	The item text.
imageClosed	The normal item image, may be NO_IMAGE to not show any image.
imageOpened	The item image shown when it's in the expanded state.
data	Optional client data pointer that can be later retrieved using GetItemData() and will be deleted by the tree when the item itself is deleted.

bool wxTreeListCtrl::IsExpanded (wxTreeListItem *item*) const

Return whether the given item is expanded.

bool wxTreeListCtrl::IsSelected (wxTreeListItem *item*) const

Return true if the item is selected.

This method can be used in both single and multiple selection modes.

wxTreeListItem wxTreeListCtrl::PrependItem (wxTreeListItem *parent,* const wxString & *text,* int *imageClosed* = NO_IMAGE, int *imageOpened* = NO_IMAGE, wxClientData * *data* = NULL)

Same as InsertItem() with wxTLI_FIRST.

void wxTreeListCtrl::Select (wxTreeListItem *item*)

Select the given item.

In single selection mode, deselects any other selected items, in multi-selection case it adds to the selection.

void wxTreeListCtrl::SelectAll ( )

Select all the control items.

Can be only used in multi-selection mode.

void wxTreeListCtrl::SetColumnWidth (unsigned *col,* int *width*)

Change the width of the given column.

Set column width to either the given value in pixels or to the value large enough to fit all of the items if width is wxCOL_WIDTH_AUTOSIZE.

Notice that setting the width of the first column is ignored as this column is always resized to fill the space left by the other columns.

void wxTreeListCtrl::SetImageList (wxImageList * *imageList*)

Sets the image list.

The image list assigned with this method will **not** be deleted by the control itself and you will need to delete it yourself, use AssignImageList() to give the image list ownership to the control.

Parameters

imageList	Image list to use, may be NULL to not show any images any more.

void wxTreeListCtrl::SetItemComparator (wxTreeListItemComparator * *comparator*)

Set the object to use for comparing the items.

This object will be used when the control is being sorted because the user clicked on a sortable column or SetSortColumn() was called.

The provided pointer is stored by the control so the object it points to must have a life-time equal or greater to that of the control itself. In addition, the pointer can be NULL to stop using custom comparator and revert to the default alphabetical comparison.

void wxTreeListCtrl::SetItemData (wxTreeListItem *item*, wxClientData * *data*)

Set the data associated with the given item.

Previous client data, if any, is deleted when this function is called so it may be used to delete the current item data object and reset it by passing NULL as *data* argument.

void wxTreeListCtrl::SetItemImage (wxTreeListItem *item*, int *closed*, int *opened* = NO_IMAGE)

Set the images for the given item.

See InsertItem() for the images parameters descriptions.

void wxTreeListCtrl::SetItemText (wxTreeListItem *item*, unsigned *col*, const wxString & *text*)

Set the text of the specified column of the given item.

void wxTreeListCtrl::SetItemText (wxTreeListItem *item*, const wxString & *text*)

Set the text of the first column of the given item.

void wxTreeListCtrl::SetSortColumn (unsigned *col*, bool *ascendingOrder* = `true`)

Sorting.

If some control columns were added with wxCOL_SORTABLE flag, clicking on them will automatically resort the control using the custom comparator set by SetItemComparator() or by doing alphabetical comparison by default.

In any case, i.e. even if the user can't sort the control by clicking on its header, you may call SetSortColumn() to sort it programmatically and call GetSortColumn() to determine whether it's sorted now and, if so, by which column and in which order. Set the column to use for sorting and the order in which to sort.

Calling this method resorts the control contents using the values of the items in the specified column. Sorting uses custom comparator set with SetItemComparator() or alphabetical comparison of items texts if none was specified.

Notice that currently there is no way to reset sort order.

Parameters

col	A valid column index.

ascendingOrder	Indicates whether the items should be sorted in ascending (A to Z) or descending (Z to A) order.

void wxTreeListCtrl::UncheckItem (wxTreeListItem *item*)

Uncheck the given item.

This is synonymous with CheckItem(wxCHK_UNCHECKED).

void wxTreeListCtrl::Unselect (wxTreeListItem *item*)

Deselect the given item.

This method can be used in multiple selection mode only.

void wxTreeListCtrl::UnselectAll ( )

Deselect all the control items.

Can be only used in multi-selection mode.

void wxTreeListCtrl::UpdateItemParentStateRecursively (wxTreeListItem *item*)

Update the state of the parent item to reflect the checked state of its children.

This method updates the parent of this item recursively: if this item and all its siblings are checked, the parent will become checked as well. If this item and all its siblings are unchecked, the parent will be unchecked. And if the siblings of this item are not all in the same state, the parent will be switched to indeterminate state. And then the same logic will be applied to the parents parent and so on recursively.

This is typically called when the state of the given item has changed from EVT_TREELIST_ITEM_CHECKED() handler in the controls which have wxTL_3STATE flag. Notice that without this flag this function can't work as it would be unable to set the state of a parent with both checked and unchecked items so it's only allowed to call it when this flag is set.

int wxTreeListCtrl::WidthFor (const wxString & *text*) const

Get the width appropriate for showing the given text.

This is typically used as second argument for AppendColumn() or with SetColumnWidth().

21.810.4 Member Data Documentation

const int wxTreeListCtrl::NO_IMAGE = -1 `[static]`

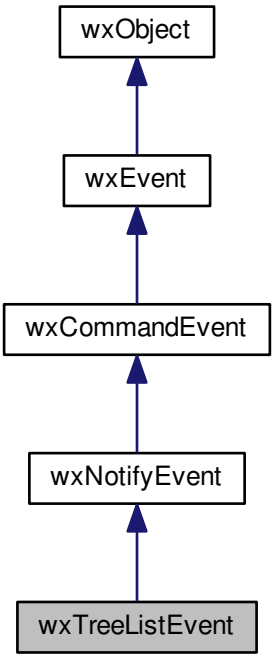
Image list methods.

Like wxTreeCtrl and wxListCtrl this class uses wxImageList so if you intend to use item icons with it, you must construct wxImageList containing them first and then specify the indices of the icons in this image list when adding the items later.A constant indicating that no image should be used for an item.

21.811 wxTreeListEvent Class Reference

`#include <wx/treelist.h>`

Inheritance diagram for wxTreeListEvent:



21.811.1 Detailed Description

Event generated by wxTreeListCtrl.

Since

2.9.3

Public Member Functions

- wxTreeListEvent ()
- wxTreeListItem GetItem () const

  Return the item affected by the event.
- wxCheckBoxState GetOldCheckedState () const

  Return the previous state of the item checkbox.
- unsigned GetColumn () const

  Return the column affected by the event.

Additional Inherited Members

21.811.2 Constructor & Destructor Documentation

wxTreeListEvent::wxTreeListEvent ( )

21.811.3 Member Function Documentation

unsigned wxTreeListEvent::GetColumn ( ) const

Return the column affected by the event.

This is currently only used with `wxEVT_TREELIST_COLUMN_SORTED` event.

wxTreeListItem wxTreeListEvent::GetItem ( ) const

Return the item affected by the event.

This is the item being selected, expanded, checked or activated (depending on the event type).

wxCheckBoxState wxTreeListEvent::GetOldCheckedState ( ) const

Return the previous state of the item checkbox.

This method can be used with `wxEVT_TREELIST_ITEM_CHECKED` events only.

Notice that the new state of the item can be retrieved using wxTreeListCtrl::GetCheckedState().

21.812 wxTreeListItem Class Reference

```
#include <wx/treelist.h>
```

21.812.1 Detailed Description

Unique identifier of an item in wxTreeListCtrl.

This is an opaque class which can't be used by the application in any other way than receiving or passing it to wxTreeListCtrl and checking for validity.

wxTreeListCtrl

Library: wxAdvanced

Category: Controls

Since

2.9.3

Public Member Functions

- wxTreeListItem ()

  Only the default constructor is publicly accessible.
- bool IsOk () const

  Return true if the item is valid.

21.812.2 Constructor & Destructor Documentation

wxTreeListItem::wxTreeListItem ( )

Only the default constructor is publicly accessible.

Default constructing a wxTreeListItem creates an invalid item.

21.812.3 Member Function Documentation

bool wxTreeListItem::IsOk ( ) const

Return true if the item is valid.

21.813 wxTreeListItemComparator Class Reference

`#include <wx/treelist.h>`

21.813.1 Detailed Description

Class defining sort order for the items in wxTreeListCtrl.

See also

wxTreeListCtrl

Library: wxAdvanced

Category: Controls

Since

2.9.3

Public Member Functions

- wxTreeListItemComparator ()

  Default constructor.
- virtual int Compare (wxTreeListCtrl *treelist, unsigned column, wxTreeListItem first, wxTreeListItem second)=0

  Pure virtual function which must be overridden to define sort order.
- virtual ~wxTreeListItemComparator ()

  Trivial but virtual destructor.

21.813.2 Constructor & Destructor Documentation

wxTreeListItemComparator::wxTreeListItemComparator ( )

Default constructor.

Notice that this class is not copyable, comparators are not passed by value.

virtual wxTreeListItemComparator::~wxTreeListItemComparator ( ) [virtual]

Trivial but virtual destructor.

Although this class is not used polymorphically by wxWidgets itself, provide virtual dtor in case it's used like this in the user code.

21.813.3 Member Function Documentation

virtual int wxTreeListItemComparator::Compare (wxTreeListCtrl * *treelist,* unsigned *column,* wxTreeListItem *first,* wxTreeListItem *second*) [pure virtual]

Pure virtual function which must be overridden to define sort order.

The comparison function should return negative, null or positive value depending on whether the first item is less than, equal to or greater than the second one. The items should be compared using their values for the given column.

Parameters

treelist	The control whose contents is being sorted.
column	The column of this control used for sorting.
first	First item to compare.
second	Second item to compare.

Returns

A negative value if the first item is less than (i.e. should appear above) the second one, zero if the two items are equal or a positive value if the first item is greater than (i.e. should appear below) the second one.

21.814 wxUIActionSimulator Class Reference

`#include <wx/uiaction.h>`

21.814.1 Detailed Description

wxUIActionSimulator is a class used to simulate user interface actions such as a mouse click or a key press.

Common usage for this class would be to provide playback and record (aka macro recording) functionality for users, or to drive unit tests by simulating user sessions.

See the wxUIActionSimulator Sample for an example of using this class.

Since

2.9.2

Library: wxCore

Public Member Functions

- wxUIActionSimulator ()

  Default constructor.
- bool MouseMove (long x, long y)

Move the mouse to the specified coordinates.

- bool MouseMove (const wxPoint &point)

  Move the mouse to the specified coordinates.
- bool MouseDown (int button=wxMOUSE_BTN_LEFT)

  Press a mouse button.
- bool MouseUp (int button=wxMOUSE_BTN_LEFT)

  Release a mouse button.
- bool MouseClick (int button=wxMOUSE_BTN_LEFT)

  Click a mouse button.
- bool MouseDblClick (int button=wxMOUSE_BTN_LEFT)

  Double-click a mouse button.
- bool MouseDragDrop (long x1, long y1, long x2, long y2, int button=wxMOUSE_BTN_LEFT)

  Perform a drag and drop operation.
- bool KeyDown (int keycode, int modifiers=wxMOD_NONE)

  Press a key.
- bool KeyUp (int keycode, int modifiers=wxMOD_NONE)

  Release a key.
- bool Char (int keycode, int modifiers=wxMOD_NONE)

  Press and release a key.
- bool Select (const wxString &text)

  Simulate selection of an item with the given text.
- bool Text (const wxString &text)

  Emulate typing in the keys representing the given string.

21.814.2 Constructor & Destructor Documentation

wxUIActionSimulator::wxUIActionSimulator ( )

Default constructor.

21.814.3 Member Function Documentation

bool wxUIActionSimulator::Char (int *keycode*, int *modifiers* = wxMOD_NONE)

Press and release a key.

Parameters

keycode	Key to operate on, as an integer. It is interpreted as a wxKeyCode.
modifiers	A combination of wxKeyModifier flags to be pressed with the given keycode.

bool wxUIActionSimulator::KeyDown (int *keycode*, int *modifiers* = wxMOD_NONE)

Press a key.

If you are using modifiers then it needs to be paired with an identical KeyUp or the modifiers will not be released (MSW and OSX).

Parameters

keycode	Key to operate on, as an integer. It is interpreted as a wxKeyCode.
modifiers	A combination of wxKeyModifier flags to be pressed with the given keycode.

bool wxUIActionSimulator::KeyUp (int *keycode,* int *modifiers* = wxMOD_NONE)

Release a key.

Parameters

keycode	Key to operate on, as an integer. It is interpreted as a wxKeyCode.
modifiers	A combination of wxKeyModifier flags to be pressed with the given keycode.

bool wxUIActionSimulator::MouseClick (int *button* = wxMOUSE_BTN_LEFT)

Click a mouse button.

Parameters

button	Button to press. See wxUIActionSimulator::MouseDown for a list of valid constants.

bool wxUIActionSimulator::MouseDblClick (int *button* = wxMOUSE_BTN_LEFT)

Double-click a mouse button.

Parameters

button	Button to press. See wxUIActionSimulator::MouseDown for a list of valid constants.

bool wxUIActionSimulator::MouseDown (int *button* = wxMOUSE_BTN_LEFT)

Press a mouse button.

Parameters

button	Button to press. Valid constants are `wxMOUSE_BTN_LEFT`, `wxMOUSE_BTN_MIDDLE`, and `wxMOUSE_BTN_RIGHT`.

bool wxUIActionSimulator::MouseDragDrop (long *x1,* long *y1,* long *x2,* long *y2,* int *button* = wxMOUSE_BTN_LEFT)

Perform a drag and drop operation.

Parameters

x1	x start coordinate, in screen coordinates.
y1	y start coordinate, in screen coordinates.
x2	x destination coordinate, in screen coordinates.
y2	y destination coordinate, in screen coordinates.
button	Button to press. See wxUIActionSimulator::MouseDown for a list of valid constants.

bool wxUIActionSimulator::MouseMove (long *x,* long *y*)

Move the mouse to the specified coordinates.

Parameters

x	x coordinate to move to, in screen coordinates.
y	y coordinate to move to, in screen coordinates.

bool wxUIActionSimulator::MouseMove (const wxPoint & *point*)

Move the mouse to the specified coordinates.

Parameters

point	Point to move to, in screen coordinates.

bool wxUIActionSimulator::MouseUp (int *button* = wxMOUSE_BTN_LEFT)

Release a mouse button.

Parameters

button	Button to press. See wxUIActionSimulator::MouseDown for a list of valid constants.

bool wxUIActionSimulator::Select (const wxString & *text*)

Simulate selection of an item with the given text.

This method selects an item in the currently focused wxChoice, wxComboBox, wxListBox and similar controls. It does it by simulating keyboard events, so the behaviour should be the same as if the item was really selected by the user.

Notice that the implementation of this method uses wxYield() and so events can be dispatched from it.

Parameters

text	The text of the item to select.

Returns

true if the item *text* was successfully selected or false if the currently focused window is not one of the controls allowing item selection or if the item with the given text was not found in it.

Since

3.1.0

bool wxUIActionSimulator::Text (const wxString & *text*)

Emulate typing in the keys representing the given string.

Currently only the ASCII letters, digits and characters for the definition of numbers (i.e. characters `a-z A-Z 0-9 + - . , 'space'`) are supported.

Parameters

text	The string to type.

21.815 wxULongLong Class Reference

`#include <wx/longlong.h>`

21.815.1 Detailed Description

This class represents an unsigned 64 bit long number.

Since wxULongLong has exactly the same API as wxLongLong, please refer to wxLongLong documentation (this page exists only as redirection).

Library: wxBase

Category: Data Structures

21.816 wxUniChar Class Reference

`#include <wx/unichar.h>`

21.816.1 Detailed Description

This class represents a single Unicode character.

It can be converted to and from `char` or `wchar_t` and implements commonly used character operations.

Library: wxBase

Category: Data Structures

Public Types

- typedef wxUint32 value_type

  A type capable of holding any Unicode code point.

Public Member Functions

- wxUniChar ()

  Default ctor.
- wxUniChar (int c)
- wxUniChar (unsigned int c)
- wxUniChar (long int c)
- wxUniChar (unsigned long int c)
- wxUniChar (short int c)

- wxUniChar (unsigned short int c)
- wxUniChar (wxLongLong_t c)
- wxUniChar (wxULongLong_t c)
- wxUniChar (const wxUniCharRef &c)
- value_type GetValue () const

  Returns Unicode code point value of the character.
- bool IsAscii () const

  Returns true if the character is an ASCII character (i.e. if its value is less than 128).
- bool GetAsChar (char *c) const

  Returns true if the character is representable as a single byte in the current locale encoding.

- wxUniChar (char c)

  Create a character from the 8-bit character value c using the current locale encoding.
- wxUniChar (unsigned char c)

  Create a character from the 8-bit character value c using the current locale encoding.

- operator char () const

  Conversions to char and wchar_t types: all of those are needed to be able to pass wxUniChars to various standard narrow and wide character functions.
- operator unsigned char () const

  Conversions to char and wchar_t types: all of those are needed to be able to pass wxUniChars to various standard narrow and wide character functions.
- operator wchar_t () const

  Conversions to char and wchar_t types: all of those are needed to be able to pass wxUniChars to various standard narrow and wide character functions.
- operator int () const

  Conversions to char and wchar_t types: all of those are needed to be able to pass wxUniChars to various standard narrow and wide character functions.
- operator unsigned int () const

  Conversions to char and wchar_t types: all of those are needed to be able to pass wxUniChars to various standard narrow and wide character functions.
- operator long int () const

  Conversions to char and wchar_t types: all of those are needed to be able to pass wxUniChars to various standard narrow and wide character functions.
- operator unsigned long int () const

  Conversions to char and wchar_t types: all of those are needed to be able to pass wxUniChars to various standard narrow and wide character functions.
- operator short int () const

  Conversions to char and wchar_t types: all of those are needed to be able to pass wxUniChars to various standard narrow and wide character functions.
- operator unsigned short int () const

  Conversions to char and wchar_t types: all of those are needed to be able to pass wxUniChars to various standard narrow and wide character functions.
- operator wxLongLong_t () const

  Conversions to char and wchar_t types: all of those are needed to be able to pass wxUniChars to various standard narrow and wide character functions.
- operator wxULongLong_t () const

  Conversions to char and wchar_t types: all of those are needed to be able to pass wxUniChars to various standard narrow and wide character functions.

- wxUniChar & operator= (const wxUniChar &c)

  Assignment operators.

- wxUniChar & operator= (wxLongLong_t c)

  Assignment operators.

- wxUniChar & operator= (wxULongLong_t c)

  Assignment operators.

21.816.2 Member Typedef Documentation

typedef wxUint32 wxUniChar::value_type

A type capable of holding any Unicode code point.

We do not use wchar_t as it cannot do the job on Win32, where wchar_t is a 16-bit type (wchar_t* is encoded using UTF-16 on Win32).

21.816.3 Constructor & Destructor Documentation

wxUniChar::wxUniChar ( )

Default ctor.

wxUniChar::wxUniChar (char *c*)

Create a character from the 8-bit character value *c* using the current locale encoding.

wxUniChar::wxUniChar (unsigned char *c*)

Create a character from the 8-bit character value *c* using the current locale encoding.

wxUniChar::wxUniChar (int *c*)

wxUniChar::wxUniChar (unsigned int *c*)

wxUniChar::wxUniChar (long int *c*)

wxUniChar::wxUniChar (unsigned long int *c*)

wxUniChar::wxUniChar (short int *c*)

wxUniChar::wxUniChar (unsigned short int *c*)

wxUniChar::wxUniChar (wxLongLong_t *c*)

wxUniChar::wxUniChar (wxULongLong_t *c*)

wxUniChar::wxUniChar (const wxUniCharRef & *c*)

21.816.4 Member Function Documentation

bool wxUniChar::GetAsChar (char * *c*) const

Returns true if the character is representable as a single byte in the current locale encoding.

This function only returns true if the character can be converted in exactly one byte, e.g. it only returns true for 7 bit ASCII characters when the encoding used is UTF-8.

It is mostly useful to test if the character can be passed to functions taking a char and is used by wxWidgets itself for this purpose.

Parameters

c	An output pointer to the value of this Unicode character as a `char`. Must be non-NULL.

Returns

true if the object is an 8 bit char and *c* was filled with its value as char or false otherwise (*c* won't be modified then).

See also

IsAscii()

Since

2.9.1

value_type wxUniChar::GetValue ( ) const

Returns Unicode code point value of the character.

bool wxUniChar::IsAscii ( ) const

Returns true if the character is an ASCII character (i.e. if its value is less than 128).

wxUniChar::operator char ( ) const

Conversions to char and wchar_t types: all of those are needed to be able to pass wxUniChars to various standard narrow and wide character functions.

wxUniChar::operator int ( ) const

Conversions to char and wchar_t types: all of those are needed to be able to pass wxUniChars to various standard narrow and wide character functions.

wxUniChar::operator long int ( ) const

Conversions to char and wchar_t types: all of those are needed to be able to pass wxUniChars to various standard narrow and wide character functions.

wxUniChar::operator short int ( ) const

Conversions to char and wchar_t types: all of those are needed to be able to pass wxUniChars to various standard narrow and wide character functions.

wxUniChar::operator unsigned char ( ) const

Conversions to char and wchar_t types: all of those are needed to be able to pass wxUniChars to various standard narrow and wide character functions.

wxUniChar::operator unsigned int ( ) const

Conversions to char and wchar_t types: all of those are needed to be able to pass wxUniChars to various standard narrow and wide character functions.

wxUniChar::operator unsigned long int ( ) const

Conversions to char and wchar_t types: all of those are needed to be able to pass wxUniChars to various standard narrow and wide character functions.

wxUniChar::operator unsigned short int ( ) const

Conversions to char and wchar_t types: all of those are needed to be able to pass wxUniChars to various standard narrow and wide character functions.

wxUniChar::operator wchar_t ( ) const

Conversions to char and wchar_t types: all of those are needed to be able to pass wxUniChars to various standard narrow and wide character functions.

wxUniChar::operator wxLongLong_t ( ) const

Conversions to char and wchar_t types: all of those are needed to be able to pass wxUniChars to various standard narrow and wide character functions.

wxUniChar::operator wxULongLong_t ( ) const

Conversions to char and wchar_t types: all of those are needed to be able to pass wxUniChars to various standard narrow and wide character functions.

wxUniChar& wxUniChar::operator= (const wxUniChar & *c*)

Assignment operators.

wxUniChar& wxUniChar::operator= (const wxUniCharRef & *c*)

Assignment operators.

wxUniChar& wxUniChar::operator= (char *c*)

Assignment operators.

wxUniChar& wxUniChar::operator= (unsigned char *c*)

Assignment operators.

wxUniChar& wxUniChar::operator= (wchar_t *c*)

Assignment operators.

wxUniChar& wxUniChar::operator= (int *c*)

Assignment operators.

wxUniChar& wxUniChar::operator= (unsigned int *c*)

Assignment operators.

wxUniChar& wxUniChar::operator= (long int *c*)

Assignment operators.

wxUniChar& wxUniChar::operator= (unsigned long int *c*)

Assignment operators.

wxUniChar& wxUniChar::operator= (short int *c*)

Assignment operators.

Assignment operators.

wxUniChar& wxUniChar::operator= (wxLongLong_t *c*)

Assignment operators.

wxUniChar& wxUniChar::operator= (wxULongLong_t *c*)

Assignment operators.

21.817 wxUniCharRef Class Reference

`#include <wx/unichar.h>`

21.817.1 Detailed Description

Writeable reference to a character in wxString.

This class can be used in the same way wxChar is used, except that changing its value updates the underlying string object.

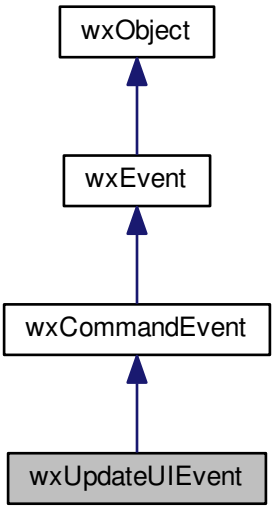
Library: wxBase

Category: Data Structures

21.818 wxUpdateUIEvent Class Reference

`#include <wx/event.h>`

Inheritance diagram for wxUpdateUIEvent:



21.818.1 Detailed Description

This class is used for pseudo-events which are called by wxWidgets to give an application the chance to update various user interface elements.

Without update UI events, an application has to work hard to check/uncheck, enable/disable, show/hide, and set the text for elements such as menu items and toolbar buttons. The code for doing this has to be mixed up with the code that is invoked when an action is invoked for a menu item or button.

With update UI events, you define an event handler to look at the state of the application and change UI elements accordingly. wxWidgets will call your member functions in idle time, so you don't have to worry where to call this code.

In addition to being a clearer and more declarative method, it also means you don't have to worry whether you're updating a toolbar or menubar identifier. The same handler can update a menu item and toolbar button, if the identifier is the same. Instead of directly manipulating the menu or button, you call functions in the event object, such as wxUpdateUIEvent::Check. wxWidgets will determine whether such a call has been made, and which UI element to update.

These events will work for popup menus as well as menubars. Just before a menu is popped up, wxMenu::UpdateUI is called to process any UI events for the window that owns the menu.

If you find that the overhead of UI update processing is affecting your application, you can do one or both of the following:

- Call wxUpdateUIEvent::SetMode with a value of wxUPDATE_UI_PROCESS_SPECIFIED, and set the extra style wxWS_EX_PROCESS_UI_UPDATES for every window that should receive update events. No other windows will receive update events.
- Call wxUpdateUIEvent::SetUpdateInterval with a millisecond value to set the delay between updates. You may need to call wxWindow::UpdateWindowUI at critical points, for example when a dialog is about to be shown, in case the user sees a slight delay before windows are updated.

Note that although events are sent in idle time, defining a wxIdleEvent handler for a window does not affect this because the events are sent from wxWindow::OnInternalIdle which is always called in idle time.

wxWidgets tries to optimize update events on some platforms. On Windows and GTK+, events for menubar items are only sent when the menu is about to be shown, and not in idle time.

Events using this class

The following event handler macros redirect the events to member function handlers '**func**' with prototypes like: void handlerFuncName(wxUpdateUIEvent& event)

Event macros:

- EVT_UPDATE_UI(id, func): Process a `wxEVT_UPDATE_UI` event for the command with the given id.
- EVT_UPDATE_UI_RANGE(id1, id2, func): Process a `wxEVT_UPDATE_UI` event for any command with id included in the given range.

Library: wxCore

Category: Events

See also

Events and Event Handling

Public Member Functions

- wxUpdateUIEvent (wxWindowID commandId=0)

  Constructor.
- void Check (bool check)

  Check or uncheck the UI element.
- void Enable (bool enable)

  Enable or disable the UI element.
- bool GetChecked () const

  Returns true if the UI element should be checked.
- bool GetEnabled () const

  Returns true if the UI element should be enabled.
- bool GetSetChecked () const

  Returns true if the application has called Check().
- bool GetSetEnabled () const

  Returns true if the application has called Enable().
- bool GetSetShown () const

  Returns true if the application has called Show().
- bool GetSetText () const

  Returns true if the application has called SetText().
- bool GetShown () const

  Returns true if the UI element should be shown.
- wxString GetText () const

  Returns the text that should be set for the UI element.
- void SetText (const wxString &text)

  Sets the text for this UI element.
- void Show (bool show)

  Show or hide the UI element.

Static Public Member Functions

- static bool CanUpdate (wxWindow *window)

  Returns true if it is appropriate to update (send UI update events to) this window.
- static wxUpdateUIMode GetMode ()

  Static function returning a value specifying how wxWidgets will send update events: to all windows, or only to those which specify that they will process the events.
- static long GetUpdateInterval ()

  Returns the current interval between updates in milliseconds.
- static void ResetUpdateTime ()

  Used internally to reset the last-updated time to the current time.
- static void SetMode (wxUpdateUIMode mode)

  Specify how wxWidgets will send update events: to all windows, or only to those which specify that they will process the events.
- static void SetUpdateInterval (long updateInterval)

  Sets the interval between updates in milliseconds.

Additional Inherited Members

21.818.2 Constructor & Destructor Documentation

wxUpdateUIEvent::wxUpdateUIEvent (wxWindowID *commandId* = 0)

Constructor.

21.818.3 Member Function Documentation

static bool wxUpdateUIEvent::CanUpdate (wxWindow * *window*) [static]

Returns true if it is appropriate to update (send UI update events to) this window.

This function looks at the mode used (see wxUpdateUIEvent::SetMode), the wxWS_EX_PROCESS_UI_UPDATES flag in *window*, the time update events were last sent in idle time, and the update interval, to determine whether events should be sent to this window now. By default this will always return true because the update mode is initially wxUPDATE_UI_PROCESS_ALL and the interval is set to 0; so update events will be sent as often as possible. You can reduce the frequency that events are sent by changing the mode and/or setting an update interval.

See also

ResetUpdateTime(), SetUpdateInterval(), SetMode()

void wxUpdateUIEvent::Check (bool *check*)

Check or uncheck the UI element.

void wxUpdateUIEvent::Enable (bool *enable*)

Enable or disable the UI element.

bool wxUpdateUIEvent::GetChecked ( ) const

Returns true if the UI element should be checked.

bool wxUpdateUIEvent::GetEnabled ( ) const

Returns true if the UI element should be enabled.

static wxUpdateUIMode wxUpdateUIEvent::GetMode ( ) [static]

Static function returning a value specifying how wxWidgets will send update events: to all windows, or only to those which specify that they will process the events.

See also

SetMode()

bool wxUpdateUIEvent::GetSetChecked ( ) const

Returns true if the application has called Check().

For wxWidgets internal use only.

bool wxUpdateUIEvent::GetSetEnabled ( ) const

Returns true if the application has called Enable().

For wxWidgets internal use only.

bool wxUpdateUIEvent::GetSetShown ( ) const

Returns true if the application has called Show().

For wxWidgets internal use only.

bool wxUpdateUIEvent::GetSetText ( ) const

Returns true if the application has called SetText().

For wxWidgets internal use only.

bool wxUpdateUIEvent::GetShown ( ) const

Returns true if the UI element should be shown.

wxString wxUpdateUIEvent::GetText ( ) const

Returns the text that should be set for the UI element.

static long wxUpdateUIEvent::GetUpdateInterval ( ) [static]

Returns the current interval between updates in milliseconds.

The value -1 disables updates, 0 updates as frequently as possible.

See also

SetUpdateInterval().

static void wxUpdateUIEvent::ResetUpdateTime ( ) [static]

Used internally to reset the last-updated time to the current time.

It is assumed that update events are normally sent in idle time, so this is called at the end of idle processing.

See also

CanUpdate(), SetUpdateInterval(), SetMode()

static void wxUpdateUIEvent::SetMode (wxUpdateUIMode *mode*) [static]

Specify how wxWidgets will send update events: to all windows, or only to those which specify that they will process the events.

Parameters

mode	this parameter may be one of the wxUpdateUIMode enumeration values. The default mode is wxUPDATE_UI_PROCESS_ALL.

void wxUpdateUIEvent::SetText (const wxString & *text*)

Sets the text for this UI element.

static void wxUpdateUIEvent::SetUpdateInterval (long *updateInterval*) `[static]`

Sets the interval between updates in milliseconds.

Set to -1 to disable updates, or to 0 to update as frequently as possible. The default is 0.

Use this to reduce the overhead of UI update events if your application has a lot of windows. If you set the value to -1 or greater than 0, you may also need to call wxWindow::UpdateWindowUI at appropriate points in your application, such as when a dialog is about to be shown.

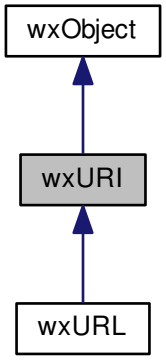
void wxUpdateUIEvent::Show (bool *show*)

Show or hide the UI element.

21.819 wxURI Class Reference

`#include <wx/uri.h>`

Inheritance diagram for wxURI:



21.819.1 Detailed Description

wxURI is used to extract information from a URI (Uniform Resource Identifier).

For information about URIs, see RFC 3986 (http://www.ietf.org/rfc/rfc3986.txt).

In short, a URL is a URI. In other words, URL is a subset of a URI - all acceptable URLs are also acceptable URIs.

wxURI automatically escapes invalid characters in a string, so there is no chance of wxURI "failing" on construction/creation.

wxURI supports copy construction and standard assignment operators. wxURI can also be inherited from to provide further functionality.

To obtain individual components you can use one of the GetXXX() methods. However, you should check HasXXX() before calling a get method, which determines whether or not the component referred to by the method is defined according to RFC 2396. Consider an undefined component equivalent to a NULL C string.

Example:

```
// protocol will hold the http protocol (i.e. "http")
wxString protocol;
wxURI myuri("http://mysite.com");
if( myuri.HasScheme() )
    protocol = myuri.GetScheme();
```

Note

On URIs with a "file" scheme wxURI does not parse the userinfo, server, or port portion. This is to keep compatibility with wxFileSystem, the old wxURL, and older url specifications.

Library: wxBase

Category: Networking

See also

wxURL

Public Member Functions

- wxURI ()

  Creates an empty URI.
- wxURI (const wxString &uri)

  Constructor for quick creation.
- wxURI (const wxURI &uri)

  Copies this URI from another URI.
- wxString BuildURI () const

  Builds the URI from its individual components and adds proper separators.
- wxString BuildUnescapedURI () const

  Builds the URI from its individual components, adds proper separators, and returns escape sequences to normal characters.
- bool Create (const wxString &uri)

  Creates this URI from the uri string.
- const wxString & GetFragment () const

  Obtains the fragment of this URI.
- wxURIHostType GetHostType () const

  Obtains the host type of this URI, which is one of wxURIHostType.
- wxString GetPassword () const

  Returns the password part of the userinfo component of this URI.
- const wxString & GetPath () const

  Returns the (normalized) path of the URI.
- const wxString & GetPort () const

  Returns a string representation of the URI's port.
- const wxString & GetQuery () const

  Returns the Query component of the URI.
- const wxString & GetScheme () const

  Returns the Scheme component of the URI.
- const wxString & GetServer () const

  Returns the Server component of the URI.
- wxString GetUser () const

  Returns the username part of the userinfo component of this URI.

- const wxString & GetUserInfo () const

  Returns the UserInfo component of the URI.
- bool HasFragment () const

  Returns true if the Fragment component of the URI exists.
- bool HasPath () const

  Returns true if the Path component of the URI exists.
- bool HasPort () const

  Returns true if the Port component of the URI exists.
- bool HasQuery () const

  Returns true if the Query component of the URI exists.
- bool HasScheme () const

  Returns true if the Scheme component of the URI exists.
- bool HasServer () const

  Returns true if the Server component of the URI exists.
- bool HasUserInfo () const

  Returns true if the User component of the URI exists.
- bool IsReference () const

  Returns true if a valid [absolute] URI, otherwise this URI is a URI reference and not a full URI, and this function returns false.
- void Resolve (const wxURI &base, int flags=wxURI_STRICT)

  Inherits this URI from a base URI - components that do not exist in this URI are copied from the base, and if this URI's path is not an absolute path (prefixed by a '/'), then this URI's path is merged with the base's path.
- bool operator== (const wxURI &uricomp) const

  Compares this URI to another URI, and returns true if this URI equals uricomp, otherwise it returns false.

Static Public Member Functions

- static wxString Unescape (const wxString &uri)

  Translates all escape sequences (normal characters and returns the result.

Additional Inherited Members

21.819.2 Constructor & Destructor Documentation

wxURI::wxURI ( )

Creates an empty URI.

wxURI::wxURI (const wxString & *uri*)

Constructor for quick creation.

Parameters

uri	URI (Uniform Resource Identifier) to initialize with.

wxURI::wxURI (const wxURI & *uri*)

Copies this URI from another URI.

Parameters

uri	URI (Uniform Resource Identifier) to initialize with.

21.819.3 Member Function Documentation

wxString wxURI::BuildUnescapedURI ( ) const

Builds the URI from its individual components, adds proper separators, and returns escape sequences to normal characters.

Note

It is preferred to call this over Unescape(BuildURI()) since BuildUnescapedURI() performs some optimizations over the plain method.

wxString wxURI::BuildURI ( ) const

Builds the URI from its individual components and adds proper separators.

If the URI is not a reference or is not resolved, the URI that is returned is the same one passed to the constructor or Create().

bool wxURI::Create (const wxString & *uri*)

Creates this URI from the *uri* string.

Returns true if this instance was correctly initialized.

Parameters

uri	String to initialize from.

const wxString& wxURI::GetFragment ( ) const

Obtains the fragment of this URI.

The fragment of a URI is the last value of the URI, and is the value after a "#" character after the path of the URI.

`"http://mysite.com/mypath#<fragment>"`

wxURIHostType wxURI::GetHostType ( ) const

Obtains the host type of this URI, which is one of wxURIHostType.

wxString wxURI::GetPassword ( ) const

Returns the password part of the userinfo component of this URI.

Note that this is explicitly depreciated by RFC 1396 and should generally be avoided if possible.

`"http://<user>:<password>@mysite.com/mypath"`

const wxString& wxURI::GetPath ( ) const

Returns the (normalized) path of the URI.

The path component of a URI comes directly after the scheme component if followed by zero or one slashes ('/'), or after the server/port component.

Absolute paths include the leading '/' character.

"http://mysite.com<path>"

const wxString& wxURI::GetPort ( ) const

Returns a string representation of the URI's port.

The Port of a URI is a value after the server, and must come after a colon (:).

"http://mysite.com:<port>"

Note

You can easily get the numeric value of the port by using wxAtoi() or wxString::Format().

const wxString& wxURI::GetQuery ( ) const

Returns the Query component of the URI.

The query component is what is commonly passed to a cgi application, and must come after the path component, and after a '?' character.

"http://mysite.com/mypath?<query>"

const wxString& wxURI::GetScheme ( ) const

Returns the Scheme component of the URI.

The first part of the URI.

"<scheme>://mysite.com"

const wxString& wxURI::GetServer ( ) const

Returns the Server component of the URI.

The server of the URI can be a server name or a type of IP address. See GetHostType() for the possible values for the host type of the server component.

"http://<server>/mypath"

wxString wxURI::GetUser ( ) const

Returns the username part of the userinfo component of this URI.

Note that this is explicitly depreciated by RFC 1396 and should generally be avoided if possible.

"http://<user>:<password>@mysite.com/mypath"

const wxString& wxURI::GetUserInfo ( ) const

Returns the UserInfo component of the URI.

The component of a URI before the server component that is postfixed by a '@' character.

"http://<userinfo>@mysite.com/mypath"

bool wxURI::HasFragment ( ) const

Returns true if the Fragment component of the URI exists.

bool wxURI::HasPath ( ) const

Returns true if the Path component of the URI exists.

bool wxURI::HasPort ( ) const

Returns true if the Port component of the URI exists.

bool wxURI::HasQuery ( ) const

Returns true if the Query component of the URI exists.

bool wxURI::HasScheme ( ) const

Returns true if the Scheme component of the URI exists.

bool wxURI::HasServer ( ) const

Returns true if the Server component of the URI exists.

bool wxURI::HasUserInfo ( ) const

Returns true if the User component of the URI exists.

bool wxURI::IsReference ( ) const

Returns true if a valid [absolute] URI, otherwise this URI is a URI reference and not a full URI, and this function returns false.

bool wxURI::operator== (const wxURI & *uricomp*) const

Compares this URI to another URI, and returns true if this URI equals *uricomp*, otherwise it returns false.

Parameters

uricomp	URI to compare to.

void wxURI::Resolve (const wxURI & *base,* int *flags* = `wxURI_STRICT`)

Inherits this URI from a base URI - components that do not exist in this URI are copied from the base, and if this URI's path is not an absolute path (prefixed by a '/'), then this URI's path is merged with the base's path.

For instance, resolving "../mydir" from "http://mysite.com/john/doe" results in the scheme (http) and server ("mysite.com") being copied into this URI, since they do not exist. In addition, since the path of this URI is not absolute (does not begin with '/'), the path of the base's is merged with this URI's path, resulting in the URI "http://mysite.com/john/mydir".

Parameters

base	Base URI to inherit from. Must be a full URI and not a reference.
flags	Currently either wxURI_STRICT or 0, in non-strict mode some compatibility layers are enabled to allow loopholes from RFCs prior to 2396.

static wxString wxURI::Unescape (const wxString & *uri*) `[static]`

Translates all escape sequences (normal characters and returns the result.

If you want to unescape an entire wxURI, use BuildUnescapedURI() instead, as it performs some optimizations over this method.

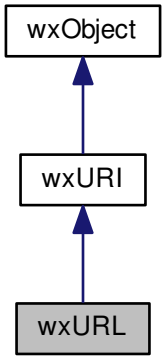
Parameters

uri	String with escaped characters to convert.

21.820 wxURL Class Reference

`#include <wx/url.h>`

Inheritance diagram for wxURL:



21.820.1 Detailed Description

wxURL is a specialization of wxURI for parsing URLs.

Please look at wxURI documentation for more info about the functions you can use to retrieve the various parts of the URL (scheme, server, port, etc).

Supports standard assignment operators, copy constructors, and comparison operators.

Library: wxNet

Category: Networking

See also

wxSocketBase, wxProtocol

Public Member Functions

- wxURL (const wxString &url=wxEmptyString)

  Constructs a URL object from the string.
- virtual ~wxURL ()

  Destroys the URL object.
- wxURLError GetError () const

  Returns the last error.
- wxInputStream * GetInputStream ()

  Creates a new input stream on the specified URL.
- wxProtocol & GetProtocol ()

  Returns a reference to the protocol which will be used to get the URL.
- bool IsOk () const

  Returns true if this object is correctly initialized, i.e. if GetError() returns wxURL_NOERR.
- void SetProxy (const wxString &url_proxy)

  Sets the proxy to use for this URL.
- wxURLError SetURL (const wxString &url)

  Initializes this object with the given URL and returns wxURL_NOERR if it's valid (see GetError() for more info).

Static Public Member Functions

- static void SetDefaultProxy (const wxString &url_proxy)

  Sets the default proxy server to use to get the URL.

Additional Inherited Members

21.820.2 Constructor & Destructor Documentation

wxURL::wxURL (const wxString & *url* = wxEmptyString)

Constructs a URL object from the string.

The URL must be valid according to RFC 1738. In particular, file URLs must be of the format "`file://hostname/path/to/file`", otherwise GetError() will return a value different from wxURL_NOERR.

It is valid to leave out the hostname but slashes must remain in place, in other words, a file URL without a hostname must contain three consecutive slashes (e.g. "`file:///somepath/myfile`").

Parameters

url	Url string to parse.

virtual wxURL::~wxURL ( ) [virtual]

Destroys the URL object.

21.820.3 Member Function Documentation

wxURLError wxURL::GetError ( ) const

Returns the last error.

This error refers to the URL parsing or to the protocol. It can be one of wxURLError.

wxInputStream* wxURL::GetInputStream ( )

Creates a new input stream on the specified URL.

You can use all but seek functionality of wxStream. Seek isn't available on all streams. For example, HTTP or FTP streams don't deal with it.

Note that this method is somewhat deprecated, all future wxWidgets applications should use wxFileSystem instead.

Example:

```
wxURL url("http://a.host/a.dir/a.file");
if (url.GetError() == wxURL_NOERR)
{
    wxInputStream *in_stream;

    in_stream = url.GetInputStream();
    // Then, you can use all IO calls of in_stream (See wxStream)
}
```

Returns

Returns the initialized stream. You will have to delete it yourself.

See also

wxInputStream

wxProtocol& wxURL::GetProtocol ( )

Returns a reference to the protocol which will be used to get the URL.

bool wxURL::IsOk ( ) const

Returns true if this object is correctly initialized, i.e. if GetError() returns wxURL_NOERR.

static void wxURL::SetDefaultProxy (const wxString & *url_proxy*) [static]

Sets the default proxy server to use to get the URL.

The string specifies the proxy like this: "<hostname>:<port number>".

Parameters

url_proxy	Specifies the proxy to use.

See also

SetProxy()

void wxURL::SetProxy (const wxString & *url_proxy*)

Sets the proxy to use for this URL.

See also

SetDefaultProxy()

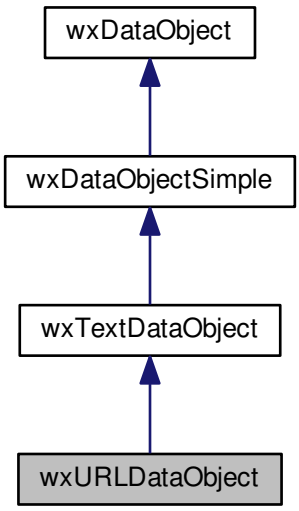
wxURLError wxURL::SetURL (const wxString & *url*)

Initializes this object with the given URL and returns wxURL_NOERR if it's valid (see GetError() for more info).

21.821 wxURLDataObject Class Reference

`#include <wx/dataobj.h>`

Inheritance diagram for wxURLDataObject:



21.821.1 Detailed Description

wxURLDataObject is a wxDataObject containing an URL and can be used e.g.

when you need to put an URL on or retrieve it from the clipboard:

```
wxTheClipboard->SetData(new wxURLDataObject(url));
```

Note

This class is derived from wxDataObjectComposite on Windows rather than wxTextDataObject on all other platforms.

Library: wxCore

Category: Clipboard and Drag & Drop

See also

Drag and Drop Overview, wxDataObject

Public Member Functions

- wxURLDataObject (const wxString &url=wxEmptyString)

  Constructor, may be used to initialize the URL.

- wxString GetURL () const

  Returns the URL stored by this object, as a string.

- void SetURL (const wxString &url)

  Sets the URL stored by this object.

Additional Inherited Members

21.821.2 Constructor & Destructor Documentation

wxURLDataObject::wxURLDataObject (const wxString & *url* = wxEmptyString)

Constructor, may be used to initialize the URL.

If *url* is empty, SetURL() can be used later.

21.821.3 Member Function Documentation

wxString wxURLDataObject::GetURL ( ) const

Returns the URL stored by this object, as a string.

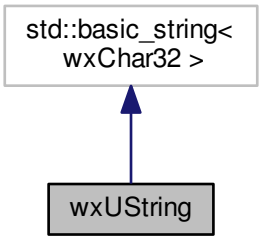
void wxURLDataObject::SetURL (const wxString & *url*)

Sets the URL stored by this object.

21.822 wxUString Class Reference

`#include <wx/ustring.h>`

Inheritance diagram for wxUString:



21.822.1 Detailed Description

wxUString is a class representing a Unicode character string where each character is stored using a 32-bit value.

This is different from wxString which may store a character either as a UTF-8 or as a UTF-16 sequence and different from `std::string` which stores a string as a sequence of simple 8-bit characters and also different from `std::wstring` which stores the string differently depending on the definition of wchar_t.

The main purpose of wxUString is a to give users a Unicode string class that has O(1) access to its content, to be identical on all platforms and to be easily convertable to wxString as well as other ways to store strings (C string literals, wide character string literals, character buffer, etc) by providing several overloads and built-in conversions to and from the various string formats.

wxUString derives from `std::basic_string<wxChar32>` and therefore offers the complete API of `std::string`.

Library: wxBase

Category: Data Structures

See also

wxString, wxString overview, Unicode overview

Public Member Functions

- wxUString ()

  Default constructor.
- wxUString (const wxUString &str)

  Copy constructor.
- wxUString (const wxChar32 *str)

  Constructs a string from a 32-bit string literal.
- wxUString (const wxU32CharBuffer &buf)

  Constructs a string from 32-bit string buffer.
- wxUString (const char *str)

  Constructs a string from C string literal using wxConvLibc to convert it to Unicode.
- wxUString (const wxCharBuffer &buf)

Constructs a string from C string buffer using wxConvLibc to convert it to Unicode.

- wxUString (const char *str, const wxMBConv &conv)

  Constructs a string from C string literal using conv to convert it to Unicode.
- wxUString (const wxCharBuffer &buf, const wxMBConv &conv)

  Constructs a string from C string literal using conv to convert it to Unicode.
- wxUString (const wxChar16 *str)

  Constructs a string from UTF-16 string literal.
- wxUString (const wxU16CharBuffer &buf)

  Constructs a string from UTF-16 string buffer.
- wxUString (const wxString &str)

  Constructs a string from wxString.
- wxUString (char ch)

  Constructs a string from using wxConvLibc to convert it to Unicode.
- wxUString (wxChar16 ch)

  Constructs a string from a UTF-16 character.
- wxUString (wxChar32 ch)

  Constructs a string from 32-bit Unicode character.
- wxUString (wxUniChar ch)

  Constructs a string from wxUniChar (returned by wxString's access operator)
- wxUString (wxUniCharRef ch)

  Constructs a string from wxUniCharRef (returned by wxString's access operator)
- wxUString (size_t n, char ch)

  Constructs a string from n characters ch.
- wxUString (size_t n, wxChar16 ch)

  Constructs a string from n characters ch.
- wxUString (size_t n, wxChar32 ch)

  Constructs a string from n characters ch.
- wxUString (size_t n, wxUniChar ch)

  Constructs a string from n characters ch.
- wxUString (size_t n, wxUniCharRef ch)

  Constructs a string from n characters ch.
- wxUString & assignFromAscii (const char *str)

  Assignment from a 7-bit ASCII string literal.
- wxUString & assignFromAscii (const char *str, size_t n)

  Assignment from a 7-bit ASCII string literal.
- wxUString & assignFromUTF8 (const char *str)

  Assignment from a UTF-8 string literal.
- wxUString & assignFromUTF8 (const char *str, size_t n)

  Assignment from a UTF-8 string literal.
- wxUString & assignFromUTF16 (const wxChar16 *str)

  Assignment from a UTF-16 string literal.
- wxUString & assignFromUTF16 (const wxChar16 *str, size_t n)

  Assignment from a UTF-16 string literal.
- wxUString & assignFromCString (const char *str)

  Assignment from a C string literal using wxConvLibc.
- wxUString & assignFromCString (const char *str, const wxMBConv &conv)

  Assignment from a C string literal using conv.
- wxCharBuffer utf8_str () const

  Conversion to a UTF-8 string.
- wxU16CharBuffer utf16_str () const

  Conversion to a UTF-16 string.

- wxWCharBuffer wc_str () const

  Conversion to a wide character string (either UTF-16 or UCS-4, depending on the size of wchar_t).
- operator wxString () const

  Implicit conversion to wxString.
- wxUString & assign (const wxUString &str)

  wxUString assignment.
- wxUString & append (const wxUString &s)

  Appending.
- wxUString & insert (size_t pos, const wxUString &s)

  Insertion.
- wxUString & operator= (const wxUString &s)

  Assignment operator.
- wxUString & operator+= (const wxUString &s)

  Concatenation operator.

Static Public Member Functions

- static wxUString FromAscii (const char *str, size_t n)

  Static construction of a wxUString from a 7-bit ASCII string.
- static wxUString FromAscii (const char *str)

  Static construction of a wxUString from a 7-bit ASCII string.
- static wxUString FromUTF8 (const char *str, size_t n)

  Static construction of a wxUString from a UTF-8 encoded string.
- static wxUString FromUTF8 (const char *str)

  Static construction of a wxUString from a UTF-8 encoded string.
- static wxUString FromUTF16 (const wxChar16 *str, size_t n)

  Static construction of a wxUString from a UTF-16 encoded string.
- static wxUString FromUTF16 (const wxChar16 *str)

  Static construction of a wxUString from a UTF-16 encoded string.

21.822.2 Constructor & Destructor Documentation

wxUString::wxUString ( )

Default constructor.

wxUString::wxUString (const wxUString & *str*)

Copy constructor.

wxUString::wxUString (const wxChar32 * *str*)

Constructs a string from a 32-bit string literal.

wxUString::wxUString (const wxU32CharBuffer & *buf*)

Constructs a string from 32-bit string buffer.

wxUString::wxUString (const char * *str*)

Constructs a string from C string literal using wxConvLibc to convert it to Unicode.

wxUString::wxUString (const wxCharBuffer & *buf*)

Constructs a string from C string buffer using wxConvLibc to convert it to Unicode.

wxUString::wxUString (const char * *str,* const wxMBConv & *conv*)

Constructs a string from C string literal using *conv* to convert it to Unicode.

wxUString::wxUString (const wxCharBuffer & *buf,* const wxMBConv & *conv*)

Constructs a string from C string literal using *conv* to convert it to Unicode.

wxUString::wxUString (const wxChar16 * *str*)

Constructs a string from UTF-16 string literal.

wxUString::wxUString (const wxU16CharBuffer & *buf*)

Constructs a string from UTF-16 string buffer.

wxUString::wxUString (const wxString & *str*)

Constructs a string from wxString.

wxUString::wxUString (char *ch*)

Constructs a string from using wxConvLibc to convert it to Unicode.

wxUString::wxUString (wxChar16 *ch*)

Constructs a string from a UTF-16 character.

wxUString::wxUString (wxChar32 *ch*)

Constructs a string from 32-bit Unicode character.

wxUString::wxUString (wxUniChar *ch*)

Constructs a string from wxUniChar (returned by wxString's access operator)

wxUString::wxUString (wxUniCharRef *ch*)

Constructs a string from wxUniCharRef (returned by wxString's access operator)

wxUString::wxUString (size_t *n,* char *ch*)

Constructs a string from *n* characters *ch*.

wxUString::wxUString (size_t *n,* wxChar16 *ch*)

Constructs a string from *n* characters *ch*.

wxUString::wxUString (size_t *n,* wxChar32 *ch*)

Constructs a string from *n* characters *ch*.

wxUString::wxUString (size_t *n,* wxUniChar *ch*)

Constructs a string from *n* characters *ch*.

wxUString::wxUString (size_t *n,* wxUniCharRef *ch*)

Constructs a string from *n* characters *ch*.

21.822.3 Member Function Documentation

wxUString& wxUString::append (const wxUString & *s*)

Appending.

wxUString additionally provides overloads for wxString, C string, UTF-16 strings, 32-bit strings, char buffers, single and repeated characters etc.

wxUString& wxUString::assign (const wxUString & *str*)

wxUString assignment.

wxUString additionally provides overloads for wxString, C string, UTF-16 strings, 32-bit strings, char buffers, single and repeated characters etc.

wxUString& wxUString::assignFromAscii (const char * *str*)

Assignment from a 7-bit ASCII string literal.

wxUString& wxUString::assignFromAscii (const char * *str,* size_t *n*)

Assignment from a 7-bit ASCII string literal.

wxUString& wxUString::assignFromCString (const char * *str*)

Assignment from a C string literal using wxConvLibc.

wxUString& wxUString::assignFromCString (const char * *str,* const wxMBConv & *conv*)

Assignment from a C string literal using *conv*.

wxUString& wxUString::assignFromUTF16 (const wxChar16 * *str*)

Assignment from a UTF-16 string literal.

wxUString& wxUString::assignFromUTF16 (const wxChar16 * *str,* size_t *n*)

Assignment from a UTF-16 string literal.

wxUString& wxUString::assignFromUTF8 (const char * *str*)

Assignment from a UTF-8 string literal.

wxUString& wxUString::assignFromUTF8 (const char * *str,* size_t *n*)

Assignment from a UTF-8 string literal.

static wxUString wxUString::FromAscii (const char * *str,* size_t *n*) `[static]`

Static construction of a wxUString from a 7-bit ASCII string.

static wxUString wxUString::FromAscii (const char * *str*) `[static]`

Static construction of a wxUString from a 7-bit ASCII string.

static wxUString wxUString::FromUTF16 (const wxChar16 * *str,* size_t *n*) `[static]`

Static construction of a wxUString from a UTF-16 encoded string.

static wxUString wxUString::FromUTF16 (const wxChar16 * *str*) `[static]`

Static construction of a wxUString from a UTF-16 encoded string.

static wxUString wxUString::FromUTF8 (const char * *str,* size_t *n*) `[static]`

Static construction of a wxUString from a UTF-8 encoded string.

static wxUString wxUString::FromUTF8 (const char * *str*) `[static]`

Static construction of a wxUString from a UTF-8 encoded string.

wxUString& wxUString::insert (size_t *pos,* const wxUString & *s*)

Insertion.

wxUString additionally provides overloads for wxString, C string, UTF-16 strings, 32-bit strings, char buffers, single characters etc.

wxUString::operator wxString ( ) const

Implicit conversion to wxString.

wxUString& wxUString::operator+= (const wxUString & *s*) `[inline]`

Concatenation operator.

wxUString additionally provides overloads for wxString, C string, UTF-16 strings, 32-bit strings, char buffers, single characters etc.

wxUString& wxUString::operator= (const wxUString & *s*) `[inline]`

Assignment operator.

wxUString additionally provides overloads for wxString, C string, UTF-16 strings, 32-bit strings, char buffers, single characters etc.

wxU16CharBuffer wxUString::utf16_str ( ) const

Conversion to a UTF-16 string.

wxCharBuffer wxUString::utf8_str ( ) const

Conversion to a UTF-8 string.

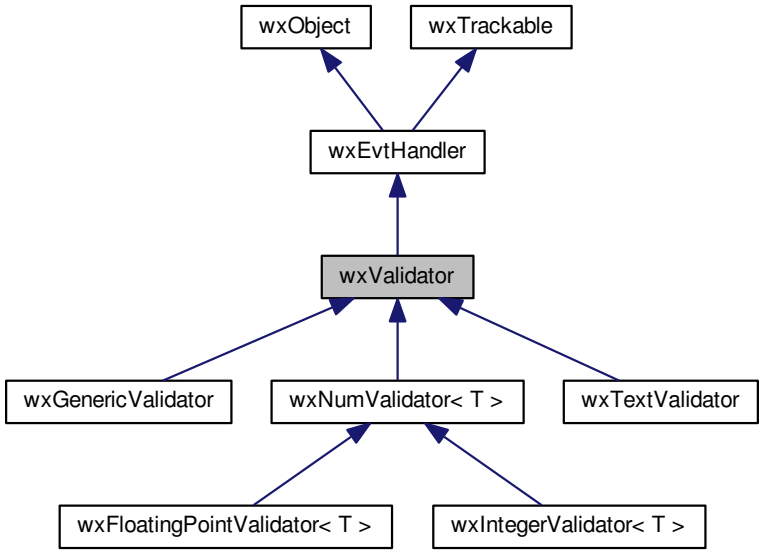
wxWCharBuffer wxUString::wc_str ( ) const

Conversion to a wide character string (either UTF-16 or UCS-4, depending on the size of wchar_t).

21.823 wxValidator Class Reference

`#include <wx/validate.h>`

Inheritance diagram for wxValidator:



21.823.1 Detailed Description

wxValidator is the base class for a family of validator classes that mediate between a class of control, and application data.

A validator has three major roles:

1. To transfer data from a C++ variable or own storage to and from a control.
2. To validate data in a control, and show an appropriate error message.
3. To filter events (such as keystrokes), thereby changing the behaviour of the associated control.

Validators can be plugged into controls dynamically.

To specify a default, "null" validator, use wxDefaultValidator.

For more information, please see wxValidator Overview.

Library: wxCore

Category: Validators

Predefined objects/pointers: wxDefaultValidator

See also

wxValidator Overview, wxTextValidator, wxGenericValidator, wxIntegerValidator, wxFloatingPointValidator

Public Member Functions

- wxValidator ()

  Constructor.
- virtual ~wxValidator ()

  Destructor.
- virtual wxObject * Clone () const

  All validator classes must implement the Clone() function, which returns an identical copy of itself.
- wxWindow * GetWindow () const

  Returns the window associated with the validator.
- void SetWindow (wxWindow *window)

  Associates a window with the validator.
- virtual bool TransferFromWindow ()

  This overridable function is called when the value in the window must be transferred to the validator.
- virtual bool TransferToWindow ()

  This overridable function is called when the value associated with the validator must be transferred to the window.
- virtual bool Validate (wxWindow *parent)

  This overridable function is called when the value in the associated window must be validated.

Static Public Member Functions

- static void SuppressBellOnError (bool suppress=true)

  This functions switches on or turns off the error sound produced by the validators if an invalid key is pressed.
- static bool IsSilent ()

  Returns if the error sound is currently disabled.

Additional Inherited Members

21.823.2 Constructor & Destructor Documentation

wxValidator::wxValidator ( )

Constructor.

virtual wxValidator::~wxValidator ( ) [virtual]

Destructor.

21.823.3 Member Function Documentation

virtual wxObject* wxValidator::Clone ( ) const [virtual]

All validator classes must implement the Clone() function, which returns an identical copy of itself.

This is because validators are passed to control constructors as references which must be copied. Unlike objects such as pens and brushes, it does not make sense to have a reference counting scheme to do this cloning because all validators should have separate data.

Returns

This base function returns NULL.

Reimplemented in wxGenericValidator, and wxTextValidator.

wxWindow* wxValidator::GetWindow ( ) const

Returns the window associated with the validator.

static bool wxValidator::IsSilent ( ) [static]

Returns if the error sound is currently disabled.

void wxValidator::SetWindow (wxWindow * *window*)

Associates a window with the validator.

This function is automatically called by wxWidgets when creating a wxWindow-derived class instance which takes a wxValidator reference.

E.g.

```
new wxTextCtrl(this, wxID_ANY, wxEmptyString,
      wxDefaultPosition, wxDefaultSize, 0,
               wxTextValidator(wxFILTER_ALPHA, &g_data.m_string));
```

will automatically link the wxTextValidator instance with the wxTextCtrl instance.

static void wxValidator::SuppressBellOnError (bool *suppress* = true) [static]

This functions switches on or turns off the error sound produced by the validators if an invalid key is pressed.

Since

2.9.1

Parameters

suppress	If true, error sound is not played when a validator detects an error. If false, error sound is enabled.

virtual bool wxValidator::TransferFromWindow ( ) [virtual]

This overridable function is called when the value in the window must be transferred to the validator.

Returns

false if there is a problem.

Reimplemented in wxTextValidator, wxGenericValidator, and wxNumValidator< T >.

virtual bool wxValidator::TransferToWindow ( ) [virtual]

This overridable function is called when the value associated with the validator must be transferred to the window.

Returns

false if there is a problem.

Reimplemented in wxTextValidator, wxGenericValidator, and wxNumValidator< T >.

virtual bool wxValidator::Validate (wxWindow * *parent*) [virtual]

This overridable function is called when the value in the associated window must be validated.

Parameters

parent	The parent of the window associated with the validator.

Returns

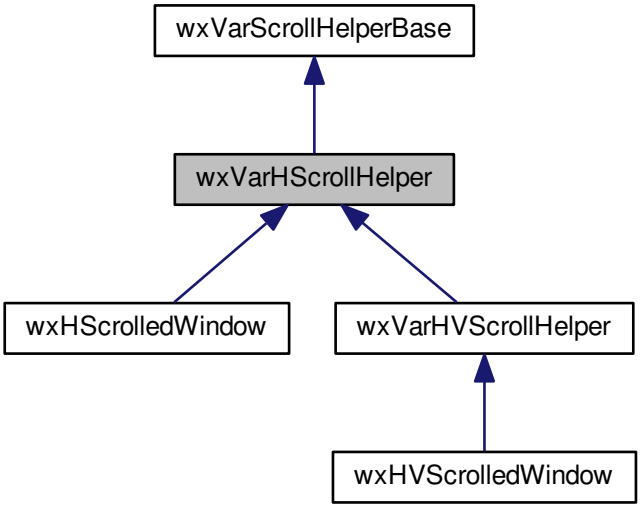
false if the value in the window is not valid; you may pop up an error dialog.

Reimplemented in wxTextValidator.

21.824 wxVarHScrollHelper Class Reference

`#include <wx/vscroll.h>`

Inheritance diagram for wxVarHScrollHelper:



21.824.1 Detailed Description

This class provides functions wrapping the wxVarScrollHelperBase class, targeted for horizontal-specific scrolling.

Like wxVarScrollHelperBase, this class is mostly only useful to those classes built into wxWidgets deriving from here, and this documentation is mostly only provided for referencing the functions provided by this class. You will likely want to derive your window from wxHScrolledWindow rather than from here directly.

Library: wxCore

Category: Miscellaneous Windows

See also

wxHScrolledWindow, wxHVScrolledWindow, wxVScrolledWindow

Public Member Functions

- wxVarHScrollHelper (wxWindow *winToScroll)

  Constructor taking the target window to be scrolled by this helper class.
- size_t GetColumnCount () const

  Returns the number of columns the target window contains.
- size_t GetVisibleColumnsBegin () const

  Returns the index of the first visible column based on the scroll position.
- size_t GetVisibleColumnsEnd () const

  Returns the index of the last visible column based on the scroll position.
- bool IsColumnVisible (size_t column) const

Returns true if the given column is currently visible (even if only partially visible) or false otherwise.

- virtual void RefreshColumn (size_t column)

  Triggers a refresh for just the given column's area of the window if it's visible.
- virtual void RefreshColumns (size_t from, size_t to)

  Triggers a refresh for the area between the specified range of columns given (inclusively).
- virtual bool ScrollColumnPages (int pages)

  Scroll by the specified number of pages which may be positive (to scroll right) or negative (to scroll left).
- virtual bool ScrollColumns (int columns)

  Scroll by the specified number of columns which may be positive (to scroll right) or negative (to scroll left).
- bool ScrollToColumn (size_t column)

  Scroll to the specified column.
- void SetColumnCount (size_t columnCount)

  Set the number of columns the window contains.

Protected Member Functions

- virtual wxCoord EstimateTotalWidth () const

  This class forwards calls from EstimateTotalSize() to this function so derived classes can override either just the height or the width estimation, or just estimate both differently if desired in any wxHVScrolledWindow derived class.
- virtual void OnGetColumnsWidthHint (size_t columnMin, size_t columnMax) const

  This function doesn't have to be overridden but it may be useful to do so if calculating the columns' sizes is a relatively expensive operation as it gives your code a chance to calculate several of them at once and cache the result if necessary.
- virtual wxCoord OnGetColumnWidth (size_t column) const =0

  This function must be overridden in the derived class, and should return the width of the given column in pixels.

21.824.2 Constructor & Destructor Documentation

wxVarHScrollHelper::wxVarHScrollHelper (wxWindow * *winToScroll*)

Constructor taking the target window to be scrolled by this helper class.

This will attach scroll event handlers to the target window to catch and handle scroll events appropriately.

21.824.3 Member Function Documentation

virtual wxCoord wxVarHScrollHelper::EstimateTotalWidth ( ) const `[protected], [virtual]`

This class forwards calls from EstimateTotalSize() to this function so derived classes can override either just the height or the width estimation, or just estimate both differently if desired in any wxHVScrolledWindow derived class.

Note

This function will not be called if EstimateTotalSize() is overridden in your derived class.

size_t wxVarHScrollHelper::GetColumnCount ( ) const

Returns the number of columns the target window contains.

See also

SetColumnCount()

size_t wxVarHScrollHelper::GetVisibleColumnsBegin ( ) const

Returns the index of the first visible column based on the scroll position.

size_t wxVarHScrollHelper::GetVisibleColumnsEnd ( ) const

Returns the index of the last visible column based on the scroll position.

This includes the last column even if it is only partially visible.

bool wxVarHScrollHelper::IsColumnVisible (size_t *column*) const

Returns true if the given column is currently visible (even if only partially visible) or false otherwise.

virtual void wxVarHScrollHelper::OnGetColumnsWidthHint (size_t *columnMin,* size_t *columnMax*) const `[protected], [virtual]`

This function doesn't have to be overridden but it may be useful to do so if calculating the columns' sizes is a relatively expensive operation as it gives your code a chance to calculate several of them at once and cache the result if necessary.

OnGetColumnsWidthHint() is normally called just before OnGetColumnWidth() but you shouldn't rely on the latter being called for all columns in the interval specified here. It is also possible that OnGetColumnWidth() will be called for units outside of this interval, so this is really just a hint, not a promise.

Finally, note that *columnMin* is inclusive, while *columnMax* is exclusive.

virtual wxCoord wxVarHScrollHelper::OnGetColumnWidth (size_t *column*) const `[protected], [pure virtual]`

This function must be overridden in the derived class, and should return the width of the given column in pixels.

virtual void wxVarHScrollHelper::RefreshColumn (size_t *column*) `[virtual]`

Triggers a refresh for just the given column's area of the window if it's visible.

virtual void wxVarHScrollHelper::RefreshColumns (size_t *from,* size_t *to*) `[virtual]`

Triggers a refresh for the area between the specified range of columns given (inclusively).

virtual bool wxVarHScrollHelper::ScrollColumnPages (int *pages*) `[virtual]`

Scroll by the specified number of pages which may be positive (to scroll right) or negative (to scroll left).

virtual bool wxVarHScrollHelper::ScrollColumns (int *columns*) `[virtual]`

Scroll by the specified number of columns which may be positive (to scroll right) or negative (to scroll left).

Returns

true if the window was scrolled, false otherwise (for example, if we're trying to scroll right but we are already showing the last column).

bool wxVarHScrollHelper::ScrollToColumn (size_t *column*)

Scroll to the specified column.

It will become the first visible column in the window.

Returns

true if we scrolled the window, false if nothing was done.

void wxVarHScrollHelper::SetColumnCount (size_t *columnCount*)

Set the number of columns the window contains.

The derived class must provide the widths for all columns with indices up to the one given here in it's OnGet↩ ColumnWidth() implementation.

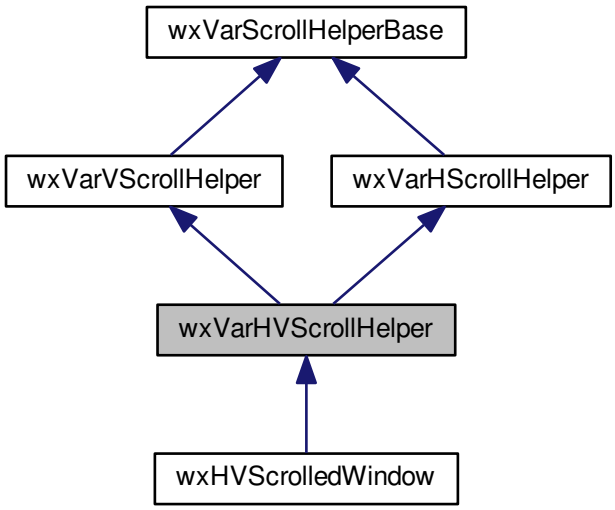
See also

GetColumnCount()

21.825 wxVarHVScrollHelper Class Reference

`#include <wx/vscroll.h>`

Inheritance diagram for wxVarHVScrollHelper:



21.825.1 Detailed Description

This class provides functions wrapping the wxVarHScrollHelper and wxVarVScrollHelper classes, targeted for scrolling a window in both axis.

Since this class is also the join class of the horizontal and vertical scrolling functionality, it also addresses some wrappers that help avoid the need to specify class scope in your wxHVScrolledWindow derived class when using wxVarScrollHelperBase functionality.

Like all three of it's scroll helper base classes, this class is mostly only useful to those classes built into wxWidgets deriving from here, and this documentation is mostly only provided for referencing the functions provided by this class. You will likely want to derive your window from wxHVScrolledWindow rather than from here directly.

Library: wxCore

Category: Miscellaneous Windows

See also

wxHScrolledWindow, wxHVScrolledWindow, wxVScrolledWindow

Public Member Functions

- wxVarHVScrollHelper (wxWindow *winToScroll)

  Constructor taking the target window to be scrolled by this helper class.
- void EnablePhysicalScrolling (bool vscrolling=true, bool hscrolling=true)

  With physical scrolling on (when this is true), the device origin is changed properly when a wxPaintDC is prepared, children are actually moved and laid out properly, and the contents of the window (pixels) are actually moved.
- wxSize GetRowColumnCount () const

  Returns the number of columns and rows the target window contains.
- wxPosition GetVisibleBegin () const

  Returns the index of the first visible column and row based on the current scroll position.
- wxPosition GetVisibleEnd () const

  Returns the index of the last visible column and row based on the scroll position.
- void SetRowColumnCount (size_t rowCount, size_t columnCount)

  Set the number of rows and columns the target window will contain.

- bool IsVisible (size_t row, size_t column) const

  Returns true if both the given row and column are currently visible (even if only partially visible) or false otherwise.
- bool IsVisible (const wxPosition &pos) const

  Returns true if both the given row and column are currently visible (even if only partially visible) or false otherwise.

- virtual void RefreshRowColumn (size_t row, size_t column)

  Triggers a refresh for just the area shared between the given row and column of the window if it is visible.
- virtual void RefreshRowColumn (const wxPosition &pos)

  Triggers a refresh for just the area shared between the given row and column of the window if it is visible.

- virtual void RefreshRowsColumns (size_t fromRow, size_t toRow, size_t fromColumn, size_t toColumn)

  Triggers a refresh for the visible area shared between all given rows and columns (inclusive) of the window.
- virtual void RefreshRowsColumns (const wxPosition &from, const wxPosition &to)

  Triggers a refresh for the visible area shared between all given rows and columns (inclusive) of the window.

- bool ScrollToRowColumn (size_t row, size_t column)

  Scroll to the specified row and column.
- bool ScrollToRowColumn (const wxPosition &pos)

  Scroll to the specified row and column.

- wxPosition VirtualHitTest (wxCoord x, wxCoord y) const

  Returns the virtual scroll unit under the device unit given accounting for scroll position or `wxNOT_FOUND` (for the row, column, or possibly both values) if none.

- wxPosition VirtualHitTest (const wxPoint &pos) const

  Returns the virtual scroll unit under the device unit given accounting for scroll position or `wxNOT_FOUND` (for the row, column, or possibly both values) if none.

Additional Inherited Members

21.825.2 Constructor & Destructor Documentation

wxVarHVScrollHelper::wxVarHVScrollHelper (wxWindow * *winToScroll*)

Constructor taking the target window to be scrolled by this helper class.

This will attach scroll event handlers to the target window to catch and handle scroll events appropriately.

21.825.3 Member Function Documentation

void wxVarHVScrollHelper::EnablePhysicalScrolling (bool *vscrolling* = `true`, bool *hscrolling* = `true`)

With physical scrolling on (when this is true), the device origin is changed properly when a wxPaintDC is prepared, children are actually moved and laid out properly, and the contents of the window (pixels) are actually moved.

When this is false, you are responsible for repainting any invalidated areas of the window yourself to account for the new scroll position.

Parameters

vscrolling	Specifies if physical scrolling should be turned on when scrolling vertically.
hscrolling	Specifies if physical scrolling should be turned on when scrolling horizontally.

wxSize wxVarHVScrollHelper::GetRowColumnCount ( ) const

Returns the number of columns and rows the target window contains.

See also

SetRowColumnCount()

wxPosition wxVarHVScrollHelper::GetVisibleBegin ( ) const

Returns the index of the first visible column and row based on the current scroll position.

wxPosition wxVarHVScrollHelper::GetVisibleEnd ( ) const

Returns the index of the last visible column and row based on the scroll position.

This includes any partially visible columns or rows.

bool wxVarHVScrollHelper::IsVisible (size_t *row*, size_t *column*) const

Returns true if both the given row and column are currently visible (even if only partially visible) or false otherwise.

bool wxVarHVScrollHelper::IsVisible (const wxPosition & *pos*) const

Returns true if both the given row and column are currently visible (even if only partially visible) or false otherwise.

virtual void wxVarHVScrollHelper::RefreshRowColumn (size_t *row,* size_t *column*) [virtual]

Triggers a refresh for just the area shared between the given row and column of the window if it is visible.

virtual void wxVarHVScrollHelper::RefreshRowColumn (const wxPosition & *pos*) [virtual]

Triggers a refresh for just the area shared between the given row and column of the window if it is visible.

virtual void wxVarHVScrollHelper::RefreshRowsColumns (size_t *fromRow,* size_t *toRow,* size_t *fromColumn,* size_t *toColumn*) [virtual]

Triggers a refresh for the visible area shared between all given rows and columns (inclusive) of the window.

If the target window for both orientations is the same, the rectangle of cells is refreshed; if the target windows differ, the entire client size opposite the orientation direction is refreshed between the specified limits.

virtual void wxVarHVScrollHelper::RefreshRowsColumns (const wxPosition & *from,* const wxPosition & *to*) [virtual]

Triggers a refresh for the visible area shared between all given rows and columns (inclusive) of the window.

If the target window for both orientations is the same, the rectangle of cells is refreshed; if the target windows differ, the entire client size opposite the orientation direction is refreshed between the specified limits.

bool wxVarHVScrollHelper::ScrollToRowColumn (size_t *row,* size_t *column*)

Scroll to the specified row and column.

It will become the first visible row and column in the window. Returns true if we scrolled the window, false if nothing was done.

bool wxVarHVScrollHelper::ScrollToRowColumn (const wxPosition & *pos*)

Scroll to the specified row and column.

It will become the first visible row and column in the window. Returns true if we scrolled the window, false if nothing was done.

void wxVarHVScrollHelper::SetRowColumnCount (size_t *rowCount,* size_t *columnCount*)

Set the number of rows and columns the target window will contain.

The derived class must provide the sizes for all rows and columns with indices up to the ones given here in it's OnGetRowHeight() and OnGetColumnWidth() implementations, respectively.

See also

GetRowColumnCount()

wxPosition wxVarHVScrollHelper::VirtualHitTest (wxCoord *x*, wxCoord *y*) const

Returns the virtual scroll unit under the device unit given accounting for scroll position or `wxNOT_FOUND` (for the row, column, or possibly both values) if none.

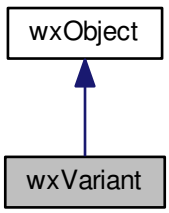
wxPosition wxVarHVScrollHelper::VirtualHitTest (const wxPoint & *pos*) const

Returns the virtual scroll unit under the device unit given accounting for scroll position or `wxNOT_FOUND` (for the row, column, or possibly both values) if none.

21.826 wxVariant Class Reference

`#include <wx/variant.h>`

Inheritance diagram for wxVariant:



21.826.1 Detailed Description

The wxVariant class represents a container for any type.

A variant's value can be changed at run time, possibly to a different type of value.

Note

> As of wxWidgets 2.9.1, wxAny has become the preferred variant class. While most controls still use wxVariant in their interface, you can start using wxAny in your code because of an implicit conversion layer. See below for more information.

As standard, wxVariant can store values of type bool, wxChar, double, long, string, string list, time, date, void pointer, list of strings, and list of variants. However, an application can extend wxVariant's capabilities by deriving from the class wxVariantData and using the wxVariantData form of the wxVariant constructor or assignment operator to assign this data to a variant. Actual values for user-defined types will need to be accessed via the wxVariantData object, unlike the case for basic data types where convenience functions such as GetLong() can be used.

Under Microsoft Windows, three additional wxVariantData-derived classes – wxVariantDataCurrency, wxVariantDataErrorCode and wxVariantDataSafeArray – are available for interoperation with OLE VARIANT when using wxAutomationObject.

Pointers to any wxObject derived class can also easily be stored in a wxVariant. wxVariant will then use wxWidgets' built-in RTTI system to set the type name (returned by GetType()) and to perform type-safety checks at runtime.

This class is useful for reducing the programming for certain tasks, such as an editor for different data types, or a remote procedure call protocol.

An optional name member is associated with a wxVariant. This might be used, for example, in CORBA or OLE automation classes, where named parameters are required.

Note that as of wxWidgets 2.7.1, wxVariant is reference counted. Additionally, the convenience macros DECLARE_VARIANT_OBJECT() and IMPLEMENT_VARIANT_OBJECT() were added so that adding (limited) support for conversion to and from wxVariant can be very easily implemented without modifying either wxVariant or the class to be stored by wxVariant. Since assignment operators cannot be declared outside the class, the shift left operators are used like this:

```
// in the header file
DECLARE_VARIANT_OBJECT(MyClass)

// in the implementation file
IMPLEMENT_VARIANT_OBJECT(MyClass)

// in the user code
wxVariant variant;
MyClass value;
variant << value;

// or
value << variant;
```

For this to work, MyClass must derive from wxObject, implement the wxWidgets RTTI system and support the assignment operator and equality operator for itself. Ideally, it should also be reference counted to make copying operations cheap and fast. This can be most easily implemented using the reference counting support offered by wxObject itself. By default, wxWidgets already implements the shift operator conversion for a few of its drawing related classes:

```
IMPLEMENT_VARIANT_OBJECT(wxColour)
IMPLEMENT_VARIANT_OBJECT(wxImage)
IMPLEMENT_VARIANT_OBJECT(wxIcon)
IMPLEMENT_VARIANT_OBJECT(wxBitmap)
```

Note that as of wxWidgets 2.9.0, wxVariantData no longer inherits from wxObject and wxVariant no longer uses the type-unsafe wxList class for list operations but the type-safe wxVariantList class. Also, wxVariantData now supports the wxVariantData::Clone() function for implementing the Unshare() function. wxVariantData::Clone() is implemented automatically by IMPLEMENT_VARIANT_OBJECT().

Since wxVariantData no longer derives from wxObject, any code that tests the type of the data using wxDynamicCast() will require adjustment. You can use the macro wxDynamicCastVariantData() with the same arguments as wxDynamicCast(), to use C++ RTTI type information instead of wxWidgets RTTI.

21.826.2 wxVariant to wxAny Conversion Layer

wxAny is a more modern, template-based variant class. It is not directly compatible with wxVariant, but there is a transparent conversion layer.

Following is an example how to use these conversions with wxPropertyGrid's property class wxPGProperty (which currently uses wxVariants both internally and in the public API):

```
// Get property value as wxAny instead of wxVariant
wxAny value = property->GetValue();

// Do something with it
DoSomethingWithString(value.As<wxString>());

// Write back new value to property
value = "New Value";
property->SetValue(value);
```

Some caveats:

- In wxAny, there are no separate types for handling integers of different sizes, so converting wxAny with 'long long' value will yield wxVariant of "long" type when the value is small enough to fit in without overflow. Otherwise, variant type "longlong" is used. Also note that wxAny holding unsigned integer will always be converted to "ulonglong" wxVariant type.

- Unlike wxVariant, wxAny does not store a (rarely needed) name string.

- Because of implicit conversion of wxVariant to wxAny, wxAny cannot usually contain value of type wxVariant. In other words, any.CheckType<wxVariant>() can never return true.

Supplied conversion functions will automatically work with all built-in wxVariant types, and also with all user-specified types generated using IMPLEMENT_VARIANT_OBJECT(). For hand-built wxVariantData classes, you will need to use supplied macros in a following manner:

```
// Declare wxVariantData for data type Foo
class wxVariantDataFoo: public wxVariantData
{
public:
    // interface
    // ...

    DECLARE_WXANY_CONVERSION()
protected:
    // data storage etc
    // ...
};

IMPLEMENT_TRIVIAL_WXANY_CONVERSION(Foo, wxVariantDataFoo)
```

Library: wxBase

wxVariantData, wxAny

Public Member Functions

- wxVariant ()

  Default constructor.
- wxVariant (wxVariantData *data, const wxString &name=wxEmptyString)

  Constructs a variant directly with a wxVariantData object.
- wxVariant (const wxVariant &variant)

  Constructs a variant from another variant by increasing the reference count.
- wxVariant (const wxAny &any)

  Constructs a variant by converting it from wxAny.
- wxVariant (const wxChar *value, const wxString &name=wxEmptyString)

  Constructs a variant from a wide string literal.
- wxVariant (const wxString &value, const wxString &name=wxEmptyString)

  Constructs a variant from a string.
- wxVariant (wxChar value, const wxString &name=wxEmptyString)

  Constructs a variant from a wide char.
- wxVariant (long value, const wxString &name=wxEmptyString)

  Constructs a variant from a long.
- wxVariant (bool value, const wxString &name=wxEmptyString)

  Constructs a variant from a bool.
- wxVariant (double value, const wxString &name=wxEmptyString)

  Constructs a variant from a double.
- wxVariant (wxLongLong value, const wxString &name=wxEmptyString)

  Constructs a variant from a wxLongLong.

- wxVariant (wxULongLong value, const wxString &name=wxEmptyString)

  Constructs a variant from a wxULongLong.
- wxVariant (const wxVariantList &value, const wxString &name=wxEmptyString)

  Constructs a variant from a list of variants.
- wxVariant (void ∗value, const wxString &name=wxEmptyString)

  Constructs a variant from a void pointer.
- wxVariant (wxObject ∗value, const wxString &name=wxEmptyString)

  Constructs a variant from a pointer to an wxObject derived class.
- wxVariant (const wxDateTime &val, const wxString &name=wxEmptyString)

  Constructs a variant from a wxDateTime.
- wxVariant (const wxArrayString &val, const wxString &name=wxEmptyString)

  Constructs a variant from a wxArrayString.
- virtual ∼wxVariant ()

  Destructor.
- wxAny GetAny () const

  Converts wxVariant into wxAny.
- wxArrayString GetArrayString () const

  Returns the string array value.
- bool GetBool () const

  Returns the boolean value.
- wxUniChar GetChar () const

  Returns the character value.
- wxVariantData ∗ GetData () const

  Returns a pointer to the internal variant data.
- wxDateTime GetDateTime () const

  Returns the date value.
- double GetDouble () const

  Returns the floating point value.
- long GetLong () const

  Returns the integer value.
- wxLongLong GetLongLong () const

  Returns the signed 64-bit integer value.
- const wxString & GetName () const

  Returns a constant reference to the variant name.
- wxString GetString () const

  Gets the string value.
- wxString GetType () const

  Returns the value type as a string.
- wxULongLong GetULongLong () const

  Returns the unsigned 64-bit integer value.
- void ∗ GetVoidPtr () const

  Gets the void pointer value.
- wxObject ∗ GetWxObjectPtr () const

  Gets the wxObject pointer value.
- bool IsNull () const

  Returns true if there is no data associated with this variant, false if there is data.
- bool IsType (const wxString &type) const

  Returns true if type matches the type of the variant, false otherwise.
- bool IsValueKindOf (const wxClassInfo ∗type) const

  Returns true if the data is derived from the class described by type, false otherwise.
- void MakeNull ()

Makes the variant null by deleting the internal data.

- wxString MakeString () const

  Makes a string representation of the variant value (for any type).
- bool Member (const wxVariant &value) const

  Returns true if value matches an element in the list.
- void SetData (wxVariantData *data)

  Sets the internal variant data, deleting the existing data if there is any.
- bool Unshare ()

  Makes sure that any data associated with this variant is not shared with other variants.
- void * operator void * () const

  Operator for implicit conversion to a pointer to a void, using GetVoidPtr().
- char operator wxChar () const

  Operator for implicit conversion to a wxChar, using GetChar().
- void * operator wxDateTime () const

  Operator for implicit conversion to a pointer to a wxDateTime, using GetDateTime().
- wxString operator wxString () const

  Operator for implicit conversion to a string, using MakeString().

List Functionality

- wxVariant operator[] (size_t idx) const

  Returns the value at idx (zero-based).
- wxVariant & operator[] (size_t idx)

  Returns a reference to the value at idx (zero-based).
- void Append (const wxVariant &value)

  Appends a value to the list.
- void Clear ()

  Makes the variant null by deleting the internal data and set the name to wxEmptyString.
- void ClearList ()

  Deletes the contents of the list.
- bool Delete (size_t item)

  Deletes the zero-based item from the list.
- size_t GetCount () const

  Returns the number of elements in the list.
- wxVariantList & GetList () const

  Returns a reference to the wxVariantList class used by wxVariant if this wxVariant is currently a list of variants.
- void Insert (const wxVariant &value)

  Inserts a value at the front of the list.
- void NullList ()

  Makes an empty list.

- bool Convert (long *value) const

  Retrieves and converts the value of this variant to the type that value is.
- bool Convert (bool *value) const

  Retrieves and converts the value of this variant to the type that value is.
- bool Convert (double *value) const

  Retrieves and converts the value of this variant to the type that value is.
- bool Convert (wxString *value) const

  Retrieves and converts the value of this variant to the type that value is.
- bool Convert (wxChar *value) const

  Retrieves and converts the value of this variant to the type that value is.
- bool Convert (wxLongLong *value) const

  Retrieves and converts the value of this variant to the type that value is.
- bool Convert (wxULongLong *value) const

Retrieves and converts the value of this variant to the type that value is.

- bool Convert (wxDateTime *value) const

  Retrieves and converts the value of this variant to the type that value is.

- bool operator!= (const wxVariant &value) const

  Inequality test operator.
- bool operator!= (const wxString &value) const

  Inequality test operator.
- bool operator!= (const wxChar *value) const

  Inequality test operator.
- bool operator!= (wxChar value) const

  Inequality test operator.
- bool operator!= (long value) const

  Inequality test operator.
- bool operator!= (bool value) const

  Inequality test operator.
- bool operator!= (double value) const

  Inequality test operator.
- bool operator!= (wxLongLong value) const

  Inequality test operator.
- bool operator!= (wxULongLong value) const

  Inequality test operator.
- bool operator!= (void *value) const

  Inequality test operator.
- bool operator!= (wxObject *value) const

  Inequality test operator.
- bool operator!= (const wxVariantList &value) const

  Inequality test operator.
- bool operator!= (const wxArrayString &value) const

  Inequality test operator.
- bool operator!= (const wxDateTime &value) const

  Inequality test operator.

- void operator= (const wxVariant &value)

  Assignment operator, using reference counting if possible.
- void operator= (wxVariantData *value)

  Assignment operator, using reference counting if possible.
- void operator= (const wxString &value)

  Assignment operator, using reference counting if possible.
- void operator= (const wxChar *value)

  Assignment operator, using reference counting if possible.
- void operator= (wxChar value)

  Assignment operator, using reference counting if possible.
- void operator= (long value)

  Assignment operator, using reference counting if possible.
- void operator= (bool value)

  Assignment operator, using reference counting if possible.
- void operator= (double value)

  Assignment operator, using reference counting if possible.
- bool operator= (wxLongLong value) const

  Assignment operator, using reference counting if possible.

- bool operator= (wxULongLong value) const

  Assignment operator, using reference counting if possible.
- void operator= (void *value)

  Assignment operator, using reference counting if possible.
- void operator= (wxObject *value)

  Assignment operator, using reference counting if possible.
- void operator= (const wxVariantList &value)

  Assignment operator, using reference counting if possible.
- void operator= (const wxDateTime &value)

  Assignment operator, using reference counting if possible.
- void operator= (const wxArrayString &value)

  Assignment operator, using reference counting if possible.

- bool operator== (const wxVariant &value) const

  Equality test operator.
- bool operator== (const wxString &value) const

  Equality test operator.
- bool operator== (const wxChar *value) const

  Equality test operator.
- bool operator== (wxChar value) const

  Equality test operator.
- bool operator== (long value) const

  Equality test operator.
- bool operator== (bool value) const

  Equality test operator.
- bool operator== (double value) const

  Equality test operator.
- bool operator== (wxLongLong value) const

  Equality test operator.
- bool operator== (wxULongLong value) const

  Equality test operator.
- bool operator== (void *value) const

  Equality test operator.
- bool operator== (wxObject *value) const

  Equality test operator.
- bool operator== (const wxVariantList &value) const

  Equality test operator.
- bool operator== (const wxArrayString &value) const

  Equality test operator.
- bool operator== (const wxDateTime &value) const

  Equality test operator.

- double operator double () const

  Operators for implicit conversion, using appropriate getter member function.
- long operator long () const

  Operators for implicit conversion, using appropriate getter member function.
- wxLongLong operator wxLongLong () const

  Operators for implicit conversion, using appropriate getter member function.
- wxULongLong operator wxULongLong () const

  Operators for implicit conversion, using appropriate getter member function.

Additional Inherited Members

21.826.3 Constructor & Destructor Documentation

wxVariant::wxVariant ( )

Default constructor.

wxVariant::wxVariant (wxVariantData * *data*, const wxString & *name* = wxEmptyString)

Constructs a variant directly with a wxVariantData object.

wxVariant will take ownership of the wxVariantData and will not increase its reference count.

wxVariant::wxVariant (const wxVariant & *variant*)

Constructs a variant from another variant by increasing the reference count.

wxVariant::wxVariant (const wxAny & *any*)

Constructs a variant by converting it from wxAny.

wxVariant::wxVariant (const wxChar * *value*, const wxString & *name* = wxEmptyString)

Constructs a variant from a wide string literal.

wxVariant::wxVariant (const wxString & *value*, const wxString & *name* = wxEmptyString)

Constructs a variant from a string.

wxVariant::wxVariant (wxChar *value*, const wxString & *name* = wxEmptyString)

Constructs a variant from a wide char.

wxVariant::wxVariant (long *value*, const wxString & *name* = wxEmptyString)

Constructs a variant from a long.

wxVariant::wxVariant (bool *value*, const wxString & *name* = wxEmptyString)

Constructs a variant from a bool.

wxVariant::wxVariant (double *value*, const wxString & *name* = wxEmptyString)

Constructs a variant from a double.

wxVariant::wxVariant (wxLongLong *value*, const wxString & *name* = wxEmptyString)

Constructs a variant from a wxLongLong.

wxVariant::wxVariant (wxULongLong *value*, const wxString & *name* = wxEmptyString)

Constructs a variant from a wxULongLong.

wxVariant::wxVariant (const wxVariantList & *value*, const wxString & *name* = wxEmptyString)

Constructs a variant from a list of variants.

wxVariant::wxVariant (void * *value*, const wxString & *name* = wxEmptyString)

Constructs a variant from a void pointer.

wxVariant::wxVariant (wxObject * *value*, const wxString & *name* = wxEmptyString)

Constructs a variant from a pointer to an wxObject derived class.

wxVariant::wxVariant (const wxDateTime & *val*, const wxString & *name* = wxEmptyString)

Constructs a variant from a wxDateTime.

wxVariant::wxVariant (const wxArrayString & *val*, const wxString & *name* = wxEmptyString)

Constructs a variant from a wxArrayString.

virtual wxVariant::~wxVariant ( ) [virtual]

Destructor.

Note

wxVariantData's destructor is protected, so wxVariantData cannot usually be deleted. Instead, wxVariantData::DecRef() should be called. See reference-counted object destruction for more info.

21.826.4 Member Function Documentation

void wxVariant::Append (const wxVariant & *value*)

Appends a value to the list.

void wxVariant::Clear ( )

Makes the variant null by deleting the internal data and set the name to wxEmptyString.

void wxVariant::ClearList ( )

Deletes the contents of the list.

bool wxVariant::Convert (long * *value*) const

Retrieves and converts the value of this variant to the type that *value* is.

bool wxVariant::Convert (bool * *value*) const

Retrieves and converts the value of this variant to the type that *value* is.

bool wxVariant::Convert (double * *value*) const

Retrieves and converts the value of this variant to the type that *value* is.

bool wxVariant::Convert (wxString * *value*) const

Retrieves and converts the value of this variant to the type that *value* is.

bool wxVariant::Convert (wxChar * *value*) const

Retrieves and converts the value of this variant to the type that *value* is.

bool wxVariant::Convert (wxLongLong * *value*) const

Retrieves and converts the value of this variant to the type that *value* is.

bool wxVariant::Convert (wxULongLong * *value*) const

Retrieves and converts the value of this variant to the type that *value* is.

bool wxVariant::Convert (wxDateTime * *value*) const

Retrieves and converts the value of this variant to the type that *value* is.

bool wxVariant::Delete (size_t *item*)

Deletes the zero-based *item* from the list.

wxAny wxVariant::GetAny ( ) const

Converts wxVariant into wxAny.

wxArrayString wxVariant::GetArrayString ( ) const

Returns the string array value.

bool wxVariant::GetBool ( ) const

Returns the boolean value.

wxUniChar wxVariant::GetChar ( ) const

Returns the character value.

size_t wxVariant::GetCount ( ) const

Returns the number of elements in the list.

wxVariantData* wxVariant::GetData ( ) const

Returns a pointer to the internal variant data.

To take ownership of this data, you must call its wxVariantData::IncRef() method. When you stop using it, wxVariantData::DecRef() must be called as well.

wxDateTime wxVariant::GetDateTime ( ) const

Returns the date value.

double wxVariant::GetDouble ( ) const

Returns the floating point value.

wxVariantList& wxVariant::GetList ( ) const

Returns a reference to the wxVariantList class used by wxVariant if this wxVariant is currently a list of variants.

long wxVariant::GetLong ( ) const

Returns the integer value.

wxLongLong wxVariant::GetLongLong ( ) const

Returns the signed 64-bit integer value.

const wxString& wxVariant::GetName ( ) const

Returns a constant reference to the variant name.

wxString wxVariant::GetString ( ) const

Gets the string value.

wxString wxVariant::GetType ( ) const

Returns the value type as a string.

The built-in types are:

- "bool"
- "char"
- "datetime"
- "double"
- "list"

- "long"
- "longlong"
- "string"
- "ulonglong"
- "arrstring"
- "void*"

If the variant is null, the value type returned is the string "null" (not the empty string).

wxULongLong wxVariant::GetULongLong ( ) const

Returns the unsigned 64-bit integer value.

void* wxVariant::GetVoidPtr ( ) const

Gets the void pointer value.

Notice that this method can be used for null objects (i.e. those for which IsNull() returns true) and will return NULL for them.

wxObject* wxVariant::GetWxObjectPtr ( ) const

Gets the wxObject pointer value.

void wxVariant::Insert (const wxVariant & *value*)

Inserts a value at the front of the list.

bool wxVariant::IsNull ( ) const

Returns true if there is no data associated with this variant, false if there is data.

bool wxVariant::IsType (const wxString & *type*) const

Returns true if *type* matches the type of the variant, false otherwise.

bool wxVariant::IsValueKindOf (const wxClassInfo * *type*) const

Returns true if the data is derived from the class described by *type*, false otherwise.

void wxVariant::MakeNull ( )

Makes the variant null by deleting the internal data.

wxString wxVariant::MakeString ( ) const

Makes a string representation of the variant value (for any type).

bool wxVariant::Member (const wxVariant & *value*) const

Returns true if *value* matches an element in the list.

void wxVariant::NullList ( )

Makes an empty list.

This differs from a null variant which has no data; a null list is of type list, but the number of elements in the list is zero.

double wxVariant::operator double ( ) const

Operators for implicit conversion, using appropriate getter member function.

long wxVariant::operator long ( ) const

Operators for implicit conversion, using appropriate getter member function.

void* wxVariant::operator void * ( ) const

Operator for implicit conversion to a pointer to a void, using GetVoidPtr().

char wxVariant::operator wxChar ( ) const

Operator for implicit conversion to a wxChar, using GetChar().

void* wxVariant::operator wxDateTime ( ) const

Operator for implicit conversion to a pointer to a wxDateTime, using GetDateTime().

wxLongLong wxVariant::operator wxLongLong ( ) const

Operators for implicit conversion, using appropriate getter member function.

wxString wxVariant::operator wxString ( ) const

Operator for implicit conversion to a string, using MakeString().

wxULongLong wxVariant::operator wxULongLong ( ) const

Operators for implicit conversion, using appropriate getter member function.

bool wxVariant::operator!= (const wxVariant & *value*) const

Inequality test operator.

bool wxVariant::operator!= (const wxString & *value*) const

Inequality test operator.

bool wxVariant::operator!= (const wxChar * *value*) const

Inequality test operator.

bool wxVariant::operator!= (wxChar *value*) const

Inequality test operator.

bool wxVariant::operator!= (long *value*) const

Inequality test operator.

bool wxVariant::operator!= (bool *value*) const

Inequality test operator.

bool wxVariant::operator!= (double *value*) const

Inequality test operator.

bool wxVariant::operator!= (wxLongLong *value*) const

Inequality test operator.

bool wxVariant::operator!= (wxULongLong *value*) const

Inequality test operator.

bool wxVariant::operator!= (void * *value*) const

Inequality test operator.

bool wxVariant::operator!= (wxObject * *value*) const

Inequality test operator.

bool wxVariant::operator!= (const wxVariantList & *value*) const

Inequality test operator.

bool wxVariant::operator!= (const wxArrayString & *value*) const

Inequality test operator.

bool wxVariant::operator!= (const wxDateTime & *value*) const

Inequality test operator.

void wxVariant::operator= (const wxVariant & *value*)

Assignment operator, using reference counting if possible.

void wxVariant::operator= (wxVariantData * *value*)

Assignment operator, using reference counting if possible.

void wxVariant::operator= (const wxString & *value*)

Assignment operator, using reference counting if possible.

void wxVariant::operator= (const wxChar * *value*)

Assignment operator, using reference counting if possible.

void wxVariant::operator= (wxChar *value*)

Assignment operator, using reference counting if possible.

void wxVariant::operator= (long *value*)

Assignment operator, using reference counting if possible.

void wxVariant::operator= (bool *value*)

Assignment operator, using reference counting if possible.

void wxVariant::operator= (double *value*)

Assignment operator, using reference counting if possible.

bool wxVariant::operator= (wxLongLong *value*) const

Assignment operator, using reference counting if possible.

bool wxVariant::operator= (wxULongLong *value*) const

Assignment operator, using reference counting if possible.

void wxVariant::operator= (void * *value*)

Assignment operator, using reference counting if possible.

void wxVariant::operator= (wxObject * *value*)

Assignment operator, using reference counting if possible.

void wxVariant::operator= (const wxVariantList & *value*)

Assignment operator, using reference counting if possible.

void wxVariant::operator= (const wxDateTime & *value*)

Assignment operator, using reference counting if possible.

void wxVariant::operator= (const wxArrayString & *value*)

Assignment operator, using reference counting if possible.

bool wxVariant::operator== (const wxVariant & *value*) const

Equality test operator.

bool wxVariant::operator== (const wxString & *value*) const

Equality test operator.

bool wxVariant::operator== (const wxChar * *value*) const

Equality test operator.

bool wxVariant::operator== (wxChar *value*) const

Equality test operator.

bool wxVariant::operator== (long *value*) const

Equality test operator.

bool wxVariant::operator== (bool *value*) const

Equality test operator.

bool wxVariant::operator== (double *value*) const

Equality test operator.

bool wxVariant::operator== (wxLongLong *value*) const

Equality test operator.

bool wxVariant::operator== (wxULongLong *value*) const

Equality test operator.

bool wxVariant::operator== (void * *value*) const

Equality test operator.

bool wxVariant::operator== (wxObject * *value*) const

Equality test operator.

bool wxVariant::operator== (const wxVariantList & *value*) const

Equality test operator.

bool wxVariant::operator== (const wxArrayString & *value*) const

Equality test operator.

bool wxVariant::operator== (const wxDateTime & *value*) const

Equality test operator.

wxVariant wxVariant::operator[] (size_t *idx*) const

Returns the value at *idx* (zero-based).

wxVariant& wxVariant::operator[] (size_t *idx*)

Returns a reference to the value at *idx* (zero-based).

This can be used to change the value at this index.

void wxVariant::SetData (wxVariantData * *data*)

Sets the internal variant data, deleting the existing data if there is any.

bool wxVariant::Unshare ( )

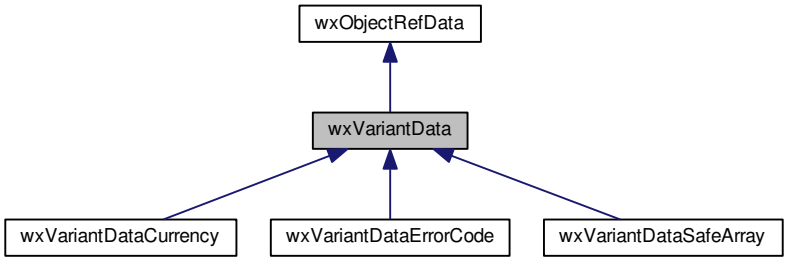
Makes sure that any data associated with this variant is not shared with other variants.

For this to work, wxVariantData::Clone() must be implemented for the data types you are working with. wxVariantData::Clone() is implemented for all the default data types.

21.827 wxVariantData Class Reference

`#include <wx/variant.h>`

Inheritance diagram for wxVariantData:



21.827.1 Detailed Description

The wxVariantData class is used to implement a new type for wxVariant.

Derive from wxVariantData, and override the pure virtual functions.

wxVariantData is reference counted, but you don't normally have to care about this, as wxVariant manages the count automatically. However, in case your application needs to take ownership of wxVariantData, be aware that the object is created with a reference count of 1, and passing it to wxVariant will not increase this. In other words, IncRef() needs to be called only if you both take ownership of wxVariantData and pass it to a wxVariant. Also note that the destructor is protected, so you can never explicitly delete a wxVariantData instance. Instead, DecRef() will delete the object automatically when the reference count reaches zero.

Library: wxBase

Category: Data Structures

See also

wxVariant, wxGetVariantCast()

Public Member Functions

- wxVariantData ()

  Default constructor.
- virtual wxVariantData * Clone () const

  This function can be overridden to clone the data.
- void DecRef ()

  Decreases reference count.
- virtual bool Eq (wxVariantData &data) const =0

  Returns true if this object is equal to data.
- virtual bool GetAny (wxAny *any) const

  Converts value to wxAny, if possible.
- virtual wxString GetType () const =0

  Returns the string type of the data.
- virtual wxClassInfo * GetValueClassInfo ()

If the data is a wxObject returns a pointer to the objects wxClassInfo structure, if the data isn't a wxObject the method returns NULL.

- void IncRef ()

  Increases reference count.

- virtual bool Read (istream &stream)

  Reads the data from stream.

- virtual bool Read (wxString &string)

  Reads the data from string.

- virtual bool Write (ostream &stream) const

  Writes the data to stream.

- virtual bool Write (wxString &string) const

  Writes the data to string.

21.827.2 Constructor & Destructor Documentation

wxVariantData::wxVariantData ( )

Default constructor.

21.827.3 Member Function Documentation

virtual wxVariantData* wxVariantData::Clone ( ) const `[virtual]`

This function can be overridden to clone the data.

You must implement this function in order for wxVariant::Unshare() to work for your data. This function is implemented for all built-in data types.

Reimplemented in wxVariantDataSafeArray, wxVariantDataErrorCode, and wxVariantDataCurrency.

void wxVariantData::DecRef ( )

Decreases reference count.

If the count reaches zero, the object is automatically deleted.

Note

The destructor of wxVariantData is protected, so delete cannot be used as normal. Instead, DecRef() should be called.

virtual bool wxVariantData::Eq (wxVariantData & *data*) const `[pure virtual]`

Returns true if this object is equal to *data*.

Implemented in wxVariantDataSafeArray, wxVariantDataErrorCode, and wxVariantDataCurrency.

virtual bool wxVariantData::GetAny (wxAny * *any*) const `[virtual]`

Converts value to wxAny, if possible.

Return true if successful.

virtual wxString wxVariantData::GetType ( ) const [pure virtual]

Returns the string type of the data.

Implemented in wxVariantDataSafeArray, wxVariantDataErrorCode, and wxVariantDataCurrency.

virtual wxClassInfo* wxVariantData::GetValueClassInfo ( ) [virtual]

If the data is a wxObject returns a pointer to the objects wxClassInfo structure, if the data isn't a wxObject the method returns NULL.

void wxVariantData::IncRef ( )

Increases reference count.

Note that initially wxVariantData has reference count of 1.

virtual bool wxVariantData::Read (istream & *stream*) [virtual]

Reads the data from *stream*.

virtual bool wxVariantData::Read (wxString & *string*) [virtual]

Reads the data from *string*.

virtual bool wxVariantData::Write (ostream & *stream*) const [virtual]

Writes the data to *stream*.

virtual bool wxVariantData::Write (wxString & *string*) const [virtual]

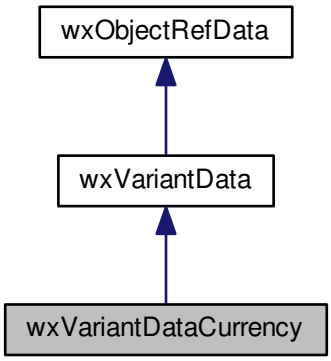
Writes the data to *string*.

Reimplemented in wxVariantDataSafeArray, wxVariantDataErrorCode, and wxVariantDataCurrency.

21.828 wxVariantDataCurrency Class Reference

```
#include <wx/msw/ole/automtn.h>
```

Inheritance diagram for wxVariantDataCurrency:



21.828.1 Detailed Description

This class represents a thin wrapper for Microsoft Windows CURRENCY type.

It is used for converting between wxVariant and OLE VARIANT with type set to VT_CURRENCY. When wxVariant stores wxVariantDataCurrency, it returns "currency" as its type.

An example of setting and getting CURRENCY value to and from wxVariant:

```
CURRENCY cy;
wxVariant variant;

// set wxVariant to currency type
if ( SUCCEEDED(VarCyFromR8(123.45, &cy)) )  // set cy to 123.45
{
    variant.SetData(new wxVariantDataCurrency(cy));

    // or instead of the line above you could write:
    // wxVariantDataCurrency wxCy;
    // wxCy.SetValue(cy);
    // variant.SetData(wxCy.Clone());
}

// get CURRENCY value from wxVariant
if ( variant.GetType() == "currency" )
{
    wxVariantDataCurrency*
        wxCy = wxDynamicCastVariantData(variant.GetData(),
      wxVariantDataCurrency);
    cy = wxCy->GetValue();
}
```

Availability: only available for the wxMSW port.

Since

2.9.5

#include <wx/msw/ole/oleutils.h>
```

Public Member Functions

- wxVariantDataCurrency ()

  Default constructor initializes the object to 0.0.
- wxVariantDataCurrency (CURRENCY value)

  Constructor from CURRENCY.
- CURRENCY GetValue () const

  Returns the stored CURRENCY value.
- void SetValue (CURRENCY value)

  Sets the stored value to value.
- virtual bool Eq (wxVariantData &data) const

  Returns true if data is of wxVariantDataCurency type and contains the same CURRENCY value.
- virtual bool Write (wxString &str) const

  Fills the provided string with the textual representation of this object.
- wxVariantData * Clone () const

  Returns a copy of itself.
- virtual wxString GetType () const

  Returns "currency".
- virtual bool GetAsAny (wxAny *any) const

  Converts the value of this object to wxAny.

21.828.2 Constructor & Destructor Documentation

wxVariantDataCurrency::wxVariantDataCurrency ( )

Default constructor initializes the object to 0.0.

wxVariantDataCurrency::wxVariantDataCurrency (CURRENCY *value*)

Constructor from CURRENCY.

21.828.3 Member Function Documentation

wxVariantData* wxVariantDataCurrency::Clone ( ) const `[virtual]`

Returns a copy of itself.

Reimplemented from wxVariantData.

virtual bool wxVariantDataCurrency::Eq (wxVariantData & *data*) const `[virtual]`

Returns true if *data* is of wxVariantDataCurency type and contains the same CURRENCY value.

Implements wxVariantData.

virtual bool wxVariantDataCurrency::GetAsAny (wxAny * *any*) const `[virtual]`

Converts the value of this object to wxAny.

virtual wxString wxVariantDataCurrency::GetType ( ) const `[virtual]`

Returns "currency".

Implements wxVariantData.

CURRENCY wxVariantDataCurrency::GetValue ( ) const

Returns the stored CURRENCY value.

void wxVariantDataCurrency::SetValue (CURRENCY *value*)

Sets the stored value to *value*.

virtual bool wxVariantDataCurrency::Write (wxString & *str*) const `[virtual]`

Fills the provided string with the textual representation of this object.

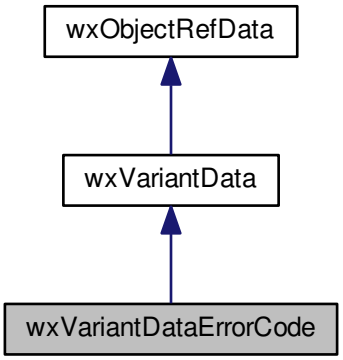
The implementation of this method using `VarBstrFromCy()` Windows API function with LOCALE_USER_DEFAULT.

Reimplemented from wxVariantData.

21.829 wxVariantDataErrorCode Class Reference

`#include <wx/msw/ole/automtn.h>`

Inheritance diagram for wxVariantDataErrorCode:



21.829.1 Detailed Description

This class represents a thin wrapper for Microsoft Windows SCODE type (which is the same as HRESULT).

It is used for converting between a wxVariant and OLE VARIANT with type set to VT_ERROR. When wxVariant stores wxVariantDataErrorCode, it returns "errorcode" as its type. This class can be used for returning error codes of automation calls or exchanging values with other applications: e.g. Microsoft Excel returns VARIANTs with VT_ERROR type for cell values with errors (one of XlCVError constants, displayed as e.g. "#DIV/0!" or "#REF!" there) etc. See wxVariantDataCurrency for an example of how to exchange values between wxVariant and a native type not directly supported by it.

Availability: only available for the wxMSW port.

Since

2.9.5

Library: wxCore

Category: Data Structures

#include <wx/msw/ole/oleutils.h>
```

Public Member Functions

- wxVariantDataErrorCode (SCODE value=S_OK)

  Constructor initializes the object to value or S_OK if no value was passed.
- SCODE GetValue () const

  Returns the stored SCODE value.
- void SetValue (SCODE value)

  Set the stored value to value.
- virtual bool Eq (wxVariantData &data) const

  Returns true if data is of wxVariantDataErrorCode type and contains the same SCODE value.
- virtual bool Write (wxString &str) const

  Fills the provided string with the textual representation of this object.
- wxVariantData * Clone () const

  Returns a copy of itself.
- virtual wxString GetType () const

  Returns "errorcode".
- virtual bool GetAsAny (wxAny *any) const

  Converts the value of this object to wxAny.

21.829.2 Constructor & Destructor Documentation

wxVariantDataErrorCode::wxVariantDataErrorCode (SCODE *value* = `S_OK`)

Constructor initializes the object to *value* or S_OK if no value was passed.

21.829.3 Member Function Documentation

wxVariantData* wxVariantDataErrorCode::Clone ( ) const [virtual]

Returns a copy of itself.

Reimplemented from wxVariantData.

virtual bool wxVariantDataErrorCode::Eq (wxVariantData & *data*) const [virtual]

Returns true if *data* is of wxVariantDataErrorCode type and contains the same SCODE value.

Implements wxVariantData.

virtual bool wxVariantDataErrorCode::GetAsAny (wxAny * *any*) const [virtual]

Converts the value of this object to wxAny.

virtual wxString wxVariantDataErrorCode::GetType ( ) const [inline], [virtual]

Returns "errorcode".

Implements wxVariantData.

SCODE wxVariantDataErrorCode::GetValue ( ) const

Returns the stored SCODE value.

void wxVariantDataErrorCode::SetValue (SCODE *value*)

Set the stored value to *value*.

virtual bool wxVariantDataErrorCode::Write (wxString & *str*) const [virtual]

Fills the provided string with the textual representation of this object.

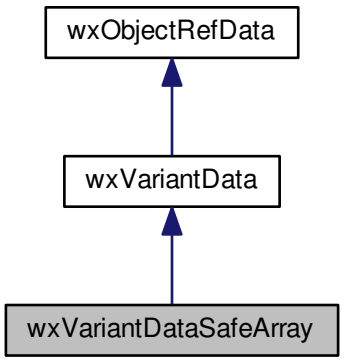
The error code is just a number, so it's output as such.

Reimplemented from wxVariantData.

21.830 wxVariantDataSafeArray Class Reference

`#include <wx/msw/ole/automtn.h>`

Inheritance diagram for wxVariantDataSafeArray:



21.830.1 Detailed Description

This class represents a thin wrapper for Microsoft Windows SAFEARRAY type.

It is used for converting between wxVariant and OLE VARIANT with type set to VT_ARRAY, which has more than one dimension. When wxVariant stores wxVariantDataSafeArray, it returns "safearray" as its type.

wxVariantDataSafeArray does NOT manage the SAFEARRAY it points to. If you want to pass it to a wxAutomationObject as a parameter:

1. Assign a SAFEARRAY pointer to it and store it in a wxVariant.
2. Call the wxAutomationObject method (CallMethod(), SetProperty() or Invoke())
3. wxAutomationObject will destroy the array after the approapriate automation call.

An example of creating a 2-dimensional SAFEARRAY containing VARIANTs and storing it in a wxVariant

```
SAFEARRAYBOUND bounds[2]; // 2 dimensions
wxSafeArray<VT_VARIANT> safeArray;
unsigned rowCount = 1000;
unsigned colCount = 20;

bounds[0].lLbound = 0; // elements start at 0
bounds[0].cElements = rowCount;
bounds[1].lLbound = 0; // elements start at 0
bounds[1].cElements = colCount;

if ( !safeArray.Create(bounds, 2) )
    return false;

long indices[2];

for ( unsigned row = 0; row < rowCount; row++ )
{
    indices[0] = row;
    for ( unsigned col = 0; col < colCount; col++ )
    {
        indices[1] = col;
        if ( !safeArray.SetElement(indices, wxString::Format("R%u C%u", row+1, col+1)) )
           return false;
    }
}
range.PutProperty("Value", wxVariant(new wxVariantDataSafeArray(safeArray.
      Detach())));
```

If you you received wxVariantDataSafeArray as a result of wxAutomationObject method call: (1) Get the data out of the array. (2) Destroy the array.

```
wxVariant result;
result = range.GetProperty("Value");
if ( result.GetType() == "safearray" )
{
    wxSafeArray<VT_VARIANT> safeArray;
    wxVariantDataSafeArray* const
        sa = wxStaticCastVariantData(variant.GetData(),
      wxVariantDataSafeArray);

    if ( !safeArray.Attach(sa.GetValue() )
    {
        if ( !safeArray.HasArray() )
            SafeArrayDestroy(sa.GetValue()); // we have to dispose the SAFEARRAY ourselves
        return false;
    }

    // get the data from the SAFEARRAY using wxSafeArray::GetElement()
    // SAFEARRAY will be disposed by safeArray's dtor
}
```

Availability: only available for the wxMSW port.

  Set the stored array.
- virtual bool Eq (wxVariantData &data) const

  Returns true if data is of wxVariantDataSafeArray type and contains the same SAFEARRAY value.*
- virtual bool Write (wxString &str) const

  Fills the provided string with the textual representation of this object.
- wxVariantData * Clone () const

  Returns a copy of itself.
- virtual wxString GetType () const

  Returns "safearray".
- virtual bool GetAsAny (wxAny *any) const

  Converts the value of this object to wxAny.

21.830.2 Constructor & Destructor Documentation

wxVariantDataSafeArray::wxVariantDataSafeArray (SAFEARRAY * *value* = NULL) [explicit]

Constructor initializes the object to *value*.

21.830.3 Member Function Documentation

wxVariantData* wxVariantDataSafeArray::Clone ( ) const [virtual]

Returns a copy of itself.

Reimplemented from wxVariantData.

virtual bool wxVariantDataSafeArray::Eq (wxVariantData & *data*) const [virtual]

Returns true if *data* is of wxVariantDataSafeArray type and contains the same SAFEARRAY* value.

Implements wxVariantData.

virtual bool wxVariantDataSafeArray::GetAsAny (wxAny * *any*) const [virtual]

Converts the value of this object to wxAny.

virtual wxString wxVariantDataSafeArray::GetType ( ) const [virtual]

Returns "safearray".

Implements wxVariantData.

SAFEARRAY* wxVariantDataSafeArray::GetValue ( ) const

Returns the stored array.

void wxVariantDataSafeArray::SetValue (SAFEARRAY * *value*)

Set the stored array.

virtual bool wxVariantDataSafeArray::Write (wxString & *str*) const [virtual]

Fills the provided string with the textual representation of this object.

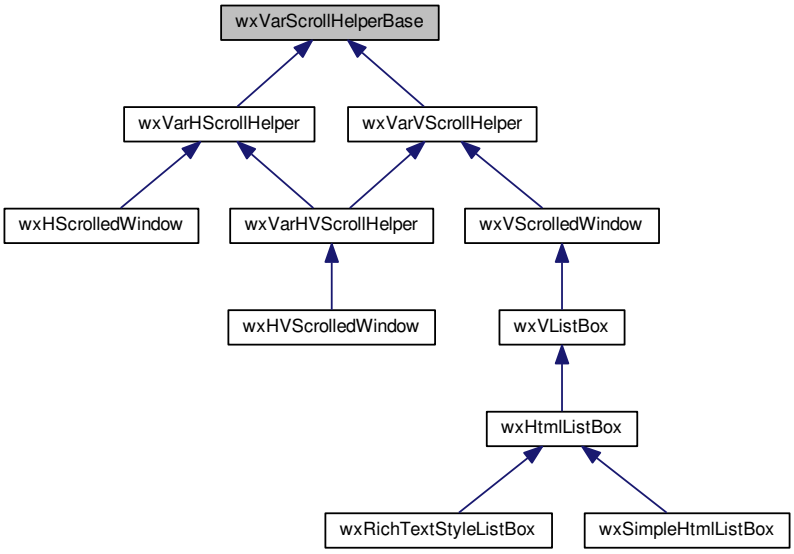
Only the address of SAFEARRAY pointer is output.

Reimplemented from wxVariantData.

21.831 wxVarScrollHelperBase Class Reference

```
#include <wx/vscroll.h>
```

Inheritance diagram for wxVarScrollHelperBase:



21.831.1 Detailed Description

This class provides all common base functionality for scroll calculations shared among all variable scrolled window implementations as well as automatic scrollbar functionality, saved scroll positions, controlling target windows to be scrolled, as well as defining all required virtual functions that need to be implemented for any orientation specific work.

Documentation of this class is provided specifically for referencing use of the functions provided by this class for use with the variable scrolled windows that derive from here. You will likely want to derive your window from one of the already implemented variable scrolled windows rather than from wxVarScrollHelperBase directly.

Library: wxCore

Category: Miscellaneous Windows

See also

wxHScrolledWindow, wxHVScrolledWindow, wxVScrolledWindow

Public Member Functions

- wxVarScrollHelperBase (wxWindow *winToScroll)

  Constructor taking the target window to be scrolled by this helper class.
- virtual ~wxVarScrollHelperBase ()

  Virtual destructor for detaching scroll event handlers attached with this helper class.
- int CalcScrolledPosition (int coord) const

  Translates the logical coordinate given to the current device coordinate.
- int CalcUnscrolledPosition (int coord) const

  Translates the device coordinate given to the corresponding logical coordinate.

- void EnablePhysicalScrolling (bool scrolling=true)

  With physical scrolling on (when this is true), the device origin is changed properly when a wxPaintDC is prepared, children are actually moved and laid out properly, and the contents of the window (pixels) are actually moved.
- virtual int GetNonOrientationTargetSize () const =0

  This function needs to be overridden in the in the derived class to return the window size with respect to the opposing orientation.
- virtual wxOrientation GetOrientation () const =0

  This function need to be overridden to return the orientation that this helper is working with, either `wxHORIZONTAL` or `wxVERTICAL`.
- virtual int GetOrientationTargetSize () const =0

  This function needs to be overridden in the in the derived class to return the window size with respect to the orientation this helper is working with.
- virtual wxWindow * GetTargetWindow () const

  This function will return the target window this helper class is currently scrolling.
- size_t GetVisibleBegin () const

  Returns the index of the first visible unit based on the scroll position.
- size_t GetVisibleEnd () const

  Returns the index of the last visible unit based on the scroll position.
- bool IsVisible (size_t unit) const

  Returns true if the given scroll unit is currently visible (even if only partially visible) or false otherwise.
- virtual void RefreshAll ()

  Recalculate all parameters and repaint all units.
- virtual void SetTargetWindow (wxWindow *target)

  Normally the window will scroll itself, but in some rare occasions you might want it to scroll (part of) another window (e.g.
- virtual void UpdateScrollbar ()

  Update the thumb size shown by the scrollbar.
- int VirtualHitTest (wxCoord coord) const

  Returns the virtual scroll unit under the device unit given accounting for scroll position or `wxNOT_FOUND` if none (i.e.

Protected Member Functions

- virtual void OnGetUnitsSizeHint (size_t unitMin, size_t unitMax) const

  This function doesn't have to be overridden but it may be useful to do so if calculating the units' sizes is a relatively expensive operation as it gives your code a chance to calculate several of them at once and cache the result if necessary.
- virtual wxCoord EstimateTotalSize () const

  When the number of scroll units change, we try to estimate the total size of all units when the full window size is needed (i.e.
- virtual wxCoord OnGetUnitSize (size_t unit) const =0

  This function must be overridden in the derived class, and should return the size of the given unit in pixels.

21.831.2 Constructor & Destructor Documentation

wxVarScrollHelperBase::wxVarScrollHelperBase (wxWindow * *winToScroll*)

Constructor taking the target window to be scrolled by this helper class.

This will attach scroll event handlers to the target window to catch and handle scroll events appropriately.

virtual wxVarScrollHelperBase::~wxVarScrollHelperBase ( ) `[virtual]`

Virtual destructor for detaching scroll event handlers attached with this helper class.

21.831.3 Member Function Documentation

int wxVarScrollHelperBase::CalcScrolledPosition (int *coord*) const

Translates the logical coordinate given to the current device coordinate.

For example, if the window is scrolled 10 units and each scroll unit represents 10 device units (which may not be the case since this class allows for variable scroll unit sizes), a call to this function with a coordinate of 15 will return -85.

See also

CalcUnscrolledPosition()

int wxVarScrollHelperBase::CalcUnscrolledPosition (int *coord*) const

Translates the device coordinate given to the corresponding logical coordinate.

For example, if the window is scrolled 10 units and each scroll unit represents 10 device units (which may not be the case since this class allows for variable scroll unit sizes), a call to this function with a coordinate of 15 will return 115.

See also

CalcScrolledPosition()

void wxVarScrollHelperBase::EnablePhysicalScrolling (bool *scrolling* = `true`)

With physical scrolling on (when this is true), the device origin is changed properly when a wxPaintDC is prepared, children are actually moved and laid out properly, and the contents of the window (pixels) are actually moved.

When this is false, you are responsible for repainting any invalidated areas of the window yourself to account for the new scroll position.

virtual wxCoord wxVarScrollHelperBase::EstimateTotalSize ( ) const `[protected], [virtual]`

When the number of scroll units change, we try to estimate the total size of all units when the full window size is needed (i.e.

to calculate the scrollbar thumb size). This is a rather expensive operation in terms of unit access, so if the user code may estimate the average size better or faster than we do, it should override this function to implement its own logic. This function should return the best guess for the total virtual window size.

Note

Although returning a totally wrong value would still work, it risks resulting in very strange scrollbar behaviour so this function should really try to make the best guess possible.

virtual int wxVarScrollHelperBase::GetNonOrientationTargetSize ( ) const `[pure virtual]`

This function needs to be overridden in the in the derived class to return the window size with respect to the opposing orientation.

If this is a vertical scrolled window, it should return the height.

See also

GetOrientationTargetSize()

virtual wxOrientation wxVarScrollHelperBase::GetOrientation ( ) const `[pure virtual]`

This function need to be overridden to return the orientation that this helper is working with, either `wxHORIZONTAL` or `wxVERTICAL`.

virtual int wxVarScrollHelperBase::GetOrientationTargetSize ( ) const `[pure virtual]`

This function needs to be overridden in the in the derived class to return the window size with respect to the orientation this helper is working with.

If this is a vertical scrolled window, it should return the width.

See also

GetNonOrientationTargetSize()

virtual wxWindow* wxVarScrollHelperBase::GetTargetWindow ( ) const `[virtual]`

This function will return the target window this helper class is currently scrolling.

See also

SetTargetWindow()

size_t wxVarScrollHelperBase::GetVisibleBegin ( ) const

Returns the index of the first visible unit based on the scroll position.

size_t wxVarScrollHelperBase::GetVisibleEnd ( ) const

Returns the index of the last visible unit based on the scroll position.

This includes the last unit even if it is only partially visible.

bool wxVarScrollHelperBase::IsVisible (size_t *unit*) const

Returns true if the given scroll unit is currently visible (even if only partially visible) or false otherwise.

virtual wxCoord wxVarScrollHelperBase::OnGetUnitSize (size_t *unit*) const `[protected], [pure virtual]`

This function must be overridden in the derived class, and should return the size of the given unit in pixels.

virtual void wxVarScrollHelperBase::OnGetUnitsSizeHint (size_t *unitMin*, size_t *unitMax*) const `[protected], [virtual]`

This function doesn't have to be overridden but it may be useful to do so if calculating the units' sizes is a relatively expensive operation as it gives your code a chance to calculate several of them at once and cache the result if necessary.

OnGetUnitsSizeHint() is normally called just before OnGetUnitSize() but you shouldn't rely on the latter being called for all units in the interval specified here. It is also possible that OnGetUnitSize() will be called for units outside of this interval, so this is really just a hint, not a promise.

Finally, note that *unitMin* is inclusive, while *unitMax* is exclusive.

virtual void wxVarScrollHelperBase::RefreshAll ( ) [virtual]

Recalculate all parameters and repaint all units.

virtual void wxVarScrollHelperBase::SetTargetWindow (wxWindow * *target*) [virtual]

Normally the window will scroll itself, but in some rare occasions you might want it to scroll (part of) another window (e.g.

a child of it in order to scroll only a portion the area between the scrollbars like a spreadsheet where only the cell area will move).

See also

GetTargetWindow()

virtual void wxVarScrollHelperBase::UpdateScrollbar ( ) [virtual]

Update the thumb size shown by the scrollbar.

int wxVarScrollHelperBase::VirtualHitTest (wxCoord *coord*) const

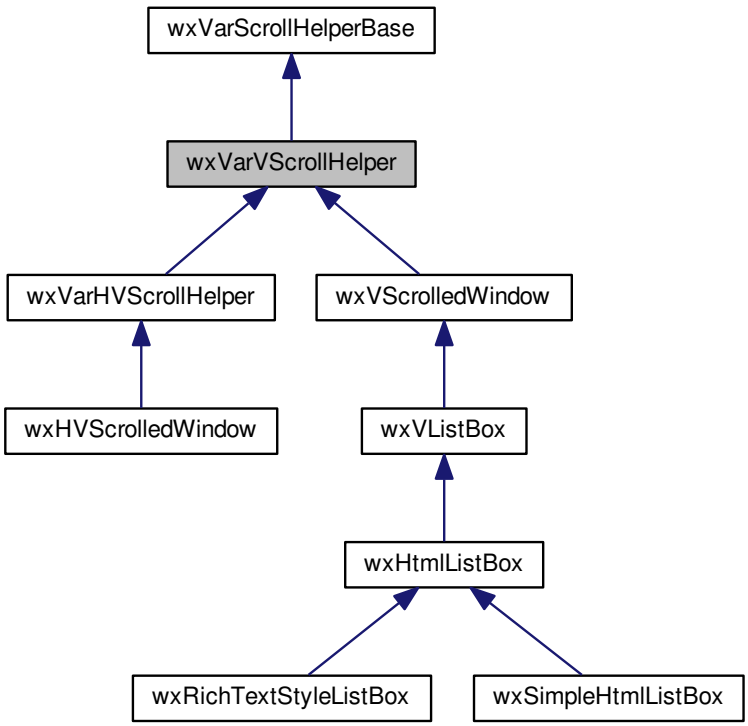
Returns the virtual scroll unit under the device unit given accounting for scroll position or `wxNOT_FOUND` if none (i.e.

if it is below the last item).

21.832 wxVarVScrollHelper Class Reference

`#include <wx/vscroll.h>`

Inheritance diagram for wxVarVScrollHelper:



21.832.1 Detailed Description

This class provides functions wrapping the wxVarScrollHelperBase class, targeted for vertical-specific scrolling.

Like wxVarScrollHelperBase, this class is mostly only useful to those classes built into wxWidgets deriving from here, and this documentation is mostly only provided for referencing the functions provided by this class. You will likely want to derive your window from wxVScrolledWindow rather than from here directly.

Library: wxCore

Category: Miscellaneous Windows

wxHScrolledWindow, wxHVScrolledWindow, wxVScrolledWindow

Public Member Functions

- wxVarVScrollHelper (wxWindow *winToScroll)

  Constructor taking the target window to be scrolled by this helper class.
- size_t GetRowCount () const

  Returns the number of rows the target window contains.

- size_t GetVisibleRowsBegin () const

  Returns the index of the first visible row based on the scroll position.
- size_t GetVisibleRowsEnd () const

  Returns the index of the last visible row based on the scroll position.
- bool IsRowVisible (size_t row) const

  Returns true if the given row is currently visible (even if only partially visible) or false otherwise.
- virtual void RefreshRow (size_t row)

  Triggers a refresh for just the given row's area of the window if it's visible.
- virtual void RefreshRows (size_t from, size_t to)

  Triggers a refresh for the area between the specified range of rows given (inclusively).
- virtual bool ScrollRowPages (int pages)

  Scroll by the specified number of pages which may be positive (to scroll down) or negative (to scroll up).
- virtual bool ScrollRows (int rows)

  Scroll by the specified number of rows which may be positive (to scroll down) or negative (to scroll up).
- bool ScrollToRow (size_t row)

  Scroll to the specified row.
- void SetRowCount (size_t rowCount)

  Set the number of rows the window contains.

Protected Member Functions

- virtual void OnGetRowsHeightHint (size_t rowMin, size_t rowMax) const

  This function doesn't have to be overridden but it may be useful to do so if calculating the rows' sizes is a relatively expensive operation as it gives your code a chance to calculate several of them at once and cache the result if necessary.
- virtual wxCoord EstimateTotalHeight () const

  This class forwards calls from EstimateTotalSize() to this function so derived classes can override either just the height or the width estimation, or just estimate both differently if desired in any wxHVScrolledWindow derived class.
- virtual wxCoord OnGetRowHeight (size_t row) const =0

  This function must be overridden in the derived class, and should return the height of the given row in pixels.

21.832.2 Constructor & Destructor Documentation

wxVarVScrollHelper::wxVarVScrollHelper (wxWindow * *winToScroll*)

Constructor taking the target window to be scrolled by this helper class.

This will attach scroll event handlers to the target window to catch and handle scroll events appropriately.

21.832.3 Member Function Documentation

virtual wxCoord wxVarVScrollHelper::EstimateTotalHeight ( ) const `[protected], [virtual]`

This class forwards calls from EstimateTotalSize() to this function so derived classes can override either just the height or the width estimation, or just estimate both differently if desired in any wxHVScrolledWindow derived class.

Note

This function will not be called if EstimateTotalSize() is overridden in your derived class.

size_t wxVarVScrollHelper::GetRowCount ( ) const

Returns the number of rows the target window contains.

See also

SetRowCount()

size_t wxVarVScrollHelper::GetVisibleRowsBegin ( ) const

Returns the index of the first visible row based on the scroll position.

size_t wxVarVScrollHelper::GetVisibleRowsEnd ( ) const

Returns the index of the last visible row based on the scroll position.

This includes the last row even if it is only partially visible.

bool wxVarVScrollHelper::IsRowVisible (size_t *row*) const

Returns true if the given row is currently visible (even if only partially visible) or false otherwise.

virtual wxCoord wxVarVScrollHelper::OnGetRowHeight (size_t *row*) const `[protected], [pure virtual]`

This function must be overridden in the derived class, and should return the height of the given row in pixels.

virtual void wxVarVScrollHelper::OnGetRowsHeightHint (size_t *rowMin,* size_t *rowMax*) const `[protected], [virtual]`

This function doesn't have to be overridden but it may be useful to do so if calculating the rows' sizes is a relatively expensive operation as it gives your code a chance to calculate several of them at once and cache the result if necessary.

OnGetRowsHeightHint() is normally called just before OnGetRowHeight() but you shouldn't rely on the latter being called for all rows in the interval specified here. It is also possible that OnGetRowHeight() will be called for units outside of this interval, so this is really just a hint, not a promise.

Finally, note that *rowMin* is inclusive, while *rowMax* is exclusive.

virtual void wxVarVScrollHelper::RefreshRow (size_t *row*) `[virtual]`

Triggers a refresh for just the given row's area of the window if it's visible.

virtual void wxVarVScrollHelper::RefreshRows (size_t *from,* size_t *to*) `[virtual]`

Triggers a refresh for the area between the specified range of rows given (inclusively).

virtual bool wxVarVScrollHelper::ScrollRowPages (int *pages*) `[virtual]`

Scroll by the specified number of pages which may be positive (to scroll down) or negative (to scroll up).

virtual bool wxVarVScrollHelper::ScrollRows (int *rows*) `[virtual]`

Scroll by the specified number of rows which may be positive (to scroll down) or negative (to scroll up).

Returns

true if the window was scrolled, false otherwise (for example, if we're trying to scroll down but we are already showing the last row).

bool wxVarVScrollHelper::ScrollToRow (size_t *row*)

Scroll to the specified row.

It will become the first visible row in the window.

Returns

true if we scrolled the window, false if nothing was done.

void wxVarVScrollHelper::SetRowCount (size_t *rowCount*)

Set the number of rows the window contains.

The derived class must provide the heights for all rows with indices up to the one given here in it's OnGetRowHeight() implementation.

GetRowCount()

21.833 wxVector< T > Class Template Reference

`#include <wx/vector.h>`

21.833.1 Detailed Description

template<typename T>class wxVector< T >

wxVector<T> is a template class which implements most of the `std::vector` class and can be used like it.

If wxWidgets is compiled in STL mode, wxVector will just be a typedef to `std::vector`. Just like for `std::vector`, objects stored in wxVector<T> need to be *assignable* but don't have to be *"default constructible"*.

Please refer to the STL documentation for further information.

Library: None; this class implementation is entirely header-based.

Category: Containers

See also

Container Classes, wxList<T>, wxArray<T>, wxVectorSort<T>

Public Types

- typedef size_t size_type
- typedef size_t difference_type
- typedef T value_type
- typedef value_type * pointer
- typedef value_type * iterator
- typedef const value_type * const_iterator
- typedef value_type & reference

Public Member Functions

- wxVector ()

  Constructor.
- wxVector (size_type size)

  Constructor initializing the vector with the given number of default-constructed objects.
- wxVector (size_type size, const value_type &value)

  Constructor initializing the vector with the given number of copies of the given object.
- template<class InputIterator >
  wxVector (InputIterator first, InputIterator last)

  Constructor initializing the vector with the elements in the given range.
- wxVector (const wxVector< T > &c)

  Copy constructor.
- ~wxVector ()

  Destructor.
- void assign (size_type n, const value_type &v)

  Resizes the vector to n and assigns v to all elements.
- template<class InputIterator >
  void assign (InputIterator first, InputIterator last)

  Assigns the elements in the given range to the vector.
- const value_type & at (size_type idx) const

  Returns item at position idx.
- value_type & at (size_type idx)

  Returns item at position idx.
- const value_type & back () const

  Return the last item.
- value_type & back ()

  Return the last item.
- const_iterator begin () const

  Return iterator to beginning of the vector.
- iterator begin ()

  Return iterator to beginning of the vector.
- reverse_iterator rbegin ()

  Return reverse iterator to end of the vector.
- reverse_iterator rend ()

  Return reverse iterator to beginning of the vector.
- size_type capacity () const

  Returns vector's current capacity, i.e. how much memory is allocated.
- void clear ()

  Clears the vector.
- bool empty () const

Returns true if the vector is empty.

- const_iterator end () const

  Returns iterator to the end of the vector.

- iterator end ()

  Returns iterator to the end of the vector.

- iterator erase (iterator it)

  Erase item pointed to by iterator it.

- iterator erase (iterator first, iterator last)

  Erase items in the range first to last (last is not erased).

- const value_type & front () const

  Returns the first item.

- value_type & front ()

  Returns the first item.

- iterator insert (iterator it, const value_type &v=value_type())

  Insert item v at given position it.

- wxVector & operator= (const wxVector &vb)

  Assignment operator.

- const value_type & operator[] (size_type idx) const

  Returns item at position idx.

- value_type & operator[] (size_type idx)

  Returns item at position idx.

- void pop_back ()

  Removes the last item.

- void push_back (const value_type &v)

  Adds an item to the end of the vector.

- void reserve (size_type n)

  Reserves memory for at least n items.

- size_type size () const

  Returns the size of the vector.

- void swap (wxVector &v)

  Efficiently exchanges contents of this vector with another one.

- void resize (size_type n)

  Makes the vector of size n.

- void resize (size_type n, const value_type &v)

  Makes the vector of size n.

21.833.2 Member Typedef Documentation

template<typename T > typedef const value_type* wxVector< T >::const_iterator

template<typename T > typedef size_t wxVector< T >::difference_type

template<typename T > typedef value_type* wxVector< T >::iterator

template<typename T > typedef value_type* wxVector< T >::pointer

template<typename T > typedef value_type& wxVector< T >::reference

template<typename T > typedef size_t wxVector< T >::size_type

template<typename T > typedef T wxVector< T >::value_type

21.833.3 Constructor & Destructor Documentation

template<typename T > wxVector< T >::wxVector ( )

Constructor.

template<typename T > wxVector< T >::wxVector (size_type *size*)

Constructor initializing the vector with the given number of default-constructed objects.

template<typename T > wxVector< T >::wxVector (size_type *size*, const value_type & *value*)

Constructor initializing the vector with the given number of copies of the given object.

template<typename T > template<class InputIterator > wxVector< T >::wxVector (InputIterator *first*, InputIterator *last*)

Constructor initializing the vector with the elements in the given range.

The *InputIterator* template parameter must be an input iterator type. This constructor adds all elements from *first* until, not not including, *last* to the vector.

Since

2.9.5

template<typename T > wxVector< T >::wxVector (const wxVector< T > & *c*)

Copy constructor.

template<typename T > wxVector< T >::~wxVector ( )

Destructor.

21.833.4 Member Function Documentation

template<typename T > void wxVector< T >::assign (size_type *n*, const value_type & *v*)

Resizes the vector to *n* and assigns *v* to all elements.

See also

resize()

Since

2.9.5

template<typename T > template<class InputIterator > void wxVector< T >::assign (InputIterator *first,* InputIterator *last*)

Assigns the elements in the given range to the vector.

The *InputIterator* template parameter must be an input iterator type. This method clears the vector and then adds all elements from *first* until, not not including, *last* to it.

Since

2.9.5

template<typename T > const value_type& wxVector< T >::at (size_type *idx*) const

Returns item at position *idx*.

template<typename T > value_type& wxVector< T >::at (size_type *idx*)

Returns item at position *idx*.

template<typename T > const value_type& wxVector< T >::back ( ) const

Return the last item.

template<typename T > value_type& wxVector< T >::back ( )

Return the last item.

template<typename T > const_iterator wxVector< T >::begin ( ) const

Return iterator to beginning of the vector.

template<typename T > iterator wxVector< T >::begin ( )

Return iterator to beginning of the vector.

template<typename T > size_type wxVector< T >::capacity ( ) const

Returns vector's current capacity, i.e. how much memory is allocated.

See also

reserve()

template<typename T > void wxVector< T >::clear ( )

Clears the vector.

template<typename T > bool wxVector< T >::empty ( ) const

Returns true if the vector is empty.

template<typename T > const_iterator wxVector< T >::end ( ) const

Returns iterator to the end of the vector.

template<typename T > iterator wxVector< T >::end ( )

Returns iterator to the end of the vector.

template<typename T > iterator wxVector< T >::erase (iterator *it*)

Erase item pointed to by iterator *it*.

Returns

Iterator pointing to the item immediately after the erased one.

template<typename T > iterator wxVector< T >::erase (iterator *first,* iterator *last*)

Erase items in the range *first* to *last* (*last* is not erased).

Returns

Iterator pointing to the item immediately after the erased range.

template<typename T > const value_type& wxVector< T >::front ( ) const

Returns the first item.

template<typename T > value_type& wxVector< T >::front ( )

Returns the first item.

template<typename T > iterator wxVector< T >::insert (iterator *it,* const value_type & *v* = value_type ( ))

Insert item *v* at given position *it*.

Returns

Iterator for the inserted item.

template<typename T > wxVector& wxVector< T >::operator= (const wxVector< T > & *vb*)

Assignment operator.

template<typename T > const value_type& wxVector< T >::operator[] (size_type *idx*) const

Returns item at position *idx*.

template<typename T > value_type& wxVector< T >::operator[] (size_type *idx*)

Returns item at position *idx*.

template<typename T > void wxVector< T >::pop_back ( )

Removes the last item.

template<typename T > void wxVector< T >::push_back (const value_type & *v*)

Adds an item to the end of the vector.

template<typename T > reverse_iterator wxVector< T >::rbegin ( )

Return reverse iterator to end of the vector.

template<typename T > reverse_iterator wxVector< T >::rend ( )

Return reverse iterator to beginning of the vector.

template<typename T > void wxVector< T >::reserve (size_type *n*)

Reserves memory for at least *n* items.

See also

capacity()

template<typename T > void wxVector< T >::resize (size_type *n*)

Makes the vector of size *n*.

If *n* is less than the current size(), the elements at the end of the vector are erased. If it is greater, then the vector is completed with either the copies of the given object *v* or `value_type()` objects until it becomes of size *n*.

template<typename T > void wxVector< T >::resize (size_type *n*, const value_type & *v*)

Makes the vector of size *n*.

If *n* is less than the current size(), the elements at the end of the vector are erased. If it is greater, then the vector is completed with either the copies of the given object *v* or `value_type()` objects until it becomes of size *n*.

template<typename T > size_type wxVector< T >::size ( ) const

Returns the size of the vector.

template<typename T > void wxVector< T >::swap (wxVector< T > & *v*)

Efficiently exchanges contents of this vector with another one.

After the execution of this function the contents of this vector is equal to the original contents of *v* and the contents of *v* becomes the original contents of this vector without copying the data.

Since

2.9.1

21.834 wxVersionInfo Class Reference

```
#include <wx/versioninfo.h>
```

21.834.1 Detailed Description

wxVersionInfo contains version information.

This class is used by wxWidgets to provide version information about the libraries it uses and itself, but you can also apply it in user space, to provide version information about your own libraries, or other libraries that you use.

Library: wxBase

Category: Data Structures

Since

2.9.2

Public Member Functions

- wxVersionInfo (const wxString &name=wxString(), int major=0, int minor=0, int micro=0, const wxString &description=wxString(), const wxString &copyright=wxString())
  Constructor.
- const wxString & GetName () const
  Get the name of the object (library).
- int GetMajor () const
  Get the major version number.
- int GetMinor () const
  Get the minor version number.
- int GetMicro () const
  Get the micro version, or release number.
- wxString ToString () const
  Get the string representation of this version object.
- wxString GetVersionString () const
  Get the string representation.
- bool HasDescription () const
  Return true if a description string has been specified.
- const wxString & GetDescription ()
  Get the description string.
- bool HasCopyright () const
  Returns true if a copyright string has been specified.
- const wxString & GetCopyright () const
  Get the copyright string.

21.834.2 Constructor & Destructor Documentation

wxVersionInfo::wxVersionInfo (const wxString & *name* = wxString (), int *major* = 0, int *minor* = 0, int *micro* = 0, const wxString & *description* = wxString (), const wxString & *copyright* = wxString ())

Constructor.

The version information objects need to be initialized with this constructor and are immutable once they are created.

Parameters

name	The name of the library or other entity that this object pertains to.
major	The major version component.
minor	The minor version component.
micro	The micro version component, 0 by default.
description	Free form description of this version, none by default.
copyright	Copyright string, none by default.

21.834.3 Member Function Documentation

const wxString& wxVersionInfo::GetCopyright ( ) const

Get the copyright string.

The copyright string may be empty.

Returns

The copyright string.

const wxString& wxVersionInfo::GetDescription ( )

Get the description string.

The description may be empty.

Returns

The description string, free-form.

int wxVersionInfo::GetMajor ( ) const

Get the major version number.

Returns

Major version number.

int wxVersionInfo::GetMicro ( ) const

Get the micro version, or release number.

Returns

Micro version, or release number.

int wxVersionInfo::GetMinor ( ) const

Get the minor version number.

Returns

Minor version number.

const wxString& wxVersionInfo::GetName ( ) const

Get the name of the object (library).

Returns

Name string.

wxString wxVersionInfo::GetVersionString ( ) const

Get the string representation.

The micro component of the version is ignored/not used if it is 0.

Returns

The version string in the form "name major.minor[.micro]".

bool wxVersionInfo::HasCopyright ( ) const

Returns true if a copyright string has been specified.

See also

GetCopyright()

bool wxVersionInfo::HasDescription ( ) const

Return true if a description string has been specified.

See also

GetDescription()

wxString wxVersionInfo::ToString ( ) const

Get the string representation of this version object.

This function returns the description if it is non-empty or GetVersionString() if there is no description.

See also

GetDescription(), GetVersionString()

21.835 wxVideoMode Struct Reference

`#include <wx/vidmode.h>`

21.835.1 Detailed Description

Determines the sizes and locations of displays connected to the system.

Library: wxCore

Category: Application and System configuration

Predefined objects/pointers: wxDefaultVideoMode

See also

wxClientDisplayRect(), wxDisplaySize(), wxDisplaySizeMM()

Public Member Functions

- wxVideoMode (int width=0, int height=0, int depth=0, int freq=0)

  Constructs this class using the given parameters.
- bool Matches (const wxVideoMode &other) const

  Returns true if this mode matches the other one in the sense that all non zero fields of the other mode have the same value in this one (except for refresh which is allowed to have a greater value).
- int GetWidth () const

  Returns the screen width in pixels (e.g. 640), 0 means unspecified.
- int GetHeight () const

  Returns the screen height in pixels (e.g. 480), 0 means unspecified.
- int GetDepth () const

  Returns bits per pixel (e.g. 32), 1 is monochrome and 0 means unspecified/known.
- bool IsOk () const

  Returns true if the object has been initialized.
- bool operator== (const wxVideoMode &m) const
- bool operator!= (const wxVideoMode &mode) const

Public Attributes

- int w

  The screen width in pixels (e.g. 640), 0 means unspecified.
- int h

  The screen height in pixels (e.g. 480), 0 means unspecified.
- int bpp

  Bits per pixel (e.g. 32), 1 is monochrome and 0 means unspecified/known.
- int refresh

  Refresh frequency in Hz, 0 means unspecified/unknown.

21.835.2 Constructor & Destructor Documentation

wxVideoMode::wxVideoMode (int *width* = 0, int *height* = 0, int *depth* = 0, int *freq* = 0)

Constructs this class using the given parameters.

21.835.3 Member Function Documentation

int wxVideoMode::GetDepth ( ) const

Returns bits per pixel (e.g. 32), 1 is monochrome and 0 means unspecified/known.

int wxVideoMode::GetHeight ( ) const

Returns the screen height in pixels (e.g. 480), 0 means unspecified.

int wxVideoMode::GetWidth ( ) const

Returns the screen width in pixels (e.g. 640), 0 means unspecified.

bool wxVideoMode::IsOk ( ) const

Returns true if the object has been initialized.

bool wxVideoMode::Matches (const wxVideoMode & *other*) const

Returns true if this mode matches the other one in the sense that all non zero fields of the other mode have the same value in this one (except for refresh which is allowed to have a greater value).

bool wxVideoMode::operator!= (const wxVideoMode & *mode*) const

bool wxVideoMode::operator== (const wxVideoMode & *m*) const

21.835.4 Member Data Documentation

int wxVideoMode::bpp

Bits per pixel (e.g. 32), 1 is monochrome and 0 means unspecified/known.

int wxVideoMode::h

The screen height in pixels (e.g. 480), 0 means unspecified.

int wxVideoMode::refresh

Refresh frequency in Hz, 0 means unspecified/unknown.

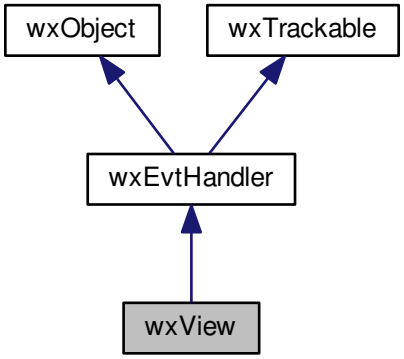
int wxVideoMode::w

The screen width in pixels (e.g. 640), 0 means unspecified.

21.836 wxView Class Reference

`#include <wx/docview.h>`

Inheritance diagram for wxView:



21.836.1 Detailed Description

The view class can be used to model the viewing and editing component of an application's file-based data.

It is part of the document/view framework supported by wxWidgets, and cooperates with the wxDocument, wxDocTemplate and wxDocManager classes.

Library: wxCore

Category: Document/View Framework

See also

wxView Overview, wxDocument, wxDocTemplate, wxDocManager

Public Member Functions

- wxView ()

  Constructor.
- virtual ~wxView ()

  Destructor.
- virtual void Activate (bool activate)

  Call this from your view frame's wxDocChildFrame::OnActivate() member to tell the framework which view is currently active.
- virtual bool Close (bool deleteWindow=true)

  Closes the view by calling OnClose().
- wxDocument * GetDocument () const

  Gets a pointer to the document associated with the view.
- wxDocManager * GetDocumentManager () const

  Returns a pointer to the document manager instance associated with this view.
- wxWindow * GetFrame () const

  Gets the frame associated with the view (if any).

- wxString GetViewName () const

  Gets the name associated with the view (passed to the wxDocTemplate constructor).
- virtual void OnActivateView (bool activate, wxView *activeView, wxView *deactiveView)

  Called when a view is activated by means of Activate().
- virtual void OnChangeFilename ()

  Called when the filename has changed.
- virtual bool OnClose (bool deleteWindow)

  Implements closing behaviour.
- virtual void OnClosingDocument ()

  Override this to clean up the view when the document is being closed.
- virtual bool OnCreate (wxDocument *doc, long flags)

  wxDocManager or wxDocument creates a wxView via a wxDocTemplate.
- virtual wxPrintout * OnCreatePrintout ()

  If the printing framework is enabled in the library, this function returns a wxPrintout object for the purposes of printing.
- virtual void OnDraw (wxDC *dc)=0

  Override this function to render the view on the given device context.
- virtual void OnUpdate (wxView *sender, wxObject *hint=0)

  Called when the view should be updated.
- virtual void SetDocument (wxDocument *doc)

  Associates the given document with the view.
- void SetFrame (wxWindow *frame)

  Sets the frame associated with this view.
- void SetViewName (const wxString &name)

  Sets the view type name.

Public Attributes

- wxDocument * m_viewDocument

  The document associated with this view.
- wxFrame * m_viewFrame

  Frame associated with the view, if any.
- wxString m_viewTypeName

  The view type name given to the wxDocTemplate constructor, copied to this variable when the view is created.

Additional Inherited Members

21.836.2 Constructor & Destructor Documentation

wxView::wxView ( )

Constructor.

Define your own default constructor to initialize application-specific data.

virtual wxView::~wxView ( ) [virtual]

Destructor.

Removes itself from the document's list of views.

21.836.3 Member Function Documentation

virtual void wxView::Activate (bool *activate*) `[virtual]`

Call this from your view frame's wxDocChildFrame::OnActivate() member to tell the framework which view is currently active.

If your windowing system doesn't call wxDocChildFrame::OnActivate(), you may need to call this function from any place where you know the view must be active, and the framework will need to get the current view.

The prepackaged view frame wxDocChildFrame calls Activate() from its wxDocChildFrame::OnActivate() member.

This function calls OnActivateView().

virtual bool wxView::Close (bool *deleteWindow* = `true`) `[virtual]`

Closes the view by calling OnClose().

If *deleteWindow* is true, this function should delete the window associated with the view.

wxDocument* wxView::GetDocument ( ) const

Gets a pointer to the document associated with the view.

wxDocManager* wxView::GetDocumentManager ( ) const

Returns a pointer to the document manager instance associated with this view.

wxWindow* wxView::GetFrame ( ) const

Gets the frame associated with the view (if any).

Note that this "frame" is not a wxFrame at all in the generic MDI implementation which uses notebook pages instead of frames and this is why this method returns a wxWindow and not a wxFrame.

wxString wxView::GetViewName ( ) const

Gets the name associated with the view (passed to the wxDocTemplate constructor).

Not currently used by the framework.

virtual void wxView::OnActivateView (bool *activate*, wxView * *activeView*, wxView * *deactiveView*) `[virtual]`

Called when a view is activated by means of Activate().

The default implementation does nothing.

virtual void wxView::OnChangeFilename ( ) `[virtual]`

Called when the filename has changed.

The default implementation constructs a suitable title and sets the title of the view frame (if any).

virtual bool wxView::OnClose (bool *deleteWindow*) `[virtual]`

Implements closing behaviour.

The default implementation calls wxDocument::Close() to close the associated document. Does not delete the view. The application may wish to do some cleaning up operations in this function, *if* a call to wxDocument::Close() succeeded. For example, if your views all share the same window, you need to disassociate the window from the view and perhaps clear the window. If *deleteWindow* is true, delete the frame associated with the view.

virtual void wxView::OnClosingDocument ( ) [virtual]

Override this to clean up the view when the document is being closed.

virtual bool wxView::OnCreate (wxDocument * *doc,* long *flags*) [virtual]

wxDocManager or wxDocument creates a wxView via a wxDocTemplate.

Just after the wxDocTemplate creates the wxView, it calls OnCreate(). The wxView can create a wxDocChildFrame (or derived class) in its wxView::OnCreate() member function. This wxDocChildFrame provides user interface elements to view and/or edit the contents of the wxDocument.

By default, simply returns true. If the function returns false, the view will be deleted.

virtual wxPrintout* wxView::OnCreatePrintout ( ) [virtual]

If the printing framework is enabled in the library, this function returns a wxPrintout object for the purposes of printing.

It should create a new object every time it is called; the framework will delete objects it creates.

By default, this function returns an instance of wxDocPrintout, which prints and previews one page by calling OnDraw().

Override to return an instance of a class other than wxDocPrintout.

virtual void wxView::OnDraw (wxDC * *dc*) [pure virtual]

Override this function to render the view on the given device context.

virtual void wxView::OnUpdate (wxView * *sender,* wxObject * *hint* = 0) [virtual]

Called when the view should be updated.

Parameters

sender	A pointer to the wxView that sent the update request, or NULL if no single view requested the update (for instance, when the document is opened).
hint	This is unused currently, but may in future contain application-specific information for making updating more efficient.

virtual void wxView::SetDocument (wxDocument * *doc*) [virtual]

Associates the given document with the view.

Normally called by the framework.

void wxView::SetFrame (wxWindow * *frame*)

Sets the frame associated with this view.

The application should call this if possible, to tell the view about the frame.

See GetFrame() for the explanation about the mismatch between the "Frame" in the method name and the type of its parameter.

void wxView::SetViewName (const wxString & *name*)

Sets the view type name.

Should only be called by the framework.

21.836.4 Member Data Documentation

wxDocument* wxView::m_viewDocument

The document associated with this view.

There may be more than one view per document, but there can never be more than one document for one view.

wxFrame* wxView::m_viewFrame

Frame associated with the view, if any.

wxString wxView::m_viewTypeName

The view type name given to the wxDocTemplate constructor, copied to this variable when the view is created.

Not currently used by the framework.

21.837 wxVisualAttributes Struct Reference

`#include <wx/window.h>`

21.837.1 Detailed Description

Struct containing all the visual attributes of a control.

Public Attributes

- wxFont font

  The font used for control label/text inside it.
- wxColour colFg

  The foreground colour.
- wxColour colBg

  The background colour.

21.837.2 Member Data Documentation

wxColour wxVisualAttributes::colBg

The background colour.

May be wxNullColour if the controls background colour is not solid.

wxColour wxVisualAttributes::colFg

The foreground colour.

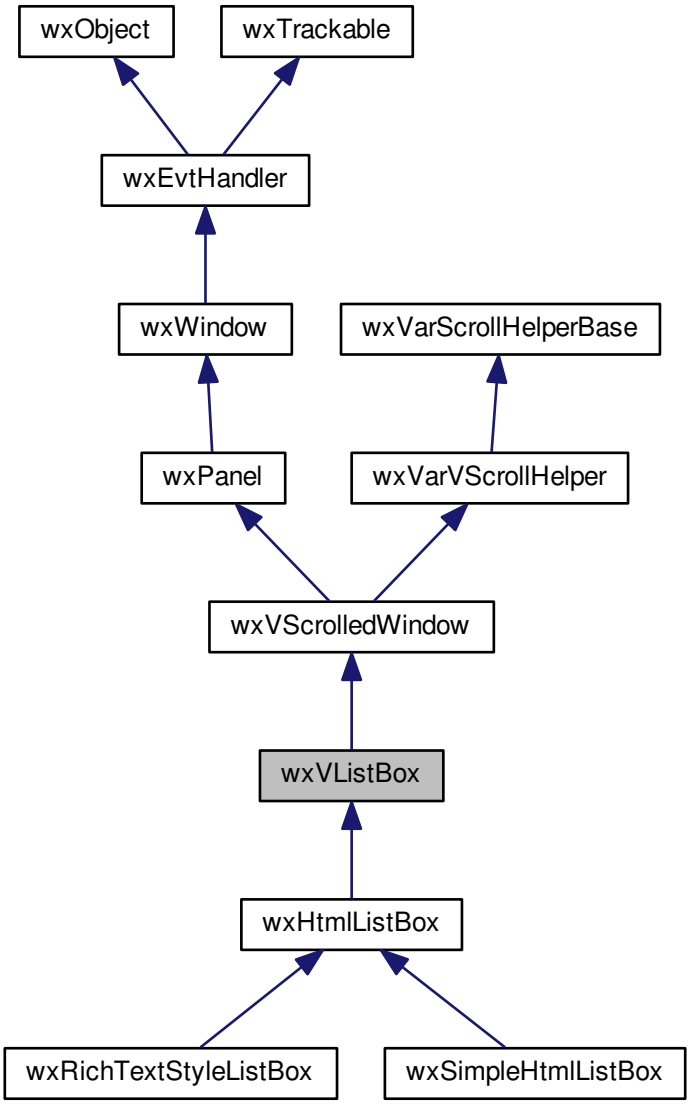
wxFont wxVisualAttributes::font

The font used for control label/text inside it.

21.838 wxVListBox Class Reference

`#include <wx/vlbox.h>`

Inheritance diagram for wxVListBox:



21.838.1 Detailed Description

wxVListBox is a wxListBox-like control with the following two main differences from a regular wxListBox: it can have an arbitrarily huge number of items because it doesn't store them itself but uses the OnDrawItem() callback to draw them (so it is a virtual listbox) and its items can have variable height as determined by OnMeasureItem() (so it is also a listbox with the lines of variable height).

Also, as a consequence of its virtual nature, it doesn't have any methods to append or insert items in it as it isn't necessary to do it: you just have to call SetItemCount() to tell the control how many items it should display. Of course, this also means that you will never use this class directly because it has pure virtual functions, but will need to derive your own class from it (for example, wxHtmlListBox).

However it emits the same events as wxListBox and the same event macros may be used with it. Since wxVListBox does not store its items itself, the events will only contain the index, not any contents such as the string of an item.

Library: wxCore

Category: Controls

See also

wxSimpleHtmlListBox, wxHtmlListBox

Public Member Functions

- wxVListBox ()

  Default constructor, you must call Create() later.
- wxVListBox (wxWindow *parent, wxWindowID id=wxID_ANY, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, long style=0, const wxString &name=wxVListBoxNameStr)

  Normal constructor which calls Create() internally.
- virtual ~wxVListBox ()

  Destructor.
- void Clear ()

  Deletes all items from the control.
- bool Create (wxWindow *parent, wxWindowID id=wxID_ANY, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, long style=0, const wxString &name=wxVListBoxNameStr)

  Creates the control.
- bool DeselectAll ()

  Deselects all the items in the listbox.
- int GetFirstSelected (unsigned long &cookie) const

  Returns the index of the first selected item in the listbox or `wxNOT_FOUND` if no items are currently selected.
- size_t GetItemCount () const

  Get the number of items in the control.
- wxPoint GetMargins () const

  Returns the margins used by the control.
- wxRect GetItemRect (size_t item) const

  Returns the rectangle occupied by this item in physical coordinates.
- int GetNextSelected (unsigned long &cookie) const

  Returns the index of the next selected item or `wxNOT_FOUND` if there are no more.
- size_t GetSelectedCount () const

  Returns the number of the items currently selected.
- int GetSelection () const

  Get the currently selected item or `wxNOT_FOUND` if there is no selection.

- const wxColour & GetSelectionBackground () const

  Returns the background colour used for the selected cells.
- bool HasMultipleSelection () const

  Returns true if the listbox was created with `wxLB_MULTIPLE` style and so supports multiple selection or false if it is a single selection listbox.
- bool IsCurrent (size_t item) const

  Returns true if this item is the current one, false otherwise.
- bool IsSelected (size_t item) const

  Returns true if this item is selected, false otherwise.
- bool Select (size_t item, bool select=true)

  Selects or deselects the specified item which must be valid (i.e. not equal to `wxNOT_FOUND`).
- bool SelectAll ()

  Selects all the items in the listbox.
- bool SelectRange (size_t from, size_t to)

  Selects all items in the specified range which may be given in any order.
- virtual void SetItemCount (size_t count)

  Set the number of items to be shown in the control.
- void SetSelection (int selection)

  Set the selection to the specified item, if it is -1 the selection is unset.
- void SetSelectionBackground (const wxColour &col)

  Sets the colour to be used for the selected cells background.
- void Toggle (size_t item)

  Toggles the state of the specified item, i.e. selects it if it was unselected and deselects it if it was selected.

- void SetMargins (const wxPoint &pt)

  Set the margins: horizontal margin is the distance between the window border and the item contents while vertical margin is half of the distance between items.
- void SetMargins (wxCoord x, wxCoord y)

  Set the margins: horizontal margin is the distance between the window border and the item contents while vertical margin is half of the distance between items.

Protected Member Functions

- virtual void OnDrawItem (wxDC &dc, const wxRect &rect, size_t n) const =0

  The derived class must implement this function to actually draw the item with the given index on the provided DC.
- virtual void OnDrawBackground (wxDC &dc, const wxRect &rect, size_t n) const

  This method is used to draw the item's background and, maybe, a border around it.
- virtual void OnDrawSeparator (wxDC &dc, wxRect &rect, size_t n) const

  This method may be used to draw separators between the lines.
- virtual wxCoord OnMeasureItem (size_t n) const =0

  The derived class must implement this method to return the height of the specified item (in pixels).

Additional Inherited Members

21.838.2 Constructor & Destructor Documentation

wxVListBox::wxVListBox ( )

Default constructor, you must call Create() later.

wxVListBox::wxVListBox (wxWindow * *parent*, wxWindowID *id* = wxID_ANY, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, long *style* = 0, const wxString & *name* = wxVListBoxNameStr)

Normal constructor which calls Create() internally.

virtual wxVListBox::~wxVListBox ( ) [virtual]

Destructor.

21.838.3 Member Function Documentation

void wxVListBox::Clear ( )

Deletes all items from the control.

bool wxVListBox::Create (wxWindow * *parent*, wxWindowID *id* = wxID_ANY, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, long *style* = 0, const wxString & *name* = wxVListBoxNameStr)

Creates the control.

To finish creating it you also should call SetItemCount() to let it know about the number of items it contains.

The only special style which may be used with wxVListBox is wxLB_MULTIPLE which indicates that the listbox should support multiple selection.

Returns

true on success or false if the control couldn't be created.

bool wxVListBox::DeselectAll ( )

Deselects all the items in the listbox.

This method is only valid for multi selection listboxes.

Returns

true if any items were changed, i.e. if there had been any selected items before, or false if all the items were already deselected.

See also

SelectAll(), Select()

int wxVListBox::GetFirstSelected (unsigned long & *cookie*) const

Returns the index of the first selected item in the listbox or wxNOT_FOUND if no items are currently selected.

cookie is an opaque parameter which should be passed to the subsequent calls to GetNextSelected(). It is needed in order to allow parallel iterations over the selected items.

Here is a typical example of using these functions:

```
unsigned long cookie;
int item = hlbox->GetFirstSelected(cookie);
while ( item != wxNOT_FOUND )
{
    // ... process item ...
    item = hlbox->GetNextSelected(cookie);
}
```

This method is only valid for multi selection listboxes.

size_t wxVListBox::GetItemCount ( ) const

Get the number of items in the control.

See also

SetItemCount()

wxRect wxVListBox::GetItemRect (size_t *item*) const

Returns the rectangle occupied by this item in physical coordinates.

If the item is not currently visible, returns an empty rectangle.

Since

2.9.0

wxPoint wxVListBox::GetMargins ( ) const

Returns the margins used by the control.

The `x` field of the returned point is the horizontal margin and the `y` field is the vertical one.

See also

SetMargins()

int wxVListBox::GetNextSelected (unsigned long & *cookie*) const

Returns the index of the next selected item or `wxNOT_FOUND` if there are no more.

This method is only valid for multi selection listboxes.

See also

GetFirstSelected()

size_t wxVListBox::GetSelectedCount ( ) const

Returns the number of the items currently selected.

It is valid for both single and multi selection controls. In the former case it may only return 0 or 1 however.

See also

IsSelected(), GetFirstSelected(), GetNextSelected()

int wxVListBox::GetSelection ( ) const

Get the currently selected item or `wxNOT_FOUND` if there is no selection.

const wxColour& wxVListBox::GetSelectionBackground ( ) const

Returns the background colour used for the selected cells.

By default the standard system colour is used.

See also

wxSystemSettings::GetColour(), SetSelectionBackground()

bool wxVListBox::HasMultipleSelection ( ) const

Returns true if the listbox was created with `wxLB_MULTIPLE` style and so supports multiple selection or false if it is a single selection listbox.

bool wxVListBox::IsCurrent (size_t *item*) const

Returns true if this item is the current one, false otherwise.

The current item is always the same as selected one for the single selection listbox and in this case this method is equivalent to IsSelected() but they are different for multi selection listboxes where many items may be selected but only one (at most) is current.

bool wxVListBox::IsSelected (size_t *item*) const

Returns true if this item is selected, false otherwise.

virtual void wxVListBox::OnDrawBackground (wxDC & *dc*, const wxRect & *rect*, size_t *n*) const `[protected], [virtual]`

This method is used to draw the item's background and, maybe, a border around it.

The base class version implements a reasonable default behaviour which consists in drawing the selected item with the standard background colour and drawing a border around the item if it is either selected or current.

Todo Change this function signature to non-const.

virtual void wxVListBox::OnDrawItem (wxDC & *dc*, const wxRect & *rect*, size_t *n*) const `[protected], [pure virtual]`

The derived class must implement this function to actually draw the item with the given index on the provided DC.

Parameters

dc	The device context to use for drawing.
rect	The bounding rectangle for the item being drawn (DC clipping region is set to this rectangle before calling this function).

n	The index of the item to be drawn.

Todo Change this function signature to non-const.

virtual void wxVListBox::OnDrawSeparator (wxDC & *dc*, wxRect & *rect*, size_t *n*) const `[protected], [virtual]`

This method may be used to draw separators between the lines.

The rectangle passed to it may be modified, typically to deflate it a bit before passing to OnDrawItem().

The base class version of this method doesn't do anything.

Parameters

dc	The device context to use for drawing.
rect	The bounding rectangle for the item.
n	The index of the item.

Todo Change this function signature to non-const.

virtual wxCoord wxVListBox::OnMeasureItem (size_t *n*) const `[protected], [pure virtual]`

The derived class must implement this method to return the height of the specified item (in pixels).

bool wxVListBox::Select (size_t *item*, bool *select* = `true`)

Selects or deselects the specified item which must be valid (i.e. not equal to `wxNOT_FOUND`).

Returns

true if the items selection status has changed or false otherwise.

This function is only valid for the multiple selection listboxes, use SetSelection() for the single selection ones.

bool wxVListBox::SelectAll ( )

Selects all the items in the listbox.

Returns

true if any items were changed, i.e. if there had been any unselected items before, or false if all the items were already selected.

This method is only valid for multi selection listboxes.

See also

DeselectAll(), Select()

bool wxVListBox::SelectRange (size_t *from*, size_t *to*)

Selects all items in the specified range which may be given in any order.

Returns

true if the items selection status has changed or false otherwise.

This method is only valid for multi selection listboxes.

See also

SelectAll(), Select()

virtual void wxVListBox::SetItemCount (size_t *count*) [virtual]

Set the number of items to be shown in the control.

This is just a synonym for wxVScrolledWindow::SetRowCount().

void wxVListBox::SetMargins (const wxPoint & *pt*)

Set the margins: horizontal margin is the distance between the window border and the item contents while vertical margin is half of the distance between items.

By default both margins are 0.

void wxVListBox::SetMargins (wxCoord *x*, wxCoord *y*)

Set the margins: horizontal margin is the distance between the window border and the item contents while vertical margin is half of the distance between items.

By default both margins are 0.

void wxVListBox::SetSelection (int *selection*)

Set the selection to the specified item, if it is -1 the selection is unset.

The selected item will be automatically scrolled into view if it isn't currently visible.

This method may be used both with single and multiple selection listboxes.

void wxVListBox::SetSelectionBackground (const wxColour & *col*)

Sets the colour to be used for the selected cells background.

The background of the standard cells may be changed by simply calling wxWindow::SetBackgroundColour().

Note

Using a non-default background colour may result in control having an appearance different from the similar native controls and should be avoided in general.

See also

GetSelectionBackground()

void wxVListBox::Toggle (size_t *item*)

Toggles the state of the specified *item*, i.e. selects it if it was unselected and deselects it if it was selected.

This method is only valid for multi selection listboxes.

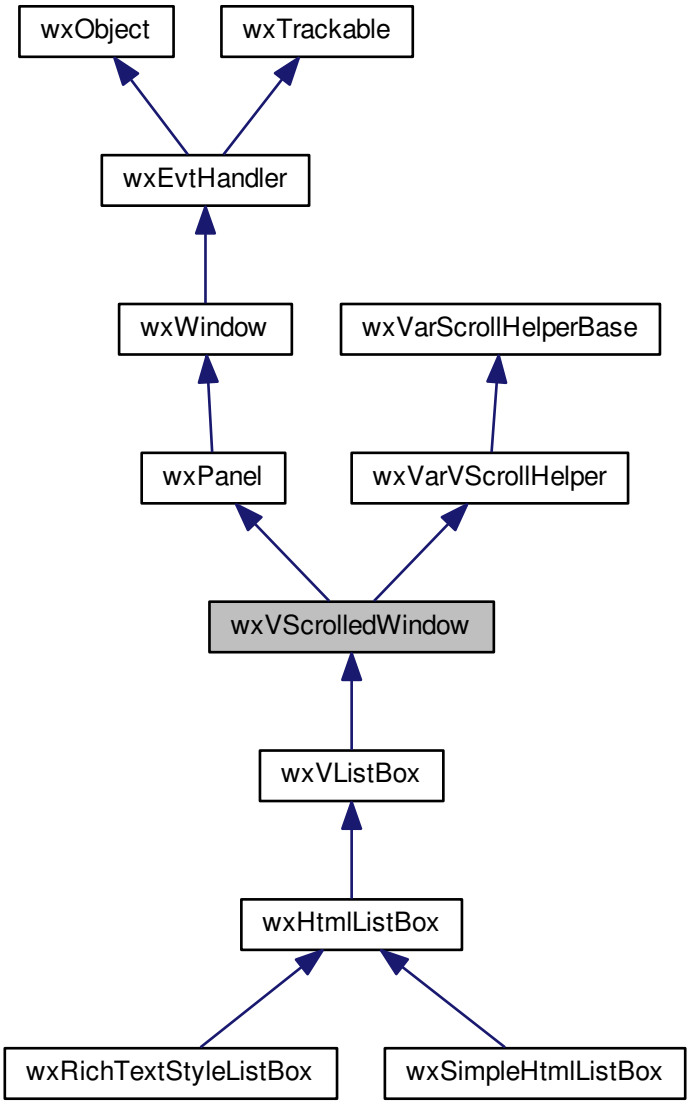
Select()

21.839 wxVScrolledWindow Class Reference

`#include <wx/vscroll.h>`

Inheritance diagram for wxVScrolledWindow:



21.839.1 Detailed Description

In the name of this class, "V" may stand for "variable" because it can be used for scrolling rows of variable heights; "virtual", because it is not necessary to know the heights of all rows in advance – only those which are shown on the screen need to be measured; or even "vertical", because this class only supports scrolling vertically.

In any case, this is a generalization of wxScrolled which can be only used when all rows have the same heights. It lacks some other wxScrolled features however, notably it can't scroll specific pixel sizes of the window or its exact client area size.

To use this class, you need to derive from it and implement the OnGetRowHeight() pure virtual method. You also must call SetRowCount() to let the base class know how many rows it should display, but from that moment on the scrolling is handled entirely by wxVScrolledWindow. You only need to draw the visible part of contents in your `OnPaint()` method as usual. You should use GetVisibleRowsBegin() and GetVisibleRowsEnd() to select the lines to display. Note that the device context origin is not shifted so the first visible row always appears at the point (0, 0) in physical as well as logical coordinates.

21.839.2 wxWidgets 2.8 Compatibility Functions

The following functions provide backwards compatibility for applications originally built using wxVScrolledWindow in 2.6 or 2.8. Originally, wxVScrolledWindow referred to scrolling "lines". We now use "units" in wxVarScrollHelperBase to avoid implying any orientation (since the functions are used for both horizontal and vertical scrolling in derived classes). And in the new wxVScrolledWindow and wxHScrolledWindow classes, we refer to them as "rows" and "columns", respectively. This is to help clear some confusion in not only those classes, but also in wxHVScrolledWindow where functions are inherited from both.

You are encouraged to update any existing code using these function to use the new replacements mentioned below, and avoid using these functions for any new code as they are deprecated.

`size_t GetFirstVisibleLine() const`	Deprecated for GetVisibleRowsBegin().
`size_t GetLastVisibleLine() const`	Deprecated for GetVisibleRowsEnd(). This function originally had a slight design flaw in that it was possible to return `(size_t)-1` (ie: a large positive number) if the scroll position was 0 and the first line wasn't completely visible.
`size_t GetLineCount() const`	Deprecated for GetRowCount().
`int HitTest(wxCoord x, wxCoord y) const` `int HitTest(const wxPoint& pt) const`	Deprecated for VirtualHitTest().
`virtual wxCoord OnGetLineHeight(size_t line) const`	Deprecated for OnGetRowHeight().
`virtual void OnGetLinesHint(size_t lineMin, size_t lineMax) const`	Deprecated for OnGetRowsHeightHint().
`virtual void RefreshLine(size_t line)`	Deprecated for RefreshRow().
`virtual void RefreshLines(size_t from, size_t to)`	Deprecated for RefreshRows().
`virtual bool ScrollLines(int lines)`	Deprecated for ScrollRows().
`virtual bool ScrollPages(int pages)`	Deprecated for ScrollRowPages().
`bool ScrollToLine(size_t line)`	Deprecated for ScrollToRow().
`void SetLineCount(size_t count)`	Deprecated for SetRowCount().

Library: wxCore

wxHScrolledWindow, wxHVScrolledWindow

Public Member Functions

- wxVScrolledWindow ()

  Default constructor, you must call Create() later.

- wxVScrolledWindow (wxWindow *parent, wxWindowID id=wxID_ANY, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, long style=0, const wxString &name=wxPanelNameStr)

  This is the normal constructor, no need to call Create() after using this constructor.

- bool Create (wxWindow *parent, wxWindowID id=wxID_ANY, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, long style=0, const wxString &name=wxPanelNameStr)

  Same as the non-default constructor, but returns a status code: true if ok, false if the window couldn't be created.

Additional Inherited Members

21.839.3 Constructor & Destructor Documentation

wxVScrolledWindow::wxVScrolledWindow ( )

Default constructor, you must call Create() later.

wxVScrolledWindow::wxVScrolledWindow (wxWindow * *parent*, wxWindowID *id* = wxID_ANY, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, long *style* = `0`, const wxString & *name* = `wxPanelNameStr`)

This is the normal constructor, no need to call Create() after using this constructor.

Note

`wxVSCROLL` is always automatically added to the style, there is no need to specify it explicitly.

Parameters

parent	The parent window, must not be NULL.
id	The identifier of this window, wxID_ANY by default.
pos	The initial window position.
size	The initial window size.
style	The window style. There are no special style bits defined for this class.
name	The name for this window; usually not used.

21.839.4 Member Function Documentation

bool wxVScrolledWindow::Create (wxWindow * *parent*, wxWindowID *id* = wxID_ANY, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, long *style* = `0`, const wxString & *name* = `wxPanelNameStr`)

Same as the non-default constructor, but returns a status code: true if ok, false if the window couldn't be created.

Just as with the constructor, the `wxVSCROLL` style is always used, there is no need to specify it explicitly.

21.840 wxWCharBuffer Class Reference

`#include <wx/buffer.h>`

Inheritance diagram for wxWCharBuffer:

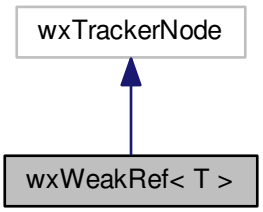
21.841 wxWeakRef< T > Class Template Reference

`#include <wx/weakref.h>`

Inheritance diagram for wxWeakRef< T >:



21.841.1 Detailed Description

template<typename T>class wxWeakRef< T >

wxWeakRef<T> is a template class for weak references to wxWidgets objects, such as wxEvtHandler, wxWindow and wxObject.

A weak reference behaves much like an ordinary pointer, but when the object pointed is destroyed, the weak reference is automatically reset to a NULL pointer.

wxWeakRef<T> can be used whenever one must keep a pointer to an object that one does not directly own, and that may be destroyed before the object holding the reference.

wxWeakRef<T> is a small object and the mechanism behind it is fast (**O(1)**). So the overall cost of using it is small.

Example:

```
wxWindow *wnd = new wxWindow( parent, wxID_ANY, "wxWindow" );
wxWeakRef<wxWindow> wr = wnd;
wxWindowRef wr2 = wnd;        // Same as above, but using a typedef
// Do things with window
wnd->Show( true );
// Weak ref is used like an ordinary pointer
```

```
wr->Show( false );
wnd->Destroy();
// Now the weak ref has been reset, so we don't risk accessing
// a dangling pointer:
wxASSERT( wr==NULL );
```

wxWeakRef<T> works for any objects that are derived from wxTrackable. By default, wxEvtHandler and wxWindow derive from wxTrackable. However, wxObject does not, so types like wxFont and wxColour are not trackable. The example below shows how to create a wxObject derived class that is trackable:

```
class wxMyTrackableObject : public wxObject, public wxTrackable
{
    // ... other members here
};
```

The following types of weak references are predefined:

```
typedef wxWeakRef<wxEvtHandler>  wxEvtHandlerRef;
typedef wxWeakRef<wxWindow>      wxWindowRef;
```

Template Parameters

T	The type to which the smart pointer points to.

Library: None; this class implementation is entirely header-based.

Category: Smart Pointers

wxSharedPtr<T>, wxScopedPtr<T>

Public Types

- typedef T element_type

  Type of the element stored by this reference.

Public Member Functions

- wxWeakRef (T *pobj=NULL)

  Constructor.
- wxWeakRef (const wxWeakRef< T > &wr)

  Copy constructor.
- virtual ~wxWeakRef ()

  Destructor.
- virtual void OnObjectDestroy ()

  Called when the tracked object is destroyed.
- void Release ()

  Release currently tracked object and rests object reference.
- T * get () const

  Returns pointer to the tracked object or NULL.
- T * operator= (wxWeakRef< T > &wr)

  Release currently tracked object and start tracking the same object as the wxWeakRef wr.
- T * operator* () const

  Implicit conversion to T.*

- T & operator* () const

  Returns a reference to the tracked object.
- T * operator-> ()

  Smart pointer member access.
- T * operator= (T *pobj)

  Releases the currently tracked object and starts tracking pobj.

21.841.2 Member Typedef Documentation

template<typename T > typedef T wxWeakRef< T >::element_type

Type of the element stored by this reference.

21.841.3 Constructor & Destructor Documentation

template<typename T > wxWeakRef< T >::wxWeakRef (T * *pobj* = NULL)

Constructor.

The weak reference is initialized to *pobj*.

template<typename T > wxWeakRef< T >::wxWeakRef (const wxWeakRef< T > & *wr*)

Copy constructor.

template<typename T > virtual wxWeakRef< T >::~wxWeakRef ( ) [virtual]

Destructor.

21.841.4 Member Function Documentation

template<typename T > T* wxWeakRef< T >::get ( ) const

Returns pointer to the tracked object or NULL.

template<typename T > virtual void wxWeakRef< T >::OnObjectDestroy ( ) [virtual]

Called when the tracked object is destroyed.

Be default sets internal pointer to NULL. You need to call this method if you override it.

template<typename T > T* wxWeakRef< T >::operator* ( ) const

Implicit conversion to T*.

Returns pointer to the tracked object or NULL.

template<typename T > T& wxWeakRef< T >::operator* ( ) const

Returns a reference to the tracked object.

If the internal pointer is NULL this method will cause an assert in debug mode.

template<typename T > T* wxWeakRef< T >::operator->( )

Smart pointer member access.

Returns a pointer to the tracked object. If the internal pointer is NULL this method will cause an assert in debug mode.

template<typename T > T* wxWeakRef< T >::operator=(wxWeakRef< T > & *wr*)

Release currently tracked object and start tracking the same object as the wxWeakRef *wr*.

template<typename T > T* wxWeakRef< T >::operator=(T * *pobj*)

Releases the currently tracked object and starts tracking *pobj*.

A weak reference may be reset by passing NULL as *pobj*.

template<typename T > void wxWeakRef< T >::Release( )

Release currently tracked object and rests object reference.

21.842 wxWeakRefDynamic< T > Class Template Reference

`#include <wx/weakref.h>`

21.842.1 Detailed Description

template<typename T>class wxWeakRefDynamic< T >

wxWeakRefDynamic<T> is a template class for weak references that is used in the same way as wxWeakRef<T>.

The only difference is that wxWeakRefDynamic defaults to using `dynamic_cast` for establishing the object reference (while wxWeakRef defaults to `static_cast`).

So, wxWeakRef will detect a type mismatch during compile time and will have a little better run-time performance. The role of wxWeakRefDynamic is to handle objects which derived type one does not know.

Note

> wxWeakRef<T> selects an implementation based on the static type of T. If T does not have wxTrackable statically, it defaults to a mixed- mode operation, where it uses `dynamic_cast` as the last measure (if available from the compiler and enabled when building wxWidgets).

For general cases, wxWeakRef<T> is the better choice.

For API documentation, see: wxWeakRef<T>.

Template Parameters

T	The type to which the smart pointer points to.

Library: None; this class implementation is entirely header-based.

Category: Smart Pointers

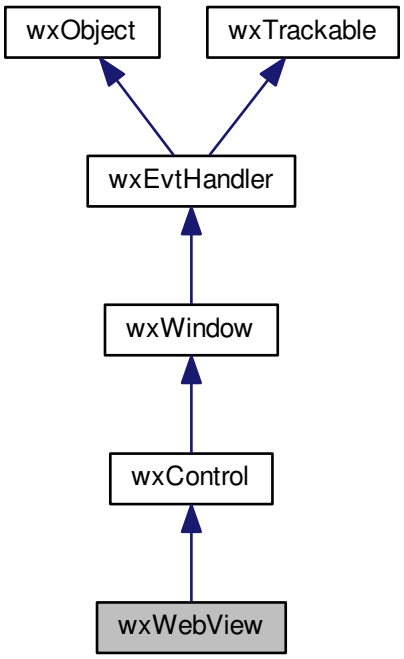
21.847 wxWebView Class Reference

`#include <wx/webview.h>`

Inheritance diagram for wxWebView:



21.847.1 Detailed Description

This control may be used to render web (HTML / CSS / javascript) documents.

It is designed to allow the creation of multiple backends for each port, although currently just one is available. It differs from wxHtmlWindow in that each backend is actually a full rendering engine, Trident on MSW and Webkit on OSX and GTK. This allows the correct viewing complex pages with javascript and css.

21.847.2 Backend Descriptions

wxWEBVIEW_BACKEND_IE (MSW)

The IE backend uses Microsoft's Trident rendering engine, specifically the version used by the locally installed copy of Internet Explorer. As such it is only available for the MSW port. By default recent versions of the `WebBrowser` control, which this backend uses, emulate Internet Explorer 7. This can be changed with a registry setting, see `this` article for more information. This backend has full support for custom schemes and virtual file systems.

wxWEBVIEW_WEBKIT (GTK)

Under GTK the WebKit backend uses `WebKitGTK+`. The current minimum version required is 1.3.1 which ships by default with Ubuntu Natty and Debian Wheezy and has the package name libwebkitgtk-dev. Custom schemes and virtual files systems are supported under this backend, however embedded resources such as images and stylesheets are currently loaded using the data:// scheme.

wxWEBVIEW_WEBKIT (OSX)

The OSX WebKit backend uses Apple's `WebView` class. This backend has full support for custom schemes and virtual file systems.

21.847.3 Asynchronous Notifications

Many of the methods in wxWebView are asynchronous, i.e. they return immediately and perform their work in the background. This includes functions such as LoadURL() and Reload(). To receive notification of the progress and completion of these functions you need to handle the events that are provided. Specifically `wxEVT_WEBVIEW_LOADED` notifies when the page or a sub-frame has finished loading and `wxEVT_WEBVIEW_ERROR` notifies that an error has occurred.

21.847.4 Virtual File Systems and Custom Schemes

wxWebView supports the registering of custom scheme handlers, for example `file` or `http`. To do this create a new class which inherits from wxWebViewHandler, where wxWebHandler::GetFile() returns a pointer to a wxFSFile which represents the given url. You can then register your handler with RegisterHandler() it will be called for all pages and resources.

wxWebViewFSHandler is provided to access the virtual file system encapsulated by wxFileSystem. The wxMemoryFSHandler documentation gives an example of how this may be used.

wxWebViewArchiveHandler is provided to allow the navigation of pages inside a zip archive. It supports paths of the form: `scheme:///C`:/example/docs.zip;protocol=zip/main.htm

Events emitted by this class

The following event handler macros redirect the events to member function handlers '**func**' with prototypes like: void handlerFuncName(wxWebViewEvent& event)

Event macros for events emitted by this class:

- EVT_WEBVIEW_NAVIGATING(id, func): Process a `wxEVT_WEBVIEW_NAVIGATING` event, generated before trying to get a resource. This event may be vetoed to prevent navigating to this resource. Note that if the displayed HTML document has several frames, one such event will be generated per frame.
- EVT_WEBVIEW_NAVIGATED(id, func): Process a `wxEVT_WEBVIEW_NAVIGATED` event generated after it was confirmed that a resource would be requested. This event may not be vetoed. Note that if the displayed HTML document has several frames, one such event will be generated per frame.
- EVT_WEBVIEW_LOADED(id, func): Process a `wxEVT_WEBVIEW_LOADED` event generated when the document is fully loaded and displayed. Note that if the displayed HTML document has several frames, one such event will be generated per frame.
- EVT_WEBVIEW_ERROR(id, func): Process a `wxEVT_WEBVIEW_ERROR` event generated when a navigation error occurs. The integer associated with this event will be a wxWebNavigationError item. The string associated with this event may contain a backend-specific more precise error message/code.
- EVT_WEBVIEW_NEWWINDOW(id, func): Process a `wxEVT_WEBVIEW_NEWWINDOW` event, generated when a new window is created. You must handle this event if you want anything to happen, for example to load the page in a new window or tab.
- EVT_WEBVIEW_TITLE_CHANGED(id, func): Process a `wxEVT_WEBVIEW_TITLE_CHANGED` event, generated when the page title changes. Use GetString to get the title.

wxWebViewHandler, wxWebViewEvent

Public Member Functions

- virtual bool Create (wxWindow *parent, wxWindowID id, const wxString &url=wxWebViewDefaultURLStr, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, long style=0, const wxString &name=wxWebViewNameStr)=0

  Creation function for two-step creation.
- virtual wxString GetCurrentTitle () const =0

  Get the title of the current web page, or its URL/path if title is not available.
- virtual wxString GetCurrentURL () const =0

  Get the URL of the currently displayed document.
- virtual void * GetNativeBackend () const =0

  Return the pointer to the native backend used by this control.
- virtual wxString GetPageSource () const =0

  Get the HTML source code of the currently displayed document.
- virtual wxString GetPageText () const =0

  Get the text of the current page.
- virtual bool IsBusy () const =0

  Returns whether the web control is currently busy (e.g. loading a page).
- virtual bool IsEditable () const =0

  Returns whether the web control is currently editable.
- virtual void LoadURL (const wxString &url)=0

  Load a web page from a URL.
- virtual void Print ()=0

  Opens a print dialog so that the user may print the currently displayed page.
- virtual void RegisterHandler (wxSharedPtr< wxWebViewHandler > handler)=0

  Registers a custom scheme handler.
- virtual void Reload (wxWebViewReloadFlags flags=wxWEBVIEW_RELOAD_DEFAULT)=0

  Reload the currently displayed URL.
- virtual void RunScript (const wxString &javascript)=0

  Runs the given javascript code.
- virtual void SetEditable (bool enable=true)=0

  Set the editable property of the web control.
- virtual void SetPage (const wxString &html, const wxString &baseUrl)=0

  Set the displayed page source to the contents of the given string.
- virtual void SetPage (wxInputStream &html, wxString baseUrl)

  Set the displayed page source to the contents of the given stream.
- virtual void Stop ()=0

  Stop the current page loading process, if any.

Clipboard

- virtual bool CanCopy () const =0
  Returns true if the current selection can be copied.
- virtual bool CanCut () const =0
  Returns true if the current selection can be cut.
- virtual bool CanPaste () const =0
  Returns true if data can be pasted.
- virtual void Copy ()=0
  Copies the current selection.
- virtual void Cut ()=0
  Cuts the current selection.
- virtual void Paste ()=0
  Pastes the current data.

Context Menu

- virtual void EnableContextMenu (bool enable=true)
  Enable or disable the right click context menu.
- virtual bool IsContextMenuEnabled () const
  Returns true if a context menu will be shown on right click.

History

- virtual bool CanGoBack () const =0
  Returns true if it is possible to navigate backward in the history of visited pages.
- virtual bool CanGoForward () const =0
  Returns true if it is possible to navigate forward in the history of visited pages.
- virtual void ClearHistory ()=0
  Clear the history, this will also remove the visible page.
- virtual void EnableHistory (bool enable=true)=0
  Enable or disable the history.
- virtual wxVector< wxSharedPtr < wxWebViewHistoryItem > > GetBackwardHistory ()=0
  Returns a list of items in the back history.
- virtual wxVector< wxSharedPtr < wxWebViewHistoryItem > > GetForwardHistory ()=0
  Returns a list of items in the forward history.
- virtual void GoBack ()=0
  Navigate back in the history of visited pages.
- virtual void GoForward ()=0
  Navigate forward in the history of visited pages.
- virtual void LoadHistoryItem (wxSharedPtr< wxWebViewHistoryItem > item)=0
  Loads a history item.

Selection

- virtual void ClearSelection ()=0
  Clears the current selection.
- virtual void DeleteSelection ()=0
  Deletes the current selection.
- virtual wxString GetSelectedSource () const =0
  Returns the currently selected source, if any.
- virtual wxString GetSelectedText () const =0
  Returns the currently selected text, if any.
- virtual bool HasSelection () const =0
  Returns true if there is a current selection.
- virtual void SelectAll ()=0
  Selects the entire page.

Undo / Redo

- virtual bool CanRedo () const =0
  Returns true if there is an action to redo.
- virtual bool CanUndo () const =0
  Returns true if there is an action to undo.
- virtual void Redo ()=0
  Redos the last action.
- virtual void Undo ()=0
  Undos the last action.

Finding

- virtual long Find (const wxString &text, wxWebViewFindFlags flags=wxWEBVIEW_FIND_DEFAULT)=0
  Finds a phrase on the current page and if found, the control will scroll the phrase into view and select it.

Zoom

- virtual bool CanSetZoomType (wxWebViewZoomType type) const =0
  Retrieve whether the current HTML engine supports a zoom type.
- virtual wxWebViewZoom GetZoom () const =0
  Get the zoom factor of the page.
- virtual wxWebViewZoomType GetZoomType () const =0
  Get how the zoom factor is currently interpreted.
- virtual void SetZoom (wxWebViewZoom zoom)=0
  Set the zoom factor of the page.
- virtual void SetZoomType (wxWebViewZoomType zoomType)=0
  Set how to interpret the zoom factor.

Static Public Member Functions

- static wxWebView * New (const wxString &backend=wxWebViewBackendDefault)
  Factory function to create a new wxWebView with two-step creation, wxWebView::Create should be called on the returned object.
- static wxWebView * New (wxWindow *parent, wxWindowID id, const wxString &url=wxWebViewDefaultURLStr, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, const wxString &backend=wxWebViewBackendDefault, long style=0, const wxString &name=wxWebViewNameStr)
  Factory function to create a new wxWebView using a wxWebViewFactory.
- static void RegisterFactory (const wxString &backend, wxSharedPtr< wxWebViewFactory > factory)
  Allows the registering of new backend for wxWebView.

Additional Inherited Members

21.847.5 Member Function Documentation

virtual bool wxWebView::CanCopy ( ) const `[pure virtual]`

Returns true if the current selection can be copied.

Note

This always returns `true` on the OSX WebKit backend.

virtual bool wxWebView::CanCut ( ) const `[pure virtual]`

Returns true if the current selection can be cut.

Note

This always returns `true` on the OSX WebKit backend.

virtual bool wxWebView::CanGoBack ( ) const `[pure virtual]`

Returns true if it is possible to navigate backward in the history of visited pages.

virtual bool wxWebView::CanGoForward ( ) const `[pure virtual]`

Returns true if it is possible to navigate forward in the history of visited pages.

virtual bool wxWebView::CanPaste ( ) const `[pure virtual]`

Returns true if data can be pasted.

Note

This always returns `true` on the OSX WebKit backend.

virtual bool wxWebView::CanRedo ( ) const `[pure virtual]`

Returns true if there is an action to redo.

virtual bool wxWebView::CanSetZoomType (wxWebViewZoomType *type*) const `[pure virtual]`

Retrieve whether the current HTML engine supports a zoom type.

Parameters

type	The zoom type to test.

Returns

Whether this type of zoom is supported by this HTML engine (and thus can be set through SetZoomType()).

virtual bool wxWebView::CanUndo ( ) const `[pure virtual]`

Returns true if there is an action to undo.

virtual void wxWebView::ClearHistory ( ) `[pure virtual]`

Clear the history, this will also remove the visible page.

virtual void wxWebView::ClearSelection ( ) `[pure virtual]`

Clears the current selection.

virtual void wxWebView::Copy ( ) [pure virtual]

Copies the current selection.

virtual bool wxWebView::Create (wxWindow * *parent*, wxWindowID *id*, const wxString & *url* = wxWebViewDefaultURLStr, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, long *style* = 0, const wxString & *name* = wxWebViewNameStr) [pure virtual]

Creation function for two-step creation.

virtual void wxWebView::Cut ( ) [pure virtual]

Cuts the current selection.

virtual void wxWebView::DeleteSelection ( ) [pure virtual]

Deletes the current selection.

Note that for wxWEBVIEW_BACKEND_WEBKIT the selection must be editable, either through SetEditable or the correct HTML attribute.

virtual void wxWebView::EnableContextMenu (bool *enable* = true) [virtual]

Enable or disable the right click context menu.

By default the standard context menu is enabled, this method can be used to disable it or re-enable it later.

Since

2.9.5

virtual void wxWebView::EnableHistory (bool *enable* = true) [pure virtual]

Enable or disable the history.

This will also clear the history.

virtual long wxWebView::Find (const wxString & *text*, wxWebViewFindFlags *flags* = wxWEBVIEW_FIND_DEFAULT) [pure virtual]

Finds a phrase on the current page and if found, the control will scroll the phrase into view and select it.

Parameters

text	The phrase to search for.
flags	The flags for the search.

Returns

If search phrase was not found in combination with the flags then wxNOT_FOUND is returned. If called for the first time with search phrase then the total number of results will be returned. Then for every time its called with the same search phrase it will return the number of the current match.

Note

This function will restart the search if the flags `wxWEBVIEW_FIND_ENTIRE_WORD` or `wxWEBVIEW_↩ FIND_MATCH_CASE` are changed, since this will require a new search. To reset the search, for example resetting the highlights call the function with an empty search phrase. This always returns `wxNOT_FOUND` on the OSX WebKit backend.

Since

2.9.5

virtual wxVector<wxSharedPtr<wxWebViewHistoryItem> > wxWebView::GetBackwardHistory ( ) [pure virtual]

Returns a list of items in the back history.

The first item in the vector is the first page that was loaded by the control.

virtual wxString wxWebView::GetCurrentTitle ( ) const [pure virtual]

Get the title of the current web page, or its URL/path if title is not available.

virtual wxString wxWebView::GetCurrentURL ( ) const [pure virtual]

Get the URL of the currently displayed document.

virtual wxVector<wxSharedPtr<wxWebViewHistoryItem> > wxWebView::GetForwardHistory ( ) [pure virtual]

Returns a list of items in the forward history.

The first item in the vector is the next item in the history with respect to the currently loaded page.

virtual void* wxWebView::GetNativeBackend ( ) const [pure virtual]

Return the pointer to the native backend used by this control.

This method can be used to retrieve the pointer to the native rendering engine used by this control. The return value needs to be down-casted to the appropriate type depending on the platform: under Windows, it's a pointer to IWebBrowser2 interface, under OS X it's a WebView pointer and under GTK it's a WebKitWebView.

For example, you could set the WebKit options using this method:

```
#include <webkit/webkit.h>

#ifdef __WXGTK__
   WebKitWebView*
    wv = static_cast<WebKitWebView*>(m_window->GetNativeBackend());

   WebKitWebSettings* settings = webkit_web_view_get_settings(wv);
   g_object_set(G_OBJECT(settings),
                "enable-frame-flattening", TRUE,
                NULL);
#endif
```

Since

2.9.5

virtual wxString wxWebView::GetPageSource ( ) const `[pure virtual]`

Get the HTML source code of the currently displayed document.

Returns

The HTML source code, or an empty string if no page is currently shown.

virtual wxString wxWebView::GetPageText ( ) const `[pure virtual]`

Get the text of the current page.

virtual wxString wxWebView::GetSelectedSource ( ) const `[pure virtual]`

Returns the currently selected source, if any.

virtual wxString wxWebView::GetSelectedText ( ) const `[pure virtual]`

Returns the currently selected text, if any.

virtual wxWebViewZoom wxWebView::GetZoom ( ) const `[pure virtual]`

Get the zoom factor of the page.

Returns

The current level of zoom.

virtual wxWebViewZoomType wxWebView::GetZoomType ( ) const `[pure virtual]`

Get how the zoom factor is currently interpreted.

Returns

How the zoom factor is currently interpreted by the HTML engine.

virtual void wxWebView::GoBack ( ) `[pure virtual]`

Navigate back in the history of visited pages.

Only valid if CanGoBack() returns true.

virtual void wxWebView::GoForward ( ) `[pure virtual]`

Navigate forward in the history of visited pages.

Only valid if CanGoForward() returns true.

virtual bool wxWebView::HasSelection ( ) const `[pure virtual]`

Returns true if there is a current selection.

virtual bool wxWebView::IsBusy ( ) const `[pure virtual]`

Returns whether the web control is currently busy (e.g. loading a page).

virtual bool wxWebView::IsContextMenuEnabled ( ) const `[virtual]`

Returns true if a context menu will be shown on right click.

Since

2.9.5

virtual bool wxWebView::IsEditable ( ) const `[pure virtual]`

Returns whether the web control is currently editable.

virtual void wxWebView::LoadHistoryItem (wxSharedPtr< wxWebViewHistoryItem > *item*) `[pure virtual]`

Loads a history item.

virtual void wxWebView::LoadURL (const wxString & *url*) `[pure virtual]`

Load a web page from a URL.

Parameters

url	The URL of the page to be loaded.

Note

Web engines generally report errors asynchronously, so if you wish to know whether loading the URL was successful, register to receive navigation error events.

static wxWebView* wxWebView::New (const wxString & *backend* = `wxWebViewBackendDefault`) `[static]`

Factory function to create a new wxWebView with two-step creation, wxWebView::Create should be called on the returned object.

Parameters

backend	The backend web rendering engine to use. `wxWebViewBackendDefault`, `wxWebViewBackendIE` and `wxWebViewBackendWebKit` are predefined where appropriate.

Returns

The created wxWebView

Since

2.9.5

static wxWebView* wxWebView::New (wxWindow * *parent*, wxWindowID *id*, const wxString & *url* = wxWebViewDefaultURLStr, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, const wxString & *backend* = wxWebViewBackendDefault, long *style* = 0, const wxString & *name* = wxWebViewNameStr) [static]

Factory function to create a new wxWebView using a wxWebViewFactory.

Parameters

parent	Parent window for the control
id	ID of this control
url	Initial URL to load
pos	Position of the control
size	Size of the control
backend	The backend web rendering engine to use. `wxWebViewBackendDefault`, `wxWebViewBackendIE` and `wxWebViewBackendWebKit` are predefined where appropriate.
style	Window style. For generic window styles, please see wxWindow.
name	Window name.

Returns

The created wxWebView, or `NULL` if the requested backend is not available

Since

2.9.5

virtual void wxWebView::Paste ( ) [pure virtual]

Pastes the current data.

virtual void wxWebView::Print ( ) [pure virtual]

Opens a print dialog so that the user may print the currently displayed page.

virtual void wxWebView::Redo ( ) [pure virtual]

Redos the last action.

static void wxWebView::RegisterFactory (const wxString & *backend*, wxSharedPtr< wxWebViewFactory > *factory*) [static]

Allows the registering of new backend for wxWebView.

backend can be used as an argument to New().

Parameters

backend	The name for the new backend to be registered under
factory	A shared pointer to the factory which creates the appropriate backend.

Since

2.9.5

virtual void wxWebView::RegisterHandler (wxSharedPtr< wxWebViewHandler > *handler*) [pure virtual]

Registers a custom scheme handler.

Parameters

handler	A shared pointer to a wxWebHandler.

virtual void wxWebView::Reload (wxWebViewReloadFlags *flags* = wxWEBVIEW_RELOAD_DEFAULT) [pure virtual]

Reload the currently displayed URL.

Parameters

flags	A bit array that may optionally contain reload options.

virtual void wxWebView::RunScript (const wxString & *javascript*) [pure virtual]

Runs the given javascript code.

Note

When using wxWEBVIEW_BACKEND_IE you must wait for the current page to finish loading before calling RunScript().

virtual void wxWebView::SelectAll ( ) [pure virtual]

Selects the entire page.

virtual void wxWebView::SetEditable (bool *enable* = true) [pure virtual]

Set the editable property of the web control.

Enabling allows the user to edit the page even if the `contenteditable` attribute is not set. The exact capabilities vary with the backend being used.

virtual void wxWebView::SetPage (const wxString & *html*, const wxString & *baseUrl*) [pure virtual]

Set the displayed page source to the contents of the given string.

Parameters

html	The string that contains the HTML data to display.
baseUrl	URL assigned to the HTML data, to be used to resolve relative paths, for instance.

Note

When using `wxWEBVIEW_BACKEND_IE` you must wait for the current page to finish loading before calling SetPage(). The baseURL parameter is not used in this backend.

virtual void wxWebView::SetPage (wxInputStream & *html*, wxString *baseUrl*) [virtual]

Set the displayed page source to the contents of the given stream.

Parameters

html	The stream to read HTML data from.
baseUrl	URL assigned to the HTML data, to be used to resolve relative paths, for instance.

virtual void wxWebView::SetZoom (wxWebViewZoom *zoom*) [pure virtual]

Set the zoom factor of the page.

Parameters

zoom	How much to zoom (scale) the HTML document.

virtual void wxWebView::SetZoomType (wxWebViewZoomType *zoomType*) [pure virtual]

Set how to interpret the zoom factor.

Parameters

zoomType	How the zoom factor should be interpreted by the HTML engine.

Note

invoke CanSetZoomType() first, some HTML renderers may not support all zoom types.

virtual void wxWebView::Stop ( ) [pure virtual]

Stop the current page loading process, if any.

May trigger an error event of type `wxWEBVIEW_NAV_ERR_USER_CANCELLED`. TODO: make `wxWEBVIEW_NAV_ERR_USER_CANCELLED` errors uniform across ports.

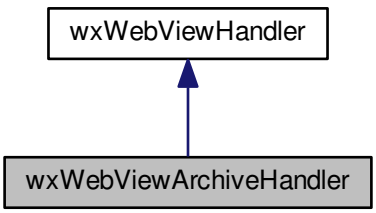
virtual void wxWebView::Undo ( ) [pure virtual]

Undos the last action.

21.848 wxWebViewArchiveHandler Class Reference

`#include <wx/webviewarchivehandler.h>`

Inheritance diagram for wxWebViewArchiveHandler:



21.848.1 Detailed Description

A custom handler for the file scheme which also supports loading from archives.

The syntax for wxWebViewArchiveHandler differs from virtual file systems in the rest of wxWidgets by using a syntax such as `scheme:///C:/example/docs.zip;protocol=zip/main.htm` Currently the only supported protocol is `zip`.

Since

2.9.3

Library: wxWebView

Category: WebView

Returns

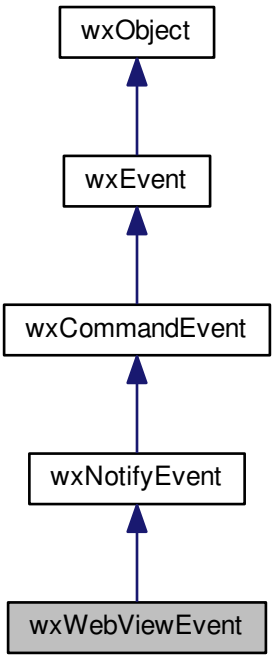
A pointer to the file represented by `uri`.

Implements wxWebViewHandler.

21.849 wxWebViewEvent Class Reference

```
#include <wx/webview.h>
```

Inheritance diagram for wxWebViewEvent:



21.849.1 Detailed Description

A navigation event holds information about events associated with wxWebView objects.

Events emitted by this class

The following event handler macros redirect the events to member function handlers '**func**' with prototypes like: void handlerFuncName(wxWebViewEvent& event)

Event macros for events emitted by this class:

- EVT_WEBVIEW_NAVIGATING(id, func): Process a `wxEVT_WEBVIEW_NAVIGATING` event, generated before trying to get a resource. This event may be vetoed to prevent navigating to this resource. Note that if the displayed HTML document has several frames, one such event will be generated per frame.
- EVT_WEBVIEW_NAVIGATED(id, func): Process a `wxEVT_WEBVIEW_NAVIGATED` event generated after it was confirmed that a resource would be requested. This event may not be vetoed. Note that if the displayed HTML document has several frames, one such event will be generated per frame.
- EVT_WEBVIEW_LOADED(id, func): Process a `wxEVT_WEBVIEW_LOADED` event generated when the document is fully loaded and displayed. Note that if the displayed HTML document has several frames, one such event will be generated per frame.
- EVT_WEBVIEW_ERROR(id, func): Process a `wxEVT_WEBVIEW_ERROR` event generated when a navigation error occurs. The integer associated with this event will be a wxWebViewNavigationError item. The string associated with this event may contain a backend-specific more precise error message/code.

- EVT_WEBVIEW_NEWWINDOW(id, func): Process a `wxEVT_WEBVIEW_NEWWINDOW` event, generated when a new window is created. You must handle this event if you want anything to happen, for example to load the page in a new window or tab.
- EVT_WEBVIEW_TITLE_CHANGED(id, func): Process a `wxEVT_WEBVIEW_TITLE_CHANGED` event, generated when the page title changes. Use GetString to get the title.

wxWebView

Public Member Functions

- virtual wxWebView * Create ()=0

  Function to create a new wxWebView with two-step creation, wxWebView::Create should be called on the returned object.

- virtual wxWebView * Create (wxWindow *parent, wxWindowID id, const wxString &url=wxWebViewDefaultURLStr, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, long style=0, const wxString &name=wxWebViewNameStr)=0

  Function to create a new wxWebView with parameters.

Additional Inherited Members

21.850.2 Member Function Documentation

virtual wxWebView* wxWebViewFactory::Create ( ) [pure virtual]

Function to create a new wxWebView with two-step creation, wxWebView::Create should be called on the returned object.

Returns

the created wxWebView

virtual wxWebView* wxWebViewFactory::Create (wxWindow * *parent*, wxWindowID *id*, const wxString & *url* = `wxWebViewDefaultURLStr`, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, long *style* = `0`, const wxString & *name* = `wxWebViewNameStr`) `[pure virtual]`

Function to create a new wxWebView with parameters.

Parameters

parent	Parent window for the control
id	ID of this control
url	Initial URL to load
pos	Position of the control
size	Size of the control
style	Window style. For generic window styles, please see wxWindow.
name	Window name.

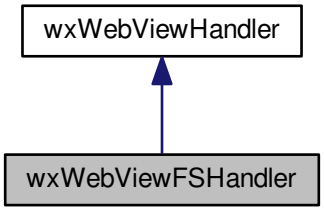
Returns

the created wxWebView

21.851 wxWebViewFSHandler Class Reference

`#include <wx/webviewfshandler.h>`

Inheritance diagram for wxWebViewFSHandler:



21.851.1 Detailed Description

A wxWebView file system handler to support standard wxFileSystem protocols of the form `example:page.htm` The handler allows wxWebView to use wxFileSystem in a similar fashion to its use with wxHtml.

The wxMemoryFSHandler documentation gives an example of how it may be used.

Since

2.9.5

wxWebViewHistoryItem::wxWebViewHistoryItem (const wxString & *url,* const wxString & *title*)

Construtor.

21.853.3 Member Function Documentation

wxString wxWebViewHistoryItem::GetTitle ( )

Returns

The title of the page.

wxString wxWebViewHistoryItem::GetUrl ( )

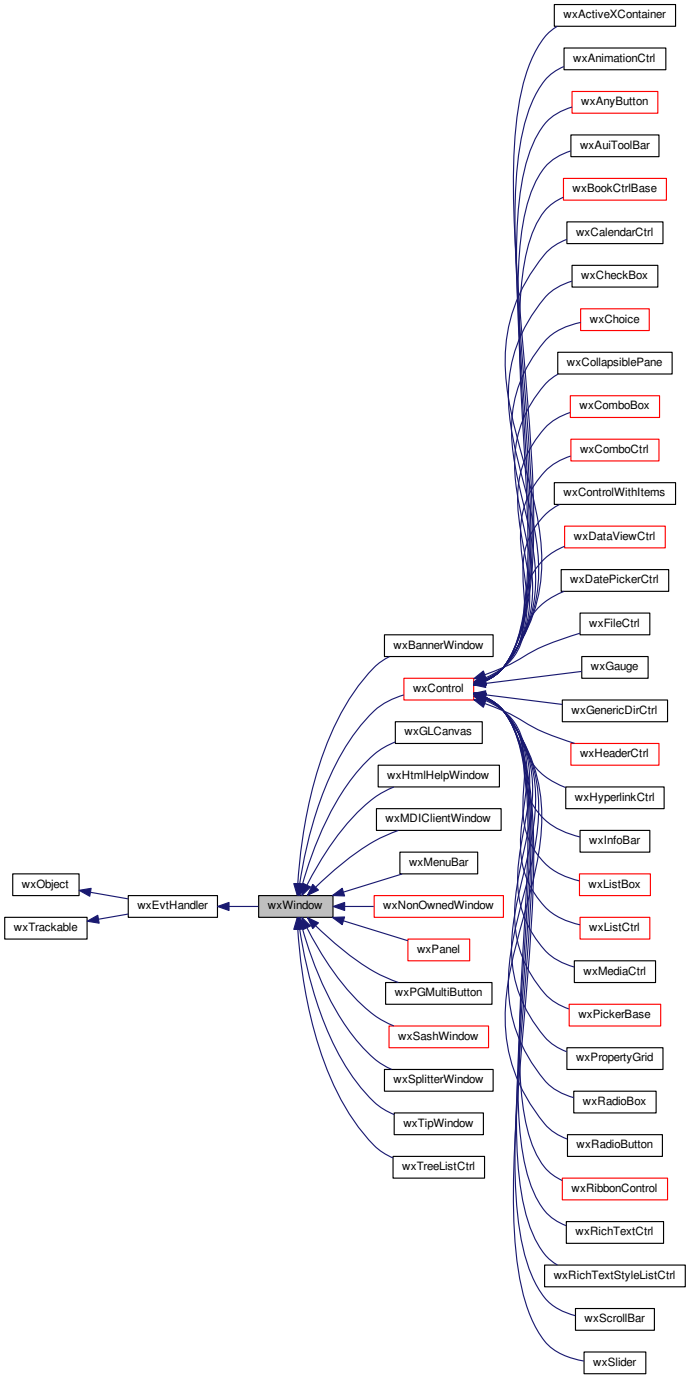
Returns

The url of the page.

21.854 wxWindow Class Reference

`#include <wx/window.h>`

Inheritance diagram for wxWindow:



21.854.1 Detailed Description

wxWindow is the base class for all windows and represents any visible object on screen.

All controls, top level windows and so on are windows. Sizers and device contexts are not, however, as they don't appear on screen themselves.

Please note that all children of the window will be deleted automatically by the destructor before the window itself is deleted which means that you don't have to worry about deleting them manually. Please see the window deletion overview for more information.

Also note that in this, and many others, wxWidgets classes some `GetXXX()` methods may be overloaded (as, for example, wxWindow::GetSize or wxWindow::GetClientSize). In this case, the overloads are non-virtual because having multiple virtual functions with the same name results in a virtual function name hiding at the derived class level (in English, this means that the derived class has to override all overloaded variants if it overrides any of them). To allow overriding them in the derived class, wxWidgets uses a unique protected virtual `DoGetXXX()` method and all `GetXXX()` ones are forwarded to it, so overriding the former changes the behaviour of the latter.

Styles

This class supports the following styles:

- wxBORDER_DEFAULT: The window class will decide the kind of border to show, if any.
- wxBORDER_SIMPLE: Displays a thin border around the window. wxSIMPLE_BORDER is the old name for this style.
- wxBORDER_SUNKEN: Displays a sunken border. wxSUNKEN_BORDER is the old name for this style.
- wxBORDER_RAISED: Displays a raised border. wxRAISED_BORDER is the old name for this style.
- wxBORDER_STATIC: Displays a border suitable for a static control. wxSTATIC_BORDER is the old name for this style. Windows only.
- wxBORDER_THEME: Displays a native border suitable for a control, on the current platform. On Windows XP or Vista, this will be a themed border; on most other platforms a sunken border will be used. For more information for themed borders on Windows, please see Themed borders on Windows.
- wxBORDER_NONE: Displays no border, overriding the default border style for the window. wxNO_BORDER is the old name for this style.
- wxBORDER_DOUBLE: This style is obsolete and should not be used.
- wxTRANSPARENT_WINDOW: The window is transparent, that is, it will not receive paint events. Windows only.
- wxTAB_TRAVERSAL: Use this to enable tab traversal for non-dialog windows.
- wxWANTS_CHARS: Use this to indicate that the window wants to get all char/key events for all keys - even for keys like TAB or ENTER which are usually used for dialog navigation and which wouldn't be generated without this style. If you need to use this style in order to get the arrows or etc., but would still like to have normal keyboard navigation take place, you should call Navigate in response to the key events for Tab and Shift-Tab.
- wxNO_FULL_REPAINT_ON_RESIZE: On Windows, this style used to disable repainting the window completely when its size is changed. Since this behaviour is now the default, the style is now obsolete and no longer has an effect.
- wxVSCROLL: Use this style to enable a vertical scrollbar. Notice that this style cannot be used with native controls which don't support scrollbars nor with top-level windows in most ports.
- wxHSCROLL: Use this style to enable a horizontal scrollbar. The same limitations as for wxVSCROLL apply to this style.

- wxALWAYS_SHOW_SB: If a window has scrollbars, disable them instead of hiding them when they are not needed (i.e. when the size of the window is big enough to not require the scrollbars to navigate it). This style is currently implemented for wxMSW, wxGTK and wxUniversal and does nothing on the other platforms.
- wxCLIP_CHILDREN: Use this style to eliminate flicker caused by the background being repainted, then children being painted over them. Windows only.
- wxFULL_REPAINT_ON_RESIZE: Use this style to force a complete redraw of the window whenever it is resized instead of redrawing just the part of the window affected by resizing. Note that this was the behaviour by default before 2.5.1 release and that if you experience redraw problems with code which previously used to work you may want to try this. Currently this style applies on GTK+ 2 and Windows only, and full repainting is always done on other platforms.

Extra Styles

This class supports the following extra styles:

- wxWS_EX_VALIDATE_RECURSIVELY: By default, wxWindow::Validate(), wxWindow::TransferDataTo() and wxWindow::TransferDataFromWindow() only work on direct children of the window (compatible behaviour). Set this flag to make them recursively descend into all subwindows.
- wxWS_EX_BLOCK_EVENTS: wxCommandEvents and the objects of the derived classes are forwarded to the parent window and so on recursively by default. Using this flag for the given window allows to block this propagation at this window, i.e. prevent the events from being propagated further upwards. Dialogs have this flag on by default for the reasons explained in the Events and Event Handling.
- wxWS_EX_TRANSIENT: Don't use this window as an implicit parent for the other windows: this must be used with transient windows as otherwise there is the risk of creating a dialog/frame with this window as a parent, which would lead to a crash if the parent were destroyed before the child.
- wxWS_EX_CONTEXTHELP: Under Windows, puts a query button on the caption. When pressed, Windows will go into a context-sensitive help mode and wxWidgets will send a `wxEVT_HELP` event if the user clicked on an application window. This style cannot be used (because of the underlying native behaviour) together with `wxMAXIMIZE_BOX` or `wxMINIMIZE_BOX`, so these two styles are automatically turned off if this one is used.
- wxWS_EX_PROCESS_IDLE: This window should always process idle events, even if the mode set by wxIdleEvent::SetMode is `wxIDLE_PROCESS_SPECIFIED`.
- wxWS_EX_PROCESS_UI_UPDATES: This window should always process UI update events, even if the mode set by wxUpdateUIEvent::SetMode is `wxUPDATE_UI_PROCESS_SPECIFIED`.

Events emitted by this class

Event macros for events emitted by this class:

- EVT_ACTIVATE(id, func): Process a `wxEVT_ACTIVATE` event. See wxActivateEvent.
- EVT_CHILD_FOCUS(func): Process a `wxEVT_CHILD_FOCUS` event. See wxChildFocusEvent.
- EVT_CONTEXT_MENU(func): A right click (or other context menu command depending on platform) has been detected. See wxContextMenuEvent.
- EVT_HELP(id, func): Process a `wxEVT_HELP` event. See wxHelpEvent.
- EVT_HELP_RANGE(id1, id2, func): Process a `wxEVT_HELP` event for a range of ids. See wxHelpEvent.
- EVT_DROP_FILES(func): Process a `wxEVT_DROP_FILES` event. See wxDropFilesEvent.
- EVT_ERASE_BACKGROUND(func): Process a `wxEVT_ERASE_BACKGROUND` event. See wxEraseEvent.

- EVT_SET_FOCUS(func): Process a `wxEVT_SET_FOCUS` event. See wxFocusEvent.
- EVT_KILL_FOCUS(func): Process a `wxEVT_KILL_FOCUS` event. See wxFocusEvent.
- EVT_IDLE(func): Process a `wxEVT_IDLE` event. See wxIdleEvent.
- EVT_JOY_*(func): Processes joystick events. See wxJoystickEvent.
- EVT_KEY_DOWN(func): Process a `wxEVT_KEY_DOWN` event (any key has been pressed). See wxKeyEvent.
- EVT_KEY_UP(func): Process a `wxEVT_KEY_UP` event (any key has been released). See wxKeyEvent.
- EVT_CHAR(func): Process a `wxEVT_CHAR` event. See wxKeyEvent.
- EVT_CHAR_HOOK(func): Process a `wxEVT_CHAR_HOOK` event. See wxKeyEvent.
- EVT_MOUSE_CAPTURE_LOST(func): Process a `wxEVT_MOUSE_CAPTURE_LOST` event. See wxMouseCaptureLostEvent.
- EVT_MOUSE_CAPTURE_CHANGED(func): Process a `wxEVT_MOUSE_CAPTURE_CHANGED` event. See wxMouseCaptureChangedEvent.
- EVT_MOUSE_*(func): See wxMouseEvent.
- EVT_PAINT(func): Process a `wxEVT_PAINT` event. See wxPaintEvent.
- EVT_POWER_*(func): The system power state changed. See wxPowerEvent.
- EVT_SCROLLWIN_*(func): Process scroll events. See wxScrollWinEvent.
- EVT_SET_CURSOR(func): Process a `wxEVT_SET_CURSOR` event. See wxSetCursorEvent.
- EVT_SIZE(func): Process a `wxEVT_SIZE` event. See wxSizeEvent.
- EVT_SYS_COLOUR_CHANGED(func): Process a `wxEVT_SYS_COLOUR_CHANGED` event. See wxSysColourChangedEvent.

Library: wxCore

Category: Miscellaneous Windows

Events and Event Handling, Window Sizing Overview

Classes

- class ChildrenRepositioningGuard

  Helper for ensuring EndRepositioningChildren() is called correctly.

Public Member Functions

- wxWindow ()

  Default constructor.
- wxWindow (wxWindow *parent, wxWindowID id, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, long style=0, const wxString &name=wxPanelNameStr)

  Constructs a window, which can be a child of a frame, dialog or any other non-control window.
- virtual ~wxWindow ()

  Destructor.

- bool Create (wxWindow *parent, wxWindowID id, const wxPoint &pos=wxDefaultPosition, const wxSize &size=wxDefaultSize, long style=0, const wxString &name=wxPanelNameStr)

Focus functions

See also the static function FindFocus().

- virtual bool AcceptsFocus () const
  This method may be overridden in the derived classes to return false to indicate that this control doesn't accept input at all (i.e. behaves like e.g. wxStaticText) and so doesn't need focus.
- virtual bool AcceptsFocusFromKeyboard () const
  This method may be overridden in the derived classes to return false to indicate that while this control can, in principle, have focus if the user clicks it with the mouse, it shouldn't be included in the TAB traversal chain when using the keyboard.
- virtual bool AcceptsFocusRecursively () const
  Overridden to indicate whether this window or one of its children accepts focus.
- bool IsFocusable () const
  Can this window itself have focus?
- bool CanAcceptFocus () const
  Can this window have focus right now?
- bool CanAcceptFocusFromKeyboard () const
  Can this window be assigned focus from keyboard right now?
- virtual bool HasFocus () const
  Returns true if the window (or in case of composite controls, its main child window) has focus.
- virtual void SetCanFocus (bool canFocus)
  This method is only implemented by ports which have support for native TAB traversal (such as GTK+ 2.0).
- virtual void SetFocus ()
  This sets the window to receive keyboard input.
- virtual void SetFocusFromKbd ()
  This function is called by wxWidgets keyboard navigation code when the user gives the focus to this window from keyboard (e.g. using `TAB` key).

Child management functions

- virtual void AddChild (wxWindow *child)
  Adds a child window.
- bool DestroyChildren ()
  Destroys all children of a window.
- wxWindow * FindWindow (long id) const
  Find a child of this window, by id.
- wxWindow * FindWindow (const wxString &name) const
  Find a child of this window, by name.
- wxWindowList & GetChildren ()
  Returns a reference to the list of the window's children.
- const wxWindowList & GetChildren () const
  Returns a const reference to the list of the window's children.
- virtual void RemoveChild (wxWindow *child)
  Removes a child window.

Sibling and parent management functions

- wxWindow * GetGrandParent () const
  Returns the grandparent of a window, or NULL if there isn't one.
- wxWindow * GetNextSibling () const
  Returns the next window after this one among the parent's children or NULL if this window is the last child.
- wxWindow * GetParent () const
  Returns the parent of the window, or NULL if there is no parent.
- wxWindow * GetPrevSibling () const
  Returns the previous window before this one among the parent's children or NULL if this window is the first child.
- bool IsDescendant (wxWindowBase *win) const

Check if the specified window is a descendant of this one.

- virtual bool Reparent (wxWindow *newParent)

  Reparents the window, i.e. the window will be removed from its current parent window (e.g.

Scrolling and scrollbars functions

Note that these methods don't work with native controls which don't use wxWidgets scrolling framework (i.e. don't derive from wxScrolledWindow).

- virtual void AlwaysShowScrollbars (bool hflag=true, bool vflag=true)

  Call this function to force one or both scrollbars to be always shown, even if the window is big enough to show its entire contents without scrolling.
- virtual int GetScrollPos (int orientation) const

  Returns the built-in scrollbar position.
- virtual int GetScrollRange (int orientation) const

  Returns the built-in scrollbar range.
- virtual int GetScrollThumb (int orientation) const

  Returns the built-in scrollbar thumb size.
- bool CanScroll (int orient) const

  Returns true if this window can have a scroll bar in this orientation.
- bool HasScrollbar (int orient) const

  Returns true if this window currently has a scroll bar for this orientation.
- virtual bool IsScrollbarAlwaysShown (int orient) const

  Return whether a scrollbar is always shown.
- virtual bool ScrollLines (int lines)

  Scrolls the window by the given number of lines down (if lines is positive) or up.
- virtual bool ScrollPages (int pages)

  Scrolls the window by the given number of pages down (if pages is positive) or up.
- virtual void ScrollWindow (int dx, int dy, const wxRect *rect=NULL)

  Physically scrolls the pixels in the window and move child windows accordingly.
- bool LineUp ()

  Same as ScrollLines (-1).
- bool LineDown ()

  Same as ScrollLines (1).
- bool PageUp ()

  Same as ScrollPages (-1).
- bool PageDown ()

  Same as ScrollPages (1).
- virtual void SetScrollPos (int orientation, int pos, bool refresh=true)

  Sets the position of one of the built-in scrollbars.
- virtual void SetScrollbar (int orientation, int position, int thumbSize, int range, bool refresh=true)

  Sets the scrollbar properties of a built-in scrollbar.

Sizing functions

See also the protected functions DoGetBestSize() and DoGetBestClientSize().

- bool BeginRepositioningChildren ()

  Prepare for changing positions of multiple child windows.
- void EndRepositioningChildren ()

  Fix child window positions after setting all of them at once.
- void CacheBestSize (const wxSize &size) const

  Sets the cached best size value.
- virtual wxSize ClientToWindowSize (const wxSize &size) const

  Converts client area size size to corresponding window size.
- virtual wxSize WindowToClientSize (const wxSize &size) const

  Converts window size size to corresponding client area size In other words, the returned value is what would GetClientSize() return if this window had given window size.
- virtual void Fit ()

  Sizes the window so that it fits around its subwindows.

- virtual void FitInside ()

  Similar to Fit(), but sizes the interior (virtual) size of a window.
- wxSize GetBestSize () const

  This functions returns the best acceptable minimal size for the window.
- int GetBestHeight (int width) const

  Returns the best height needed by this window if it had the given width.
- int GetBestWidth (int height) const

  Returns the best width needed by this window if it had the given height.
- void GetClientSize (int ∗width, int ∗height) const

  Returns the size of the window 'client area' in pixels.
- wxSize GetClientSize () const

  This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.
- virtual wxSize GetEffectiveMinSize () const

  Merges the window's best size into the min size and returns the result.
- virtual wxSize GetMaxClientSize () const

  Returns the maximum size of window's client area.
- virtual wxSize GetMaxSize () const

  Returns the maximum size of the window.
- virtual wxSize GetMinClientSize () const

  Returns the minimum size of window's client area, an indication to the sizer layout mechanism that this is the minimum required size of its client area.
- virtual wxSize GetMinSize () const

  Returns the minimum size of the window, an indication to the sizer layout mechanism that this is the minimum required size.
- int GetMinWidth () const

  Returns the horizontal component of window minimal size.
- int GetMinHeight () const

  Returns the vertical component of window minimal size.
- int GetMaxWidth () const

  Returns the horizontal component of window maximal size.
- int GetMaxHeight () const

  Returns the vertical component of window maximal size.
- void GetSize (int ∗width, int ∗height) const

  Returns the size of the entire window in pixels, including title bar, border, scrollbars, etc.
- wxSize GetSize () const

  See the GetSize(int∗,int∗) overload for more info.
- wxSize GetVirtualSize () const

  This gets the virtual size of the window in pixels.
- void GetVirtualSize (int ∗width, int ∗height) const

  Like the other GetVirtualSize() overload but uses pointers instead.
- virtual wxSize GetBestVirtualSize () const

  Return the largest of ClientSize and BestSize (as determined by a sizer, interior children, or other means)
- virtual double GetContentScaleFactor () const

  Returns the magnification of the backing store of this window, eg 2.0 for a window on a retina screen.
- virtual wxSize GetWindowBorderSize () const

  Returns the size of the left/right and top/bottom borders of this window in x and y components of the result respectively.
- virtual bool InformFirstDirection (int direction, int size, int availableOtherDir)

  wxSizer and friends use this to give a chance to a component to recalc its min size once one of the final size components is known.
- void InvalidateBestSize ()

  Resets the cached best size value so it will be recalculated the next time it is needed.
- void PostSizeEvent ()

  Posts a size event to the window.
- void PostSizeEventToParent ()

  Posts a size event to the parent of this window.
- virtual void SendSizeEvent (int flags=0)

  This function sends a dummy size event to the window allowing it to re-layout its children positions.

- void SendSizeEventToParent (int flags=0)

  Safe wrapper for GetParent()->SendSizeEvent().
- void SetClientSize (int width, int height)

  This sets the size of the window client area in pixels.
- void SetClientSize (const wxSize &size)

  This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.
- void SetClientSize (const wxRect &rect)

  This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.
- void SetContainingSizer (wxSizer *sizer)

  This normally does not need to be called by user code.
- void SetInitialSize (const wxSize &size=wxDefaultSize)

  A smart SetSize that will fill in default size components with the window's best size values.
- virtual void SetMaxClientSize (const wxSize &size)

  Sets the maximum client size of the window, to indicate to the sizer layout mechanism that this is the maximum possible size of its client area.
- virtual void SetMaxSize (const wxSize &size)

  Sets the maximum size of the window, to indicate to the sizer layout mechanism that this is the maximum possible size.
- virtual void SetMinClientSize (const wxSize &size)

  Sets the minimum client size of the window, to indicate to the sizer layout mechanism that this is the minimum required size of window's client area.
- virtual void SetMinSize (const wxSize &size)

  Sets the minimum size of the window, to indicate to the sizer layout mechanism that this is the minimum required size.
- void SetSize (int x, int y, int width, int height, int sizeFlags=wxSIZE_AUTO)

  Sets the size of the window in pixels.
- void SetSize (const wxRect &rect)

  Sets the size of the window in pixels.
- void SetSize (const wxSize &size)

  This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.
- void SetSize (int width, int height)

  This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.
- virtual void SetSizeHints (const wxSize &minSize, const wxSize &maxSize=wxDefaultSize, const wxSize &incSize=wxDefaultSize)

  Use of this function for windows which are not toplevel windows (such as wxDialog or wxFrame) is discouraged.
- virtual void SetSizeHints (int minW, int minH, int maxW=-1, int maxH=-1, int incW=-1, int incH=-1)

  This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.
- void SetVirtualSize (int width, int height)

  Sets the virtual size of the window in pixels.
- void SetVirtualSize (const wxSize &size)

  This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.

Positioning functions

- void Center (int dir=wxBOTH)

  A synonym for Centre().
- void CenterOnParent (int dir=wxBOTH)

  A synonym for CentreOnParent().
- void Centre (int direction=wxBOTH)

  Centres the window.
- void CentreOnParent (int direction=wxBOTH)

  Centres the window on its parent.
- void GetPosition (int *x, int *y) const

This gets the position of the window in pixels, relative to the parent window for the child windows or relative to the display origin for the top level windows.

- wxPoint GetPosition () const

  This gets the position of the window in pixels, relative to the parent window for the child windows or relative to the display origin for the top level windows.
- wxRect GetRect () const

  Returns the position and size of the window as a wxRect object.
- void GetScreenPosition (int *x, int *y) const

  Returns the window position in screen coordinates, whether the window is a child window or a top level one.
- wxPoint GetScreenPosition () const

  Returns the window position in screen coordinates, whether the window is a child window or a top level one.
- wxRect GetScreenRect () const

  Returns the position and size of the window on the screen as a wxRect object.
- virtual wxPoint GetClientAreaOrigin () const

  Get the origin of the client area of the window relative to the window top left corner (the client area may be shifted because of the borders, scrollbars, other decorations...)
- wxRect GetClientRect () const

  Get the client rectangle in window (i.e. client) coordinates.
- void Move (int x, int y, int flags=wxSIZE_USE_EXISTING)

  Moves the window to the given position.
- void Move (const wxPoint &pt, int flags=wxSIZE_USE_EXISTING)

  Moves the window to the given position.
- void SetPosition (const wxPoint &pt)

  A synonym for Centre().

Coordinate conversion functions

- void ClientToScreen (int *x, int *y) const

  Converts to screen coordinates from coordinates relative to this window.
- wxPoint ClientToScreen (const wxPoint &pt) const

  Converts to screen coordinates from coordinates relative to this window.
- wxPoint ConvertDialogToPixels (const wxPoint &pt) const

  Converts a point or size from dialog units to pixels.
- wxSize ConvertDialogToPixels (const wxSize &sz) const

  This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.
- wxPoint ConvertPixelsToDialog (const wxPoint &pt) const

  Converts a point or size from pixels to dialog units.
- wxSize ConvertPixelsToDialog (const wxSize &sz) const

  This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.
- void ScreenToClient (int *x, int *y) const

  Converts from screen to client window coordinates.
- wxPoint ScreenToClient (const wxPoint &pt) const

  Converts from screen to client window coordinates.

Drawing-related functions

- virtual void ClearBackground ()

  Clears the window by filling it with the current background colour.
- void Freeze ()

  Freezes the window or, in other words, prevents any updates from taking place on screen, the window is not redrawn at all.
- void Thaw ()

  Re-enables window updating after a previous call to Freeze().
- bool IsFrozen () const

  Returns true if the window is currently frozen by a call to Freeze().
- wxColour GetBackgroundColour () const

  Returns the background colour of the window.

- virtual wxBackgroundStyle GetBackgroundStyle () const

  Returns the background style of the window.
- virtual int GetCharHeight () const

  Returns the character height for this window.
- virtual int GetCharWidth () const

  Returns the average character width for this window.
- virtual wxVisualAttributes GetDefaultAttributes () const

  Currently this is the same as calling wxWindow::GetClassDefaultAttributes(wxWindow::GetWindowVariant()).
- wxFont GetFont () const

  Returns the font for this window.
- wxColour GetForegroundColour () const

  Returns the foreground colour of the window.
- void GetTextExtent (const wxString &string, int ∗w, int ∗h, int ∗descent=NULL, int ∗externalLeading=NULL, const wxFont ∗font=NULL) const

  Gets the dimensions of the string as it would be drawn on the window with the currently selected font.
- wxSize GetTextExtent (const wxString &string) const

  Gets the dimensions of the string as it would be drawn on the window with the currently selected font.
- const wxRegion & GetUpdateRegion () const

  Returns the region specifying which parts of the window have been damaged.
- wxRect GetUpdateClientRect () const

  Get the update rectangle bounding box in client coords.
- virtual bool HasTransparentBackground ()

  Returns true if this window background is transparent (as, for example, for wxStaticText) and should show the parent window background.
- virtual void Refresh (bool eraseBackground=true, const wxRect ∗rect=NULL)

  Causes this window, and all of its children recursively (except under wxGTK1 where this is not implemented), to be repainted.
- void RefreshRect (const wxRect &rect, bool eraseBackground=true)

  Redraws the contents of the given rectangle: only the area inside it will be repainted.
- virtual void Update ()

  Calling this method immediately repaints the invalidated area of the window and all of its children recursively (this normally only happens when the flow of control returns to the event loop).
- virtual bool SetBackgroundColour (const wxColour &colour)

  Sets the background colour of the window.
- virtual bool SetBackgroundStyle (wxBackgroundStyle style)

  Sets the background style of the window.
- virtual bool IsTransparentBackgroundSupported (wxString ∗reason=NULL) const

  Checks whether using transparent background might work.
- virtual bool SetFont (const wxFont &font)

  Sets the font for this window.
- virtual bool SetForegroundColour (const wxColour &colour)

  Sets the foreground colour of the window.
- void SetOwnBackgroundColour (const wxColour &colour)

  Sets the background colour of the window but prevents it from being inherited by the children of this window.
- bool InheritsBackgroundColour () const

  Return true if this window inherits the background colour from its parent.
- bool UseBgCol () const

  Return true if a background colour has been set for this window.
- void SetOwnFont (const wxFont &font)

  Sets the font of the window but prevents it from being inherited by the children of this window.
- void SetOwnForegroundColour (const wxColour &colour)

  Sets the foreground colour of the window but prevents it from being inherited by the children of this window.
- void SetPalette (const wxPalette &pal)
- virtual bool ShouldInheritColours () const

  Return true from here to allow the colours of this window to be changed by InheritAttributes().
- virtual void SetThemeEnabled (bool enable)

  This function tells a window if it should use the system's "theme" code to draw the windows' background instead of its own background drawing code.
- virtual bool GetThemeEnabled () const

Clears the window by filling it with the current background colour.

- virtual bool CanSetTransparent ()

  Returns true if the system supports transparent windows and calling SetTransparent() may succeed.
- virtual bool SetTransparent (wxByte alpha)

  Set the transparency of the window.

Event-handling functions

wxWindow allows you to build a (sort of) stack of event handlers which can be used to override the window's own event handling.

- wxEvtHandler * GetEventHandler () const

  Returns the event handler for this window.
- bool HandleAsNavigationKey (const wxKeyEvent &event)

  This function will generate the appropriate call to Navigate() if the key event is one normally used for keyboard navigation and return true in this case.
- bool HandleWindowEvent (wxEvent &event) const

  Shorthand for:
- bool ProcessWindowEvent (wxEvent &event)

  Convenient wrapper for ProcessEvent().
- bool ProcessWindowEventLocally (wxEvent &event)

  Wrapper for wxEvtHandler::ProcessEventLocally().
- wxEvtHandler * PopEventHandler (bool deleteHandler=false)

  Removes and returns the top-most event handler on the event handler stack.
- void PushEventHandler (wxEvtHandler *handler)

  Pushes this event handler onto the event stack for the window.
- bool RemoveEventHandler (wxEvtHandler *handler)

  Find the given handler in the windows event handler stack and removes (but does not delete) it from the stack.
- void SetEventHandler (wxEvtHandler *handler)

  Sets the event handler for this window.
- virtual void SetNextHandler (wxEvtHandler *handler)

  wxWindows cannot be used to form event handler chains; this function thus will assert when called.
- virtual void SetPreviousHandler (wxEvtHandler *handler)

  wxWindows cannot be used to form event handler chains; this function thus will assert when called.

Window styles functions

- long GetExtraStyle () const

  Returns the extra style bits for the window.
- virtual long GetWindowStyleFlag () const

  Gets the window style that was passed to the constructor or Create() method.
- long GetWindowStyle () const

  See GetWindowStyleFlag() for more info.
- bool HasExtraStyle (int exFlag) const

  Returns true if the window has the given exFlag bit set in its extra styles.
- bool HasFlag (int flag) const

  Returns true if the window has the given flag bit set.
- virtual void SetExtraStyle (long exStyle)

  Sets the extra style bits for the window.
- virtual void SetWindowStyleFlag (long style)

  Sets the style of the window.
- void SetWindowStyle (long style)

  See SetWindowStyleFlag() for more info.
- bool ToggleWindowStyle (int flag)

  Turns the given flag on if it's currently turned off and vice versa.

Tab order functions

- void MoveAfterInTabOrder (wxWindow *win)

Moves this window in the tab navigation order after the specified win.

- void MoveBeforeInTabOrder (wxWindow *win)

  Same as MoveAfterInTabOrder() except that it inserts this window just before win instead of putting it right after it.
- bool Navigate (int flags=wxNavigationKeyEvent::IsForward)

  Performs a keyboard navigation action starting from this window.
- bool NavigateIn (int flags=wxNavigationKeyEvent::IsForward)

  Performs a keyboard navigation action inside this window.

Z order functions

- virtual void Lower ()

  Lowers the window to the bottom of the window hierarchy (Z-order).
- virtual void Raise ()

  Raises the window to the top of the window hierarchy (Z-order).

Window status functions

- bool Hide ()

  Equivalent to calling wxWindow::Show(false).
- virtual bool HideWithEffect (wxShowEffect effect, unsigned int timeout=0)

  This function hides a window, like Hide(), but using a special visual effect if possible.
- bool IsEnabled () const

  Returns true if the window is enabled, i.e. if it accepts user input, false otherwise.
- bool IsExposed (int x, int y) const

  Returns true if the given point or rectangle area has been exposed since the last repaint.
- bool IsExposed (wxPoint &pt) const

  This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.
- bool IsExposed (int x, int y, int w, int h) const

  This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.
- bool IsExposed (wxRect &rect) const

  This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.
- virtual bool IsShown () const

  Returns true if the window is shown, false if it has been hidden.
- virtual bool IsShownOnScreen () const

  Returns true if the window is physically visible on the screen, i.e. it is shown and all its parents up to the toplevel window are shown as well.
- bool Disable ()

  Disables the window.
- virtual bool Enable (bool enable=true)

  Enable or disable the window for user input.
- virtual bool Show (bool show=true)

  Shows or hides the window.
- virtual bool ShowWithEffect (wxShowEffect effect, unsigned int timeout=0)

  This function shows a window, like Show(), but using a special visual effect if possible.

Context-sensitive help functions

- wxString GetHelpText () const

  Gets the help text to be used as context-sensitive help for this window.
- void SetHelpText (const wxString &helpText)

  Sets the help text to be used as context-sensitive help for this window.
- virtual wxString GetHelpTextAtPoint (const wxPoint &point, wxHelpEvent::Origin origin) const

  Gets the help text to be used as context-sensitive help for this window.
- wxToolTip * GetToolTip () const

  Get the associated tooltip or NULL if none.
- wxString GetToolTipText () const

Get the text of the associated tooltip or empty string if none.

- void SetToolTip (const wxString &tipString)

  Attach a tooltip to the window.
- void SetToolTip (wxToolTip *tip)

  This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.
- void UnsetToolTip ()

  Unset any existing tooltip.

Popup/context menu functions

- int GetPopupMenuSelectionFromUser (wxMenu &menu, const wxPoint &pos=wxDefaultPosition)

  This function shows a popup menu at the given position in this window and returns the selected id.
- int GetPopupMenuSelectionFromUser (wxMenu &menu, int x, int y)

  This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.
- bool PopupMenu (wxMenu *menu, const wxPoint &pos=wxDefaultPosition)

  Pops up the given menu at the specified coordinates, relative to this window, and returns control when the user has dismissed the menu.
- bool PopupMenu (wxMenu *menu, int x, int y)

  This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.

- virtual wxValidator * GetValidator ()

  Validator functions.
- virtual void SetValidator (const wxValidator &validator)

  Deletes the current validator (if any) and sets the window validator, having called wxValidator::Clone to create a new validator of this type.
- virtual bool TransferDataFromWindow ()

  Transfers values from child controls to data areas specified by their validators.
- virtual bool TransferDataToWindow ()

  Transfers values to child controls from data areas specified by their validators.
- virtual bool Validate ()

  Validates the current values of the child controls using their validators.

wxWindow properties functions

- wxWindowID GetId () const

  Returns the identifier of the window.
- virtual wxString GetLabel () const

  Generic way of getting a label from any window, for identification purposes.
- virtual wxLayoutDirection GetLayoutDirection () const

  Returns the layout direction for this window, Note that `wxLayout_Default` is returned if layout direction is not supported.
- virtual wxCoord AdjustForLayoutDirection (wxCoord x, wxCoord width, wxCoord widthTotal) const

  Mirror coordinates for RTL layout if this window uses it and if the mirroring is not done automatically like Win32.
- virtual wxString GetName () const

  Returns the window's name.
- wxWindowVariant GetWindowVariant () const

  Returns the value previously passed to SetWindowVariant().
- void SetId (wxWindowID winid)

  Sets the identifier of the window.
- virtual void SetLabel (const wxString &label)

  Sets the window's label.
- virtual void SetLayoutDirection (wxLayoutDirection dir)

  Sets the layout direction for this window.
- virtual void SetName (const wxString &name)

Sets the window's name.

- void SetWindowVariant (wxWindowVariant variant)

  Chooses a different variant of the window display to use.
- wxAcceleratorTable * GetAcceleratorTable ()

  Gets the accelerator table for this window.
- wxAccessible * GetAccessible ()

  Returns the accessible object for this window, if any.
- virtual void SetAcceleratorTable (const wxAcceleratorTable &accel)

  Sets the accelerator table for this window.
- void SetAccessible (wxAccessible *accessible)

  Sets the accessible for this window.

Window deletion functions

- bool Close (bool force=false)

  This function simply generates a wxCloseEvent whose handler usually tries to close the window.
- virtual bool Destroy ()

  Destroys the window safely.
- bool IsBeingDeleted () const

  Returns true if this window is in process of being destroyed.

Drag and drop functions

- virtual wxDropTarget * GetDropTarget () const

  Returns the associated drop target, which may be NULL.
- virtual void SetDropTarget (wxDropTarget *target)

  Associates a drop target with this window.
- virtual void DragAcceptFiles (bool accept)

  Enables or disables eligibility for drop file events (OnDropFiles).

Constraints, sizers and window layout functions

- wxSizer * GetContainingSizer () const

  Returns the sizer of which this window is a member, if any, otherwise NULL.
- wxSizer * GetSizer () const

  Returns the sizer associated with the window by a previous call to SetSizer(), or NULL.
- void SetSizer (wxSizer *sizer, bool deleteOld=true)

  Sets the window to have the given layout sizer.
- void SetSizerAndFit (wxSizer *sizer, bool deleteOld=true)

  This method calls SetSizer() and then wxSizer::SetSizeHints which sets the initial window size to the size needed to accommodate all sizer elements and sets the size hints which, if this window is a top level one, prevent the user from resizing it to be less than this minimal size.
- wxLayoutConstraints * GetConstraints () const

  Returns a pointer to the window's layout constraints, or NULL if there are none.
- void SetConstraints (wxLayoutConstraints *constraints)

  Sets the window to have the given layout constraints.
- virtual bool Layout ()

  Invokes the constraint-based layout algorithm or the sizer-based algorithm for this window.
- void SetAutoLayout (bool autoLayout)

  Determines whether the Layout() function will be called automatically when the window is resized.
- bool GetAutoLayout () const

  Returns the sizer of which this window is a member, if any, otherwise NULL.

Mouse functions

- void CaptureMouse ()

  Directs all mouse input to this window.
- wxCaret * GetCaret () const

  Returns the caret() associated with the window.

- const wxCursor & GetCursor () const

  Return the cursor associated with this window.
- virtual bool HasCapture () const

  Returns true if this window has the current mouse capture.
- void ReleaseMouse ()

  Releases mouse input captured with CaptureMouse().
- void SetCaret (wxCaret *caret)

  Sets the caret() associated with the window.
- virtual bool SetCursor (const wxCursor &cursor)

  Sets the window's cursor.
- virtual void WarpPointer (int x, int y)

  Moves the pointer to the given position on the window.

Miscellaneous functions

- wxHitTest HitTest (wxCoord x, wxCoord y) const

  Return where the given point lies, exactly.
- wxHitTest HitTest (const wxPoint &pt) const

  This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.
- wxBorder GetBorder (long flags) const

  Get the window border style from the given flags: this is different from simply doing flags & wxBORDER_MASK because it uses GetDefaultBorder() to translate wxBORDER_DEFAULT to something reasonable.
- wxBorder GetBorder () const

  Get border for the flags of this window.
- virtual void DoUpdateWindowUI (wxUpdateUIEvent &event)

  Does the window-specific updating after processing the update event.
- virtual WXWidget GetHandle () const

  Returns the platform-specific handle of the physical window.
- virtual bool HasMultiplePages () const

  This method should be overridden to return true if this window has multiple pages.
- virtual void InheritAttributes ()

  This function is (or should be, in case of custom controls) called during window creation to intelligently set up the window visual attributes, that is the font and the foreground and background colours.
- virtual void InitDialog ()

  Sends an `wxEVT_INIT_DIALOG` event, whose handler usually transfers data to the dialog via validators.
- virtual bool IsDoubleBuffered () const

  Returns true if the window contents is double-buffered by the system, i.e. if any drawing done on the window is really done on a temporary backing surface and transferred to the screen all at once later.
- void SetDoubleBuffered (bool on)

  Turn on or off double buffering of the window if the system supports it.
- virtual bool IsRetained () const

  Returns true if the window is retained, false otherwise.
- bool IsThisEnabled () const

  Returns true if this window is intrinsically enabled, false otherwise, i.e. if Enable() Enable(false) had been called.
- virtual bool IsTopLevel () const

  Returns true if the given window is a top-level one.
- virtual void OnInternalIdle ()

  This virtual function is normally only used internally, but sometimes an application may need it to implement functionality that should not be disabled by an application defining an OnIdle handler in a derived class.
- virtual bool SendIdleEvents (wxIdleEvent &event)

  Send idle event to window and all subwindows.
- virtual bool RegisterHotKey (int hotkeyId, int modifiers, int virtualKeyCode)

  Registers a system wide hotkey.
- virtual bool UnregisterHotKey (int hotkeyId)

  Unregisters a system wide hotkey.
- virtual void UpdateWindowUI (long flags=wxUPDATE_UI_NONE)

  This function sends one or more wxUpdateUIEvent to the window.

Static Public Member Functions

Miscellaneous static functions

- static wxVisualAttributes GetClassDefaultAttributes (wxWindowVariant variant=wxWINDOW_VARIANT_NORMAL)

  Returns the default font and colours which are used by the control.
- static wxWindow * FindFocus ()

  Finds the window or control which currently has the keyboard focus.
- static wxWindow * FindWindowById (long id, const wxWindow *parent=0)

  Find the first window with the given id.
- static wxWindow * FindWindowByLabel (const wxString &label, const wxWindow *parent=0)

  Find a window by its label.
- static wxWindow * FindWindowByName (const wxString &name, const wxWindow *parent=0)

  Find a window by its name (as given in a window constructor or Create() function call).
- static wxWindow * GetCapture ()

  Returns the currently captured window.
- static wxWindowID NewControlId (int count=1)

  Create a new ID or range of IDs that are not currently in use.
- static void UnreserveControlId (wxWindowID id, int count=1)

  Unreserve an ID or range of IDs that was reserved by NewControlId().

Protected Member Functions

- virtual void DoCentre (int direction)

  Centres the window.
- virtual wxSize DoGetBestSize () const

  Implementation of GetBestSize() that can be overridden.
- virtual wxSize DoGetBestClientSize () const

  Override this method to return the best size for a custom control.
- virtual int DoGetBestClientHeight (int width) const

  Override this method to implement height-for-width best size calculation.
- virtual int DoGetBestClientWidth (int height) const

  Override this method to implement width-for-height best size calculation.
- virtual void SetInitialBestSize (const wxSize &size)

  Sets the initial window size if none is given (i.e. at least one of the components of the size passed to ctor/Create() is wxDefaultCoord).
- void SendDestroyEvent ()

  Generate wxWindowDestroyEvent for this window.
- virtual bool ProcessEvent (wxEvent &event)

  This function is public in wxEvtHandler but protected in wxWindow because for wxWindows you should always call ProcessEvent() on the pointer returned by GetEventHandler() and not on the wxWindow object itself.
- bool SafelyProcessEvent (wxEvent &event)

  See ProcessEvent() for more info about why you shouldn't use this function and the reason for making this function protected in wxWindow.
- virtual void QueueEvent (wxEvent *event)

  See ProcessEvent() for more info about why you shouldn't use this function and the reason for making this function protected in wxWindow.
- virtual void AddPendingEvent (const wxEvent &event)

  See ProcessEvent() for more info about why you shouldn't use this function and the reason for making this function protected in wxWindow.
- void ProcessPendingEvents ()

  See ProcessEvent() for more info about why you shouldn't use this function and the reason for making this function protected in wxWindow.
- bool ProcessThreadEvent (const wxEvent &event)

  See ProcessEvent() for more info about why you shouldn't use this function and the reason for making this function protected in wxWindow.

Additional Inherited Members

21.854.2 Constructor & Destructor Documentation

wxWindow::wxWindow ( )

Default constructor.

wxWindow::wxWindow (wxWindow * *parent*, wxWindowID *id*, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, long *style* = 0, const wxString & *name* = wxPanelNameStr)

Constructs a window, which can be a child of a frame, dialog or any other non-control window.

Parameters

parent	Pointer to a parent window.
id	Window identifier. If wxID_ANY, will automatically create an identifier.
pos	Window position. wxDefaultPosition indicates that wxWidgets should generate a default position for the window. If using the wxWindow class directly, supply an actual position.
size	Window size. wxDefaultSize indicates that wxWidgets should generate a default size for the window. If no suitable size can be found, the window will be sized to 20x20 pixels so that the window is visible but obviously not correctly sized.
style	Window style. For generic window styles, please see wxWindow.
name	Window name.

virtual wxWindow::~wxWindow ( ) [virtual]

Destructor.

Deletes all sub-windows, then deletes itself. Instead of using the **delete** operator explicitly, you should normally use Destroy() so that wxWidgets can delete a window only when it is safe to do so, in idle time.

See also

Window Deletion Overview, Destroy(), wxCloseEvent

21.854.3 Member Function Documentation

virtual bool wxWindow::AcceptsFocus ( ) const [virtual]

This method may be overridden in the derived classes to return false to indicate that this control doesn't accept input at all (i.e. behaves like e.g. wxStaticText) and so doesn't need focus.

See also

AcceptsFocusFromKeyboard()

Reimplemented in wxPanel.

virtual bool wxWindow::AcceptsFocusFromKeyboard ( ) const [virtual]

This method may be overridden in the derived classes to return false to indicate that while this control can, in principle, have focus if the user clicks it with the mouse, it shouldn't be included in the TAB traversal chain when using the keyboard.

virtual bool wxWindow::AcceptsFocusRecursively ( ) const `[virtual]`

Overridden to indicate whether this window or one of its children accepts focus.

Usually it's the same as AcceptsFocus() but is overridden for container windows.

virtual void wxWindow::AddChild (wxWindow * *child*) `[virtual]`

Adds a child window.

This is called automatically by window creation functions so should not be required by the application programmer. Notice that this function is mostly internal to wxWidgets and shouldn't be called by the user code.

Parameters

child	Child window to add.

virtual void wxWindow::AddPendingEvent (const wxEvent & *event*) `[protected], [virtual]`

See ProcessEvent() for more info about why you shouldn't use this function and the reason for making this function protected in wxWindow.

Reimplemented from wxEvtHandler.

virtual wxCoord wxWindow::AdjustForLayoutDirection (wxCoord *x*, wxCoord *width*, wxCoord *widthTotal*) const `[virtual]`

Mirror coordinates for RTL layout if this window uses it and if the mirroring is not done automatically like Win32.

virtual void wxWindow::AlwaysShowScrollbars (bool *hflag* = `true`, bool *vflag* = `true`) `[virtual]`

Call this function to force one or both scrollbars to be always shown, even if the window is big enough to show its entire contents without scrolling.

Since

2.9.0

Parameters

hflag	Whether the horizontal scroll bar should always be visible.
vflag	Whether the vertical scroll bar should always be visible.

Remarks

This function is currently only implemented under Mac/Carbon.

bool wxWindow::BeginRepositioningChildren ( )

Prepare for changing positions of multiple child windows.

This method should be called before changing positions of multiple child windows to reduce flicker and, in MSW case, even avoid display corruption in some cases. It is used internally by wxWidgets and called automatically when the window size changes but it can also be useful to call it from outside of the library if a repositioning involving multiple children is done without changing the window size.

If this method returns true, then EndRepositioningChildren() must be called after setting all children positions. Use ChildrenRepositioningGuard class to ensure that this requirement is satisfied.

Since

2.9.5

void wxWindow::CacheBestSize (const wxSize & *size*) const

Sets the cached best size value.

See also

GetBestSize()

bool wxWindow::CanAcceptFocus ( ) const

Can this window have focus right now?

If this method returns true, it means that calling SetFocus() will put focus either to this window or one of its children, if you need to know whether this window accepts focus itself, use IsFocusable()

bool wxWindow::CanAcceptFocusFromKeyboard ( ) const

Can this window be assigned focus from keyboard right now?

bool wxWindow::CanScroll (int *orient*) const

Returns true if this window can have a scroll bar in this orientation.

Parameters

orient	Orientation to check, either wxHORIZONTAL or wxVERTICAL.

Since

2.9.1

virtual bool wxWindow::CanSetTransparent ( ) [virtual]

Returns true if the system supports transparent windows and calling SetTransparent() may succeed.

If this function returns false, transparent windows are definitely not supported by the current system.

Reimplemented in wxTopLevelWindow.

void wxWindow::CaptureMouse ( )

Directs all mouse input to this window.

Call ReleaseMouse() to release the capture.

Note that wxWidgets maintains the stack of windows having captured the mouse and when the mouse is released the capture returns to the window which had had captured it previously and it is only really released if there were no previous window. In particular, this means that you must release the mouse as many times as you capture it, unless the window receives the wxMouseCaptureLostEvent event.

Any application which captures the mouse in the beginning of some operation must handle wxMouseCaptureLost↩Event and cancel this operation when it receives the event. The event handler must not recapture mouse.

See also

ReleaseMouse(), wxMouseCaptureLostEvent

void wxWindow::Center (int *dir* = **wxBOTH**)

A synonym for Centre().

void wxWindow::CenterOnParent (int *dir* = **wxBOTH**)

A synonym for CentreOnParent().

void wxWindow::Centre (int *direction* = **wxBOTH**)

Centres the window.

Parameters

direction	Specifies the direction for the centring. May be wxHORIZONTAL, wxVERTICAL or wxBOTH. It may also include the wxCENTRE_ON_SCREEN flag if you want to centre the window on the entire screen and not on its parent window.

Remarks

If the window is a top level one (i.e. doesn't have a parent), it will be centred relative to the screen anyhow.

See also

Center()

void wxWindow::CentreOnParent (int *direction* = **wxBOTH**)

Centres the window on its parent.

This is a more readable synonym for Centre().

Parameters

direction	Specifies the direction for the centring. May be wxHORIZONTAL, wxVERTICAL or wxBOTH.

Remarks

This methods provides for a way to centre top level windows over their parents instead of the entire screen. If there is no parent or if the window is not a top level window, then behaviour is the same as Centre().

See also

wxTopLevelWindow::CentreOnScreen

virtual void wxWindow::ClearBackground ( ) [virtual]

Clears the window by filling it with the current background colour.

Does not cause an erase background event to be generated.

Notice that this uses wxClientDC to draw on the window and the results of doing it while also drawing on wxPaintDC for this window are undefined. Hence this method shouldn't be used from EVT_PAINT handlers, just use wxDC::Clear() on the wxPaintDC you already use there instead.

void wxWindow::ClientToScreen (int * *x*, int * *y*) const

Converts to screen coordinates from coordinates relative to this window.

Parameters

x	A pointer to a integer value for the x coordinate. Pass the client coordinate in, and a screen coordinate will be passed out.
y	A pointer to a integer value for the y coordinate. Pass the client coordinate in, and a screen coordinate will be passed out.

wxPerl Note: In wxPerl this method returns a 2-element list instead of modifying its parameters.

wxPoint wxWindow::ClientToScreen (const wxPoint & *pt*) const

Converts to screen coordinates from coordinates relative to this window.

Parameters

pt	The client position for the second form of the function.

virtual wxSize wxWindow::ClientToWindowSize (const wxSize & *size*) const [virtual]

Converts client area size *size* to corresponding window size.

In other words, the returned value is what would GetSize() return if this window had client area of given size. Components with wxDefaultCoord value are left unchanged. Note that the conversion is not always exact, it assumes that non-client area doesn't change and so doesn't take into account things like menu bar (un)wrapping or (dis)appearance of the scrollbars.

Since

2.8.8

See also

WindowToClientSize()

bool wxWindow::Close (bool *force* = false)

This function simply generates a wxCloseEvent whose handler usually tries to close the window.

It doesn't close the window itself, however.

Parameters

force	false if the window's close handler should be able to veto the destruction of this window, true if it cannot.

Returns

true if the event was handled and not vetoed, false otherwise.

Remarks

Close calls the close handler for the window, providing an opportunity for the window to choose whether to destroy the window. Usually it is only used with the top level windows (wxFrame and wxDialog classes) as the others are not supposed to have any special OnClose() logic. The close handler should check whether the window is being deleted forcibly, using wxCloseEvent::CanVeto, in which case it should destroy the window using wxWindow::Destroy. Note that calling Close does not guarantee that the window will be destroyed; but it provides a way to simulate a manual close of a window, which may or may not be implemented by destroying the window. The default implementation of wxDialog::OnCloseWindow does not necessarily delete the dialog, since it will simply simulate an wxID_CANCEL event which is handled by the appropriate button event handler and may do anything at all. To guarantee that the window will be destroyed, call wxWindow::Destroy instead

See also

Window Deletion Overview, Destroy(), wxCloseEvent

wxPoint wxWindow::ConvertDialogToPixels (const wxPoint & *pt*) const

Converts a point or size from dialog units to pixels.

For the x dimension, the dialog units are multiplied by the average character width and then divided by 4. For the y dimension, the dialog units are multiplied by the average character height and then divided by 8.

Remarks

Dialog units are used for maintaining a dialog's proportions even if the font changes. You can also use these functions programmatically. A convenience macro is defined:

```
#define wxDLG_UNIT(parent, pt) parent->ConvertDialogToPixels(pt)
```

See also

ConvertPixelsToDialog()

wxSize wxWindow::ConvertDialogToPixels (const wxSize & *sz*) const

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.

wxPoint wxWindow::ConvertPixelsToDialog (const wxPoint & *pt*) const

Converts a point or size from pixels to dialog units.

For the x dimension, the pixels are multiplied by 4 and then divided by the average character width. For the y dimension, the pixels are multiplied by 8 and then divided by the average character height.

Remarks

Dialog units are used for maintaining a dialog's proportions even if the font changes.

See also

ConvertDialogToPixels()

wxSize wxWindow::ConvertPixelsToDialog (const wxSize & *sz*) const

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.

bool wxWindow::Create (wxWindow * *parent*, wxWindowID *id*, const wxPoint & *pos* = wxDefaultPosition, const wxSize & *size* = wxDefaultSize, long *style* = 0, const wxString & *name* = wxPanelNameStr)

virtual bool wxWindow::Destroy ( ) [virtual]

Destroys the window safely.

Use this function instead of the delete operator, since different window classes can be destroyed differently. Frames and dialogs are not destroyed immediately when this function is called – they are added to a list of windows to be deleted on idle time, when all the window's events have been processed. This prevents problems with events being sent to non-existent windows.

Returns

true if the window has either been successfully deleted, or it has been added to the list of windows pending real deletion.

bool wxWindow::DestroyChildren ( )

Destroys all children of a window.

Called automatically by the destructor.

bool wxWindow::Disable ( )

Disables the window.

Same as Enable() Enable(false).

Returns

Returns true if the window has been disabled, false if it had been already disabled before the call to this function.

virtual void wxWindow::DoCentre (int *direction*) [protected], [virtual]

Centres the window.

Parameters

direction	Specifies the direction for the centring. May be wxHORIZONTAL, wxVERTICAL or wxBOTH. It may also include the wxCENTRE_ON_SCREEN flag.

Remarks

This function is not meant to be called directly by user code, but via Centre, Center, CentreOnParent, or CenterOnParent. This function can be overridden to fine-tune centring behaviour.

virtual int wxWindow::DoGetBestClientHeight (int *width*) const [protected], [virtual]

Override this method to implement height-for-width best size calculation.

Return the height needed to fully display the control contents if its width is fixed to the given value. Custom classes implementing wrapping should override this method and return the height corresponding to the number of lines needed to lay out the control contents at this width.

Currently this method is not used by wxWidgets yet, however it is planned that it will be used by the new sizer classes implementing height-for-width layout strategy in the future.

Notice that implementing this method or even implementing both it and DoGetBestClientWidth() doesn't replace overriding DoGetBestClientSize(), i.e. you still need to implement the latter as well in order to provide the best size when neither width nor height are constrained.

By default returns wxDefaultCoord meaning that the vertical component of DoGetBestClientSize() return value should be used.

Since

2.9.4

virtual wxSize wxWindow::DoGetBestClientSize ( ) const `[protected], [virtual]`

Override this method to return the best size for a custom control.

A typical implementation of this method should compute the minimal size needed to fully display the control contents taking into account the current font size.

The default implementation simply returns wxDefaultSize and GetBestSize() returns an arbitrary hardcoded size for the window, so you must override it when implementing a custom window class.

Notice that the best size returned by this function is cached internally, so if anything that results in the best size changing (e.g. change to the control contents) happens, you need to call InvalidateBestSize() to notify wxWidgets about it.

See also

Window Sizing Overview

Since

2.9.0

virtual int wxWindow::DoGetBestClientWidth (int *height*) const `[protected], [virtual]`

Override this method to implement width-for-height best size calculation.

This method is exactly the same as DoGetBestClientHeight() except that it determines the width assuming the height is fixed instead of vice versa.

Since

2.9.4

virtual wxSize wxWindow::DoGetBestSize ( ) const `[protected], [virtual]`

Implementation of GetBestSize() that can be overridden.

Notice that it is usually more convenient to override DoGetBestClientSize() rather than this method itself as you need to explicitly account for the window borders size if you do the latter.

The default implementation of this function is designed for use in container windows, such as wxPanel, and works something like this:

1. If the window has a sizer then it is used to calculate the best size.
2. Otherwise if the window has layout constraints then those are used to calculate the best size.
3. Otherwise if the window has children then the best size is set to be large enough to show all the children.
4. Otherwise if there are no children then the window's minimal size will be used as its best size.
5. Otherwise if there is no minimal size set, then the current size is used for the best size.

See also

Window Sizing Overview

Reimplemented in wxRichTextCtrl.

virtual void wxWindow::DoUpdateWindowUI (wxUpdateUIEvent & *event*) [virtual]

Does the window-specific updating after processing the update event.

This function is called by UpdateWindowUI() in order to check return values in the wxUpdateUIEvent and act appropriately. For example, to allow frame and dialog title updating, wxWidgets implements this function as follows:

```
// do the window-specific processing after processing the update event
void wxTopLevelWindowBase::DoUpdateWindowUI(wxUpdateUIEvent& event)
{
    if ( event.GetSetEnabled() )
        Enable(event.GetEnabled());

    if ( event.GetSetText() )
    {
        if ( event.GetText() != GetTitle() )
            SetTitle(event.GetText());
    }
}
```

virtual void wxWindow::DragAcceptFiles (bool *accept*) [virtual]

Enables or disables eligibility for drop file events (OnDropFiles).

Parameters

accept	If true, the window is eligible for drop file events. If false, the window will not accept drop file events.

Remarks

Windows only until version 2.8.9, available on all platforms since 2.8.10. Cannot be used together with SetDropTarget() on non-Windows platforms.

See also

SetDropTarget()

virtual bool wxWindow::Enable (bool *enable* = true) [virtual]

Enable or disable the window for user input.

Note that when a parent window is disabled, all of its children are disabled as well and they are reenabled again when the parent is.

Parameters

enable	If true, enables the window for input. If false, disables the window.

Returns

Returns true if the window has been enabled or disabled, false if nothing was done, i.e. if the window had already been in the specified state.

See also

IsEnabled(), Disable(), wxRadioBox::Enable

void wxWindow::EndRepositioningChildren ( )

Fix child window positions after setting all of them at once.

This method must be called if and only if the previous call to BeginRepositioningChildren() returned true.

Since

2.9.5

static wxWindow* wxWindow::FindFocus ( ) [static]

Finds the window or control which currently has the keyboard focus.

Remarks

Note that this is a static function, so it can be called without needing a wxWindow pointer.

See also

SetFocus(), HasFocus()

wxWindow* wxWindow::FindWindow (long *id*) const

Find a child of this window, by *id*.

May return *this* if it matches itself.

Notice that only real children, not top level windows using this window as parent, are searched by this function.

wxWindow* wxWindow::FindWindow (const wxString & *name*) const

Find a child of this window, by name.

May return *this* if it matches itself.

Notice that only real children, not top level windows using this window as parent, are searched by this function.

static wxWindow* wxWindow::FindWindowById (long *id,* const wxWindow * *parent* = 0) [static]

Find the first window with the given *id*.

If *parent* is NULL, the search will start from all top-level frames and dialog boxes; if non-NULL, the search will be limited to the given window hierarchy. The search is recursive in both cases.

See also

FindWindow()

Returns

Window with the given *id* or NULL if not found.

static wxWindow* wxWindow::FindWindowByLabel (const wxString & *label,* const wxWindow * *parent* = 0) [static]

Find a window by its label.

Depending on the type of window, the label may be a window title or panel item label. If *parent* is NULL, the search will start from all top-level frames and dialog boxes; if non-NULL, the search will be limited to the given window hierarchy. The search is recursive in both cases.

See also

FindWindow()

Returns

Window with the given *label* or NULL if not found.

static wxWindow* wxWindow::FindWindowByName (const wxString & *name,* const wxWindow * *parent* = 0) [static]

Find a window by its name (as given in a window constructor or Create() function call).

If *parent* is NULL, the search will start from all top-level frames and dialog boxes; if non-NULL, the search will be limited to the given window hierarchy.

The search is recursive in both cases. If no window with such name is found, FindWindowByLabel() is called.

See also

FindWindow()

Returns

Window with the given *name* or NULL if not found.

virtual void wxWindow::Fit ( ) [virtual]

Sizes the window so that it fits around its subwindows.

This function won't do anything if there are no subwindows and will only really work correctly if sizers are used for the subwindows layout.

Also, if the window has exactly one subwindow it is better (faster and the result is more precise as Fit() adds some margin to account for fuzziness of its calculations) to call:

```
window->SetClientSize(child->GetSize());
```

instead of calling Fit().

See also

Window Sizing Overview

virtual void wxWindow::FitInside ( ) [virtual]

Similar to Fit(), but sizes the interior (virtual) size of a window.

Mainly useful with scrolled windows to reset scrollbars after sizing changes that do not trigger a size event, and/or scrolled windows without an interior sizer. This function similarly won't do anything if there are no subwindows.

void wxWindow::Freeze ( )

Freezes the window or, in other words, prevents any updates from taking place on screen, the window is not redrawn at all.

Thaw() must be called to reenable window redrawing. Calls to these two functions may be nested but to ensure that the window is properly repainted again, you must thaw it exactly as many times as you froze it.

If the window has any children, they are recursively frozen too.

This method is useful for visual appearance optimization (for example, it is a good idea to use it before doing many large text insertions in a row into a wxTextCtrl under wxGTK) but is not implemented on all platforms nor for all controls so it is mostly just a hint to wxWidgets and not a mandatory directive.

See also

wxWindowUpdateLocker, Thaw(), IsFrozen()

wxAcceleratorTable* wxWindow::GetAcceleratorTable ( )

Gets the accelerator table for this window.

See wxAcceleratorTable.

wxAccessible* wxWindow::GetAccessible ( )

Returns the accessible object for this window, if any.

See also wxAccessible.

bool wxWindow::GetAutoLayout ( ) const

Returns the sizer of which this window is a member, if any, otherwise NULL.

wxColour wxWindow::GetBackgroundColour ( ) const

Returns the background colour of the window.

See also

SetBackgroundColour(), SetForegroundColour(), GetForegroundColour()

virtual wxBackgroundStyle wxWindow::GetBackgroundStyle ( ) const `[virtual]`

Returns the background style of the window.

See also

SetBackgroundColour(), GetForegroundColour(), SetBackgroundStyle(), SetTransparent()

int wxWindow::GetBestHeight (int *width*) const

Returns the best height needed by this window if it had the given width.

See also

DoGetBestClientHeight()

Since

2.9.4

wxSize wxWindow::GetBestSize ( ) const

This functions returns the best acceptable minimal size for the window.

For example, for a static control, it will be the minimal size such that the control label is not truncated. For windows containing subwindows (typically wxPanel), the size returned by this function will be the same as the size the window would have had after calling Fit().

Override virtual DoGetBestSize() or, better, because it's usually more convenient, DoGetBestClientSize() when writing your own custom window class to change the value returned by this public non-virtual method.

Notice that the best size respects the minimal and maximal size explicitly set for the window, if any. So even if some window believes that it needs 200 pixels horizontally, calling SetMaxSize() with a width of 100 would ensure that GetBestSize() returns the width of at most 100 pixels.

See also

CacheBestSize(), Window Sizing Overview

virtual wxSize wxWindow::GetBestVirtualSize ( ) const `[virtual]`

Return the largest of ClientSize and BestSize (as determined by a sizer, interior children, or other means)

int wxWindow::GetBestWidth (int *height*) const

Returns the best width needed by this window if it had the given height.

See also

DoGetBestClientWidth()

Since

2.9.4

wxBorder wxWindow::GetBorder (long *flags*) const

Get the window border style from the given flags: this is different from simply doing flags & wxBORDER_MASK because it uses GetDefaultBorder() to translate wxBORDER_DEFAULT to something reasonable.

wxBorder wxWindow::GetBorder ( ) const

Get border for the flags of this window.

static wxWindow* wxWindow::GetCapture ( ) [static]

Returns the currently captured window.

See also

HasCapture(), CaptureMouse(), ReleaseMouse(), wxMouseCaptureLostEvent, wxMouseCaptureChanged↩ Event

wxCaret* wxWindow::GetCaret ( ) const

Returns the caret() associated with the window.

virtual int wxWindow::GetCharHeight ( ) const [virtual]

Returns the character height for this window.

virtual int wxWindow::GetCharWidth ( ) const [virtual]

Returns the average character width for this window.

wxWindowList& wxWindow::GetChildren ( )

Returns a reference to the list of the window's children.

`wxWindowList` is a type-safe wxList-like class whose elements are of type `wxWindow*`.

const wxWindowList& wxWindow::GetChildren ( ) const

Returns a const reference to the list of the window's children.

`wxWindowList` is a type-safe wxList-like class whose elements are of type `wxWindow*`.

static wxVisualAttributes wxWindow::GetClassDefaultAttributes (wxWindowVariant *variant* = wxWINDOW_VARIANT_NORMAL) [static]

Returns the default font and colours which are used by the control.

This is useful if you want to use the same font or colour in your own control as in a standard control – which is a much better idea than hard coding specific colours or fonts which might look completely out of place on the users system, especially if it uses themes.

The *variant* parameter is only relevant under Mac currently and is ignore under other platforms. Under Mac, it will change the size of the returned font. See SetWindowVariant() for more about this.

This static method is "overridden" in many derived classes and so calling, for example, wxButton::GetClassDefault↩ Attributes() will typically return the values appropriate for a button which will be normally different from those returned by, say, wxListCtrl::GetClassDefaultAttributes().

The `wxVisualAttributes` structure has at least the fields `font`, `colFg` and `colBg`. All of them may be invalid if it was not possible to determine the default control appearance or, especially for the background colour, if the field doesn't make sense as is the case for `colBg` for the controls with themed background.

See also

InheritAttributes()

virtual wxPoint wxWindow::GetClientAreaOrigin ( ) const [virtual]

Get the origin of the client area of the window relative to the window top left corner (the client area may be shifted because of the borders, scrollbars, other decorations...)

Reimplemented in wxFrame.

wxRect wxWindow::GetClientRect ( ) const

Get the client rectangle in window (i.e. client) coordinates.

void wxWindow::GetClientSize (int * *width*, int * *height*) const

Returns the size of the window 'client area' in pixels.

The client area is the area which may be drawn on by the programmer, excluding title bar, border, scrollbars, etc. Note that if this window is a top-level one and it is currently minimized, the return size is empty (both width and height are 0).

wxPerl Note: In wxPerl this method takes no parameters and returns a 2-element list (width, height).

See also

GetSize(), GetVirtualSize()

wxSize wxWindow::GetClientSize ( ) const

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.

wxLayoutConstraints* wxWindow::GetConstraints ( ) const

Returns a pointer to the window's layout constraints, or NULL if there are none.

wxSizer* wxWindow::GetContainingSizer ( ) const

Returns the sizer of which this window is a member, if any, otherwise NULL.

virtual double wxWindow::GetContentScaleFactor ( ) const [virtual]

Returns the magnification of the backing store of this window, eg 2.0 for a window on a retina screen.

Since

2.9.5

const wxCursor& wxWindow::GetCursor ( ) const

Return the cursor associated with this window.

See also

SetCursor()

virtual wxVisualAttributes wxWindow::GetDefaultAttributes ( ) const [virtual]

Currently this is the same as calling wxWindow::GetClassDefaultAttributes(wxWindow::GetWindowVariant()).

One advantage of using this function compared to the static version is that the call is automatically dispatched to the correct class (as usual with virtual functions) and you don't have to specify the class name explicitly.

The other one is that in the future this function could return different results, for example it might return a different font for an "Ok" button than for a generic button if the users GUI is configured to show such buttons in bold font. Of course, the down side is that it is impossible to call this function without actually having an object to apply it to whereas the static version can be used without having to create an object first.

virtual wxDropTarget* wxWindow::GetDropTarget ( ) const [virtual]

Returns the associated drop target, which may be NULL.

See also

SetDropTarget(), Drag and Drop Overview

virtual wxSize wxWindow::GetEffectiveMinSize ( ) const [virtual]

Merges the window's best size into the min size and returns the result.

This is the value used by sizers to determine the appropriate amount of space to allocate for the widget.

This is the method called by a wxSizer when it queries the size of a window or control.

See also

GetBestSize(), SetInitialSize(), Window Sizing Overview

wxEvtHandler* wxWindow::GetEventHandler ( ) const

Returns the event handler for this window.

By default, the window is its own event handler.

See also

SetEventHandler(), PushEventHandler(), PopEventHandler(), wxEvtHandler::ProcessEvent, wxEvtHandler

long wxWindow::GetExtraStyle ( ) const

Returns the extra style bits for the window.

wxFont wxWindow::GetFont ( ) const

Returns the font for this window.

See also

SetFont()

wxColour wxWindow::GetForegroundColour ( ) const

Returns the foreground colour of the window.

Remarks

The meaning of foreground colour varies according to the window class; it may be the text colour or other colour, or it may not be used at all.

See also

SetForegroundColour(), SetBackgroundColour(), GetBackgroundColour()

wxWindow* wxWindow::GetGrandParent ( ) const

Returns the grandparent of a window, or NULL if there isn't one.

virtual WXWidget wxWindow::GetHandle ( ) const `[virtual]`

Returns the platform-specific handle of the physical window.

Cast it to an appropriate handle, such as **HWND** for Windows, **Widget** for Motif or **GtkWidget** for GTK.

wxPerl Note: This method will return an integer in wxPerl.

wxString wxWindow::GetHelpText ( ) const

Gets the help text to be used as context-sensitive help for this window.

Note that the text is actually stored by the current wxHelpProvider implementation, and not in the window object itself.

See also

SetHelpText(), GetHelpTextAtPoint(), wxHelpProvider

virtual wxString wxWindow::GetHelpTextAtPoint (const wxPoint & *point*, wxHelpEvent::Origin *origin*) const `[virtual]`

Gets the help text to be used as context-sensitive help for this window.

This method should be overridden if the help message depends on the position inside the window, otherwise GetHelpText() can be used.

Parameters

point	Coordinates of the mouse at the moment of help event emission.
origin	Help event origin, see also wxHelpEvent::GetOrigin.

wxWindowID wxWindow::GetId ( ) const

Returns the identifier of the window.

Remarks

Each window has an integer identifier. If the application has not provided one (or the default wxID_ANY) a unique identifier with a negative value will be generated.

See also

SetId(), Window IDs

virtual wxString wxWindow::GetLabel ( ) const [virtual]

Generic way of getting a label from any window, for identification purposes.

Remarks

The interpretation of this function differs from class to class. For frames and dialogs, the value returned is the title. For buttons or static text controls, it is the button text. This function can be useful for meta-programs (such as testing tools or special-needs access programs) which need to identify windows by name.

Reimplemented in wxButton, wxControl, and wxCommandLinkButton.

virtual wxLayoutDirection wxWindow::GetLayoutDirection ( ) const [virtual]

Returns the layout direction for this window, Note that `wxLayout_Default` is returned if layout direction is not supported.

virtual wxSize wxWindow::GetMaxClientSize ( ) const [virtual]

Returns the maximum size of window's client area.

This is an indication to the sizer layout mechanism that this is the maximum possible size as well as the upper bound on window's size settable using SetClientSize().

See also

GetMaxSize(), Window Sizing Overview

int wxWindow::GetMaxHeight ( ) const

Returns the vertical component of window maximal size.

The returned value is wxDefaultCoord if the maximal width was not set.

See also

GetMaxSize()

virtual wxSize wxWindow::GetMaxSize ( ) const [virtual]

Returns the maximum size of the window.

This is an indication to the sizer layout mechanism that this is the maximum possible size as well as the upper bound on window's size settable using SetSize().

See also

GetMaxClientSize(), Window Sizing Overview

int wxWindow::GetMaxWidth ( ) const

Returns the horizontal component of window maximal size.

The returned value is wxDefaultCoord if the maximal width was not set.

See also

GetMaxSize()

virtual wxSize wxWindow::GetMinClientSize ( ) const `[virtual]`

Returns the minimum size of window's client area, an indication to the sizer layout mechanism that this is the minimum required size of its client area.

It normally just returns the value set by SetMinClientSize(), but it can be overridden to do the calculation on demand.

See also

GetMinSize(), Window Sizing Overview

int wxWindow::GetMinHeight ( ) const

Returns the vertical component of window minimal size.

The returned value is wxDefaultCoord if the minimal height was not set.

See also

GetMinSize()

virtual wxSize wxWindow::GetMinSize ( ) const `[virtual]`

Returns the minimum size of the window, an indication to the sizer layout mechanism that this is the minimum required size.

This method normally just returns the value set by SetMinSize(), but it can be overridden to do the calculation on demand.

See also

GetMinClientSize(), Window Sizing Overview

int wxWindow::GetMinWidth ( ) const

Returns the horizontal component of window minimal size.

The returned value is wxDefaultCoord if the minimal width was not set.

See also

GetMinSize()

virtual wxString wxWindow::GetName ( ) const `[virtual]`

Returns the window's name.

Remarks

This name is not guaranteed to be unique; it is up to the programmer to supply an appropriate name in the window constructor or via SetName().

See also

SetName()

wxWindow* wxWindow::GetNextSibling ( ) const

Returns the next window after this one among the parent's children or NULL if this window is the last child.

Since

2.8.8

See also

GetPrevSibling()

wxWindow* wxWindow::GetParent ( ) const

Returns the parent of the window, or NULL if there is no parent.

int wxWindow::GetPopupMenuSelectionFromUser (wxMenu & *menu,* const wxPoint & *pos* = wxDefaultPosition)

This function shows a popup menu at the given position in this window and returns the selected id.

It can be more convenient than the general purpose PopupMenu() function for simple menus proposing a choice in a list of strings to the user.

Notice that to avoid unexpected conflicts between the (usually consecutive range of) ids used by the menu passed to this function and the existing EVT_UPDATE_UI() handlers, this function temporarily disables UI updates for the window, so you need to manually disable (or toggle or ...) any items which should be disabled in the menu before showing it.

The parameter *menu* is the menu to show. The parameter *pos* (or the parameters *x* and *y*) is the position at which to show the menu in client coordinates. It is recommended to not explicitly specify coordinates when calling this method in response to mouse click, because some of the ports (namely, wxGTK) can do a better job of positioning the menu in that case.

Returns

The selected menu item id or `wxID_NONE` if none selected or an error occurred.

Since

2.9.0

int wxWindow::GetPopupMenuSelectionFromUser (wxMenu & *menu,* int *x,* int *y*)

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.

void wxWindow::GetPosition (int * *x*, int * *y*) const

This gets the position of the window in pixels, relative to the parent window for the child windows or relative to the display origin for the top level windows.

Parameters

x	Receives the x position of the window if non-NULL.
y	Receives the y position of the window if non-NULL.

wxPerl Note: In wxPerl this method is implemented as GetPositionXY() returning a 2-element list (x, y).

See also

GetScreenPosition()

wxPoint wxWindow::GetPosition ( ) const

This gets the position of the window in pixels, relative to the parent window for the child windows or relative to the display origin for the top level windows.

See also

GetScreenPosition()

wxWindow* wxWindow::GetPrevSibling ( ) const

Returns the previous window before this one among the parent's children or NULL if this window is the first child.

Since

2.8.8

See also

GetNextSibling()

wxRect wxWindow::GetRect ( ) const

Returns the position and size of the window as a wxRect object.

See also

GetScreenRect()

void wxWindow::GetScreenPosition (int* *x*, int* *y*) const

Returns the window position in screen coordinates, whether the window is a child window or a top level one.

Parameters

x	Receives the x position of the window on the screen if non-NULL.
y	Receives the y position of the window on the screen if non-NULL.

See also

GetPosition()

wxPoint wxWindow::GetScreenPosition ( ) const

Returns the window position in screen coordinates, whether the window is a child window or a top level one.

See also

GetPosition()

wxRect wxWindow::GetScreenRect ( ) const

Returns the position and size of the window on the screen as a wxRect object.

See also

GetRect()

virtual int wxWindow::GetScrollPos (int *orientation*) const `[virtual]`

Returns the built-in scrollbar position.

See also

SetScrollbar()

virtual int wxWindow::GetScrollRange (int *orientation*) const `[virtual]`

Returns the built-in scrollbar range.

See also

SetScrollbar()

virtual int wxWindow::GetScrollThumb (int *orientation*) const `[virtual]`

Returns the built-in scrollbar thumb size.

See also

SetScrollbar()

void wxWindow::GetSize (int * *width,* int * *height*) const

Returns the size of the entire window in pixels, including title bar, border, scrollbars, etc.

Note that if this window is a top-level one and it is currently minimized, the returned size is the restored window size, not the size of the window icon.

Parameters

width	Receives the window width.

height	Receives the window height.

wxPerl Note: In wxPerl this method is implemented as GetSizeWH() returning a 2-element list (width, height).

See also

GetClientSize(), GetVirtualSize(), Window Sizing Overview

wxSize wxWindow::GetSize ( ) const

See the GetSize(int*,int*) overload for more info.

wxSizer* wxWindow::GetSizer ( ) const

Returns the sizer associated with the window by a previous call to SetSizer(), or NULL.

void wxWindow::GetTextExtent (const wxString & *string*, int * *w*, int * *h*, int * *descent* = NULL, int * *externalLeading* = NULL, const wxFont * *font* = NULL) const

Gets the dimensions of the string as it would be drawn on the window with the currently selected font.

The text extent is returned in the *w* and *h* pointers.

Parameters

string	String whose extent is to be measured.
w	Return value for width.
h	Return value for height.
descent	Return value for descent (optional).
externalLeading	Return value for external leading (optional).
font	Font to use instead of the current window font (optional).

wxPerl Note: In wxPerl this method takes only the *string* and optionally *font* parameters, and returns a 4-element list (x, y, descent, externalLeading).

wxSize wxWindow::GetTextExtent (const wxString & *string*) const

Gets the dimensions of the string as it would be drawn on the window with the currently selected font.

virtual bool wxWindow::GetThemeEnabled ( ) const [virtual]

Clears the window by filling it with the current background colour.

Does not cause an erase background event to be generated.

Notice that this uses wxClientDC to draw on the window and the results of doing it while also drawing on wxPaintDC for this window are undefined. Hence this method shouldn't be used from EVT_PAINT handlers, just use wxDC::Clear() on the wxPaintDC you already use there instead.

wxToolTip* wxWindow::GetToolTip ( ) const

Get the associated tooltip or NULL if none.

wxString wxWindow::GetToolTipText ( ) const

Get the text of the associated tooltip or empty string if none.

wxRect wxWindow::GetUpdateClientRect ( ) const

Get the update rectangle bounding box in client coords.

const wxRegion& wxWindow::GetUpdateRegion ( ) const

Returns the region specifying which parts of the window have been damaged.

Should only be called within an wxPaintEvent handler.

See also

wxRegion, wxRegionIterator

virtual wxValidator* wxWindow::GetValidator ( ) [virtual]

Validator functions.

Returns a pointer to the current validator for the window, or NULL if there is none.

wxSize wxWindow::GetVirtualSize ( ) const

This gets the virtual size of the window in pixels.

By default it returns the client size of the window, but after a call to SetVirtualSize() it will return the size set with that method.

See also

Window Sizing Overview

void wxWindow::GetVirtualSize (int * *width*, int * *height*) const

Like the other GetVirtualSize() overload but uses pointers instead.

Parameters

width	Receives the window virtual width.
height	Receives the window virtual height.

virtual wxSize wxWindow::GetWindowBorderSize ( ) const [virtual]

Returns the size of the left/right and top/bottom borders of this window in x and y components of the result respectively.

long wxWindow::GetWindowStyle ( ) const

See GetWindowStyleFlag() for more info.

virtual long wxWindow::GetWindowStyleFlag ( ) const [virtual]

Gets the window style that was passed to the constructor or Create() method.

GetWindowStyle() is another name for the same function.

Reimplemented in wxAuiToolBar.

wxWindowVariant wxWindow::GetWindowVariant ( ) const

Returns the value previously passed to SetWindowVariant().

bool wxWindow::HandleAsNavigationKey (const wxKeyEvent & *event*)

This function will generate the appropriate call to Navigate() if the key event is one normally used for keyboard navigation and return true in this case.

Returns

Returns true if the key pressed was for navigation and was handled, false otherwise.

See also

Navigate()

bool wxWindow::HandleWindowEvent (wxEvent & *event*) const

Shorthand for:

```
GetEventHandler()->SafelyProcessEvent(event);
```

See also

ProcessWindowEvent()

virtual bool wxWindow::HasCapture ( ) const [virtual]

Returns true if this window has the current mouse capture.

See also

CaptureMouse(), ReleaseMouse(), wxMouseCaptureLostEvent, wxMouseCaptureChangedEvent

bool wxWindow::HasExtraStyle (int *exFlag*) const

Returns true if the window has the given *exFlag* bit set in its extra styles.

See also

SetExtraStyle()

bool wxWindow::HasFlag (int *flag*) const

Returns true if the window has the given *flag* bit set.

virtual bool wxWindow::HasFocus ( ) const `[virtual]`

Returns true if the window (or in case of composite controls, its main child window) has focus.

Since

2.9.0

See also

FindFocus()

virtual bool wxWindow::HasMultiplePages ( ) const `[virtual]`

This method should be overridden to return true if this window has multiple pages.

All standard class with multiple pages such as wxNotebook, wxListbook and wxTreebook already override it to return true and user-defined classes with similar behaviour should also do so, to allow the library to handle such windows appropriately.

bool wxWindow::HasScrollbar (int *orient*) const

Returns true if this window currently has a scroll bar for this orientation.

This method may return false even when CanScroll() for the same orientation returns true, but if CanScroll() returns false, i.e. scrolling in this direction is not enabled at all, HasScrollbar() always returns false as well.

Parameters

orient	Orientation to check, either wxHORIZONTAL or wxVERTICAL.

virtual bool wxWindow::HasTransparentBackground ( ) `[virtual]`

Returns true if this window background is transparent (as, for example, for wxStaticText) and should show the parent window background.

This method is mostly used internally by the library itself and you normally shouldn't have to call it. You may, however, have to override it in your wxWindow-derived class to ensure that background is painted correctly.

bool wxWindow::Hide ( )

Equivalent to calling wxWindow::Show(false).

virtual bool wxWindow::HideWithEffect (wxShowEffect *effect*, unsigned int *timeout* = 0) `[virtual]`

This function hides a window, like Hide(), but using a special visual effect if possible.

The parameters of this function are the same as for ShowWithEffect(), please see their description there.

Since

2.9.0

wxHitTest wxWindow::HitTest (wxCoord *x*, wxCoord *y*) const

Return where the given point lies, exactly.

This method is used to test whether the point lies inside the client window area or on one of its scrollbars.

The point coordinates are specified in client window coordinates.

wxHitTest wxWindow::HitTest (const wxPoint & *pt*) const

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.

virtual bool wxWindow::InformFirstDirection (int *direction*, int *size*, int *availableOtherDir*) [virtual]

wxSizer and friends use this to give a chance to a component to recalc its min size once one of the final size components is known.

Override this function when that is useful (such as for wxStaticText which can stretch over several lines). Parameter availableOtherDir tells the item how much more space there is available in the opposite direction (-1 if unknown).

virtual void wxWindow::InheritAttributes ( ) [virtual]

This function is (or should be, in case of custom controls) called during window creation to intelligently set up the window visual attributes, that is the font and the foreground and background colours.

By "intelligently" the following is meant: by default, all windows use their own GetClassDefaultAttributes() default attributes. However if some of the parents attributes are explicitly (that is, using SetFont() and not wxWindow::SetOwnFont) changed and if the corresponding attribute hadn't been explicitly set for this window itself, then this window takes the same value as used by the parent. In addition, if the window overrides ShouldInheritColours() to return false, the colours will not be changed no matter what and only the font might.

This rather complicated logic is necessary in order to accommodate the different usage scenarios. The most common one is when all default attributes are used and in this case, nothing should be inherited as in modern GUIs different controls use different fonts (and colours) than their siblings so they can't inherit the same value from the parent. However it was also deemed desirable to allow to simply change the attributes of all children at once by just changing the font or colour of their common parent, hence in this case we do inherit the parents attributes.

bool wxWindow::InheritsBackgroundColour ( ) const

Return true if this window inherits the background colour from its parent.

See also

SetOwnBackgroundColour(), InheritAttributes()

virtual void wxWindow::InitDialog ( ) [virtual]

Sends an `wxEVT_INIT_DIALOG` event, whose handler usually transfers data to the dialog via validators.

Reimplemented in wxPanel.

void wxWindow::InvalidateBestSize ( )

Resets the cached best size value so it will be recalculated the next time it is needed.

See also

CacheBestSize()

bool wxWindow::IsBeingDeleted ( ) const

Returns true if this window is in process of being destroyed.

Top level windows are not deleted immediately but are rather scheduled for later destruction to give them time to process any pending messages; see Destroy() description.

This function returns true if this window, or one of its parent windows, is scheduled for destruction and can be useful to avoid manipulating it as it's usually useless to do something with a window which is on the point of disappearing anyhow.

bool wxWindow::IsDescendant (wxWindowBase * *win*) const

Check if the specified window is a descendant of this one.

Returns true if the window is a descendant (i.e. a child or grand-child or grand-grand-child or ...) of this one.

Notice that a window can never be a descendant of another one if they are in different top level windows, i.e. a child of a wxDialog is not considered to be a descendant of dialogs parent wxFrame.

Parameters

win	Any window, possible NULL (false is always returned then).

Since

2.9.4

virtual bool wxWindow::IsDoubleBuffered ( ) const `[virtual]`

Returns true if the window contents is double-buffered by the system, i.e. if any drawing done on the window is really done on a temporary backing surface and transferred to the screen all at once later.

See also

wxBufferedDC

bool wxWindow::IsEnabled ( ) const

Returns true if the window is enabled, i.e. if it accepts user input, false otherwise.

Notice that this method can return false even if this window itself hadn't been explicitly disabled when one of its parent windows is disabled. To get the intrinsic status of this window, use IsThisEnabled()

See also

Enable()

bool wxWindow::IsExposed (int *x*, int *y*) const

Returns true if the given point or rectangle area has been exposed since the last repaint.

Call this in an paint event handler to optimize redrawing by only redrawing those areas, which have been exposed.

bool wxWindow::IsExposed (wxPoint & *pt*) const

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.

bool wxWindow::IsExposed (int *x,* int *y,* int *w,* int *h*) const

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.

bool wxWindow::IsExposed (wxRect & *rect*) const

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.

bool wxWindow::IsFocusable ( ) const

Can this window itself have focus?

bool wxWindow::IsFrozen ( ) const

Returns true if the window is currently frozen by a call to Freeze().

See also

Freeze(), Thaw()

virtual bool wxWindow::IsRetained ( ) const `[virtual]`

Returns true if the window is retained, false otherwise.

Remarks

Retained windows are only available on X platforms.

virtual bool wxWindow::IsScrollbarAlwaysShown (int *orient*) const `[virtual]`

Return whether a scrollbar is always shown.

Parameters

orient	Orientation to check, either wxHORIZONTAL or wxVERTICAL.

See also

AlwaysShowScrollbars()

virtual bool wxWindow::IsShown ( ) const `[virtual]`

Returns true if the window is shown, false if it has been hidden.

See also

IsShownOnScreen()

virtual bool wxWindow::IsShownOnScreen ( ) const `[virtual]`

Returns true if the window is physically visible on the screen, i.e. it is shown and all its parents up to the toplevel window are shown as well.

See also

IsShown()

bool wxWindow::IsThisEnabled ( ) const

Returns true if this window is intrinsically enabled, false otherwise, i.e. if Enable() Enable(false) had been called.

This method is mostly used for wxWidgets itself, user code should normally use IsEnabled() instead.

virtual bool wxWindow::IsTopLevel ( ) const `[virtual]`

Returns true if the given window is a top-level one.

Currently all frames and dialogs are considered to be top-level windows (even if they have a parent window).

virtual bool wxWindow::IsTransparentBackgroundSupported (wxString * *reason* = NULL) const `[virtual]`

Checks whether using transparent background might work.

If this function returns false, calling SetBackgroundStyle() with wxBG_STYLE_TRANSPARENT is not going to work. If it returns true, setting transparent style should normally succeed.

Notice that this function would typically be called on the parent of a window you want to set transparent background style for as the window for which this method is called must be fully created.

Parameters

reason	If not NULL, a reason message is provided if transparency is not supported.

Returns

true if background transparency is supported.

Since

2.9.4

virtual bool wxWindow::Layout ( ) `[virtual]`

Invokes the constraint-based layout algorithm or the sizer-based algorithm for this window.

This function does not get called automatically when the window is resized because lots of windows deriving from wxWindow does not need this functionality. If you want to have Layout() called automatically, you should derive from wxPanel (see wxPanel::Layout).

See also

Window Sizing Overview

Reimplemented in wxTopLevelWindow, and wxPanel.

bool wxWindow::LineDown ( )

Same as ScrollLines (1).

bool wxWindow::LineUp ( )

Same as ScrollLines (-1).

virtual void wxWindow::Lower ( ) [virtual]

Lowers the window to the bottom of the window hierarchy (Z-order).

Remarks

This function only works for wxTopLevelWindow-derived classes.

See also

Raise()

void wxWindow::Move (int *x*, int *y*, int *flags* = wxSIZE_USE_EXISTING)

Moves the window to the given position.

Parameters

x	Required x position.
y	Required y position.
flags	See SetSize() for more info about this parameter.

Remarks

Implementations of SetSize can also implicitly implement the Move() function, which is defined in the base wxWindow class as the call:

```
SetSize(x, y, wxDefaultCoord, wxDefaultCoord,
      wxSIZE_USE_EXISTING);
```

See also

SetSize()

void wxWindow::Move (const wxPoint & *pt*, int *flags* = wxSIZE_USE_EXISTING)

Moves the window to the given position.

Parameters

pt	wxPoint object representing the position.
flags	See SetSize() for more info about this parameter.

Remarks

Implementations of SetSize() can also implicitly implement the Move() function, which is defined in the base wxWindow class as the call:

```
SetSize(x, y, wxDefaultCoord, wxDefaultCoord,
      wxSIZE_USE_EXISTING);
```

See also

SetSize()

void wxWindow::MoveAfterInTabOrder (wxWindow * *win*)

Moves this window in the tab navigation order after the specified *win*.

This means that when the user presses `TAB` key on that other window, the focus switches to this window.

Default tab order is the same as creation order, this function and MoveBeforeInTabOrder() allow to change it after creating all the windows.

Parameters

win	A sibling of this window which should precede it in tab order, must not be NULL

void wxWindow::MoveBeforeInTabOrder (wxWindow * *win*)

Same as MoveAfterInTabOrder() except that it inserts this window just before *win* instead of putting it right after it.

bool wxWindow::Navigate (int *flags* = wxNavigationKeyEvent::IsForward)

Performs a keyboard navigation action starting from this window.

This method is equivalent to calling NavigateIn() method on the parent window.

Parameters

flags	A combination of wxNavigationKeyEvent::IsForward and wxNavigationKeyEvent::WinChange.

Returns

Returns true if the focus was moved to another window or false if nothing changed.

Remarks

You may wish to call this from a text control custom keypress handler to do the default navigation behaviour for the tab key, since the standard default behaviour for a multiline text control with the wxTE_PROCESS_TAB style is to insert a tab and not navigate to the next control. See also wxNavigationKeyEvent and HandleAsNavigationKey.

bool wxWindow::NavigateIn (int *flags* = wxNavigationKeyEvent::IsForward)

Performs a keyboard navigation action inside this window.

See Navigate() for more information.

static wxWindowID wxWindow::NewControlId (int *count* = `1`) `[static]`

Create a new ID or range of IDs that are not currently in use.

The IDs will be reserved until assigned to a wxWindow ID or unreserved with UnreserveControlId().

See Window IDs for more information.

Parameters

count	The number of sequential IDs to reserve.

Returns

Returns the ID or the first ID of the range (i.e. the most negative), or wxID_NONE if the specified number of identifiers couldn't be allocated.

See also

UnreserveControlId(), wxIdManager, Window IDs

virtual void wxWindow::OnInternalIdle ( ) [virtual]

This virtual function is normally only used internally, but sometimes an application may need it to implement functionality that should not be disabled by an application defining an OnIdle handler in a derived class.

This function may be used to do delayed painting, for example, and most implementations call UpdateWindowUI() in order to send update events to the window in idle time.

bool wxWindow::PageDown ( )

Same as ScrollPages (1).

bool wxWindow::PageUp ( )

Same as ScrollPages (-1).

wxEvtHandler* wxWindow::PopEventHandler (bool *deleteHandler* = false)

Removes and returns the top-most event handler on the event handler stack.

E.g. in the case of: when calling `W->PopEventHandler()`, the event handler `A` will be removed and `B` will be the first handler of the stack.

Note that it's an error to call this function when no event handlers were pushed on this window (i.e. when the window itself is its only event handler).

Parameters

deleteHandler	If this is true, the handler will be deleted after it is removed (and the returned value will be NULL).

See also

How Events are Processed

bool wxWindow::PopupMenu (wxMenu * *menu,* const wxPoint & *pos* = wxDefaultPosition)

Pops up the given menu at the specified coordinates, relative to this window, and returns control when the user has dismissed the menu.

If a menu item is selected, the corresponding menu event is generated and will be processed as usual. If coordinates are not specified, the current mouse cursor position is used.

menu is the menu to pop up.

The position where the menu will appear can be specified either as a wxPoint *pos* or by two integers (*x* and *y*).

Remarks

Just before the menu is popped up, wxMenu::UpdateUI is called to ensure that the menu items are in the correct state. The menu does not get deleted by the window. It is recommended to not explicitly specify coordinates when calling PopupMenu in response to mouse click, because some of the ports (namely, wxG↩ TK) can do a better job of positioning the menu in that case.

See also

wxMenu

bool wxWindow::PopupMenu (wxMenu * *menu,* int *x,* int *y*)

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.

void wxWindow::PostSizeEvent ( )

Posts a size event to the window.

This is the same as SendSizeEvent() with `wxSEND_EVENT_POST` argument.

void wxWindow::PostSizeEventToParent ( )

Posts a size event to the parent of this window.

This is the same as SendSizeEventToParent() with `wxSEND_EVENT_POST` argument.

virtual bool wxWindow::ProcessEvent (wxEvent & *event*) [protected], [virtual]

This function is public in wxEvtHandler but protected in wxWindow because for wxWindows you should always call ProcessEvent() on the pointer returned by GetEventHandler() and not on the wxWindow object itself.

For convenience, a ProcessWindowEvent() method is provided as a synonym for

```
GetEventHandler()->ProcessEvent()
```

Note that it's still possible to call these functions directly on the wxWindow object (e.g. casting it to wxEvtHandler) but doing that will create subtle bugs when windows with event handlers pushed on them are involved.

This holds also for all other wxEvtHandler functions.

Reimplemented from wxEvtHandler.

void wxWindow::ProcessPendingEvents ( ) [protected]

See ProcessEvent() for more info about why you shouldn't use this function and the reason for making this function protected in wxWindow.

bool wxWindow::ProcessThreadEvent (const wxEvent & *event*) [protected]

See ProcessEvent() for more info about why you shouldn't use this function and the reason for making this function protected in wxWindow.

bool wxWindow::ProcessWindowEvent (wxEvent & *event*)

Convenient wrapper for ProcessEvent().

This is the same as writing

```
GetEventHandler()->ProcessEvent(event);
```

but more convenient. Notice that ProcessEvent() itself can't be called for wxWindow objects as it ignores the event handlers associated with the window; use this function instead.

bool wxWindow::ProcessWindowEventLocally (wxEvent & *event*)

Wrapper for wxEvtHandler::ProcessEventLocally().

This method is similar to ProcessWindowEvent() but can be used to search for the event handler only in this window and any event handlers pushed on top of it. Unlike ProcessWindowEvent() it won't propagate the event upwards. But it will use the validator and event handlers associated with this window, if any.

Since

2.9.1

void wxWindow::PushEventHandler (wxEvtHandler * *handler*)

Pushes this event handler onto the event stack for the window.

An event handler is an object that is capable of processing the events sent to a window. By default, the window is its own event handler, but an application may wish to substitute another, for example to allow central implementation of event-handling for a variety of different window classes.

wxWindow::PushEventHandler allows an application to set up a *stack* of event handlers, where an event not handled by one event handler is handed to the next one in the chain.

E.g. if you have two event handlers `A` and `B` and a wxWindow instance `W` and you call:

```
W->PushEventHandler(A);
W->PushEventHandler(B);
```

you will end up with the following situation:

Note that you can use wxWindow::PopEventHandler to remove the event handler.

Parameters

handler	Specifies the handler to be pushed. It must not be part of a wxEvtHandler chain; an assert will fail if it's not unlinked (see wxEvtHandler::IsUnlinked).

See also

How Events are Processed

virtual void wxWindow::QueueEvent (wxEvent * *event*) [protected], [virtual]

See ProcessEvent() for more info about why you shouldn't use this function and the reason for making this function protected in wxWindow.

Reimplemented from wxEvtHandler.

virtual void wxWindow::Raise ( ) [virtual]

Raises the window to the top of the window hierarchy (Z-order).

Notice that this function only requests the window manager to raise this window to the top of Z-order. Depending on its configuration, the window manager may raise the window, not do it at all or indicate that a window requested to be raised in some other way, e.g. by flashing its icon if it is minimized.

Remarks

This function only works for wxTopLevelWindow-derived classes.

See also

Lower()

virtual void wxWindow::Refresh (bool *eraseBackground* = true, const wxRect * *rect* = NULL) [virtual]

Causes this window, and all of its children recursively (except under wxGTK1 where this is not implemented), to be repainted.

Note that repainting doesn't happen immediately but only during the next event loop iteration, if you need to update the window immediately you should use Update() instead.

Parameters

eraseBackground	If true, the background will be erased.
rect	If non-NULL, only the given rectangle will be treated as damaged.

See also

RefreshRect()

Reimplemented in wxMenuBar.

void wxWindow::RefreshRect (const wxRect & *rect*, bool *eraseBackground* = true)

Redraws the contents of the given rectangle: only the area inside it will be repainted.

This is the same as Refresh() but has a nicer syntax as it can be called with a temporary wxRect object as argument like this `RefreshRect(wxRect(x, y, w, h))`.

virtual bool wxWindow::RegisterHotKey (int *hotkeyId*, int *modifiers*, int *virtualKeyCode*) [virtual]

Registers a system wide hotkey.

Every time the user presses the hotkey registered here, this window will receive a hotkey event.

It will receive the event even if the application is in the background and does not have the input focus because the user is working with some other application.

Parameters

hotkeyId	Numeric identifier of the hotkey. For applications this must be between 0 and 0xBFFF. If this function is called from a shared DLL, it must be a system wide unique identifier between 0xC000 and 0xFFFF. This is a MSW specific detail.
modifiers	A bitwise combination of wxMOD_SHIFT, wxMOD_CONTROL, wxMOD_ALT or wxMOD_WIN specifying the modifier keys that have to be pressed along with the key.
virtualKeyCode	The virtual key code of the hotkey.

Returns

true if the hotkey was registered successfully. false if some other application already registered a hotkey with this modifier/virtualKeyCode combination.

Remarks

Use EVT_HOTKEY(hotkeyId, fnc) in the event table to capture the event. This function is currently only implemented under Windows. It is used in the Windows CE port for detecting hardware button presses.

See also

UnregisterHotKey()

void wxWindow::ReleaseMouse ( )

Releases mouse input captured with CaptureMouse().

See also

CaptureMouse(), HasCapture(), ReleaseMouse(), wxMouseCaptureLostEvent, wxMouseCaptureChanged↩ Event

virtual void wxWindow::RemoveChild (wxWindow * *child*) [virtual]

Removes a child window.

This is called automatically by window deletion functions so should not be required by the application programmer. Notice that this function is mostly internal to wxWidgets and shouldn't be called by the user code.

Parameters

child	Child window to remove.

bool wxWindow::RemoveEventHandler (wxEvtHandler * *handler*)

Find the given *handler* in the windows event handler stack and removes (but does not delete) it from the stack.

See wxEvtHandler::Unlink() for more info.

Parameters

handler	The event handler to remove, must be non-NULL and must be present in this windows event handlers stack.

Returns

Returns true if it was found and false otherwise (this also results in an assert failure so this function should only be called when the handler is supposed to be there).

See also

PushEventHandler(), PopEventHandler()

virtual bool wxWindow::Reparent (wxWindow * *newParent*) `[virtual]`

Reparents the window, i.e. the window will be removed from its current parent window (e.g.

a non-standard toolbar in a wxFrame) and then re-inserted into another.

Notice that currently you need to explicitly call wxNotebook::RemovePage() before reparenting a notebook page.

Parameters

newParent	New parent.

bool wxWindow::SafelyProcessEvent (wxEvent & *event*) [protected]

See ProcessEvent() for more info about why you shouldn't use this function and the reason for making this function protected in wxWindow.

void wxWindow::ScreenToClient (int * *x*, int * *y*) const

Converts from screen to client window coordinates.

Parameters

x	Stores the screen x coordinate and receives the client x coordinate.
y	Stores the screen x coordinate and receives the client x coordinate.

wxPoint wxWindow::ScreenToClient (const wxPoint & *pt*) const

Converts from screen to client window coordinates.

Parameters

pt	The screen position.

virtual bool wxWindow::ScrollLines (int *lines*) [virtual]

Scrolls the window by the given number of lines down (if *lines* is positive) or up.

Returns

Returns true if the window was scrolled, false if it was already on top/bottom and nothing was done.

Remarks

This function is currently only implemented under MSW and wxTextCtrl under wxGTK (it also works for wxScrolled classes under all platforms).

See also

ScrollPages()

Reimplemented in wxRibbonGallery, and wxRibbonPage.

virtual bool wxWindow::ScrollPages (int *pages*) [virtual]

Scrolls the window by the given number of pages down (if *pages* is positive) or up.

Returns

Returns true if the window was scrolled, false if it was already on top/bottom and nothing was done.

Remarks

This function is currently only implemented under MSW and wxGTK.

See also

ScrollLines()

virtual void wxWindow::ScrollWindow (int *dx*, int *dy*, const wxRect * *rect* = NULL) [virtual]

Physically scrolls the pixels in the window and move child windows accordingly.

Parameters

dx	Amount to scroll horizontally.
dy	Amount to scroll vertically.
rect	Rectangle to scroll, if it is NULL, the whole window is scrolled (this is always the case under wxGTK which doesn't support this parameter)

Remarks

Note that you can often use wxScrolled instead of using this function directly.

void wxWindow::SendDestroyEvent ( ) [protected]

Generate wxWindowDestroyEvent for this window.

This is called by the window itself when it is being destroyed and usually there is no need to call it but see wxWindowDestroyEvent for explanations of when you might want to do it.

virtual bool wxWindow::SendIdleEvents (wxIdleEvent & *event*) [virtual]

Send idle event to window and all subwindows.

Returns true if more idle time is requested.

virtual void wxWindow::SendSizeEvent (int *flags* = 0) [virtual]

This function sends a dummy size event to the window allowing it to re-layout its children positions.

It is sometimes useful to call this function after adding or deleting a children after the frame creation or if a child size changes. Note that if the frame is using either sizers or constraints for the children layout, it is enough to call wxWindow::Layout() directly and this function should not be used in this case.

If *flags* includes wxSEND_EVENT_POST value, this function posts the event, i.e. schedules it for later processing, instead of dispatching it directly. You can also use PostSizeEvent() as a more readable equivalent of calling this function with this flag.

Parameters

flags	May include wxSEND_EVENT_POST. Default value is 0.

void wxWindow::SendSizeEventToParent (int *flags* = 0)

Safe wrapper for GetParent()->SendSizeEvent().

This function simply checks that the window has a valid parent which is not in process of being deleted and calls SendSizeEvent() on it. It is used internally by windows such as toolbars changes to whose state should result in parent re-layout (e.g. when a toolbar is added to the top of the window, all the other windows must be shifted down).

See also

PostSizeEventToParent()

Parameters

flags	See description of this parameter in SendSizeEvent() documentation.

virtual void wxWindow::SetAcceleratorTable (const wxAcceleratorTable & *accel*) [virtual]

Sets the accelerator table for this window.

See wxAcceleratorTable.

void wxWindow::SetAccessible (wxAccessible * *accessible*)

Sets the accessible for this window.

Any existing accessible for this window will be deleted first, if not identical to *accessible*. See also wxAccessible.

void wxWindow::SetAutoLayout (bool *autoLayout*)

Determines whether the Layout() function will be called automatically when the window is resized.

This method is called implicitly by SetSizer() but if you use SetConstraints() you should call it manually or otherwise the window layout won't be correctly updated when its size changes.

Parameters

autoLayout	Set this to true if you wish the Layout() function to be called automatically when the window is resized.

See also

SetSizer(), SetConstraints()

virtual bool wxWindow::SetBackgroundColour (const wxColour & *colour*) [virtual]

Sets the background colour of the window.

Notice that as with SetForegroundColour(), setting the background colour of a native control may not affect the entire control and could be not supported at all depending on the control and platform.

Please see InheritAttributes() for explanation of the difference between this method and SetOwnBackground↩Colour().

Parameters

colour	The colour to be used as the background colour; pass wxNullColour to reset to the default colour. Note that you may want to use wxSystemSettings::GetColour() to retrieve a suitable colour to use rather than setting an hard-coded one.

Remarks

The background colour is usually painted by the default wxEraseEvent event handler function under Windows and automatically under GTK. Note that setting the background colour does not cause an immediate refresh, so you may wish to call wxWindow::ClearBackground or wxWindow::Refresh after calling this function. Using this function will disable attempts to use themes for this window, if the system supports them. Use with care since usually the themes represent the appearance chosen by the user to be used for all applications on the system.

Returns

true if the colour was really changed, false if it was already set to this colour and nothing was done.

See also

GetBackgroundColour(), SetForegroundColour(), GetForegroundColour(), ClearBackground(), Refresh(), wxEraseEvent, wxSystemSettings

Reimplemented in wxListCtrl.

virtual bool wxWindow::SetBackgroundStyle (wxBackgroundStyle *style*) [virtual]

Sets the background style of the window.

The default background style is `wxBG_STYLE_ERASE` which indicates that the window background may be erased in `EVT_ERASE_BACKGROUND` handler. This is a safe, compatibility default; however you may want to change it to `wxBG_STYLE_SYSTEM` if you don't define any erase background event handlers at all, to avoid unnecessary generation of erase background events and always let system erase the background. And you should change the background style to `wxBG_STYLE_PAINT` if you define an `EVT_PAINT` handler which completely overwrites the window background as in this case erasing it previously, either in `EVT_ERASE_BACKGROUND` handler or in the system default handler, would result in flicker as the background pixels will be repainted twice every time the window is redrawn. Do ensure that the background is entirely erased by your `EVT_PAINT` handler in this case however as otherwise garbage may be left on screen.

Notice that in previous versions of wxWidgets a common way to work around the above mentioned flickering problem was to define an empty `EVT_ERASE_BACKGROUND` handler. Setting background style to `wxBG_STYLE_PAINT` is a simpler and more efficient solution to the same problem.

Under wxGTK and wxOSX, you can use wxBG_STYLE_TRANSPARENT to obtain full transparency of the window background. Note that wxGTK supports this only since GTK 2.12 with a compositing manager enabled, call IsTransparentBackgroundSupported() to check whether this is the case.

Also, on order for `SetBackgroundStyle(wxBG_STYLE_TRANSPARENT)` to work, it must be called before Create(). If you're using your own wxWindow-derived class you should write your code in the following way:

```
class MyWidget : public wxWindow
{
public:
    MyWidget(wxWindow* parent, ...)
        : wxWindow() // Use default ctor here!
    {
        // Do this first:
        SetBackgroundStyle(wxBG_STYLE_TRANSPARENT);

        // And really create the window afterwards:
        Create(parent, ...);
    }
};
```

See also

SetBackgroundColour(), GetForegroundColour(), SetTransparent(), IsTransparentBackgroundSupported()

virtual void wxWindow::SetCanFocus (bool *canFocus*) [virtual]

This method is only implemented by ports which have support for native TAB traversal (such as GTK+ 2.0).

It is called by wxWidgets' container control code to give the native system a hint when doing TAB traversal. A call to this does not disable or change the effect of programmatically calling SetFocus().

See also

wxFocusEvent, wxPanel::SetFocus, wxPanel::SetFocusIgnoringChildren

void wxWindow::SetCaret (wxCaret * *caret*)

Sets the caret() associated with the window.

void wxWindow::SetClientSize (int *width,* int *height*)

This sets the size of the window client area in pixels.

Using this function to size a window tends to be more device-independent than SetSize(), since the application need not worry about what dimensions the border or title bar have when trying to fit the window around panel items, for example.

See also

Window Sizing Overview

void wxWindow::SetClientSize (const wxSize & *size*)

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.

void wxWindow::SetClientSize (const wxRect & *rect*)

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.

void wxWindow::SetConstraints (wxLayoutConstraints * *constraints*)

Sets the window to have the given layout constraints.

The window will then own the object, and will take care of its deletion. If an existing layout constraints object is already owned by the window, it will be deleted.

Parameters

constraints	The constraints to set. Pass NULL to disassociate and delete the window's constraints.

Remarks

You must call SetAutoLayout() to tell a window to use the constraints automatically in OnSize; otherwise, you must override OnSize and call Layout() explicitly. When setting both a wxLayoutConstraints and a wxSizer, only the sizer will have effect.

void wxWindow::SetContainingSizer (wxSizer * *sizer*)

This normally does not need to be called by user code.

It is called when a window is added to a sizer, and is used so the window can remove itself from the sizer when it is destroyed.

virtual bool wxWindow::SetCursor (const wxCursor & *cursor*) [virtual]

Sets the window's cursor.

Notice that the window cursor also sets it for the children of the window implicitly.

The *cursor* may be wxNullCursor in which case the window cursor will be reset back to default.

Parameters

cursor	Specifies the cursor that the window should normally display.

See also

wxSetCursor, wxCursor

void wxWindow::SetDoubleBuffered (bool *on*)

Turn on or off double buffering of the window if the system supports it.

virtual void wxWindow::SetDropTarget (wxDropTarget * *target*) `[virtual]`

Associates a drop target with this window.

If the window already has a drop target, it is deleted.

See also

GetDropTarget(), Drag and Drop Overview

void wxWindow::SetEventHandler (wxEvtHandler * *handler*)

Sets the event handler for this window.

Note that if you use this function you may want to use as the "next" handler of *handler* the window itself; in this way when *handler* doesn't process an event, the window itself will have a chance to do it.

Parameters

handler	Specifies the handler to be set. Cannot be NULL.

See also

How Events are Processed

virtual void wxWindow::SetExtraStyle (long *exStyle*) `[virtual]`

Sets the extra style bits for the window.

The currently defined extra style bits are reported in the class description.

virtual void wxWindow::SetFocus ( ) `[virtual]`

This sets the window to receive keyboard input.

See also

HasFocus(), wxFocusEvent, wxPanel::SetFocus, wxPanel::SetFocusIgnoringChildren

Reimplemented in wxPanel.

virtual void wxWindow::SetFocusFromKbd ( ) [virtual]

This function is called by wxWidgets keyboard navigation code when the user gives the focus to this window from keyboard (e.g. using TAB key).

By default this method simply calls SetFocus() but can be overridden to do something in addition to this in the derived classes.

virtual bool wxWindow::SetFont (const wxFont & *font*) [virtual]

Sets the font for this window.

This function should not be called for the parent window if you don't want its font to be inherited by its children, use SetOwnFont() instead in this case and see InheritAttributes() for more explanations.

Please notice that the given font is not automatically used for wxPaintDC objects associated with this window, you need to call wxDC::SetFont too. However this font is used by any standard controls for drawing their text as well as by GetTextExtent().

Parameters

font	Font to associate with this window, pass wxNullFont to reset to the default font.

Returns

true if the font was really changed, false if it was already set to this font and nothing was done.

See also

GetFont(), InheritAttributes()

Reimplemented in wxRichTextCtrl, wxAuiToolBar, wxAuiNotebook, and wxInfoBar.

virtual bool wxWindow::SetForegroundColour (const wxColour & *colour*) [virtual]

Sets the foreground colour of the window.

The meaning of foreground colour varies according to the window class; it may be the text colour or other colour, or it may not be used at all. Additionally, not all native controls support changing their foreground colour so this method may change their colour only partially or even not at all.

Please see InheritAttributes() for explanation of the difference between this method and SetOwnForeground↩ Colour().

Parameters

colour	The colour to be used as the foreground colour; pass wxNullColour to reset to the default colour.

Returns

true if the colour was really changed, false if it was already set to this colour and nothing was done.

See also

GetForegroundColour(), SetBackgroundColour(), GetBackgroundColour(), ShouldInheritColours()

void wxWindow::SetHelpText (const wxString & *helpText*)

Sets the help text to be used as context-sensitive help for this window.

Note that the text is actually stored by the current wxHelpProvider implementation, and not in the window object itself.

See also

GetHelpText(), wxHelpProvider::AddHelp()

void wxWindow::SetId (wxWindowID *winid*)

Sets the identifier of the window.

Remarks

Each window has an integer identifier. If the application has not provided one, an identifier will be generated. Normally, the identifier should be provided on creation and should not be modified subsequently.

See also

GetId(), Window IDs

virtual void wxWindow::SetInitialBestSize (const wxSize & *size*) [protected], [virtual]

Sets the initial window size if none is given (i.e. at least one of the components of the size passed to ctor/Create() is wxDefaultCoord).

Deprecated Use SetInitialSize() instead.

void wxWindow::SetInitialSize (const wxSize & *size* = wxDefaultSize)

A *smart* SetSize that will fill in default size components with the window's *best* size values.

Also sets the window's minsize to the value passed in for use with sizers. This means that if a full or partial size is passed to this function then the sizers will use that size instead of the results of GetBestSize() to determine the minimum needs of the window for layout.

Most controls will use this to set their initial size, and their min size to the passed in value (if any.)

See also

SetSize(), GetBestSize(), GetEffectiveMinSize(), Window Sizing Overview

virtual void wxWindow::SetLabel (const wxString & *label*) [virtual]

Sets the window's label.

Parameters

label	The window label.

See also

GetLabel()

Reimplemented in wxButton, wxControl, and wxCommandLinkButton.

virtual void wxWindow::SetLayoutDirection (wxLayoutDirection *dir*) [virtual]

Sets the layout direction for this window.

virtual void wxWindow::SetMaxClientSize (const wxSize & *size*) [virtual]

Sets the maximum client size of the window, to indicate to the sizer layout mechanism that this is the maximum possible size of its client area.

Note that this method is just a shortcut for:

```
SetMaxSize(ClientToWindowSize(size));
```

See also

SetMaxSize(), Window Sizing Overview

virtual void wxWindow::SetMaxSize (const wxSize & *size*) [virtual]

Sets the maximum size of the window, to indicate to the sizer layout mechanism that this is the maximum possible size.

See also

SetMaxClientSize(), Window Sizing Overview

Reimplemented in wxTopLevelWindow.

virtual void wxWindow::SetMinClientSize (const wxSize & *size*) [virtual]

Sets the minimum client size of the window, to indicate to the sizer layout mechanism that this is the minimum required size of window's client area.

You may need to call this if you change the window size after construction and before adding to its parent sizer.

Note, that just as with SetMinSize(), calling this method doesn't prevent the program from explicitly making the window smaller than the specified size.

Note that this method is just a shortcut for:

```
SetMinSize(ClientToWindowSize(size));
```

See also

SetMinSize(), Window Sizing Overview

virtual void wxWindow::SetMinSize (const wxSize & *size*) [virtual]

Sets the minimum size of the window, to indicate to the sizer layout mechanism that this is the minimum required size.

You may need to call this if you change the window size after construction and before adding to its parent sizer.

Notice that calling this method doesn't prevent the program from making the window explicitly smaller than the specified size by calling SetSize(), it just ensures that it won't become smaller than this size during the automatic layout.

See also

SetMinClientSize(), Window Sizing Overview

Reimplemented in wxTopLevelWindow.

virtual void wxWindow::SetName (const wxString & *name*) [virtual]

Sets the window's name.

Parameters

name	A name to set for the window.

See also

GetName()

virtual void wxWindow::SetNextHandler (wxEvtHandler * *handler*) [virtual]

wxWindows cannot be used to form event handler chains; this function thus will assert when called.

Note that instead you can use PushEventHandler() or SetEventHandler() to implement a stack of event handlers to override wxWindow's own event handling mechanism.

Reimplemented from wxEvtHandler.

void wxWindow::SetOwnBackgroundColour (const wxColour & *colour*)

Sets the background colour of the window but prevents it from being inherited by the children of this window.

See also

SetBackgroundColour(), InheritAttributes()

void wxWindow::SetOwnFont (const wxFont & *font*)

Sets the font of the window but prevents it from being inherited by the children of this window.

See also

SetFont(), InheritAttributes()

void wxWindow::SetOwnForegroundColour (const wxColour & *colour*)

Sets the foreground colour of the window but prevents it from being inherited by the children of this window.

See also

SetForegroundColour(), InheritAttributes()

void wxWindow::SetPalette (const wxPalette & *pal*)

Deprecated use wxDC::SetPalette instead.

void wxWindow::SetPosition (const wxPoint & *pt*)

A synonym for Centre().

virtual void wxWindow::SetPreviousHandler (wxEvtHandler * *handler*) [virtual]

wxWindows cannot be used to form event handler chains; this function thus will assert when called.

Note that instead you can use PushEventHandler() or SetEventHandler() to implement a stack of event handlers to override wxWindow's own event handling mechanism.

Reimplemented from wxEvtHandler.

virtual void wxWindow::SetScrollbar (int *orientation*, int *position*, int *thumbSize*, int *range*, bool *refresh* = true) [virtual]

Sets the scrollbar properties of a built-in scrollbar.

Parameters

orientation	Determines the scrollbar whose page size is to be set. May be wxHORIZONTAL or wxVERTICAL.
position	The position of the scrollbar in scroll units.
thumbSize	The size of the thumb, or visible portion of the scrollbar, in scroll units.
range	The maximum position of the scrollbar. Value of -1 can be used to ask for the scrollbar to be shown but in the disabled state: this can be used to avoid removing the scrollbar even when it is not needed (currently this is only implemented in wxMSW port).
refresh	true to redraw the scrollbar, false otherwise.

Remarks

Let's say you wish to display 50 lines of text, using the same font. The window is sized so that you can only see 16 lines at a time. You would use:

```
SetScrollbar(wxVERTICAL, 0, 16, 50);
```

Note that with the window at this size, the thumb position can never go above 50 minus 16, or 34. You can determine how many lines are currently visible by dividing the current view size by the character height in pixels. When defining your own scrollbar behaviour, you will always need to recalculate the scrollbar settings when the window size changes. You could therefore put your scrollbar calculations and SetScrollbar call into a function named AdjustScrollbars, which can be called initially and also from your wxSizeEvent handler function.

See also

Scrolled Windows, wxScrollBar, wxScrolled, wxScrollWinEvent

Reimplemented in wxScrollBar.

virtual void wxWindow::SetScrollPos (int *orientation,* int *pos,* bool *refresh* = `true`) [virtual]

Sets the position of one of the built-in scrollbars.

Parameters

orientation	Determines the scrollbar whose position is to be set. May be wxHORIZONTAL or wxVERTICAL.
pos	Position in scroll units.
refresh	true to redraw the scrollbar, false otherwise.

Remarks

This function does not directly affect the contents of the window: it is up to the application to take note of scrollbar attributes and redraw contents accordingly.

See also

SetScrollbar(), GetScrollPos(), GetScrollThumb(), wxScrollBar, wxScrolled

void wxWindow::SetSize (int *x,* int *y,* int *width,* int *height,* int *sizeFlags* = **wxSIZE_AUTO)**

Sets the size of the window in pixels.

Parameters

x	Required x position in pixels, or wxDefaultCoord to indicate that the existing value should be used.
y	Required y position in pixels, or wxDefaultCoord to indicate that the existing value should be used.
width	Required width in pixels, or wxDefaultCoord to indicate that the existing value should be used.
height	Required height position in pixels, or wxDefaultCoord to indicate that the existing value should be used.
sizeFlags	Indicates the interpretation of other parameters. It is a bit list of the following: • `wxSIZE_AUTO_WIDTH`: a wxDefaultCoord width value is taken to indicate a wxWidgets-supplied default width. • `wxSIZE_AUTO_HEIGHT`: a wxDefaultCoord height value is taken to indicate a wxWidgets-supplied default height. • `wxSIZE_AUTO`: wxDefaultCoord size values are taken to indicate a wxWidgets-supplied default size. • `wxSIZE_USE_EXISTING`: existing dimensions should be used if wxDefaultCoord values are supplied. • `wxSIZE_ALLOW_MINUS_ONE`: allow negative dimensions (i.e. value of wxDefaultCoord) to be interpreted as real dimensions, not default values. • `wxSIZE_FORCE`: normally, if the position and the size of the window are already the same as the parameters of this function, nothing is done. but with this flag a window resize may be forced even in this case (supported in wx 2.6.2 and later and only implemented for MSW and ignored elsewhere currently).

Remarks

This overload sets the position and optionally size, of the window. Parameters may be wxDefaultCoord to indicate either that a default should be supplied by wxWidgets, or that the current value of the dimension should be used.

See also

Move(), Window Sizing Overview

void wxWindow::SetSize (const wxRect & *rect*)

Sets the size of the window in pixels.

The size is specified using a wxRect, wxSize or by a couple of `int` objects.

Remarks

This form must be used with non-default width and height values.

See also

Move(), Window Sizing Overview

void wxWindow::SetSize (const wxSize & *size*)

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.

void wxWindow::SetSize (int *width,* int *height*)

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.

virtual void wxWindow::SetSizeHints (const wxSize & *minSize,* const wxSize & *maxSize* = wxDefaultSize, const wxSize & *incSize* = wxDefaultSize) [virtual]

Use of this function for windows which are not toplevel windows (such as wxDialog or wxFrame) is discouraged.

Please use SetMinSize() and SetMaxSize() instead.

See also

wxTopLevelWindow::SetSizeHints, Window Sizing Overview

Reimplemented in wxTopLevelWindow.

virtual void wxWindow::SetSizeHints (int *minW,* int *minH,* int *maxW* = -1, int *maxH* = -1, int *incW* = -1, int *incH* = -1) [virtual]

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.

Reimplemented in wxTopLevelWindow.

void wxWindow::SetSizer (wxSizer * *sizer,* bool *deleteOld* = true)

Sets the window to have the given layout sizer.

The window will then own the object, and will take care of its deletion. If an existing layout constraints object is already owned by the window, it will be deleted if the *deleteOld* parameter is true.

Note that this function will also call SetAutoLayout() implicitly with true parameter if the *sizer* is non-NULL and false otherwise so that the sizer will be effectively used to layout the window children whenever it is resized.

Parameters

sizer	The sizer to set. Pass NULL to disassociate and conditionally delete the window's sizer. See below.
deleteOld	If true (the default), this will delete any pre-existing sizer. Pass false if you wish to handle deleting the old sizer yourself but remember to do it yourself in this case to avoid memory leaks.

Remarks

SetSizer enables and disables Layout automatically.

void wxWindow::SetSizerAndFit (wxSizer * *sizer,* bool *deleteOld* = `true`)

This method calls SetSizer() and then wxSizer::SetSizeHints which sets the initial window size to the size needed to accommodate all sizer elements and sets the size hints which, if this window is a top level one, prevent the user from resizing it to be less than this minimal size.

virtual void wxWindow::SetThemeEnabled (bool *enable*) `[virtual]`

This function tells a window if it should use the system's "theme" code to draw the windows' background instead of its own background drawing code.

This does not always have any effect since the underlying platform obviously needs to support the notion of themes in user defined windows. One such platform is GTK+ where windows can have (very colourful) backgrounds defined by a user's selected theme.

Dialogs, notebook pages and the status bar have this flag set to true by default so that the default look and feel is simulated best.

void wxWindow::SetToolTip (const wxString & *tipString*)

Attach a tooltip to the window.

wxToolTip pointer can be NULL in the overload taking the pointer, meaning to unset any existing tooltips; however UnsetToolTip() provides a more readable alternative to this operation.

Notice that these methods are always available, even if wxWidgets was compiled with `wxUSE_TOOLTIPS` set to 0, but don't do anything in this case.

See also

GetToolTip(), wxToolTip

void wxWindow::SetToolTip (wxToolTip * *tip*)

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.

virtual bool wxWindow::SetTransparent (wxByte *alpha*) `[virtual]`

Set the transparency of the window.

If the system supports transparent windows, returns true, otherwise returns false and the window remains fully opaque. See also CanSetTransparent().

The parameter *alpha* is in the range 0..255 where 0 corresponds to a fully transparent window and 255 to the fully opaque one. The constants `wxIMAGE_ALPHA_TRANSPARENT` and `wxIMAGE_ALPHA_OPAQUE` can be used.

Reimplemented in wxTopLevelWindow.

virtual void wxWindow::SetValidator (const wxValidator & *validator*) `[virtual]`

Deletes the current validator (if any) and sets the window validator, having called wxValidator::Clone to create a new validator of this type.

void wxWindow::SetVirtualSize (int *width,* int *height*)

Sets the virtual size of the window in pixels.

See also

Window Sizing Overview

void wxWindow::SetVirtualSize (const wxSize & *size*)

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.

void wxWindow::SetWindowStyle (long *style*)

See SetWindowStyleFlag() for more info.

virtual void wxWindow::SetWindowStyleFlag (long *style*) `[virtual]`

Sets the style of the window.

Please note that some styles cannot be changed after the window creation and that Refresh() might need to be called after changing the others for the change to take place immediately.

See Window styles for more information about flags.

See also

GetWindowStyleFlag()

Reimplemented in wxListCtrl, and wxAuiToolBar.

void wxWindow::SetWindowVariant (wxWindowVariant *variant*)

Chooses a different variant of the window display to use.

Window variants currently just differ in size, as can be seen from wxWindowVariant documentation. Under all platforms but OS X, this function does nothing more than change the font used by the window. However under OS X it is implemented natively and selects the appropriate variant of the native widget, which has better appearance than just scaled down or up version of the normal variant, so it should be preferred to directly tweaking the font size.

By default the controls naturally use the normal variant.

virtual bool wxWindow::ShouldInheritColours ( ) const `[virtual]`

Return true from here to allow the colours of this window to be changed by InheritAttributes().

Returning false forbids inheriting them from the parent window.

The base class version returns false, but this method is overridden in wxControl where it returns true.

Reimplemented in wxRichTextCtrl.

virtual bool wxWindow::Show (bool *show* = `true`) `[virtual]`

Shows or hides the window.

You may need to call Raise() for a top level window if you want to bring it to top, although this is not needed if Show() is called immediately after the frame creation.

Notice that the default state of newly created top level windows is hidden (to allow you to create their contents without flicker) unlike for all the other, not derived from wxTopLevelWindow, windows that are by default created in the shown state.

Parameters

show	If true displays the window. Otherwise, hides it.

Returns

true if the window has been shown or hidden or false if nothing was done because it already was in the requested state.

See also

IsShown(), Hide(), wxRadioBox::Show, wxShowEvent.

Reimplemented in wxDialog.

virtual bool wxWindow::ShowWithEffect (wxShowEffect *effect*, unsigned int *timeout* = `0`) `[virtual]`

This function shows a window, like Show(), but using a special visual effect if possible.

Parameters

effect	The effect to use.
timeout	The *timeout* parameter specifies the time of the animation, in milliseconds. If the default value of 0 is used, the default animation time for the current platform is used.

Note

Currently this function is only implemented in wxMSW and wxOSX (for wxTopLevelWindows only in Carbon version and for any kind of windows in Cocoa) and does the same thing as Show() in the other ports.

Since

2.9.0

See also

HideWithEffect()

void wxWindow::Thaw ( )

Re-enables window updating after a previous call to Freeze().

To really thaw the control, it must be called exactly the same number of times as Freeze().

If the window has any children, they are recursively thawed too.

See also

wxWindowUpdateLocker, Freeze(), IsFrozen()

bool wxWindow::ToggleWindowStyle (int *flag*)

Turns the given *flag* on if it's currently turned off and vice versa.

This function cannot be used if the value of the flag is 0 (which is often the case for default flags).

Also, please notice that not all styles can be changed after the control creation.

Returns

Returns true if the style was turned on by this function, false if it was switched off.

See also

SetWindowStyleFlag(), HasFlag()

virtual bool wxWindow::TransferDataFromWindow ( ) [virtual]

Transfers values from child controls to data areas specified by their validators.

Returns false if a transfer failed.

If the window has `wxWS_EX_VALIDATE_RECURSIVELY` extra style flag set, the method will also call TransferDataFromWindow() of all child windows.

See also

TransferDataToWindow(), wxValidator, Validate()

virtual bool wxWindow::TransferDataToWindow ( ) [virtual]

Transfers values to child controls from data areas specified by their validators.

If the window has `wxWS_EX_VALIDATE_RECURSIVELY` extra style flag set, the method will also call TransferDataToWindow() of all child windows.

Returns

Returns false if a transfer failed.

See also

TransferDataFromWindow(), wxValidator, Validate()

virtual bool wxWindow::UnregisterHotKey (int *hotkeyId*) [virtual]

Unregisters a system wide hotkey.

Parameters

hotkeyId	Numeric identifier of the hotkey. Must be the same id that was passed to RegisterHotKey().

Returns

true if the hotkey was unregistered successfully, false if the id was invalid.

Remarks

This function is currently only implemented under MSW.

See also

RegisterHotKey()

static void wxWindow::UnreserveControlId (wxWindowID *id*, int *count* = 1) [static]

Unreserve an ID or range of IDs that was reserved by NewControlId().

See Window IDs for more information.

Parameters

id	The starting ID of the range of IDs to unreserve.
count	The number of sequential IDs to unreserve.

See also

NewControlId(), wxIdManager, Window IDs

void wxWindow::UnsetToolTip ( )

Unset any existing tooltip.

Since

2.9.0

See also

SetToolTip()

virtual void wxWindow::Update ( ) [virtual]

Calling this method immediately repaints the invalidated area of the window and all of its children recursively (this normally only happens when the flow of control returns to the event loop).

Notice that this function doesn't invalidate any area of the window so nothing happens if nothing has been invalidated (i.e. marked as requiring a redraw). Use Refresh() first if you want to immediately redraw the window unconditionally.

virtual void wxWindow::UpdateWindowUI (long *flags* = wxUPDATE_UI_NONE) [virtual]

This function sends one or more wxUpdateUIEvent to the window.

The particular implementation depends on the window; for example a wxToolBar will send an update UI event for each toolbar button, and a wxFrame will send an update UI event for each menubar menu item.

You can call this function from your application to ensure that your UI is up-to-date at this point (as far as your wxUpdateUIEvent handlers are concerned). This may be necessary if you have called wxUpdateUIEvent::SetMode() or wxUpdateUIEvent::SetUpdateInterval() to limit the overhead that wxWidgets incurs by sending update UI events in idle time. *flags* should be a bitlist of one or more of the wxUpdateUI enumeration.

If you are calling this function from an OnInternalIdle or OnIdle function, make sure you pass the wxUPDATE_UI_FROMIDLE flag, since this tells the window to only update the UI elements that need to be updated in idle time. Some windows update their elements only when necessary, for example when a menu is about to be shown. The following is an example of how to call UpdateWindowUI from an idle function.

```
void MyWindow::OnInternalIdle()
{
    if (wxUpdateUIEvent::CanUpdate(this))
        UpdateWindowUI(wxUPDATE_UI_FROMIDLE);
}
```

See also

wxUpdateUIEvent, DoUpdateWindowUI(), OnInternalIdle()

bool wxWindow::UseBgCol ( ) const

Return true if a background colour has been set for this window.

virtual bool wxWindow::Validate ( ) [virtual]

Validates the current values of the child controls using their validators.

If the window has `wxWS_EX_VALIDATE_RECURSIVELY` extra style flag set, the method will also call Validate() of all child windows.

Returns

Returns false if any of the validations failed.

See also

TransferDataFromWindow(), TransferDataToWindow(), wxValidator

virtual void wxWindow::WarpPointer (int *x*, int *y*) [virtual]

Moves the pointer to the given position on the window.

Note

Apple Human Interface Guidelines forbid moving the mouse cursor programmatically so you should avoid using this function in Mac applications (and probably avoid using it under the other platforms without good reason as well).

Parameters

x	The new x position for the cursor.
y	The new y position for the cursor.

virtual wxSize wxWindow::WindowToClientSize (const wxSize & *size*) const `[virtual]`

Converts window size *size* to corresponding client area size In other words, the returned value is what would GetClientSize() return if this window had given window size.

Components with wxDefaultCoord value are left unchanged.

Note that the conversion is not always exact, it assumes that non-client area doesn't change and so doesn't take into account things like menu bar (un)wrapping or (dis)appearance of the scrollbars.

Since

2.8.8

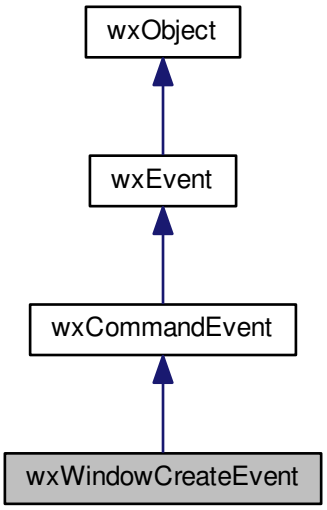
See also

ClientToWindowSize()

21.855 wxWindowCreateEvent Class Reference

`#include <wx/event.h>`

Inheritance diagram for wxWindowCreateEvent:



21.855.1 Detailed Description

This event is sent just after the actual window associated with a wxWindow object has been created.

Since it is derived from wxCommandEvent, the event propagates up the window hierarchy.

Events using this class

The following event handler macros redirect the events to member function handlers '**func**' with prototypes like: void handlerFuncName(wxWindowCreateEvent& event)

Event macros:

- EVT_WINDOW_CREATE(func): Process a `wxEVT_CREATE` event.

Library: wxCore

Category: Events

See also

Events and Event Handling, wxWindowDestroyEvent

Public Member Functions

- wxWindowCreateEvent (wxWindow *win=NULL)

  Constructor.

- wxWindow * GetWindow () const

  Return the window being created.

Additional Inherited Members

21.855.2 Constructor & Destructor Documentation

wxWindowCreateEvent::wxWindowCreateEvent (wxWindow * *win* = `NULL`)

Constructor.

21.855.3 Member Function Documentation

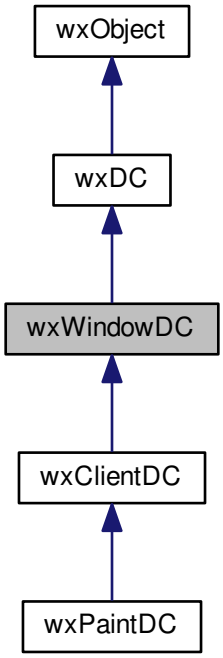
wxWindow* wxWindowCreateEvent::GetWindow ( ) const

Return the window being created.

21.856 wxWindowDC Class Reference

```
#include <wx/dcclient.h>
```

Inheritance diagram for wxWindowDC:



21.856.1 Detailed Description

A wxWindowDC must be constructed if an application wishes to paint on the whole area of a window (client and decorations).

This should normally be constructed as a temporary stack object; don't store a wxWindowDC object.

To draw on a window from inside an EVT_PAINT() handler, construct a wxPaintDC object instead.

To draw on the client area of a window from outside an EVT_PAINT() handler, construct a wxClientDC object.

A wxWindowDC object is initialized to use the same font and colours as the window it is associated with.

Library: wxCore

Category: Device Contexts

wxDC, wxMemoryDC, wxPaintDC, wxClientDC, wxScreenDC

Public Member Functions

- wxWindowDC (wxWindow *window)

  Constructor.

Additional Inherited Members

21.856.2 Constructor & Destructor Documentation

wxWindowDC::wxWindowDC (wxWindow * *window*)

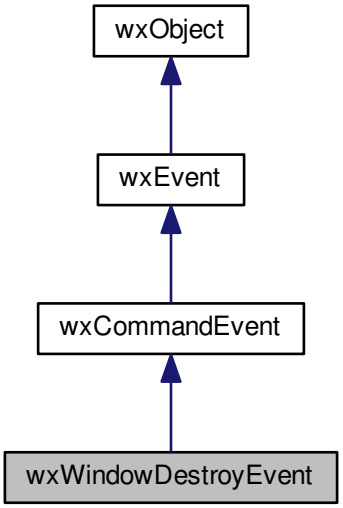
Constructor.

Pass a pointer to the window on which you wish to paint.

21.857 wxWindowDestroyEvent Class Reference

`#include <wx/event.h>`

Inheritance diagram for wxWindowDestroyEvent:



21.857.1 Detailed Description

This event is sent as early as possible during the window destruction process.

For the top level windows, as early as possible means that this is done by wxFrame or wxDialog destructor, i.e. after the destructor of the derived class was executed and so any methods specific to the derived class can't be called any more from this event handler. If you need to do this, you must call wxWindow::SendDestroyEvent() from your derived class destructor.

For the child windows, this event is generated just before deleting the window from wxWindow::Destroy() (which is also called when the parent window is deleted) or from the window destructor if operator `delete` was used directly (which is not recommended for this very reason).

It is usually pointless to handle this event in the window itself but it ca be very useful to receive notifications about the window destruction in the parent window or in any other object interested in this window.

Library: wxCore

Category: Events

See also

Events and Event Handling, wxWindowCreateEvent

Public Member Functions

- wxWindowDestroyEvent (wxWindow *win=NULL)

  Constructor.
- wxWindow * GetWindow () const

  Return the window being destroyed.

Additional Inherited Members

21.857.2 Constructor & Destructor Documentation

wxWindowDestroyEvent::wxWindowDestroyEvent (wxWindow * *win* = NULL)

Constructor.

21.857.3 Member Function Documentation

wxWindow* wxWindowDestroyEvent::GetWindow ( ) const

Return the window being destroyed.

21.858 wxWindowDisabler Class Reference

```
#include <wx/utils.h>
```

21.858.1 Detailed Description

This class disables all windows of the application (may be with the exception of one of them) in its constructor and enables them back in its destructor.

This is useful when you want to indicate to the user that the application is currently busy and cannot respond to user input.

Library: wxCore

Category: Miscellaneous

See also

wxBusyCursor

Public Member Functions

- wxWindowDisabler (bool disable=true)

  Disables all top level windows of the applications.

- wxWindowDisabler (wxWindow *winToSkip)

  Disables all top level windows of the applications with the exception of winToSkip if it is not NULL.

- ~wxWindowDisabler ()

  Reenables the windows disabled by the constructor.

21.858.2 Constructor & Destructor Documentation

wxWindowDisabler::wxWindowDisabler (bool *disable* = `true`)

Disables all top level windows of the applications.

If *disable* is `false` nothing is done. This can be convenient if the windows should be disabled depending on some condition.

Since

2.9.0

wxWindowDisabler::wxWindowDisabler (wxWindow * *winToSkip*)

Disables all top level windows of the applications with the exception of *winToSkip* if it is not NULL.

Notice that under MSW if *winToSkip* appears in the taskbar, the user will be able to close the entire application (even though its main window is disabled) by right clicking on the taskbar icon and selecting the appropriate "Close" command from the context menu. To prevent this from happening you may want to use wxFRAME_TOOL_WIND↩OW, if applicable, or wxFRAME_NO_TASKBAR style when creating the window that will remain enabled.

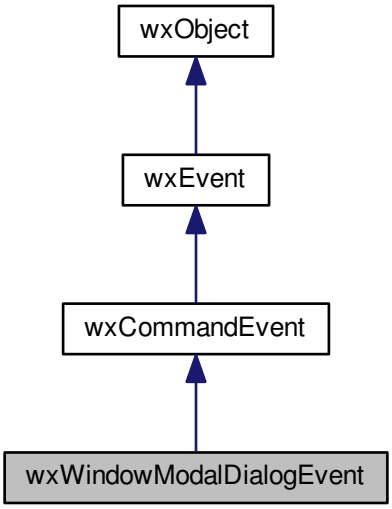
wxWindowDisabler::~wxWindowDisabler ( )

Reenables the windows disabled by the constructor.

21.859 wxWindowModalDialogEvent Class Reference

`#include <wx/dialog.h>`

Inheritance diagram for wxWindowModalDialogEvent:



21.859.1 Detailed Description

Event sent by wxDialog::ShowWindowModal() when the dialog closes.

Since

2.9.0

Public Member Functions

- wxWindowModalDialogEvent (wxEventType commandType=wxEVT_NULL, int id=0)

  Constructor.
- wxDialog * GetDialog () const

  Return the corresponding dialog.
- int GetReturnCode () const

  Return the dialog's return code.
- virtual wxEvent * Clone () const

  Clone the event.

Additional Inherited Members

21.859.2 Constructor & Destructor Documentation

wxWindowModalDialogEvent::wxWindowModalDialogEvent (wxEventType *commandType* = wxEVT_NULL, int *id* = 0)

Constructor.

21.859.3 Member Function Documentation

virtual wxEvent* wxWindowModalDialogEvent::Clone ( ) const `[virtual]`

Clone the event.

Implements wxEvent.

wxDialog* wxWindowModalDialogEvent::GetDialog ( ) const

Return the corresponding dialog.

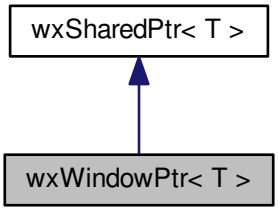
int wxWindowModalDialogEvent::GetReturnCode ( ) const

Return the dialog's return code.

21.860 wxWindowPtr< T > Class Template Reference

`#include <wx/windowptr.h>`

Inheritance diagram for wxWindowPtr< T >:



21.860.1 Detailed Description

template<typename T>class wxWindowPtr< T >

A reference-counted smart pointer for holding wxWindow instances.

This specialization of wxSharedPtr<T> is useful for holding wxWindow-derived objects. Unlike wxSharedPtr<T> or `std::shared_ptr<>`, it doesn't use the delete operator to destroy the value when reference count drops to zero, but calls wxWindow::Destroy() to safely destroy the window.

The template parameter T must be wxWindow or a class derived from it.

Library: wxCore

Category: Smart Pointers

Since

3.0

See also

wxSharedPtr<T>

Public Member Functions

- wxWindowPtr ()

  Default constructor.
- wxWindowPtr (T *ptr)

  Constructor.
- template<typename Deleter >
  wxWindowPtr (T *ptr, Deleter d)

  Constructor.
- wxWindowPtr (const wxWindowPtr< T > &tocopy)

  Copy constructor.
- wxWindowPtr< T > & operator= (T *ptr)

  Assignment operator.
- wxWindowPtr< T > & operator= (const wxWindowPtr< T > &tocopy)

  Assignment operator.
- void reset (T *ptr=NULL)

  Reset pointer to ptr.

21.860.2 Constructor & Destructor Documentation

template<typename T > wxWindowPtr< T >::wxWindowPtr ( )

Default constructor.

template<typename T > wxWindowPtr< T >::wxWindowPtr (T * *ptr*) `[explicit]`

Constructor.

Creates shared pointer from the raw pointer *ptr* and takes ownership of it.

template<typename T > template<typename Deleter > wxWindowPtr< T >::wxWindowPtr (T * *ptr*, Deleter *d*) `[explicit]`

Constructor.

Creates shared pointer from the raw pointer *ptr* and deleter *d* and takes ownership of it.

Parameters

ptr	The raw pointer.
d	Deleter - a functor that is called instead of delete to free the *ptr* raw pointer when its reference count drops to zero.

template<typename T > wxWindowPtr< T >::wxWindowPtr (const wxWindowPtr< T > & *tocopy*)

Copy constructor.

21.860.3 Member Function Documentation

template<typename T > wxWindowPtr<T>& wxWindowPtr< T >::operator= (T * *ptr*)

Assignment operator.

Releases any previously held pointer and creates a reference to *ptr*.

template<typename T > wxWindowPtr<T>& wxWindowPtr< T >::operator= (const wxWindowPtr< T > & *tocopy*)

Assignment operator.

Releases any previously held pointer and creates a reference to the same object as *topcopy*.

template<typename T > void wxWindowPtr< T >::reset (T * *ptr* = NULL)

Reset pointer to *ptr*.

If the reference count of the previously owned pointer was 1 it will be deleted.

21.861 wxWindowUpdateLocker Class Reference

`#include <wx/wupdlock.h>`

21.861.1 Detailed Description

This tiny class prevents redrawing of a wxWindow during its lifetime by using wxWindow::Freeze() and wxWindow::Thaw() methods.

It is typically used for creating automatic objects to temporarily suppress window updates before a batch of operations is performed:

```
void MyFrame::Foo()
    {
        m_text = new wxTextCtrl(this, ...);

        wxWindowUpdateLocker noUpdates(m_text);
        m_text->AppendText();
        ... many other operations with m_text...
        m_text->WriteText();
    }
```

Using this class is easier and safer than calling wxWindow::Freeze() and wxWindow::Thaw() because you don't risk to forget calling the latter.

Library: wxBase

Category: Miscellaneous

Public Member Functions

- wxWindowUpdateLocker (wxWindow *win)

  Creates an object preventing the updates of the specified win.
- ~wxWindowUpdateLocker ()

  Destructor reenables updates for the window this object is associated with.

21.861.2 Constructor & Destructor Documentation

wxWindowUpdateLocker::wxWindowUpdateLocker (wxWindow * *win*)

Creates an object preventing the updates of the specified *win*.

The parameter must be non-NULL and the window must exist for longer than wxWindowUpdateLocker object itself.

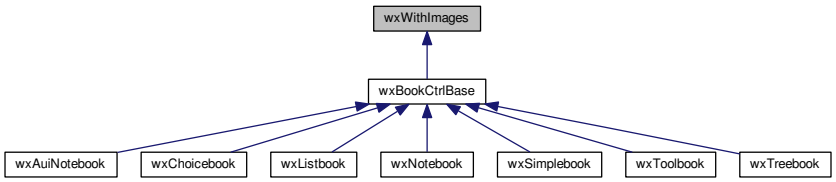
wxWindowUpdateLocker::~wxWindowUpdateLocker ( )

Destructor reenables updates for the window this object is associated with.

21.862 wxWithImages Class Reference

`#include <wx/withimages.h>`

Inheritance diagram for wxWithImages:



21.862.1 Detailed Description

A mixin class to be used with other classes that use a wxImageList.

Public Types

- enum { NO_IMAGE = -1 }

Public Member Functions

- wxWithImages ()
- virtual ~wxWithImages ()
- void AssignImageList (wxImageList *imageList)

  Sets the image list for the page control and takes ownership of the list.
- virtual void SetImageList (wxImageList *imageList)

  Sets the image list to use.
- wxImageList * GetImageList () const

  Returns the associated image list, may be NULL.

Protected Member Functions

- bool HasImageList () const

  Return true if we have a valid image list.
- wxIcon GetImage (int iconIndex) const

  Return the image with the given index from the image list.

21.862.2 Member Enumeration Documentation

anonymous enum

Enumerator

NO_IMAGE

21.862.3 Constructor & Destructor Documentation

wxWithImages::wxWithImages ( )

virtual wxWithImages::~wxWithImages ( ) `[virtual]`

21.862.4 Member Function Documentation

void wxWithImages::AssignImageList (wxImageList * *imageList*)

Sets the image list for the page control and takes ownership of the list.

See also

wxImageList, SetImageList()

wxIcon wxWithImages::GetImage (int *iconIndex*) const `[protected]`

Return the image with the given index from the image list.

If there is no image list or if index == NO_IMAGE, silently returns wxNullIcon.

wxImageList* wxWithImages::GetImageList ( ) const

Returns the associated image list, may be NULL.

See also

wxImageList, SetImageList()

bool wxWithImages::HasImageList ( ) const `[protected]`

Return true if we have a valid image list.

virtual void wxWithImages::SetImageList (wxImageList * *imageList*) `[virtual]`

Sets the image list to use.

It does not take ownership of the image list, you must delete it yourself.

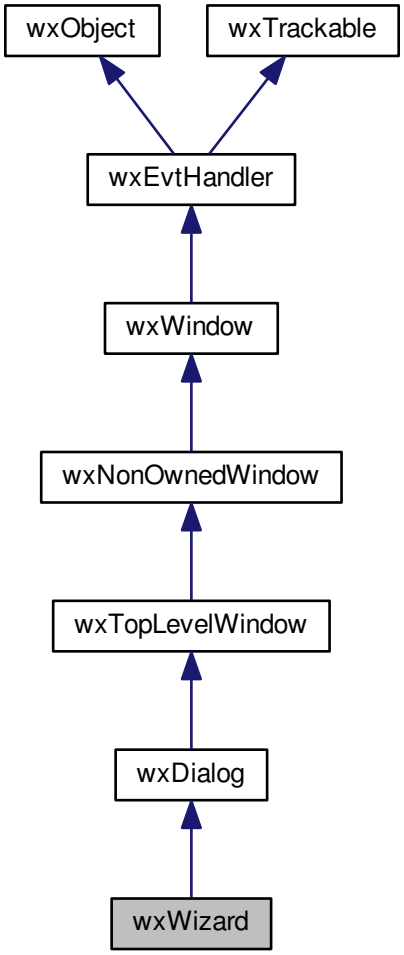
See also

wxImageList, AssignImageList()

21.863 wxWizard Class Reference

`#include <wx/wizard.h>`

Inheritance diagram for wxWizard:



21.863.1 Detailed Description

wxWizard is the central class for implementing 'wizard-like' dialogs.

These dialogs are mostly familiar to Windows users and are nothing other than a sequence of 'pages', each displayed inside a dialog which has the buttons to navigate to the next (and previous) pages.

The wizards are typically used to decompose a complex dialog into several simple steps and are mainly useful to the novice users, hence it is important to keep them as simple as possible.

To show a wizard dialog, you must first create an instance of the wxWizard class using either the non-default constructor or a default one followed by call to the wxWizard::Create function. Then you should add all pages you want the wizard to show and call wxWizard::RunWizard(). Finally, don't forget to call "`wizard->Destroy()`", otherwise your application will hang on exit due to an undestroyed window.

You can supply a bitmap to display on the left of the wizard, either for all pages or for individual pages. If you need to have the bitmap resize to the height of the wizard, call wxWizard::SetBitmapPlacement() and if necessary, wxWizard::SetBitmapBackgroundColour() and wxWizard::SetMinimumBitmapWidth().

To make wizard pages scroll when the display is too small to fit the whole dialog, you can switch layout adaptation on globally with wxDialog::EnableLayoutAdaptation() or per dialog with wxDialog::SetLayoutAdaptationMode(). For more about layout adaptation, see Automatic Scrolled Dialogs.

Events emitted by this class

The following event handler macros redirect the events to member function handlers '**func**' with prototypes like: void handlerFuncName(wxWizardEvent& event)

Event macros for events emitted by this class: For some events, Veto() can be called to prevent the event from happening.

- EVT_WIZARD_PAGE_CHANGED(id, func): The page has just been changed (this event cannot be vetoed).
- EVT_WIZARD_PAGE_CHANGING(id, func): The page is being changed (this event can be vetoed).
- EVT_WIZARD_BEFORE_PAGE_CHANGED(id, func): Called after Next is clicked but before GetNext is called. Unlike EVT_WIZARD_CHANGING, the handler for this function can change state that might affect the return value of GetNext. This event can be vetoed.
- EVT_WIZARD_PAGE_SHOWN(id, func): The page was shown and laid out (this event cannot be vetoed).
- EVT_WIZARD_CANCEL(id, func): The user attempted to cancel the wizard (this event may also be vetoed).
- EVT_WIZARD_HELP(id, func): The wizard help button was pressed.
- EVT_WIZARD_FINISHED(id, func): The wizard finished button was pressed.

21.863.2 Extended styles

Use the wxWindow::SetExtraStyle() function to set the following style. You will need to use two-step construction (use the default constructor, call SetExtraStyle(), then call Create).

Extra Styles

This class supports the following extra styles:

- wxWIZARD_EX_HELPBUTTON: Shows a Help button using wxID_HELP.

See also wxDialog for other extended styles.

Library: wxAdvanced

Category: Common Dialogs

See also

wxWizardEvent, wxWizardPage, Wizard Sample

Public Member Functions

- wxWizard ()

  Default constructor.
- wxWizard (wxWindow *parent, int id=wxID_ANY, const wxString &title=wxEmptyString, const wxBitmap &bitmap=wxNullBitmap, const wxPoint &pos=wxDefaultPosition, long style=wxDEFAULT_DIALOG_STYLE)

  Constructor which really creates the wizard – if you use this constructor, you shouldn't call Create().
- bool Create (wxWindow *parent, int id=wxID_ANY, const wxString &title=wxEmptyString, const wxBitmap &bitmap=wxNullBitmap, const wxPoint &pos=wxDefaultPosition, long style=wxDEFAULT_DIALOG_STYLE)

  Creates the wizard dialog.
- virtual void FitToPage (const wxWizardPage *firstPage)

  This method is obsolete, use GetPageAreaSizer() instead.
- const wxBitmap & GetBitmap () const

  Returns the bitmap used for the wizard.
- const wxColour & GetBitmapBackgroundColour () const

  Returns the colour that should be used to fill the area not taken up by the wizard or page bitmap, if a non-zero bitmap placement flag has been set.
- int GetBitmapPlacement () const

  Returns the flags indicating how the wizard or page bitmap should be expanded and positioned to fit the page height.
- virtual wxWizardPage * GetCurrentPage () const

  Get the current page while the wizard is running.
- int GetMinimumBitmapWidth () const

  Returns the minimum width for the bitmap that will be constructed to contain the actual wizard or page bitmap if a non-zero bitmap placement flag has been set.
- virtual wxSizer * GetPageAreaSizer () const

  Returns pointer to page area sizer.
- virtual wxSize GetPageSize () const

  Returns the size available for the pages.
- virtual bool HasNextPage (wxWizardPage *page)

  Return true if this page is not the last one in the wizard.
- virtual bool HasPrevPage (wxWizardPage *page)

  Returns true if this page is not the last one in the wizard.
- virtual bool RunWizard (wxWizardPage *firstPage)

  Executes the wizard starting from the given page, returning true if it was successfully finished or false if user cancelled it.
- void SetBitmap (const wxBitmap &bitmap)

  Sets the bitmap used for the wizard.
- void SetBitmapBackgroundColour (const wxColour &colour)

  Sets the colour that should be used to fill the area not taken up by the wizard or page bitmap, if a non-zero bitmap placement flag has been set.
- void SetBitmapPlacement (int placement)

  Sets the flags indicating how the wizard or page bitmap should be expanded and positioned to fit the page height.
- virtual void SetBorder (int border)

  Sets width of border around page area.
- void SetMinimumBitmapWidth (int width)

  Sets the minimum width for the bitmap that will be constructed to contain the actual wizard or page bitmap if a non-zero bitmap placement flag has been set.
- virtual void SetPageSize (const wxSize &sizePage)

  Sets the minimal size to be made available for the wizard pages.

Additional Inherited Members

21.863.3 Constructor & Destructor Documentation

wxWizard::wxWizard ( )

Default constructor.

Use this if you wish to derive from wxWizard and then call Create(), for example if you wish to set an extra style with wxWindow::SetExtraStyle() between the two calls.

wxWizard::wxWizard (wxWindow * *parent*, int *id* = wxID_ANY, const wxString & *title* = wxEmptyString, const wxBitmap & *bitmap* = wxNullBitmap, const wxPoint & *pos* = wxDefaultPosition, long *style* = wxDEFAULT_DIALOG_STYLE)

Constructor which really creates the wizard – if you use this constructor, you shouldn't call Create().

Notice that unlike almost all other wxWidgets classes, there is no *size* parameter in the wxWizard constructor because the wizard will have a predefined default size by default. If you want to change this, you should use the GetPageAreaSizer() function.

Parameters

parent	The parent window, may be NULL.
id	The id of the dialog, will usually be just wxID_ANY.
title	The title of the dialog.
bitmap	The default bitmap used in the left side of the wizard. See also GetBitmap().
pos	The position of the dialog, it will be centered on the screen by default.
style	Window style is passed to wxDialog.

21.863.4 Member Function Documentation

bool wxWizard::Create (wxWindow * *parent*, int *id* = wxID_ANY, const wxString & *title* = wxEmptyString, const wxBitmap & *bitmap* = wxNullBitmap, const wxPoint & *pos* = wxDefaultPosition, long *style* = wxDEFAULT_DIALOG_STYLE)

Creates the wizard dialog.

Must be called if the default constructor had been used to create the object.

Notice that unlike almost all other wxWidgets classes, there is no *size* parameter in the wxWizard constructor because the wizard will have a predefined default size by default. If you want to change this, you should use the GetPageAreaSizer() function.

Parameters

parent	The parent window, may be NULL.
id	The id of the dialog, will usually be just -1.
title	The title of the dialog.
bitmap	The default bitmap used in the left side of the wizard. See also GetBitmap().
pos	The position of the dialog, it will be centered on the screen by default.
style	Window style is passed to wxDialog.

virtual void wxWizard::FitToPage (const wxWizardPage * *firstPage*) [virtual]

This method is obsolete, use GetPageAreaSizer() instead.

Sets the page size to be big enough for all the pages accessible via the given *firstPage*, i.e. this page, its next page and so on.

This method may be called more than once and it will only change the page size if the size required by the new page is bigger than the previously set one. This is useful if the decision about which pages to show is taken during run-time, as in this case, the wizard won't be able to get to all pages starting from a single one and you should call *Fit* separately for the others.

const wxBitmap& wxWizard::GetBitmap ( ) const

Returns the bitmap used for the wizard.

const wxColour& wxWizard::GetBitmapBackgroundColour ( ) const

Returns the colour that should be used to fill the area not taken up by the wizard or page bitmap, if a non-zero bitmap placement flag has been set.

See also SetBitmapPlacement().

int wxWizard::GetBitmapPlacement ( ) const

Returns the flags indicating how the wizard or page bitmap should be expanded and positioned to fit the page height.

By default, placement is 0 (no expansion is done).

See also SetBitmapPlacement() for the possible values.

virtual wxWizardPage* wxWizard::GetCurrentPage ( ) const [virtual]

Get the current page while the wizard is running.

NULL is returned if RunWizard() is not being executed now.

int wxWizard::GetMinimumBitmapWidth ( ) const

Returns the minimum width for the bitmap that will be constructed to contain the actual wizard or page bitmap if a non-zero bitmap placement flag has been set.

See also SetBitmapPlacement().

virtual wxSizer* wxWizard::GetPageAreaSizer ( ) const [virtual]

Returns pointer to page area sizer.

The wizard is laid out using sizers and the page area sizer is the place-holder for the pages. All pages are resized before being shown to match the wizard page area.

Page area sizer has a minimal size that is the maximum of several values. First, all pages (or other objects) added to the sizer. Second, all pages reachable by repeatedly applying wxWizardPage::GetNext() to any page inserted into the sizer.

Third, the minimal size specified using SetPageSize() and FitToPage(). Fourth, the total wizard height may be increased to accommodate the bitmap height. Fifth and finally, wizards are never smaller than some built-in minimal size to avoid wizards that are too small.

The caller can use wxSizer::SetMinSize to enlarge it beyond the minimal size. If `wxRESIZE_BORDER` was passed to constructor, user can resize wizard and consequently the page area (but not make it smaller than the minimal size).

It is recommended to add the first page to the page area sizer. For simple wizards, this will enlarge the wizard to fit the biggest page.

For non-linear wizards, the first page of every separate chain should be added. Caller-specified size can be accomplished using wxSizer::SetMinSize(). Adding pages to the page area sizer affects the default border width around page area that can be altered with SetBorder().

virtual wxSize wxWizard::GetPageSize ( ) const [virtual]

Returns the size available for the pages.

virtual bool wxWizard::HasNextPage (wxWizardPage * *page*) [virtual]

Return true if this page is not the last one in the wizard.

The base class version implements this by calling page->GetNext but this could be undesirable if, for example, the pages are created on demand only.

See also

HasPrevPage()

virtual bool wxWizard::HasPrevPage (wxWizardPage * *page*) [virtual]

Returns true if this page is not the last one in the wizard.

The base class version implements this by calling page->GetPrev but this could be undesirable if, for example, the pages are created on demand only.

See also

HasNextPage()

virtual bool wxWizard::RunWizard (wxWizardPage * *firstPage*) [virtual]

Executes the wizard starting from the given page, returning true if it was successfully finished or false if user cancelled it.

The *firstPage* cannot be NULL.

void wxWizard::SetBitmap (const wxBitmap & *bitmap*)

Sets the bitmap used for the wizard.

void wxWizard::SetBitmapBackgroundColour (const wxColour & *colour*)

Sets the colour that should be used to fill the area not taken up by the wizard or page bitmap, if a non-zero bitmap placement flag has been set.

See also SetBitmapPlacement().

void wxWizard::SetBitmapPlacement (int *placement*)

Sets the flags indicating how the wizard or page bitmap should be expanded and positioned to fit the page height.

By default, placement is 0 (no expansion is done). *placement* is a bitlist with the following possible values:

- **wxWIZARD_VALIGN_TOP:** Aligns the bitmap at the top.

- **wxWIZARD_VALIGN_CENTRE:** Centres the bitmap vertically.
- **wxWIZARD_VALIGN_BOTTOM:** Aligns the bitmap at the bottom.
- **wxWIZARD_HALIGN_LEFT:** Left-aligns the bitmap.
- **wxWIZARD_HALIGN_CENTRE:** Centres the bitmap horizontally.
- **wxWIZARD_HALIGN_RIGHT:** Right-aligns the bitmap.
- **wxWIZARD_TILE:** todo 52.

See also SetMinimumBitmapWidth().

virtual void wxWizard::SetBorder (int *border*) `[virtual]`

Sets width of border around page area.

Default is zero. For backward compatibility, if there are no pages in GetPageAreaSizer(), the default is 5 pixels.

If there is a five point border around all controls in a page and the border around page area is left as zero, a five point white space along all dialog borders will be added to the control border in order to space page controls ten points from the dialog border and non-page controls.

void wxWizard::SetMinimumBitmapWidth (int *width*)

Sets the minimum width for the bitmap that will be constructed to contain the actual wizard or page bitmap if a non-zero bitmap placement flag has been set.

If this is not set when using bitmap placement, the initial layout may be incorrect.

See also SetBitmapPlacement().

virtual void wxWizard::SetPageSize (const wxSize & *sizePage*) `[virtual]`

Sets the minimal size to be made available for the wizard pages.

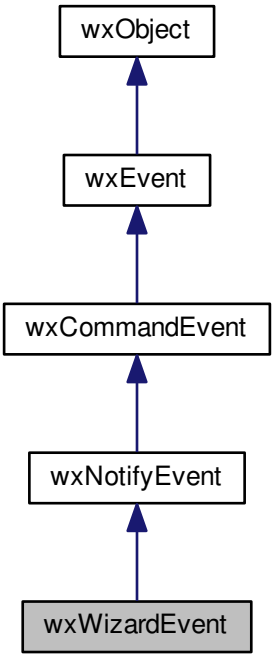
The wizard will take into account the size of the bitmap (if any) itself. Also, the wizard will never be smaller than the default size.

The recommended way to use this function is to lay out all wizard pages using the sizers (even though the wizard is not resizable) and then use wxSizer::CalcMin() in a loop to calculate the maximum of minimal sizes of the pages and pass it to SetPageSize().

21.864 wxWizardEvent Class Reference

`#include <wx/wizard.h>`

Inheritance diagram for wxWizardEvent:



21.864.1 Detailed Description

wxWizardEvent class represents an event generated by the wxWizard: this event is first sent to the page itself and, if not processed there, goes up the window hierarchy as usual.

Events using this class

The following event handler macros redirect the events to member function handlers '**func**' with prototypes like: void handlerFuncName(wxWizardEvent& event)

Event macros:

- EVT_WIZARD_PAGE_CHANGED(id, func): The page has been just changed (this event cannot be vetoed).
- EVT_WIZARD_PAGE_CHANGING(id, func): The page is being changed (this event can be vetoed).
- EVT_WIZARD_BEFORE_PAGE_CHANGED(id, func): Called after Next is clicked but before GetNext is called. Unlike EVT_WIZARD_CHANGING, the handler for this function can change state that might affect the return value of GetNext. This event can be vetoed.
- EVT_WIZARD_PAGE_SHOWN(id, func): The page was shown and laid out (this event cannot be vetoed).
- EVT_WIZARD_CANCEL(id, func): The user attempted to cancel the wizard (this event may also be vetoed).
- EVT_WIZARD_HELP(id, func): The wizard help button was pressed.
- EVT_WIZARD_FINISHED(id, func): The wizard finished button was pressed.

Library: wxAdvanced

Category: Events

See also

wxWizard, Wizard Sample

Public Member Functions

- wxWizardEvent (wxEventType type=wxEVT_NULL, int id=wxID_ANY, bool direction=true, wxWizardPage *page=0)

  Constructor.

- bool GetDirection () const

  Return the direction in which the page is changing: for `EVT_WIZARD_PAGE_CHANGING`, return true if we're going forward or false otherwise and for `EVT_WIZARD_PAGE_CHANGED` return true if we came from the previous page and false if we returned from the next one.

- wxWizardPage * GetPage () const

  Returns the wxWizardPage which was active when this event was generated.

Additional Inherited Members

21.864.2 Constructor & Destructor Documentation

wxWizardEvent::wxWizardEvent (wxEventType *type* = wxEVT_NULL, int *id* = wxID_ANY, bool *direction* = `true`, wxWizardPage * *page* = `0`)

Constructor.

It is not normally used by the user code as the objects of this type are constructed by wxWizard.

21.864.3 Member Function Documentation

bool wxWizardEvent::GetDirection ( ) const

Return the direction in which the page is changing: for `EVT_WIZARD_PAGE_CHANGING`, return true if we're going forward or false otherwise and for `EVT_WIZARD_PAGE_CHANGED` return true if we came from the previous page and false if we returned from the next one.

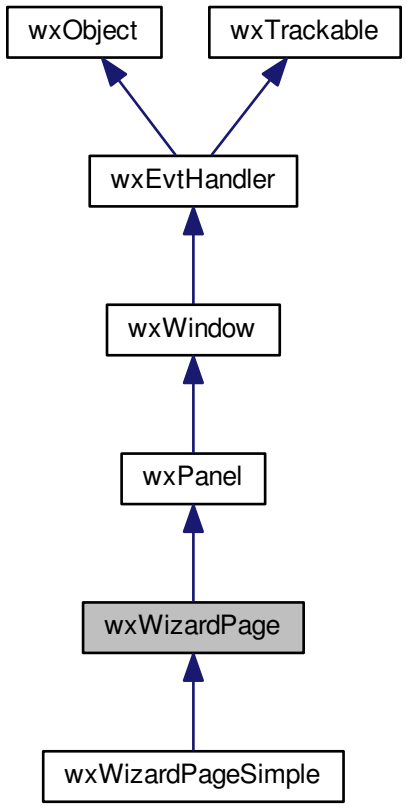
wxWizardPage* wxWizardEvent::GetPage ( ) const

Returns the wxWizardPage which was active when this event was generated.

21.865 wxWizardPage Class Reference

```
#include <wx/wizard.h>
```

Inheritance diagram for wxWizardPage:



21.865.1 Detailed Description

wxWizardPage is one of the screens in wxWizard: it must know what are the following and preceding pages (which may be NULL for the first/last page).

Except for this extra knowledge, wxWizardPage is just a panel, so the controls may be placed directly on it in the usual way.

This class allows the programmer to decide the order of pages in the wizard dynamically (during run-time) and so provides maximal flexibility. Usually, however, the order of pages is known in advance in which case wxWizard↩ PageSimple class is enough and it is simpler to use.

21.865.2 Virtual functions to override

To use this class, you must override wxWizardPage::GetPrev() and wxWizardPage::GetNext() pure virtual functions (or you may use wxWizardPageSimple instead). wxWizardPage::GetBitmap() can also be overridden, but this should be very rarely needed.

Library: wxAdvanced

Category: Miscellaneous Windows

See also

wxWizard, Wizard Sample

Public Member Functions

- wxWizardPage ()

  Default constructor.
- wxWizardPage (wxWizard *parent, const wxBitmap &bitmap=wxNullBitmap)

  Constructor accepts an optional bitmap which will be used for this page instead of the default one for this wizard (note that all bitmaps used should be of the same size).
- bool Create (wxWizard *parent, const wxBitmap &bitmap=wxNullBitmap)

  Creates the wizard page.
- virtual wxBitmap GetBitmap () const

  This method is called by wxWizard to get the bitmap to display alongside the page.
- virtual wxWizardPage * GetNext () const =0

  Get the page which should be shown when the user chooses the "Next" button: if NULL is returned, this button will be disabled.
- virtual wxWizardPage * GetPrev () const =0

  Get the page which should be shown when the user chooses the "Back" button: if NULL is returned, this button will be disabled.

Additional Inherited Members

21.865.3 Constructor & Destructor Documentation

wxWizardPage::wxWizardPage ( )

Default constructor.

wxWizardPage::wxWizardPage (wxWizard * *parent,* const wxBitmap & *bitmap* = wxNullBitmap)

Constructor accepts an optional bitmap which will be used for this page instead of the default one for this wizard (note that all bitmaps used should be of the same size).

Notice that no other parameters are needed because the wizard will resize and reposition the page anyhow.

Parameters

parent	The parent wizard
bitmap	The page-specific bitmap if different from the global one

21.865.4 Member Function Documentation

bool wxWizardPage::Create (wxWizard * *parent,* const wxBitmap & *bitmap* = wxNullBitmap)

Creates the wizard page.

Must be called if the default constructor had been used to create the object.

Parameters

parent	The parent wizard
bitmap	The page-specific bitmap if different from the global one

virtual wxBitmap wxWizardPage::GetBitmap ( ) const `[virtual]`

This method is called by wxWizard to get the bitmap to display alongside the page.

By default, `m_bitmap` member variable which was set in the wxWizardPage() constructor.

If the bitmap was not explicitly set (i.e. if wxNullBitmap is returned), the default bitmap for the wizard should be used.

The only cases when you would want to override this function is if the page bitmap depends dynamically on the user choices, i.e. almost never.

virtual wxWizardPage* wxWizardPage::GetNext ( ) const `[pure virtual]`

Get the page which should be shown when the user chooses the `"Next"` button: if NULL is returned, this button will be disabled.

The last page of the wizard will usually return NULL from here, but the others will not.

See also

GetPrev()

virtual wxWizardPage* wxWizardPage::GetPrev ( ) const `[pure virtual]`

Get the page which should be shown when the user chooses the `"Back"` button: if NULL is returned, this button will be disabled.

The first page of the wizard will usually return NULL from here, but the others will not.

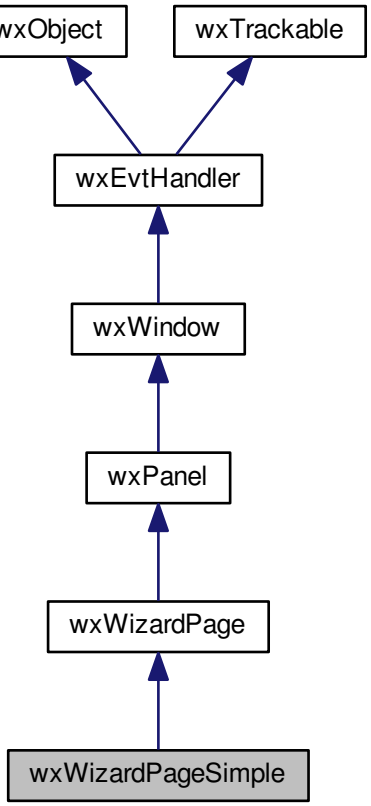
See also

GetNext()

21.866 wxWizardPageSimple Class Reference

`#include <wx/wizard.h>`

Inheritance diagram for wxWizardPageSimple:



21.866.1 Detailed Description

wxWizardPageSimple is the simplest possible wxWizardPage implementation: it just returns the pointers given to its constructor from wxWizardPage::GetNext() and wxWizardPage::GetPrev() functions.

This makes it very easy to use the objects of this class in the wizards where the pages order is known statically - on the other hand, if this is not the case you must derive your own class from wxWizardPage instead.

Library: wxAdvanced

Category: Miscellaneous Windows

See also

wxWizard, Wizard Sample

Public Member Functions

- wxWizardPageSimple ()

  Default constructor.
- wxWizardPageSimple (wxWizard *parent, wxWizardPage *prev=NULL, wxWizardPage *next=NULL, const wxBitmap &bitmap=wxNullBitmap)

  Constructor takes the previous and next pages.
- bool Create (wxWizard *parent=NULL, wxWizardPage *prev=NULL, wxWizardPage *next=NULL, const wxBitmap &bitmap=wxNullBitmap)

  Creates the wizard page.
- wxWizardPageSimple & Chain (wxWizardPageSimple *next)

  A helper chaining this page with the next one.
- void SetNext (wxWizardPage *next)

  Sets the next page.
- void SetPrev (wxWizardPage *prev)

  Sets the previous page.

Static Public Member Functions

- static void Chain (wxWizardPageSimple *first, wxWizardPageSimple *second)

  A convenience function to make the pages follow each other.

Additional Inherited Members

21.866.2 Constructor & Destructor Documentation

wxWizardPageSimple::wxWizardPageSimple ( )

Default constructor.

wxWizardPageSimple::wxWizardPageSimple (wxWizard * *parent*, wxWizardPage * *prev* = NULL, wxWizardPage * *next* = NULL, const wxBitmap & *bitmap* = wxNullBitmap)

Constructor takes the previous and next pages.

They may be modified later by SetPrev() or SetNext().

21.866.3 Member Function Documentation

wxWizardPageSimple& wxWizardPageSimple::Chain (wxWizardPageSimple * *next*)

A helper chaining this page with the next one.

Notice that this method returns a reference to the next page, so the calls to it can, in turn, be chained:

```
wxWizardPageSimple* firstPage = new FirstPage;
(*firstPage).Chain(new SecondPage)
            .Chain(new ThirdPage)
            .Chain(new LastPage);
```

This makes this method the simplest way to define the order of changes in fully static wizards, i.e. in those where the order doesn't depend on the choices made by the user in the wizard pages during run-time.

Parameters

next	A non-NULL pointer to the next page.

Returns

Reference to *next* on which Chain() can be called again.

Since

2.9.5

static void wxWizardPageSimple::Chain (wxWizardPageSimple * *first*, wxWizardPageSimple * *second*) [static]

A convenience function to make the pages follow each other.

Example:

```
wxRadioboxPage *page3 = new wxRadioboxPage(wizard);
wxValidationPage *page4 = new wxValidationPage(wizard);

wxWizardPageSimple::Chain(page3, page4);
```

bool wxWizardPageSimple::Create (wxWizard * *parent* = NULL, wxWizardPage * *prev* = NULL, wxWizardPage * *next* = NULL, const wxBitmap & *bitmap* = wxNullBitmap)

Creates the wizard page.

Must be called if the default constructor had been used to create the object.

void wxWizardPageSimple::SetNext (wxWizardPage * *next*)

Sets the next page.

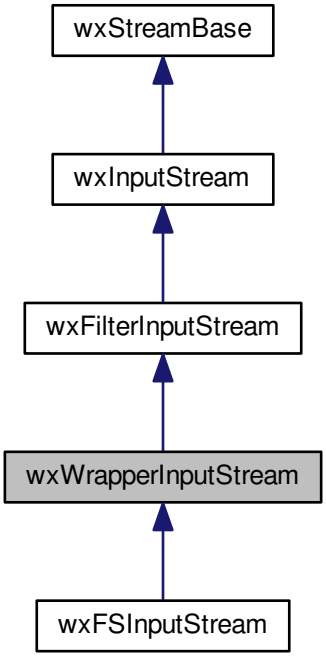
void wxWizardPageSimple::SetPrev (wxWizardPage * *prev*)

Sets the previous page.

21.867 wxWrapperInputStream Class Reference

`#include <wx/stream.h>`

Inheritance diagram for wxWrapperInputStream:



21.867.1 Detailed Description

A wrapper input stream is a kind of filter stream which forwards all the operations to its base stream.

This is useful to build utility classes such as wxFSInputStream.

Note

The interface of this class is the same as that of wxInputStream. Only a constructor differs and it is documented below.

Library: wxBase

Category: Streams

See also

wxFSInputStream, wxFilterInputStream

Since

2.9.4

Public Member Functions

- wxWrapperInputStream (wxInputStream &stream)

Initializes a wrapper stream.

- wxWrapperInputStream (wxInputStream *stream)

  Initializes a wrapper stream.

Protected Member Functions

- wxWrapperInputStream ()

  Default constructor, use InitParentStream() to finish initialization.

- void InitParentStream (wxInputStream &stream)

  Set up the wrapped stream for an object initialized using the default constructor.

- void InitParentStream (wxInputStream *stream)

  Set up the wrapped stream for an object initialized using the default constructor.

21.867.2 Constructor & Destructor Documentation

wxWrapperInputStream::wxWrapperInputStream (wxInputStream & *stream*)

Initializes a wrapper stream.

If the parent stream is passed as a pointer then the new wrapper stream takes ownership of it. If it is passed by reference then it does not.

wxWrapperInputStream::wxWrapperInputStream (wxInputStream * *stream*)

Initializes a wrapper stream.

If the parent stream is passed as a pointer then the new wrapper stream takes ownership of it. If it is passed by reference then it does not.

wxWrapperInputStream::wxWrapperInputStream ( ) [protected]

Default constructor, use InitParentStream() to finish initialization.

This constructor can be used by the derived classes from their own constructors when the parent stream can't be specified immediately. The derived class must call InitParentStream() later to do it.

21.867.3 Member Function Documentation

void wxWrapperInputStream::InitParentStream (wxInputStream & *stream*) [protected]

Set up the wrapped stream for an object initialized using the default constructor.

The ownership logic is the same as for the non-default constructor, i.e. this object takes ownership of the stream if it's passed by pointer but not if it's passed by reference.

void wxWrapperInputStream::InitParentStream (wxInputStream * *stream*) [protected]

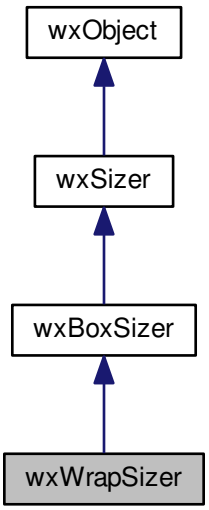
Set up the wrapped stream for an object initialized using the default constructor.

The ownership logic is the same as for the non-default constructor, i.e. this object takes ownership of the stream if it's passed by pointer but not if it's passed by reference.

21.868 wxWrapSizer Class Reference

`#include <wx/wrapsizer.h>`

Inheritance diagram for wxWrapSizer:



21.868.1 Detailed Description

A wrap sizer lays out its items in a single line, like a box sizer – as long as there is space available in that direction.

Once all available space in the primary direction has been used, a new line is added and items are added there.

So a wrap sizer has a primary orientation for adding items, and adds lines as needed in the secondary direction.

Library: wxCore

Category: Window Layout

See also

wxBoxSizer, wxSizer, Sizers Overview

Public Member Functions

- wxWrapSizer (int orient=wxHORIZONTAL, int flags=wxWRAPSIZER_DEFAULT_FLAGS)

  Constructor for a wxWrapSizer.
- virtual bool InformFirstDirection (int direction, int size, int availableOtherDir)

  Not used by an application.
- virtual void RecalcSizes ()

  Implements the calculation of a box sizer's dimensions and then sets the size of its children (calling wxWindow::SetSize if the child is a window).

- virtual wxSize CalcMin ()

  Implements the calculation of a box sizer's minimal.

Protected Member Functions

- virtual bool IsSpaceItem (wxSizerItem *item) const

  Can be overridden in the derived classes to treat some normal items as spacers.

Additional Inherited Members

21.868.2 Constructor & Destructor Documentation

wxWrapSizer::wxWrapSizer (int *orient* = wxHORIZONTAL, int *flags* = wxWRAPSIZER_DEFAULT_FLAGS)

Constructor for a wxWrapSizer.

orient determines the primary direction of the sizer (the most common case being `wxHORIZONTAL`). The flags parameter can be a combination of the values `wxEXTEND_LAST_ON_EACH_LINE` which will cause the last item on each line to use any remaining space on that line and `wxREMOVE_LEADING_SPACES` which removes any spacer elements from the beginning of a row.

Both of these flags are on by default.

21.868.3 Member Function Documentation

virtual wxSize wxWrapSizer::CalcMin ( ) [virtual]

Implements the calculation of a box sizer's minimal.

It is used internally only and must not be called by the user. Documented for information.

Reimplemented from wxBoxSizer.

virtual bool wxWrapSizer::InformFirstDirection (int *direction*, int *size*, int *availableOtherDir*) [virtual]

Not used by an application.

This is the mechanism by which sizers can inform sub-items of the first determined size component. The sub-item can then better determine its size requirements.

Returns true if the information was used (and the sub-item min size was updated).

Reimplemented from wxSizer.

virtual bool wxWrapSizer::IsSpaceItem (wxSizerItem * *item*) const [protected], [virtual]

Can be overridden in the derived classes to treat some normal items as spacers.

This method is used to determine whether the given *item* should be considered to be a spacer for the purposes of `wxREMOVE_LEADING_SPACES` implementation. By default only returns true for the real spacers.

virtual void wxWrapSizer::RecalcSizes ( ) [virtual]

Implements the calculation of a box sizer's dimensions and then sets the size of its children (calling wxWindow::SetSize if the child is a window).

It is used internally only and must not be called by the user (call Layout() if you want to resize). Documented for information.

Reimplemented from wxBoxSizer.

21.869 wxXLocale Class Reference

`#include <wx/xlocale.h>`

21.869.1 Detailed Description

This class represents a locale object used by so-called xlocale API.

Unlike wxLocale it doesn't provide any non-trivial operations but simply provides a portable wrapper for POSIX `locale_t` type.

It exists solely to be provided as an argument to various `wxFoo_l()` functions which are the extensions of the standard locale-dependent functions (hence the name xlocale). These functions do exactly the same thing as the corresponding standard `foo()` except that instead of using the global program locale they use the provided wxXLocale object.

See Locale-dependent functions for a list of wxXLocale-enabled functions.

Conversely, if a program wanted to output the number in French locale, even if the current locale is different, it could use wxXLocale(wxLANGUAGE_FRENCH).

21.869.2 Availability

This class is fully implemented only under the platforms where xlocale POSIX API or equivalent is available. Currently the xlocale API is available under most of the recent Unix systems (including Linux, various BSD and Mac OS X) and Microsoft Visual C++ standard library provides a similar API starting from version 8 (Visual Studio 2005).

If neither POSIX API nor Microsoft proprietary equivalent are available, this class is still available but works in degraded mode: the only supported locale is the C one and attempts to create wxXLocale object for any other locale will fail. You can use the preprocessor macro `wxHAS_XLOCALE_SUPPORT` to test if full xlocale API is available or only skeleton C locale support is present.

Notice that wxXLocale is new in wxWidgets 2.9.0 and is not compiled in if `wxUSE_XLOCALE` was set to 0 during the library compilation.

Library: wxBase

Category: Application and System configuration

Predefined objects/pointers:

- wxNullXLocale

See also

wxLocale

Public Member Functions

- wxXLocale ()

  Creates an uninitialized locale object, IsOk() method will return false.

- wxXLocale (wxLanguage lang)

  Creates the locale object corresponding to the specified language.
- wxXLocale (const char *loc)

  Creates the locale object corresponding to the specified locale string.
- bool IsOk () const

  Returns true if this object is initialized, i.e. represents a valid locale or false otherwise.
- bool operator== (const wxXLocale &loc) const

  Comparison operator.

Static Public Member Functions

- static wxXLocale & GetCLocale ()

  Returns the global object representing the "C" locale.

21.869.3 Constructor & Destructor Documentation

wxXLocale::wxXLocale ( )

Creates an uninitialized locale object, IsOk() method will return false.

wxXLocale::wxXLocale (wxLanguage *lang*)

Creates the locale object corresponding to the specified language.

wxXLocale::wxXLocale (const char * *loc*)

Creates the locale object corresponding to the specified locale string.

The locale string is system-dependent, use constructor taking wxLanguage for better portability.

21.869.4 Member Function Documentation

static wxXLocale& wxXLocale::GetCLocale ( ) [static]

Returns the global object representing the "C" locale.

For an even shorter access to this object a global `wxCLocale` variable (implemented as a macro) is provided and can be used instead of calling this method.

bool wxXLocale::IsOk ( ) const

Returns true if this object is initialized, i.e. represents a valid locale or false otherwise.

bool wxXLocale::operator== (const wxXLocale & *loc*) const

Comparison operator.

21.870 wxXmlAttribute Class Reference

`#include <wx/xml/xml.h>`

21.870.1 Detailed Description

Represents a node attribute.

Example: in `<img src="hello.gif" id="3"/>`, `src` is an attribute with value `hello.gif` and `id` is an attribute with value `3`.

Library: wxXML

Category: XML

See also

wxXmlDocument, wxXmlNode

Public Member Functions

- wxXmlAttribute ()

  Default constructor.
- wxXmlAttribute (const wxString &name, const wxString &value, wxXmlAttribute *next=NULL)

  Creates the attribute with given name and value.
- virtual ~wxXmlAttribute ()

  The virtual destructor.
- wxString GetName () const

  Returns the name of this attribute.
- wxXmlAttribute * GetNext () const

  Returns the sibling of this attribute or NULL if there are no siblings.
- wxString GetValue () const

  Returns the value of this attribute.
- void SetName (const wxString &name)

  Sets the name of this attribute.
- void SetNext (wxXmlAttribute *next)

  Sets the sibling of this attribute.
- void SetValue (const wxString &value)

  Sets the value of this attribute.

21.870.2 Constructor & Destructor Documentation

wxXmlAttribute::wxXmlAttribute ( )

Default constructor.

wxXmlAttribute::wxXmlAttribute (const wxString & *name*, const wxString & *value*, wxXmlAttribute * *next* = `NULL`)

Creates the attribute with given *name* and *value*.

If *next* is not NULL, then sets it as sibling of this attribute.

virtual wxXmlAttribute::~wxXmlAttribute ( ) `[virtual]`

The virtual destructor.

21.870.3 Member Function Documentation

wxString wxXmlAttribute::GetName ( ) const

Returns the name of this attribute.

wxXmlAttribute* wxXmlAttribute::GetNext ( ) const

Returns the sibling of this attribute or NULL if there are no siblings.

wxString wxXmlAttribute::GetValue ( ) const

Returns the value of this attribute.

void wxXmlAttribute::SetName (const wxString & *name*)

Sets the name of this attribute.

void wxXmlAttribute::SetNext (wxXmlAttribute * *next*)

Sets the sibling of this attribute.

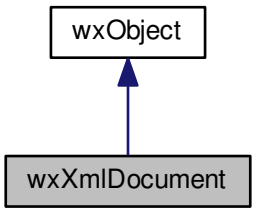
void wxXmlAttribute::SetValue (const wxString & *value*)

Sets the value of this attribute.

21.871 wxXmlDocument Class Reference

`#include <wx/xml/xml.h>`

Inheritance diagram for wxXmlDocument:



21.871.1 Detailed Description

This class holds XML data/document as parsed by XML parser in the root node.

wxXmlDocument internally uses the expat library which comes with wxWidgets to parse the given stream.

A simple example of using XML classes is:

```
wxXmlDocument doc;
if (!doc.Load("myfile.xml"))
    return false;

// start processing the XML file
if (doc.GetRoot()->GetName() != "myroot-node")
    return false;

// examine prologue
wxXmlNode *prolog = doc.GetDocumentNode()->GetChildren();
while (prolog) {

    if (prolog->GetType() == wxXML_PI_NODE && prolog->
      GetName() == "target") {

        // process Process Instruction contents
        wxString pi = prolog->GetContent();

        ...

    }
}

wxXmlNode *child = doc.GetRoot()->GetChildren();
while (child) {

    if (child->GetName() == "tag1") {

        // process text enclosed by tag1/tag1
        wxString content = child->GetNodeContent();

        ...

        // process attributes of tag1
        wxString attrvalue1 =
            child->GetAttribute("attr1", "default-value");
        wxString attrvalue2 =
            child->GetAttribute("attr2", "default-value");

        ...

    } else if (child->GetName() == "tag2") {

        // process tag2 ...
    }

    child = child->GetNext();
}
```

Note that if you want to preserve the original formatting of the loaded file including whitespaces and indentation, you need to turn off whitespace-only textnode removal and automatic indentation:

```
wxXmlDocument doc;
doc.Load("myfile.xml", "UTF-8", wxXMLDOC_KEEP_WHITESPACE_NODES);

// myfile2.xml will be identical to myfile.xml saving it this way:
doc.Save("myfile2.xml", wxXML_NO_INDENTATION);
```

Using default parameters, you will get a reformatted document which in general is different from the original loaded content:

```
wxXmlDocument doc;
doc.Load("myfile.xml");
doc.Save("myfile2.xml");  // myfile2.xml != myfile.xml
```

Library: wxXML

Public Member Functions

- wxXmlDocument ()

  Default constructor.
- wxXmlDocument (const wxXmlDocument &doc)

  Copy constructor.
- wxXmlDocument (const wxString &filename, const wxString &encoding="UTF-8"))

  Loads the given filename using the given encoding.
- wxXmlDocument (wxInputStream &stream, const wxString &encoding="UTF-8")

  Loads the XML document from given stream using the given encoding.
- virtual ~wxXmlDocument ()

  Virtual destructor.
- void AppendToProlog (wxXmlNode *node)

  Appends a Process Instruction or Comment node to the document prologue.
- wxXmlNode * DetachDocumentNode ()

  Detaches the document node and returns it.
- wxXmlNode * DetachRoot ()

  Detaches the root entity node and returns it.
- wxString GetEncoding () const

  Returns encoding of in-memory representation of the document (same as passed to Load() or constructor, defaults to UTF-8).
- const wxString & GetFileEncoding () const

  Returns encoding of document (may be empty).
- wxXmlNode * GetDocumentNode () const

  Returns the document node of the document.
- wxXmlNode * GetRoot () const

  Returns the root element node of the document.
- const wxString & GetVersion () const

  Returns the version of document.
- bool IsOk () const

  Returns true if the document has been loaded successfully.
- virtual bool Load (const wxString &filename, const wxString &encoding="UTF-8", int flags=wxXMLDOC_NONE)

  Parses filename as an xml document and loads its data.
- virtual bool Load (wxInputStream &stream, const wxString &encoding="UTF-8", int flags=wxXMLDOC_NONE)

  Like Load(const wxString&, const wxString&, int) but takes the data from given input stream.
- virtual bool Save (const wxString &filename, int indentstep=2) const

  Saves XML tree creating a file named with given string.
- virtual bool Save (wxOutputStream &stream, int indentstep=2) const

  Saves XML tree in the given output stream.
- void SetDocumentNode (wxXmlNode *node)

  Sets the document node of this document.
- void SetEncoding (const wxString &enc)

  Sets the encoding of the document.
- void SetFileEncoding (const wxString &encoding)

  Sets the enconding of the file which will be used to save the document.
- void SetRoot (wxXmlNode *node)

  Sets the root element node of this document.
- void SetVersion (const wxString &version)

  Sets the version of the XML file which will be used to save the document.
- wxXmlDocument & operator= (const wxXmlDocument &doc)

  Deep copies the given document.

Static Public Member Functions

- static wxVersionInfo GetLibraryVersionInfo ()
  Get expat library version information.

Additional Inherited Members

21.871.2 Constructor & Destructor Documentation

wxXmlDocument::wxXmlDocument ( )

Default constructor.

wxXmlDocument::wxXmlDocument (const wxXmlDocument & *doc*)

Copy constructor.

Deep copies all the XML tree of the given document.

wxXmlDocument::wxXmlDocument (const wxString & *filename,* const wxString & *encoding* = "UTF-8")

Loads the given filename using the given encoding.

See Load().

wxXmlDocument::wxXmlDocument (wxInputStream & *stream,* const wxString & *encoding* = "UTF-8")

Loads the XML document from given stream using the given encoding.

See Load().

virtual wxXmlDocument::~wxXmlDocument ( ) [virtual]

Virtual destructor.

Frees the document root node.

21.871.3 Member Function Documentation

void wxXmlDocument::AppendToProlog (wxXmlNode * *node*)

Appends a Process Instruction or Comment node to the document prologue.

Calling this function will create a prologue or attach the node to the end of an existing prologue.

Since

2.9.2

wxXmlNode* wxXmlDocument::DetachDocumentNode ( )

Detaches the document node and returns it.

The document node will be set to NULL and thus IsOk() will return false after calling this function.

Note that the caller is responsible for deleting the returned node in order to avoid memory leaks.

Since

2.9.2

wxXmlNode* wxXmlDocument::DetachRoot ( )

Detaches the root entity node and returns it.

After calling this function, the document node will remain together with any prologue nodes, but IsOk() will return false since the root entity will be missing.

Note that the caller is responsible for deleting the returned node in order to avoid memory leaks.

wxXmlNode* wxXmlDocument::GetDocumentNode ( ) const

Returns the document node of the document.

Since

2.9.2

wxString wxXmlDocument::GetEncoding ( ) const

Returns encoding of in-memory representation of the document (same as passed to Load() or constructor, defaults to UTF-8).

Note

this is meaningless in Unicode build where data are stored as `wchar_t*`.

const wxString& wxXmlDocument::GetFileEncoding ( ) const

Returns encoding of document (may be empty).

Note

This is the encoding original file was saved in, **not** the encoding of in-memory representation!

static wxVersionInfo wxXmlDocument::GetLibraryVersionInfo ( ) [static]

Get expat library version information.

Since

2.9.2

See also

wxVersionInfo

wxXmlNode* wxXmlDocument::GetRoot ( ) const

Returns the root element node of the document.

const wxString& wxXmlDocument::GetVersion ( ) const

Returns the version of document.

This is the value in the <?xml version="1.0"?> header of the XML document. If the version attribute was not explicitly given in the header, this function returns an empty string.

bool wxXmlDocument::IsOk ( ) const

Returns true if the document has been loaded successfully.

virtual bool wxXmlDocument::Load (const wxString & *filename*, const wxString & *encoding* = "UTF-8", int *flags* = wxXMLDOC_NONE) [virtual]

Parses *filename* as an xml document and loads its data.

If *flags* does not contain wxXMLDOC_KEEP_WHITESPACE_NODES, then, while loading, all nodes of type wxXML_TEXT_NODE (see wxXmlNode) are automatically skipped if they contain whitespaces only.

The removal of these nodes makes the load process slightly faster and requires less memory however makes impossible to recreate exactly the loaded text with a Save() call later. Read the initial description of this class for more info.

Returns true on success, false otherwise.

virtual bool wxXmlDocument::Load (wxInputStream & *stream*, const wxString & *encoding* = "UTF-8", int *flags* = wxXMLDOC_NONE) [virtual]

Like Load(const wxString&, const wxString&, int) but takes the data from given input stream.

wxXmlDocument& wxXmlDocument::operator= (const wxXmlDocument & *doc*)

Deep copies the given document.

virtual bool wxXmlDocument::Save (const wxString & *filename*, int *indentstep* = 2) const [virtual]

Saves XML tree creating a file named with given string.

If *indentstep* is greater than or equal to zero, then, while saving, an automatic indentation is added with steps composed by indentstep spaces.

If *indentstep* is wxXML_NO_INDENTATION, then, automatic indentation is turned off.

virtual bool wxXmlDocument::Save (wxOutputStream & *stream*, int *indentstep* = 2) const [virtual]

Saves XML tree in the given output stream.

See Save(const wxString&, int) for a description of *indentstep*.

void wxXmlDocument::SetDocumentNode (wxXmlNode * *node*)

Sets the document node of this document.

Deletes any previous document node. Use DetachDocumentNode() and then SetDocumentNode() if you want to replace the document node without deleting the old document tree.

Since

2.9.2

void wxXmlDocument::SetEncoding (const wxString & *enc*)

Sets the encoding of the document.

void wxXmlDocument::SetFileEncoding (const wxString & *encoding*)

Sets the enconding of the file which will be used to save the document.

void wxXmlDocument::SetRoot (wxXmlNode * *node*)

Sets the root element node of this document.

Will create the document node if necessary. Any previous root element node is deleted.

void wxXmlDocument::SetVersion (const wxString & *version*)

Sets the version of the XML file which will be used to save the document.

21.872 wxXmlNode Class Reference

`#include <wx/xml/xml.h>`

21.872.1 Detailed Description

Represents a node in an XML document.

See wxXmlDocument.

Node has a name and may have content and attributes.

Most common node types are `wxXML_TEXT_NODE` (name and attributes are irrelevant) and `wxXML_ELEMENT_NODE`.

Example: in `<title>hi</title>` there is an element with the name `title` and irrelevant content and one child of type `wxXML_TEXT_NODE` with `hi` as content.

The `wxXML_PI_NODE` type sets the name to the PI target and the contents to the instructions. Note that whilst the PI instructions are often in the form of pseudo-attributes these do not use the nodes attribute system. It is the users responsibility to code and decode the instruction text.

If `wxUSE_UNICODE` is 0, all strings are encoded in the encoding given to wxXmlDocument::Load (default is UTF-8).

Library: wxXML

wxXmlDocument, wxXmlAttribute

Public Member Functions

- wxXmlNode (wxXmlNode *parent, wxXmlNodeType type, const wxString &name, const wxString &content=wxEmptyString, wxXmlAttribute *attrs=NULL, wxXmlNode *next=NULL, int lineNo=-1)

  Creates this XML node and eventually insert it into an existing XML tree.
- wxXmlNode (wxXmlNodeType type, const wxString &name, const wxString &content=wxEmptyString, int lineNo=-1)

  A simplified version of the first constructor form, assuming a NULL parent.
- wxXmlNode (const wxXmlNode &node)

  Copy constructor.
- virtual ~wxXmlNode ()

  The virtual destructor.
- virtual void AddAttribute (const wxString &name, const wxString &value)

  Appends a attribute with given name and value to the list of attributes for this node.
- virtual void AddAttribute (wxXmlAttribute *attr)

  Appends given attribute to the list of attributes for this node.
- virtual void AddChild (wxXmlNode *child)

  Adds node child as the last child of this node.
- virtual bool DeleteAttribute (const wxString &name)

  Removes the first attributes which has the given name from the list of attributes for this node.
- bool GetAttribute (const wxString &attrName, wxString *value) const

  Returns true if a attribute named attrName could be found.
- wxString GetAttribute (const wxString &attrName, const wxString &defaultVal=wxEmptyString) const

  Returns the value of the attribute named attrName if it does exist.
- wxXmlAttribute * GetAttributes () const

  Return a pointer to the first attribute of this node.
- wxXmlNode * GetChildren () const

  Returns the first child of this node.
- const wxString & GetContent () const

  Returns the content of this node.
- int GetDepth (wxXmlNode *grandparent=NULL) const

  Returns the number of nodes which separate this node from `grandparent`.
- bool GetNoConversion () const

  Returns a flag indicating whether encoding conversion is necessary when saving.
- int GetLineNumber () const

  Returns line number of the node in the input XML file or `-1` if it is unknown.
- const wxString & GetName () const

  Returns the name of this node.
- wxXmlNode * GetNext () const

  Returns a pointer to the sibling of this node or NULL if there are no siblings.
- wxString GetNodeContent () const

  Returns the content of the first child node of type `wxXML_TEXT_NODE` or `wxXML_CDATA_SECTION_NODE`.
- wxXmlNode * GetParent () const

  Returns a pointer to the parent of this node or NULL if this node has no parent.
- wxXmlNodeType GetType () const

  Returns the type of this node.
- bool HasAttribute (const wxString &attrName) const

  Returns true if this node has a attribute named attrName.
- virtual bool InsertChild (wxXmlNode *child, wxXmlNode *followingNode)

  Inserts the child node immediately before followingNode in the children list.
- virtual bool InsertChildAfter (wxXmlNode *child, wxXmlNode *precedingNode)

Inserts the child node immediately after precedingNode in the children list.

- bool IsWhitespaceOnly () const

  Returns true if the content of this node is a string containing only whitespaces (spaces, tabs, new lines, etc).

- virtual bool RemoveChild (wxXmlNode *child)

  Removes the given node from the children list.

- void SetAttributes (wxXmlAttribute *attr)

  Sets as first attribute the given wxXmlAttribute object.

- void SetChildren (wxXmlNode *child)

  Sets as first child the given node.

- void SetContent (const wxString &con)

  Sets the content of this node.

- void SetName (const wxString &name)

  Sets the name of this node.

- void SetNext (wxXmlNode *next)

  Sets as sibling the given node.

- void SetNoConversion (bool noconversion)

  Sets a flag to indicate whether encoding conversion is necessary when saving.

- void SetParent (wxXmlNode *parent)

  Sets as parent the given node.

- void SetType (wxXmlNodeType type)

  Sets the type of this node.

- wxXmlNode & operator= (const wxXmlNode &node)

  See the copy constructor for more info.

21.872.2 Constructor & Destructor Documentation

wxXmlNode::wxXmlNode (wxXmlNode * *parent*, wxXmlNodeType *type*, const wxString & *name*, const wxString & *content* = wxEmptyString, wxXmlAttribute * *attrs* = NULL, wxXmlNode * *next* = NULL, int *lineNo* = -1)

Creates this XML node and eventually insert it into an existing XML tree.

Parameters

parent	The parent node to which append this node instance. If this argument is NULL this new node will be floating and it can be appended later to another one using the AddChild() or InsertChild() functions. Otherwise the child is already added to the XML tree by this constructor and it shouldn't be done again.
type	One of the wxXmlNodeType enumeration value.
name	The name of the node. This is the string which appears between angular brackets.
content	The content of the node. Only meaningful when type is wxXML_TEXT_NODE or wxXML_CDATA_SECTION_NODE.
attrs	If not NULL, this wxXmlAttribute object and its eventual siblings are attached to the node.
next	If not NULL, this node and its eventual siblings are attached to the node.
lineNo	Number of line this node was present at in input file or -1.

wxXmlNode::wxXmlNode (wxXmlNodeType *type*, const wxString & *name*, const wxString & *content* = wxEmptyString, int *lineNo* = -1)

A simplified version of the first constructor form, assuming a NULL parent.

Parameters

type	One of the wxXmlNodeType enumeration value.
name	The name of the node. This is the string which appears between angular brackets.
content	The content of the node. Only meaningful when type is `wxXML_TEXT_NODE` or `wxXML_↩ CDATA_SECTION_NODE`.
lineNo	Number of line this node was present at in input file or -1.

wxXmlNode::wxXmlNode (const wxXmlNode & *node*)

Copy constructor.

Note that this does NOT copy siblings and parent pointer, i.e. GetParent() and GetNext() will return NULL after using copy ctor and are never unmodified by operator=(). On the other hand, it DOES copy children and attributes.

virtual wxXmlNode::~wxXmlNode ( ) [virtual]

The virtual destructor.

Deletes attached children and attributes.

21.872.3 Member Function Documentation

virtual void wxXmlNode::AddAttribute (const wxString & *name,* const wxString & *value*) [virtual]

Appends a attribute with given *name* and *value* to the list of attributes for this node.

virtual void wxXmlNode::AddAttribute (wxXmlAttribute * *attr*) [virtual]

Appends given attribute to the list of attributes for this node.

virtual void wxXmlNode::AddChild (wxXmlNode * *child*) [virtual]

Adds node *child* as the last child of this node.

Note

Note that this function works in O(n) time where *n* is the number of existing children. Consequently, adding large number of child nodes using this method can be expensive, because it has O(n^2) time complexity in number of nodes to be added. Use InsertChildAfter() to populate XML tree in linear time.

See also

InsertChild(), InsertChildAfter()

virtual bool wxXmlNode::DeleteAttribute (const wxString & *name*) [virtual]

Removes the first attributes which has the given *name* from the list of attributes for this node.

bool wxXmlNode::GetAttribute (const wxString & *attrName,* wxString * *value*) const

Returns true if a attribute named attrName could be found.

The value of that attribute is saved in value (which must not be NULL).

wxString wxXmlNode::GetAttribute (const wxString & *attrName,* const wxString & *defaultVal* = wxEmptyString) const

Returns the value of the attribute named *attrName* if it does exist.

If it does not exist, the *defaultVal* is returned.

wxXmlAttribute* wxXmlNode::GetAttributes ( ) const

Return a pointer to the first attribute of this node.

wxXmlNode* wxXmlNode::GetChildren ( ) const

Returns the first child of this node.

To get a pointer to the second child of this node (if it does exist), use the GetNext() function on the returned value.

const wxString& wxXmlNode::GetContent ( ) const

Returns the content of this node.

Can be an empty string. Be aware that for nodes of type `wxXML_ELEMENT_NODE` (the most used node type) the content is an empty string. See GetNodeContent() for more details.

int wxXmlNode::GetDepth (wxXmlNode * *grandparent* = `NULL`) const

Returns the number of nodes which separate this node from `grandparent`.

This function searches only the parents of this node until it finds *grandparent* or the NULL node (which is the parent of non-linked nodes or the parent of a wxXmlDocument's root element node).

int wxXmlNode::GetLineNumber ( ) const

Returns line number of the node in the input XML file or `-1` if it is unknown.

const wxString& wxXmlNode::GetName ( ) const

Returns the name of this node.

Can be an empty string (e.g. for nodes of type `wxXML_TEXT_NODE` or `wxXML_CDATA_SECTION_NODE`).

wxXmlNode* wxXmlNode::GetNext ( ) const

Returns a pointer to the sibling of this node or NULL if there are no siblings.

bool wxXmlNode::GetNoConversion ( ) const

Returns a flag indicating whether encoding conversion is necessary when saving.

The default is false.

You can improve saving efficiency considerably by setting this value.

wxString wxXmlNode::GetNodeContent ( ) const

Returns the content of the first child node of type `wxXML_TEXT_NODE` or `wxXML_CDATA_SECTION_NODE`.

This function is very useful since the XML snippet "`tagnametagcontent/tagname`" is represented by expat with the following tag tree:

```
wxXML_ELEMENT_NODE name="tagname", content=""
|-- wxXML_TEXT_NODE name="", content="tagcontent"
```

or eventually:

```
wxXML_ELEMENT_NODE name="tagname", content=""
|-- wxXML_CDATA_SECTION_NODE name="", content="tagcontent"
```

An empty string is returned if the node has no children of type `wxXML_TEXT_NODE` or `wxXML_CDATA_SECTION_NODE`, or if the content of the first child of such types is empty.

wxXmlNode* wxXmlNode::GetParent ( ) const

Returns a pointer to the parent of this node or NULL if this node has no parent.

wxXmlNodeType wxXmlNode::GetType ( ) const

Returns the type of this node.

bool wxXmlNode::HasAttribute (const wxString & *attrName*) const

Returns true if this node has a attribute named *attrName*.

virtual bool wxXmlNode::InsertChild (wxXmlNode * *child*, wxXmlNode * *followingNode*) [virtual]

Inserts the *child* node immediately before *followingNode* in the children list.

Returns

true if *followingNode* has been found and the *child* node has been inserted.

Note

For historical reasons, *followingNode* may be NULL. In that case, then *child* is prepended to the list of children and becomes the first child of this node, i.e. it behaves identically to using the first children (as returned by GetChildren()) for *followingNode*).

See also

AddChild(), InsertChildAfter()

virtual bool wxXmlNode::InsertChildAfter (wxXmlNode * *child*, wxXmlNode * *precedingNode*) [virtual]

Inserts the *child* node immediately after *precedingNode* in the children list.

Returns

true if *precedingNode* has been found and the *child* node has been inserted.

Parameters

child	The child to insert.
precedingNode	The node to insert *child* after. As a special case, this can be NULL if this node has no children yet – in that case, *child* will become this node's only child node.

Since

2.8.8

See also

InsertChild(), AddChild()

bool wxXmlNode::IsWhitespaceOnly ( ) const

Returns true if the content of this node is a string containing only whitespaces (spaces, tabs, new lines, etc).

Note that this function is locale-independent since the parsing of XML documents must always produce the exact same tree regardless of the locale it runs under.

wxXmlNode& wxXmlNode::operator= (const wxXmlNode & *node*)

See the copy constructor for more info.

virtual bool wxXmlNode::RemoveChild (wxXmlNode * *child*) [virtual]

Removes the given node from the children list.

Returns true if the node was found and removed or false if the node could not be found. Note that the caller is responsible for deleting the removed node in order to avoid memory leaks.

void wxXmlNode::SetAttributes (wxXmlAttribute * *attr*)

Sets as first attribute the given wxXmlAttribute object.

The caller is responsible for deleting any previously present attributes attached to this node.

void wxXmlNode::SetChildren (wxXmlNode * *child*)

Sets as first child the given node.

The caller is responsible for deleting any previously present children node.

void wxXmlNode::SetContent (const wxString & *con*)

Sets the content of this node.

void wxXmlNode::SetName (const wxString & *name*)

Sets the name of this node.

void wxXmlNode::SetNext (wxXmlNode * *next*)

Sets as sibling the given node.

The caller is responsible for deleting any previously present sibling node.

void wxXmlNode::SetNoConversion (bool *noconversion*)

Sets a flag to indicate whether encoding conversion is necessary when saving.

The default is false.

You can improve saving efficiency considerably by setting this value.

void wxXmlNode::SetParent (wxXmlNode * *parent*)

Sets as parent the given node.

The caller is responsible for deleting any previously present parent node.

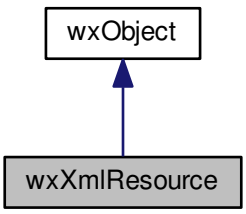
void wxXmlNode::SetType (wxXmlNodeType *type*)

Sets the type of this node.

21.873 wxXmlResource Class Reference

`#include <wx/xrc/xmlres.h>`

Inheritance diagram for wxXmlResource:



21.873.1 Detailed Description

This is the main class for interacting with the XML-based resource system.

The class holds XML resources from one or more .xml files, binary files or zip archive files.

Note that this is a singleton class and you'll never allocate/deallocate it. Just use the static wxXmlResource::Get() getter.

See also

XML Based Resource System (XRC), XRC File Format

Library: wxXRC

Category: XML Based Resource System (XRC)

Public Member Functions

- wxXmlResource (const wxString &filemask, int flags=wxXRC_USE_LOCALE, const wxString &domain=wxEmptyString)

  Constructor.
- wxXmlResource (int flags=wxXRC_USE_LOCALE, const wxString &domain=wxEmptyString)

  Constructor.
- virtual ~wxXmlResource ()

  Destructor.
- void AddHandler (wxXmlResourceHandler *handler)

  Initializes only a specific handler (or custom handler).
- void InsertHandler (wxXmlResourceHandler *handler)

  Add a new handler at the begining of the handler list.
- bool AttachUnknownControl (const wxString &name, wxWindow *control, wxWindow *parent=NULL)

  Attaches an unknown control to the given panel/window/dialog.
- void ClearHandlers ()

  Removes all handlers and deletes them (this means that any handlers added using AddHandler() must be allocated on the heap).
- int CompareVersion (int major, int minor, int release, int revision) const

  Compares the XRC version to the argument.
- const wxString & GetDomain () const

  Returns the domain (message catalog) that will be used to load translatable strings in the XRC.
- int GetFlags () const

  Returns flags, which may be a bitlist of wxXmlResourceFlags enumeration values.
- const wxXmlNode * GetResourceNode (const wxString &name) const

  Returns the wxXmlNode containing the definition of the object with the given name or NULL.
- long GetVersion () const

  *Returns version information (a.b.c.d = d + 256*c + 2562*b + 2563*a).*
- void InitAllHandlers ()

  Initializes handlers for all supported controls/windows.
- bool Load (const wxString &filemask)

  Loads resources from XML files that match given filemask.
- bool LoadFile (const wxFileName &file)

  Simpler form of Load() for loading a single XRC file.
- bool LoadAllFiles (const wxString &dirname)

  Loads all .xrc files from directory dirname.
- wxBitmap LoadBitmap (const wxString &name)

  Loads a bitmap resource from a file.
- wxDialog * LoadDialog (wxWindow *parent, const wxString &name)

  Loads a dialog.
- bool LoadDialog (wxDialog *dlg, wxWindow *parent, const wxString &name)

  Loads a dialog.
- wxFrame * LoadFrame (wxWindow *parent, const wxString &name)

  Loads a frame from the resource.
- bool LoadFrame (wxFrame *frame, wxWindow *parent, const wxString &name)

  Loads the contents of a frame onto an existing wxFrame.

- wxIcon LoadIcon (const wxString &name)

  Loads an icon resource from a file.
- wxMenu * LoadMenu (const wxString &name)

  Loads menu from resource.
- wxPanel * LoadPanel (wxWindow *parent, const wxString &name)

  Loads a panel.
- bool LoadPanel (wxPanel *panel, wxWindow *parent, const wxString &name)

  Loads a panel.
- wxToolBar * LoadToolBar (wxWindow *parent, const wxString &name)

  Loads a toolbar.
- void SetDomain (const wxString &domain)

  Sets the domain (message catalog) that will be used to load translatable strings in the XRC.
- void SetFlags (int flags)

  Sets flags (bitlist of wxXmlResourceFlags enumeration values).
- bool Unload (const wxString &filename)

  This function unloads a resource previously loaded by Load().

- wxMenuBar * LoadMenuBar (wxWindow *parent, const wxString &name)

  Loads a menubar from resource.
- wxMenuBar * LoadMenuBar (const wxString &name)

  Loads a menubar from resource.

- wxObject * LoadObject (wxWindow *parent, const wxString &name, const wxString &classname)

  Load an object from the resource specifying both the resource name and the class name.
- bool LoadObject (wxObject *instance, wxWindow *parent, const wxString &name, const wxString &classname)

  Load an object from the resource specifying both the resource name and the class name.

- wxObject * LoadObjectRecursively (wxWindow *parent, const wxString &name, const wxString &classname)

  Load an object from anywhere in the resource tree.
- bool LoadObjectRecursively (wxObject *instance, wxWindow *parent, const wxString &name, const wxString &classname)

  Load an object from anywhere in the resource tree.

Static Public Member Functions

- static void AddSubclassFactory (wxXmlSubclassFactory *factory)

  Registers subclasses factory for use in XRC.
- static wxString FindXRCIDById (int numId)

  Returns a string ID corresponding to the given numeric ID.
- static wxXmlResource * Get ()

  Gets the global resources object or creates one if none exists.
- static int GetXRCID (const wxString &str_id, int value_if_not_found=wxID_NONE)

  Returns a numeric ID that is equivalent to the string ID used in an XML resource.
- static wxXmlResource * Set (wxXmlResource *res)

  Sets the global resources object and returns a pointer to the previous one (may be NULL).

Protected Member Functions

- void ReportError (const wxXmlNode *context, const wxString &message)

  Reports error in XRC resources to the user.

- virtual void DoReportError (const wxString &xrcFile, const wxXmlNode *position, const wxString &message)

  Implementation of XRC resources errors reporting.

Additional Inherited Members

21.873.2 Constructor & Destructor Documentation

wxXmlResource::wxXmlResource (const wxString & *filemask*, int *flags* = wxXRC_USE_LOCALE, const wxString & *domain* = wxEmptyString)

Constructor.

Parameters

filemask	The XRC file, archive file, or wildcard specification that will be used to load all resource files inside a zip archive.
flags	One or more value of the wxXmlResourceFlags enumeration.
domain	The name of the gettext catalog to search for translatable strings. By default all loaded catalogs will be searched. This provides a way to allow the strings to only come from a specific catalog.

wxXmlResource::wxXmlResource (int *flags* = wxXRC_USE_LOCALE, const wxString & *domain* = wxEmptyString)

Constructor.

Parameters

flags	One or more value of the wxXmlResourceFlags enumeration.
domain	The name of the gettext catalog to search for translatable strings. By default all loaded catalogs will be searched. This provides a way to allow the strings to only come from a specific catalog.

virtual wxXmlResource::~wxXmlResource ( ) [virtual]

Destructor.

21.873.3 Member Function Documentation

void wxXmlResource::AddHandler (wxXmlResourceHandler * *handler*)

Initializes only a specific handler (or custom handler).

Convention says that the handler name is equal to the control's name plus 'XmlHandler', for example wxTextCtrl↩ XmlHandler, wxHtmlWindowXmlHandler.

The XML resource compiler (wxxrc) can create include file that contains initialization code for all controls used within the resource. Note that this handler must be allocated on the heap, since it will be deleted by ClearHandlers() later.

static void wxXmlResource::AddSubclassFactory (wxXmlSubclassFactory * *factory*) [static]

Registers subclasses factory for use in XRC.

This is useful only for language bindings developers who need a way to implement subclassing in wxWidgets ports that don't support wxRTTI (e.g. wxPython).

bool wxXmlResource::AttachUnknownControl (const wxString & *name*, wxWindow * *control*, wxWindow * *parent* = NULL)

Attaches an unknown control to the given panel/window/dialog.

Unknown controls are used in conjunction with <object class="unknown">.

void wxXmlResource::ClearHandlers ( )

Removes all handlers and deletes them (this means that any handlers added using AddHandler() must be allocated on the heap).

int wxXmlResource::CompareVersion (int *major*, int *minor*, int *release*, int *revision*) const

Compares the XRC version to the argument.

Returns -1 if the XRC version is less than the argument, +1 if greater, and 0 if they are equal.

virtual void wxXmlResource::DoReportError (const wxString & *xrcFile*, const wxXmlNode * *position*, const wxString & *message*) [protected], [virtual]

Implementation of XRC resources errors reporting.

This method is called by ReportError() and shouldn't be called directly; use ReportError() or wxXmlResourceHandler::ReportError() to log errors.

Default implementation uses wxLogError().

Parameters

xrcFile	File the error occurred in or empty string if it couldn't be determined.
position	XML node where the error occurred or NULL if it couldn't be determined.
message	Text of the error message. See ReportError() documentation for details of the string's format.

Note

You may override this method in a derived class to customize errors reporting. If you do so, you'll need to either use the derived class in all your code or call wxXmlResource::Set() to change the global wxXmlResource instance to your class.

Since

2.9.0

See also

ReportError()

static wxString wxXmlResource::FindXRCIDById (int *numId*) `[static]`

Returns a string ID corresponding to the given numeric ID.

The string returned is such that calling GetXRCID() with it as parameter yields *numId*. If there is no string identifier corresponding to the given numeric one, an empty string is returned.

Notice that, unlike GetXRCID(), this function is slow as it checks all of the identifiers used in XRC.

Since

2.9.0

static wxXmlResource* wxXmlResource::Get ( ) `[static]`

Gets the global resources object or creates one if none exists.

const wxString& wxXmlResource::GetDomain ( ) const

Returns the domain (message catalog) that will be used to load translatable strings in the XRC.

int wxXmlResource::GetFlags ( ) const

Returns flags, which may be a bitlist of wxXmlResourceFlags enumeration values.

const wxXmlNode* wxXmlResource::GetResourceNode (const wxString & *name*) const

Returns the wxXmlNode containing the definition of the object with the given name or NULL.

This function recursively searches all the loaded XRC files for an object with the specified *name*. If the object is found, the wxXmlNode corresponding to it is returned, so this function can be used to access additional information defined in the XRC file and not used by wxXmlResource itself, e.g. contents of application-specific XML tags.

Parameters

name	The name of the resource which must be unique for this function to work correctly, if there is more than one resource with the given name the choice of the one returned by this function is undefined.

Returns

The node corresponding to the resource with the given name or NULL.

long wxXmlResource::GetVersion ( ) const

Returns version information (a.b.c.d = d + 256*c + 2562*b + 2563*a).

static int wxXmlResource::GetXRCID (const wxString & *str_id,* int *value_if_not_found* = wxID_NONE) `[static]`

Returns a numeric ID that is equivalent to the string ID used in an XML resource.

If an unknown *str_id* is requested (i.e. other than wxID_XXX or integer), a new record is created which associates the given string with a number.

If *value_if_not_found* is `wxID_NONE`, the number is obtained via wxNewId(). Otherwise *value_if_not_found* is used.

Macro `XRCID(name)` is provided for convenient use in event tables.

Note

IDs returned by XRCID() cannot be used with the `EVT_*_RANGE` macros, because the order in which they are assigned to symbolic *name* values is not guaranteed.

void wxXmlResource::InitAllHandlers ( )

Initializes handlers for all supported controls/windows.

This will make the executable quite big because it forces linking against most of the wxWidgets library.

void wxXmlResource::InsertHandler (wxXmlResourceHandler * *handler*)

Add a new handler at the begining of the handler list.

bool wxXmlResource::Load (const wxString & *filemask*)

Loads resources from XML files that match given filemask.

Example:

```
if (!wxXmlResource::Get()->Load("rc/*.xrc"))
    wxLogError("Couldn't load resources!");
```

Note

If wxUSE_FILESYS is enabled, this method understands wxFileSystem URLs (see wxFileSystem::FindFirst()). If you are sure that the argument is name of single XRC file (rather than an URL or a wildcard), use LoadFile() instead.

See also

LoadFile(), LoadAllFiles()

bool wxXmlResource::LoadAllFiles (const wxString & *dirname*)

Loads all .xrc files from directory *dirname*.

Tries to load as many files as possible; if there's an error while loading one file, it still attempts to load other files.

Since

2.9.0

See also

LoadFile(), Load()

wxBitmap wxXmlResource::LoadBitmap (const wxString & *name*)

Loads a bitmap resource from a file.

wxDialog* wxXmlResource::LoadDialog (wxWindow * *parent,* const wxString & *name*)

Loads a dialog.

parent points to parent window (if any).

bool wxXmlResource::LoadDialog (wxDialog * *dlg*, wxWindow * *parent*, const wxString & *name*)

Loads a dialog.

parent points to parent window (if any).

This form is used to finish creation of an already existing instance (the main reason for this is that you may want to use derived class with a new event table). Example:

```
MyDialog dlg;
wxXmlResource::Get()->LoadDialog(&dlg, mainFrame, "my_dialog");
dlg.ShowModal();
```

bool wxXmlResource::LoadFile (const wxFileName & *file*)

Simpler form of Load() for loading a single XRC file.

Since

2.9.0

See also

Load(), LoadAllFiles()

wxFrame* wxXmlResource::LoadFrame (wxWindow * *parent*, const wxString & *name*)

Loads a frame from the resource.

parent points to parent window (if any).

bool wxXmlResource::LoadFrame (wxFrame * *frame*, wxWindow * *parent*, const wxString & *name*)

Loads the contents of a frame onto an existing wxFrame.

This form is used to finish creation of an already existing instance (the main reason for this is that you may want to use derived class with a new event table).

wxIcon wxXmlResource::LoadIcon (const wxString & *name*)

Loads an icon resource from a file.

wxMenu* wxXmlResource::LoadMenu (const wxString & *name*)

Loads menu from resource.

Returns NULL on failure.

wxMenuBar* wxXmlResource::LoadMenuBar (wxWindow * *parent*, const wxString & *name*)

Loads a menubar from resource.

Returns NULL on failure.

wxMenuBar* **wxXmlResource::LoadMenuBar** (**const wxString &** *name*)

Loads a menubar from resource.

Returns NULL on failure.

wxObject* **wxXmlResource::LoadObject** (**wxWindow** * *parent,* **const wxString &** *name,* **const wxString &** *classname*)

Load an object from the resource specifying both the resource name and the class name.

The first overload lets you load nonstandard container windows and returns NULL on failure. The second one lets you finish the creation of an existing instance and returns false on failure.

In either case, only the resources defined at the top level of XRC files can be loaded by this function, use LoadObjectRecursively() if you need to load an object defined deeper in the hierarchy.

bool wxXmlResource::LoadObject (**wxObject** * *instance,* **wxWindow** * *parent,* **const wxString &** *name,* **const wxString &** *classname*)

Load an object from the resource specifying both the resource name and the class name.

The first overload lets you load nonstandard container windows and returns NULL on failure. The second one lets you finish the creation of an existing instance and returns false on failure.

In either case, only the resources defined at the top level of XRC files can be loaded by this function, use LoadObjectRecursively() if you need to load an object defined deeper in the hierarchy.

wxObject* **wxXmlResource::LoadObjectRecursively** (**wxWindow** * *parent,* **const wxString &** *name,* **const wxString &** *classname*)

Load an object from anywhere in the resource tree.

These methods are similar to LoadObject() but may be used to load an object from anywhere in the resource tree and not only the top level. Note that you will very rarely need to do this as in normal use the entire container window (defined at the top level) is loaded and not its individual children but this method can be useful in some particular situations.

Since

2.9.1

bool wxXmlResource::LoadObjectRecursively (**wxObject** * *instance,* **wxWindow** * *parent,* **const wxString &** *name,* **const wxString &** *classname*)

Load an object from anywhere in the resource tree.

These methods are similar to LoadObject() but may be used to load an object from anywhere in the resource tree and not only the top level. Note that you will very rarely need to do this as in normal use the entire container window (defined at the top level) is loaded and not its individual children but this method can be useful in some particular situations.

Since

2.9.1

wxPanel* **wxXmlResource::LoadPanel** (**wxWindow** * *parent,* **const wxString &** *name*)

Loads a panel.

parent points to the parent window.

bool wxXmlResource::LoadPanel (wxPanel * *panel,* wxWindow * *parent,* const wxString & *name*)

Loads a panel.

parent points to the parent window. This form is used to finish creation of an already existing instance.

wxToolBar* wxXmlResource::LoadToolBar (wxWindow * *parent,* const wxString & *name*)

Loads a toolbar.

void wxXmlResource::ReportError (const wxXmlNode * *context,* const wxString & *message*) `[protected]`

Reports error in XRC resources to the user.

Any errors in XRC input files should be reported using this method (or its wxXmlResourceHandler::ReportError() equivalent). Unlike wxLogError(), this method presents the error to the user in a more usable form. In particular, the output is compiler-like and contains information about the exact location of the error.

Parameters

context	XML node the error occurred in or relates to. This can be NULL, but should be the most specific node possible, as its line number is what is reported to the user.
message	Text of the error message. This string should always be in English (i.e. not wrapped in _()). It shouldn't be a sentence – it should start with lower-case letter and shouldn't have a trailing period or exclamation point.

Since

2.9.0

See also

wxXmlResourceHandler::ReportError(), DoReportError()

static wxXmlResource* wxXmlResource::Set (wxXmlResource * *res*) `[static]`

Sets the global resources object and returns a pointer to the previous one (may be NULL).

void wxXmlResource::SetDomain (const wxString & *domain*)

Sets the domain (message catalog) that will be used to load translatable strings in the XRC.

void wxXmlResource::SetFlags (int *flags*)

Sets flags (bitlist of wxXmlResourceFlags enumeration values).

bool wxXmlResource::Unload (const wxString & *filename*)

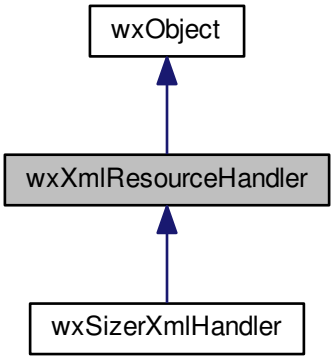
This function unloads a resource previously loaded by Load().

Returns true if the resource was successfully unloaded and false if it hasn't been found in the list of loaded resources.

21.874 wxXmlResourceHandler Class Reference

`#include <wx/xrc/xmlres.h>`

Inheritance diagram for wxXmlResourceHandler:



21.874.1 Detailed Description

wxSizerXmlHandler is a class for resource handlers capable of creating a wxSizer object from an XML node.

wxXmlResourceHandler is an abstract base class for resource handlers capable of creating a control from an XML node.

See also

wxXmlResourceHandler, wxSizer

Library: wxXRC

Category: XML Based Resource System (XRC)

See XML Based Resource System (XRC) for details.

Library: wxXRC

Category: XML Based Resource System (XRC)

Public Member Functions

- wxXmlResourceHandler ()

  Default constructor.
- virtual ~wxXmlResourceHandler ()

  Destructor.

- wxObject * CreateResource (wxXmlNode *node, wxObject *parent, wxObject *instance)

  Creates an object (menu, dialog, control, ...) from an XML node.
- virtual wxObject * DoCreateResource ()=0

  Called from CreateResource after variables were filled.
- virtual bool CanHandle (wxXmlNode *node)=0

  Returns true if it understands this node and can create a resource from it, false otherwise.
- void SetParentResource (wxXmlResource *res)

  Sets the parent resource.

Protected Member Functions

- void AddStyle (const wxString &name, int value)

  Add a style flag (e.g.
- void AddWindowStyles ()

  Add styles common to all wxWindow-derived classes.
- void CreateChildren (wxObject *parent, bool this_hnd_only=false)

  Creates children.
- void CreateChildrenPrivately (wxObject *parent, wxXmlNode *rootnode=NULL)

  Helper function.
- wxObject * CreateResFromNode (wxXmlNode *node, wxObject *parent, wxObject *instance=NULL)

  Creates a resource from a node.
- wxAnimation * GetAnimation (const wxString &param="animation")

  Creates an animation (see wxAnimation) from the filename specified in param.
- wxBitmap GetBitmap (const wxString &param="bitmap", const wxArtClient &defaultArtClient=wxART_OTHER, wxSize size=wxDefaultSize)

  Gets a bitmap.
- wxBitmap GetBitmap (const wxXmlNode *node, const wxArtClient &defaultArtClient=wxART_OTHER, wxSize size=wxDefaultSize)

  Gets a bitmap from an XmlNode.
- bool GetBool (const wxString &param, bool defaultv=false)

  Gets a bool flag (1, t, yes, on, true are true, everything else is false).
- wxColour GetColour (const wxString &param, const wxColour &defaultColour=wxNullColour)

  Gets colour in HTML syntax (#RRGGBB).
- wxFileSystem & GetCurFileSystem ()

  Returns the current file system.
- wxCoord GetDimension (const wxString &param, wxCoord defaultv=0, wxWindow *windowToUse=0)

  Gets a dimension (may be in dialog units).
- wxDirection GetDirection (const wxString &param, wxDirection dirDefault=wxLEFT)

  Gets a direction.
- wxFont GetFont (const wxString &param="font")

  Gets a font.
- int GetID ()

  Returns the XRCID.
- wxIcon GetIcon (const wxString &param="icon", const wxArtClient &defaultArtClient=wxART_OTHER, wxSize size=wxDefaultSize)

  Returns an icon.
- wxIcon GetIcon (const wxXmlNode *node, const wxArtClient &defaultArtClient=wxART_OTHER, wxSize size=wxDefaultSize)

  Gets an icon from an XmlNode.
- wxIconBundle GetIconBundle (const wxString &param, const wxArtClient &defaultArtClient=wxART_OTHER)

Returns an icon bundle.

- wxImageList * GetImageList (const wxString &param="imagelist")

  Creates an image list from the param markup data.
- long GetLong (const wxString &param, long defaultv=0)

  Gets the integer value from the parameter.
- float GetFloat (const wxString &param, float defaultv=0)

  Gets a float value from the parameter.
- wxString GetName ()

  Returns the resource name.
- bool IsObjectNode (const wxXmlNode *node) const

  Checks if the given node is an object node.
- wxString GetNodeContent (wxXmlNode *node)

  Gets node content from wxXML_ENTITY_NODE.
- wxXmlNode * GetNodeParent (const wxXmlNode *node) const

  Gets the parent of the node given.
- wxXmlNode * GetNodeNext (const wxXmlNode *node) const

  Gets the next sibling node related to the given node, possibly NULL.
- wxXmlNode * GetNodeChildren (const wxXmlNode *node) const

  Gets the first child of the given node or NULL.
- wxXmlNode * GetParamNode (const wxString &param)

  Finds the node or returns NULL.
- wxString GetParamValue (const wxString &param)

  Finds the parameter value or returns the empty string.
- wxString GetParamValue (const wxXmlNode *node)

  Returns the node parameter value.
- wxPoint GetPosition (const wxString &param="pos")

  Gets the position (may be in dialog units).
- wxSize GetSize (const wxString &param="size", wxWindow *windowToUse=0)

  Gets the size (may be in dialog units).
- int GetStyle (const wxString &param="style", int defaults=0)

  Gets style flags from text in form "flag | flag2| flag3 |..." Only understands flags added with AddStyle().
- wxString GetText (const wxString &param, bool translate=true)

  Gets text from param and does some conversions:
- bool HasParam (const wxString &param)

  Check to see if a parameter exists.
- bool IsOfClass (wxXmlNode *node, const wxString &classname)

  Convenience function.
- void SetupWindow (wxWindow *wnd)

  Sets common window options.
- void ReportError (wxXmlNode *context, const wxString &message)

  Reports error in XRC resources to the user.
- void ReportError (const wxString &message)

  Like ReportError(wxXmlNode, const wxString&), but uses the node of currently processed object (m_node) as the context.*
- void ReportParamError (const wxString &param, const wxString &message)

  Like ReportError(wxXmlNode, const wxString&), but uses the node of parameter param of the currently processed object as the context.*
- wxXmlResource * GetResource () const

  After CreateResource has been called this will return the current wxXmlResource object.
- wxXmlNode * GetNode () const

  After CreateResource has been called this will return the XML node being processed.

- wxString GetClass () const

  After CreateResource has been called this will return the class name of the XML resource node being processed.
- wxObject * GetParent () const

  After CreateResource has been called this will return the current item's parent, if any.
- wxObject * GetInstance () const

  After CreateResource has been called this will return the instance that the XML resource content should be created upon, if it has already been created.
- wxWindow * GetParentAsWindow () const

  After CreateResource has been called this will return the item's parent as a wxWindow.

Additional Inherited Members

21.874.2 Constructor & Destructor Documentation

wxXmlResourceHandler::wxXmlResourceHandler ( )

Default constructor.

virtual wxXmlResourceHandler::~wxXmlResourceHandler ( ) [virtual]

Destructor.

21.874.3 Member Function Documentation

void wxXmlResourceHandler::AddStyle (const wxString & *name,* int *value*) [protected]

Add a style flag (e.g.

`wxMB_DOCKABLE`) to the list of flags understood by this handler.

void wxXmlResourceHandler::AddWindowStyles ( ) [protected]

Add styles common to all wxWindow-derived classes.

virtual bool wxXmlResourceHandler::CanHandle (wxXmlNode * *node*) [pure virtual]

Returns true if it understands this node and can create a resource from it, false otherwise.

Note

You must not call any wxXmlResourceHandler methods except IsOfClass() from this method! The instance is not yet initialized with node data at the time CanHandle() is called and it is only safe to operate on node directly or to call IsOfClass().

Implemented in wxSizerXmlHandler.

void wxXmlResourceHandler::CreateChildren (wxObject * *parent,* bool *this_hnd_only* = `false`) [protected]

Creates children.

void wxXmlResourceHandler::CreateChildrenPrivately (wxObject * *parent*, wxXmlNode * *rootnode* = NULL) [protected]

Helper function.

wxObject* wxXmlResourceHandler::CreateResFromNode (wxXmlNode * *node*, wxObject * *parent*, wxObject * *instance* = NULL) [protected]

Creates a resource from a node.

wxObject* wxXmlResourceHandler::CreateResource (wxXmlNode * *node*, wxObject * *parent*, wxObject * *instance*)

Creates an object (menu, dialog, control, ...) from an XML node.

Should check for validity. *parent* is a higher-level object (usually window, dialog or panel) that is often necessary to create the resource.

If **instance** is non-NULL it should not create a new instance via 'new' but should rather use this one, and call its Create method.

virtual wxObject* wxXmlResourceHandler::DoCreateResource ( ) [pure virtual]

Called from CreateResource after variables were filled.

Implemented in wxSizerXmlHandler.

wxAnimation* wxXmlResourceHandler::GetAnimation (const wxString & *param* = "animation") [protected]

Creates an animation (see wxAnimation) from the filename specified in *param*.

wxBitmap wxXmlResourceHandler::GetBitmap (const wxString & *param* = "bitmap", const wxArtClient & *defaultArtClient* = wxART_OTHER, wxSize *size* = wxDefaultSize) [protected]

Gets a bitmap.

wxBitmap wxXmlResourceHandler::GetBitmap (const wxXmlNode * *node*, const wxArtClient & *defaultArtClient* = wxART_OTHER, wxSize *size* = wxDefaultSize) [protected]

Gets a bitmap from an XmlNode.

Since

2.9.1

bool wxXmlResourceHandler::GetBool (const wxString & *param*, bool *defaultv* = false) [protected]

Gets a bool flag (1, t, yes, on, true are true, everything else is false).

wxString wxXmlResourceHandler::GetClass ( ) const [protected]

After CreateResource has been called this will return the class name of the XML resource node being processed.

Since

2.9.5

wxColour wxXmlResourceHandler::GetColour (const wxString & *param*, const wxColour & *defaultColour* = wxNullColour) [protected]

Gets colour in HTML syntax (#RRGGBB).

wxFileSystem& wxXmlResourceHandler::GetCurFileSystem ( ) [protected]

Returns the current file system.

wxCoord wxXmlResourceHandler::GetDimension (const wxString & *param*, wxCoord *defaultv* = 0, wxWindow * *windowToUse* = 0) [protected]

Gets a dimension (may be in dialog units).

wxDirection wxXmlResourceHandler::GetDirection (const wxString & *param*, wxDirection *dirDefault* = wxLEFT) [protected]

Gets a direction.

If the given *param* is not present or has empty value, *dirDefault* is returned by default. Otherwise the value of the parameter is parsed and a warning is generated if it's not one of `wxLEFT`, `wxTOP`, `wxRIGHT` or `wxBOTTOM`.

Since

2.9.3

float wxXmlResourceHandler::GetFloat (const wxString & *param*, float *defaultv* = 0) [protected]

Gets a float value from the parameter.

wxFont wxXmlResourceHandler::GetFont (const wxString & *param* = "font") [protected]

Gets a font.

wxIcon wxXmlResourceHandler::GetIcon (const wxString & *param* = "icon", const wxArtClient & *defaultArtClient* = wxART_OTHER, wxSize *size* = wxDefaultSize) [protected]

Returns an icon.

wxIcon wxXmlResourceHandler::GetIcon (const wxXmlNode * *node*, const wxArtClient & *defaultArtClient* = wxART_OTHER, wxSize *size* = wxDefaultSize) [protected]

Gets an icon from an XmlNode.

Since

2.9.1

wxIconBundle wxXmlResourceHandler::GetIconBundle (const wxString & *param,* const wxArtClient & *defaultArtClient* = wxART_OTHER) [protected]

Returns an icon bundle.

Note

Bundles can be loaded either with stock IDs or from files that contain more than one image (e.g. Windows icon files). If a file contains only single image, a bundle with only one icon will be created.

Since

2.9.0

int wxXmlResourceHandler::GetID ( ) [protected]

Returns the XRCID.

wxImageList* wxXmlResourceHandler::GetImageList (const wxString & *param* = "imagelist") [protected]

Creates an image list from the *param* markup data.

Returns

The new instance of wxImageList or NULL if no data is found.

Since

2.9.1

wxObject* wxXmlResourceHandler::GetInstance ( ) const [protected]

After CreateResource has been called this will return the instance that the XML resource content should be created upon, if it has already been created.

If NULL then the handler should create the object itself.

Since

2.9.5

long wxXmlResourceHandler::GetLong (const wxString & *param,* long *defaultv* = 0) [protected]

Gets the integer value from the parameter.

wxString wxXmlResourceHandler::GetName ( ) [protected]

Returns the resource name.

wxXmlNode* wxXmlResourceHandler::GetNode ( ) const [protected]

After CreateResource has been called this will return the XML node being processed.

Since

2.9.5

wxXmlNode* **wxXmlResourceHandler::GetNodeChildren** (**const wxXmlNode** * ***node***) **const** [protected]

Gets the first child of the given node or NULL.

This method is safe to call with NULL argument, it just returns NULL in this case.

Since

3.1.0

wxString **wxXmlResourceHandler::GetNodeContent** (**wxXmlNode** * ***node***) [protected]

Gets node content from wxXML_ENTITY_NODE.

wxXmlNode* **wxXmlResourceHandler::GetNodeNext** (**const wxXmlNode** * ***node***) **const** [protected]

Gets the next sibling node related to the given node, possibly NULL.

This method is safe to call with NULL argument, it just returns NULL in this case.

Since

3.1.0

wxXmlNode* **wxXmlResourceHandler::GetNodeParent** (**const wxXmlNode** * ***node***) **const** [protected]

Gets the parent of the node given.

This method is safe to call with NULL argument, it just returns NULL in this case.

Since

3.1.0

wxXmlNode* **wxXmlResourceHandler::GetParamNode** (**const wxString** & ***param***) [protected]

Finds the node or returns NULL.

wxString **wxXmlResourceHandler::GetParamValue** (**const wxString** & ***param***) [protected]

Finds the parameter value or returns the empty string.

wxString **wxXmlResourceHandler::GetParamValue** (**const wxXmlNode** * ***node***) [protected]

Returns the node parameter value.

Since

2.9.1

wxObject* wxXmlResourceHandler::GetParent ( ) const [protected]

After CreateResource has been called this will return the current item's parent, if any.

Since

2.9.5

wxWindow* wxXmlResourceHandler::GetParentAsWindow ( ) const [protected]

After CreateResource has been called this will return the item's parent as a wxWindow.

Since

2.9.5

wxPoint wxXmlResourceHandler::GetPosition (const wxString & *param* = "pos") [protected]

Gets the position (may be in dialog units).

wxXmlResource* wxXmlResourceHandler::GetResource ( ) const [protected]

After CreateResource has been called this will return the current wxXmlResource object.

Since

2.9.5

wxSize wxXmlResourceHandler::GetSize (const wxString & *param* = "size", wxWindow * *windowToUse* = 0) [protected]

Gets the size (may be in dialog units).

int wxXmlResourceHandler::GetStyle (const wxString & *param* = "style", int *defaults* = 0) [protected]

Gets style flags from text in form "flag | flag2| flag3 |..." Only understands flags added with AddStyle().

wxString wxXmlResourceHandler::GetText (const wxString & *param*, bool *translate* = true) [protected]

Gets text from param and does some conversions:

- replaces \n, \r, \t by respective characters (according to C syntax)
- replaces $ by and $$ by $ (needed for _File to File translation because of XML syntax)
- calls wxGetTranslations (unless disabled in wxXmlResource)

bool wxXmlResourceHandler::HasParam (const wxString & *param*) [protected]

Check to see if a parameter exists.

bool wxXmlResourceHandler::IsObjectNode (const wxXmlNode * *node*) const [protected]

Checks if the given node is an object node.

Object nodes are those named "object" or "object_ref".

Since

3.1.0

bool wxXmlResourceHandler::IsOfClass (wxXmlNode * *node,* const wxString & *classname*) [protected]

Convenience function.

Returns true if the node has a property class equal to classname, e.g. object class="wxDialog".

void wxXmlResourceHandler::ReportError (wxXmlNode * *context,* const wxString & *message*) [protected]

Reports error in XRC resources to the user.

See wxXmlResource::ReportError() for more information.

Since

2.9.0

void wxXmlResourceHandler::ReportError (const wxString & *message*) [protected]

Like ReportError(wxXmlNode*, const wxString&), but uses the node of currently processed object (m_node) as the context.

Since

2.9.0

void wxXmlResourceHandler::ReportParamError (const wxString & *param,* const wxString & *message*) [protected]

Like ReportError(wxXmlNode*, const wxString&), but uses the node of parameter *param* of the currently processed object as the context.

This is convenience function for reporting errors in particular parameters.

Since

2.9.0

void wxXmlResourceHandler::SetParentResource (wxXmlResource * *res*)

Sets the parent resource.

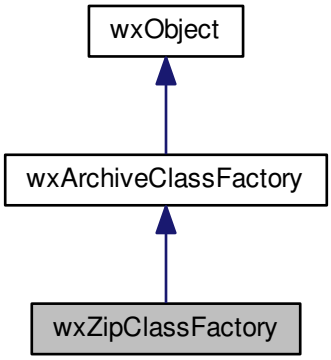
void wxXmlResourceHandler::SetupWindow (wxWindow * *wnd*) [protected]

Sets common window options.

21.875 wxZipClassFactory Class Reference

`#include <wx/zipstrm.h>`

Inheritance diagram for wxZipClassFactory:



21.875.1 Detailed Description

Class factory for the zip archive format.

See the base class for details.

Library: wxBase

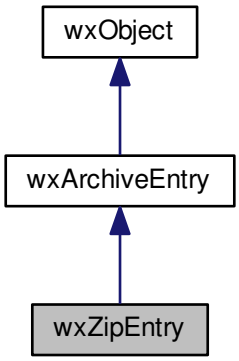
`#include <wx/zipstrm.h>`

Inheritance diagram for wxZipEntry:



21.876.1 Detailed Description

Holds the meta-data for an entry in a zip.

21.876.2 Field availability

When reading a zip from a stream that is seekable, wxZipEntry::GetNextEntry() returns a fully populated wxZipEntry object except for wxZipEntry::GetLocalExtra(). wxZipEntry::GetLocalExtra() becomes available when the entry is opened, either by calling wxZipInputStream::OpenEntry() or by making an attempt to read the entry's data.

For zips on non-seekable streams, the following fields are always available when wxZipEntry::GetNextEntry() returns:

- wxZipEntry::GetDateTime
- wxZipEntry::GetInternalFormat
- wxZipEntry::GetInternalName
- wxZipEntry::GetFlags
- wxZipEntry::GetLocalExtra
- wxZipEntry::GetMethod
- wxZipEntry::GetName

- wxZipEntry::GetOffset
- wxZipEntry::IsDir

The following fields are also usually available when GetNextEntry() returns, however, if the zip was also written to a non-seekable stream the zipper is permitted to store them after the entry's data. In that case they become available when the entry's data has been read to Eof(), or CloseEntry() has been called. (GetFlags() & wxZIP_SUMS_FOLLOW) != 0 indicates that one or more of these come after the data:

- wxZipEntry::GetCompressedSize
- wxZipEntry::GetCrc
- wxZipEntry::GetSize

The following are stored at the end of the zip, and become available when the end of the zip has been reached, i.e. after GetNextEntry() returns NULL and Eof() is true:

- wxZipEntry::GetComment
- wxZipEntry::GetExternalAttributes
- wxZipEntry::GetExtra
- wxZipEntry::GetMode
- wxZipEntry::GetSystemMadeBy
- wxZipEntry::IsReadOnly
- wxZipEntry::IsMadeByUnix
- wxZipEntry::IsText

Library: wxBase

Public Member Functions

- wxZipEntry (const wxString &name=wxEmptyString, const wxDateTime &dt=Now(), wxFileOffset size=wxInvalidOffset)
- wxZipEntry (const wxZipEntry &entry)

  Copy constructor.
- wxZipEntry * Clone () const

  Make a copy of this entry.
- wxFileOffset GetCompressedSize () const

  The compressed size of this entry in bytes.
- wxUint32 GetCrc () const

  CRC32 for this entry's data.
- int GetFlags () const

  Returns a combination of the bits flags in the enumeration `wxZipFlags`.
- bool IsMadeByUnix () const

Returns true if GetSystemMadeBy() is a flavour of unix.

- wxZipEntry & operator= (const wxZipEntry &entry)

  Assignment operator.

- wxString GetComment () const

  Gets and sets the short comment for this entry.
- void SetComment (const wxString &comment)

  Gets and sets the short comment for this entry.

- wxUint32 GetExternalAttributes () const

  The low 8 bits are always the DOS/Windows file attributes for this entry.
- void SetExternalAttributes (wxUint32 attr)

  The low 8 bits are always the DOS/Windows file attributes for this entry.

- const char * GetExtra () const

  The extra field from the entry's central directory record.
- size_t GetExtraLen () const

  The extra field from the entry's central directory record.
- void SetExtra (const char *extra, size_t len)

  The extra field from the entry's central directory record.

- const char * GetLocalExtra () const

  The extra field from the entry's local record.
- size_t GetLocalExtraLen () const

  The extra field from the entry's local record.
- void SetLocalExtra (const char *extra, size_t len)

  The extra field from the entry's local record.

- int GetMethod () const

  The compression method.
- void SetMethod (int method)

  The compression method.

- int GetMode () const

  If IsMadeByUnix() is true then returns the unix permission bits stored in GetExternalAttributes().
- void SetMode (int mode)

  Sets the DOS attributes in GetExternalAttributes() to be consistent with the mode given.

- int GetSystemMadeBy () const

  The originating file-system.
- void SetSystemMadeBy (int system)

  The originating file-system.

- wxString GetInternalName (const wxString &name, wxPathFormat format=wxPATH_NATIVE, bool *pIsDir=NULL)

  A static member that translates a filename into the internal format used within the archive.
- wxString GetInternalName () const

  Returns the entry's filename in the internal format used within the archive.

- bool IsText () const

  Indicates that this entry's data is text in an 8-bit encoding.

- void SetIsText (bool isText=true)

  Indicates that this entry's data is text in an 8-bit encoding.

- void SetNotifier (wxZipNotifier &notifier)

  Sets the notifier (see wxZipNotifier) for this entry.

- void UnsetNotifier ()

  Sets the notifier (see wxZipNotifier) for this entry.

Additional Inherited Members

21.876.3 Constructor & Destructor Documentation

wxZipEntry::wxZipEntry (const wxString & *name* = wxEmptyString, const wxDateTime & *dt* = Now(), wxFileOffset *size* = wxInvalidOffset)

wxZipEntry::wxZipEntry (const wxZipEntry & *entry*)

Copy constructor.

21.876.4 Member Function Documentation

wxZipEntry* wxZipEntry::Clone ( ) const

Make a copy of this entry.

wxString wxZipEntry::GetComment ( ) const

Gets and sets the short comment for this entry.

wxFileOffset wxZipEntry::GetCompressedSize ( ) const

The compressed size of this entry in bytes.

wxUint32 wxZipEntry::GetCrc ( ) const

CRC32 for this entry's data.

wxUint32 wxZipEntry::GetExternalAttributes ( ) const

The low 8 bits are always the DOS/Windows file attributes for this entry.

The values of these attributes are given in the enumeration wxZipAttributes.

The remaining bits can store platform specific permission bits or attributes, and their meaning depends on the value of SetSystemMadeBy(). If IsMadeByUnix() is true then the high 16 bits are unix mode bits.

The following other accessors access these bits:

- IsReadOnly() / SetIsReadOnly()
- IsDir() / SetIsDir()
- GetMode() / SetMode()

const char* wxZipEntry::GetExtra ( ) const

The extra field from the entry's central directory record.

The extra field is used to store platform or application specific data. See Pkware's document 'appnote.txt' for information on its format.

size_t wxZipEntry::GetExtraLen ( ) const

The extra field from the entry's central directory record.

The extra field is used to store platform or application specific data. See Pkware's document 'appnote.txt' for information on its format.

int wxZipEntry::GetFlags ( ) const

Returns a combination of the bits flags in the enumeration `wxZipFlags`.

wxString wxZipEntry::GetInternalName (const wxString & *name*, wxPathFormat *format* = wxPATH_NATIVE, bool * *pIsDir* = NULL)

A static member that translates a filename into the internal format used within the archive.

If the third parameter is provided, the bool pointed to is set to indicate whether the name looks like a directory name (i.e. has a trailing path separator).

See also

Looking Up an Archive Entry by Name

wxString wxZipEntry::GetInternalName ( ) const [virtual]

Returns the entry's filename in the internal format used within the archive.

The name can include directory components, i.e. it can be a full path.

The names of directory entries are returned without any trailing path separator. This gives a canonical name that can be used in comparisons.

Implements wxArchiveEntry.

const char* wxZipEntry::GetLocalExtra ( ) const

The extra field from the entry's local record.

The extra field is used to store platform or application specific data. See Pkware's document 'appnote.txt' for information on its format.

size_t wxZipEntry::GetLocalExtraLen ( ) const

The extra field from the entry's local record.

The extra field is used to store platform or application specific data. See Pkware's document 'appnote.txt' for information on its format.

int wxZipEntry::GetMethod ( ) const

The compression method.

The enumeration wxZipMethod lists the possible values.

The default constructor sets this to `wxZIP_METHOD_DEFAULT`, which allows wxZipOutputStream to choose the method when writing the entry.

int wxZipEntry::GetMode ( ) const

If IsMadeByUnix() is true then returns the unix permission bits stored in GetExternalAttributes().

Otherwise synthesises them from the DOS attributes.

int wxZipEntry::GetSystemMadeBy ( ) const

The originating file-system.

The default constructor sets this to `wxZIP_SYSTEM_MSDOS`. Set it to `wxZIP_SYSTEM_UNIX` in order to be able to store unix permissions using SetMode().

bool wxZipEntry::IsMadeByUnix ( ) const

Returns true if GetSystemMadeBy() is a flavour of unix.

bool wxZipEntry::IsText ( ) const

Indicates that this entry's data is text in an 8-bit encoding.

wxZipEntry& wxZipEntry::operator= (const wxZipEntry & *entry*)

Assignment operator.

void wxZipEntry::SetComment (const wxString & *comment*)

Gets and sets the short comment for this entry.

void wxZipEntry::SetExternalAttributes (wxUint32 *attr*)

The low 8 bits are always the DOS/Windows file attributes for this entry.

The values of these attributes are given in the enumeration wxZipAttributes.

The remaining bits can store platform specific permission bits or attributes, and their meaning depends on the value of SetSystemMadeBy(). If IsMadeByUnix() is true then the high 16 bits are unix mode bits.

The following other accessors access these bits:

- IsReadOnly() / SetIsReadOnly()
- IsDir() / SetIsDir()
- GetMode() / SetMode()

void wxZipEntry::SetExtra (const char * *extra*, size_t *len*)

The extra field from the entry's central directory record.

The extra field is used to store platform or application specific data. See Pkware's document 'appnote.txt' for information on its format.

void wxZipEntry::SetIsText (bool *isText* = `true`)

Indicates that this entry's data is text in an 8-bit encoding.

void wxZipEntry::SetLocalExtra (const char * *extra*, size_t *len*)

The extra field from the entry's local record.

The extra field is used to store platform or application specific data. See Pkware's document 'appnote.txt' for information on its format.

void wxZipEntry::SetMethod (int *method*)

The compression method.

The enumeration wxZipMethod lists the possible values.

The default constructor sets this to `wxZIP_METHOD_DEFAULT`, which allows wxZipOutputStream to choose the method when writing the entry.

void wxZipEntry::SetMode (int *mode*)

Sets the DOS attributes in GetExternalAttributes() to be consistent with the *mode* given.

If IsMadeByUnix() is true then also stores *mode* in GetExternalAttributes(). Note that the default constructor sets GetSystemMadeBy() to `wxZIP_SYSTEM_MSDOS` by default. So to be able to store unix permissions when creating zips, call SetSystemMadeBy(wxZIP_SYSTEM_UNIX).

void wxZipEntry::SetNotifier (wxZipNotifier & *notifier*)

Sets the notifier (see wxZipNotifier) for this entry.

Whenever the wxZipInputStream updates this entry, it will then invoke the associated notifier's wxZipNotifier::OnEntryUpdated() method.

Setting a notifier is not usually necessary. It is used to handle certain cases when modifying an zip in a pipeline (i.e. between non-seekable streams).

See also

Archives on Non-Seekable Streams, wxZipNotifier

void wxZipEntry::SetSystemMadeBy (int *system*)

The originating file-system.

The default constructor sets this to `wxZIP_SYSTEM_MSDOS`. Set it to `wxZIP_SYSTEM_UNIX` in order to be able to store unix permissions using SetMode().

void wxZipEntry::UnsetNotifier ( ) [virtual]

Sets the notifier (see wxZipNotifier) for this entry.

Whenever the wxZipInputStream updates this entry, it will then invoke the associated notifier's wxZipNotifier::OnEntryUpdated() method.

Setting a notifier is not usually necessary. It is used to handle certain cases when modifying an zip in a pipeline (i.e. between non-seekable streams).

See also

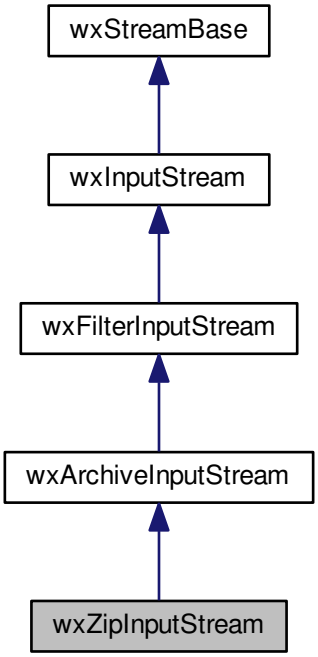
Archives on Non-Seekable Streams, wxZipNotifier

Reimplemented from wxArchiveEntry.

21.877 wxZipInputStream Class Reference

`#include <wx/zipstrm.h>`

Inheritance diagram for wxZipInputStream:



21.877.1 Detailed Description

Input stream for reading zip files.

wxZipInputStream::GetNextEntry() returns a wxZipEntry object containing the meta-data for the next entry in the zip (and gives away ownership). Reading from the wxZipInputStream then returns the entry's data. Eof() becomes

true after an attempt has been made to read past the end of the entry's data. When there are no more entries, GetNextEntry() returns NULL and sets Eof().

Note that in general zip entries are not seekable, and wxZipInputStream::SeekI() always returns wxInvalidOffset.

Library: wxBase

Category: Archive support, Streams

See also

Archive Formats, wxZipEntry, wxZipOutputStream

Public Member Functions

- bool CloseEntry ()

  Closes the current entry.
- wxString GetComment ()

  Returns the zip comment.
- wxZipEntry * GetNextEntry ()

  Closes the current entry if one is open, then reads the meta-data for the next entry and returns it in a wxZipEntry object, giving away ownership.
- int GetTotalEntries ()

  For a zip on a seekable stream returns the total number of entries in the zip.
- bool OpenEntry (wxZipEntry &entry)

  Closes the current entry if one is open, then opens the entry specified by the entry object.

- wxZipInputStream (wxInputStream &stream, wxMBConv &conv=wxConvLocal)

  Constructor.
- wxZipInputStream (wxInputStream *stream, wxMBConv &conv=wxConvLocal)

  Constructor.

Additional Inherited Members

21.877.2 Constructor & Destructor Documentation

wxZipInputStream::wxZipInputStream (wxInputStream & *stream,* wxMBConv & *conv* = `wxConvLocal`)

Constructor.

In a Unicode build the second parameter *conv* is used to translate the filename and comment fields into Unicode. It has no effect on the stream's data. If the parent stream is passed as a pointer then the new filter stream takes ownership of it. If it is passed by reference then it does not.

wxZipInputStream::wxZipInputStream (wxInputStream * *stream,* wxMBConv & *conv* = `wxConvLocal`)

Constructor.

In a Unicode build the second parameter *conv* is used to translate the filename and comment fields into Unicode. It has no effect on the stream's data. If the parent stream is passed as a pointer then the new filter stream takes ownership of it. If it is passed by reference then it does not.

21.877.3 Member Function Documentation

bool wxZipInputStream::CloseEntry ( ) [virtual]

Closes the current entry.

On a non-seekable stream reads to the end of the current entry first.

Implements wxArchiveInputStream.

wxString wxZipInputStream::GetComment ( )

Returns the zip comment.

This is stored at the end of the zip, therefore when reading a zip from a non-seekable stream, it returns the empty string until the end of the zip has been reached, i.e. when GetNextEntry() returns NULL.

wxZipEntry* wxZipInputStream::GetNextEntry ( )

Closes the current entry if one is open, then reads the meta-data for the next entry and returns it in a wxZipEntry object, giving away ownership.

The stream is then open and can be read.

int wxZipInputStream::GetTotalEntries ( )

For a zip on a seekable stream returns the total number of entries in the zip.

For zips on non-seekable streams returns the number of entries returned so far by GetNextEntry().

bool wxZipInputStream::OpenEntry (wxZipEntry & *entry*)

Closes the current entry if one is open, then opens the entry specified by the *entry* object.

entry should be from the same zip file, and the zip should be on a seekable stream.

21.878 wxZipNotifier Class Reference

```
#include <wx/zipstrm.h>
```

21.878.1 Detailed Description

If you need to know when a wxZipInputStream updates a wxZipEntry, you can create a notifier by deriving from this abstract base class, overriding wxZipNotifier::OnEntryUpdated().

An instance of your notifier class can then be assigned to wxZipEntry objects, using wxZipEntry::SetNotifier().

Setting a notifier is not usually necessary. It is used to handle certain cases when modifying an zip in a pipeline (i.e. between non-seekable streams). See Archives on Non-Seekable Streams.

Library: wxBase

Category: Archive support, Streams

Public Member Functions

- virtual void OnEntryUpdated (wxZipEntry &entry)=0

  Override this to receive notifications when an wxZipEntry object changes.

21.878.2 Member Function Documentation

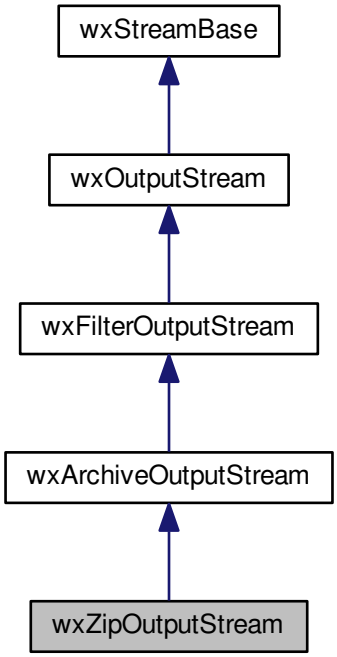
virtual void wxZipNotifier::OnEntryUpdated (wxZipEntry & *entry*) `[pure virtual]`

Override this to receive notifications when an wxZipEntry object changes.

21.879 wxZipOutputStream Class Reference

`#include <wx/zipstrm.h>`

Inheritance diagram for wxZipOutputStream:



21.879.1 Detailed Description

Output stream for writing zip files.

wxZipOutputStream::PutNextEntry() is used to create a new entry in the output zip, then the entry's data is written to the wxZipOutputStream. Another call to wxZipOutputStream::PutNextEntry() closes the current entry and begins the next.

Library: wxBase

Category: Archive support, Streams

See also

Archive Formats, wxZipEntry, wxZipInputStream

Public Member Functions

- virtual ~wxZipOutputStream ()

  The destructor calls Close() to finish writing the zip if it has not been called already.
- bool Close ()

  Finishes writing the zip, returning true if successful.
- bool CloseEntry ()

  Close the current entry.
- bool CopyArchiveMetaData (wxZipInputStream &inputStream)

  Transfers the zip comment from the wxZipInputStream to this output stream.
- bool CopyEntry (wxZipEntry *entry, wxZipInputStream &inputStream)

  Takes ownership of entry and uses it to create a new entry in the zip.
- bool PutNextDirEntry (const wxString &name, const wxDateTime &dt=wxDateTime::Now())

  Create a new directory entry (see wxArchiveEntry::IsDir) with the given name and timestamp.
- void SetComment (const wxString &comment)

  Sets a comment for the zip as a whole.

- wxZipOutputStream (wxOutputStream &stream, int level=-1, wxMBConv &conv=wxConvLocal)

  Constructor.
- wxZipOutputStream (wxOutputStream *stream, int level=-1, wxMBConv &conv=wxConvLocal)

  Constructor.

- int GetLevel () const

  Set the compression level that will be used the next time an entry is created.
- void SetLevel (int level)

  Set the compression level that will be used the next time an entry is created.

- bool PutNextEntry (wxZipEntry *entry)

  Takes ownership of entry and uses it to create a new entry in the zip.
- bool PutNextEntry (const wxString &name, const wxDateTime &dt=wxDateTime::Now(), wxFileOffset size=wxInvalidOffset)

  Create a new entry with the given name, timestamp and size.

Additional Inherited Members

21.879.2 Constructor & Destructor Documentation

wxZipOutputStream::wxZipOutputStream (wxOutputStream & *stream,* int *level* = -1, wxMBConv & *conv* = wxConvLocal)

Constructor.

level is the compression level to use. It can be a value between 0 and 9 or -1 to use the default value which currently is equivalent to 6.

If the parent stream is passed as a pointer then the new filter stream takes ownership of it. If it is passed by reference then it does not. In a Unicode build the third parameter *conv* is used to translate the filename and comment fields to an 8-bit encoding. It has no effect on the stream's data.

wxZipOutputStream::wxZipOutputStream (wxOutputStream * *stream,* int *level* = -1, wxMBConv & *conv* = wxConvLocal)

Constructor.

level is the compression level to use. It can be a value between 0 and 9 or -1 to use the default value which currently is equivalent to 6.

If the parent stream is passed as a pointer then the new filter stream takes ownership of it. If it is passed by reference then it does not. In a Unicode build the third parameter *conv* is used to translate the filename and comment fields to an 8-bit encoding. It has no effect on the stream's data.

virtual wxZipOutputStream::~wxZipOutputStream ( ) [virtual]

The destructor calls Close() to finish writing the zip if it has not been called already.

21.879.3 Member Function Documentation

bool wxZipOutputStream::Close ( ) [virtual]

Finishes writing the zip, returning true if successful.

Called by the destructor if not called explicitly.

Reimplemented from wxArchiveOutputStream.

bool wxZipOutputStream::CloseEntry ( ) [virtual]

Close the current entry.

It is called implicitly whenever another new entry is created with CopyEntry() or PutNextEntry(), or when the zip is closed.

Implements wxArchiveOutputStream.

bool wxZipOutputStream::CopyArchiveMetaData (wxZipInputStream & *inputStream*)

Transfers the zip comment from the wxZipInputStream to this output stream.

bool wxZipOutputStream::CopyEntry (wxZipEntry * *entry*, wxZipInputStream & *inputStream*)

Takes ownership of *entry* and uses it to create a new entry in the zip.

entry is then opened in *inputStream* and its contents copied to this stream.

CopyEntry() is much more efficient than transferring the data using Read() and Write() since it will copy them without decompressing and recompressing them.

For zips on seekable streams, *entry* must be from the same zip file as *inputStream*. For non-seekable streams, *entry* must also be the last thing read from *inputStream*.

int wxZipOutputStream::GetLevel ( ) const

Set the compression level that will be used the next time an entry is created.

It can be a value between 0 and 9 or -1 to use the default value which currently is equivalent to 6.

bool wxZipOutputStream::PutNextDirEntry (const wxString & *name*, const wxDateTime & *dt* = wxDateTime::Now()) [virtual]

Create a new directory entry (see wxArchiveEntry::IsDir) with the given name and timestamp.

PutNextEntry() can also be used to create directory entries, by supplying a name with a trailing path separator.

Implements wxArchiveOutputStream.

bool wxZipOutputStream::PutNextEntry (wxZipEntry * *entry*)

Takes ownership of *entry* and uses it to create a new entry in the zip.

bool wxZipOutputStream::PutNextEntry (const wxString & *name*, const wxDateTime & *dt* = wxDateTime::Now(), wxFileOffset *size* = wxInvalidOffset) [virtual]

Create a new entry with the given name, timestamp and size.

Implements wxArchiveOutputStream.

void wxZipOutputStream::SetComment (const wxString & *comment*)

Sets a comment for the zip as a whole.

It is written at the end of the zip.

void wxZipOutputStream::SetLevel (int *level*)

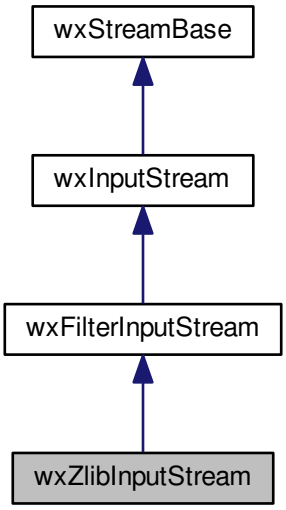
Set the compression level that will be used the next time an entry is created.

It can be a value between 0 and 9 or -1 to use the default value which currently is equivalent to 6.

21.880 wxZlibInputStream Class Reference

```
#include <wx/zstream.h>
```

Inheritance diagram for wxZlibInputStream:



21.880.1 Detailed Description

This filter stream decompresses a stream that is in zlib or gzip format.

Note that reading the gzip format requires zlib version 1.2.1 or greater, (the builtin version does support gzip format).

The stream is not seekable, wxInputStream::SeekI returns wxInvalidOffset. Also wxStreamBase::GetSize() is not supported, it always returns 0.

Library: wxBase

Category: Archive support, Streams

See also

wxInputStream, wxZlibOutputStream.

Public Member Functions

- wxZlibInputStream (wxInputStream &stream, int flags=wxZLIB_AUTO)

  If the parent stream is passed as a pointer then the new filter stream takes ownership of it.
- wxZlibInputStream (wxInputStream *stream, int flags=wxZLIB_AUTO)

  If the parent stream is passed as a pointer then the new filter stream takes ownership of it.

- bool SetDictionary (const char *data, const size_t datalen)

  Sets the dictionary to the specified chunk of data.
- bool SetDictionary (const wxMemoryBuffer &buf)

  Sets the dictionary to the specified chunk of data.

Static Public Member Functions

- static bool CanHandleGZip ()

  Returns true if zlib library in use can handle gzip compressed data.

Additional Inherited Members

21.880.2 Constructor & Destructor Documentation

wxZlibInputStream::wxZlibInputStream (wxInputStream & *stream,* int *flags* = wxZLIB_AUTO)

If the parent stream is passed as a pointer then the new filter stream takes ownership of it.

If it is passed by reference then it does not.

The *flags* wxZLIB_ZLIB and wxZLIB_GZIP specify whether the input data is in zlib or gzip format. If wxZLIB_AUTO is used, then zlib will autodetect the stream type, this is the default.

If *flags* is wxZLIB_NO_HEADER, then the data is assumed to be a raw deflate stream without either zlib or gzip headers. This is a lower level mode, which is not usually used directly. It can be used to read a raw deflate stream embedded in a higher level protocol.

The values of the wxZLibFlags enumeration can be used.

wxZlibInputStream::wxZlibInputStream (wxInputStream * *stream,* int *flags* = wxZLIB_AUTO)

If the parent stream is passed as a pointer then the new filter stream takes ownership of it.

If it is passed by reference then it does not.

The *flags* wxZLIB_ZLIB and wxZLIB_GZIP specify whether the input data is in zlib or gzip format. If wxZLIB_AUTO is used, then zlib will autodetect the stream type, this is the default.

If *flags* is wxZLIB_NO_HEADER, then the data is assumed to be a raw deflate stream without either zlib or gzip headers. This is a lower level mode, which is not usually used directly. It can be used to read a raw deflate stream embedded in a higher level protocol.

The values of the wxZLibFlags enumeration can be used.

21.880.3 Member Function Documentation

static bool wxZlibInputStream::CanHandleGZip ( ) [static]

Returns true if zlib library in use can handle gzip compressed data.

bool wxZlibInputStream::SetDictionary (const char * *data,* const size_t *datalen*)

Sets the dictionary to the specified chunk of data.

This can improve compression rate but note that the dictionary has to be the same when you deflate the data as when you inflate the data, otherwise you will inflate corrupted data.

Returns true if the dictionary was successfully set.

bool wxZlibInputStream::SetDictionary (const wxMemoryBuffer & *buf*)

Sets the dictionary to the specified chunk of data.

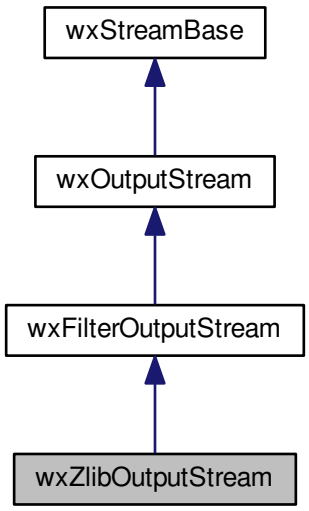
This can improve compression rate but note that the dictionary has to be the same when you deflate the data as when you inflate the data, otherwise you will inflate corrupted data.

Returns true if the dictionary was successfully set.

21.881 wxZlibOutputStream Class Reference

`#include <wx/zstream.h>`

Inheritance diagram for wxZlibOutputStream:



21.881.1 Detailed Description

This stream compresses all data written to it.

The compressed output can be in zlib or gzip format. Note that writing the gzip format requires zlib version 1.2.1 or greater (the builtin version does support gzip format).

The stream is not seekable, wxOutputStream::SeekO() returns wxInvalidOffset.

Library: wxBase

Category: Archive support, Streams

wxOutputStream, wxZlibInputStream

Public Member Functions

- wxZlibOutputStream (wxOutputStream &stream, int level=-1, int flags=wxZLIB_ZLIB)

Creates a new write-only compressed stream.

- wxZlibOutputStream (wxOutputStream *stream, int level=-1, int flags=wxZLIB_ZLIB)

  Creates a new write-only compressed stream.

- bool SetDictionary (const char *data, const size_t datalen)

  Sets the dictionary to the specified chunk of data.

- bool SetDictionary (const wxMemoryBuffer &buf)

  Sets the dictionary to the specified chunk of data.

Static Public Member Functions

- static bool CanHandleGZip ()

  Returns true if zlib library in use can handle gzip compressed data.

Additional Inherited Members

21.881.2 Constructor & Destructor Documentation

wxZlibOutputStream::wxZlibOutputStream (wxOutputStream & *stream,* int *level* = −1, int *flags* = wxZLIB_ZLIB)

Creates a new write-only compressed stream.

level means level of compression. It is number between 0 and 9 (including these values) where 0 means no compression and 9 best but slowest compression. -1 is default value (currently equivalent to 6).

If the parent stream is passed as a pointer then the new filter stream takes ownership of it. If it is passed by reference then it does not.

The *flags* wxZLIB_ZLIB and wxZLIB_GZIP specify whether the output data will be in zlib or gzip format. wxZLIB_↩ ZLIB is the default.

If *flags* is wxZLIB_NO_HEADER, then a raw deflate stream is output without either zlib or gzip headers. This is a lower level mode, which is not usually used directly. It can be used to embed a raw deflate stream in a higher level protocol.

The values of the wxZlibCompressionLevels and wxZLibFlags enumerations can be used.

wxZlibOutputStream::wxZlibOutputStream (wxOutputStream * *stream,* int *level* = −1, int *flags* = wxZLIB_ZLIB)

Creates a new write-only compressed stream.

level means level of compression. It is number between 0 and 9 (including these values) where 0 means no compression and 9 best but slowest compression. -1 is default value (currently equivalent to 6).

If the parent stream is passed as a pointer then the new filter stream takes ownership of it. If it is passed by reference then it does not.

The *flags* wxZLIB_ZLIB and wxZLIB_GZIP specify whether the output data will be in zlib or gzip format. wxZLIB_↩ ZLIB is the default.

If *flags* is wxZLIB_NO_HEADER, then a raw deflate stream is output without either zlib or gzip headers. This is a lower level mode, which is not usually used directly. It can be used to embed a raw deflate stream in a higher level protocol.

The values of the wxZlibCompressionLevels and wxZLibFlags enumerations can be used.

21.881.3 Member Function Documentation

static bool wxZlibOutputStream::CanHandleGZip ( ) [static]

Returns true if zlib library in use can handle gzip compressed data.

bool wxZlibOutputStream::SetDictionary (const char * *data,* const size_t *datalen*)

Sets the dictionary to the specified chunk of data.

This can improve compression rate but note that the dictionary has to be the same when you deflate the data as when you inflate the data, otherwise you will inflate corrupted data.

Returns true if the dictionary was successfully set.

bool wxZlibOutputStream::SetDictionary (const wxMemoryBuffer & *buf*)

Sets the dictionary to the specified chunk of data.

This can improve compression rate but note that the dictionary has to be the same when you deflate the data as when you inflate the data, otherwise you will inflate corrupted data.

Returns true if the dictionary was successfully set.

22.88 interface/wx/app.h File Reference

Classes

- class wxAppConsole

  This class is essential for writing console-only or hybrid apps without having to define `wxUSE_GUI=0`.
- class wxApp

  The wxApp class represents the application itself when `wxUSE_GUI=1`.

Macros

- #define wxDECLARE_APP(className)

  This is used in headers to create a forward declaration of the wxGetApp() function implemented by wxIMPLEMENT_APP().
- #define wxIMPLEMENT_APP(className)

  This is used in the application class implementation file to make the application class known to wxWidgets for dynamic construction.
- #define wxDISABLE_DEBUG_SUPPORT()

  Use this macro to disable all debugging code in release build when not using wxIMPLEMENT_APP().

Functions

- wxAppDerivedClass & wxGetApp ()

  This function doesn't exist in wxWidgets but it is created by using the wxIMPLEMENT_APP() macro.
- bool wxHandleFatalExceptions (bool doIt=true)

  If doIt is true, the fatal exceptions (also known as general protection faults under Windows or segmentation violations in the Unix world) will be caught and passed to wxApp::OnFatalException.
- bool wxInitialize ()

  This function is used in wxBase only and only if you don't create wxApp object at all.
- void wxUninitialize ()

  This function is for use in console (wxBase) programs only.
- void wxWakeUpIdle ()

  This function wakes up the (internal and platform dependent) idle system, i.e.
- bool wxYield ()

  Calls wxAppConsole::Yield.
- bool wxSafeYield (wxWindow *win=NULL, bool onlyIfNeeded=false)

  Calls wxApp::SafeYield.
- int wxEntry (int &argc, wxChar **argv)

  This function initializes wxWidgets in a platform-dependent way.
- int wxEntry (HINSTANCE hInstance, HINSTANCE hPrevInstance=NULL, char *pCmdLine=NULL, int nCmdShow=SW_SHOWNORMAL)

  *See wxEntry(int&,wxChar**) for more info about this function.*
- void wxExit ()

  Exits application after calling wxApp::OnExit.

Variables

- wxApp * wxTheApp

  The global pointer to the singleton wxApp object.

22.88.1 Variable Documentation

wxApp* wxTheApp

The global pointer to the singleton wxApp object.

See also

wxApp::GetInstance()

22.89 docs/doxygen/overviews/archive.h File Reference

22.90 interface/wx/archive.h File Reference

Classes

- class wxArchiveInputStream

  This is an abstract base class which serves as a common interface to archive input streams such as wxZipInputStream.
- class wxArchiveOutputStream

This is an abstract base class which serves as a common interface to archive output streams such as wxZipOutputStream.

- class wxArchiveEntry

  This is an abstract base class which serves as a common interface to archive entry classes such as wxZipEntry.

- class wxArchiveClassFactory

  Allows the creation of streams to handle archive formats such as zip and tar.

- class wxArchiveNotifier

  If you need to know when a wxArchiveInputStream updates a wxArchiveEntry object, you can create a notifier by deriving from this abstract base class, overriding wxArchiveNotifier::OnEntryUpdated.

- class wxArchiveIterator

  An input iterator template class that can be used to transfer an archive's catalogue to a container.

22.91 docs/doxygen/overviews/aui.h File Reference

22.92 docs/doxygen/overviews/backwardcompatibility.h File Reference

22.93 docs/doxygen/overviews/bitmap.h File Reference

22.94 interface/wx/bitmap.h File Reference

Classes

- class wxBitmapHandler

  This is the base class for implementing bitmap file loading/saving, and bitmap creation from data.

- class wxBitmap

  This class encapsulates the concept of a platform-dependent bitmap, either monochrome or colour or colour with alpha channel support.

- class wxMask

  This class encapsulates a monochrome mask bitmap, where the masked area is black and the unmasked area is white.

Macros

- #define wxBITMAP_SCREEN_DEPTH (-1)

  In wxBitmap and wxBitmapHandler context this value means: "use the screen depth".

Variables

- wxBitmap wxNullBitmap

  An empty wxBitmap object.

22.94.1 Macro Definition Documentation

#define wxBITMAP_SCREEN_DEPTH (-1)

In wxBitmap and wxBitmapHandler context this value means: "use the screen depth".

22.94.2 Variable Documentation

wxBitmap wxNullBitmap

An empty wxBitmap object.

22.95 docs/doxygen/overviews/bookctrl.h File Reference

22.96 interface/wx/bookctrl.h File Reference

Classes

- class wxBookCtrlBase

  A book control is a convenient way of displaying multiple pages of information, displayed one page at a time.
- class wxBookCtrlEvent

  This class represents the events generated by book controls (wxNotebook, wxListbook, wxChoicebook, wxTreebook, wxAuiNotebook).

Macros

- #define wxBK_DEFAULT 0x0000

  wxBookCtrl flags (common for wxNotebook, wxListbook, wxChoicebook, wxTreebook)
- #define wxBK_TOP 0x0010
- #define wxBK_BOTTOM 0x0020
- #define wxBK_LEFT 0x0040
- #define wxBK_RIGHT 0x0080
- #define wxBK_ALIGN_MASK (wxBK_TOP | wxBK_BOTTOM | wxBK_LEFT | wxBK_RIGHT)
- #define wxBookCtrl TheBestBookCtrlForTheCurrentPlatform

  wxBookCtrl is defined to one of the 'real' book controls.

Enumerations

- enum {
  wxBK_HITTEST_NOWHERE = 1,
  wxBK_HITTEST_ONICON = 2,
  wxBK_HITTEST_ONLABEL = 4,
  wxBK_HITTEST_ONITEM = wxBK_HITTEST_ONICON | wxBK_HITTEST_ONLABEL,
  wxBK_HITTEST_ONPAGE = 8 }

  Bit flags returned by wxBookCtrl::HitTest().

22.96.1 Macro Definition Documentation

#define wxBK_ALIGN_MASK (wxBK_TOP | wxBK_BOTTOM | wxBK_LEFT | wxBK_RIGHT)

#define wxBK_BOTTOM 0x0020

#define wxBK_DEFAULT 0x0000

wxBookCtrl flags (common for wxNotebook, wxListbook, wxChoicebook, wxTreebook)

#define wxBK_LEFT 0x0040

#define wxBK_RIGHT 0x0080

#define wxBK_TOP 0x0010

#define wxBookCtrl TheBestBookCtrlForTheCurrentPlatform

wxBookCtrl is defined to one of the 'real' book controls.

See wxBookCtrl Overview for more info.

22.96.2 Enumeration Type Documentation

anonymous enum

Bit flags returned by wxBookCtrl::HitTest().

Notice that wxOSX currently only returns wxBK_HITTEST_ONLABEL or wxBK_HITTEST_NOWHERE and never the other values, so you should only test for these two in the code that should be portable under OS X.

Enumerator

wxBK_HITTEST_NOWHERE No tab at the specified point.

wxBK_HITTEST_ONICON The point is over an icon.

wxBK_HITTEST_ONLABEL The point is over a tab label.

wxBK_HITTEST_ONITEM The point if over a tab item but not over its icon or label.

wxBK_HITTEST_ONPAGE The point is over the page area.

22.97 interface/wx/persist/bookctrl.h File Reference

Classes

- class wxPersistentBookCtrl

  Persistence adapter for wxBookCtrlBase.

Functions

- wxPersistentObject * wxCreatePersistentObject (wxBookCtrlBase *book)

  Overload allowing persistence adapter creation for wxBookCtrlBase-derived objects.

22.97.1 Function Documentation

wxPersistentObject* wxCreatePersistentObject (wxBookCtrlBase * *book*)

Overload allowing persistence adapter creation for wxBookCtrlBase-derived objects.

22.105 docs/doxygen/overviews/customwidgets.h File Reference

22.106 docs/doxygen/overviews/dataobject.h File Reference

22.107 docs/doxygen/overviews/datetime.h File Reference

22.108 interface/wx/datetime.h File Reference

Classes

- class wxDateTime

  wxDateTime class represents an absolute moment in time.
- class wxDateTime::TimeZone

  Class representing a time zone.
- struct wxDateTime::Tm

  Contains broken down date-time representation.
- class wxDateTimeWorkDays
- class wxDateSpan

  This class is a "logical time span" and is useful for implementing program logic for such things as "add one month to the date" which, in general, doesn't mean to add 60∗60∗24∗31 seconds to it, but to take the same date the next month (to understand that this is indeed different consider adding one month to Feb, 15 – we want to get Mar, 15, of course).
- class wxTimeSpan

  wxTimeSpan class represents a time interval.
- class wxDateTimeHolidayAuthority

Macros

- #define wxInvalidDateTime wxDefaultDateTime

Variables

- const wxDateTime wxDefaultDateTime

  Global instance of an empty wxDateTime object.

22.108.1 Macro Definition Documentation

#define wxInvalidDateTime wxDefaultDateTime

22.108.2 Variable Documentation

const wxDateTime wxDefaultDateTime

Global instance of an empty wxDateTime object.

Todo Would it be better to rename this wxNullDateTime so it's consistent with the rest of the "empty/invalid/null" global objects?

22.109 docs/doxygen/overviews/dc.h File Reference

22.110 interface/wx/dc.h File Reference

Classes

- struct wxFontMetrics

  Simple collection of various font metrics.
- class wxDC

  A wxDC is a "device context" onto which graphics and text can be drawn.

- class wxDCClipper

  wxDCClipper is a helper class for setting a clipping region on a wxDC during its lifetime.
- class wxDCBrushChanger

  wxDCBrushChanger is a small helper class for setting a brush on a wxDC and unsetting it automatically in the destructor, restoring the previous one.
- class wxDCPenChanger

  wxDCPenChanger is a small helper class for setting a pen on a wxDC and unsetting it automatically in the destructor, restoring the previous one.
- class wxDCTextColourChanger

  wxDCTextColourChanger is a small helper class for setting a foreground text colour on a wxDC and unsetting it automatically in the destructor, restoring the previous one.
- class wxDCFontChanger

  wxDCFontChanger is a small helper class for setting a font on a wxDC and unsetting it automatically in the destructor, restoring the previous one.

Enumerations

- enum wxRasterOperationMode {
  wxCLEAR,
  wxXOR,
  wxINVERT,
  wxOR_REVERSE,
  wxAND_REVERSE,
  wxCOPY,
  wxAND,
  wxAND_INVERT,
  wxNO_OP,
  wxNOR,
  wxEQUIV,
  wxSRC_INVERT,
  wxOR_INVERT,
  wxNAND,
  wxOR,
  wxSET }

  Logical raster operations which can be used with wxDC::SetLogicalFunction and some other wxDC functions (e.g.
- enum wxFloodFillStyle {
  wxFLOOD_SURFACE = 1,
  wxFLOOD_BORDER }

  Flood styles used by wxDC::FloodFill.
- enum wxMappingMode {
  wxMM_TEXT = 1,
  wxMM_METRIC,
  wxMM_LOMETRIC,
  wxMM_TWIPS,
  wxMM_POINTS }

  The mapping used to transform logical units to device units.

22.110.1 Enumeration Type Documentation

enum wxFloodFillStyle

Flood styles used by wxDC::FloodFill.

Enumerator

wxFLOOD_SURFACE The flooding occurs until a colour other than the given colour is encountered.

wxFLOOD_BORDER The area to be flooded is bounded by the given colour.

enum wxMappingMode

The mapping used to transform *logical* units to *device* units.

See wxDC::SetMapMode.

Enumerator

wxMM_TEXT Each logical unit is 1 device pixel. This is the default mapping mode for all wxDC-derived classes.

wxMM_METRIC Each logical unit is 1 millimeter.

wxMM_LOMETRIC Each logical unit is 1/10 of a millimeter.

wxMM_TWIPS Each logical unit is 1/20 of a *"printer point"*, or 1/1440 of an inch (also known as "twip"). Equivalent to about 17.64 micrometers.

wxMM_POINTS Each logical unit is a *"printer point"* i.e. 1/72 of an inch. Equivalent to about 353 micrometers.

enum wxRasterOperationMode

Logical raster operations which can be used with wxDC::SetLogicalFunction and some other wxDC functions (e.g. wxDC::Blit and wxDC::StretchBlit).

The description of the values below refer to how a generic *src* source pixel and the corresponding *dst* destination pixel gets combined together to produce the final pixel. E.g. `wxCLEAR` and `wxSET` completely ignore the source and the destination pixel and always put zeroes or ones in the final surface.

Enumerator

wxCLEAR 0

wxXOR *src* XOR *dst*

wxINVERT NOT *dst*.

wxOR_REVERSE *src* OR (NOT *dst*)

wxAND_REVERSE *src* AND (NOT *dst*)

wxCOPY *src*

wxAND *src* AND *dst*

wxAND_INVERT (NOT *src*) AND *dst*

wxNO_OP *dst*

wxNOR (NOT *src*) AND (NOT *dst*)

wxEQUIV (NOT *src*) XOR *dst*

wxSRC_INVERT (NOT *src*)

wxOR_INVERT (NOT *src*) OR *dst*

wxNAND (NOT *src*) OR (NOT *dst*)

wxOR *src* OR *dst*

wxSET 1

22.111 docs/doxygen/overviews/debugging.h File Reference

22.112 docs/doxygen/overviews/dialog.h File Reference

22.113 interface/wx/dialog.h File Reference

Classes

- class wxDialog

  A dialog box is a window with a title bar and sometimes a system menu, which can be moved around the screen.
- class wxDialogLayoutAdapter

  This abstract class is the base for classes that help wxWidgets perform run-time layout adaptation of dialogs.
- class wxWindowModalDialogEvent

  Event sent by wxDialog::ShowWindowModal() when the dialog closes.

Macros

- #define wxDIALOG_NO_PARENT 0x00000020

  Don't make owned by apps top window.
- #define wxDEFAULT_DIALOG_STYLE (wxCAPTION | wxSYSTEM_MENU | wxCLOSE_BOX)
- #define wxDIALOG_ADAPTATION_NONE 0

  Don't do any layout adaptation.
- #define wxDIALOG_ADAPTATION_STANDARD_SIZER 1

  Only look for wxStdDialogButtonSizer for non-scrolling part.
- #define wxDIALOG_ADAPTATION_ANY_SIZER 2

  Also look for any suitable sizer for non-scrolling part.
- #define wxDIALOG_ADAPTATION_LOOSE_BUTTONS 3

  Also look for 'loose' standard buttons for non-scrolling part.

Enumerations

- enum wxDialogLayoutAdaptationMode {
  wxDIALOG_ADAPTATION_MODE_DEFAULT = 0,
  wxDIALOG_ADAPTATION_MODE_ENABLED = 1,
  wxDIALOG_ADAPTATION_MODE_DISABLED = 2 }

  Modes used for wxDialog::SetLayoutAdaptationMode().

22.113.1 Macro Definition Documentation

#define wxDEFAULT_DIALOG_STYLE (wxCAPTION | wxSYSTEM_MENU | wxCLOSE_BOX)

#define wxDIALOG_ADAPTATION_ANY_SIZER 2

Also look for any suitable sizer for non-scrolling part.

#define wxDIALOG_ADAPTATION_LOOSE_BUTTONS 3

Also look for 'loose' standard buttons for non-scrolling part.

#define wxDIALOG_ADAPTATION_NONE 0

Don't do any layout adaptation.

#define wxDIALOG_ADAPTATION_STANDARD_SIZER 1

Only look for wxStdDialogButtonSizer for non-scrolling part.

#define wxDIALOG_NO_PARENT 0x00000020

Don't make owned by apps top window.

22.113.2 Enumeration Type Documentation

enum wxDialogLayoutAdaptationMode

Modes used for wxDialog::SetLayoutAdaptationMode().

Enumerator

wxDIALOG_ADAPTATION_MODE_DEFAULT Use global adaptation enabled status.

wxDIALOG_ADAPTATION_MODE_ENABLED Enable this dialog overriding global status.

wxDIALOG_ADAPTATION_MODE_DISABLED Disable this dialog overriding global status.

22.114 docs/doxygen/overviews/dnd.h File Reference

22.115 interface/wx/dnd.h File Reference

Classes

- class wxDropTarget
  This class represents a target for a drag and drop operation.
- class wxDropSource
  This class represents a source for a drag and drop operation.
- class wxTextDropTarget
  A predefined drop target for dealing with text data.
- class wxFileDropTarget
  This is a drop target which accepts files (dragged from File Manager or Explorer).

Macros

- #define wxDROP_ICON(name)
  This macro creates either a cursor (MSW) or an icon (elsewhere) with the given name (of type `const char*`).

Enumerations

- enum {
  wxDrag_CopyOnly = 0,
  wxDrag_AllowMove = 1,
  wxDrag_DefaultMove = 3 }

Possible flags for drag and drop operations.

- enum wxDragResult {
  wxDragError,
  wxDragNone,
  wxDragCopy,
  wxDragMove,
  wxDragLink,
  wxDragCancel }

  Result returned from a wxDropSource::DoDragDrop() call.

Functions

- bool wxIsDragResultOk (wxDragResult res)

  Returns true if res indicates that something was done during a DnD operation, i.e.

22.115.1 Enumeration Type Documentation

anonymous enum

Possible flags for drag and drop operations.

Enumerator

wxDrag_CopyOnly Allow only copying.

wxDrag_AllowMove Allow moving too (copying is always allowed).

wxDrag_DefaultMove Allow moving and make it default operation.

enum wxDragResult

Result returned from a wxDropSource::DoDragDrop() call.

Enumerator

wxDragError Error prevented the D&D operation from completing.

wxDragNone Drag target didn't accept the data.

wxDragCopy The data was successfully copied.

wxDragMove The data was successfully moved (MSW only).

wxDragLink Operation is a drag-link.

wxDragCancel The operation was cancelled by user (not an error).

22.116 docs/doxygen/overviews/docview.h File Reference

22.117 interface/wx/docview.h File Reference

Classes

- class wxDocTemplate

  The wxDocTemplate class is used to model the relationship between a document class and a view class.
- class wxDocManager

The wxDocManager class is part of the document/view framework supported by wxWidgets, and cooperates with the wxView, wxDocument and wxDocTemplate classes.

- class wxView

  The view class can be used to model the viewing and editing component of an application's file-based data.
- class wxDocChildFrame

  The wxDocChildFrame class provides a default frame for displaying documents on separate windows.
- class wxDocParentFrame

  The wxDocParentFrame class provides a default top-level frame for applications using the document/view framework.
- class wxDocument

  The document class can be used to model an application's file-based data.

Typedefs

- typedef wxVector< wxDocument * > wxDocVector

  A vector of wxDocument pointers.
- typedef wxVector< wxView * > wxViewVector

  A vector of wxView pointers.
- typedef wxVector< wxDocTemplate * > wxDocTemplateVector

  A vector of wxDocTemplate pointers.

Functions

- bool wxTransferFileToStream (const wxString &filename, ostream &stream)

  Copies the given file to stream.
- bool wxTransferStreamToFile (istream &stream, const wxString &filename)

  Copies the given stream to the file filename.

22.117.1 Typedef Documentation

typedef wxVector<wxDocTemplate*> wxDocTemplateVector

A vector of wxDocTemplate pointers.

Since

2.9.5

typedef wxVector<wxDocument*> wxDocVector

A vector of wxDocument pointers.

Since

2.9.5

typedef wxVector<wxView*> wxViewVector

A vector of wxView pointers.

Since

2.9.5

22.118 docs/doxygen/overviews/envvars.h File Reference

22.119 docs/doxygen/overviews/eventhandling.h File Reference

22.121 docs/doxygen/overviews/file.h File Reference

22.122 interface/wx/file.h File Reference

Classes

- class wxTempFile

  wxTempFile provides a relatively safe way to replace the contents of the existing file.
- class wxFile

  A wxFile performs raw file I/O.

22.123 docs/doxygen/overviews/filesystem.h File Reference

22.124 docs/doxygen/overviews/font.h File Reference

22.125 interface/wx/font.h File Reference

Classes

- class wxFontInfo

  This class is a helper used for wxFont creation using named parameter idiom: it allows to specify various wxFont attributes using the chained calls to its clearly named methods instead of passing them in the fixed order to wxFont constructors.
- class wxFont

  A font is an object which determines the appearance of text.
- class wxFontList

  A font list is a list containing all fonts which have been created.

Enumerations

- enum wxFontFamily {
  wxFONTFAMILY_DEFAULT = wxDEFAULT,
  wxFONTFAMILY_DECORATIVE = wxDECORATIVE,
  wxFONTFAMILY_ROMAN = wxROMAN,
  wxFONTFAMILY_SCRIPT = wxSCRIPT,
  wxFONTFAMILY_SWISS = wxSWISS,
  wxFONTFAMILY_MODERN = wxMODERN,
  wxFONTFAMILY_TELETYPE = wxTELETYPE,
  wxFONTFAMILY_MAX,
  wxFONTFAMILY_UNKNOWN = wxFONTFAMILY_MAX }

  Standard font families: these are used mainly during wxFont creation to specify the generic properties of the font without hardcoding in the sources a specific face name.

- enum wxFontStyle {
  wxFONTSTYLE_NORMAL = wxNORMAL,
  wxFONTSTYLE_ITALIC = wxITALIC,
  wxFONTSTYLE_SLANT = wxSLANT,
  wxFONTSTYLE_MAX }

  Font styles.

- enum wxFontWeight {
  wxFONTWEIGHT_NORMAL = wxNORMAL,
  wxFONTWEIGHT_LIGHT = wxLIGHT,
  wxFONTWEIGHT_BOLD = wxBOLD,
  wxFONTWEIGHT_MAX }

  Font weights.

- enum wxFontSymbolicSize {
  wxFONTSIZE_XX_SMALL = -3,
  wxFONTSIZE_X_SMALL,
  wxFONTSIZE_SMALL,
  wxFONTSIZE_MEDIUM,
  wxFONTSIZE_LARGE,
  wxFONTSIZE_X_LARGE,
  wxFONTSIZE_XX_LARGE }

  Symbolic font sizes.

- enum wxFontFlag {
  wxFONTFLAG_DEFAULT = 0,
  wxFONTFLAG_ITALIC = 1 << 0,
  wxFONTFLAG_SLANT = 1 << 1,
  wxFONTFLAG_LIGHT = 1 << 2,
  wxFONTFLAG_BOLD = 1 << 3,
  wxFONTFLAG_ANTIALIASED = 1 << 4,
  wxFONTFLAG_NOT_ANTIALIASED = 1 << 5,
  wxFONTFLAG_UNDERLINED = 1 << 6,
  wxFONTFLAG_STRIKETHROUGH = 1 << 7,
  wxFONTFLAG_MASK }

  The font flag bits for the new font ctor accepting one combined flags word.

- enum wxFontEncoding {
  wxFONTENCODING_SYSTEM = -1,
  wxFONTENCODING_DEFAULT,
  wxFONTENCODING_ISO8859_1,

  wxFONTENCODING_MACGREEK,
  wxFONTENCODING_MACCYRILLIC,
  wxFONTENCODING_MACDEVANAGARI,
  wxFONTENCODING_MACGURMUKHI,
  wxFONTENCODING_MACGUJARATI,
  wxFONTENCODING_MACORIYA,
  wxFONTENCODING_MACBENGALI,

Font encodings.

Functions

- bool wxFromString (const wxString &string, wxFont *font)

  Converts string to a wxFont best represented by the given string.
- wxString wxToString (const wxFont &font)

  Converts the given wxFont into a string.

Variables

- wxFont wxNullFont

  An empty wxFont.
- wxFont * wxNORMAL_FONT

  Equivalent to wxSystemSettings::GetFont(wxSYS_DEFAULT_GUI_FONT).
- wxFont * wxSMALL_FONT

  A font using the `wxFONTFAMILY_SWISS` family and 2 points smaller than wxNORMAL_FONT.
- wxFont * wxITALIC_FONT

  A font using the `wxFONTFAMILY_ROMAN` family and `wxFONTSTYLE_ITALIC` style and of the same size of wxNORMAL_FONT.
- wxFont * wxSWISS_FONT

  A font identic to wxNORMAL_FONT except for the family used which is `wxFONTFAMILY_SWISS`.
- wxFontList * wxTheFontList

  The global wxFontList instance.

22.125.1 Enumeration Type Documentation

enum wxFontEncoding

Font encodings.

See wxFont::SetEncoding().

Enumerator

wxFONTENCODING_SYSTEM Default system encoding. Default system encoding.

wxFONTENCODING_DEFAULT Default application encoding: this is the encoding set by calls to wxFont::SetDefaultEncoding(). Initially, the default application encoding is the same as default system encoding.

wxFONTENCODING_ISO8859_1 West European (Latin1)

wxFONTENCODING_ISO8859_2 Central and East European (Latin2)

enum wxFontFamily

Standard font families: these are used mainly during wxFont creation to specify the generic properties of the font without hardcoding in the sources a specific face name.

wxFontFamily thus allows to group the font face names of fonts with similar properties. Most wxWidgets ports use lists of fonts for each font family inspired by the data taken from http://www.codestyle.org/css/font-family.

Enumerator

wxFONTFAMILY_DEFAULT Chooses a default font.

wxFONTFAMILY_DECORATIVE A decorative font.

wxFONTFAMILY_ROMAN A formal, serif font.

wxFONTFAMILY_SCRIPT A handwriting font.

wxFONTFAMILY_SWISS A sans-serif font.

wxFONTFAMILY_MODERN A fixed pitch font. Note that wxFont currently does not make distinctions between wxFONTFAMILY_MODERN and wxFONTFAMILY_TELETYPE.

wxFONTFAMILY_TELETYPE A teletype (i.e. monospaced) font. Monospace fonts have a fixed width like typewriters and often have strong angular or block serifs. Monospace font faces are often used code samples and have a simple, functional font style. See also wxFont::IsFixedWidth() for an easy way to test for monospace property.

wxFONTFAMILY_MAX

wxFONTFAMILY_UNKNOWN Invalid font family value, returned by wxFont::GetFamily() when the font is invalid for example.

enum wxFontFlag

The font flag bits for the new font ctor accepting one combined flags word.

Enumerator

wxFONTFLAG_DEFAULT no special flags: font with default weight/slant/anti-aliasing

wxFONTFLAG_ITALIC slant flags (default: no slant)

wxFONTFLAG_SLANT

wxFONTFLAG_LIGHT weight flags (default: medium)

wxFONTFLAG_BOLD

wxFONTFLAG_ANTIALIASED anti-aliasing flag: force on or off (default: the current system default)

wxFONTFLAG_NOT_ANTIALIASED

wxFONTFLAG_UNDERLINED Underlined style (not underlined by default).

wxFONTFLAG_STRIKETHROUGH Strike-through style (implemented in MSW, GTK, and OSX)

wxFONTFLAG_MASK the mask of all currently used flags

enum wxFontStyle

Font styles.

Enumerator

wxFONTSTYLE_NORMAL The font is drawn without slant.

wxFONTSTYLE_ITALIC The font is slanted in an italic style.

wxFONTSTYLE_SLANT The font is slanted, but in a roman style. Note that under wxMSW this style is the same as wxFONTSTYLE_ITALIC.

wxFONTSTYLE_MAX

enum wxFontSymbolicSize

Symbolic font sizes.

The elements of this enum correspond to CSS absolute size specifications, see http://www.w3.org/TR/CSS21/fonts.html#font-size-props

See also

wxFont::SetSymbolicSize()

Since

2.9.2

Enumerator

wxFONTSIZE_XX_SMALL Extra small.
wxFONTSIZE_X_SMALL Very small.
wxFONTSIZE_SMALL Small.
wxFONTSIZE_MEDIUM Normal.
wxFONTSIZE_LARGE Large.
wxFONTSIZE_X_LARGE Very large.
wxFONTSIZE_XX_LARGE Extra large.

enum wxFontWeight

Font weights.

Enumerator

wxFONTWEIGHT_NORMAL Normal font.
wxFONTWEIGHT_LIGHT Light font.
wxFONTWEIGHT_BOLD Bold font.
wxFONTWEIGHT_MAX

22.125.2 Variable Documentation

wxFont* wxITALIC_FONT

A font using the `wxFONTFAMILY_ROMAN` family and `wxFONTSTYLE_ITALIC` style and of the same size of wxNORMAL_FONT.

wxFont* wxNORMAL_FONT

Equivalent to wxSystemSettings::GetFont(wxSYS_DEFAULT_GUI_FONT).

See also

wxSystemSettings

wxFont wxNullFont

An empty wxFont.

wxFont* wxSMALL_FONT

A font using the `wxFONTFAMILY_SWISS` family and 2 points smaller than wxNORMAL_FONT.

wxFont* wxSWISS_FONT

A font identic to wxNORMAL_FONT except for the family used which is `wxFONTFAMILY_SWISS`.

wxFontList* wxTheFontList

The global wxFontList instance.

22.128 interface/wx/grid.h File Reference

Classes

- class wxGridCellRenderer

  This class is responsible for actually drawing the cell in the grid.
- class wxGridCellAutoWrapStringRenderer

  This class may be used to format string data in a cell.
- class wxGridCellBoolRenderer

  This class may be used to format boolean data in a cell.
- class wxGridCellDateTimeRenderer

  This class may be used to format a date/time data in a cell.
- class wxGridCellEnumRenderer

  This class may be used to render in a cell a number as a textual equivalent.
- class wxGridCellFloatRenderer

  This class may be used to format floating point data in a cell.
- class wxGridCellNumberRenderer

  This class may be used to format integer data in a cell.
- class wxGridCellStringRenderer

  This class may be used to format string data in a cell; it is the default for string cells.
- class wxGridCellEditor

  This class is responsible for providing and manipulating the in-place edit controls for the grid.
- class wxGridCellAutoWrapStringEditor

  Grid cell editor for wrappable string/text data.
- class wxGridCellBoolEditor

  Grid cell editor for boolean data.
- class wxGridCellChoiceEditor

  Grid cell editor for string data providing the user a choice from a list of strings.
- class wxGridCellEnumEditor

  Grid cell editor which displays an enum number as a textual equivalent (eg.
- class wxGridCellTextEditor

  Grid cell editor for string/text data.
- class wxGridCellFloatEditor

The editor for floating point numbers data.

- class wxGridCellNumberEditor

  Grid cell editor for numeric integer data.
- class wxGridCellAttr

  This class can be used to alter the cells' appearance in the grid by changing their attributes from the defaults.
- class wxGridCornerHeaderRenderer

  Base class for corner window renderer.
- class wxGridHeaderLabelsRenderer

  Common base class for row and column headers renderers.
- class wxGridRowHeaderRenderer

  Base class for row headers renderer.
- class wxGridColumnHeaderRenderer

  Base class for column headers renderer.
- class wxGridRowHeaderRendererDefault

  Default row header renderer.
- class wxGridColumnHeaderRendererDefault

  Default column header renderer.
- class wxGridCornerHeaderRendererDefault

  Default corner window renderer.
- class wxGridCellAttrProvider

  Class providing attributes to be used for the grid cells.
- class wxGridCellCoords

  Represents coordinates of a grid cell.
- class wxGridTableBase

  The almost abstract base class for grid tables.
- class wxGridTableMessage

  A simple class used to pass messages from the table to the grid.
- class wxGridStringTable

  Simplest type of data table for a grid for small tables of strings that are stored in memory.
- class wxGridSizesInfo

  wxGridSizesInfo stores information about sizes of all wxGrid rows or columns.
- class wxGrid

  wxGrid and its related classes are used for displaying and editing tabular data.
- class wxGridUpdateLocker

  This small class can be used to prevent wxGrid from redrawing during its lifetime by calling wxGrid::BeginBatch() in its constructor and wxGrid::EndBatch() in its destructor.
- class wxGridEvent

  This event class contains information about various grid events.
- class wxGridSizeEvent

  This event class contains information about a row/column resize event.
- class wxGridRangeSelectEvent
- class wxGridEditorCreatedEvent

Enumerations

- enum wxGridCellFloatFormat {
  wxGRID_FLOAT_FORMAT_FIXED = 0x0010,
  wxGRID_FLOAT_FORMAT_SCIENTIFIC = 0x0020,
  wxGRID_FLOAT_FORMAT_COMPACT = 0x0040,
  wxGRID_FLOAT_FORMAT_UPPER = 0x0080,
  wxGRID_FLOAT_FORMAT_DEFAULT = wxGRID_FLOAT_FORMAT_FIXED }

Specifier used to format the data to string for the numbers handled by wxGridCellFloatRenderer and wxGridCellFloatEditor.

- enum wxGridTableRequest {
  wxGRIDTABLE_REQUEST_VIEW_GET_VALUES = 2000,
  wxGRIDTABLE_REQUEST_VIEW_SEND_VALUES,
  wxGRIDTABLE_NOTIFY_ROWS_INSERTED,
  wxGRIDTABLE_NOTIFY_ROWS_APPENDED,
  wxGRIDTABLE_NOTIFY_ROWS_DELETED,
  wxGRIDTABLE_NOTIFY_COLS_INSERTED,
  wxGRIDTABLE_NOTIFY_COLS_APPENDED,
  wxGRIDTABLE_NOTIFY_COLS_DELETED }
- enum wxGridRenderStyle {

22.128.1 Enumeration Type Documentation

enum wxGridCellFloatFormat

Specifier used to format the data to string for the numbers handled by wxGridCellFloatRenderer and wxGridCellFloatEditor.

Since

2.9.3

Enumerator

wxGRID_FLOAT_FORMAT_FIXED Decimal floating point (f).

wxGRID_FLOAT_FORMAT_SCIENTIFIC Scientific notation (mantissa/exponent) using e character (e).

wxGRID_FLOAT_FORMAT_COMPACT Use the shorter of e or f (g).

wxGRID_FLOAT_FORMAT_UPPER To use in combination with one of the above formats for the upper case version (F/E/G)

wxGRID_FLOAT_FORMAT_DEFAULT The format used by default (wxGRID_FLOAT_FORMAT_FIXED).

enum wxGridRenderStyle

Rendering styles supported by wxGrid::Render() method.

Since

2.9.4

Enumerator

wxGRID_DRAW_ROWS_HEADER Draw grid row header labels.

wxGRID_DRAW_COLS_HEADER Draw grid column header labels.

wxGRID_DRAW_CELL_LINES Draw grid cell border lines.

wxGRID_DRAW_BOX_RECT Draw a bounding rectangle around the rendered cell area. Useful where row or column headers are not drawn or where there is multi row or column cell clipping and therefore no cell border at the rendered outer boundary.

wxGRID_DRAW_SELECTION Draw the grid cell selection highlight if a selection is present. At present the highlight colour drawn depends on whether the grid window loses focus before drawing begins.

wxGRID_DRAW_DEFAULT The default render style. Includes all except wxGRID_DRAW_SELECTION.

enum wxGridTableRequest

Classes

- class wxConnection

A wxConnection object represents the connection between a client and a server.

- class wxClient

  A wxClient object represents the client part of a client-server DDE-like (Dynamic Data Exchange) conversation.

- class wxServer

  A wxServer object represents the server part of a client-server DDE-like (Dynamic Data Exchange) conversation.

22.134 docs/doxygen/overviews/listctrl.h File Reference

22.135 interface/wx/listctrl.h File Reference

Classes

- class wxListCtrl

  A list control presents lists in a number of formats: list view, report view, icon view and small icon view.

- class wxListEvent

  A list event holds information about events associated with wxListCtrl objects.

- class wxListItemAttr

  Represents the attributes (color, font, ...) of a wxListCtrl's wxListItem.

- class wxListView

  This class currently simply presents a simpler to use interface for the wxListCtrl – it can be thought of as a façade for that complicated class.

- class wxListItem

  This class stores information about a wxListCtrl item or column.

Macros

22.136 docs/doxygen/overviews/log.h File Reference

22.137 interface/wx/log.h File Reference

Classes

- class wxLogRecordInfo

  Information about a log record (unit of the log output).
- class wxLogFormatter

  wxLogFormatter class is used to format the log messages.
- class wxLog

  wxLog class defines the interface for the log targets used by wxWidgets logging functions as explained in the Logging Overview.
- class wxLogChain

  This simple class allows you to chain log sinks, that is to install a new sink but keep passing log messages to the old one instead of replacing it completely as wxLog::SetActiveTarget does.
- class wxLogInterposer

  A special version of wxLogChain which uses itself as the new log target.
- class wxLogInterposerTemp

  A special version of wxLogChain which uses itself as the new log target.
- class wxLogStream

  This class can be used to redirect the log messages to a C++ stream.
- class wxLogStderr

  This class can be used to redirect the log messages to a C file stream (not to be confused with C++ streams).
- class wxLogBuffer

  wxLogBuffer is a very simple implementation of log sink which simply collects all the logged messages in a string (except the debug messages which are output in the usual way immediately as we're presumably not interested in collecting them for later).
- class wxLogNull

  This class allows you to temporarily suspend logging.
- class wxLogWindow

  This class represents a background log window: to be precise, it collects all log messages in the log frame which it manages but also passes them on to the log target which was active at the moment of its creation.

- class wxLogGui

  This is the default log target for the GUI wxWidgets applications.
- class wxLogTextCtrl

  Using these target all the log messages can be redirected to a text control.

Macros

- #define wxDISABLE_DEBUG_LOGGING_IN_RELEASE_BUILD()

  Use this macro to disable logging at debug and trace levels in release build when not using wxIMPLEMENT_APP().

Typedefs

- typedef unsigned long wxLogLevel

  The type used to specify a log level.

Enumerations

- enum wxLogLevelValues {
  wxLOG_FatalError,
  wxLOG_Error,
  wxLOG_Warning,
  wxLOG_Message,
  wxLOG_Status,
  wxLOG_Info,
  wxLOG_Debug,
  wxLOG_Trace,
  wxLOG_Progress,
  wxLOG_User = 100,
  wxLOG_Max = 10000 }

  Different standard log levels (you may also define your own) used with by standard wxLog functions wxLogGeneric(), wxLogError(), wxLogWarning(), etc...

Functions

- void wxSafeShowMessage (const wxString &title, const wxString &text)

  This function shows a message to the user in a safe way and should be safe to call even before the application has been initialized or if it is currently in some other strange state (for example, about to crash).
- unsigned long wxSysErrorCode ()

  Returns the error code from the last system call.
- const wxChar * wxSysErrorMsg (unsigned long errCode=0)

  Returns the error message corresponding to the given system error code.
- void wxLogGeneric (wxLogLevel level, const char *formatString,...)

  Logs a message with the given wxLogLevel.
- void wxVLogGeneric (wxLogLevel level, const char *formatString, va_list argPtr)
- void wxLogMessage (const char *formatString,...)

  For all normal, informational messages.
- void wxVLogMessage (const char *formatString, va_list argPtr)
- void wxLogVerbose (const char *formatString,...)

  For verbose output.
- void wxVLogVerbose (const char *formatString, va_list argPtr)
- void wxLogWarning (const char *formatString,...)

  For warnings - they are also normally shown to the user, but don't interrupt the program work.

- void wxVLogWarning (const char *formatString, va_list argPtr)
- void wxLogFatalError (const char *formatString,...)

  Like wxLogError(), but also terminates the program with the exit code 3.
- void wxVLogFatalError (const char *formatString, va_list argPtr)
- void wxLogError (const char *formatString,...)

  The functions to use for error messages, i.e.
- void wxVLogError (const char *formatString, va_list argPtr)
- void wxLogTrace (const char *mask, const char *formatString,...)

  Log a message at `wxLOG_Trace` log level (see wxLogLevelValues enum).
- void wxVLogTrace (const char *mask, const char *formatString, va_list argPtr)
- void wxLogTrace (wxTraceMask mask, const char *formatString,...)

  Like wxLogDebug(), trace functions only do something in debug builds and expand to nothing in the release one.
- void wxVLogTrace (wxTraceMask mask, const char *formatString, va_list argPtr)
- void wxLogDebug (const char *formatString,...)

  The right functions for debug output.
- void wxVLogDebug (const char *formatString, va_list argPtr)
- void wxLogStatus (wxFrame *frame, const char *formatString,...)

  Messages logged by this function will appear in the statusbar of the frame or of the top level application window by default (i.e.
- void wxVLogStatus (wxFrame *frame, const char *formatString, va_list argPtr)
- void wxLogStatus (const char *formatString,...)
- void wxVLogStatus (const char *formatString, va_list argPtr)
- void wxLogSysError (const char *formatString,...)

  Mostly used by wxWidgets itself, but might be handy for logging errors after system call (API function) failure.
- void wxVLogSysError (const char *formatString, va_list argPtr)

22.137.1 Typedef Documentation

typedef unsigned long wxLogLevel

The type used to specify a log level.

Default values of wxLogLevel used by wxWidgets are contained in the wxLogLevelValues enumeration.

22.137.2 Enumeration Type Documentation

enum wxLogLevelValues

Different standard log levels (you may also define your own) used with by standard wxLog functions wxLogGeneric(), wxLogError(), wxLogWarning(), etc...

Enumerator

wxLOG_FatalError program can't continue, abort immediately

wxLOG_Error a serious error, user must be informed about it

wxLOG_Warning user is normally informed about it but may be ignored

wxLOG_Message normal message (i.e. normal output of a non GUI app)

wxLOG_Status informational: might go to the status line of GUI app

wxLOG_Info informational message (a.k.a. 'Verbose')

wxLOG_Debug never shown to the user, disabled in release mode

wxLOG_Trace trace messages are also only enabled in debug mode

wxLOG_Progress used for progress indicator (not yet)

wxLOG_User user defined levels start here

wxLOG_Max

22.138 interface/wx/protocol/log.h File Reference

Classes

- class wxProtocolLog

  Class allowing to log network operations performed by wxProtocol.

  Combines various styles.

Classes

- class wxPGValidationInfo

  wxPGValidationInfo
- class wxPropertyGrid

  wxPropertyGrid is a specialized grid for editing properties - in other words name = value pairs.
- class wxPropertyGridEvent

  A property grid event holds information about events associated with wxPropertyGrid objects.

Typedefs

- typedef wxByte wxPGVFBFlags
- typedef int(∗ wxPGSortCallback)(wxPropertyGrid ∗propGrid, wxPGProperty ∗p1, wxPGProperty ∗p2)

  This callback function is used for sorting properties.

Enumerations

- enum wxPG_VALIDATION_FAILURE_BEHAVIOR_FLAGS {
  wxPG_VFB_STAY_IN_PROPERTY = 0x01,
  wxPG_VFB_BEEP = 0x02,
  wxPG_VFB_MARK_CELL = 0x04,
  wxPG_VFB_SHOW_MESSAGE = 0x08,
  wxPG_VFB_SHOW_MESSAGEBOX = 0x10,
  wxPG_VFB_SHOW_MESSAGE_ON_STATUSBAR = 0x20,
  wxPG_VFB_DEFAULT }

- enum wxPG_KEYBOARD_ACTIONS {
  wxPG_ACTION_INVALID = 0,
  wxPG_ACTION_NEXT_PROPERTY,
  wxPG_ACTION_PREV_PROPERTY,
  wxPG_ACTION_EXPAND_PROPERTY,
  wxPG_ACTION_COLLAPSE_PROPERTY,
  wxPG_ACTION_CANCEL_EDIT,
  wxPG_ACTION_EDIT,
  wxPG_ACTION_PRESS_BUTTON,
  wxPG_ACTION_MAX }

22.144.1 Macro Definition Documentation

#define wxPG_DEFAULT_STYLE (0)

Combines various styles.

#define wxPGMAN_DEFAULT_STYLE (0)

Combines various styles.

22.144.2 Typedef Documentation

typedef int(∗ wxPGSortCallback)(wxPropertyGrid ∗propGrid, wxPGProperty ∗p1, wxPGProperty ∗p2)

This callback function is used for sorting properties.

Call wxPropertyGrid::SetSortFunction() to set it.

Sort function should return a value greater than 0 if position of p1 is after p2. So, for instance, when comparing property names, you can use following implementation:

```
1 int MyPropertySortFunction(wxPropertyGrid* propGrid,
2                            wxPGProperty* p1,
3                            wxPGProperty* p2)
4 {
5     return p1->GetBaseName().compare( p2->GetBaseName() );
6 }
```

typedef wxByte wxPGVFBFlags

22.144.3 Enumeration Type Documentation

enum wxPG_EX_WINDOW_STYLES

Combines various styles.

Enumerator

wxPG_EX_INIT_NOCAT NOTE: wxPG_EX_xxx are extra window styles and must be set using SetExtra↩ Style() member function. Speeds up switching to wxPG_HIDE_CATEGORIES mode. Initially, if wxPG_↩ HIDE_CATEGORIES is not defined, the non-categorized data storage is not activated, and switching the mode first time becomes somewhat slower. wxPG_EX_INIT_NOCAT activates the non-categorized data storage right away.

NOTE: If you do plan not switching to non-categoric mode, or if you don't plan to use categories at all, then using this style will result in waste of resources.

wxPG_EX_NO_FLAT_TOOLBAR Extended window style that sets wxPropertyGridManager tool bar to not use flat style.

wxPG_EX_MODE_BUTTONS Shows alphabetic/categoric mode buttons from tool bar.

wxPG_EX_HELP_AS_TOOLTIPS Show property help strings as tool tips instead as text on the status bar. You can set the help strings using SetPropertyHelpString member function.

wxPG_EX_NATIVE_DOUBLE_BUFFERING Allows relying on native double-buffering.

wxPG_EX_AUTO_UNSPECIFIED_VALUES Set this style to let user have ability to set values of properties to unspecified state. Same as setting wxPG_PROP_AUTO_UNSPECIFIED for all properties.

wxPG_EX_WRITEONLY_BUILTIN_ATTRIBUTES If this style is used, built-in attributes (such as wxPG_↩ FLOAT_PRECISION and wxPG_STRING_PASSWORD) are not stored into property's attribute storage (thus they are not readable). Note that this option is global, and applies to all wxPG property containers.

wxPG_EX_HIDE_PAGE_BUTTONS Hides page selection buttons from tool bar.

wxPG_EX_MULTIPLE_SELECTION Allows multiple properties to be selected by user (by pressing SHI↩ FT when clicking on a property, or by dragging with left mouse button down). You can get array of selected properties with wxPropertyGridInterface::GetSelectedProperties(). In multiple selection mode wxPropertyGridInterface::GetSelection() returns property which has editor active (usually the first one selected). Other useful member functions are ClearSelection(), AddToSelection() and RemoveFrom↩ Selection().

wxPG_EX_ENABLE_TLP_TRACKING This enables top-level window tracking which allows wxPropertyGrid to notify the application of last-minute property value changes by user. This style is not enabled by default because it may cause crashes when wxPropertyGrid is used in with wxAUI or similar system.

Remarks

If you are not in fact using any system that may change wxPropertyGrid's top-level parent window on its own, then you are recommended to enable this style.

wxPG_EX_NO_TOOLBAR_DIVIDER Don't show divider above toolbar, on Windows.

wxPG_EX_TOOLBAR_SEPARATOR Show a separator below the toolbar.

enum wxPG_KEYBOARD_ACTIONS

22.144.4 wxPropertyGrid Action Identifiers

These are used with wxPropertyGrid::AddActionTrigger() and wxPropertyGrid::ClearActionTriggers().

Enumerator

wxPG_ACTION_INVALID

wxPG_ACTION_NEXT_PROPERTY Select the next property.

wxPG_ACTION_PREV_PROPERTY Select the previous property.

wxPG_ACTION_EXPAND_PROPERTY Expand the selected property, if it has child items.

wxPG_ACTION_COLLAPSE_PROPERTY Collapse the selected property, if it has child items.

wxPG_ACTION_CANCEL_EDIT Cancel and undo any editing done in the currently active property editor.

wxPG_ACTION_EDIT Move focus to the editor control of the currently selected property.

wxPG_ACTION_PRESS_BUTTON Causes editor's button (if any) to be pressed.

wxPG_ACTION_MAX

enum wxPG_VALIDATION_FAILURE_BEHAVIOR_FLAGS

22.144.5 wxPropertyGrid Validation Failure behaviour Flags

Enumerator

wxPG_VFB_STAY_IN_PROPERTY Prevents user from leaving property unless value is valid. If this behaviour flag is not used, then value change is instead cancelled.

wxPG_VFB_BEEP Calls wxBell() on validation failure.

wxPG_VFB_MARK_CELL Cell with invalid value will be marked (with red colour).

wxPG_VFB_SHOW_MESSAGE Display a text message explaining the situation. To customize the way the message is displayed, you need to reimplement wxPropertyGrid::DoShowPropertyError() in a derived class. Default behaviour is to display the text on the top-level frame's status bar, if present, and otherwise using wxMessageBox.

wxPG_VFB_SHOW_MESSAGEBOX Similar to wxPG_VFB_SHOW_MESSAGE, except always displays the message using wxMessageBox.

wxPG_VFB_SHOW_MESSAGE_ON_STATUSBAR Similar to wxPG_VFB_SHOW_MESSAGE, except always displays the message on the status bar (when present - you can reimplement wxPropertyGrid::GetStatusBar() in a derived class to specify this yourself).

wxPG_VFB_DEFAULT Defaults.

enum wxPG_WINDOW_STYLES

22.144.6 wxPropertyGrid Window Styles

SetWindowStyleFlag method can be used to modify some of these at run-time.

Enumerator

wxPG_AUTO_SORT This will cause Sort() automatically after an item is added. When inserting a lot of items in this mode, it may make sense to use Freeze() before operations and Thaw() afterwards to increase performance.

wxPG_HIDE_CATEGORIES Categories are not initially shown (even if added). IMPORTANT NOTE: If you do not plan to use categories, then this style will waste resources. This flag can also be changed using wxPropertyGrid::EnableCategories method.

wxPG_ALPHABETIC_MODE This style combines non-categoric mode and automatic sorting.

wxPG_BOLD_MODIFIED Modified values are shown in bold font. Changing this requires Refresh() to show changes.

wxPG_SPLITTER_AUTO_CENTER When wxPropertyGrid is resized, splitter moves to the center. This behaviour stops once the user manually moves the splitter.

wxPG_TOOLTIPS Display tool tips for cell text that cannot be shown completely. If wxUSE_TOOLTIPS is 0, then this doesn't have any effect.

wxPG_HIDE_MARGIN Disables margin and hides all expand/collapse buttons that would appear outside the margin (for sub-properties). Toggling this style automatically expands all collapsed items.

wxPG_STATIC_SPLITTER This style prevents user from moving the splitter.

wxPG_STATIC_LAYOUT Combination of other styles that make it impossible for user to modify the layout.

wxPG_LIMITED_EDITING Disables wxTextCtrl based editors for properties which can be edited in another way. Equals calling wxPropertyGrid::LimitPropertyEditing() for all added properties.

wxPG_TOOLBAR wxPropertyGridManager only: Show tool bar for mode and page selection.

wxPG_DESCRIPTION wxPropertyGridManager only: Show adjustable text box showing description or help text, if available, for currently selected property.

wxPG_NO_INTERNAL_BORDER wxPropertyGridManager only: don't show an internal border around the property grid. Recommended if you use a header.

Classes

- class wxSizer

  wxSizer is the abstract base class used for laying out subwindows in a window.
- class wxStdDialogButtonSizer

  This class creates button layouts which conform to the standard button spacing and ordering defined by the platform or toolkit's user interface guidelines (if such things exist).
- class wxSizerItem

  The wxSizerItem class is used to track the position, size and other attributes of each item managed by a wxSizer.
- class wxSizerFlags

  Container for sizer items flags providing readable names for them.
- class wxFlexGridSizer

  A flex grid sizer is a sizer which lays out its children in a two-dimensional table with all table fields in one row having the same height and all fields in one column having the same width, but all rows or all columns are not necessarily the same height or width as in the wxGridSizer.
- class wxGridSizer

  A grid sizer is a sizer which lays out its children in a two-dimensional table with all table fields having the same size, i.e.
- class wxStaticBoxSizer

  wxStaticBoxSizer is a sizer derived from wxBoxSizer but adds a static box around the sizer.
- class wxBoxSizer

  The basic idea behind a box sizer is that windows will most often be laid out in rather simple basic geometry, typically in a row or a column or several hierarchies of either.

Enumerations

- enum wxFlexSizerGrowMode {
  wxFLEX_GROWMODE_NONE,
  wxFLEX_GROWMODE_SPECIFIED,
  wxFLEX_GROWMODE_ALL }

  Values which define the behaviour for resizing wxFlexGridSizer cells in the "non-flexible" direction.

22.155.1 Enumeration Type Documentation

enum wxFlexSizerGrowMode

Values which define the behaviour for resizing wxFlexGridSizer cells in the "non-flexible" direction.

Enumerator

wxFLEX_GROWMODE_NONE Don't resize the cells in non-flexible direction at all.

wxFLEX_GROWMODE_SPECIFIED Uniformly resize only the specified ones (default).

wxFLEX_GROWMODE_ALL Uniformly resize all cells.

22.156 docs/doxygen/overviews/splitterwindow.h File Reference

22.157 docs/doxygen/overviews/stream.h File Reference

22.158 interface/wx/stream.h File Reference

Classes

- class wxStreamBase

  This class is the base class of most stream related classes in wxWidgets.
- class wxStreamBuffer

  wxStreamBuffer is a cache manager for wxStreamBase: it manages a stream buffer linked to a stream.
- class wxOutputStream

  wxOutputStream is an abstract base class which may not be used directly.
- class wxInputStream

  wxInputStream is an abstract base class which may not be used directly.
- class wxCountingOutputStream

  wxCountingOutputStream is a specialized output stream which does not write any data anywhere, instead it counts how many bytes would get written if this were a normal stream.
- class wxBufferedInputStream

  This stream acts as a cache.
- class wxFilterClassFactory

  Allows the creation of filter streams to handle compression formats such as gzip and bzip2.
- class wxFilterOutputStream

  A filter stream has the capability of a normal stream but it can be placed on top of another stream.
- class wxFilterInputStream

  A filter stream has the capability of a normal stream but it can be placed on top of another stream.
- class wxBufferedOutputStream

  This stream acts as a cache.
- class wxWrapperInputStream

  A wrapper input stream is a kind of filter stream which forwards all the operations to its base stream.

Enumerations

- enum wxStreamError {
  wxSTREAM_NO_ERROR = 0,
  wxSTREAM_EOF,
  wxSTREAM_WRITE_ERROR,
  wxSTREAM_READ_ERROR }

  These enumeration values are returned by various functions in the context of wxStream classes.
- enum wxStreamProtocolType {
  wxSTREAM_PROTOCOL,
  wxSTREAM_MIMETYPE,
  wxSTREAM_ENCODING,
  wxSTREAM_FILEEXT }

  Enumeration values used by wxFilterClassFactory.

22.158.1 Enumeration Type Documentation

enum wxStreamError

These enumeration values are returned by various functions in the context of wxStream classes.

Enumerator

wxSTREAM_NO_ERROR No error occurred.

wxSTREAM_EOF EOF reached in Read() or similar.

wxSTREAM_WRITE_ERROR generic write error on the last write call.

wxSTREAM_READ_ERROR generic read error on the last read call.

enum wxStreamProtocolType

Enumeration values used by wxFilterClassFactory.

Enumerator

wxSTREAM_PROTOCOL wxFileSystem protocol (should be only one).

wxSTREAM_MIMETYPE MIME types the stream handles.

wxSTREAM_ENCODING The HTTP Content-Encodings the stream handles.

wxSTREAM_FILEEXT File extensions the stream handles.

22.160 interface/wx/string.h File Reference

Classes

- class wxString

  String class for passing textual data to or receiving it from wxWidgets.
- class wxStringBufferLength

  This tiny class allows you to conveniently access the wxString internal buffer as a writable pointer without any risk of forgetting to restore the string to the usable state later, and allows the user to set the internal length of the string.
- class wxStringBuffer

  This tiny class allows you to conveniently access the wxString internal buffer as a writable pointer without any risk of forgetting to restore the string to the usable state later.

Functions

- template<bool(T)(const wxUniChar &c) >
  bool wxStringCheck (const wxString &val)

  Allows to extend a function with the signature:

- bool operator== (const wxString &s1, const wxString &s2)

  Comparison operator for string types.
- bool operator!= (const wxString &s1, const wxString &s2)

  Comparison operator for string types.
- bool operator< (const wxString &s1, const wxString &s2)

Comparison operator for string types.

- bool operator> (const wxString &s1, const wxString &s2)

  Comparison operator for string types.
- bool operator<= (const wxString &s1, const wxString &s2)

  Comparison operator for string types.
- bool operator>= (const wxString &s1, const wxString &s2)

  Comparison operator for string types.
- bool operator== (const wxString &s1, const wxCStrData &s2)

  Comparison operator for string types.
- bool operator== (const wxCStrData &s1, const wxString &s2)

  Comparison operator for string types.
- bool operator!= (const wxString &s1, const wxCStrData &s2)

  Comparison operator for string types.
- bool operator!= (const wxCStrData &s1, const wxString &s2)

  Comparison operator for string types.
- bool operator== (const wxString &s1, const wxWCharBuffer &s2)

  Comparison operator for string types.
- bool operator== (const wxWCharBuffer &s1, const wxString &s2)

  Comparison operator for string types.
- bool operator!= (const wxString &s1, const wxWCharBuffer &s2)

  Comparison operator for string types.
- bool operator!= (const wxWCharBuffer &s1, const wxString &s2)

  Comparison operator for string types.
- bool operator== (const wxString &s1, const wxCharBuffer &s2)

  Comparison operator for string types.
- bool operator== (const wxCharBuffer &s1, const wxString &s2)

  Comparison operator for string types.
- bool operator!= (const wxString &s1, const wxCharBuffer &s2)

  Comparison operator for string types.
- bool operator!= (const wxCharBuffer &s1, const wxString &s2)

  Comparison operator for string types.

- bool operator== (const wxUniChar &c, const wxString &s)

  Comparison operators char types.
- bool operator== (const wxUniCharRef &c, const wxString &s)

  Comparison operators char types.
- bool operator== (char c, const wxString &s)

  Comparison operators char types.
- bool operator== (wchar_t c, const wxString &s)

  Comparison operators char types.
- bool operator== (int c, const wxString &s)

  Comparison operators char types.
- bool operator== (const wxString &s, const wxUniChar &c)

  Comparison operators char types.
- bool operator== (const wxString &s, const wxUniCharRef &c)

  Comparison operators char types.
- bool operator== (const wxString &s, char c)

  Comparison operators char types.
- bool operator== (const wxString &s, wchar_t c)

  Comparison operators char types.
- bool operator!= (const wxUniChar &c, const wxString &s)

Comparison operators char types.

- bool operator!= (const wxUniCharRef &c, const wxString &s)

  Comparison operators char types.
- bool operator!= (char c, const wxString &s)

  Comparison operators char types.
- bool operator!= (wchar_t c, const wxString &s)

  Comparison operators char types.
- bool operator!= (int c, const wxString &s)

  Comparison operators char types.
- bool operator!= (const wxString &s, const wxUniChar &c)

  Comparison operators char types.
- bool operator!= (const wxString &s, const wxUniCharRef &c)

  Comparison operators char types.
- bool operator!= (const wxString &s, char c)

  Comparison operators char types.
- bool operator!= (const wxString &s, wchar_t c)

  Comparison operators char types.

Variables

- wxString wxEmptyString

  The global wxString instance of an empty string.

22.160.1 Function Documentation

bool operator!= (const wxString & *s1*, const wxString & *s2*) `[inline]`

Comparison operator for string types.

bool operator!= (const wxString & *s1*, const wxCStrData & *s2*) `[inline]`

Comparison operator for string types.

bool operator!= (const wxCStrData & *s1*, const wxString & *s2*) `[inline]`

Comparison operator for string types.

bool operator!= (const wxString & *s1*, const wxWCharBuffer & *s2*) `[inline]`

Comparison operator for string types.

bool operator!= (const wxWCharBuffer & *s1*, const wxString & *s2*) `[inline]`

Comparison operator for string types.

bool operator!= (const wxString & *s1*, const wxCharBuffer & *s2*) `[inline]`

Comparison operator for string types.

bool operator!= (const wxCharBuffer & *s1*, const wxString & *s2*) [inline]

Comparison operator for string types.

bool operator!= (const wxUniChar & *c*, const wxString & *s*) [inline]

Comparison operators char types.

bool operator!= (const wxUniCharRef & *c*, const wxString & *s*) [inline]

Comparison operators char types.

bool operator!= (char *c*, const wxString & *s*) [inline]

Comparison operators char types.

bool operator!= (wchar_t *c*, const wxString & *s*) [inline]

Comparison operators char types.

bool operator!= (int *c*, const wxString & *s*) [inline]

Comparison operators char types.

bool operator!= (const wxString & *s*, const wxUniChar & *c*) [inline]

Comparison operators char types.

bool operator!= (const wxString & *s*, const wxUniCharRef & *c*) [inline]

Comparison operators char types.

bool operator!= (const wxString & *s*, char *c*) [inline]

Comparison operators char types.

bool operator!= (const wxString & *s*, wchar_t *c*) [inline]

Comparison operators char types.

bool operator< (const wxString & *s1*, const wxString & *s2*) [inline]

Comparison operator for string types.

bool operator<= (const wxString & *s1*, const wxString & *s2*) [inline]

Comparison operator for string types.

bool operator== (const wxString & *s1,* const wxString & *s2*) [inline]

Comparison operator for string types.

bool operator== (const wxString & *s1,* const wxCStrData & *s2*) [inline]

Comparison operator for string types.

bool operator== (const wxCStrData & *s1,* const wxString & *s2*) [inline]

Comparison operator for string types.

bool operator== (const wxString & *s1,* const wxWCharBuffer & *s2*) [inline]

Comparison operator for string types.

bool operator== (const wxWCharBuffer & *s1,* const wxString & *s2*) [inline]

Comparison operator for string types.

bool operator== (const wxString & *s1,* const wxCharBuffer & *s2*) [inline]

Comparison operator for string types.

bool operator== (const wxCharBuffer & *s1,* const wxString & *s2*) [inline]

Comparison operator for string types.

bool operator== (const wxUniChar & *c,* const wxString & *s*) [inline]

Comparison operators char types.

bool operator== (const wxUniCharRef & *c,* const wxString & *s*) [inline]

Comparison operators char types.

bool operator== (char *c,* const wxString & *s*) [inline]

Comparison operators char types.

bool operator== (wchar_t *c,* const wxString & *s*) [inline]

Comparison operators char types.

bool operator== (int *c,* const wxString & *s*) [inline]

Comparison operators char types.

bool operator== (const wxString & *s*, const wxUniChar & *c*) `[inline]`

Comparison operators char types.

bool operator== (const wxString & *s*, const wxUniCharRef & *c*) `[inline]`

Comparison operators char types.

bool operator== (const wxString & *s*, char *c*) `[inline]`

Comparison operators char types.

bool operator== (const wxString & *s*, wchar_t *c*) `[inline]`

Comparison operators char types.

bool operator> (const wxString & *s1*, const wxString & *s2*) `[inline]`

Comparison operator for string types.

bool operator>= (const wxString & *s1*, const wxString & *s2*) `[inline]`

Comparison operator for string types.

22.160.2 Variable Documentation

wxString wxEmptyString

The global wxString instance of an empty string.

Used extensively in the entire wxWidgets API.

22.161 docs/doxygen/overviews/thread.h File Reference

22.162 interface/wx/thread.h File Reference

Classes

- class wxCondition

  wxCondition variables correspond to pthread conditions or to Win32 event objects.
- class wxCriticalSectionLocker

  This is a small helper class to be used with wxCriticalSection objects.
- class wxThreadHelper

  The wxThreadHelper class is a mix-in class that manages a single background thread, either detached or joinable (see wxThread for the differences).
- class wxCriticalSection

  A critical section object is used for exactly the same purpose as a wxMutex.
- class wxThread

  A thread is basically a path of execution through a program.
- class wxSemaphore

wxSemaphore is a counter limiting the number of threads concurrently accessing a shared resource.

- class wxMutexLocker

  This is a small helper class to be used with wxMutex objects.

- class wxMutex

  A mutex object is a synchronization object whose state is set to signaled when it is not owned by any thread, and nonsignaled when it is owned.

Macros

- #define wxCRIT_SECT_DECLARE(cs)

  This macro declares a (static) critical section object named cs if `wxUSE_THREADS` is 1 and does nothing if it is 0.

- #define wxCRIT_SECT_DECLARE_MEMBER(cs)

  This macro declares a critical section object named cs if `wxUSE_THREADS` is 1 and does nothing if it is 0.

- #define wxCRIT_SECT_LOCKER(name, cs)

  This macro creates a wxCriticalSectionLocker named name and associated with the critical section cs if `wxUSE_THREADS` is 1 and does nothing if it is 0.

- #define wxCRITICAL_SECTION(name)

  This macro combines wxCRIT_SECT_DECLARE() and wxCRIT_SECT_LOCKER(): it creates a static critical section object and also the lock object associated with it.

- #define wxLEAVE_CRIT_SECT(critical_section)

  This macro is equivalent to critical_section.Leave() if `wxUSE_THREADS` is 1 and does nothing if it is 0.

- #define wxENTER_CRIT_SECT(critical_section)

  This macro is equivalent to critical_section.Enter() if `wxUSE_THREADS` is 1 and does nothing if it is 0.

Enumerations

- enum wxCondError {
  wxCOND_NO_ERROR = 0,
  wxCOND_INVALID,
  wxCOND_TIMEOUT,
  wxCOND_MISC_ERROR }

  See wxCondition.

- enum wxCriticalSectionType {
  wxCRITSEC_DEFAULT,
  wxCRITSEC_NON_RECURSIVE }

  Possible critical section types.

- enum wxThreadWait {
  wxTHREAD_WAIT_BLOCK,
  wxTHREAD_WAIT_YIELD,
  wxTHREAD_WAIT_DEFAULT = wxTHREAD_WAIT_YIELD }

  The possible thread wait types.

- enum wxThreadKind {
  wxTHREAD_DETACHED,
  wxTHREAD_JOINABLE }

  The possible thread kinds.

- enum wxThreadError {
  wxTHREAD_NO_ERROR = 0,
  wxTHREAD_NO_RESOURCE,
  wxTHREAD_RUNNING,
  wxTHREAD_NOT_RUNNING,
  wxTHREAD_KILLED,
  wxTHREAD_MISC_ERROR }

  The possible thread errors.

- enum wxSemaError {
  wxSEMA_NO_ERROR = 0,
  wxSEMA_INVALID,
  wxSEMA_BUSY,
  wxSEMA_TIMEOUT,
  wxSEMA_OVERFLOW,
  wxSEMA_MISC_ERROR }

  See wxSemaphore.
- enum wxMutexType {
  wxMUTEX_DEFAULT,
  wxMUTEX_RECURSIVE }

  The possible wxMutex kinds.
- enum wxMutexError {
  wxMUTEX_NO_ERROR = 0,
  wxMUTEX_INVALID,
  wxMUTEX_DEAD_LOCK,
  wxMUTEX_BUSY,
  wxMUTEX_UNLOCKED,
  wxMUTEX_TIMEOUT,
  wxMUTEX_MISC_ERROR }

  The possible wxMutex errors.

Functions

- bool wxIsMainThread ()

  Returns true if this thread is the main one.
- void wxMutexGuiEnter ()

  This function must be called when any thread other than the main GUI thread wants to get access to the GUI library.
- void wxMutexGuiLeave ()

  This function is only defined on platforms which support preemptive threads.

22.162.1 Enumeration Type Documentation

enum wxCondError

See wxCondition.

Enumerator

wxCOND_NO_ERROR

wxCOND_INVALID

wxCOND_TIMEOUT WaitTimeout() has timed out.

wxCOND_MISC_ERROR

enum wxCriticalSectionType

Possible critical section types.

Enumerator

wxCRITSEC_DEFAULT

wxCRITSEC_NON_RECURSIVE Recursive critical section under both Windows and Unix. Non-recursive critical section under Unix, recursive under Windows

enum wxMutexError

The possible wxMutex errors.

Enumerator

wxMUTEX_NO_ERROR The operation completed successfully.

wxMUTEX_INVALID The mutex hasn't been initialized.

wxMUTEX_DEAD_LOCK The mutex is already locked by the calling thread.

wxMUTEX_BUSY The mutex is already locked by another thread.

wxMUTEX_UNLOCKED An attempt to unlock a mutex which is not locked.

wxMUTEX_TIMEOUT wxMutex::LockTimeout() has timed out.

wxMUTEX_MISC_ERROR Any other error.

enum wxMutexType

The possible wxMutex kinds.

Enumerator

wxMUTEX_DEFAULT Normal non-recursive mutex: try to always use this one.

wxMUTEX_RECURSIVE Recursive mutex: don't use these ones with wxCondition.

enum wxSemaError

See wxSemaphore.

Enumerator

wxSEMA_NO_ERROR

wxSEMA_INVALID semaphore hasn't been initialized successfully

wxSEMA_BUSY returned by TryWait() if Wait() would block

wxSEMA_TIMEOUT returned by WaitTimeout()

wxSEMA_OVERFLOW Post() would increase counter past the max.

wxSEMA_MISC_ERROR

enum wxThreadError

The possible thread errors.

Enumerator

wxTHREAD_NO_ERROR No error.

wxTHREAD_NO_RESOURCE No resource left to create a new thread.

wxTHREAD_RUNNING The thread is already running.

wxTHREAD_NOT_RUNNING The thread isn't running.

wxTHREAD_KILLED Thread we waited for had to be killed.

wxTHREAD_MISC_ERROR Some other error.

enum wxThreadKind

The possible thread kinds.

Enumerator

wxTHREAD_DETACHED Detached thread.

wxTHREAD_JOINABLE Joinable thread.

enum wxThreadWait

The possible thread wait types.

Since

2.9.2

Enumerator

wxTHREAD_WAIT_BLOCK No events are processed while waiting. This is the default under all platforms except for wxMSW.

wxTHREAD_WAIT_YIELD Yield for event dispatching while waiting. This flag is dangerous as it exposes the program using it to unexpected reentrancies in the same way as calling wxYield() function does so you are strongly advised to avoid its use and not wait for the thread termination from the main (GUI) thread at all to avoid making your application unresponsive.

Also notice that this flag is not portable as it is only implemented in wxMSW and simply ignored under the other platforms.

wxTHREAD_WAIT_DEFAULT Default wait mode for wxThread::Wait() and wxThread::Delete(). For compatibility reasons, the default wait mode is currently wxTHREAD_WAIT_YIELD if WXWIN_COMPATIBILIT↩ Y_2_8 is defined (and it is by default). However, as mentioned above, you're strongly encouraged to not use wxTHREAD_WAIT_YIELD and pass wxTHREAD_WAIT_BLOCK to wxThread method explicitly.

22.163 docs/doxygen/overviews/tips.h File Reference

22.164 docs/doxygen/overviews/toolbar.h File Reference

22.165 interface/wx/ribbon/toolbar.h File Reference

Classes

- class wxRibbonToolBar

  A ribbon tool bar is similar to a traditional toolbar which has no labels.

22.166 interface/wx/toolbar.h File Reference

Classes

- class wxToolBarToolBase

  A toolbar tool represents one item on the toolbar.
- class wxToolBar

  A toolbar is a bar of buttons and/or other controls usually placed below the menu bar in a wxFrame.

Enumerations

- enum wxToolBarToolStyle {
  wxTOOL_STYLE_BUTTON = 1,
  wxTOOL_STYLE_SEPARATOR = 2,
  wxTOOL_STYLE_CONTROL }

  wxTB_RIGHT,
  wxTB_DEFAULT_STYLE = wxTB_HORIZONTAL }

  wxToolBar style flags

22.166.1 Enumeration Type Documentation

anonymous enum

wxToolBar style flags

Enumerator

wxTB_HORIZONTAL lay out the toolbar horizontally

wxTB_TOP

wxTB_VERTICAL lay out the toolbar vertically

wxTB_LEFT

wxTB_3DBUTTONS show 3D buttons (wxToolBarSimple only)

wxTB_FLAT "flat" buttons (Win32/GTK only)

wxTB_DOCKABLE dockable toolbar (GTK only)

wxTB_NOICONS don't show the icons (they're shown by default)

wxTB_TEXT show the text (not shown by default)

wxTB_NODIVIDER don't show the divider between toolbar and the window (Win32 only)

wxTB_NOALIGN no automatic alignment (Win32 only, useless)

wxTB_HORZ_LAYOUT show the text and the icons alongside, not vertically stacked (Win32/GTK)

wxTB_HORZ_TEXT

wxTB_NO_TOOLTIPS don't show the toolbar short help tooltips

wxTB_BOTTOM lay out toolbar at the bottom of the window

wxTB_RIGHT lay out toolbar at the right edge of the window

wxTB_DEFAULT_STYLE flags that are closest to the native look

enum wxToolBarToolStyle

Enumerator

wxTOOL_STYLE_BUTTON

wxTOOL_STYLE_SEPARATOR

wxTOOL_STYLE_CONTROL

22.167 docs/doxygen/overviews/treectrl.h File Reference

22.168 interface/wx/treectrl.h File Reference

Classes

- class wxTreeCtrl

  A tree control presents information as a hierarchy, with items that may be expanded to show further items.
- class wxTreeEvent

  A tree event holds information about events associated with wxTreeCtrl objects.

Classes

- class wxAboutDialogInfo

  wxAboutDialogInfo contains information shown in the standard About dialog displayed by the wxAboutBox() function.

Functions

- void wxAboutBox (const wxAboutDialogInfo &info, wxWindow *parent=NULL)

  This function shows the standard about dialog containing the information specified in info.
- void wxGenericAboutBox (const wxAboutDialogInfo &info, wxWindow *parent=NULL)

  This function does the same thing as wxAboutBox() except that it always uses the generic wxWidgets version of the dialog instead of the native one.

22.179 interface/wx/accel.h File Reference

Classes

- class wxAcceleratorEntry

  An object used by an application wishing to create an accelerator table (see wxAcceleratorTable).
- class wxAcceleratorTable

  An accelerator table allows the application to specify a table of keyboard shortcuts for menu or button commands.

Enumerations

- enum wxAcceleratorEntryFlags {
  wxACCEL_NORMAL,
  wxACCEL_ALT,
  wxACCEL_CTRL,
  wxACCEL_SHIFT,
  wxACCEL_RAW_CTRL,
  wxACCEL_CMD }

  wxAcceleratorEntry flags

Variables

- wxAcceleratorTable wxNullAcceleratorTable

  An empty accelerator table.

22.179.1 Enumeration Type Documentation

enum wxAcceleratorEntryFlags

wxAcceleratorEntry flags

Enumerator

wxACCEL_NORMAL no modifiers

wxACCEL_ALT hold Alt key down

wxACCEL_CTRL hold Ctrl key down, corresponds to Command key on OS X

wxACCEL_SHIFT hold Shift key down

wxACCEL_RAW_CTRL corresponds to real Ctrl key on OS X, identic to `wxACCEL_CTRL` on other platforms

wxACCEL_CMD deprecated, identic to `wxACCEL_CTRL` on all platforms.

22.179.2 Variable Documentation

wxAcceleratorTable wxNullAcceleratorTable

An empty accelerator table.

22.180 interface/wx/access.h File Reference

Classes

- class wxAccessible

  The wxAccessible class allows wxWidgets applications, and wxWidgets itself, to return extended information about user interface elements to client applications such as screen readers.

Macros

- #define wxACC_STATE_SYSTEM_ALERT_HIGH 0x00000001

  Represents a status of the system.
- #define wxACC_STATE_SYSTEM_ALERT_MEDIUM 0x00000002

  Represents a status of the system.
- #define wxACC_STATE_SYSTEM_ALERT_LOW 0x00000004

  Represents a status of the system.
- #define wxACC_STATE_SYSTEM_ANIMATED 0x00000008

  Represents a status of the system.
- #define wxACC_STATE_SYSTEM_BUSY 0x00000010

  Represents a status of the system.
- #define wxACC_STATE_SYSTEM_CHECKED 0x00000020

  Represents a status of the system.

  Represents a status of the system.
- #define wxACC_STATE_SYSTEM_OFFSCREEN 0x00040000

  Represents a status of the system.
- #define wxACC_STATE_SYSTEM_PRESSED 0x00080000

  Represents a status of the system.
- #define wxACC_STATE_SYSTEM_PROTECTED 0x00100000

  Represents a status of the system.
- #define wxACC_STATE_SYSTEM_READONLY 0x00200000

  Represents a status of the system.
- #define wxACC_STATE_SYSTEM_SELECTABLE 0x00400000

  Represents a status of the system.
- #define wxACC_STATE_SYSTEM_SELECTED 0x00800000

  Represents a status of the system.
- #define wxACC_STATE_SYSTEM_SELFVOICING 0x01000000

  Represents a status of the system.
- #define wxACC_STATE_SYSTEM_UNAVAILABLE 0x02000000

  Represents a status of the system.

- #define wxACC_EVENT_SYSTEM_SOUND 0x0001

  An event identifier that can be sent via wxAccessible::NotifyEvent.
- #define wxACC_EVENT_SYSTEM_ALERT 0x0002

  An event identifier that can be sent via wxAccessible::NotifyEvent.
- #define wxACC_EVENT_SYSTEM_FOREGROUND 0x0003

  An event identifier that can be sent via wxAccessible::NotifyEvent.
- #define wxACC_EVENT_SYSTEM_MENUSTART 0x0004

  An event identifier that can be sent via wxAccessible::NotifyEvent.
- #define wxACC_EVENT_SYSTEM_MENUEND 0x0005

  An event identifier that can be sent via wxAccessible::NotifyEvent.
- #define wxACC_EVENT_SYSTEM_MENUPOPUPSTART 0x0006

  An event identifier that can be sent via wxAccessible::NotifyEvent.
- #define wxACC_EVENT_SYSTEM_MENUPOPUPEND 0x0007

  An event identifier that can be sent via wxAccessible::NotifyEvent.
- #define wxACC_EVENT_SYSTEM_CAPTURESTART 0x0008

  An event identifier that can be sent via wxAccessible::NotifyEvent.
- #define wxACC_EVENT_SYSTEM_CAPTUREEND 0x0009

  An event identifier that can be sent via wxAccessible::NotifyEvent.
- #define wxACC_EVENT_SYSTEM_MOVESIZESTART 0x000A

  An event identifier that can be sent via wxAccessible::NotifyEvent.
- #define wxACC_EVENT_SYSTEM_MOVESIZEEND 0x000B

  An event identifier that can be sent via wxAccessible::NotifyEvent.

- #define wxACC_EVENT_SYSTEM_CONTEXTHELPSTART 0x000C

  An event identifier that can be sent via wxAccessible::NotifyEvent.
- #define wxACC_EVENT_SYSTEM_CONTEXTHELPEND 0x000D

  An event identifier that can be sent via wxAccessible::NotifyEvent.
- #define wxACC_EVENT_SYSTEM_DRAGDROPSTART 0x000E

  An event identifier that can be sent via wxAccessible::NotifyEvent.
- #define wxACC_EVENT_SYSTEM_DRAGDROPEND 0x000F

  An event identifier that can be sent via wxAccessible::NotifyEvent.
- #define wxACC_EVENT_SYSTEM_DIALOGSTART 0x0010

  An event identifier that can be sent via wxAccessible::NotifyEvent.
- #define wxACC_EVENT_SYSTEM_DIALOGEND 0x0011

  An event identifier that can be sent via wxAccessible::NotifyEvent.
- #define wxACC_EVENT_SYSTEM_SCROLLINGSTART 0x0012

  An event identifier that can be sent via wxAccessible::NotifyEvent.
- #define wxACC_EVENT_SYSTEM_SCROLLINGEND 0x0013

  An event identifier that can be sent via wxAccessible::NotifyEvent.
- #define wxACC_EVENT_SYSTEM_SWITCHSTART 0x0014

  An event identifier that can be sent via wxAccessible::NotifyEvent.
- #define wxACC_EVENT_SYSTEM_SWITCHEND 0x0015

  An event identifier that can be sent via wxAccessible::NotifyEvent.
- #define wxACC_EVENT_SYSTEM_MINIMIZESTART 0x0016

  An event identifier that can be sent via wxAccessible::NotifyEvent.
- #define wxACC_EVENT_SYSTEM_MINIMIZEEND 0x0017

  An event identifier that can be sent via wxAccessible::NotifyEvent.
- #define wxACC_EVENT_OBJECT_CREATE 0x8000

  An event identifier that can be sent via wxAccessible::NotifyEvent.
- #define wxACC_EVENT_OBJECT_DESTROY 0x8001

  An event identifier that can be sent via wxAccessible::NotifyEvent.
- #define wxACC_EVENT_OBJECT_SHOW 0x8002

  An event identifier that can be sent via wxAccessible::NotifyEvent.
- #define wxACC_EVENT_OBJECT_HIDE 0x8003

  An event identifier that can be sent via wxAccessible::NotifyEvent.
- #define wxACC_EVENT_OBJECT_REORDER 0x8004

  An event identifier that can be sent via wxAccessible::NotifyEvent.
- #define wxACC_EVENT_OBJECT_FOCUS 0x8005

  An event identifier that can be sent via wxAccessible::NotifyEvent.
- #define wxACC_EVENT_OBJECT_SELECTION 0x8006

  An event identifier that can be sent via wxAccessible::NotifyEvent.
- #define wxACC_EVENT_OBJECT_SELECTIONADD 0x8007

  An event identifier that can be sent via wxAccessible::NotifyEvent.
- #define wxACC_EVENT_OBJECT_SELECTIONREMOVE 0x8008

  An event identifier that can be sent via wxAccessible::NotifyEvent.
- #define wxACC_EVENT_OBJECT_SELECTIONWITHIN 0x8009

  An event identifier that can be sent via wxAccessible::NotifyEvent.
- #define wxACC_EVENT_OBJECT_STATECHANGE 0x800A

  An event identifier that can be sent via wxAccessible::NotifyEvent.
- #define wxACC_EVENT_OBJECT_LOCATIONCHANGE 0x800B

  An event identifier that can be sent via wxAccessible::NotifyEvent.
- #define wxACC_EVENT_OBJECT_NAMECHANGE 0x800C

  An event identifier that can be sent via wxAccessible::NotifyEvent.
- #define wxACC_EVENT_OBJECT_DESCRIPTIONCHANGE 0x800D

An event identifier that can be sent via wxAccessible::NotifyEvent.

- #define wxACC_EVENT_OBJECT_VALUECHANGE 0x800E

  An event identifier that can be sent via wxAccessible::NotifyEvent.

- #define wxACC_EVENT_OBJECT_PARENTCHANGE 0x800F

  An event identifier that can be sent via wxAccessible::NotifyEvent.

- #define wxACC_EVENT_OBJECT_HELPCHANGE 0x8010

  An event identifier that can be sent via wxAccessible::NotifyEvent.

- #define wxACC_EVENT_OBJECT_DEFACTIONCHANGE 0x8011

  An event identifier that can be sent via wxAccessible::NotifyEvent.

- #define wxACC_EVENT_OBJECT_ACCELERATORCHANGE 0x8012

  An event identifier that can be sent via wxAccessible::NotifyEvent.

Enumerations

- enum wxAccStatus {
  wxACC_FAIL,
  wxACC_FALSE,
  wxACC_OK,
  wxACC_NOT_IMPLEMENTED,
  wxACC_NOT_SUPPORTED }

  wxAccessible functions return a wxAccStatus error code, which may be one of this enum's values.

- enum wxNavDir {
  wxNAVDIR_DOWN,
  wxNAVDIR_FIRSTCHILD,
  wxNAVDIR_LASTCHILD,
  wxNAVDIR_LEFT,
  wxNAVDIR_NEXT,
  wxNAVDIR_PREVIOUS,
  wxNAVDIR_RIGHT,
  wxNAVDIR_UP }

  Directions of navigation are represented by this enum.

- enum wxAccRole {
  wxROLE_NONE,
  wxROLE_SYSTEM_ALERT,
  wxROLE_SYSTEM_ANIMATION,
  wxROLE_SYSTEM_APPLICATION,
  wxROLE_SYSTEM_BORDER,
  wxROLE_SYSTEM_BUTTONDROPDOWN,
  wxROLE_SYSTEM_BUTTONDROPDOWNGRID,
  wxROLE_SYSTEM_BUTTONMENU,
  wxROLE_SYSTEM_CARET,
  wxROLE_SYSTEM_CELL,
  wxROLE_SYSTEM_CHARACTER,
  wxROLE_SYSTEM_CHART,
  wxROLE_SYSTEM_CHECKBUTTON,
  wxROLE_SYSTEM_CLIENT,
  wxROLE_SYSTEM_CLOCK,
  wxROLE_SYSTEM_COLUMN,
  wxROLE_SYSTEM_COLUMNHEADER,
  wxROLE_SYSTEM_COMBOBOX,
  wxROLE_SYSTEM_CURSOR,
  wxROLE_SYSTEM_DIAGRAM,
  wxROLE_SYSTEM_DIAL,
  wxROLE_SYSTEM_DIALOG,
  wxROLE_SYSTEM_DOCUMENT,
  wxROLE_SYSTEM_DROPLIST,
  wxROLE_SYSTEM_EQUATION,
  wxROLE_SYSTEM_GRAPHIC,
  wxROLE_SYSTEM_GRIP,
  wxROLE_SYSTEM_GROUPING,
  wxROLE_SYSTEM_HELPBALLOON,
  wxROLE_SYSTEM_HOTKEYFIELD,
  wxROLE_SYSTEM_INDICATOR,
  wxROLE_SYSTEM_LINK,
  wxROLE_SYSTEM_LIST,
  wxROLE_SYSTEM_LISTITEM,
  wxROLE_SYSTEM_MENUBAR,
  wxROLE_SYSTEM_MENUITEM,
  wxROLE_SYSTEM_MENUPOPUP,
  wxROLE_SYSTEM_OUTLINE,
  wxROLE_SYSTEM_OUTLINEITEM,
  wxROLE_SYSTEM_PAGETAB,
  wxROLE_SYSTEM_PAGETABLIST,
  wxROLE_SYSTEM_PANE,
  wxROLE_SYSTEM_PROGRESSBAR,
  wxROLE_SYSTEM_PROPERTYPAGE,
  wxROLE_SYSTEM_PUSHBUTTON,
  wxROLE_SYSTEM_RADIOBUTTON,
  wxROLE_SYSTEM_ROW,
  wxROLE_SYSTEM_ROWHEADER,
  wxROLE_SYSTEM_SCROLLBAR,
  wxROLE_SYSTEM_SEPARATOR,
  wxROLE_SYSTEM_SLIDER,
  wxROLE_SYSTEM_SOUND,
  wxROLE_SYSTEM_SPINBUTTON,
  wxROLE_SYSTEM_STATICTEXT,
  wxROLE_SYSTEM_STATUSBAR,
  wxROLE_SYSTEM_TABLE,
  wxROLE_SYSTEM_TEXT,
  wxROLE_SYSTEM_TITLEBAR,
  wxROLE_SYSTEM_TOOLBAR,
  wxROLE_SYSTEM_TOOLTIP,
  wxROLE_SYSTEM_WHITESPACE,
  wxROLE_SYSTEM_WINDOW }

The role of a user interface element is represented by the values of this enum.

- enum wxAccObject {
  wxOBJID_WINDOW = 0x00000000,
  wxOBJID_SYSMENU = 0xFFFFFFFF,
  wxOBJID_TITLEBAR = 0xFFFFFFFE,
  wxOBJID_MENU = 0xFFFFFFFD,
  wxOBJID_CLIENT = 0xFFFFFFFC,
  wxOBJID_VSCROLL = 0xFFFFFFFB,
  wxOBJID_HSCROLL = 0xFFFFFFFA,
  wxOBJID_SIZEGRIP = 0xFFFFFFF9,
  wxOBJID_CARET = 0xFFFFFFF8,
  wxOBJID_CURSOR = 0xFFFFFFF7,
  wxOBJID_ALERT = 0xFFFFFFF6,
  wxOBJID_SOUND = 0xFFFFFFF5 }

  Objects are represented by a wxAccObject enum value.
- enum wxAccSelectionFlags {
  wxACC_SEL_NONE = 0,
  wxACC_SEL_TAKEFOCUS = 1,
  wxACC_SEL_TAKESELECTION = 2,
  wxACC_SEL_EXTENDSELECTION = 4,
  wxACC_SEL_ADDSELECTION = 8,
  wxACC_SEL_REMOVESELECTION = 16 }

  Selection actions are identified by the wxAccSelectionFlags values.

22.180.1 Macro Definition Documentation

#define wxACC_EVENT_OBJECT_ACCELERATORCHANGE 0x8012

An event identifier that can be sent via wxAccessible::NotifyEvent.

#define wxACC_EVENT_OBJECT_CREATE 0x8000

An event identifier that can be sent via wxAccessible::NotifyEvent.

#define wxACC_EVENT_OBJECT_DEFACTIONCHANGE 0x8011

An event identifier that can be sent via wxAccessible::NotifyEvent.

#define wxACC_EVENT_OBJECT_DESCRIPTIONCHANGE 0x800D

An event identifier that can be sent via wxAccessible::NotifyEvent.

#define wxACC_EVENT_OBJECT_DESTROY 0x8001

An event identifier that can be sent via wxAccessible::NotifyEvent.

#define wxACC_EVENT_OBJECT_FOCUS 0x8005

An event identifier that can be sent via wxAccessible::NotifyEvent.

#define wxACC_EVENT_OBJECT_HELPCHANGE 0x8010

An event identifier that can be sent via wxAccessible::NotifyEvent.

#define wxACC_EVENT_OBJECT_HIDE 0x8003

An event identifier that can be sent via wxAccessible::NotifyEvent.

#define wxACC_EVENT_OBJECT_LOCATIONCHANGE 0x800B

An event identifier that can be sent via wxAccessible::NotifyEvent.

#define wxACC_EVENT_OBJECT_NAMECHANGE 0x800C

An event identifier that can be sent via wxAccessible::NotifyEvent.

#define wxACC_EVENT_OBJECT_PARENTCHANGE 0x800F

An event identifier that can be sent via wxAccessible::NotifyEvent.

#define wxACC_EVENT_OBJECT_REORDER 0x8004

An event identifier that can be sent via wxAccessible::NotifyEvent.

#define wxACC_EVENT_OBJECT_SELECTION 0x8006

An event identifier that can be sent via wxAccessible::NotifyEvent.

#define wxACC_EVENT_OBJECT_SELECTIONADD 0x8007

An event identifier that can be sent via wxAccessible::NotifyEvent.

#define wxACC_EVENT_OBJECT_SELECTIONREMOVE 0x8008

An event identifier that can be sent via wxAccessible::NotifyEvent.

#define wxACC_EVENT_OBJECT_SELECTIONWITHIN 0x8009

An event identifier that can be sent via wxAccessible::NotifyEvent.

#define wxACC_EVENT_OBJECT_SHOW 0x8002

An event identifier that can be sent via wxAccessible::NotifyEvent.

#define wxACC_EVENT_OBJECT_STATECHANGE 0x800A

An event identifier that can be sent via wxAccessible::NotifyEvent.

#define wxACC_EVENT_OBJECT_VALUECHANGE 0x800E

An event identifier that can be sent via wxAccessible::NotifyEvent.

#define wxACC_EVENT_SYSTEM_ALERT 0x0002

An event identifier that can be sent via wxAccessible::NotifyEvent.

#define wxACC_EVENT_SYSTEM_CAPTUREEND 0x0009

An event identifier that can be sent via wxAccessible::NotifyEvent.

#define wxACC_EVENT_SYSTEM_CAPTURESTART 0x0008

An event identifier that can be sent via wxAccessible::NotifyEvent.

#define wxACC_EVENT_SYSTEM_CONTEXTHELPEND 0x000D

An event identifier that can be sent via wxAccessible::NotifyEvent.

#define wxACC_EVENT_SYSTEM_CONTEXTHELPSTART 0x000C

An event identifier that can be sent via wxAccessible::NotifyEvent.

#define wxACC_EVENT_SYSTEM_DIALOGEND 0x0011

An event identifier that can be sent via wxAccessible::NotifyEvent.

#define wxACC_EVENT_SYSTEM_DIALOGSTART 0x0010

An event identifier that can be sent via wxAccessible::NotifyEvent.

#define wxACC_EVENT_SYSTEM_DRAGDROPEND 0x000F

An event identifier that can be sent via wxAccessible::NotifyEvent.

#define wxACC_EVENT_SYSTEM_DRAGDROPSTART 0x000E

An event identifier that can be sent via wxAccessible::NotifyEvent.

#define wxACC_EVENT_SYSTEM_FOREGROUND 0x0003

An event identifier that can be sent via wxAccessible::NotifyEvent.

#define wxACC_EVENT_SYSTEM_MENUEND 0x0005

An event identifier that can be sent via wxAccessible::NotifyEvent.

#define wxACC_EVENT_SYSTEM_MENUPOPUPEND 0x0007

An event identifier that can be sent via wxAccessible::NotifyEvent.

#define wxACC_EVENT_SYSTEM_MENUPOPUPSTART 0x0006

An event identifier that can be sent via wxAccessible::NotifyEvent.

#define wxACC_EVENT_SYSTEM_MENUSTART 0x0004

An event identifier that can be sent via wxAccessible::NotifyEvent.

#define wxACC_EVENT_SYSTEM_MINIMIZEEND 0x0017

An event identifier that can be sent via wxAccessible::NotifyEvent.

#define wxACC_EVENT_SYSTEM_MINIMIZESTART 0x0016

An event identifier that can be sent via wxAccessible::NotifyEvent.

#define wxACC_EVENT_SYSTEM_MOVESIZEEND 0x000B

An event identifier that can be sent via wxAccessible::NotifyEvent.

#define wxACC_EVENT_SYSTEM_MOVESIZESTART 0x000A

An event identifier that can be sent via wxAccessible::NotifyEvent.

#define wxACC_EVENT_SYSTEM_SCROLLINGEND 0x0013

An event identifier that can be sent via wxAccessible::NotifyEvent.

#define wxACC_EVENT_SYSTEM_SCROLLINGSTART 0x0012

An event identifier that can be sent via wxAccessible::NotifyEvent.

#define wxACC_EVENT_SYSTEM_SOUND 0x0001

An event identifier that can be sent via wxAccessible::NotifyEvent.

#define wxACC_EVENT_SYSTEM_SWITCHEND 0x0015

An event identifier that can be sent via wxAccessible::NotifyEvent.

#define wxACC_EVENT_SYSTEM_SWITCHSTART 0x0014

An event identifier that can be sent via wxAccessible::NotifyEvent.

#define wxACC_STATE_SYSTEM_ALERT_HIGH 0x00000001

Represents a status of the system.

#define wxACC_STATE_SYSTEM_ALERT_LOW 0x00000004

Represents a status of the system.

#define wxACC_STATE_SYSTEM_ALERT_MEDIUM 0x00000002

Represents a status of the system.

#define wxACC_STATE_SYSTEM_ANIMATED 0x00000008

Represents a status of the system.

#define wxACC_STATE_SYSTEM_BUSY 0x00000010

Represents a status of the system.

#define wxACC_STATE_SYSTEM_CHECKED 0x00000020

Represents a status of the system.

#define wxACC_STATE_SYSTEM_COLLAPSED 0x00000040

Represents a status of the system.

#define wxACC_STATE_SYSTEM_DEFAULT 0x00000080

Represents a status of the system.

#define wxACC_STATE_SYSTEM_EXPANDED 0x00000100

Represents a status of the system.

#define wxACC_STATE_SYSTEM_EXTSELECTABLE 0x00000200

Represents a status of the system.

#define wxACC_STATE_SYSTEM_FLOATING 0x00000400

Represents a status of the system.

#define wxACC_STATE_SYSTEM_FOCUSABLE 0x00000800

Represents a status of the system.

#define wxACC_STATE_SYSTEM_FOCUSED 0x00001000

Represents a status of the system.

#define wxACC_STATE_SYSTEM_HOTTRACKED 0x00002000

Represents a status of the system.

#define wxACC_STATE_SYSTEM_INVISIBLE 0x00004000

Represents a status of the system.

#define wxACC_STATE_SYSTEM_MARQUEED 0x00008000

Represents a status of the system.

#define wxACC_STATE_SYSTEM_MIXED 0x00010000

Represents a status of the system.

#define wxACC_STATE_SYSTEM_MULTISELECTABLE 0x00020000

Represents a status of the system.

#define wxACC_STATE_SYSTEM_OFFSCREEN 0x00040000

Represents a status of the system.

#define wxACC_STATE_SYSTEM_PRESSED 0x00080000

Represents a status of the system.

#define wxACC_STATE_SYSTEM_PROTECTED 0x00100000

Represents a status of the system.

#define wxACC_STATE_SYSTEM_READONLY 0x00200000

Represents a status of the system.

#define wxACC_STATE_SYSTEM_SELECTABLE 0x00400000

Represents a status of the system.

#define wxACC_STATE_SYSTEM_SELECTED 0x00800000

Represents a status of the system.

#define wxACC_STATE_SYSTEM_SELFVOICING 0x01000000

Represents a status of the system.

#define wxACC_STATE_SYSTEM_UNAVAILABLE 0x02000000

Represents a status of the system.

22.180.2 Enumeration Type Documentation

enum wxAccObject

Objects are represented by a wxAccObject enum value.

Enumerator

wxOBJID_WINDOW
wxOBJID_SYSMENU
wxOBJID_TITLEBAR
wxOBJID_MENU
wxOBJID_CLIENT
wxOBJID_VSCROLL
wxOBJID_HSCROLL
wxOBJID_SIZEGRIP
wxOBJID_CARET
wxOBJID_CURSOR
wxOBJID_ALERT
wxOBJID_SOUND

enum wxAccRole

The role of a user interface element is represented by the values of this enum.

Enumerator

enum wxAccSelectionFlags

Selection actions are identified by the wxAccSelectionFlags values.

Enumerator

wxACC_SEL_NONE

wxACC_SEL_TAKEFOCUS

wxACC_SEL_TAKESELECTION

wxACC_SEL_EXTENDSELECTION

wxACC_SEL_ADDSELECTION

wxACC_SEL_REMOVESELECTION

enum wxAccStatus

wxAccessible functions return a wxAccStatus error code, which may be one of this enum's values.

Enumerator

wxACC_FAIL The function failed.

wxACC_FALSE The function returned false.

wxACC_OK The function completed successfully.

wxACC_NOT_IMPLEMENTED The function is not implemented.

wxACC_NOT_SUPPORTED The function is not supported.

enum wxNavDir

Directions of navigation are represented by this enum.

Enumerator

wxNAVDIR_DOWN

wxNAVDIR_FIRSTCHILD

wxNAVDIR_LASTCHILD

wxNAVDIR_LEFT

wxNAVDIR_NEXT

wxNAVDIR_PREVIOUS

wxNAVDIR_RIGHT

wxNAVDIR_UP

22.181 interface/wx/affinematrix2d.h File Reference

Classes

- class wxAffineMatrix2D

  A 3x2 matrix representing an affine 2D transformation.

22.182 interface/wx/affinematrix2dbase.h File Reference

Classes

- class wxMatrix2D

  A simple container for 2x2 matrix.
- class wxAffineMatrix2DBase

  A 2x3 matrix representing an affine 2D transformation.

22.183 interface/wx/animate.h File Reference

Classes

- class wxAnimationCtrl

  This is a static control which displays an animation.
- class wxAnimation

  This class encapsulates the concept of a platform-dependent animation.

Macros

- #define wxAC_NO_AUTORESIZE (0x0010)
- #define wxAC_DEFAULT_STYLE (wxBORDER_NONE)

Enumerations

- enum wxAnimationType {
  wxANIMATION_TYPE_INVALID,
  wxANIMATION_TYPE_GIF,
  wxANIMATION_TYPE_ANI,
  wxANIMATION_TYPE_ANY }

  Supported animation types.

Variables

- wxAnimation wxNullAnimation

  An empty animation object.

22.183.1 Macro Definition Documentation

#define wxAC_DEFAULT_STYLE (wxBORDER_NONE)

#define wxAC_NO_AUTORESIZE (0x0010)

22.183.2 Enumeration Type Documentation

enum wxAnimationType

Supported animation types.

Enumerator

wxANIMATION_TYPE_INVALID

wxANIMATION_TYPE_GIF represents an animated GIF file.

wxANIMATION_TYPE_ANI represents an ANI file.

wxANIMATION_TYPE_ANY autodetect the filetype.

22.183.3 Variable Documentation

wxAnimation wxNullAnimation

An empty animation object.

22.184 interface/wx/any.h File Reference

Classes

- class wxAny

  The wxAny class represents a container for any type.
- union wxAnyValueBuffer

  Type for buffer within wxAny for holding data.
- class wxAnyValueType

  wxAnyValueType is base class for value type functionality for C++ data types used with wxAny.

Enumerations

- enum { WX_ANY_VALUE_BUFFER_SIZE = 16 }

  Size of the wxAny value buffer.

22.184.1 Enumeration Type Documentation

anonymous enum

Size of the wxAny value buffer.

Enumerator

WX_ANY_VALUE_BUFFER_SIZE

22.185 interface/wx/anybutton.h File Reference

Classes

- class wxAnyButton

  A class for common button functionality used as the base for the various button classes.

Macros

- #define wxBU_LEFT 0x0040
- #define wxBU_TOP 0x0080
- #define wxBU_RIGHT 0x0100

#define wxBU_RIGHT 0x0100

#define wxBU_TOP 0x0080

22.186 interface/wx/appprogress.h File Reference

Classes

- class wxAppProgressIndicator

  A helper class that can be used to update the progress bar in the taskbar button.

22.187 interface/wx/apptrait.h File Reference

Classes

- class wxAppTraits

  The wxAppTraits class defines various configurable aspects of a wxApp.

22.188 interface/wx/arrstr.h File Reference

Classes

- class wxArrayString

  wxArrayString is an efficient container for storing wxString objects.
- class wxSortedArrayString

  wxSortedArrayString is an efficient container for storing wxString objects which always keeps the string in alphabetical order.

Functions

- int wxStringSortAscending (const wxString &s1, const wxString &s2)

  Comparison function comparing strings in alphabetical order.
- int wxStringSortDescending (const wxString &s1, const wxString &s2)

  Comparison function comparing strings in reverse alphabetical order.
- int wxDictionaryStringSortAscending (const wxString &s1, const wxString &s2)

  Comparison function comparing strings in dictionary order.
- wxArrayString wxSplit (const wxString &str, const wxChar sep, const wxChar escape= '\\')

  Splits the given wxString object using the separator sep and returns the result as a wxArrayString.
- wxString wxJoin (const wxArrayString &arr, const wxChar sep, const wxChar escape= '\\')

  Concatenate all lines of the given wxArrayString object using the separator sep and returns the result as a wxString.

22.188.1 Function Documentation

int wxDictionaryStringSortAscending (const wxString & *s1*, const wxString & *s2*)

Comparison function comparing strings in dictionary order.

Comparison function comparing strings in reverse dictionary order.

The "dictionary order" differs from the alphabetical order in that the strings differing not only in case are compared case-insensitively to ensure that "Aa" comes before "AB" in the sorted array, unlike with wxStringSortAscending().

This function can be used with wxSortedArrayString::Sort() or passed as an argument to wxSortedArrayString constructor.

See also

wxStringSortAscending(), wxDictionaryStringSortDescending()

Since

3.1.0

See wxDictionaryStringSortAscending() for the dictionary sort description.

See also

wxStringSortDescending()

Since

3.1.0

int wxStringSortAscending (const wxString & *s1*, const wxString & *s2*)

Comparison function comparing strings in alphabetical order.

This function can be used with wxSortedArrayString::Sort() or passed as an argument to wxSortedArrayString constructor.

See also

wxStringSortDescending(), wxDictionaryStringSortAscending()

Since

3.1.0

int wxStringSortDescending (const wxString & *s1*, const wxString & *s2*)

Comparison function comparing strings in reverse alphabetical order.

This function can be used with wxSortedArrayString::Sort() or passed as an argument to wxSortedArrayString constructor.

See also

wxStringSortAscending(), wxDictionaryStringSortAscending()

Since

3.1.0

22.189 interface/wx/artprov.h File Reference

Classes

- class wxArtProvider

  wxArtProvider class is used to customize the look of wxWidgets application.

Typedefs

- typedef wxString wxArtClient

  This type identifies the client of the art objects requested to wxArtProvider.
- typedef wxString wxArtID

  This type identifies a specific art object which can be requested to wxArtProvider.

Variables

- wxArtClient wxART_TOOLBAR
- wxArtClient wxART_MENU
- wxArtClient wxART_FRAME_ICON

Functions

- void wxAtomicInc (wxAtomicInt &value)

  This function increments value in an atomic manner.

- wxInt32 wxAtomicDec (wxAtomicInt &value)

  This function decrements value in an atomic manner.

22.191 interface/wx/aui/auibar.h File Reference

Classes

- class wxAuiToolBarEvent

  wxAuiToolBarEvent is used for the events generated by wxAuiToolBar.

- class wxAuiToolBarItem

  wxAuiToolBarItem is part of the wxAUI class framework, representing a toolbar element.

- class wxAuiToolBarArt

  wxAuiToolBarArt is part of the wxAUI class framework.

- class wxAuiDefaultToolBarArt

  wxAuiDefaultToolBarArt is part of the wxAUI class framework.

- class wxAuiToolBar

  wxAuiToolBar is a dockable toolbar, part of the wxAUI class framework.

Enumerations

- enum wxAuiToolBarStyle {
  wxAUI_TB_TEXT = 1 << 0,
  wxAUI_TB_NO_TOOLTIPS = 1 << 1,
  wxAUI_TB_NO_AUTORESIZE = 1 << 2,

Classes

- class wxAuiNotebook

  wxAuiNotebook is part of the wxAUI class framework, which represents a notebook control, managing multiple windows with associated tabs.
- class wxAuiTabContainerButton

  A simple class which holds information about wxAuiNotebook tab buttons and their state.
- class wxAuiTabContainer

  wxAuiTabContainer is a class which contains information about each tab.
- class wxAuiTabArt

  Tab art provider defines all the drawing functions used by wxAuiNotebook.
- class wxAuiNotebookEvent

  This class is used by the events generated by wxAuiNotebook.
- class wxAuiDefaultTabArt

  Default art provider for wxAuiNotebook.
- class wxAuiSimpleTabArt

  Another standard tab art provider for wxAuiNotebook.

  wxAUI_BUTTON_CUSTOM1 = 201,
  wxAUI_BUTTON_CUSTOM2 = 202,
  wxAUI_BUTTON_CUSTOM3 = 203 }

  These are the possible pane button / wxAuiNotebook button / wxAuiToolBar button identifiers.

22.193.1 Enumeration Type Documentation

enum wxAuiButtonId

These are the possible pane button / wxAuiNotebook button / wxAuiToolBar button identifiers.

Enumerator

wxAUI_BUTTON_CLOSE Shows a close button on the pane.

wxAUI_BUTTON_MAXIMIZE_RESTORE Shows a maximize/restore button on the pane.

wxAUI_BUTTON_MINIMIZE Shows a minimize button on the pane.

wxAUI_BUTTON_PIN Shows a pin button on the pane.

wxAUI_BUTTON_OPTIONS Shows an option button on the pane (not implemented)

wxAUI_BUTTON_WINDOWLIST Shows a window list button on the pane (for wxAuiNotebook)

wxAUI_BUTTON_LEFT Shows a left button on the pane (for wxAuiNotebook)

wxAUI_BUTTON_RIGHT Shows a right button on the pane (for wxAuiNotebook)

wxAUI_BUTTON_UP Shows an up button on the pane (not implemented)

wxAUI_BUTTON_DOWN Shows a down button on the pane (not implemented)

wxAUI_BUTTON_CUSTOM1 Shows one of three possible custom buttons on the pane (not implemented)

wxAUI_BUTTON_CUSTOM2 Shows one of three possible custom buttons on the pane (not implemented)

wxAUI_BUTTON_CUSTOM3 Shows one of three possible custom buttons on the pane (not implemented)

enum wxAuiPaneButtonState

These are the possible pane button / wxAuiNotebook button / wxAuiToolBar button states.

Enumerator

wxAUI_BUTTON_STATE_NORMAL Normal button state.

wxAUI_BUTTON_STATE_HOVER Hovered button state.

wxAUI_BUTTON_STATE_PRESSED Pressed button state.

wxAUI_BUTTON_STATE_DISABLED Disabled button state.

wxAUI_BUTTON_STATE_HIDDEN Hidden button state.

wxAUI_BUTTON_STATE_CHECKED Checked button state.

enum wxAuiPaneDockArtGradients

These are the possible gradient dock art settings for wxAuiDefaultDockArt.

Enumerator

wxAUI_GRADIENT_NONE No gradient on the captions, in other words a solid colour.

wxAUI_GRADIENT_VERTICAL Vertical gradient on the captions, in other words a gradal change in colours from top to bottom.

wxAUI_GRADIENT_HORIZONTAL Horizontal gradient on the captions, in other words a gradual change in colours from left to right.

22.194 interface/wx/aui/framemanager.h File Reference

Classes

- class wxAuiManager

  wxAuiManager is the central class of the wxAUI class framework.
- class wxAuiPaneInfo

  wxAuiPaneInfo is part of the wxAUI class framework.
- class wxAuiManagerEvent

  Event used to indicate various actions taken with wxAuiManager.

Enumerations

- enum wxAuiManagerDock {
  wxAUI_DOCK_NONE = 0,
  wxAUI_DOCK_TOP = 1,
  wxAUI_DOCK_RIGHT = 2,
  wxAUI_DOCK_BOTTOM = 3,
  wxAUI_DOCK_LEFT = 4,
  wxAUI_DOCK_CENTER = 5,
  wxAUI_DOCK_CENTRE = wxAUI_DOCK_CENTER }
- enum wxAuiManagerOption {
  wxAUI_MGR_ALLOW_FLOATING = 1 << 0,
  wxAUI_MGR_ALLOW_ACTIVE_PANE = 1 << 1,
  wxAUI_MGR_TRANSPARENT_DRAG = 1 << 2,
  wxAUI_MGR_TRANSPARENT_HINT = 1 << 3,
  wxAUI_MGR_VENETIAN_BLINDS_HINT = 1 << 4,
  wxAUI_MGR_RECTANGLE_HINT = 1 << 5,
  wxAUI_MGR_HINT_FADE = 1 << 6,
  wxAUI_MGR_NO_VENETIAN_BLINDS_FADE = 1 << 7,
  wxAUI_MGR_LIVE_RESIZE = 1 << 8,
  wxAUI_MGR_DEFAULT }

  wxAuiManager behaviour and visual effects style flags.

22.194.1 Enumeration Type Documentation

enum wxAuiManagerDock

Todo wxAuiPaneInfo dock direction types used with wxAuiManager.

Enumerator

wxAUI_DOCK_NONE

wxAUI_DOCK_TOP

wxAUI_DOCK_RIGHT

wxAUI_DOCK_BOTTOM

wxAUI_DOCK_LEFT

wxAUI_DOCK_CENTER

wxAUI_DOCK_CENTRE

enum wxAuiManagerOption

wxAuiManager behaviour and visual effects style flags.

Enumerator

wxAUI_MGR_ALLOW_FLOATING Allow a pane to be undocked to take the form of a wxMiniFrame.

wxAUI_MGR_ALLOW_ACTIVE_PANE Change the color of the title bar of the pane when it is activated.

wxAUI_MGR_TRANSPARENT_DRAG Make the pane transparent during its movement.

wxAUI_MGR_TRANSPARENT_HINT The possible location for docking is indicated by a translucent area.

wxAUI_MGR_VENETIAN_BLINDS_HINT The possible location for docking is indicated by a gradually appearing partially transparent area.

wxAUI_MGR_RECTANGLE_HINT The possible location for docking is indicated by a rectangular outline.

wxAUI_MGR_HINT_FADE The translucent area where the pane could be docked appears gradually.

wxAUI_MGR_NO_VENETIAN_BLINDS_FADE Used in complement of wxAUI_MGR_VENETIAN_BLINDS_HINT to show the hint immediately.

wxAUI_MGR_LIVE_RESIZE When a docked pane is resized, its content is refreshed in live (instead of moving the border alone and refreshing the content at the end).

wxAUI_MGR_DEFAULT Default behavior.

22.195 interface/wx/bannerwindow.h File Reference

Classes

- class wxBannerWindow

  A simple banner window showing either a bitmap or text.

22.196 interface/wx/base64.h File Reference

Enumerations

- enum wxBase64DecodeMode {
  wxBase64DecodeMode_Strict,
  wxBase64DecodeMode_SkipWS,
  wxBase64DecodeMode_Relaxed }

  Elements of this enum specify the possible behaviours of wxBase64Decode when an invalid character is encountered.

Functions

- size_t wxBase64Encode (char *dst, size_t dstLen, const void *src, size_t srcLen)

  This function encodes the given data using base64.
- wxString wxBase64Encode (const void *src, size_t srcLen)

  This function encodes the given data using base64 and returns the output as a wxString.
- wxString wxBase64Encode (const wxMemoryBuffer &buf)

  This function encodes the given data using base64 and returns the output as a wxString.
- size_t wxBase64DecodedSize (size_t srcLen)

  Returns the size of the buffer necessary to contain the data encoded in a base64 string of length srcLen.
- size_t wxBase64EncodedSize (size_t len)

  Returns the length of the string with base64 representation of a buffer of specified size len.
- size_t wxBase64Decode (void *dst, size_t dstLen, const char *src, size_t srcLen=wxNO_LEN, wxBase64DecodeMode mode=wxBase64DecodeMode_Strict, size_t *posErr=NULL)

  This function decodes a Base64-encoded string.
- size_t wxBase64Decode (void *dst, size_t dstLen, const wxString &str, wxBase64DecodeMode mode=wxBase64DecodeMode_Strict, size_t *posErr=NULL)

  Decode a Base64-encoded wxString.
- wxMemoryBuffer wxBase64Decode (const char *src, size_t srcLen=wxNO_LEN, wxBase64DecodeMode mode=wxBase64DecodeMode_Strict, size_t *posErr=NULL)

  Decode a Base64-encoded string and return decoded contents in a buffer.
- wxMemoryBuffer wxBase64Decode (const wxString &src, wxBase64DecodeMode mode=wxBase64DecodeMode_Strict, size_t *posErr=NULL)

  Decode a Base64-encoded wxString and return decoded contents in a buffer.

22.197 interface/wx/bmpbuttn.h File Reference

Classes

- class wxBitmapButton

  A bitmap button is a control that contains a bitmap.

22.198 interface/wx/bmpcbox.h File Reference

Classes

- class wxBitmapComboBox

  A combobox that displays bitmap in front of the list items.

22.199 interface/wx/brush.h File Reference

Classes

- class wxBrush

  A brush is a drawing tool for filling in areas.
- class wxBrushList

  A brush list is a list containing all brushes which have been created.

Enumerations

- enum wxBrushStyle {
  wxBRUSHSTYLE_INVALID = -1,
  wxBRUSHSTYLE_SOLID = wxSOLID,
  wxBRUSHSTYLE_TRANSPARENT = wxTRANSPARENT,
  wxBRUSHSTYLE_STIPPLE_MASK_OPAQUE = wxSTIPPLE_MASK_OPAQUE,
  wxBRUSHSTYLE_STIPPLE_MASK = wxSTIPPLE_MASK,
  wxBRUSHSTYLE_STIPPLE = wxSTIPPLE,
  wxBRUSHSTYLE_BDIAGONAL_HATCH,
  wxBRUSHSTYLE_CROSSDIAG_HATCH,
  wxBRUSHSTYLE_FDIAGONAL_HATCH,
  wxBRUSHSTYLE_CROSS_HATCH,
  wxBRUSHSTYLE_HORIZONTAL_HATCH,
  wxBRUSHSTYLE_VERTICAL_HATCH,
  wxBRUSHSTYLE_FIRST_HATCH,
  wxBRUSHSTYLE_LAST_HATCH }

  The possible brush styles.

Variables

- wxBrush wxNullBrush

  An empty brush.
- wxBrush * wxBLUE_BRUSH

  Blue brush.
- wxBrush * wxGREEN_BRUSH

  Green brush.

- wxBrush * wxYELLOW_BRUSH
  Yellow brush.
- wxBrush * wxWHITE_BRUSH
  White brush.
- wxBrush * wxBLACK_BRUSH
  Black brush.
- wxBrush * wxGREY_BRUSH
  Grey brush.
- wxBrush * wxMEDIUM_GREY_BRUSH
  Medium grey brush.
- wxBrush * wxLIGHT_GREY_BRUSH
  Light grey brush.
- wxBrush * wxTRANSPARENT_BRUSH
  Transparent brush.
- wxBrush * wxCYAN_BRUSH
  Cyan brush.
- wxBrush * wxRED_BRUSH
  Red brush.
- wxBrushList * wxTheBrushList
  The global wxBrushList instance.

22.199.1 Enumeration Type Documentation

enum wxBrushStyle

The possible brush styles.

Enumerator

wxBRUSHSTYLE_INVALID

wxBRUSHSTYLE_SOLID Solid.

wxBRUSHSTYLE_TRANSPARENT Transparent (no fill).

wxBRUSHSTYLE_STIPPLE_MASK_OPAQUE Uses a bitmap as a stipple; the mask is used for blitting monochrome using text foreground and background colors.

wxBRUSHSTYLE_STIPPLE_MASK Uses a bitmap as a stipple; mask is used for masking areas in the stipple bitmap.

wxBRUSHSTYLE_STIPPLE Uses a bitmap as a stipple.

wxBRUSHSTYLE_BDIAGONAL_HATCH Backward diagonal hatch.

wxBRUSHSTYLE_CROSSDIAG_HATCH Cross-diagonal hatch.

wxBRUSHSTYLE_FDIAGONAL_HATCH Forward diagonal hatch.

wxBRUSHSTYLE_CROSS_HATCH Cross hatch.

wxBRUSHSTYLE_HORIZONTAL_HATCH Horizontal hatch.

wxBRUSHSTYLE_VERTICAL_HATCH Vertical hatch.

wxBRUSHSTYLE_FIRST_HATCH First of the hatch styles (inclusive).

wxBRUSHSTYLE_LAST_HATCH Last of the hatch styles (inclusive).

22.199.2 Variable Documentation

wxBrush* wxBLACK_BRUSH

Black brush.

Except for the color it has all standard attributes (`wxBRUSHSTYLE_SOLID`, no stipple bitmap, etc...).

wxBrush* wxBLUE_BRUSH

Blue brush.

Except for the color it has all standard attributes (`wxBRUSHSTYLE_SOLID`, no stipple bitmap, etc...).

wxBrush* wxCYAN_BRUSH

Cyan brush.

Except for the color it has all standard attributes (`wxBRUSHSTYLE_SOLID`, no stipple bitmap, etc...).

wxBrush* wxGREEN_BRUSH

Green brush.

Except for the color it has all standard attributes (`wxBRUSHSTYLE_SOLID`, no stipple bitmap, etc...).

wxBrush* wxGREY_BRUSH

Grey brush.

Except for the color it has all standard attributes (`wxBRUSHSTYLE_SOLID`, no stipple bitmap, etc...).

wxBrush* wxLIGHT_GREY_BRUSH

Light grey brush.

Except for the color it has all standard attributes (`wxBRUSHSTYLE_SOLID`, no stipple bitmap, etc...).

wxBrush* wxMEDIUM_GREY_BRUSH

Medium grey brush.

Except for the color it has all standard attributes (`wxBRUSHSTYLE_SOLID`, no stipple bitmap, etc...).

wxBrush wxNullBrush

An empty brush.

wxBrush::IsOk() always returns false for this object.

wxBrush* wxRED_BRUSH

Red brush.

Except for the color it has all standard attributes (`wxBRUSHSTYLE_SOLID`, no stipple bitmap, etc...).

wxBrushList* wxTheBrushList

The global wxBrushList instance.

wxBrush* wxTRANSPARENT_BRUSH

Transparent brush.

Except for the color it has all standard attributes (`wxBRUSHSTYLE_SOLID`, no stipple bitmap, etc...).

wxBrush* wxWHITE_BRUSH

White brush.

Except for the color it has all standard attributes (`wxBRUSHSTYLE_SOLID`, no stipple bitmap, etc...).

wxBrush* wxYELLOW_BRUSH

Yellow brush.

Except for the color it has all standard attributes (`wxBRUSHSTYLE_SOLID`, no stipple bitmap, etc...).

22.200 interface/wx/buffer.h File Reference

Classes

- class wxScopedCharTypeBuffer< T >

  wxScopedCharTypeBuffer<T> is a template class for storing characters.
- class wxCharTypeBuffer< T >

  wxCharTypeBuffer<T> is a template class for storing characters.
- class wxCharBuffer

  This is a specialization of wxCharTypeBuffer<T> for `char` type.
- class wxWCharBuffer

  This is a specialization of wxCharTypeBuffer<T> for `wchar_t` type.
- class wxMemoryBuffer

  *A **wxMemoryBuffer** is a useful data structure for storing arbitrary sized blocks of memory.*

Typedefs

- typedef wxScopedCharTypeBuffer < char > wxScopedCharBuffer

  Scoped char buffer.
- typedef wxScopedCharTypeBuffer < wchar_t > wxScopedWCharBuffer

  Scoped wchar_t buffer.

22.200.1 Typedef Documentation

typedef wxScopedCharTypeBuffer<char> wxScopedCharBuffer

Scoped char buffer.

typedef wxScopedCharTypeBuffer<wchar_t> wxScopedWCharBuffer

Scoped wchar_t buffer.

22.201 interface/wx/busyinfo.h File Reference

Classes

- class wxBusyInfo

  This class makes it easy to tell your user that the program is temporarily busy.
- class wxBusyInfoFlags

  Parameters for wxBusyInfo.

22.202 interface/wx/button.h File Reference

Classes

- class wxButton

  A button is a control that contains a text string, and is one of the most common elements of a GUI.

22.203 interface/wx/calctrl.h File Reference

Classes

- class wxCalendarEvent

  The wxCalendarEvent class is used together with wxCalendarCtrl.
- class wxCalendarDateAttr

  wxCalendarDateAttr is a custom attributes for a calendar date.
- class wxCalendarCtrl

  The calendar control allows the user to pick a date.

Enumerations

- enum {
  wxCAL_SUNDAY_FIRST = 0x0000,
  wxCAL_MONDAY_FIRST = 0x0001,
  wxCAL_SHOW_HOLIDAYS = 0x0002,
  wxCAL_NO_YEAR_CHANGE = 0x0004,

  wxCAL_SHOW_SURROUNDING_WEEKS = 0x0020,
  wxCAL_SHOW_WEEK_NUMBERS = 0x0040 }
- enum wxCalendarDateBorder {
  wxCAL_BORDER_NONE,
  wxCAL_BORDER_SQUARE,
  wxCAL_BORDER_ROUND }

  Possible kinds of borders which may be used to decorate a date using wxCalendarDateAttr.
- enum wxCalendarHitTestResult {
  wxCAL_HITTEST_NOWHERE,
  wxCAL_HITTEST_HEADER,
  wxCAL_HITTEST_DAY,
  wxCAL_HITTEST_INCMONTH,
  wxCAL_HITTEST_DECMONTH,
  wxCAL_HITTEST_SURROUNDING_WEEK,
  wxCAL_HITTEST_WEEK }

  Possible return values from wxCalendarCtrl::HitTest().

Variables

- wxEventType wxEVT_CALENDAR_SEL_CHANGED
- wxEventType wxEVT_CALENDAR_PAGE_CHANGED
- wxEventType wxEVT_CALENDAR_DOUBLECLICKED
- wxEventType wxEVT_CALENDAR_WEEKDAY_CLICKED
- wxEventType wxEVT_CALENDAR_WEEK_CLICKED

22.203.1 Enumeration Type Documentation

anonymous enum

Enumerator

wxCAL_SUNDAY_FIRST

wxCAL_MONDAY_FIRST

wxCAL_SHOW_HOLIDAYS

wxCAL_NO_YEAR_CHANGE

wxCAL_NO_MONTH_CHANGE

wxCAL_SEQUENTIAL_MONTH_SELECTION

wxCAL_SHOW_SURROUNDING_WEEKS

wxCAL_SHOW_WEEK_NUMBERS

enum wxCalendarDateBorder

Possible kinds of borders which may be used to decorate a date using wxCalendarDateAttr.

Enumerator

wxCAL_BORDER_NONE No Border (Default)

wxCAL_BORDER_SQUARE Rectangular Border.

wxCAL_BORDER_ROUND Round Border.

enum wxCalendarHitTestResult

Possible return values from wxCalendarCtrl::HitTest().

Enumerator

wxCAL_HITTEST_NOWHERE Hit outside of anything.

wxCAL_HITTEST_HEADER Hit on the header (weekdays).

wxCAL_HITTEST_DAY Hit on a day in the calendar.

wxCAL_HITTEST_INCMONTH Hit on next month arrow (in alternate month selector mode).

wxCAL_HITTEST_DECMONTH Hit on previous month arrow (in alternate month selector mode).

wxCAL_HITTEST_SURROUNDING_WEEK Hit on surrounding week of previous/next month (if shown).

wxCAL_HITTEST_WEEK Hit on week of the year number (if shown).

wxEventType wxEVT_CALENDAR_DOUBLECLICKED

wxEventType wxEVT_CALENDAR_PAGE_CHANGED

wxEventType wxEVT_CALENDAR_SEL_CHANGED

wxEventType wxEVT_CALENDAR_WEEK_CLICKED

wxEventType wxEVT_CALENDAR_WEEKDAY_CLICKED

22.204 interface/wx/caret.h File Reference

Classes

- class wxCaret

  A caret is a blinking cursor showing the position where the typed text will appear.

22.205 interface/wx/chartype.h File Reference

Macros

- #define wxT(string)

  This macro can be used with character and string literals (in other words, `'x'` or `"foo"`) to automatically convert them to wide strings in Unicode builds of wxWidgets.
- #define wxT_2(string)

  Compatibility macro which expands to wxT() in wxWidgets 2 only.
- #define wxS(string)

  wxS is a macro which can be used with character and string literals (in other words, `'x'` or `"foo"`) to convert them either to wide characters or wide strings in `wchar_t`-based (UTF-16) builds, or to keep them unchanged in `char`-based (UTF-8) builds.
- #define _T(string)

  This macro is exactly the same as wxT() and is defined in wxWidgets simply because it may be more intuitive for Windows programmers as the standard Win32 headers also define it (as well as yet another name for the same macro which is _TEXT()).

Typedefs

- typedef wxUSE_UNICODE_dependent wxChar

  wxChar is defined to be
  - `char` *when* `wxUSE_UNICODE==0`
  - `wchar_t` *when* `wxUSE_UNICODE==1` *(the default).*
- typedef wxUSE_UNICODE_dependent wxSChar

  wxSChar is defined to be
  - `signed char` *when* `wxUSE_UNICODE==0`
  - `wchar_t` *when* `wxUSE_UNICODE==1` *(the default).*
- typedef wxUSE_UNICODE_dependent wxUChar

  wxUChar is defined to be
  - `unsigned char` *when* `wxUSE_UNICODE==0`
  - `wchar_t` *when* `wxUSE_UNICODE==1` *(the default).*

- typedef
  wxUSE_UNICODE_WCHAR_dependent wxStringCharType

  wxStringCharType is defined to be:
  - `char` *when* `wxUSE_UNICODE==0`
  - `char` *when* `wxUSE_UNICODE_WCHAR==0` *and* `wxUSE_UNICODE==1`
  - `wchar_t` *when* `wxUSE_UNICODE_WCHAR==1` *and* `wxUSE_UNICODE==1`

22.206 interface/wx/checkbox.h File Reference

Classes

- class wxCheckBox

  A checkbox is a labelled box which by default is either on (checkmark is visible) or off (no checkmark).

Macros

- #define wxCHK_2STATE 0x4000
- #define wxCHK_3STATE 0x1000
- #define wxCHK_ALLOW_3RD_STATE_FOR_USER 0x2000

Enumerations

- enum wxCheckBoxState {
  wxCHK_UNCHECKED,
  wxCHK_CHECKED,
  wxCHK_UNDETERMINED }

  The possible states of a 3-state wxCheckBox (Compatible with the 2-state wxCheckBox).

22.206.1 Macro Definition Documentation

#define wxCHK_2STATE 0x4000

#define wxCHK_3STATE 0x1000

#define wxCHK_ALLOW_3RD_STATE_FOR_USER 0x2000

22.206.2 Enumeration Type Documentation

enum wxCheckBoxState

The possible states of a 3-state wxCheckBox (Compatible with the 2-state wxCheckBox).

Enumerator

wxCHK_UNCHECKED

wxCHK_CHECKED

wxCHK_UNDETERMINED 3-state checkbox only

22.207 interface/wx/checklst.h File Reference

Classes

- class wxCheckListBox

  A wxCheckListBox is like a wxListBox, but allows items to be checked or unchecked.

22.208 interface/wx/choicdlg.h File Reference

Classes

- class wxMultiChoiceDialog

  This class represents a dialog that shows a list of strings, and allows the user to select one or more.
- class wxSingleChoiceDialog

  This class represents a dialog that shows a list of strings, and allows the user to select one.

Macros

- #define wxCHOICE_WIDTH 150

  Default width of the choice dialog.
- #define wxCHOICE_HEIGHT 200

  Default height of the choice dialog.
- #define wxCHOICEDLG_STYLE (wxDEFAULT_DIALOG_STYLE | wxOK | wxCANCEL | wxCENTRE | wx↩ RESIZE_BORDER)

  Default style of the choice dialog.

Functions

- int wxGetSingleChoiceIndex (const wxString &message, const wxString &caption, const wxArrayString &a↩ Choices, wxWindow *parent=NULL, int x=wxDefaultCoord, int y=wxDefaultCoord, bool centre=true, int width=wxCHOICE_WIDTH, int height=wxCHOICE_HEIGHT, int initialSelection=0)

  Same as wxGetSingleChoice() but returns the index representing the selected string.
- int wxGetSingleChoiceIndex (const wxString &message, const wxString &caption, int n, const wxString &choices[], wxWindow *parent=NULL, int x=wxDefaultCoord, int y=wxDefaultCoord, bool centre=true, int width=wxCHOICE_WIDTH, int height=wxCHOICE_HEIGHT, int initialSelection=0)
- int wxGetSingleChoiceIndex (const wxString &message, const wxString &caption, const wxArrayString &choices, int initialSelection, wxWindow *parent=NULL)
- int wxGetSingleChoiceIndex (const wxString &message, const wxString &caption, int n, const wxString *choices, int initialSelection, wxWindow *parent=NULL)
- wxString wxGetSingleChoice (const wxString &message, const wxString &caption, const wxArrayString &aChoices, wxWindow *parent=NULL, int x=wxDefaultCoord, int y=wxDefaultCoord, bool centre=true, int width=wxCHOICE_WIDTH, int height=wxCHOICE_HEIGHT, int initialSelection=0)

  Pops up a dialog box containing a message, OK/Cancel buttons and a single-selection listbox.
- wxString wxGetSingleChoice (const wxString &message, const wxString &caption, int n, const wxString &choices[], wxWindow *parent=NULL, int x=wxDefaultCoord, int y=wxDefaultCoord, bool centre=true, int width=wxCHOICE_WIDTH, int height=wxCHOICE_HEIGHT, int initialSelection=0)
- wxString wxGetSingleChoice (const wxString &message, const wxString &caption, const wxArrayString &choices, int initialSelection, wxWindow *parent=NULL)
- wxString wxGetSingleChoice (const wxString &message, const wxString &caption, int n, const wxString *choices, int initialSelection, wxWindow *parent=NULL)

- wxString wxGetSingleChoiceData (const wxString &message, const wxString &caption, const wxArrayString &aChoices, const wxString &client_data[], wxWindow *parent=NULL, int x=wxDefaultCoord, int y=wxDefaultCoord, bool centre=true, int width=wxCHOICE_WIDTH, int height=wxCHOICE_HEIGHT, int initialSelection=0)

  Same as wxGetSingleChoice but takes an array of client data pointers corresponding to the strings, and returns one of these pointers or NULL if Cancel was pressed.
- wxString wxGetSingleChoiceData (const wxString &message, const wxString &caption, int n, const wxString &choices[], const wxString &client_data[], wxWindow *parent=NULL, int x=wxDefaultCoord, int y=wxDefaultCoord, bool centre=true, int width=wxCHOICE_WIDTH, int height=wxCHOICE_HEIGHT, int initialSelection=0)
- void * wxGetSingleChoiceData (const wxString &message, const wxString &caption, const wxArrayString &choices, void **client_data, int initialSelection, wxWindow *parent=NULL)
- void * wxGetSingleChoiceData (const wxString &message, const wxString &caption, int n, const wxString *choices, void **client_data, int initialSelection, wxWindow *parent=NULL)
- int wxGetSelectedChoices (wxArrayInt &selections, const wxString &message, const wxString &caption, const wxArrayString &aChoices, wxWindow *parent=NULL, int x=wxDefaultCoord, int y=wxDefaultCoord, bool centre=true, int width=wxCHOICE_WIDTH, int height=wxCHOICE_HEIGHT)

  Pops up a dialog box containing a message, OK/Cancel buttons and a multiple-selection listbox.
- int wxGetSelectedChoices (wxArrayInt &selections, const wxString &message, const wxString &caption, int n, const wxString &choices[], wxWindow *parent=NULL, int x=wxDefaultCoord, int y=wxDefaultCoord, bool centre=true, int width=wxCHOICE_WIDTH, int height=wxCHOICE_HEIGHT)

22.208.1 Macro Definition Documentation

#define wxCHOICE_HEIGHT 200

Default height of the choice dialog.

#define wxCHOICE_WIDTH 150

Default width of the choice dialog.

#define wxCHOICEDLG_STYLE (wxDEFAULT_DIALOG_STYLE | wxOK | wxCANCEL | wxCENTRE | wxRESIZE_BORDER)

Default style of the choice dialog.

Remarks

wxRESIZE_BORDER is not used under WinCE.

22.209 interface/wx/choice.h File Reference

Classes

- class wxChoice

  A choice item is used to select one of a list of strings.

22.210 interface/wx/choicebk.h File Reference

Classes

- class wxChoicebook

wxChoicebook is a class similar to wxNotebook, but uses a wxChoice control to show the labels instead of the tabs.

Macros

- #define wxCHB_DEFAULT wxBK_DEFAULT
- #define wxCHB_TOP wxBK_TOP
- #define wxCHB_BOTTOM wxBK_BOTTOM
- #define wxCHB_LEFT wxBK_LEFT
- #define wxCHB_RIGHT wxBK_RIGHT
- #define wxCHB_ALIGN_MASK wxBK_ALIGN_MASK

22.214 interface/wx/cmdline.h File Reference

Classes

- struct wxCmdLineEntryDesc

  The structure wxCmdLineEntryDesc is used to describe a command line switch, option or parameter.
- class wxCmdLineArg

  The interface wxCmdLineArg provides information for an instance of argument passed on command line.
- class wxCmdLineArgs

  An ordered collection of wxCmdLineArg providing an iterator to enumerate the arguments passed on command line.
- class wxCmdLineParser

  wxCmdLineParser is a class for parsing the command line.

Enumerations

- enum wxCmdLineEntryFlags {
  wxCMD_LINE_OPTION_MANDATORY = 0x01,
  wxCMD_LINE_PARAM_OPTIONAL = 0x02,
  wxCMD_LINE_PARAM_MULTIPLE = 0x04,
  wxCMD_LINE_OPTION_HELP = 0x08,
  wxCMD_LINE_NEEDS_SEPARATOR = 0x10,
  wxCMD_LINE_SWITCH_NEGATABLE = 0x20 }

  wxCmdLineEntryDesc::flags field is a combination of these bit masks.
- enum wxCmdLineParamType {
  wxCMD_LINE_VAL_STRING,
  wxCMD_LINE_VAL_NUMBER,
  wxCMD_LINE_VAL_DATE,
  wxCMD_LINE_VAL_DOUBLE,
  wxCMD_LINE_VAL_NONE }

  The possible values of wxCmdLineEntryDesc::type which specify the type of the value accepted by an option.
- enum wxCmdLineEntryType {
  wxCMD_LINE_SWITCH,
  wxCMD_LINE_OPTION,
  wxCMD_LINE_PARAM,
  wxCMD_LINE_USAGE_TEXT,
  wxCMD_LINE_NONE }

  The type of a command line entity used for wxCmdLineEntryDesc::kind.
- enum wxCmdLineSwitchState {
  wxCMD_SWITCH_OFF,
  wxCMD_SWITCH_ON }

  The state of a switch as returned by wxCmdLineParser::FoundSwitch().
- enum wxCmdLineSplitType {
  wxCMD_LINE_SPLIT_DOS,
  wxCMD_LINE_SPLIT_UNIX }

  Flags determining wxCmdLineParser::ConvertStringToArgs() behaviour.

22.214.1 Enumeration Type Documentation

enum wxCmdLineEntryFlags

wxCmdLineEntryDesc::flags field is a combination of these bit masks.

Notice that by default (i.e. if flags are just 0), options are optional (sic) and each call to wxCmdLineParser::AddParam() allows one more parameter - this may be changed by giving non-default flags to it, i.e. use `wxCMD_LINE_OPTION_MANDATORY` to require that the option is given and `wxCMD_LINE_PARAM_OPTIONAL` to make a parameter optional.

Also, `wxCMD_LINE_PARAM_MULTIPLE` may be specified if the programs accepts a variable number of parameters - but it only can be given for the last parameter in the command line description. If you use this flag, you will probably need to use wxCmdLineEntryDesc::GetParamCount() to retrieve the number of parameters effectively specified after calling wxCmdLineEntryDesc::Parse().

`wxCMD_LINE_NEEDS_SEPARATOR` can be specified to require a separator (either a colon, an equal sign or white space) between the option name and its value. By default, no separator is required.

`wxCMD_LINE_SWITCH_NEGATABLE` can be specified if you want to allow the user to specify the switch in both normal form and in negated one (e.g. /R-). You will need to use wxCmdLineParser::FoundSwitch() to distinguish between the normal and negated forms of the switch. This flag is new since wxWidgets 2.9.2.

Enumerator

wxCMD_LINE_OPTION_MANDATORY This option must be given.

wxCMD_LINE_PARAM_OPTIONAL The parameter may be omitted.

wxCMD_LINE_PARAM_MULTIPLE The parameter may be repeated.

wxCMD_LINE_OPTION_HELP This option is a help request.

wxCMD_LINE_NEEDS_SEPARATOR Must have a separator before the value.

wxCMD_LINE_SWITCH_NEGATABLE This switch can be negated (e.g. /S-)

enum wxCmdLineEntryType

The type of a command line entity used for wxCmdLineEntryDesc::kind.

Enumerator

wxCMD_LINE_SWITCH A boolean argument of the program; e.g. `-v` to enable verbose mode.

wxCMD_LINE_OPTION An argument with an associated value; e.g. `"-o filename"` to specify an optional output filename.

wxCMD_LINE_PARAM A parameter: a required program argument.

wxCMD_LINE_USAGE_TEXT Additional usage text. See wxCmdLineParser::AddUsageText.

wxCMD_LINE_NONE Use this to terminate the list.

enum wxCmdLineParamType

The possible values of wxCmdLineEntryDesc::type which specify the type of the value accepted by an option.

Enumerator

wxCMD_LINE_VAL_STRING

wxCMD_LINE_VAL_NUMBER

wxCMD_LINE_VAL_DATE

wxCMD_LINE_VAL_DOUBLE

wxCMD_LINE_VAL_NONE

enum wxCmdLineSplitType

Flags determining wxCmdLineParser::ConvertStringToArgs() behaviour.

Enumerator

wxCMD_LINE_SPLIT_DOS

wxCMD_LINE_SPLIT_UNIX

enum wxCmdLineSwitchState

The state of a switch as returned by wxCmdLineParser::FoundSwitch().

Since

2.9.2

Enumerator

wxCMD_SWITCH_OFF The switch was found in negated form, i.e. followed by a '-'.

wxCMD_SWITCH_ON The switch was not found at all on the command line. The switch was found (and was not negated)

22.215 interface/wx/cmdproc.h File Reference

Classes

- class wxCommand

  wxCommand is a base class for modelling an application command, which is an action usually performed by selecting a menu item, pressing a toolbar button or any other means provided by the application to change the data or view.

- class wxCommandProcessor

  wxCommandProcessor is a class that maintains a history of wxCommands, with undo/redo functionality built-in.

22.216 interface/wx/cmndata.h File Reference

Classes

- class wxPageSetupDialogData

  This class holds a variety of information related to wxPageSetupDialog.

- class wxPrintData

  This class holds a variety of information related to printers and printer device contexts.

- class wxPrintDialogData

  This class holds information related to the visual characteristics of wxPrintDialog.

Enumerations

- enum wxPrintBin {
  wxPRINTBIN_DEFAULT,

Classes

- class wxColourDialog

  This class represents the colour chooser dialog.

Functions

- wxColour wxGetColourFromUser (wxWindow *parent, const wxColour &colInit, const wxString &caption=wxEmptyString, wxColourData *data=NULL)

  Shows the colour selection dialog and returns the colour selected by user or invalid colour (use wxColour::IsOk() to test whether a colour is valid) if the dialog was cancelled.

22.219 interface/wx/colour.h File Reference

Classes

- class wxColour

  A colour is an object representing a combination of Red, Green, and Blue (RGB) intensity values, and is used to determine drawing colours.

Enumerations

- enum {
  wxC2S_NAME = 1,
  wxC2S_CSS_SYNTAX = 2,
  wxC2S_HTML_SYNTAX = 4 }

  Flags for wxColour -> wxString conversion (see wxColour::GetAsString).

Functions

- bool wxFromString (const wxString &string, wxColour *colour)

  Converts string to a wxColour best represented by the given string.
- wxString wxToString (const wxColour &colour)

  Converts the given wxColour into a string.

Variables

- const unsigned char wxALPHA_TRANSPARENT = 0
- const unsigned char wxALPHA_OPAQUE = 0xff

Predefined colors.

- wxColour wxNullColour
- wxColour wxTransparentColour
- wxColour * wxBLACK
- wxColour * wxBLUE
- wxColour * wxCYAN
- wxColour * wxGREEN
- wxColour * wxYELLOW
- wxColour * wxLIGHT_GREY

Classes

- class wxColourData

  This class holds a variety of information related to colour dialogs.

22.221 interface/wx/combo.h File Reference

Classes

- class wxComboPopup

  In order to use a custom popup with wxComboCtrl, an interface class must be derived from wxComboPopup.
- struct wxComboCtrlFeatures

  Features enabled for wxComboCtrl.
- class wxComboCtrl

  A combo control is a generic combobox that allows totally custom popup.

Enumerations

- enum {
  wxCC_SPECIAL_DCLICK = 0x0100,
  wxCC_STD_BUTTON = 0x0200 }

22.221.1 Enumeration Type Documentation

anonymous enum

Enumerator

wxCC_SPECIAL_DCLICK

wxCC_STD_BUTTON

22.222 interface/wx/combobox.h File Reference

Classes

- class wxComboBox

  A combobox is like a combination of an edit control and a listbox.

22.223 interface/wx/commandlinkbutton.h File Reference

Classes

- class wxCommandLinkButton

  Objects of this class are similar in appearance to the normal wxButtons but are similar to the links in a web page in functionality.

22.224 interface/wx/containr.h File Reference

Classes

- class wxNavigationEnabled< W >

  A helper class implementing TAB navigation among the window children.

22.225 interface/wx/control.h File Reference

Classes

- class wxControl

  This is the base class for a control or "widget".

Enumerations

- enum wxEllipsizeFlags {
  wxELLIPSIZE_FLAGS_NONE = 0,
  wxELLIPSIZE_FLAGS_PROCESS_MNEMONICS = 1,
  wxELLIPSIZE_FLAGS_EXPAND_TABS = 2,
  wxELLIPSIZE_FLAGS_DEFAULT }

  Flags used by wxControl::Ellipsize function.
- enum wxEllipsizeMode {
  wxELLIPSIZE_NONE,
  wxELLIPSIZE_START,
  wxELLIPSIZE_MIDDLE,
  wxELLIPSIZE_END }

  The different ellipsization modes supported by the wxControl::Ellipsize function.

22.225.1 Enumeration Type Documentation

enum wxEllipsizeFlags

Flags used by wxControl::Ellipsize function.

Enumerator

wxELLIPSIZE_FLAGS_NONE No special flags.

wxELLIPSIZE_FLAGS_PROCESS_MNEMONICS Take mnemonics into account when calculating the text width. With this flag when calculating the size of the passed string, mnemonics characters (see wxControl::SetLabel) will be automatically reduced to a single character. This leads to correct calculations only if the string passed to Ellipsize() will be used with wxControl::SetLabel. If you don't want ampersand to be interpreted as mnemonics (e.g. because you use wxControl::SetLabelText) then don't use this flag.

wxELLIPSIZE_FLAGS_EXPAND_TABS Expand tabs in spaces when calculating the text width. This flag tells wxControl::Ellipsize() to calculate the width of tab characters `'\t'` as 6 spaces.

wxELLIPSIZE_FLAGS_DEFAULT The default flags for wxControl::Ellipsize.

enum wxEllipsizeMode

The different ellipsization modes supported by the wxControl::Ellipsize function.

Enumerator

wxELLIPSIZE_NONE Don't ellipsize the text at all.

Since

2.9.1

wxELLIPSIZE_START Put the ellipsis at the start of the string, if the string needs ellipsization.

wxELLIPSIZE_MIDDLE Put the ellipsis in the middle of the string, if the string needs ellipsization.

wxELLIPSIZE_END Put the ellipsis at the end of the string, if the string needs ellipsization.

22.226 interface/wx/ribbon/control.h File Reference

Classes

- class wxRibbonControl

  wxRibbonControl serves as a base class for all controls which share the ribbon characteristics of having a ribbon art provider, and (optionally) non-continuous resizing.

22.227 interface/wx/convauto.h File Reference

Classes

- class wxConvAuto

  This class implements a Unicode to/from multibyte converter capable of automatically recognizing the encoding of the multibyte text on input.

Enumerations

- enum wxBOM {
  wxBOM_Unknown = -1,
  wxBOM_None,
  wxBOM_UTF32BE,
  wxBOM_UTF32LE,
  wxBOM_UTF16BE,
  wxBOM_UTF16LE,
  wxBOM_UTF8 }

  Constants representing various BOM types.

22.227.1 Enumeration Type Documentation

enum wxBOM

Constants representing various BOM types.

BOM is an abbreviation for "Byte Order Mark", a special Unicode character which may be inserted into the beginning of a text stream to indicate its encoding.

Since

2.9.3

Enumerator

wxBOM_Unknown Unknown BOM. This is returned if BOM presence couldn't be determined and normally happens because not enough bytes of input have been analysed.

wxBOM_None No BOM. The stream doesn't contain BOM character at all.

wxBOM_UTF32BE UTF-32 big endian BOM. The stream is encoded in big endian variant of UTF-32.

wxBOM_UTF32LE UTF-32 little endian BOM. The stream is encoded in little endian variant of UTF-32.

wxBOM_UTF16BE UTF-16 big endian BOM. The stream is encoded in big endian variant of UTF-16.

wxBOM_UTF16LE UTF-16 little endian BOM. The stream is encoded in little endian variant of UTF-16.

wxBOM_UTF8 UTF-8 BOM. The stream is encoded in UTF-8.

Notice that contrary to a popular belief, it's perfectly possible and, n fact, common under Microsoft Windows systems, to have a BOM in an UTF-8 stream: while it's not used to indicate the endianness of UTF-8 stream (as it's byte-oriented), the BOM can still be useful just as an unambiguous indicator of UTF-8 being used.

22.228 interface/wx/cpp.h File Reference

Macros

- #define wxCONCAT(x1, x2)

  This macro returns the concatenation of the arguments passed.
- #define wxCONCAT3(x1, x2, x3)
- #define wxCONCAT4(x1, x2, x3, x4)
- #define wxCONCAT5(x1, x2, x3, x4, x5)
- #define wxSTRINGIZE(x)

  Returns the string representation of the given symbol which can be either a literal or a macro (hence the advantage of using this macro instead of the standard preprocessor # operator which doesn't work with macros).
- #define wxSTRINGIZE_T(x)

  Returns the string representation of the given symbol as either an ASCII or Unicode string, depending on the current build.
- #define __WXFUNCTION__

  This macro expands to the name of the current function if the compiler supports any of ***`__FUNCTION__`****,* ***`__func__`*** *or equivalent variables or macros or to NULL if none of them is available.*

22.229 interface/wx/cshelp.h File Reference

Classes

- class wxHelpProvider

wxHelpProvider is an abstract class used by a program implementing context-sensitive help to show the help text for the given window.

- class wxHelpControllerHelpProvider

  wxHelpControllerHelpProvider is an implementation of wxHelpProvider which supports both context identifiers and plain text help strings.

- class wxContextHelp

  This class changes the cursor to a query and puts the application into a 'context-sensitive help mode'.

- class wxContextHelpButton

  Instances of this class may be used to add a question mark button that when pressed, puts the application into context-help mode.

- class wxSimpleHelpProvider

  wxSimpleHelpProvider is an implementation of wxHelpProvider which supports only plain text help strings, and shows the string associated with the control (if any) in a tooltip.

22.230 interface/wx/ctrlsub.h File Reference

Classes

- class wxItemContainerImmutable

  wxItemContainer defines an interface which is implemented by all controls which have string subitems each of which may be selected.

- class wxItemContainer

  This class is an abstract base class for some wxWidgets controls which contain several items such as wxListBox, wxCheckListBox, wxComboBox or wxChoice.

- class wxControlWithItems

  This is convenience class that derives from both wxControl and wxItemContainer.

22.231 interface/wx/cursor.h File Reference

Classes

- class wxCursor

  A cursor is a small bitmap usually used for denoting where the mouse pointer is, with a picture that might indicate the interpretation of a mouse click.

Variables

Predefined cursors.

Classes

- class wxCustomBackgroundWindow< W >

  A helper class making it possible to use custom background for any window.

22.233 interface/wx/dataobj.h File Reference

Classes

- class wxDataFormat

  A wxDataFormat is an encapsulation of a platform-specific format handle which is used by the system for the clipboard and drag and drop operations.
- class wxDataObject

  A wxDataObject represents data that can be copied to or from the clipboard, or dragged and dropped.
- class wxCustomDataObject

  wxCustomDataObject is a specialization of wxDataObjectSimple for some application-specific data in arbitrary (either custom or one of the standard ones).
- class wxDataObjectComposite

  wxDataObjectComposite is the simplest wxDataObject derivation which may be used to support multiple formats.
- class wxDataObjectSimple

  This is the simplest possible implementation of the wxDataObject class.
- class wxBitmapDataObject

  wxBitmapDataObject is a specialization of wxDataObject for bitmap data.
- class wxURLDataObject

  wxURLDataObject is a wxDataObject containing an URL and can be used e.g.
- class wxTextDataObject

  wxTextDataObject is a specialization of wxDataObjectSimple for text data.
- class wxFileDataObject

  wxFileDataObject is a specialization of wxDataObject for file names.
- class wxHTMLDataObject

  wxHTMLDataObject is used for working with HTML-formatted text.

Variables

- const wxDataFormat wxFormatInvalid

22.233.1 Variable Documentation

const wxDataFormat wxFormatInvalid

22.234 interface/wx/dataview.h File Reference

Classes

- class wxDataViewModel

  wxDataViewModel is the base class for all data model to be displayed by a wxDataViewCtrl.
- class wxDataViewListModel

  Base class with abstract API for wxDataViewIndexListModel and wxDataViewVirtualListModel.
- class wxDataViewIndexListModel

  wxDataViewIndexListModel is a specialized data model which lets you address an item by its position (row) rather than its wxDataViewItem (which you can obtain from this class).
- class wxDataViewVirtualListModel

  wxDataViewVirtualListModel is a specialized data model which lets you address an item by its position (row) rather than its wxDataViewItem and as such offers the exact same interface as wxDataViewIndexListModel.
- class wxDataViewItemAttr

  This class is used to indicate to a wxDataViewCtrl that a certain item (see wxDataViewItem) has extra font attributes for its renderer.
- class wxDataViewItem

  wxDataViewItem is a small opaque class that represents an item in a wxDataViewCtrl in a persistent way, i.e.
- class wxDataViewCtrl

  wxDataViewCtrl is a control to display data either in a tree like fashion or in a tabular form or both.
- class wxDataViewModelNotifier

  A wxDataViewModelNotifier instance is owned by a wxDataViewModel and mirrors its notification interface.
- class wxDataViewRenderer

  This class is used by wxDataViewCtrl to render the individual cells.
- class wxDataViewTextRenderer

  wxDataViewTextRenderer is used for rendering text.
- class wxDataViewIconTextRenderer

  The wxDataViewIconTextRenderer class is used to display text with a small icon next to it as it is typically done in a file manager.
- class wxDataViewProgressRenderer

  This class is used by wxDataViewCtrl to render progress bars.
- class wxDataViewSpinRenderer

  This is a specialized renderer for rendering integer values.
- class wxDataViewToggleRenderer

  This class is used by wxDataViewCtrl to render toggle controls.
- class wxDataViewChoiceRenderer

  A wxDataViewCtrl renderer using wxChoice control and values of strings in it.
- class wxDataViewChoiceByIndexRenderer

  A wxDataViewCtrl renderer using wxChoice control and indexes into it.
- class wxDataViewDateRenderer

  This class is used by wxDataViewCtrl to render calendar controls.
- class wxDataViewCustomRenderer

  You need to derive a new class from wxDataViewCustomRenderer in order to write a new renderer.
- class wxDataViewBitmapRenderer

  This class is used by wxDataViewCtrl to render bitmap controls.
- class wxDataViewColumn

This class represents a column in a wxDataViewCtrl.

- class wxDataViewListCtrl

  This class is a wxDataViewCtrl which internally uses a wxDataViewListStore and forwards most of its API to that class.

- class wxDataViewTreeCtrl

  This class is a wxDataViewCtrl which internally uses a wxDataViewTreeStore and forwards most of its API to that class.

- class wxDataViewListStore

  wxDataViewListStore is a specialised wxDataViewModel for storing a simple table of data.

- class wxDataViewTreeStore

  wxDataViewTreeStore is a specialised wxDataViewModel for storing simple trees very much like wxTreeCtrl does and it offers a similar API.

- class wxDataViewIconText

  wxDataViewIconText is used by wxDataViewIconTextRenderer for data transfer.

- class wxDataViewEvent

  This is the event class for the wxDataViewCtrl notifications.

Macros

- #define wxDVC_DEFAULT_RENDERER_SIZE 20
- #define wxDVC_DEFAULT_WIDTH 80
- #define wxDVC_TOGGLE_DEFAULT_WIDTH 30
- #define wxDVC_DEFAULT_MINWIDTH 30
- #define wxDVR_DEFAULT_ALIGNMENT -1
- #define wxDV_SINGLE 0x0000
- #define wxDV_MULTIPLE 0x0001
- #define wxDV_NO_HEADER 0x0002
- #define wxDV_HORIZ_RULES 0x0004
- #define wxDV_VERT_RULES 0x0008
- #define wxDV_ROW_LINES 0x0010
- #define wxDV_VARIABLE_LINE_HEIGHT 0x0020

Enumerations

- enum wxDataViewCellMode {
  wxDATAVIEW_CELL_INERT,
  wxDATAVIEW_CELL_ACTIVATABLE,
  wxDATAVIEW_CELL_EDITABLE }

  The mode of a data-view cell; see wxDataViewRenderer for more info.

- enum wxDataViewCellRenderState {
  wxDATAVIEW_CELL_SELECTED = 1,
  wxDATAVIEW_CELL_PRELIT = 2,
  wxDATAVIEW_CELL_INSENSITIVE = 4,
  wxDATAVIEW_CELL_FOCUSED = 8 }

  The values of this enum controls how a wxDataViewRenderer should display its contents in a cell.

- enum wxDataViewColumnFlags {
  wxDATAVIEW_COL_RESIZABLE = 1,
  wxDATAVIEW_COL_SORTABLE = 2,
  wxDATAVIEW_COL_REORDERABLE = 4,
  wxDATAVIEW_COL_HIDDEN = 8 }

  The flags used by wxDataViewColumn.

#define wxDVC_DEFAULT_WIDTH 80

#define wxDVC_TOGGLE_DEFAULT_WIDTH 30

#define wxDVR_DEFAULT_ALIGNMENT -1

22.234.2 Enumeration Type Documentation

enum wxDataViewCellMode

The mode of a data-view cell; see wxDataViewRenderer for more info.

Enumerator

wxDATAVIEW_CELL_INERT The cell only displays information and cannot be manipulated or otherwise interacted with in any way. Note that this doesn't mean that the row being drawn can't be selected, just that a particular element of it cannot be individually modified.

wxDATAVIEW_CELL_ACTIVATABLE Indicates that the cell can be *activated* by clicking it or using keyboard. Activating a cell is an alternative to showing inline editor when the value can be edited in a simple way that doesn't warrant full editor control. The most typical use of cell activation is toggling the checkbox in wxDataViewToggleRenderer; others would be e.g. an embedded volume slider or a five-star rating column.

The exact means of activating a cell are platform-dependent, but they are usually similar to those used for inline editing of values. Typically, a cell would be activated by Space or Enter keys or by left mouse click.

Note

Do not confuse this with item activation in wxDataViewCtrl and the wxEVT_DATAVIEW_ITEM_↩ ACTIVATED event. That one is used for activating the item (or, to put it differently, the entire row) similarly to analogous messages in wxTreeCtrl and wxListCtrl, and the effect differs (play a song, open a file etc.). Cell activation, on the other hand, is all about interacting with the individual cell.

See also

wxDataViewCustomRenderer::ActivateCell()

wxDATAVIEW_CELL_EDITABLE Indicates that the user can edit the data in-place in an inline editor control that will show up when the user wants to edit the cell. A typical example of this behaviour is changing the filename in a file managers.

Editing is typically triggered by slowly double-clicking the cell or by a platform-dependent keyboard shortcut (F2 is typical on Windows, Space and/or Enter is common elsewhere and supported on Windows too).

See also

wxDataViewCustomRenderer::CreateEditorCtrl()

enum wxDataViewCellRenderState

The values of this enum controls how a wxDataViewRenderer should display its contents in a cell.

Enumerator

wxDATAVIEW_CELL_SELECTED

wxDATAVIEW_CELL_PRELIT

wxDATAVIEW_CELL_INSENSITIVE

wxDATAVIEW_CELL_FOCUSED

Classes

- class wxDatePickerCtrl

  This control allows the user to select a date.

Enumerations

- enum {
  wxDP_DEFAULT = 0,
  wxDP_SPIN = 1,
  wxDP_DROPDOWN = 2,
  wxDP_SHOWCENTURY = 4,
  wxDP_ALLOWNONE = 8 }

wxDatePickerCtrl styles

22.235.1 Enumeration Type Documentation

anonymous enum

wxDatePickerCtrl styles

Enumerator

wxDP_DEFAULT default style on this platform, either wxDP_SPIN or wxDP_DROPDOWN

wxDP_SPIN a spin control-like date picker (not supported in generic version)

wxDP_DROPDOWN a combobox-like date picker (not supported in mac version)

wxDP_SHOWCENTURY always show century in the default date display (otherwise it depends on the system date format which may include the century or not)

wxDP_ALLOWNONE allow not having any valid date in the control (by default it always has some date, today initially if no valid date specified in ctor)

22.236 interface/wx/dateevt.h File Reference

Classes

- class wxDateEvent

  This event class holds information about a date change and is used together with wxDatePickerCtrl.

Variables

- wxEventType wxEVT_DATE_CHANGED
- wxEventType wxEVT_TIME_CHANGED

22.236.1 Variable Documentation

wxEventType wxEVT_DATE_CHANGED

wxEventType wxEVT_TIME_CHANGED

22.237 interface/wx/datstrm.h File Reference

Classes

- class wxDataOutputStream

  This class provides functions that write binary data types in a portable way.
- class wxDataInputStream

  This class provides functions that read binary data types in a portable way.

22.238 interface/wx/dcbuffer.h File Reference

Classes

- class wxBufferedDC

This class provides a simple way to avoid flicker: when drawing on it, everything is in fact first drawn on an in-memory buffer (a wxBitmap) and then copied to the screen, using the associated wxDC, only once, when this object is destroyed.

- class wxAutoBufferedPaintDC

  This wxDC derivative can be used inside of an `EVT_PAINT()` event handler to achieve double-buffered drawing.

- class wxBufferedPaintDC

  This is a subclass of wxBufferedDC which can be used inside of an `EVT_PAINT()` event handler to achieve double-buffered drawing.

Macros

- #define wxBUFFER_VIRTUAL_AREA 0x01
- #define wxBUFFER_CLIENT_AREA 0x02
- #define wxBUFFER_USES_SHARED_BUFFER 0x04

Functions

- wxDC * wxAutoBufferedPaintDCFactory (wxWindow *window)

  Check if the window is natively double buffered and will return a wxPaintDC if it is, a wxBufferedPaintDC otherwise.

22.238.1 Macro Definition Documentation

#define wxBUFFER_CLIENT_AREA 0x02

#define wxBUFFER_USES_SHARED_BUFFER 0x04

#define wxBUFFER_VIRTUAL_AREA 0x01

22.238.2 Function Documentation

wxDC* wxAutoBufferedPaintDCFactory (wxWindow * *window*)

Check if the window is natively double buffered and will return a wxPaintDC if it is, a wxBufferedPaintDC otherwise.

It is the caller's responsibility to delete the wxDC pointer when finished with it.

22.239 interface/wx/dcclient.h File Reference

Classes

- class wxPaintDC

  A wxPaintDC must be constructed if an application wishes to paint on the client area of a window from within an EVT_PAINT() event handler.

- class wxClientDC

  A wxClientDC must be constructed if an application wishes to paint on the client area of a window from outside an EVT_PAINT() handler.

- class wxWindowDC

  A wxWindowDC must be constructed if an application wishes to paint on the whole area of a window (client and decorations).

22.240 interface/wx/dcgraph.h File Reference

Classes

- class wxGCDC

  wxGCDC is a device context that draws on a wxGraphicsContext.

22.241 interface/wx/dcmemory.h File Reference

Classes

- class wxMemoryDC

  A memory device context provides a means to draw graphics onto a bitmap.

22.242 interface/wx/dcmirror.h File Reference

Classes

- class wxMirrorDC

  wxMirrorDC is a simple wrapper class which is always associated with a real wxDC object and either forwards all of its operations to it without changes (no mirroring takes place) or exchanges x and y coordinates which makes it possible to reuse the same code to draw a figure and its mirror – i.e.

22.243 interface/wx/dcprint.h File Reference

Classes

- class wxPrinterDC

  A printer device context is specific to MSW and Mac, and allows access to any printer with a Windows or Macintosh driver.

22.244 interface/wx/dcps.h File Reference

Classes

- class wxPostScriptDC

  This defines the wxWidgets Encapsulated PostScript device context, which can write PostScript files on any platform.

22.245 interface/wx/dcscreen.h File Reference

Classes

- class wxScreenDC

  A wxScreenDC can be used to paint on the screen.

22.246 interface/wx/dcsvg.h File Reference

Classes

- class wxSVGFileDC

  A wxSVGFileDC is a device context onto which graphics and text can be drawn, and the output produced as a vector file, in SVG format.
- class wxSVGBitmapHandler

  Abstract base class for handling bitmaps inside a wxSVGFileDC.
- class wxSVGBitmapEmbedHandler

  Handler embedding bitmaps as base64-encoded PNGs into the SVG.
- class wxSVGBitmapFileHandler

  Handler saving a bitmap to an external file and linking to it from the SVG.

22.247 interface/wx/dde.h File Reference

Classes

- class wxDDEConnection

  A wxDDEConnection object represents the connection between a client and a server.
- class wxDDEClient

  A wxDDEClient object represents the client part of a client-server DDE (Dynamic Data Exchange) conversation.
- class wxDDEServer

  A wxDDEServer object represents the server part of a client-server DDE (Dynamic Data Exchange) conversation.

Functions

- void wxDDECleanUp ()

  Called when wxWidgets exits, to clean up the DDE system.
- void wxDDEInitialize ()

  Initializes the DDE system.

22.248 interface/wx/debug.h File Reference

Macros

- #define wxDEBUG_LEVEL

  Preprocessor symbol defining the level of debug support available.
- #define __WXDEBUG__

  Compatibility macro indicating presence of debug support.
- #define wxASSERT(condition)

  Assert macro.
- #define wxASSERT_LEVEL_2(condition)

  Assert macro for expensive run-time checks.
- #define wxASSERT_LEVEL_2_MSG(condition, msg)

  Assert macro with a custom message for expensive run-time checks.
- #define wxASSERT_MIN_BITSIZE(type, size)

  This macro results in a compile time assertion failure if the size of the given `type` is less than `size` bits.
- #define wxASSERT_MSG(condition, message)

Assert macro with message.

- #define wxASSERT_MSG_AT(condition, message, file, line, func)

  Assert macro pretending to assert at the specified location.

- #define wxCHECK(condition, retValue)

  Checks that the condition is true, returns with the given return value if not (stops execution in debug mode).

- #define wxCHECK_MSG(condition, retValue, message)

  Checks that the condition is true, returns with the given return value if not (stops execution in debug mode).

- #define wxCHECK_RET(condition, message)

  Checks that the condition is true, and returns if not (stops execution with the given error message in debug mode).

- #define wxCHECK2(condition, operation)

  Checks that the condition is true, and if not, it will wxFAIL() and execute the given `operation` if it is not.

- #define wxCHECK2_MSG(condition, operation, message)

  This is the same as wxCHECK2(), but wxFAIL_MSG() with the specified `message` is called instead of wxFAIL() if the `condition` is false.

- #define wxCOMPILE_TIME_ASSERT(condition, message)

  Using wxCOMPILE_TIME_ASSERT() results in a compilation error if the specified `condition` is false.

- #define wxCOMPILE_TIME_ASSERT2(condition, message, name)

  This macro is identical to wxCOMPILE_TIME_ASSERT() except that it allows you to specify a unique `name` for the struct internally defined by this macro to avoid getting the compilation errors described for wxCOMPILE_TIME_AS↩SERT().

- #define wxDISABLE_ASSERTS_IN_RELEASE_BUILD() wxDisableAsserts()

  Use this macro to disable asserts in release build when not using wxIMPLEMENT_APP().

- #define wxFAIL

  Will always generate an assert error if this code is reached (in debug mode).

- #define wxFAIL_MSG(message)

  Will always generate an assert error with specified message if this code is reached (in debug mode).

- #define wxFAIL_MSG_AT(message, file, line, func)

  Assert failure macro pretending to assert at the specified location.

Typedefs

- typedef void(∗ wxAssertHandler_t)(const wxString &file, int line, const wxString &func, const wxString &cond, const wxString &msg)

  Type for the function called in case of assert failure.

Functions

- void wxAbort ()

  Exits the program immediately.

- void wxDisableAsserts ()

  Disable the condition checks in the assertions.

- bool wxIsDebuggerRunning ()

  Returns true if the program is running under debugger, false otherwise.

- wxAssertHandler_t wxSetAssertHandler (wxAssertHandler_t handler)

  Sets the function to be called in case of assertion failure.

- void wxSetDefaultAssertHandler ()

  Reset the assert handler to default function which shows a message box when an assert happens.

- void wxTrap ()

  Generate a debugger exception meaning that the control is passed to the debugger if one is attached to the process.

22.249 interface/wx/debugrpt.h File Reference

Classes

- class wxDebugReportPreview

  This class presents the debug report to the user and allows him to veto report entirely or remove some parts of it.
- class wxDebugReportCompress

  wxDebugReportCompress is a wxDebugReport which compresses all the files in this debug report into a single ZIP file in its wxDebugReport::Process() function.
- class wxDebugReport

  wxDebugReport is used to generate a debug report, containing information about the program current state.
- class wxDebugReportPreviewStd

  wxDebugReportPreviewStd is a standard debug report preview window.
- class wxDebugReportUpload

  This class is used to upload a compressed file using HTTP POST request.

- #define wxSETUP 0x00020000
- #define wxICON_NONE 0x00040000
- #define wxICON_AUTH_NEEDED 0x00080000
- #define wxICON_MASK (wxICON_EXCLAMATION|wxICON_HAND|wxICON_QUESTION|wxICON_INFO↩ RMATION|wxICON_NONE)
- #define wxNOT_FOUND (-1)
- #define wxPRINT_QUALITY_HIGH -1

  Predefined print quality constants.
- #define wxPRINT_QUALITY_MEDIUM -2
- #define wxPRINT_QUALITY_LOW -3
- #define wxPRINT_QUALITY_DRAFT -4
- #define wxSTAY_ON_TOP 0x8000

  Top level window styles common to wxFrame and wxDialog.
- #define wxICONIZE 0x4000
- #define wxMINIMIZE wxICONIZE
- #define wxMAXIMIZE 0x2000
- #define wxCLOSE_BOX 0x1000
- #define wxSYSTEM_MENU 0x0800
- #define wxMINIMIZE_BOX 0x0400
- #define wxMAXIMIZE_BOX 0x0200
- #define wxTINY_CAPTION 0x0080
- #define wxRESIZE_BORDER 0x0040
- #define wxINT32_SWAP_ALWAYS(wxInt32_value)

  This macro will swap the bytes of the value variable from little endian to big endian or vice versa unconditionally, i.e.
- #define wxUINT32_SWAP_ALWAYS(wxUint32_value)
- #define wxINT16_SWAP_ALWAYS(wxInt16_value)
- #define wxUINT16_SWAP_ALWAYS(wxUint16_value)
- #define wxINT32_SWAP_ON_BE(wxInt32_value)

  This macro will swap the bytes of the value variable from little endian to big endian or vice versa if the program is compiled on a big-endian architecture (such as Sun work stations).
- #define wxUINT32_SWAP_ON_BE(wxUint32_value)

- #define wxINT16_SWAP_ON_BE(wxInt16_value)
- #define wxUINT16_SWAP_ON_BE(wxUint16_value)
- #define wxINT32_SWAP_ON_LE(wxInt32_value)

  This macro will swap the bytes of the value variable from little endian to big endian or vice versa if the program is compiled on a little-endian architecture (such as Intel PCs).
- #define wxUINT32_SWAP_ON_LE(wxUint32_value)
- #define wxINT16_SWAP_ON_LE(wxInt16_value)
- #define wxUINT16_SWAP_ON_LE(wxUint16_value)
- #define wxDECLARE_NO_ASSIGN_CLASS(classname)

  This macro can be used in a class declaration to disable the generation of default assignment operator.
- #define wxDECLARE_NO_COPY_CLASS(classname)

  This macro can be used in a class declaration to disable the generation of default copy ctor and assignment operator.
- #define wxDECLARE_NO_COPY_TEMPLATE_CLASS(classname, arg)

  Analog of wxDECLARE_NO_COPY_CLASS() for template classes.
- #define wxDECLARE_NO_COPY_TEMPLATE_CLASS_2(classname, arg1, arg2)

  Analog of wxDECLARE_NO_COPY_TEMPLATE_CLASS() for templates with 2 parameters.
- #define wxDEPRECATED(function)

  Generate deprecation warning with the given message when a function is used.
- #define wxDEPRECATED_BUT_USED_INTERNALLY(function)

  This is a special version of wxDEPRECATED() macro which only does something when the deprecated function is used from the code outside wxWidgets itself but doesn't generate warnings when it is used from wxWidgets.
- #define wxDEPRECATED_INLINE(func, body)

  This macro is similar to wxDEPRECATED() but can be used to not only declare the function function as deprecated but to also provide its (inline) implementation body.
- #define wxDEPRECATED_ACCESSOR(func, what)

  A helper macro allowing to easily define a simple deprecated accessor.
- #define wxDEPRECATED_BUT_USED_INTERNALLY_INLINE(func, body)

  Combination of wxDEPRECATED_BUT_USED_INTERNALLY() and wxDEPRECATED_INLINE().
- #define wxEXPLICIT

  `wxEXPLICIT` is a macro which expands to the C++ `explicit` keyword if the compiler supports it or nothing otherwise.
- #define wxOVERRIDE

  `wxOVERRIDE` expands to the C++11 `override` keyword if it's supported by the compiler or nothing otherwise.
- #define wxSUPPRESS_GCC_PRIVATE_DTOR_WARNING(name)

  GNU C++ compiler gives a warning for any class whose destructor is private unless it has a friend.

- #define wxINT8_MIN CHAR_MIN

  C99-like sized MIN/MAX constants for all integer types.
- #define wxINT8_MAX CHAR_MAX

  C99-like sized MIN/MAX constants for all integer types.
- #define wxUINT8_MAX UCHAR_MAX

  C99-like sized MIN/MAX constants for all integer types.
- #define wxINT16_MIN SHRT_MIN

  C99-like sized MIN/MAX constants for all integer types.
- #define wxINT16_MAX SHRT_MAX

  C99-like sized MIN/MAX constants for all integer types.
- #define wxUINT16_MAX USHRT_MAX

  C99-like sized MIN/MAX constants for all integer types.
- #define wxINT32_MIN INT_MIN-or-LONG_MIN

  C99-like sized MIN/MAX constants for all integer types.
- #define wxINT32_MAX INT_MAX-or-LONG_MAX

  C99-like sized MIN/MAX constants for all integer types.

- #define wxUINT32_MAX UINT_MAX-or-LONG_MAX

  C99-like sized MIN/MAX constants for all integer types.
- #define wxINT64_MIN LLONG_MIN

  C99-like sized MIN/MAX constants for all integer types.
- #define wxINT64_MAX LLONG_MAX

  C99-like sized MIN/MAX constants for all integer types.
- #define wxUINT64_MAX ULLONG_MAX

  C99-like sized MIN/MAX constants for all integer types.

Typedefs

- typedef int wxPrintQuality

  Specifies the print quality as either a predefined level or explicit resolution.
- typedef int wxCoord

  The type for screen and DC coordinates.
- typedef float wxFloat32

  32 bit IEEE float (1 sign, 8 exponent bits, 23 fraction bits).
- typedef double wxFloat64

  64 bit IEEE float (1 sign, 11 exponent bits, 52 fraction bits).
- typedef double wxDouble

  Native fastest representation that has at least wxFloat64 precision, so use the IEEE types for storage, and this for calculations.

- typedef signed char wxInt8

  8 bit type (the mapping is more complex than a simple `typedef` and is not shown here).
- typedef unsigned char wxUint8

  8 bit type (the mapping is more complex than a simple `typedef` and is not shown here).
- typedef wxUint8 wxByte

  8 bit type (the mapping is more complex than a simple `typedef` and is not shown here).

- typedef signed short wxInt16

  16 bit type (the mapping is more complex than a simple `typedef` and is not shown here).
- typedef unsigned short wxUint16

  16 bit type (the mapping is more complex than a simple `typedef` and is not shown here).
- typedef wxUint16 wxWord

  16 bit type (the mapping is more complex than a simple `typedef` and is not shown here).
- typedef wxUint16 wxChar16

  16 bit type (the mapping is more complex than a simple `typedef` and is not shown here).

- typedef int wxInt32

  32 bit type (the mapping is more complex than a simple `typedef` and is not shown here).
- typedef unsigned int wxUint32

  32 bit type (the mapping is more complex than a simple `typedef` and is not shown here).
- typedef wxUint32 wxDword

  32 bit type (the mapping is more complex than a simple `typedef` and is not shown here).
- typedef wxUint32 wxChar32

  32 bit type (the mapping is more complex than a simple `typedef` and is not shown here).

- typedef wxLongLong_t wxInt64

  64 bit type (the mapping is more complex than a simple `typedef` and is not shown here).
- typedef wxULongLong_t wxUint64

64 bit type (the mapping is more complex than a simple `typedef` and is not shown here).

- typedef ssize_t wxIntPtr

  Signed and unsigned integral types big enough to contain all of `long`, `size_t` and `void*`.

- typedef size_t wxUIntPtr

  Signed and unsigned integral types big enough to contain all of `long`, `size_t` and `void*`.

Enumerations

- enum wxGeometryCentre {
  wxCENTRE = 0x0001,
  wxCENTER = wxCENTRE }

  Generic flags.

- enum wxOrientation {
  wxHORIZONTAL = 0x0004,
  wxVERTICAL = 0x0008,
  wxBOTH = wxVERTICAL | wxHORIZONTAL,
  wxORIENTATION_MASK = wxBOTH }

  A generic orientation value.

- enum wxDirection {
  wxLEFT = 0x0010,
  wxRIGHT = 0x0020,
  wxUP = 0x0040,
  wxDOWN = 0x0080,
  wxTOP = wxUP,
  wxBOTTOM = wxDOWN,
  wxNORTH = wxUP,
  wxSOUTH = wxDOWN,
  wxWEST = wxLEFT,
  wxEAST = wxRIGHT,
  wxALL = (wxUP | wxDOWN | wxRIGHT | wxLEFT),
  wxDIRECTION_MASK = wxALL }

  A generic direction value.

- enum wxAlignment {
  wxALIGN_INVALID = -1,
  wxALIGN_NOT = 0x0000,
  wxALIGN_CENTER_HORIZONTAL = 0x0100,
  wxALIGN_CENTRE_HORIZONTAL = wxALIGN_CENTER_HORIZONTAL,
  wxALIGN_LEFT = wxALIGN_NOT,
  wxALIGN_TOP = wxALIGN_NOT,
  wxALIGN_RIGHT = 0x0200,
  wxALIGN_BOTTOM = 0x0400,
  wxALIGN_CENTER_VERTICAL = 0x0800,
  wxALIGN_CENTRE_VERTICAL = wxALIGN_CENTER_VERTICAL,
  wxALIGN_CENTER = (wxALIGN_CENTER_HORIZONTAL | wxALIGN_CENTER_VERTICAL),
  wxALIGN_CENTRE = wxALIGN_CENTER,
  wxALIGN_MASK = 0x0f00 }

  Generic alignment values.

- enum wxSizerFlagBits {
  wxFIXED_MINSIZE = 0x8000,
  wxRESERVE_SPACE_EVEN_IF_HIDDEN = 0x0002,
  wxSIZER_FLAG_BITS_MASK = 0x8002 }

  Miscellaneous flags for wxSizer items.

- enum wxStretch {
  wxSTRETCH_NOT = 0x0000,
  wxSHRINK = 0x1000,
  wxGROW = 0x2000,
  wxEXPAND = wxGROW,
  wxSHAPED = 0x4000,
  wxTILE = wxSHAPED | wxFIXED_MINSIZE,
  wxSTRETCH_MASK = 0x7000 }

  Generic stretch values.

- enum wxBorder {
  wxBORDER_DEFAULT = 0,
  wxBORDER_NONE = 0x00200000,
  wxBORDER_STATIC = 0x01000000,
  wxBORDER_SIMPLE = 0x02000000,
  wxBORDER_RAISED = 0x04000000,
  wxBORDER_SUNKEN = 0x08000000,
  wxBORDER_DOUBLE = 0x10000000,
  wxBORDER_THEME = wxBORDER_DOUBLE,
  wxBORDER_MASK = 0x1f200000 }

  Border flags for wxWindow.

- enum wxBackgroundStyle {
  wxBG_STYLE_ERASE,
  wxBG_STYLE_SYSTEM,
  wxBG_STYLE_PAINT,
  wxBG_STYLE_COLOUR,
  wxBG_STYLE_TRANSPARENT }

  Background styles.

- enum wxStandardID {
  wxID_AUTO_LOWEST,
  wxID_AUTO_HIGHEST,
  wxID_NONE = -3,
  wxID_SEPARATOR = -2,
  wxID_ANY = -1,
  wxID_LOWEST = 4999,
  wxID_OPEN,
  wxID_CLOSE,
  wxID_NEW,
  wxID_SAVE,
  wxID_SAVEAS,
  wxID_REVERT,
  wxID_EXIT,
  wxID_UNDO,
  wxID_REDO,
  wxID_HELP,
  wxID_PRINT,
  wxID_PRINT_SETUP,
  wxID_PAGE_SETUP,
  wxID_PREVIEW,
  wxID_ABOUT,
  wxID_HELP_CONTENTS,
  wxID_HELP_INDEX,
  wxID_HELP_SEARCH,
  wxID_HELP_COMMANDS,
  wxID_HELP_PROCEDURES,
  wxID_HELP_CONTEXT,
  wxID_CLOSE_ALL,
  wxID_PREFERENCES,
  wxID_EDIT = 5030,
  wxID_CUT,
  wxID_COPY,
  wxID_PASTE,
  wxID_CLEAR,
  wxID_FIND,
  wxID_DUPLICATE,
  wxID_SELECTALL,
  wxID_DELETE,
  wxID_REPLACE,
  wxID_REPLACE_ALL,
  wxID_PROPERTIES,
  wxID_VIEW_DETAILS,
  wxID_VIEW_LARGEICONS,
  wxID_VIEW_SMALLICONS,
  wxID_VIEW_LIST,
  wxID_VIEW_SORTDATE,
  wxID_VIEW_SORTNAME,
  wxID_VIEW_SORTSIZE,
  wxID_VIEW_SORTTYPE,
  wxID_FILE = 5050,
  wxID_FILE1,
  wxID_FILE2,
  wxID_FILE3,
  wxID_FILE4,
  wxID_FILE5,
  wxID_FILE6,
  wxID_FILE7,
  wxID_FILE8,
  wxID_FILE9,
  wxID_OK = 5100,
  wxID_CANCEL,
  wxID_APPLY,
  wxID_YES,

Standard IDs.

- enum wxItemKind {
  wxITEM_SEPARATOR = -1,
  wxITEM_NORMAL,
  wxITEM_CHECK,
  wxITEM_RADIO,
  wxITEM_DROPDOWN,
  wxITEM_MAX }

Item kinds for use with wxMenu, wxMenuItem, and wxToolBar.

- enum wxHitTest {
  wxHT_NOWHERE,
  wxHT_SCROLLBAR_FIRST = wxHT_NOWHERE,
  wxHT_SCROLLBAR_ARROW_LINE_1,
  wxHT_SCROLLBAR_ARROW_LINE_2,
  wxHT_SCROLLBAR_ARROW_PAGE_1,
  wxHT_SCROLLBAR_ARROW_PAGE_2,
  wxHT_SCROLLBAR_THUMB,
  wxHT_SCROLLBAR_BAR_1,
  wxHT_SCROLLBAR_BAR_2,
  wxHT_SCROLLBAR_LAST,
  wxHT_WINDOW_OUTSIDE,
  wxHT_WINDOW_INSIDE,
  wxHT_WINDOW_VERT_SCROLLBAR,
  wxHT_WINDOW_HORZ_SCROLLBAR,
  wxHT_WINDOW_CORNER,
  wxHT_MAX }

Generic hit test results.

- enum wxDataFormatId {
  wxDF_INVALID = 0,
  wxDF_TEXT = 1,
  wxDF_BITMAP = 2,
  wxDF_METAFILE = 3,
  wxDF_SYLK = 4,
  wxDF_DIF = 5,
  wxDF_TIFF = 6,
  wxDF_OEMTEXT = 7,
  wxDF_DIB = 8,
  wxDF_PALETTE = 9,
  wxDF_PENDATA = 10,
  wxDF_RIFF = 11,
  wxDF_WAVE = 12,
  wxDF_UNICODETEXT = 13,
  wxDF_ENHMETAFILE = 14,
  wxDF_FILENAME = 15,
  wxDF_LOCALE = 16,
  wxDF_PRIVATE = 20,
  wxDF_HTML = 30,
  wxDF_MAX }

Data format IDs used by wxDataFormat.

- enum wxKeyCode {
  WXK_NONE = 0,
  WXK_CONTROL_A = 1,
  WXK_CONTROL_B,
  WXK_CONTROL_C,
  WXK_CONTROL_D,
  WXK_CONTROL_E,
  WXK_CONTROL_F,
  WXK_CONTROL_G,
  WXK_CONTROL_H,
  WXK_CONTROL_I,
  WXK_CONTROL_J,
  WXK_CONTROL_K,
  WXK_CONTROL_L,
  WXK_CONTROL_M,
  WXK_CONTROL_N,
  WXK_CONTROL_O,
  WXK_CONTROL_P,
  WXK_CONTROL_Q,
  WXK_CONTROL_R,
  WXK_CONTROL_S,
  WXK_CONTROL_T,
  WXK_CONTROL_U,
  WXK_CONTROL_V,
  WXK_CONTROL_W,
  WXK_CONTROL_X,
  WXK_CONTROL_Y,
  WXK_CONTROL_Z,

  WXK_RETURN = 13,
  WXK_ESCAPE = 27,
  WXK_SPACE = 32,
  WXK_DELETE = 127,
  WXK_START = 300,
  WXK_LBUTTON,
  WXK_RBUTTON,
  WXK_CANCEL,
  WXK_MBUTTON,
  WXK_CLEAR,
  WXK_SHIFT,
  WXK_ALT,
  WXK_CONTROL,
  WXK_RAW_CONTROL,
  WXK_MENU,
  WXK_PAUSE,
  WXK_CAPITAL,
  WXK_END,
  WXK_HOME,
  WXK_LEFT,
  WXK_UP,
  WXK_RIGHT,
  WXK_DOWN,
  WXK_SELECT,
  WXK_PRINT,
  WXK_EXECUTE,
  WXK_SNAPSHOT,
  WXK_INSERT,
  WXK_HELP,
  WXK_NUMPAD0,
  WXK_NUMPAD1,
  WXK_NUMPAD2,
  WXK_NUMPAD3,
  WXK_NUMPAD4,
  WXK_NUMPAD5,

Virtual keycodes used by wxKeyEvent and some other wxWidgets functions.

- enum wxKeyModifier {
  wxMOD_NONE = 0x0000,
  wxMOD_ALT = 0x0001,
  wxMOD_CONTROL = 0x0002,
  wxMOD_ALTGR = wxMOD_ALT | wxMOD_CONTROL,
  wxMOD_SHIFT = 0x0004,
  wxMOD_META = 0x0008,
  wxMOD_WIN = wxMOD_META,
  wxMOD_RAW_CONTROL,
  wxMOD_CMD = wxMOD_CONTROL,
  wxMOD_ALL = 0xffff }

This enum contains bit mask constants used in wxKeyEvent.

- enum wxPaperSize {
  wxPAPER_10X11,
  wxPAPER_10X14,
  wxPAPER_11X17,
  wxPAPER_12X11,
  wxPAPER_15X11,
  wxPAPER_9X11,
  wxPAPER_A2,
  wxPAPER_A3,
  wxPAPER_A3_EXTRA,
  wxPAPER_A3_EXTRA_TRANSVERSE,
  wxPAPER_A3_ROTATED,

  wxPAPER_A5,
  wxPAPER_A5_EXTRA,
  wxPAPER_A5_ROTATED,
  wxPAPER_A5_TRANSVERSE,
  wxPAPER_A6,
  wxPAPER_A6_ROTATED,
  wxPAPER_A_PLUS,
  wxPAPER_B4,
  wxPAPER_B4_JIS_ROTATED,
  wxPAPER_B5,
  wxPAPER_B5_EXTRA,
  wxPAPER_B5_JIS_ROTATED,
  wxPAPER_B5_TRANSVERSE,
  wxPAPER_B6_JIS,
  wxPAPER_B6_JIS_ROTATED,
  wxPAPER_B_PLUS,
  wxPAPER_CSHEET,
  wxPAPER_DBL_JAPANESE_POSTCARD,
  wxPAPER_DBL_JAPANESE_POSTCARD_ROTATED,
  wxPAPER_DSHEET,
  wxPAPER_ENV_10,
  wxPAPER_ENV_11,
  wxPAPER_ENV_12,
  wxPAPER_ENV_14,
  wxPAPER_ENV_9,
  wxPAPER_ENV_B4,
  wxPAPER_ENV_B5,
  wxPAPER_ENV_B6,
  wxPAPER_ENV_C3,
  wxPAPER_ENV_C4,
  wxPAPER_ENV_C5,
  wxPAPER_ENV_C6,
  wxPAPER_ENV_C65,
  wxPAPER_ENV_DL,
  wxPAPER_ENV_INVITE,
  wxPAPER_ENV_ITALY,
  wxPAPER_ENV_MONARCH,
  wxPAPER_ENV_PERSONAL,
  wxPAPER_ESHEET,
  wxPAPER_EXECUTIVE,
  wxPAPER_FANFOLD_LGL_GERMAN,
  wxPAPER_FANFOLD_STD_GERMAN,
  wxPAPER_FANFOLD_US,
  wxPAPER_FOLIO,
  wxPAPER_ISO_B4,
  wxPAPER_JAPANESE_POSTCARD,

Paper size types for use with the printing framework.

- enum wxPrintOrientation {
  wxPORTRAIT,
  wxLANDSCAPE }

  Printing orientation.
- enum wxDuplexMode {
  wxDUPLEX_SIMPLEX,
  wxDUPLEX_HORIZONTAL,
  wxDUPLEX_VERTICAL }

  Duplex printing modes.
- enum wxPrintMode {
  wxPRINT_MODE_NONE = 0,
  wxPRINT_MODE_PREVIEW = 1,
  wxPRINT_MODE_FILE = 2,
  wxPRINT_MODE_PRINTER = 3,
  wxPRINT_MODE_STREAM = 4 }

  Print mode (currently PostScript only).
- enum wxUpdateUI {
  wxUPDATE_UI_NONE,
  wxUPDATE_UI_RECURSE,
  wxUPDATE_UI_FROMIDLE }

  Flags which can be used in wxWindow::UpdateWindowUI().

Functions

- template<typename T >
  wxDELETE (T *&ptr)

  A function which deletes and nulls the pointer.
- template<typename T >
  wxDELETEA (T *&array)

  A function which deletes and nulls the pointer.
- template<typename T >
  wxSwap (T &first, T &second)

  Swaps the contents of two variables.
- void wxVaCopy (va_list argptrDst, va_list argptrSrc)

  This macro is the same as the standard C99 `va_copy` for the compilers which support it or its replacement for those that don't.

Variables

- wxCoord wxDefaultCoord = -1

  A special value meaning "use default coordinate".

#define wxINT16_MAX SHRT_MAX

C99-like sized MIN/MAX constants for all integer types.

For each `n` in the set 8, 16, 32, 64 we define `wxINTn_MIN`, `wxINTn_MAX` and `wxUINTc_MAX` (`wxUINTc_MIN` is always 0 and so is not defined).

#define wxINT16_MIN SHRT_MIN

C99-like sized MIN/MAX constants for all integer types.

For each `n` in the set 8, 16, 32, 64 we define `wxINTn_MIN`, `wxINTn_MAX` and `wxUINTc_MAX` (`wxUINTc_MIN` is always 0 and so is not defined).

#define wxINT32_MAX INT_MAX-or-LONG_MAX

C99-like sized MIN/MAX constants for all integer types.

For each `n` in the set 8, 16, 32, 64 we define `wxINTn_MIN`, `wxINTn_MAX` and `wxUINTc_MAX` (`wxUINTc_MIN` is always 0 and so is not defined).

#define wxINT32_MIN INT_MIN-or-LONG_MIN

C99-like sized MIN/MAX constants for all integer types.

For each `n` in the set 8, 16, 32, 64 we define `wxINTn_MIN`, `wxINTn_MAX` and `wxUINTc_MAX` (`wxUINTc_MIN` is always 0 and so is not defined).

#define wxINT64_MAX LLONG_MAX

C99-like sized MIN/MAX constants for all integer types.

For each `n` in the set 8, 16, 32, 64 we define `wxINTn_MIN`, `wxINTn_MAX` and `wxUINTc_MAX` (`wxUINTc_MIN` is always 0 and so is not defined).

#define wxINT64_MIN LLONG_MIN

C99-like sized MIN/MAX constants for all integer types.

For each n in the set 8, 16, 32, 64 we define wxINTn_MIN, wxINTn_MAX and wxUINTc_MAX (wxUINTc_MIN is always 0 and so is not defined).

#define wxINT8_MAX CHAR_MAX

C99-like sized MIN/MAX constants for all integer types.

For each n in the set 8, 16, 32, 64 we define wxINTn_MIN, wxINTn_MAX and wxUINTc_MAX (wxUINTc_MIN is always 0 and so is not defined).

#define wxINT8_MIN CHAR_MIN

C99-like sized MIN/MAX constants for all integer types.

For each n in the set 8, 16, 32, 64 we define wxINTn_MIN, wxINTn_MAX and wxUINTc_MAX (wxUINTc_MIN is always 0 and so is not defined).

22.250.2 Typedef Documentation

typedef wxUint8 wxByte

8 bit type (the mapping is more complex than a simple `typedef` and is not shown here).

typedef wxUint16 wxChar16

16 bit type (the mapping is more complex than a simple `typedef` and is not shown here).

typedef wxUint32 wxChar32

32 bit type (the mapping is more complex than a simple `typedef` and is not shown here).

typedef int wxCoord

The type for screen and DC coordinates.

typedef double wxDouble

Native fastest representation that has at least wxFloat64 precision, so use the IEEE types for storage, and this for calculations.

(The mapping is more complex than a simple `typedef` and is not shown here).

typedef wxUint32 wxDword

32 bit type (the mapping is more complex than a simple `typedef` and is not shown here).

typedef float wxFloat32

32 bit IEEE float (1 sign, 8 exponent bits, 23 fraction bits).

(The mapping is more complex than a simple `typedef` and is not shown here).

typedef double wxFloat64

64 bit IEEE float (1 sign, 11 exponent bits, 52 fraction bits).

(The mapping is more complex than a simple `typedef` and is not shown here).

typedef signed short wxInt16

16 bit type (the mapping is more complex than a simple `typedef` and is not shown here).

typedef int wxInt32

32 bit type (the mapping is more complex than a simple `typedef` and is not shown here).

typedef wxLongLong_t wxInt64

64 bit type (the mapping is more complex than a simple `typedef` and is not shown here).

typedef signed char wxInt8

8 bit type (the mapping is more complex than a simple `typedef` and is not shown here).

typedef ssize_t wxIntPtr

Signed and unsigned integral types big enough to contain all of `long`, `size_t` and `void*`.

(The mapping is more complex than a simple `typedef` and is not shown here).

typedef int wxPrintQuality

Specifies the print quality as either a predefined level or explicit resolution.

The print quality may be one of wxPRINT_QUALITY_HIGH, wxPRINT_QUALITY_MEDIUM, wxPRINT_QUALITY_LOW or wxPRINT_QUALITY_DRAFT (which are all negative) or express the desired resolution, in DPI, e.g. 600.

typedef unsigned short wxUint16

16 bit type (the mapping is more complex than a simple `typedef` and is not shown here).

typedef unsigned int wxUint32

32 bit type (the mapping is more complex than a simple `typedef` and is not shown here).

typedef wxULongLong_t wxUint64

64 bit type (the mapping is more complex than a simple `typedef` and is not shown here).

typedef unsigned char wxUint8

8 bit type (the mapping is more complex than a simple `typedef` and is not shown here).

typedef size_t wxUIntPtr

Signed and unsigned integral types big enough to contain all of `long`, `size_t` and `void*`.

(The mapping is more complex than a simple `typedef` and is not shown here).

typedef wxUint16 wxWord

16 bit type (the mapping is more complex than a simple `typedef` and is not shown here).

22.250.3 Enumeration Type Documentation

enum wxAlignment

Generic alignment values.

Can be combined together.

Enumerator

wxALIGN_INVALID A value different from any valid alignment value. Note that you shouldn't use 0 for this as it's the value of (valid) alignments wxALIGN_LEFT and wxALIGN_TOP.

Since

2.9.1

wxALIGN_NOT

wxALIGN_CENTER_HORIZONTAL

wxALIGN_CENTRE_HORIZONTAL

wxALIGN_LEFT

wxALIGN_TOP

wxALIGN_RIGHT

wxALIGN_BOTTOM

wxALIGN_CENTER_VERTICAL

wxALIGN_CENTRE_VERTICAL

wxALIGN_CENTER

wxALIGN_CENTRE

wxALIGN_MASK A mask to extract alignment from the combination of flags.

enum wxBackgroundStyle

Background styles.

See also

wxWindow::SetBackgroundStyle()

Enumerator

wxBG_STYLE_ERASE Default background style value indicating that the background may be erased in the user-defined EVT_ERASE_BACKGROUND handler. If no such handler is defined (or if it skips the event), the effect of this style is the same as wxBG_STYLE_SYSTEM. If an empty handler (*not* skipping the event) is defined, the effect is the same as wxBG_STYLE_PAINT, i.e. the background is not erased at all until EVT_PAINT handler is executed.

This is the only background style value for which erase background events are generated at all.

wxBG_STYLE_SYSTEM Use the default background, as determined by the system or the current theme. If the window has been assigned a non-default background colour, it will be used for erasing its background. Otherwise the default background (which might be a gradient or a pattern) will be used.

EVT_ERASE_BACKGROUND event will not be generated at all for windows with this style.

wxBG_STYLE_PAINT Indicates that the background is only erased in the user-defined EVT_PAINT handler. Using this style avoids flicker which would result from redrawing the background twice if the EVT_PAINT handler entirely overwrites it. It must not be used however if the paint handler leaves any parts of the window unpainted as their contents is then undetermined. Only use it if you repaint the whole window in your handler.

EVT_ERASE_BACKGROUND event will not be generated at all for windows with this style.

wxBG_STYLE_COLOUR

wxBG_STYLE_TRANSPARENT Indicates that the window background is not erased, letting the parent window show through. Currently this style is only supported in wxOSX and wxGTK with compositing available, see wxWindow::IsTransparentBackgroundSupported().

enum wxBorder

Border flags for wxWindow.

Enumerator

wxBORDER_DEFAULT This is different from wxBORDER_NONE as by default the controls do have a border.

wxBORDER_NONE

wxBORDER_STATIC

wxBORDER_SIMPLE

wxBORDER_RAISED

wxBORDER_SUNKEN

wxBORDER_DOUBLE

wxBORDER_THEME

wxBORDER_MASK

enum wxDataFormatId

Data format IDs used by wxDataFormat.

Enumerator

wxDF_INVALID

wxDF_TEXT

wxDF_BITMAP

wxDF_METAFILE

wxDF_SYLK

wxDF_DIF

wxDF_TIFF

wxDF_OEMTEXT

wxDF_DIB

wxDF_PALETTE

wxDF_PENDATA

wxDF_RIFF

wxDF_WAVE

wxDF_UNICODETEXT

wxDF_ENHMETAFILE

wxDF_FILENAME

wxDF_LOCALE

wxDF_PRIVATE

wxDF_HTML

wxDF_MAX

enum wxDirection

A generic direction value.

Enumerator

wxLEFT

wxRIGHT

wxUP

wxDOWN

wxTOP

wxBOTTOM

wxNORTH

wxSOUTH

wxWEST

wxEAST

wxALL

wxDIRECTION_MASK A mask to extract direction from the combination of flags.

enum wxDuplexMode

Duplex printing modes.

Enumerator

wxDUPLEX_SIMPLEX Non-duplex.

wxDUPLEX_HORIZONTAL

wxDUPLEX_VERTICAL

enum wxGeometryCentre

Generic flags.

Enumerator

wxCENTRE

wxCENTER

enum wxHitTest

Generic hit test results.

Enumerator

wxHT_NOWHERE

wxHT_SCROLLBAR_FIRST

wxHT_SCROLLBAR_ARROW_LINE_1 left or upper arrow to scroll by line

wxHT_SCROLLBAR_ARROW_LINE_2 right or down

wxHT_SCROLLBAR_ARROW_PAGE_1 left or upper arrow to scroll by page

wxHT_SCROLLBAR_ARROW_PAGE_2 right or down

wxHT_SCROLLBAR_THUMB on the thumb

wxHT_SCROLLBAR_BAR_1 bar to the left/above the thumb

wxHT_SCROLLBAR_BAR_2 bar to the right/below the thumb

wxHT_SCROLLBAR_LAST

wxHT_WINDOW_OUTSIDE not in this window at all

wxHT_WINDOW_INSIDE in the client area

wxHT_WINDOW_VERT_SCROLLBAR on the vertical scrollbar

wxHT_WINDOW_HORZ_SCROLLBAR on the horizontal scrollbar

wxHT_WINDOW_CORNER on the corner between 2 scrollbars

wxHT_MAX

enum wxItemKind

Item kinds for use with wxMenu, wxMenuItem, and wxToolBar.

See also

wxMenu::Append(), wxMenuItem::wxMenuItem(), wxToolBar::AddTool()

Enumerator

wxITEM_SEPARATOR

wxITEM_NORMAL Normal tool button / menu item.

See also

wxToolBar::AddTool(), wxMenu::AppendItem().

wxITEM_CHECK Check (or toggle) tool button / menu item.

See also

wxToolBar::AddCheckTool(), wxMenu::AppendCheckItem().

wxITEM_RADIO Radio tool button / menu item.

See also

wxToolBar::AddRadioTool(), wxMenu::AppendRadioItem().

wxITEM_DROPDOWN Normal tool button with a dropdown arrow next to it. Clicking the dropdown arrow sends a `wxEVT_TOOL_DROPDOWN` event and may also display the menu previously associated with the item with wxToolBar::SetDropdownMenu(). Currently this type of tools is supported under MSW and GTK.

wxITEM_MAX

enum wxKeyCode

Virtual keycodes used by wxKeyEvent and some other wxWidgets functions.

Note that the range `0..255` corresponds to the characters of the current locale, in particular the `32..127` subrange is for the ASCII symbols, and all the special key values such as `WXK_END` lie above this range.

Enumerator

WXK_NONE No key. This value is returned by wxKeyEvent::GetKeyCode() if there is no non-Unicode representation for the pressed key (e.g. a Cyrillic letter was entered when not using a Cyrillic locale) and by wxKeyEvent::GetUnicodeKey() if there is no Unicode representation for the key (this happens for the special, non printable, keys only, e.g. WXK_HOME).

Since

2.9.2 (you can simply use 0 with previous versions).

WXK_CONTROL_A

WXK_CONTROL_B

WXK_CONTROL_C

WXK_CONTROL_D

WXK_CONTROL_E

WXK_CONTROL_F

WXK_CONTROL_G

WXK_CONTROL_H

WXK_CONTROL_I

WXK_CONTROL_J

WXK_CONTROL_K

WXK_CONTROL_L

WXK_CONTROL_R

WXK_CONTROL_S

WXK_CONTROL_T

WXK_CONTROL_U

WXK_CONTROL_V

WXK_CONTROL_W

WXK_CONTROL_X

WXK_CONTROL_Y

WXK_CONTROL_Z

WXK_BACK Backspace.

WXK_TAB

WXK_RETURN

WXK_ESCAPE

WXK_SPACE

WXK_DELETE

WXK_START Special key values. These are, by design, not compatible with Unicode characters. If you want to get a Unicode character from a key event, use wxKeyEvent::GetUnicodeKey() instead.

WXK_LBUTTON

WXK_RBUTTON

WXK_CANCEL

WXK_MBUTTON

WXK_CLEAR

WXK_SHIFT

WXK_ALT

WXK_CONTROL Note that under Mac OS X, to improve compatibility with other systems, 'WXK_CONTROL' represents the 'Command' key. Use this constant to work with keyboard shortcuts. See 'WXK_RAW_C↩ ONTROL' to get the state of the actual 'Control' key.

WXK_RAW_CONTROL Under Mac OS X, where the 'Command' key is mapped to 'Control' to improve compatibility with other systems, WXK_RAW_CONTROL may be used to obtain the state of the actual 'Control' key ('WXK_CONTROL' would obtain the status of the 'Command' key). Under Windows/Linux/Others, this is equivalent to WXK_CONTROL

enum wxKeyModifier

This enum contains bit mask constants used in wxKeyEvent.

Enumerator

wxMOD_NONE

wxMOD_ALT

wxMOD_CONTROL Ctlr Key, corresponds to Command key on OS X.

wxMOD_ALTGR

wxMOD_SHIFT

wxMOD_META

wxMOD_WIN

wxMOD_RAW_CONTROL used to describe the true Ctrl Key under OSX, identic to `wxMOD_CONTROL` on other platforms

wxMOD_CMD deprecated, identic to `wxMOD_CONTROL` on all platforms

wxMOD_ALL

enum wxOrientation

A generic orientation value.

Enumerator

wxHORIZONTAL

wxVERTICAL

wxBOTH A mask value to indicate both vertical and horizontal orientations.

wxORIENTATION_MASK A synonym for `wxBOTH`.

enum wxPaperSize

Paper size types for use with the printing framework.

22.250.4 Variable Documentation

wxCoord wxDefaultCoord = -1

A special value meaning "use default coordinate".

22.251 interface/wx/dialup.h File Reference

Classes

- class wxDialUpManager

  This class encapsulates functions dealing with verifying the connection status of the workstation (connected to the Internet via a direct connection, connected through a modem or not connected at all) and to establish this connection if possible/required (i.e.
- class wxDialUpEvent

  This is the event class for the dialup events sent by wxDialUpManager.

22.252 interface/wx/dir.h File Reference

Classes

- class wxDirTraverser

  wxDirTraverser is an abstract interface which must be implemented by objects passed to wxDir::Traverse() function.
- class wxDir

  wxDir is a portable equivalent of Unix open/read/closedir functions which allow enumerating of the files in a directory.

Enumerations

- enum wxDirTraverseResult {
  wxDIR_IGNORE = -1,
  wxDIR_STOP,
  wxDIR_CONTINUE }

  Possible return values of wxDirTraverser callback functions.
- enum wxDirFlags {
  wxDIR_FILES = 0x0001,
  wxDIR_DIRS = 0x0002,
  wxDIR_HIDDEN = 0x0004,
  wxDIR_DOTDOT = 0x0008,
  wxDIR_NO_FOLLOW = 0x0010,
  wxDIR_DEFAULT = wxDIR_FILES | wxDIR_DIRS | wxDIR_HIDDEN }

  These flags affect the behaviour of GetFirst/GetNext() and Traverse(), determining what types are included in the list of items they produce.

22.252.1 Enumeration Type Documentation

enum wxDirFlags

These flags affect the behaviour of GetFirst/GetNext() and Traverse(), determining what types are included in the list of items they produce.

Enumerator

wxDIR_FILES Includes files.

wxDIR_DIRS Includes directories.

wxDIR_HIDDEN Includes hidden files.

wxDIR_DOTDOT Includes "." and "..".

wxDIR_NO_FOLLOW Don't follow symbolic links during the directory traversal. This flag is ignored under systems not supporting symbolic links (i.e. non-Unix ones).

Notice that this flag is *not* included in wxDIR_DEFAULT and so the default behaviour of wxDir::Traverse() is to follow symbolic links, even if they lead outside of the directory being traversed.

Since

2.9.5

wxDIR_DEFAULT Default directory traversal flags include both files and directories, even hidden. Notice that by default wxDIR_NO_FOLLOW is *not* included, meaning that symbolic links are followed by default. If this is not desired, you must pass that flag explicitly.

enum wxDirTraverseResult

Possible return values of wxDirTraverser callback functions.

Enumerator

wxDIR_IGNORE Ignore this directory but continue with others.

wxDIR_STOP Stop traversing.

wxDIR_CONTINUE Continue into this directory.

22.253 interface/wx/dirctrl.h File Reference

Classes

- class wxGenericDirCtrl

  This control can be used to place a directory listing (with optional files) on an arbitrary window.
- class wxDirFilterListCtrl

Enumerations

- enum {
  wxDIRCTRL_DIR_ONLY = 0x0010,

Classes

- class wxDisplay

  Determines the sizes and locations of displays connected to the system.

22.256 interface/wx/docmdi.h File Reference

Classes

- class wxDocMDIParentFrame

  The wxDocMDIParentFrame class provides a default top-level frame for applications using the document/view framework.
- class wxDocMDIChildFrame

  The wxDocMDIChildFrame class provides a default frame for displaying documents on separate windows.

22.257 interface/wx/dragimag.h File Reference

Classes

- class wxDragImage

  This class is used when you wish to drag an object on the screen, and a simple cursor is not enough.

22.258 interface/wx/dynarray.h File Reference

Classes

- class wxArray< T >

  This section describes the so called "dynamic arrays".

Macros

- #define WX_APPEND_ARRAY(wxArray_arrayToModify, wxArray_arrayToBeAppended)

  This macro may be used to append all elements of the wxArray_arrayToBeAppended array to the wxArray_arrayTo↩Modify.
- #define WX_CLEAR_ARRAY(wxArray_arrayToBeCleared)

  This macro may be used to delete all elements of the array before emptying it.
- #define WX_PREPEND_ARRAY(wxArray_arrayToModify, wxArray_arrayToBePrepended)

  This macro may be used to prepend all elements of the wxArray_arrayToBePrepended array to the wxArray_array↩ToModify.

- #define WX_DECLARE_OBJARRAY(T, name)

  This macro declares a new object array class named name and containing the elements of type T.
- #define WX_DECLARE_EXPORTED_OBJARRAY(T, name)

  This macro declares a new object array class named name and containing the elements of type T.
- #define WX_DECLARE_USER_EXPORTED_OBJARRAY(T, name)

  This macro declares a new object array class named name and containing the elements of type T.

- #define WX_DEFINE_ARRAY(T, name)

  This macro defines a new array class named name and containing the elements of type T.
- #define WX_DEFINE_EXPORTED_ARRAY(T, name)

  This macro defines a new array class named name and containing the elements of type T.
- #define WX_DEFINE_USER_EXPORTED_ARRAY(T, name, exportspec)

  This macro defines a new array class named name and containing the elements of type T.

- #define WX_DEFINE_OBJARRAY(name)

This macro defines the methods of the array class name not defined by the WX_DECLARE_OBJARRAY() macro.

- #define WX_DEFINE_EXPORTED_OBJARRAY(name)

  This macro defines the methods of the array class name not defined by the WX_DECLARE_OBJARRAY() macro.
- #define WX_DEFINE_USER_EXPORTED_OBJARRAY(name)

  This macro defines the methods of the array class name not defined by the WX_DECLARE_OBJARRAY() macro.

- #define WX_DEFINE_SORTED_ARRAY(T, name)

  This macro defines a new sorted array class named name and containing the elements of type T.
- #define WX_DEFINE_SORTED_EXPORTED_ARRAY(T, name)

  This macro defines a new sorted array class named name and containing the elements of type T.
- #define WX_DEFINE_SORTED_USER_EXPORTED_ARRAY(T, name)

  This macro defines a new sorted array class named name and containing the elements of type T.

Typedefs

- typedef wxArray< int > wxArrayInt

  Predefined specialization of wxArray<T> for standard types.
- typedef wxArray< long > wxArrayLong

  Predefined specialization of wxArray<T> for standard types.
- typedef wxArray< short > wxArrayShort

  Predefined specialization of wxArray<T> for standard types.
- typedef wxArray< double > wxArrayDouble

  Predefined specialization of wxArray<T> for standard types.
- typedef wxArray< void * > wxArrayPtrVoid

  Predefined specialization of wxArray<T> for standard types.

22.258.1 Macro Definition Documentation

#define WX_APPEND_ARRAY(*wxArray_arrayToModify, wxArray_arrayToBeAppended*)

This macro may be used to append all elements of the *wxArray_arrayToBeAppended* array to the *wxArray_array↩ ToModify*.

The two arrays must be of the same type.

#define WX_CLEAR_ARRAY(*wxArray_arrayToBeCleared*)

This macro may be used to delete all elements of the array before emptying it.

It cannot be used with wxObjArrays - but they will delete their elements anyway when you call Empty().

#define WX_DECLARE_EXPORTED_OBJARRAY(*T, name*)

This macro declares a new object array class named *name* and containing the elements of type *T*.

An exported array is used when compiling wxWidgets as a DLL under Windows and the array needs to be visible outside the DLL. An user exported array needed for exporting an array from a user DLL.

Example:

```
1 class MyClass;
2 WX_DECLARE_OBJARRAY(MyClass, wxArrayOfMyClass); // note: not "MyClass *"!
```

You must use WX_DEFINE_OBJARRAY() macro to define the array class, otherwise you would get link errors.

#define WX_DECLARE_OBJARRAY(*T, name*)

This macro declares a new object array class named *name* and containing the elements of type *T*.

An exported array is used when compiling wxWidgets as a DLL under Windows and the array needs to be visible outside the DLL. An user exported array needed for exporting an array from a user DLL.

Example:

```
1 class MyClass;
2 WX_DECLARE_OBJARRAY(MyClass, wxArrayOfMyClass); // note: not "MyClass *"!
```

You must use WX_DEFINE_OBJARRAY() macro to define the array class, otherwise you would get link errors.

#define WX_DECLARE_USER_EXPORTED_OBJARRAY(*T, name*)

This macro declares a new object array class named *name* and containing the elements of type *T*.

An exported array is used when compiling wxWidgets as a DLL under Windows and the array needs to be visible outside the DLL. An user exported array needed for exporting an array from a user DLL.

Example:

```
1 class MyClass;
2 WX_DECLARE_OBJARRAY(MyClass, wxArrayOfMyClass); // note: not "MyClass *"!
```

You must use WX_DEFINE_OBJARRAY() macro to define the array class, otherwise you would get link errors.

#define WX_DEFINE_ARRAY(*T, name*)

This macro defines a new array class named *name* and containing the elements of type *T*.

An exported array is used when compiling wxWidgets as a DLL under Windows and the array needs to be visible outside the DLL. An user exported array needed for exporting an array from a user DLL.

Example:

```
1 WX_DEFINE_ARRAY_INT(int, MyArrayInt);
2
3 class MyClass;
4 WX_DEFINE_ARRAY(MyClass *, ArrayOfMyClass);
```

Note that wxWidgets predefines the following standard array classes: **wxArrayInt**, **wxArrayLong**, **wxArrayShort**, **wxArrayDouble**, **wxArrayPtrVoid**.

#define WX_DEFINE_EXPORTED_ARRAY(*T, name*)

This macro defines a new array class named *name* and containing the elements of type *T*.

An exported array is used when compiling wxWidgets as a DLL under Windows and the array needs to be visible outside the DLL. An user exported array needed for exporting an array from a user DLL.

Example:

```
1 WX_DEFINE_ARRAY_INT(int, MyArrayInt);
2
3 class MyClass;
4 WX_DEFINE_ARRAY(MyClass *, ArrayOfMyClass);
```

Note that wxWidgets predefines the following standard array classes: **wxArrayInt**, **wxArrayLong**, **wxArrayShort**, **wxArrayDouble**, **wxArrayPtrVoid**.

#define WX_DEFINE_EXPORTED_OBJARRAY(*name*)

This macro defines the methods of the array class *name* not defined by the WX_DECLARE_OBJARRAY() macro.

You must include the file <wx/arrimpl.cpp> before using this macro and you must have the full declaration of the class of array elements in scope! If you forget to do the first, the error will be caught by the compiler, but, unfortunately, many compilers will not give any warnings if you forget to do the second - but the objects of the class will not be copied correctly and their real destructor will not be called.

An exported array is used when compiling wxWidgets as a DLL under Windows and the array needs to be visible outside the DLL. An user exported array needed for exporting an array from a user DLL.

Example of usage:

```
1 // first declare the class!
2 class MyClass
3 {
4 public:
5     MyClass(const MyClass&);
6
7     // ...
8
9     virtual ~MyClass();
10 };
11
12 #include <wx/arrimpl.cpp>
13 WX_DEFINE_OBJARRAY(wxArrayOfMyClass);
```

#define WX_DEFINE_OBJARRAY(*name*)

This macro defines the methods of the array class *name* not defined by the WX_DECLARE_OBJARRAY() macro.

You must include the file <wx/arrimpl.cpp> before using this macro and you must have the full declaration of the class of array elements in scope! If you forget to do the first, the error will be caught by the compiler, but, unfortunately, many compilers will not give any warnings if you forget to do the second - but the objects of the class will not be copied correctly and their real destructor will not be called.

An exported array is used when compiling wxWidgets as a DLL under Windows and the array needs to be visible outside the DLL. An user exported array needed for exporting an array from a user DLL.

Example of usage:

```
1 // first declare the class!
2 class MyClass
3 {
4 public:
5     MyClass(const MyClass&);
6
7     // ...
8
9     virtual ~MyClass();
10 };
11
12 #include <wx/arrimpl.cpp>
13 WX_DEFINE_OBJARRAY(wxArrayOfMyClass);
```

#define WX_DEFINE_SORTED_ARRAY(*T*, *name*)

This macro defines a new sorted array class named *name* and containing the elements of type *T*.

An exported array is used when compiling wxWidgets as a DLL under Windows and the array needs to be visible outside the DLL. An user exported array needed for exporting an array from a user DLL.

Example:

```
1 WX_DEFINE_SORTED_ARRAY_INT(int, MySortedArrayInt);
2
3 class MyClass;
4 WX_DEFINE_SORTED_ARRAY(MyClass *, ArrayOfMyClass);
```

You will have to initialize the objects of this class by passing a comparison function to the array object constructor like this:

```
1 int CompareInts(int n1, int n2)
2 {
3     return n1 - n2;
4 }
5
6 MySortedArrayInt sorted(CompareInts);
7
8 int CompareMyClassObjects(MyClass *item1, MyClass *item2)
9 {
10     // sort the items by their address...
11     return Stricmp(item1->GetAddress(), item2->GetAddress());
12 }
13
14 ArrayOfMyClass another(CompareMyClassObjects);
```

#define WX_DEFINE_SORTED_EXPORTED_ARRAY(*T, name*)

This macro defines a new sorted array class named *name* and containing the elements of type *T*.

An exported array is used when compiling wxWidgets as a DLL under Windows and the array needs to be visible outside the DLL. An user exported array needed for exporting an array from a user DLL.

Example:

```
1 WX_DEFINE_SORTED_ARRAY_INT(int, MySortedArrayInt);
2
3 class MyClass;
4 WX_DEFINE_SORTED_ARRAY(MyClass *, ArrayOfMyClass);
```

You will have to initialize the objects of this class by passing a comparison function to the array object constructor like this:

```
1 int CompareInts(int n1, int n2)
2 {
3     return n1 - n2;
4 }
5
6 MySortedArrayInt sorted(CompareInts);
7
8 int CompareMyClassObjects(MyClass *item1, MyClass *item2)
9 {
10     // sort the items by their address...
11     return Stricmp(item1->GetAddress(), item2->GetAddress());
12 }
13
14 ArrayOfMyClass another(CompareMyClassObjects);
```

#define WX_DEFINE_SORTED_USER_EXPORTED_ARRAY(*T, name*)

This macro defines a new sorted array class named *name* and containing the elements of type *T*.

An exported array is used when compiling wxWidgets as a DLL under Windows and the array needs to be visible outside the DLL. An user exported array needed for exporting an array from a user DLL.

Example:

```
1 WX_DEFINE_SORTED_ARRAY_INT(int, MySortedArrayInt);
2
3 class MyClass;
4 WX_DEFINE_SORTED_ARRAY(MyClass *, ArrayOfMyClass);
```

You will have to initialize the objects of this class by passing a comparison function to the array object constructor like this:

```
1 int CompareInts(int n1, int n2)
2 {
3     return n1 - n2;
4 }
5
6 MySortedArrayInt sorted(CompareInts);
7
8 int CompareMyClassObjects(MyClass *item1, MyClass *item2)
9 {
10     // sort the items by their address...
11     return Stricmp(item1->GetAddress(), item2->GetAddress());
12 }
13
14 ArrayOfMyClass another(CompareMyClassObjects);
```

#define WX_DEFINE_USER_EXPORTED_ARRAY(*T, name, exportspec*)

This macro defines a new array class named *name* and containing the elements of type *T*.

An exported array is used when compiling wxWidgets as a DLL under Windows and the array needs to be visible outside the DLL. An user exported array needed for exporting an array from a user DLL.

Example:

```
1 WX_DEFINE_ARRAY_INT(int, MyArrayInt);
2
3 class MyClass;
4 WX_DEFINE_ARRAY(MyClass *, ArrayOfMyClass);
```

Note that wxWidgets predefines the following standard array classes: **wxArrayInt**, **wxArrayLong**, **wxArrayShort**, **wxArrayDouble**, **wxArrayPtrVoid**.

#define WX_DEFINE_USER_EXPORTED_OBJARRAY(*name*)

This macro defines the methods of the array class *name* not defined by the WX_DECLARE_OBJARRAY() macro.

You must include the file <wx/arrimpl.cpp> before using this macro and you must have the full declaration of the class of array elements in scope! If you forget to do the first, the error will be caught by the compiler, but, unfortunately, many compilers will not give any warnings if you forget to do the second - but the objects of the class will not be copied correctly and their real destructor will not be called.

An exported array is used when compiling wxWidgets as a DLL under Windows and the array needs to be visible outside the DLL. An user exported array needed for exporting an array from a user DLL.

Example of usage:

```
1 // first declare the class!
2 class MyClass
3 {
4 public:
5     MyClass(const MyClass&);
6
7     // ...
8
9     virtual ~MyClass();
10 };
11
12 #include <wx/arrimpl.cpp>
13 WX_DEFINE_OBJARRAY(wxArrayOfMyClass);
```

#define WX_PREPEND_ARRAY(*wxArray_arrayToModify, wxArray_arrayToBePrepended*)

This macro may be used to prepend all elements of the *wxArray_arrayToBePrepended* array to the *wxArray_array↩ ToModify*.

The two arrays must be of the same type.

22.258.2 Typedef Documentation

typedef wxArray<double> wxArrayDouble

Predefined specialization of wxArray<T> for standard types.

typedef wxArray<int> wxArrayInt

Predefined specialization of wxArray<T> for standard types.

typedef wxArray<long> wxArrayLong

Predefined specialization of wxArray<T> for standard types.

typedef wxArray<void*> wxArrayPtrVoid

Predefined specialization of wxArray<T> for standard types.

typedef wxArray<short> wxArrayShort

Predefined specialization of wxArray<T> for standard types.

22.259 interface/wx/dynlib.h File Reference

Classes

- class wxDynamicLibraryDetails

  This class is used for the objects returned by the wxDynamicLibrary::ListLoaded() method and contains the information about a single module loaded into the address space of the current process.
- class wxDynamicLibrary

  wxDynamicLibrary is a class representing dynamically loadable library (Windows DLL, shared library under Unix etc).

Macros

- #define wxDYNLIB_FUNCTION(type, name, dynlib)

  When loading a function from a DLL you always have to cast the returned `void *` pointer to the correct type and, even more annoyingly, you have to repeat this type twice if you want to declare and define a function pointer all in one line.

Enumerations

- enum wxDynamicLibraryCategory {
  wxDL_LIBRARY,
  wxDL_MODULE }

  Dynamic library category used with wxDynamicLibrary::CanonicalizeName().
- enum wxPluginCategory {
  wxDL_PLUGIN_GUI,
  wxDL_PLUGIN_BASE }

  Dynamic library plugin category used with wxDynamicLibrary::CanonicalizePluginName().

22.259.1 Enumeration Type Documentation

enum wxDynamicLibraryCategory

Dynamic library category used with wxDynamicLibrary::CanonicalizeName().

Enumerator

wxDL_LIBRARY Standard library.
wxDL_MODULE Loadable module/plugin.

enum wxPluginCategory

Dynamic library plugin category used with wxDynamicLibrary::CanonicalizePluginName().

Enumerator

wxDL_PLUGIN_GUI Plugin that uses GUI classes.
wxDL_PLUGIN_BASE wxBase-only plugin.

22.260 interface/wx/editlbox.h File Reference

Classes

- class wxEditableListBox
  An editable listbox is composite control that lets the user easily enter, delete and reorder a list of strings.

Macros

- #define wxEL_ALLOW_NEW 0x0100
- #define wxEL_ALLOW_EDIT 0x0200
- #define wxEL_ALLOW_DELETE 0x0400
- #define wxEL_NO_REORDER 0x0800
- #define wxEL_DEFAULT_STYLE (wxEL_ALLOW_NEW | wxEL_ALLOW_EDIT | wxEL_ALLOW_DELETE)

22.260.1 Macro Definition Documentation

#define wxEL_ALLOW_DELETE 0x0400

#define wxEL_ALLOW_EDIT 0x0200

#define wxEL_ALLOW_NEW 0x0100

#define wxEL_DEFAULT_STYLE (wxEL_ALLOW_NEW | wxEL_ALLOW_EDIT | wxEL_ALLOW_DELETE)

#define wxEL_NO_REORDER 0x0800

22.261 interface/wx/encconv.h File Reference

Classes

- class wxEncodingConverter
  This class is capable of converting strings between two 8-bit encodings/charsets.

22.262 interface/wx/event.h File Reference

Classes

- class wxEvent

  An event is a structure holding information about an event passed to a callback or member function.
- class wxEventBlocker

  This class is a special event handler which allows to discard any event (or a set of event types) directed to a specific window.
- class wxPropagationDisabler

  Helper class to temporarily change an event to not propagate.
- class wxPropagateOnce

  Helper class to temporarily lower propagation level.
- class wxEvtHandler

  A class that can handle events from the windowing system.
- class wxKeyEvent

  This event class contains information about key press and release events.
- class wxJoystickEvent

  This event class contains information about joystick events, particularly events received by windows.
- class wxScrollWinEvent

  A scroll event holds information about events sent from scrolling windows.
- class wxSysColourChangedEvent

  This class is used for system colour change events, which are generated when the user changes the colour settings using the control panel.
- class wxCommandEvent

  This event class contains information about command events, which originate from a variety of simple controls.
- class wxWindowCreateEvent

  This event is sent just after the actual window associated with a wxWindow object has been created.
- class wxPaintEvent

  A paint event is sent when a window's contents needs to be repainted.
- class wxMaximizeEvent

  An event being sent when a top level window is maximized.
- class wxUpdateUIEvent

  This class is used for pseudo-events which are called by wxWidgets to give an application the chance to update various user interface elements.
- class wxClipboardTextEvent

  This class represents the events generated by a control (typically a wxTextCtrl but other windows can generate these events as well) when its content gets copied or cut to, or pasted from the clipboard.
- class wxMouseEvent

  This event class contains information about the events generated by the mouse: they include mouse buttons press and release events and mouse move events.
- class wxDropFilesEvent

  This class is used for drop files events, that is, when files have been dropped onto the window.
- class wxActivateEvent

  An activate event is sent when a window or application is being activated or deactivated.
- class wxContextMenuEvent

  This class is used for context menu events, sent to give the application a chance to show a context (popup) menu for a wxWindow.
- class wxEraseEvent

  An erase event is sent when a window's background needs to be repainted.
- class wxFocusEvent

  A focus event is sent when a window's focus changes.

- class wxChildFocusEvent

  A child focus event is sent to a (parent-)window when one of its child windows gains focus, so that the window could restore the focus back to its corresponding child if it loses it now and regains later.

- class wxMouseCaptureLostEvent

  A mouse capture lost event is sent to a window that had obtained mouse capture, which was subsequently lost due to an "external" event (for example, when a dialog box is shown or if another application captures the mouse).

- class wxDisplayChangedEvent
- class wxPaletteChangedEvent
- class wxQueryNewPaletteEvent
- class wxNotifyEvent

  This class is not used by the event handlers by itself, but is a base class for other event classes (such as wxBookCtrlEvent).

- class wxThreadEvent

  This class adds some simple functionality to wxEvent to facilitate inter-thread communication.

- class wxHelpEvent

  A help event is sent when the user has requested context-sensitive help.

- class wxScrollEvent

  A scroll event holds information about events sent from stand-alone scrollbars (see wxScrollBar) and sliders (see wxSlider).

- class wxIdleEvent

  This class is used for idle events, which are generated when the system becomes idle.

- class wxInitDialogEvent

  A wxInitDialogEvent is sent as a dialog or panel is being initialised.

- class wxWindowDestroyEvent

  This event is sent as early as possible during the window destruction process.

- class wxNavigationKeyEvent

  This event class contains information about navigation events, generated by navigation keys such as tab and page down.

- class wxMouseCaptureChangedEvent

  An mouse capture changed event is sent to a window that loses its mouse capture.

- class wxCloseEvent

  This event class contains information about window and session close events.

- class wxMenuEvent

  This class is used for a variety of menu-related events.

- class wxShowEvent

  An event being sent when the window is shown or hidden.

- class wxIconizeEvent

  An event being sent when the frame is iconized (minimized) or restored.

- class wxMoveEvent

  A move event holds information about wxTopLevelWindow move change events.

- class wxSizeEvent

  A size event holds information about size change events of wxWindow.

- class wxSetCursorEvent

  A wxSetCursorEvent is generated from wxWindow when the mouse cursor is about to be set as a result of mouse motion.

Macros

- #define wxDEFINE_EVENT(name, cls) const wxEventTypeTag< cls > name(wxNewEventType())

  Define a new event type associated with the specified event class.
- #define wxDECLARE_EVENT(name, cls) wxDECLARE_EXPORTED_EVENT(wxEMPTY_PARAMETER_↩ VALUE, name, cls)

  Declares a custom event type.
- #define wxDECLARE_EXPORTED_EVENT(expdecl, name, cls) extern const expdecl wxEventTypeTag< cls > name;

  Variant of wxDECLARE_EVENT() used for event types defined inside a shared library.
- #define wxEVENT_HANDLER_CAST(functype, func) (&func)

  Helper macro for definition of custom event table macros.
- #define wx__DECLARE_EVT1(evt, id, fn) wx__DECLARE_EVT2(evt, id, wxID_ANY, fn)

  This macro is used to define event table macros for handling custom events.
- #define wx__DECLARE_EVT2(evt, id1, id2, fn) DECLARE_EVENT_TABLE_ENTRY(evt, id1, id2, fn, NULL),

  Generalized version of the wx__DECLARE_EVT1() macro taking a range of IDs instead of a single one.
- #define wx__DECLARE_EVT0(evt, fn) wx__DECLARE_EVT1(evt, wxID_ANY, fn)

  Simplified version of the wx__DECLARE_EVT1() macro, to be used when the event type must be handled regardless of the ID associated with the specific event instances.
- #define wxDECLARE_EVENT_TABLE()

  Use this macro inside a class declaration to declare a static event table for that class.
- #define wxBEGIN_EVENT_TABLE(theClass, baseClass)

  Use this macro in a source file to start listing static event handlers for a specific class.
- #define wxEND_EVENT_TABLE()

  Use this macro in a source file to end listing static event handlers for a specific class.

Typedefs

- typedef int wxEventType

  A value uniquely identifying the type of the event.

Enumerations

- enum wxEventPropagation {
  wxEVENT_PROPAGATE_NONE = 0,
  wxEVENT_PROPAGATE_MAX = INT_MAX }

  The predefined constants for the number of times we propagate event upwards window child-parent chain.
- enum wxEventCategory {
  wxEVT_CATEGORY_UI = 1,
  wxEVT_CATEGORY_USER_INPUT = 2,
  wxEVT_CATEGORY_SOCKET = 4,
  wxEVT_CATEGORY_TIMER = 8,
  wxEVT_CATEGORY_THREAD = 16,
  wxEVT_CATEGORY_ALL }

  The different categories for a wxEvent; see wxEvent::GetEventCategory.
- enum wxKeyCategoryFlags {
  WXK_CATEGORY_ARROW,
  WXK_CATEGORY_PAGING,
  WXK_CATEGORY_JUMP,
  WXK_CATEGORY_TAB,
  WXK_CATEGORY_CUT,
  WXK_CATEGORY_NAVIGATION }

  Flags for categories of keys.

- enum {
  wxJOYSTICK1,
  wxJOYSTICK2 }
- enum {
  wxJOY_BUTTON_ANY = -1,
  wxJOY_BUTTON1 = 1,
  wxJOY_BUTTON2 = 2,
  wxJOY_BUTTON3 = 4,
  wxJOY_BUTTON4 = 8 }
- enum wxUpdateUIMode {
  wxUPDATE_UI_PROCESS_ALL,
  wxUPDATE_UI_PROCESS_SPECIFIED }

  The possibles modes to pass to wxUpdateUIEvent::SetMode().
- enum wxMouseWheelAxis {
  wxMOUSE_WHEEL_VERTICAL,
  wxMOUSE_WHEEL_HORIZONTAL }

  Possible axis values for mouse wheel scroll events.
- enum wxIdleMode {
  wxIDLE_PROCESS_ALL,
  wxIDLE_PROCESS_SPECIFIED }

  See wxIdleEvent::SetMode() for more info.

Functions

- wxEventType wxNewEventType ()

  Generates a new unique event type.
- void wxPostEvent (wxEvtHandler ∗dest, const wxEvent &event)

  In a GUI application, this function posts event to the specified dest object using wxEvtHandler::AddPendingEvent().
- void wxQueueEvent (wxEvtHandler ∗dest, wxEvent ∗event)

  Queue an event for processing on the given object.

Variables

- wxEventType wxEVT_NULL

  A special event type usually used to indicate that some wxEvent has yet no type assigned.
- wxEventType wxEVT_ANY
- wxEventType wxEVT_BUTTON
- wxEventType wxEVT_CHECKBOX
- wxEventType wxEVT_CHOICE
- wxEventType wxEVT_LISTBOX

22.262.1 Enumeration Type Documentation

anonymous enum

Enumerator

wxJOYSTICK1

wxJOYSTICK2

anonymous enum

Enumerator

wxJOY_BUTTON_ANY

wxJOY_BUTTON1

wxJOY_BUTTON2

wxJOY_BUTTON3

wxJOY_BUTTON4

enum **wxEventCategory**

The different categories for a wxEvent; see wxEvent::GetEventCategory.

Note

They are used as OR-combinable flags by wxEventLoopBase::YieldFor.

Enumerator

wxEVT_CATEGORY_UI This is the category for those events which are generated to update the appearance of the GUI but which (usually) do not comport data processing, i.e. which do not provide input or output data (e.g. size events, scroll events, etc). They are events NOT directly generated by the user's input devices.

wxEVT_CATEGORY_USER_INPUT This category groups those events which are generated directly from the user through input devices like mouse and keyboard and usually result in data to be processed from the application (e.g. mouse clicks, key presses, etc).

wxEVT_CATEGORY_SOCKET This category is for wxSocketEvent.

wxEVT_CATEGORY_TIMER This category is for wxTimerEvent.

wxEVT_CATEGORY_THREAD This category is for any event used to send notifications from the secondary threads to the main one or in general for notifications among different threads (which may or may not be user-generated). See e.g. wxThreadEvent.

wxEVT_CATEGORY_ALL This mask is used in wxEventLoopBase::YieldFor to specify that all event categories should be processed.

enum **wxEventPropagation**

The predefined constants for the number of times we propagate event upwards window child-parent chain.

Enumerator

wxEVENT_PROPAGATE_NONE don't propagate it at all

wxEVENT_PROPAGATE_MAX propagate it until it is processed

enum **wxIdleMode**

See wxIdleEvent::SetMode() for more info.

Enumerator

wxIDLE_PROCESS_ALL Send idle events to all windows.

wxIDLE_PROCESS_SPECIFIED Send idle events to windows that have the wxWS_EX_PROCESS_IDLE flag specified.

enum wxKeyCategoryFlags

Flags for categories of keys.

These values are used by wxKeyEvent::IsKeyInCategory(). They may be combined via the bitwise operators |, &, and ~.

Since

2.9.1

Enumerator

WXK_CATEGORY_ARROW arrow keys, on and off numeric keypads

WXK_CATEGORY_PAGING page up and page down keys, on and off numeric keypads

WXK_CATEGORY_JUMP home and end keys, on and off numeric keypads

WXK_CATEGORY_TAB tab key, on and off numeric keypads

WXK_CATEGORY_CUT backspace and delete keys, on and off numeric keypads

WXK_CATEGORY_NAVIGATION union of WXK_CATEGORY_ARROW, WXK_CATEGORY_PAGING, and WXK_CATEGORY_JUMP categories

enum wxMouseWheelAxis

Possible axis values for mouse wheel scroll events.

Since

2.9.4

Enumerator

wxMOUSE_WHEEL_VERTICAL Vertical scroll event.

wxMOUSE_WHEEL_HORIZONTAL Horizontal scroll event.

enum wxUpdateUIMode

The possibles modes to pass to wxUpdateUIEvent::SetMode().

Enumerator

wxUPDATE_UI_PROCESS_ALL Send UI update events to all windows.

wxUPDATE_UI_PROCESS_SPECIFIED Send UI update events to windows that have the wxWS_EX_PROCESS_UI_UPDATES flag specified.

22.263 interface/wx/eventfilter.h File Reference

Classes

- class wxEventFilter

  A global event filter for pre-processing all the events generated in the program.

22.264 interface/wx/evtloop.h File Reference

Classes

- class wxEventLoopBase

  Base class for all event loop implementations.
- class wxEventLoopActivator

  Makes an event loop temporarily active.
- class wxGUIEventLoop

  A generic implementation of the GUI event loop.

22.265 interface/wx/fdrepdlg.h File Reference

Classes

- class wxFindDialogEvent

  wxFindReplaceDialog events.
- class wxFindReplaceData

  wxFindReplaceData holds the data for wxFindReplaceDialog.
- class wxFindReplaceDialog

  wxFindReplaceDialog is a standard modeless dialog which is used to allow the user to search for some text (and possibly replace it with something else).

Enumerations

- enum wxFindReplaceFlags {
  wxFR_DOWN = 1,
  wxFR_WHOLEWORD = 2,
  wxFR_MATCHCASE = 4 }

  See wxFindDialogEvent::GetFlags().
- enum wxFindReplaceDialogStyles {
  wxFR_REPLACEDIALOG = 1,
  wxFR_NOUPDOWN = 2,
  wxFR_NOMATCHCASE = 4,
  wxFR_NOWHOLEWORD = 8 }

  These flags can be specified in wxFindReplaceDialog ctor or Create():

Variables

- wxEventType wxEVT_FIND
- wxEventType wxEVT_FIND_NEXT
- wxEventType wxEVT_FIND_REPLACE
- wxEventType wxEVT_FIND_REPLACE_ALL
- wxEventType wxEVT_FIND_CLOSE

22.265.1 Enumeration Type Documentation

enum wxFindReplaceDialogStyles

These flags can be specified in wxFindReplaceDialog ctor or Create():

Enumerator

wxFR_REPLACEDIALOG replace dialog (otherwise find dialog)
wxFR_NOUPDOWN don't allow changing the search direction
wxFR_NOMATCHCASE don't allow case sensitive searching
wxFR_NOWHOLEWORD don't allow whole word searching

enum wxFindReplaceFlags

See wxFindDialogEvent::GetFlags().

Enumerator

wxFR_DOWN downward search/replace selected (otherwise - upwards)
wxFR_WHOLEWORD whole word search/replace selected
wxFR_MATCHCASE case sensitive search/replace selected (otherwise - case insensitive)

22.265.2 Variable Documentation

wxEventType wxEVT_FIND

wxEventType wxEVT_FIND_CLOSE

wxEventType wxEVT_FIND_NEXT

wxEventType wxEVT_FIND_REPLACE

wxEventType wxEVT_FIND_REPLACE_ALL

22.266 interface/wx/ffile.h File Reference

Classes

- class wxFFile
  wxFFile implements buffered file I/O.

22.267 interface/wx/fileconf.h File Reference

Classes

- class wxFileConfig
  wxFileConfig implements wxConfigBase interface for storing and retrieving configuration information using plain text files.

22.268 interface/wx/filectrl.h File Reference

Classes

- class wxFileCtrl
  This control allows the user to select a file.
- class wxFileCtrlEvent
  A file control event holds information about events associated with wxFileCtrl objects.

Macros

- #define wxFC_DEFAULT_STYLE wxFC_OPEN

Enumerations

- enum {
  wxFC_OPEN = 0x0001,
  wxFC_SAVE = 0x0002,
  wxFC_MULTIPLE = 0x0004,
  wxFC_NOSHOWHIDDEN = 0x0008 }

Classes

- class wxFileDialog

  This class represents the file chooser dialog.

Macros

- #define wxFD_DEFAULT_STYLE wxFD_OPEN

Enumerations

- enum {
  wxFD_OPEN = 0x0001,
  wxFD_SAVE = 0x0002,
  wxFD_OVERWRITE_PROMPT = 0x0004,
  wxFD_NO_FOLLOW = 0x0008,
  wxFD_FILE_MUST_EXIST = 0x0010,
  wxFD_MULTIPLE = 0x0020,
  wxFD_CHANGE_DIR = 0x0080,
  wxFD_PREVIEW = 0x0100 }

Functions

- wxString wxFileSelector (const wxString &message, const wxString &default_path=wxEmptyString, const wxString &default_filename=wxEmptyString, const wxString &default_extension=wxEmptyString, const wxString &wildcard=wxFileSelectorDefaultWildcardStr, int flags=0, wxWindow *parent=NULL, int x=wxDefaultCoord, int y=wxDefaultCoord)

  Pops up a file selector box.
- wxString wxFileSelectorEx (const wxString &message=wxFileSelectorPromptStr, const wxString &default_path=wxEmptyString, const wxString &default_filename=wxEmptyString, int *indexDefaultExtension=NULL, const wxString &wildcard=wxFileSelectorDefaultWildcardStr, int flags=0, wxWindow *parent=NULL, int x=wxDefaultCoord, int y=wxDefaultCoord)

  An extended version of wxFileSelector.
- wxString wxLoadFileSelector (const wxString &what, const wxString &extension, const wxString &default_name=wxEmptyString, wxWindow *parent=NULL)

  Ask for filename to load.
- wxString wxSaveFileSelector (const wxString &what, const wxString &extension, const wxString &default_name=wxEmptyString, wxWindow *parent=NULL)

  Ask for filename to save.

Variables

- const char wxFileSelectorDefaultWildcardStr [ ]

  Default wildcard string used in wxFileDialog corresponding to all files.

22.269.3 Variable Documentation

const char wxFileSelectorDefaultWildcardStr[ ]

Default wildcard string used in wxFileDialog corresponding to all files.

It is defined as "∗.∗" under MSW and OS/2 and "∗" everywhere else.

22.270 interface/wx/filefn.h File Reference

Classes

- class wxPathList

  The path list is a convenient way of storing a number of directories, and when presented with a filename without a directory, searching for an existing file in those directories.

Macros

- #define wxCHANGE_UMASK(mask)

  Under Unix this macro changes the current process umask to the given value, unless it is equal to -1 in which case nothing is done, and restores it to the original value on scope exit.

Typedefs

- typedef off_t wxFileOffset

  The type used to store and provide byte offsets or byte sizes for files or streams.

Enumerations

- enum wxPosixPermissions {
  wxS_IRUSR = 00400,
  wxS_IWUSR = 00200,
  wxS_IXUSR = 00100,
  wxS_IRGRP = 00040,
  wxS_IWGRP = 00020,
  wxS_IXGRP = 00010,
  wxS_IROTH = 00004,
  wxS_IWOTH = 00002,
  wxS_IXOTH = 00001,
  wxPOSIX_USER_READ = wxS_IRUSR,
  wxPOSIX_USER_WRITE = wxS_IWUSR,
  wxPOSIX_USER_EXECUTE = wxS_IXUSR,
  wxPOSIX_GROUP_READ = wxS_IRGRP,
  wxPOSIX_GROUP_WRITE = wxS_IWGRP,
  wxPOSIX_GROUP_EXECUTE = wxS_IXGRP,
  wxPOSIX_OTHERS_READ = wxS_IROTH,
  wxPOSIX_OTHERS_WRITE = wxS_IWOTH,
  wxPOSIX_OTHERS_EXECUTE = wxS_IXOTH,
  wxS_DEFAULT,
  wxS_DIR_DEFAULT }

  File permission bit names.
- enum wxSeekMode {
  wxFromStart,
  wxFromCurrent,
  wxFromEnd }

  Parameter indicating how file offset should be interpreted.
- enum wxFileKind {
  wxFILE_KIND_UNKNOWN,
  wxFILE_KIND_DISK,
  wxFILE_KIND_TERMINAL,
  wxFILE_KIND_PIPE }

  File kind enumerations returned from wxGetFileKind().

Functions

- bool wxGetDiskSpace (const wxString &path, wxLongLong total=NULL, wxLongLong free=NULL)

  This function returns the total number of bytes and number of free bytes on the disk containing the directory path (it should exist).
- wxString wxGetOSDirectory ()

  Returns the Windows directory under Windows; other platforms return an empty string.
- int wxParseCommonDialogsFilter (const wxString &wildCard, wxArrayString &descriptions, wxArrayString &filters)

  Parses the wildCard, returning the number of filters.
- void wxDos2UnixFilename (wxChar *s)

  Converts a DOS to a Unix filename by replacing backslashes with forward slashes.
- void wxUnix2DosFilename (wxChar *s)

  Converts a Unix to a DOS filename by replacing forward slashes with backslashes.
- bool wxDirExists (const wxString &dirname)

  Returns true if dirname exists and is a directory.
- void wxSplitPath (const wxString &fullname, wxString *path, wxString *name, wxString *ext)
- time_t wxFileModificationTime (const wxString &filename)

  Returns time of last modification of given file.

- bool wxRenameFile (const wxString &file1, const wxString &file2, bool overwrite=true)

  Renames file1 to file2, returning true if successful.
- bool wxCopyFile (const wxString &file1, const wxString &file2, bool overwrite=true)

  Copies file1 to file2, returning true if successful.
- bool wxFileExists (const wxString &filename)

  Returns true if the file exists and is a plain file.
- bool wxMatchWild (const wxString &pattern, const wxString &text, bool dot_special)

  Returns true if the pattern matches the text; if dot_special is true, filenames beginning with a dot are not matched with wildcard characters.
- wxString wxGetWorkingDirectory (char *buf=NULL, int sz=1000)
- wxString wxPathOnly (const wxString &path)

  Returns the directory part of the filename.
- bool wxIsWild (const wxString &pattern)

  Returns true if the pattern contains wildcards.
- bool wxIsAbsolutePath (const wxString &filename)

  Returns true if the argument is an absolute filename, i.e. with a slash or drive name at the beginning.
- wxString wxGetCwd ()

  Returns a string containing the current (or working) directory.
- bool wxSetWorkingDirectory (const wxString &dir)

  Sets the current working directory, returning true if the operation succeeded.
- bool wxConcatFiles (const wxString &file1, const wxString &file2, const wxString &file3)

  Concatenates file1 and file2 to file3, returning true if successful.
- bool wxRemoveFile (const wxString &file)

  Removes file, returning true if successful.
- bool wxMkdir (const wxString &dir, int perm=wxS_DIR_DEFAULT)

  Makes the directory dir, returning true if successful.
- bool wxRmdir (const wxString &dir, int flags=0)

  Removes the directory dir, returning true if successful.
- wxString wxFindNextFile ()

  Returns the next file that matches the path passed to wxFindFirstFile().
- wxString wxFindFirstFile (const wxString &spec, int flags=0)

  This function does directory searching; returns the first file that matches the path spec, or the empty string.
- wxFileKind wxGetFileKind (int fd)

  Returns the type of an open file.
- wxFileKind wxGetFileKind (FILE *fp)
- wxString wxFileNameFromPath (const wxString &path)
- char * wxFileNameFromPath (char *path)
- char * wxGetTempFileName (const wxString &prefix, char *buf=NULL)
- bool wxGetTempFileName (const wxString &prefix, wxString &buf)

Variables

- const int wxInvalidOffset = -1

  A special return value of many wxWidgets classes to indicate that an invalid offset was given.

22.271 interface/wx/filehistory.h File Reference

Classes

- class wxFileHistory

  The wxFileHistory encapsulates a user interface convenience, the list of most recently visited files as shown on a menu (usually the File menu).

22.272 interface/wx/filename.h File Reference

Classes

- class wxFileName

  wxFileName encapsulates a file name.

Enumerations

- enum wxPathFormat {
  wxPATH_NATIVE = 0,
  wxPATH_UNIX,
  wxPATH_BEOS = wxPATH_UNIX,
  wxPATH_MAC,
  wxPATH_DOS,
  wxPATH_WIN = wxPATH_DOS,
  wxPATH_OS2 = wxPATH_DOS,
  wxPATH_VMS,
  wxPATH_MAX }

  The various values for the path format: this mainly affects the path separator but also whether or not the path has the drive part (as under Windows).
- enum wxSizeConvention {
  wxSIZE_CONV_TRADITIONAL,
  wxSIZE_CONV_IEC,
  wxSIZE_CONV_SI }

  Different conventions for human readable sizes.
- enum wxPathNormalize {
  wxPATH_NORM_ENV_VARS = 0x0001,
  wxPATH_NORM_DOTS = 0x0002,
  wxPATH_NORM_TILDE = 0x0004,
  wxPATH_NORM_CASE = 0x0008,
  wxPATH_NORM_ABSOLUTE = 0x0010,
  wxPATH_NORM_LONG = 0x0020,
  wxPATH_NORM_SHORTCUT = 0x0040,
  wxPATH_NORM_ALL = 0x00ff & ~wxPATH_NORM_CASE }

  The kind of normalization to do with the file name: these values can be or'd together to perform several operations at once.
- enum {
  wxPATH_RMDIR_FULL = 1,
  wxPATH_RMDIR_RECURSIVE = 2 }

  Flags for wxFileName::Rmdir().
- enum {
  wxFILE_EXISTS_REGULAR = 0x0001,
  wxFILE_EXISTS_DIR = 0x0002,
  wxFILE_EXISTS_SYMLINK = 0x1004,
  wxFILE_EXISTS_DEVICE = 0x0008,
  wxFILE_EXISTS_FIFO = 0x0016,
  wxFILE_EXISTS_SOCKET = 0x0032,
  wxFILE_EXISTS_NO_FOLLOW }

  Flags for wxFileName::Exists().

Variables

- wxULongLong wxInvalidSize

  The return value of wxFileName::GetSize() in case of error.

22.272.1 Enumeration Type Documentation

anonymous enum

Flags for wxFileName::Rmdir().

Enumerator

wxPATH_RMDIR_FULL Delete the specified directory and its subdirectories if they are empty.

wxPATH_RMDIR_RECURSIVE Delete the specified directory and all the files and subdirectories in it recursively. This flag is obviously **dangerous** and should be used with care and after asking the user for confirmation.

anonymous enum

Flags for wxFileName::Exists().

Since

2.9.5

Enumerator

wxFILE_EXISTS_REGULAR Check for existence of a regular file.

wxFILE_EXISTS_DIR Check for existence of a directory.

wxFILE_EXISTS_SYMLINK Check for existence of a symlink. Notice that this flag also sets wxFILE_EXISTS_NO_FOLLOW, otherwise it would never be satisfied as wxFileName::Exists() would be checking for the existence of the symlink target and not the symlink itself.

wxFILE_EXISTS_DEVICE Check for existence of a device.

wxFILE_EXISTS_FIFO Check for existence of a FIFO.

wxFILE_EXISTS_SOCKET Check for existence of a socket.

wxFILE_EXISTS_NO_FOLLOW Don't dereference a contained symbolic link. Check for existence of anything

enum wxPathFormat

The various values for the path format: this mainly affects the path separator but also whether or not the path has the drive part (as under Windows).

See wxFileName for more info.

Enumerator

wxPATH_NATIVE the path format for the current platform.

wxPATH_UNIX

wxPATH_BEOS

wxPATH_MAC

wxPATH_DOS

wxPATH_WIN

wxPATH_OS2

wxPATH_VMS

wxPATH_MAX Not a valid value for specifying path format.

enum wxPathNormalize

The kind of normalization to do with the file name: these values can be or'd together to perform several operations at once.

See wxFileName::Normalize() for more info.

Enumerator

wxPATH_NORM_ENV_VARS Replace environment variables with their values. wxFileName understands both Unix and Windows (but only under Windows) environment variables expansion: i.e. "`$var`", "`$(var)`" and "`${var}`" are always understood and in addition under Windows "`%var%`" is also.

wxPATH_NORM_DOTS Squeeze all "`..`" and "`.`".

wxPATH_NORM_TILDE Replace "`~`" and "`~user`" (Unix only).

wxPATH_NORM_CASE If the platform is case insensitive, make lowercase the path.

wxPATH_NORM_ABSOLUTE Make the path absolute.

wxPATH_NORM_LONG Expand the path to the "long" form (Windows only).

wxPATH_NORM_SHORTCUT Resolve the shortcut, if it is a shortcut (Windows only).

wxPATH_NORM_ALL A value indicating all normalization flags except for `wxPATH_NORM_CASE`.

enum wxSizeConvention

Different conventions for human readable sizes.

See also

wxFileName::GetHumanReadableSize().

Since

2.9.1

Enumerator

wxSIZE_CONV_TRADITIONAL 1024 bytes = 1KB.

wxSIZE_CONV_IEC 1024 bytes = 1KiB.

wxSIZE_CONV_SI 1000 bytes = 1KB.

22.272.2 Variable Documentation

wxULongLong wxInvalidSize

The return value of wxFileName::GetSize() in case of error.

22.273 interface/wx/filepicker.h File Reference

Classes

- class wxFilePickerCtrl

  This control allows the user to select a file.
- class wxDirPickerCtrl

  This control allows the user to select a directory.
- class wxFileDirPickerEvent

  This event class is used for the events generated by wxFilePickerCtrl and by wxDirPickerCtrl.

Macros

- #define wxFLP_OPEN 0x0400

22.273.2 Variable Documentation

wxEventType wxEVT_DIRPICKER_CHANGED

wxEventType wxEVT_FILEPICKER_CHANGED

22.274 interface/wx/filesys.h File Reference

Classes

- class wxFileSystem

  This class provides an interface for opening files on different file systems.
- class wxFSFile

  This class represents a single file opened by wxFileSystem.
- class wxFileSystemHandler

  Classes derived from wxFileSystemHandler are used to access virtual file systems.
- class wxFSInputStream

  Input stream for virtual file stream files.

Enumerations

- enum wxFileSystemOpenFlags {
  wxFS_READ = 1,
  wxFS_SEEKABLE = 4 }

  Open Bit Flags.

22.274.1 Enumeration Type Documentation

enum wxFileSystemOpenFlags

Open Bit Flags.

Enumerator

wxFS_READ Open for reading.

wxFS_SEEKABLE Returned stream will be seekable.

22.275 interface/wx/fontdata.h File Reference

Classes

- class wxFontData

  This class holds a variety of information related to font dialogs.

22.276 interface/wx/fontdlg.h File Reference

Classes

- class wxFontDialog

  This class represents the font chooser dialog.

Functions

- wxFont wxGetFontFromUser (wxWindow *parent, const wxFont &fontInit, const wxString &caption=wxEmptyString)

  Shows the font selection dialog and returns the font selected by user or invalid font (use wxFont::IsOk() to test whether a font is valid) if the dialog was cancelled.

22.277 interface/wx/fontenum.h File Reference

Classes

- class wxFontEnumerator

  wxFontEnumerator enumerates either all available fonts on the system or only the ones with given attributes - either only fixed-width (suited for use in programs such as terminal emulators and the like) or the fonts available in the given encoding).

22.278 interface/wx/fontmap.h File Reference

Classes

- class wxFontMapper

  wxFontMapper manages user-definable correspondence between logical font names and the fonts present on the machine.

22.279 interface/wx/fontpicker.h File Reference

Classes

- class wxFontPickerCtrl

  This control allows the user to select a font.
- class wxFontPickerEvent

  This event class is used for the events generated by wxFontPickerCtrl.

Macros

- #define wxFNTP_FONTDESC_AS_LABEL 0x0008
- #define wxFNTP_USEFONT_FOR_LABEL 0x0010
- #define wxFONTBTN_DEFAULT_STYLE (wxFNTP_FONTDESC_AS_LABEL | wxFNTP_USEFONT_FOR↩_LABEL)
- #define wxFNTP_USE_TEXTCTRL (wxPB_USE_TEXTCTRL)
- #define wxFNTP_DEFAULT_STYLE (wxFNTP_FONTDESC_AS_LABEL|wxFNTP_USEFONT_FOR_LAB↩EL)

Variables

- wxEventType wxEVT_FONTPICKER_CHANGED

22.279.1 Macro Definition Documentation

#define wxFNTP_DEFAULT_STYLE (wxFNTP_FONTDESC_AS_LABEL|wxFNTP_USEFONT_FOR_LABEL)

#define wxFNTP_FONTDESC_AS_LABEL 0x0008

#define wxFNTP_USE_TEXTCTRL (wxPB_USE_TEXTCTRL)

#define wxFNTP_USEFONT_FOR_LABEL 0x0010

22.279.2 Variable Documentation

wxEventType wxEVT_FONTPICKER_CHANGED

22.280 interface/wx/fontutil.h File Reference

Classes

- class wxNativeFontInfo

  wxNativeFontInfo is platform-specific font representation: this class should be considered as an opaque font description only used by the native functions, the user code can only get the objects of this type from somewhere and pass it somewhere else (possibly save them somewhere using ToString() and restore them using FromString())

22.281 interface/wx/frame.h File Reference

Classes

- class wxFrame

  A frame is a window whose size and position can (usually) be changed by the user.

Macros

- #define wxFRAME_NO_TASKBAR 0x0002

  Frame specific styles.
- #define wxFRAME_TOOL_WINDOW 0x0004
- #define wxFRAME_FLOAT_ON_PARENT 0x0008

22.281.1 Macro Definition Documentation

#define wxFRAME_FLOAT_ON_PARENT 0x0008

#define wxFRAME_NO_TASKBAR 0x0002

Frame specific styles.

#define wxFRAME_TOOL_WINDOW 0x0004

22.282 interface/wx/fs_arc.h File Reference

Classes

- class wxArchiveFSHandler

  A file system handler for accessing files inside of archives.

Typedefs

- typedef wxArchiveFSHandler wxZipFSHandler

22.282.1 Typedef Documentation

typedef wxArchiveFSHandler wxZipFSHandler

22.283 interface/wx/fs_filter.h File Reference

Classes

- class wxFilterFSHandler

  Filter file system handler.

22.284 interface/wx/fs_inet.h File Reference

Classes

- class wxInternetFSHandler

  A file system handler for accessing files from internet servers.

22.285 interface/wx/fs_mem.h File Reference

Classes

- class wxMemoryFSHandler

  This wxFileSystem handler can store arbitrary data in memory stream and make them accessible via an URL.

22.286 interface/wx/fswatcher.h File Reference

Classes

- class wxFileSystemWatcher

  The wxFileSystemWatcher class allows to receive notifications of file system changes.
- class wxFileSystemWatcherEvent

  A class of events sent when a file system event occurs.

Enumerations

- enum wxFSWFlags {
  wxFSW_EVENT_CREATE = 0x01,
  wxFSW_EVENT_DELETE = 0x02,
  wxFSW_EVENT_RENAME = 0x04,
  wxFSW_EVENT_MODIFY = 0x08,
  wxFSW_EVENT_ACCESS = 0x10,
  wxFSW_EVENT_ATTRIB = 0x20,
  wxFSW_EVENT_UNMOUNT = 0x2000,
  wxFSW_EVENT_WARNING = 0x40,
  wxFSW_EVENT_ERROR = 0x80,
  wxFSW_EVENT_ALL }

  These are the possible types of file system change events.

- enum wxFSWWarningType {
  wxFSW_WARNING_NONE,
  wxFSW_WARNING_GENERAL,
  wxFSW_WARNING_OVERFLOW }

  Possible warning types for the warning events generated by wxFileSystemWatcher.

Variables

- wxEventType wxEVT_FSWATCHER

22.286.1 Enumeration Type Documentation

enum wxFSWFlags

These are the possible types of file system change events.

Not all of these events are reported on all platforms currently.

Since

2.9.1

Enumerator

wxFSW_EVENT_CREATE File or directory was created.

wxFSW_EVENT_DELETE File or directory was deleted.

wxFSW_EVENT_RENAME File or directory was renamed. Notice that under MSW this event is sometimes – although not always – followed by a wxFSW_EVENT_MODIFY for the new file.

Under OS X this event is currently not detected and instead separate wxFSW_EVENT_CREATE and wxFSW_EVENT_DELETE events are.

wxFSW_EVENT_MODIFY File or directory was modified. Depending on the program doing the file modification, multiple such events can be reported for a single logical file update.

Under OS X this event is currently not detected.

wxFSW_EVENT_ACCESS File or directory was accessed. This event is currently only detected under Linux.

wxFSW_EVENT_ATTRIB The item's metadata was changed, e.g. its permissions or timestamps. This event is currently only detected under Linux.

Since

2.9.5

wxFSW_EVENT_UNMOUNT The file system containing a watched item was unmounted. wxFSW_EVENT_UNMOUNT cannot be set; unmount events are produced automatically. This flag is therefore not included in wxFSW_EVENT_ALL.

This event is currently only detected under Linux.

Since

2.9.5

wxFSW_EVENT_WARNING A warning condition arose. This is something that probably needs to be shown to the user in an interactive program as it can indicate a relatively serious problem, e.g. some events could have been missed because of an overflow. But more events will still be coming in the future, unlike for the error condition below.

wxFSW_EVENT_ERROR An error condition arose. Errors are fatal, i.e. no more events will be reported after an error and the program can stop watching the directories currently being monitored.

wxFSW_EVENT_ALL

enum wxFSWWarningType

Possible warning types for the warning events generated by wxFileSystemWatcher.

Since

3.0

Enumerator

wxFSW_WARNING_NONE This is not a warning at all.

wxFSW_WARNING_GENERAL A generic warning. Further information may be provided in the user-readable message available from wxFileSystemWatcherEvent::GetErrorDescription()

wxFSW_WARNING_OVERFLOW An overflow event. This warning indicates that some file system changes were not signaled by any events, usually because there were too many of them and the internally used queue has overflown. If such event is received it is recommended to completely rescan the files or directories being monitored.

22.286.2 Variable Documentation

wxEventType wxEVT_FSWATCHER

22.287 interface/wx/gauge.h File Reference

Classes

- class wxGauge

  A gauge is a horizontal or vertical bar which shows a quantity (often time).

Macros

- #define wxGA_HORIZONTAL wxHORIZONTAL
- #define wxGA_VERTICAL wxVERTICAL
- #define wxGA_PROGRESS 0x0010
- #define wxGA_SMOOTH 0x0020
- #define wxGA_TEXT 0x0040

22.287.1 Macro Definition Documentation

#define wxGA_HORIZONTAL wxHORIZONTAL

#define wxGA_PROGRESS 0x0010

#define wxGA_SMOOTH 0x0020

#define wxGA_TEXT 0x0040

#define wxGA_VERTICAL wxVERTICAL

22.288 interface/wx/gbsizer.h File Reference

Classes

- class wxGBPosition

This class represents the position of an item in a virtual grid of rows and columns managed by a wxGridBagSizer.

- class wxGridBagSizer

  A wxSizer that can lay out items in a virtual grid like a wxFlexGridSizer but in this case explicit positioning of the items is allowed using wxGBPosition, and items can optionally span more than one row and/or column using wxGBSpan.

- class wxGBSizerItem

  The wxGBSizerItem class is used by the wxGridBagSizer for tracking the items in the sizer.

- class wxGBSpan

  This class is used to hold the row and column spanning attributes of items in a wxGridBagSizer.

Variables

- const wxGBSpan wxDefaultSpan

22.288.1 Variable Documentation

const wxGBSpan wxDefaultSpan

22.289 interface/wx/gdicmn.h File Reference

Classes

- class wxRealPoint

  A wxRealPoint is a useful data structure for graphics operations.

- class wxRect

  A class for manipulating rectangles.

- class wxPoint

  A wxPoint is a useful data structure for graphics operations.

- class wxColourDatabase

  wxWidgets maintains a database of standard RGB colours for a predefined set of named colours.

- class wxSize

  A wxSize is a useful data structure for graphics operations.

Macros

- #define wxBITMAP(bitmapName)

  This macro loads a bitmap from either application resources (on the platforms for which they exist, i.e. Windows) or from an XPM file.

- #define wxBITMAP_PNG(bitmapName)

  Creates a bitmap from either application resources or embedded image data in PNG format.

- #define wxBITMAP_PNG_FROM_DATA(bitmapName)

  Creates a bitmap from embedded image data in PNG format.

- #define wxICON(iconName)

  This macro loads an icon from either application resources (on the platforms for which they exist, i.e. Windows) or from an XPM file.

Enumerations

- enum wxBitmapType {
  wxBITMAP_TYPE_INVALID,
  wxBITMAP_TYPE_BMP,

  wxCURSOR_CROSS_REVERSE,
  wxCURSOR_DOUBLE_ARROW,
  wxCURSOR_BASED_ARROW_UP,
  wxCURSOR_BASED_ARROW_DOWN,
  wxCURSOR_ARROWWAIT,
  wxCURSOR_MAX }

  Standard cursors.

Functions

- bool wxColourDisplay ()

  Returns true if the display is colour, false otherwise.
- int wxDisplayDepth ()

  Returns the depth of the display (a value of 1 denotes a monochrome display).
- void wxSetCursor (const wxCursor &cursor)

  Globally sets the cursor; only has an effect on Windows, Mac and GTK+.
- void wxClientDisplayRect (int *x, int *y, int *width, int *height)

  Returns the dimensions of the work area on the display.
- wxRect wxGetClientDisplayRect ()

  Returns the dimensions of the work area on the display.
- wxSize wxGetDisplayPPI ()

  Returns the display resolution in pixels per inch.
- void wxDisplaySize (int *width, int *height)

  Returns the display size in pixels.
- wxSize wxGetDisplaySize ()

Returns the display size in pixels.

- void wxDisplaySizeMM (int *width, int *height)

  Returns the display size in millimeters.

- wxSize wxGetDisplaySizeMM ()

  Returns the display size in millimeters.

Variables

- const wxPoint wxDefaultPosition

  Global instance of a wxPoint initialized with values (-1,-1).

- wxColourDatabase * wxTheColourDatabase

  Global instance of a wxColourDatabase.

- const wxSize wxDefaultSize

  Global instance of a wxSize object initialized to (-1,-1).

22.289.1 Enumeration Type Documentation

enum wxBitmapType

Bitmap type flags.

See wxBitmap and wxImage classes.

enum wxPolygonFillMode

Polygon filling mode.

See wxDC::DrawPolygon.

Enumerator

wxODDEVEN_RULE

wxWINDING_RULE

enum wxStockCursor

Standard cursors.

Notice that under wxMSW some of these cursors are defined in `wx.rc` file and not by the system itself so you should include this file from your own resource file (possibly creating a trivial resource file just containing a single include line if you don't need it otherwise) to be able to use them.

See wxCursor.

Enumerator

wxCURSOR_NONE

wxCURSOR_ARROW A standard arrow cursor.

wxCURSOR_RIGHT_ARROW A standard arrow cursor pointing to the right.

wxCURSOR_BULLSEYE Bullseye cursor.

wxCURSOR_CHAR Rectangular character cursor.

wxCURSOR_CROSS A cross cursor.

wxCURSOR_HAND A hand cursor.

wxCURSOR_IBEAM An I-beam cursor (vertical line).

wxCURSOR_LEFT_BUTTON Represents a mouse with the left button depressed.

wxCURSOR_MAGNIFIER A magnifier icon.

wxCURSOR_MIDDLE_BUTTON Represents a mouse with the middle button depressed.

wxCURSOR_NO_ENTRY A no-entry sign cursor.

wxCURSOR_PAINT_BRUSH A paintbrush cursor.

wxCURSOR_PENCIL A pencil cursor.

wxCURSOR_POINT_LEFT A cursor that points left.
wxCURSOR_POINT_RIGHT A cursor that points right.
wxCURSOR_QUESTION_ARROW An arrow and question mark.
wxCURSOR_RIGHT_BUTTON Represents a mouse with the right button depressed.
wxCURSOR_SIZENESW A sizing cursor pointing NE-SW.
wxCURSOR_SIZENS A sizing cursor pointing N-S.
wxCURSOR_SIZENWSE A sizing cursor pointing NW-SE.
wxCURSOR_SIZEWE A sizing cursor pointing W-E.
wxCURSOR_SIZING A general sizing cursor.
wxCURSOR_SPRAYCAN A spraycan cursor.
wxCURSOR_WAIT A wait cursor.
wxCURSOR_WATCH A watch cursor.
wxCURSOR_BLANK Transparent cursor.
wxCURSOR_DEFAULT Standard X11 cursor (only in wxGTK).
wxCURSOR_COPY_ARROW MacOS Theme Plus arrow (only in wxMac).
wxCURSOR_CROSS_REVERSE Only available on wxX11.
wxCURSOR_DOUBLE_ARROW Only available on wxX11.
wxCURSOR_BASED_ARROW_UP Only available on wxX11.
wxCURSOR_BASED_ARROW_DOWN Only available on wxX11.
wxCURSOR_ARROWWAIT A wait cursor with a standard arrow.
wxCURSOR_MAX

22.289.2 Variable Documentation

const wxPoint wxDefaultPosition

Global instance of a wxPoint initialized with values (-1,-1).

const wxSize wxDefaultSize

Global instance of a wxSize object initialized to (-1,-1).

wxColourDatabase* wxTheColourDatabase

Global instance of a wxColourDatabase.

22.290 interface/wx/gdiobj.h File Reference

Classes

- class wxGDIObject
  This class allows platforms to implement functionality to optimise GDI objects, such as wxPen, wxBrush and wxFont.

22.291 interface/wx/generic/aboutdlgg.h File Reference

Classes

- class wxGenericAboutDialog
  This class defines a customizable About dialog.

Functions

- void wxGenericAboutBox (const wxAboutDialogInfo &info, wxWindow *parent=NULL)

  Show generic about dialog.

22.291.1 Function Documentation

void wxGenericAboutBox (const wxAboutDialogInfo & *info*, wxWindow * *parent* = NULL)

Show generic about dialog.

This function does the same thing as wxAboutBox() except that it always uses the generic wxWidgets version of the dialog instead of the native one.

22.292 interface/wx/generic/helpext.h File Reference

Classes

- class wxExtHelpController

  This class implements help via an external browser.

Classes

- class wxGLContext

  An instance of a wxGLContext represents the state of an OpenGL state machine and the connection between OpenGL and the system.
- class wxGLCanvas

  wxGLCanvas is a class for displaying OpenGL graphics.

Enumerations

- enum {
  WX_GL_RGBA = 1,
  WX_GL_BUFFER_SIZE,
  WX_GL_LEVEL,
  WX_GL_DOUBLEBUFFER,
  WX_GL_STEREO,
  WX_GL_AUX_BUFFERS,
  WX_GL_MIN_RED,
  WX_GL_MIN_GREEN,
  WX_GL_MIN_BLUE,
  WX_GL_MIN_ALPHA,
  WX_GL_DEPTH_SIZE,
  WX_GL_STENCIL_SIZE,
  WX_GL_MIN_ACCUM_RED,
  WX_GL_MIN_ACCUM_GREEN,
  WX_GL_MIN_ACCUM_BLUE,
  WX_GL_MIN_ACCUM_ALPHA,
  WX_GL_SAMPLE_BUFFERS,
  WX_GL_SAMPLES,
  WX_GL_CORE_PROFILE,
  WX_GL_MAJOR_VERSION,
  WX_GL_MINOR_VERSION }

22.294.1 Enumeration Type Documentation

anonymous enum

Constants for use with wxGLCanvas.

Note

Not all implementations support options such as stereo, auxiliary buffers, alpha channel, and accumulator buffer, use wxGLCanvas::IsDisplaySupported() to check for individual attributes support.

Enumerator

WX_GL_RGBA Use true color (the default if no attributes at all are specified); do not use a palette.

WX_GL_BUFFER_SIZE Specifies the number of bits for buffer if not WX_GL_RGBA.

WX_GL_LEVEL Must be followed by 0 for main buffer, >0 for overlay, <0 for underlay.

WX_GL_DOUBLEBUFFER Use double buffering if present (on if no attributes specified).

WX_GL_STEREO Use stereoscopic display.

WX_GL_AUX_BUFFERS Specifies number of auxiliary buffers.

WX_GL_MIN_RED Use red buffer with most bits (> MIN_RED bits)

WX_GL_MIN_GREEN Use green buffer with most bits (> MIN_GREEN bits)

WX_GL_MIN_BLUE Use blue buffer with most bits (> MIN_BLUE bits)

WX_GL_MIN_ALPHA Use alpha buffer with most bits (> MIN_ALPHA bits)

WX_GL_DEPTH_SIZE Specifies number of bits for Z-buffer (typically 0, 16 or 32).

WX_GL_STENCIL_SIZE Specifies number of bits for stencil buffer.

WX_GL_MIN_ACCUM_RED Specifies minimal number of red accumulator bits.

WX_GL_MIN_ACCUM_GREEN Specifies minimal number of green accumulator bits.

WX_GL_MIN_ACCUM_BLUE Specifies minimal number of blue accumulator bits.

WX_GL_MIN_ACCUM_ALPHA Specifies minimal number of alpha accumulator bits.

WX_GL_SAMPLE_BUFFERS 1 for multisampling support (antialiasing)

WX_GL_SAMPLES 4 for 2x2 antialiasing supersampling on most graphics cards

WX_GL_CORE_PROFILE Request an OpenGL core profile. Notice that using this attribute will result in also requesting OpenGL at least version 3.0.

See WX_GL_MAJOR_VERSION and WX_GL_MINOR_VERSION for more precise version selection.

Since

3.1.0

WX_GL_MAJOR_VERSION Request specific OpenGL core major version number (>= 3). This attribute should be followed by the major version number requested.

It has no effect under OS X where specifying WX_GL_CORE_PROFILE will result in using OpenGL version at least 3.2 but can still be used there for portability.

Since

3.1.0

WX_GL_MINOR_VERSION Request specific OpenGL core minor version number. This attribute has the same semantics as WX_GL_MAJOR_VERSION but is for the minor OpenGL version, e.g. 2 if OpenGL 3.2 is requested.

Since

3.1.0

22.295 interface/wx/graphics.h File Reference

Classes

- class wxGraphicsPath

  A wxGraphicsPath is a native representation of a geometric path.
- class wxGraphicsObject

  This class is the superclass of native graphics objects like pens etc.
- class wxGraphicsBitmap

  Represents a bitmap.
- class wxGraphicsContext

  A wxGraphicsContext instance is the object that is drawn upon.
- class wxGraphicsGradientStop

  Represents a single gradient stop in a collection of gradient stops as represented by wxGraphicsGradientStops.
- class wxGraphicsGradientStops

  Represents a collection of wxGraphicGradientStop values for use with CreateLinearGradientBrush and CreateRadialGradientBrush.

- class wxGraphicsRenderer

  A wxGraphicsRenderer is the instance corresponding to the rendering engine used.
- class wxGraphicsBrush

  A wxGraphicsBrush is a native representation of a brush.
- class wxGraphicsFont

  A wxGraphicsFont is a native representation of a font.
- class wxGraphicsPen

  A wxGraphicsPen is a native representation of a pen.
- class wxGraphicsMatrix

  A wxGraphicsMatrix is a native representation of an affine matrix.

Enumerations

- enum wxAntialiasMode {
  wxANTIALIAS_NONE,
  wxANTIALIAS_DEFAULT }

  Anti-aliasing modes used by wxGraphicsContext::SetAntialiasMode().
- enum wxInterpolationQuality {
  wxINTERPOLATION_DEFAULT,
  wxINTERPOLATION_NONE,
  wxINTERPOLATION_FAST,
  wxINTERPOLATION_GOOD,
  wxINTERPOLATION_BEST }

  Interpolation quality used by wxGraphicsContext::SetInterpolationQuality().
- enum wxCompositionMode {
  wxCOMPOSITION_INVALID = -1,
  wxCOMPOSITION_CLEAR,
  wxCOMPOSITION_SOURCE,
  wxCOMPOSITION_OVER,
  wxCOMPOSITION_IN,
  wxCOMPOSITION_OUT,
  wxCOMPOSITION_ATOP,
  wxCOMPOSITION_DEST,
  wxCOMPOSITION_DEST_OVER,
  wxCOMPOSITION_DEST_IN,
  wxCOMPOSITION_DEST_OUT,
  wxCOMPOSITION_DEST_ATOP,
  wxCOMPOSITION_XOR,
  wxCOMPOSITION_ADD }

  Compositing is done using Porter-Duff compositions (see `http://keithp.com/~keithp/porterduff/p253-porter.↩pdf` *) with wxGraphicsContext::SetCompositionMode().*

Variables

- const wxGraphicsPen wxNullGraphicsPen
- const wxGraphicsBrush wxNullGraphicsBrush
- const wxGraphicsFont wxNullGraphicsFont
- const wxGraphicsBitmap wxNullGraphicsBitmap
- const wxGraphicsMatrix wxNullGraphicsMatrix
- const wxGraphicsPath wxNullGraphicsPath

22.295.1 Enumeration Type Documentation

enum wxAntialiasMode

Anti-aliasing modes used by wxGraphicsContext::SetAntialiasMode().

Enumerator

wxANTIALIAS_NONE No anti-aliasing.

wxANTIALIAS_DEFAULT The default anti-aliasing.

enum wxCompositionMode

Compositing is done using Porter-Duff compositions (see http://keithp.com/~keithp/porterduff/p253-porter.pdf) with wxGraphicsContext::SetCompositionMode().

The description give a short equation on how the values of a resulting pixel are calculated. *R* = Result, *S* = Source, *D* = Destination, colors premultiplied with alpha *Ra*, *Sa*, *Da* their alpha components

Enumerator

wxCOMPOSITION_INVALID Indicates invalid or unsupported composition mode. This value can't be passed to wxGraphicsContext::SetCompositionMode().

Since

2.9.2

wxCOMPOSITION_CLEAR *R* = 0

wxCOMPOSITION_SOURCE *R* = S

wxCOMPOSITION_OVER *R* = *S* + *D*∗(1 - *Sa*)

wxCOMPOSITION_IN *R* = *S*∗*Da*

wxCOMPOSITION_OUT *R* = *S*∗(1 - *Da*)

wxCOMPOSITION_ATOP *R* = *S*∗*Da* + *D*∗(1 - *Sa*)

wxCOMPOSITION_DEST *R* = *D*, essentially a noop

wxCOMPOSITION_DEST_OVER *R* = *S*∗(1 - *Da*) + *D*

wxCOMPOSITION_DEST_IN *R* = *D*∗*Sa*

wxCOMPOSITION_DEST_OUT *R* = *D*∗(1 - *Sa*)

wxCOMPOSITION_DEST_ATOP *R* = *S*∗(1 - *Da*) + *D*∗*Sa*

wxCOMPOSITION_XOR *R* = *S*∗(1 - *Da*) + *D*∗(1 - *Sa*)

wxCOMPOSITION_ADD *R* = *S* + *D*

enum wxInterpolationQuality

Interpolation quality used by wxGraphicsContext::SetInterpolationQuality().

Enumerator

wxINTERPOLATION_DEFAULT default interpolation, based on type of context, in general medium quality

wxINTERPOLATION_NONE no interpolation

wxINTERPOLATION_FAST fast interpolation, suited for interactivity

wxINTERPOLATION_GOOD better quality

wxINTERPOLATION_BEST best quality, not suited for interactivity

22.295.2 Variable Documentation

22.296 interface/wx/hash.h File Reference

Classes

- class wxHashTable

22.297 interface/wx/hashmap.h File Reference

Classes

- class wxHashMap

  This is a simple, type-safe, and reasonably efficient hash map class, whose interface is a subset of the interface of STL containers.

22.298 interface/wx/hashset.h File Reference

Classes

- class wxHashSet

  This is a simple, type-safe, and reasonably efficient hash set class, whose interface is a subset of the interface of STL containers.

22.299 interface/wx/headercol.h File Reference

Classes

- class wxHeaderColumn

  Represents a column header in controls displaying tabular data such as wxDataViewCtrl or wxGrid.
- class wxSettableHeaderColumn

  Adds methods to set the column attributes to wxHeaderColumn.
- class wxHeaderColumnSimple

  Simple container for the information about the column.

Enumerations

- enum {
  wxCOL_WIDTH_DEFAULT = -1,
  wxCOL_WIDTH_AUTOSIZE = -2 }

  Column width special values.
- enum {
  wxCOL_RESIZABLE = 1,
  wxCOL_SORTABLE = 2,
  wxCOL_REORDERABLE = 4,
  wxCOL_HIDDEN = 8,
  wxCOL_DEFAULT_FLAGS = wxCOL_RESIZABLE | wxCOL_REORDERABLE }

  Bit flags used as wxHeaderColumn flags.

22.299.1 Enumeration Type Documentation

anonymous enum

Column width special values.

Enumerator

wxCOL_WIDTH_DEFAULT Special value used for column width meaning unspecified or default.

wxCOL_WIDTH_AUTOSIZE Size the column automatically to fit all values.

Note

On OS X, this style is only implemented in the Cocoa build on OS X >= 10.5; it behaves identically to wxCOL_WIDTH_DEFAULT otherwise.

anonymous enum

Bit flags used as wxHeaderColumn flags.

Enumerator

wxCOL_RESIZABLE Column can be resized (included in default flags).

wxCOL_SORTABLE Column can be clicked to toggle the sort order by its contents.

wxCOL_REORDERABLE Column can be dragged to change its order (included in default).

wxCOL_HIDDEN Column is not shown at all.

wxCOL_DEFAULT_FLAGS Default flags for wxHeaderColumn ctor.

22.300 interface/wx/headerctrl.h File Reference

Classes

- class wxHeaderCtrl

  wxHeaderCtrl is the control containing the column headings which is usually used for display of tabular data.
- class wxHeaderCtrlSimple

  wxHeaderCtrlSimple is a concrete header control which can be used directly, without inheriting from it as you need to do when using wxHeaderCtrl itself.
- class wxHeaderCtrlEvent

  Event class representing the events generated by wxHeaderCtrl.

Enumerations

- enum {
  wxHD_ALLOW_REORDER = 0x0001,
  wxHD_ALLOW_HIDE = 0x0002,
  wxHD_DEFAULT_STYLE = wxHD_ALLOW_REORDER }

Variables

22.301 interface/wx/help.h File Reference

Classes

- class wxHelpControllerBase

  This is the abstract base class a family of classes by which applications may invoke a help viewer to provide on-line help.
- class wxHelpController

  This is an alias for one of a family of help controller classes which is most appropriate for the current platform.

Macros

- #define wxHELP_NETSCAPE 1

Enumerations

- enum wxHelpSearchMode {
  wxHELP_SEARCH_INDEX,
  wxHELP_SEARCH_ALL }

  Help search modes for wxHelpController::KeywordSearch().

22.301.1 Macro Definition Documentation

#define wxHELP_NETSCAPE 1

22.301.2 Enumeration Type Documentation

enum wxHelpSearchMode

Help search modes for wxHelpController::KeywordSearch().

Enumerator

wxHELP_SEARCH_INDEX Search the index only.

wxHELP_SEARCH_ALL Search all entries.

22.302 interface/wx/html/helpctrl.h File Reference

Classes

- class wxHtmlHelpController

  This help controller provides an easy way of displaying HTML help in your application (see HTML Sample, test example).
- class wxHtmlModalHelp

  This class uses wxHtmlHelpController to display help in a modal dialog.

Macros

- #define wxID_HTML_HELPFRAME (wxID_HIGHEST + 1)
- #define wxHF_EMBEDDED 0x00008000

  This style indicates that the window is embedded in the application and must not be destroyed by the help controller.
- #define wxHF_DIALOG 0x00010000

  Create a dialog for the help window.
- #define wxHF_FRAME 0x00020000

  Create a frame for the help window.
- #define wxHF_MODAL 0x00040000

  Make the dialog modal when displaying help.

22.302.1 Macro Definition Documentation

#define wxHF_DIALOG 0x00010000

Create a dialog for the help window.

#define wxHF_EMBEDDED 0x00008000

This style indicates that the window is embedded in the application and must not be destroyed by the help controller.

#define wxHF_FRAME 0x00020000

Create a frame for the help window.

#define wxHF_MODAL 0x00040000

Make the dialog modal when displaying help.

#define wxID_HTML_HELPFRAME (wxID_HIGHEST + 1)

Classes

- class wxHtmlSelection
- class wxHtmlRenderingState

  Selection state is passed to wxHtmlCell::Draw so that it can render itself differently e.g.
- class wxHtmlRenderingStyle

  wxHtmlSelection is data holder with information about text selection.
- class wxHtmlRenderingInfo

  This class contains information given to cells when drawing them.
- class wxHtmlCell

  Internal data structure.
- class wxHtmlContainerCell

  The wxHtmlContainerCell class is an implementation of a cell that may contain more cells in it.
- class wxHtmlLinkInfo

  This class stores all necessary information about hypertext links (as represented by <A> tag in HTML documents).
- class wxHtmlColourCell

  This cell changes the colour of either the background or the foreground.
- class wxHtmlWidgetCell

  wxHtmlWidgetCell is a class that provides a connection between HTML cells and widgets (an object derived from wxWindow).
- class wxHtmlWordCell

This html cell represents a single word or text fragment in the document stream.

- class wxHtmlWordWithTabsCell

  wxHtmlWordCell is a specialization for storing text fragments with embedded tab characters.

- class wxHtmlFontCell

  This cell represents a font change in the document stream.

- class wxHtmlTagHandler
- class wxHtmlParser

  *Classes derived from this handle the **generic** parsing of HTML documents: it scans the document and divide it into blocks of tags (where one block consists of beginning and ending tag and of text between these two tags).*

Enumerations

- enum wxHtmlURLType {
  wxHTML_URL_PAGE,
  wxHTML_URL_IMAGE,
  wxHTML_URL_OTHER }

22.310.1 Enumeration Type Documentation

enum **wxHtmlURLType**

Enumerator

wxHTML_URL_PAGE

wxHTML_URL_IMAGE

wxHTML_URL_OTHER

22.311 interface/wx/html/htmltag.h File Reference

Classes

- class wxHtmlTag

  This class represents a single HTML tag.

22.312 interface/wx/html/htmlwin.h File Reference

Classes

- class wxHtmlWindowInterface

  Abstract interface to a HTML rendering window (such as wxHtmlWindow or wxHtmlListBox) that is passed to wxHtmlWinParser.
- class wxHtmlWindow

  wxHtmlWindow is probably the only class you will directly use unless you want to do something special (like adding new tag handlers or MIME filters).
- class wxHtmlLinkEvent

  This event class is used for the events generated by wxHtmlWindow.
- class wxHtmlCellEvent

  This event class is used for the events generated by wxHtmlWindow.

Macros

- #define wxHW_SCROLLBAR_NEVER 0x0002
- #define wxHW_SCROLLBAR_AUTO 0x0004
- #define wxHW_NO_SELECTION 0x0008
- #define wxHW_DEFAULT_STYLE wxHW_SCROLLBAR_AUTO

Enumerations

- enum wxHtmlOpeningStatus {
  wxHTML_OPEN,
  wxHTML_BLOCK,
  wxHTML_REDIRECT }

  Enum for wxHtmlWindow::OnOpeningURL and wxHtmlWindowInterface::OnOpeningURL.

Variables

- wxEventType wxEVT_HTML_CELL_CLICKED
- wxEventType wxEVT_HTML_CELL_HOVER
- wxEventType wxEVT_HTML_LINK_CLICKED

22.312.1 Macro Definition Documentation

#define wxHW_DEFAULT_STYLE wxHW_SCROLLBAR_AUTO

#define wxHW_NO_SELECTION 0x0008

#define wxHW_SCROLLBAR_AUTO 0x0004

#define wxHW_SCROLLBAR_NEVER 0x0002

22.312.2 Enumeration Type Documentation

enum wxHtmlOpeningStatus

Enum for wxHtmlWindow::OnOpeningURL and wxHtmlWindowInterface::OnOpeningURL.

Enumerator

wxHTML_OPEN Open the requested URL.

wxHTML_BLOCK Do not open the URL.

wxHTML_REDIRECT Redirect to another URL (returned from OnOpeningURL)

22.312.3 Variable Documentation

wxEventType wxEVT_HTML_CELL_CLICKED

wxEventType wxEVT_HTML_CELL_HOVER

wxEventType wxEVT_HTML_LINK_CLICKED

22.313 interface/wx/html/htmprint.h File Reference

Classes

- class wxHtmlDCRenderer

  This class can render HTML document into a specified area of a DC.
- class wxHtmlEasyPrinting

  This class provides very simple interface to printing architecture.
- class wxHtmlPrintout

  This class serves as printout class for HTML documents.

Enumerations

- enum {
  wxPAGE_ODD,
  wxPAGE_EVEN,
  wxPAGE_ALL }

22.313.1 Enumeration Type Documentation

anonymous enum

Enumerator

wxPAGE_ODD

wxPAGE_EVEN

wxPAGE_ALL

22.314 interface/wx/html/webkit.h File Reference

Classes

- class wxWebKitCtrl

  This control is a native wrapper around the Safari web browsing engine.
- class wxWebKitBeforeLoadEvent
- class wxWebKitStateChangedEvent
- class wxWebKitNewWindowEvent

Enumerations

- enum {
  wxWEBKIT_STATE_START = 1,
  wxWEBKIT_STATE_NEGOTIATING = 2,
  wxWEBKIT_STATE_REDIRECTING = 4,
  wxWEBKIT_STATE_TRANSFERRING = 8,

wxEventType wxEVT_WEBKIT_NEW_WINDOW

wxEventType wxEVT_WEBKIT_STATE_CHANGED

22.315 interface/wx/html/winpars.h File Reference

Classes

- class wxHtmlTagsModule

  This class provides easy way of filling wxHtmlWinParser's table of tag handlers.

- class wxHtmlWinTagHandler

  This is basically wxHtmlTagHandler except that it is extended with protected member m_WParser pointing to the wxHtmlWinParser object (value of this member is identical to wxHtmlParser's m_Parser).

- class wxHtmlWinParser

  This class is derived from wxHtmlParser and its main goal is to parse HTML input so that it can be displayed in wxHtmlWindow.

22.316 interface/wx/htmllbox.h File Reference

Classes

- class wxHtmlListBox

  wxHtmlListBox is an implementation of wxVListBox which shows HTML content in the listbox rows.

- class wxSimpleHtmlListBox

  wxSimpleHtmlListBox is an implementation of wxHtmlListBox which shows HTML content in the listbox rows.

22.317 interface/wx/hyperlink.h File Reference

Classes

- class wxHyperlinkEvent

  This event class is used for the events generated by wxHyperlinkCtrl.

- class wxHyperlinkCtrl

  This class shows a static text element which links to an URL.

Macros

- #define wxHL_CONTEXTMENU 0x0001
- #define wxHL_ALIGN_LEFT 0x0002
- #define wxHL_ALIGN_RIGHT 0x0004
- #define wxHL_ALIGN_CENTRE 0x0008
- #define wxHL_DEFAULT_STYLE (wxHL_CONTEXTMENU|wxNO_BORDER|wxHL_ALIGN_CENTRE)

Variables

- wxEventType wxEVT_HYPERLINK

22.317.1 Macro Definition Documentation

#define wxHL_ALIGN_CENTRE 0x0008

#define wxHL_ALIGN_LEFT 0x0002

#define wxHL_ALIGN_RIGHT 0x0004

#define wxHL_CONTEXTMENU 0x0001

22.317.2 Variable Documentation

wxEventType wxEVT_HYPERLINK

22.318 interface/wx/icon.h File Reference

Classes

- class wxIcon

  An icon is a small rectangular bitmap usually used for denoting a minimized application.

Macros

- #define wxICON_SCREEN_DEPTH (-1)

  In wxIcon context this value means: "use the screen depth".

Variables

- wxIcon wxNullIcon

  An empty wxIcon.

22.318.1 Macro Definition Documentation

#define wxICON_SCREEN_DEPTH (-1)

In wxIcon context this value means: "use the screen depth".

22.318.2 Variable Documentation

wxIcon wxNullIcon

An empty wxIcon.

22.319 interface/wx/iconbndl.h File Reference

Classes

- class wxIconBundle

  This class contains multiple copies of an icon in different sizes.

Variables

- wxIconBundle wxNullIconBundle

  An empty wxIconBundle.

22.319.1 Variable Documentation

wxIconBundle wxNullIconBundle

An empty wxIconBundle.

22.320 interface/wx/iconloc.h File Reference

Classes

- class wxIconLocation

  wxIconLocation is a tiny class describing the location of an (external, i.e.

22.321 interface/wx/image.h File Reference

Classes

- class wxImageHandler

  This is the base class for implementing image file loading/saving, and image creation from data.
- class wxImage

  This class encapsulates a platform-independent image.
- class wxImage::RGBValue

  A simple class which stores red, green and blue values as 8 bit unsigned integers in the range of 0-255.
- class wxImage::HSVValue

  A simple class which stores hue, saturation and value as doubles in the range 0.0-1.0.
- class wxImageHistogram

Macros

- #define wxIMAGE_OPTION_QUALITY wxString("quality")

  Image option names.
- #define wxIMAGE_OPTION_FILENAME wxString("FileName")
- #define wxIMAGE_OPTION_RESOLUTION wxString("Resolution")
- #define wxIMAGE_OPTION_RESOLUTIONX wxString("ResolutionX")
- #define wxIMAGE_OPTION_RESOLUTIONY wxString("ResolutionY")
- #define wxIMAGE_OPTION_RESOLUTIONUNIT wxString("ResolutionUnit")
- #define wxIMAGE_OPTION_MAX_WIDTH wxString("MaxWidth")
- #define wxIMAGE_OPTION_MAX_HEIGHT wxString("MaxHeight")
- #define wxIMAGE_OPTION_ORIGINAL_WIDTH wxString("OriginalWidth")
- #define wxIMAGE_OPTION_ORIGINAL_HEIGHT wxString("OriginalHeight")
- #define wxIMAGE_OPTION_BMP_FORMAT wxString("wxBMP_FORMAT")
- #define wxIMAGE_OPTION_CUR_HOTSPOT_X wxString("HotSpotX")
- #define wxIMAGE_OPTION_CUR_HOTSPOT_Y wxString("HotSpotY")
- #define wxIMAGE_OPTION_GIF_COMMENT wxString("GifComment")
- #define wxIMAGE_OPTION_PNG_FORMAT wxString("PngFormat")

- #define wxIMAGE_OPTION_PNG_BITDEPTH wxString("PngBitDepth")
- #define wxIMAGE_OPTION_PNG_FILTER wxString("PngF")

- #define wxIMAGE_OPTION_TIFF_SAMPLESPERPIXEL wxString("SamplesPerPixel")
- #define wxIMAGE_OPTION_TIFF_COMPRESSION wxString("Compression")
- #define wxIMAGE_OPTION_TIFF_PHOTOMETRIC wxString("Photometric")
- #define wxIMAGE_OPTION_TIFF_IMAGEDESCRIPTOR wxString("ImageDescriptor")

Enumerations

- enum wxImageResolution {
  wxIMAGE_RESOLUTION_NONE = 0,
  wxIMAGE_RESOLUTION_INCHES = 1,
  wxIMAGE_RESOLUTION_CM = 2 }

  Possible values for the image resolution option.
- enum wxImageResizeQuality {
  wxIMAGE_QUALITY_NEAREST,
  wxIMAGE_QUALITY_BILINEAR,
  wxIMAGE_QUALITY_BICUBIC,
  wxIMAGE_QUALITY_BOX_AVERAGE,
  wxIMAGE_QUALITY_NORMAL,
  wxIMAGE_QUALITY_HIGH }

  Image resize algorithm.
- enum wxImagePNGType {
  wxPNG_TYPE_COLOUR = 0,
  wxPNG_TYPE_GREY = 2,
  wxPNG_TYPE_GREY_RED = 3,
  wxPNG_TYPE_PALETTE = 4 }

  Possible values for PNG image type option.
- enum {
  wxBMP_24BPP = 24,
  wxBMP_8BPP = 8,
  wxBMP_8BPP_GREY = 9,
  wxBMP_8BPP_GRAY = wxBMP_8BPP_GREY,
  wxBMP_8BPP_RED = 10,
  wxBMP_8BPP_PALETTE = 11,
  wxBMP_4BPP = 4,
  wxBMP_1BPP = 1,
  wxBMP_1BPP_BW = 2 }

Functions

- void wxInitAllImageHandlers ()

  Initializes all available image handlers.

Variables

- const unsigned char wxIMAGE_ALPHA_TRANSPARENT = 0

  Constant used to indicate the alpha value conventionally defined as the complete transparency.
- const unsigned char wxIMAGE_ALPHA_OPAQUE = 0xff

Constant used to indicate the alpha value conventionally defined as the complete opacity.

- const unsigned char wxIMAGE_ALPHA_THRESHOLD = 0x80
- wxImage wxNullImage

  An instance of an empty image without an alpha channel.

22.321.1 Macro Definition Documentation

#define wxIMAGE_OPTION_BMP_FORMAT wxString("wxBMP_FORMAT")

22.321.2 Enumeration Type Documentation

anonymous enum

Enumerator

wxBMP_24BPP
wxBMP_8BPP
wxBMP_8BPP_GREY
wxBMP_8BPP_GRAY
wxBMP_8BPP_RED
wxBMP_8BPP_PALETTE
wxBMP_4BPP
wxBMP_1BPP
wxBMP_1BPP_BW

enum wxImagePNGType

Possible values for PNG image type option.

See also

wxImage::GetOptionInt().

Enumerator

wxPNG_TYPE_COLOUR Colour PNG image.
wxPNG_TYPE_GREY Greyscale PNG image converted from RGB.
wxPNG_TYPE_GREY_RED Greyscale PNG image using red as grey.
wxPNG_TYPE_PALETTE Palette encoding.

enum wxImageResizeQuality

Image resize algorithm.

This is used with wxImage::Scale() and wxImage::Rescale().

Enumerator

wxIMAGE_QUALITY_NEAREST Simplest and fastest algorithm.
wxIMAGE_QUALITY_BILINEAR Compromise between wxIMAGE_QUALITY_NEAREST and wxIMAGE_↩ QUALITY_BICUBIC.
wxIMAGE_QUALITY_BICUBIC Highest quality but slowest execution time.
wxIMAGE_QUALITY_BOX_AVERAGE Use surrounding pixels to calculate an average that will be used for new pixels. This method is typically used when reducing the size of an image.
wxIMAGE_QUALITY_NORMAL Default image resizing algorithm used by wxImage::Scale(). Currently the same as wxIMAGE_QUALITY_NEAREST.
wxIMAGE_QUALITY_HIGH Best image resizing algorithm. Since version 2.9.2 this results in wxIMAGE_Q↩ UALITY_BOX_AVERAGE being used when reducing the size of the image (meaning that both the new width and height will be smaller than the original size). Otherwise wxIMAGE_QUALITY_BICUBIC is used.

enum wxImageResolution

Possible values for the image resolution option.

See also

wxImage::GetOptionInt().

Enumerator

wxIMAGE_RESOLUTION_NONE Resolution not specified.

wxIMAGE_RESOLUTION_INCHES Resolution specified in inches.

wxIMAGE_RESOLUTION_CM Resolution specified in centimetres.

22.321.3 Variable Documentation

const unsigned char wxIMAGE_ALPHA_OPAQUE = 0xff

Constant used to indicate the alpha value conventionally defined as the complete opacity.

const unsigned char wxIMAGE_ALPHA_THRESHOLD = 0x80

const unsigned char wxIMAGE_ALPHA_TRANSPARENT = 0

Constant used to indicate the alpha value conventionally defined as the complete transparency.

wxImage wxNullImage

An instance of an empty image without an alpha channel.

22.322 interface/wx/imaglist.h File Reference

Classes

- class wxImageList

  A wxImageList contains a list of images, which are stored in an unspecified form.

Macros

- #define wxIMAGELIST_DRAW_NORMAL 0x0001

  Flags for Draw.
- #define wxIMAGELIST_DRAW_TRANSPARENT 0x0002
- #define wxIMAGELIST_DRAW_SELECTED 0x0004
- #define wxIMAGELIST_DRAW_FOCUSED 0x0008

Enumerations

- enum {
  wxIMAGE_LIST_NORMAL,
  wxIMAGE_LIST_SMALL,
  wxIMAGE_LIST_STATE }

  Flag values for Set/GetImageList.

22.322.1 Macro Definition Documentation

#define wxIMAGELIST_DRAW_FOCUSED 0x0008

#define wxIMAGELIST_DRAW_NORMAL 0x0001

Flags for Draw.

#define wxIMAGELIST_DRAW_SELECTED 0x0004

#define wxIMAGELIST_DRAW_TRANSPARENT 0x0002

22.322.2 Enumeration Type Documentation

anonymous enum

Flag values for Set/GetImageList.

Enumerator

wxIMAGE_LIST_NORMAL

wxIMAGE_LIST_SMALL

wxIMAGE_LIST_STATE

22.323 interface/wx/infobar.h File Reference

Classes

- class wxInfoBar

  An info bar is a transient window shown at top or bottom of its parent window to display non-critical information to the user.

22.324 interface/wx/init.h File Reference

Classes

- class wxInitializer

  Create an object of this class on the stack to initialize/cleanup the library automatically.

Functions

- bool wxEntryStart (int &argc, wxChar ∗∗argv)

  This function can be used to perform the initialization of wxWidgets if you can't use the default initialization code for any reason.
- bool wxEntryStart (HINSTANCE hInstance, HINSTANCE hPrevInstance=NULL, char ∗pCmdLine=NULL, int nCmdShow=SW_SHOWNORMAL)

  See wxEntryStart(int&,wxChar∗∗) for more info about this function.
- void wxEntryCleanup ()

  Free resources allocated by a successful call to wxEntryStart().
- bool wxInitialize (int argc=0, wxChar ∗∗argv=NULL)

Initialize the library (may be called as many times as needed, but each call to wxInitialize() must be matched by wxUninitialize()).

- void wxUninitialize ()

  This function is for use in console (wxBase) programs only.

22.325 interface/wx/intl.h File Reference

Classes

- struct wxLanguageInfo

  Encapsulates a wxLanguage identifier together with OS-specific information related to that language.

- class wxLocale

  wxLocale class encapsulates all language-dependent settings and is a generalization of the C locale concept.

Enumerations

- enum wxLayoutDirection {
  wxLayout_Default,
  wxLayout_LeftToRight,
  wxLayout_RightToLeft }

  This is the layout direction stored in wxLanguageInfo and returned by wxApp::GetLayoutDirection(), wxWindow::GetLayoutDirection(), wxDC::GetLayoutDirection() for RTL (right-to-left) languages support.

- enum wxLocaleCategory {
  wxLOCALE_CAT_NUMBER,
  wxLOCALE_CAT_DATE,
  wxLOCALE_CAT_MONEY,
  wxLOCALE_CAT_DEFAULT }

  The category of locale settings.

- enum wxLocaleInfo {
  wxLOCALE_THOUSANDS_SEP,
  wxLOCALE_DECIMAL_POINT,
  wxLOCALE_SHORT_DATE_FMT,
  wxLOCALE_LONG_DATE_FMT,
  wxLOCALE_DATE_TIME_FMT,
  wxLOCALE_TIME_FMT }

  The values understood by wxLocale::GetInfo().

22.325.1 Enumeration Type Documentation

enum wxLayoutDirection

This is the layout direction stored in wxLanguageInfo and returned by wxApp::GetLayoutDirection(), wxWindow::GetLayoutDirection(), wxDC::GetLayoutDirection() for RTL (right-to-left) languages support.

Enumerator

wxLayout_Default

wxLayout_LeftToRight

wxLayout_RightToLeft

enum wxLocaleCategory

The category of locale settings.

See also

wxLocale::GetInfo()

Enumerator

wxLOCALE_CAT_NUMBER Number formatting.

wxLOCALE_CAT_DATE Date/time formatting.

wxLOCALE_CAT_MONEY Monetary values formatting.

wxLOCALE_CAT_DEFAULT Default category for the wxLocaleInfo value. This category can be used for values which only make sense for a single category, e.g. wxLOCALE_SHORT_DATE_FMT which can only be used with wxLOCALE_CAT_DATE. As this is the default value of the second parameter of wxLocale::GetInfo(), wxLOCALE_CAT_DATE can be omitted when asking for wxLOCALE_SHORT_DATE_FMT value.

Since

2.9.0

enum wxLocaleInfo

The values understood by wxLocale::GetInfo().

Note that for the `wxLOCALE_*_FMT` constants (the date and time formats), the strings returned by wxLocale::GetInfo() use strftime() or, equivalently, wxDateTime::Format() format. If the relevant format couldn't be determined, an empty string is returned – there is no fallback value so that the application could determine the best course of actions itself in such case.

All of these values are used with `wxLOCALE_CAT_DATE` in wxLocale::GetInfo() or, more typically, with `wxLOCALE_CAT_DEFAULT` as they only apply to a single category.

Enumerator

wxLOCALE_THOUSANDS_SEP The thousands separator. This value can be used with either wxLOCALE_CAT_NUMBER or wxLOCALE_CAT_MONEY categories.

wxLOCALE_DECIMAL_POINT The character used as decimal point. This value can be used with either wxLOCALE_CAT_NUMBER or wxLOCALE_CAT_MONEY categories.

wxLOCALE_SHORT_DATE_FMT Short date format. Notice that short and long date formats may be the same under POSIX systems currently but may, and typically are, different under MSW or OS X.

Since

2.9.0

wxLOCALE_LONG_DATE_FMT Long date format.

Since

2.9.0

wxLOCALE_DATE_TIME_FMT Date and time format.

Since

2.9.0

wxLOCALE_TIME_FMT Time format.

Since

2.9.0

Classes

- class wxLayoutAlgorithm

  wxLayoutAlgorithm implements layout of subwindows in MDI or SDI frames.
- class wxSashLayoutWindow

  wxSashLayoutWindow responds to OnCalculateLayout events generated by wxLayoutAlgorithm.
- class wxQueryLayoutInfoEvent

  This event is sent when wxLayoutAlgorithm wishes to get the size, orientation and alignment of a window.
- class wxCalculateLayoutEvent

  This event is sent by wxLayoutAlgorithm to calculate the amount of the remaining client area that the window should occupy.

Enumerations

- enum wxLayoutOrientation {
  wxLAYOUT_HORIZONTAL,
  wxLAYOUT_VERTICAL }

  Enumeration used by wxLayoutAlgorithm.
- enum wxLayoutAlignment {
  wxLAYOUT_NONE,
  wxLAYOUT_TOP,
  wxLAYOUT_LEFT,
  wxLAYOUT_RIGHT,
  wxLAYOUT_BOTTOM }

  Enumeration used by wxLayoutAlgorithm.

Variables

- wxEventType wxEVT_QUERY_LAYOUT_INFO
- wxEventType wxEVT_CALCULATE_LAYOUT

22.331.1 Enumeration Type Documentation

enum wxLayoutAlignment

Enumeration used by wxLayoutAlgorithm.

Enumerator

wxEventType wxEVT_QUERY_LAYOUT_INFO

22.332 interface/wx/link.h File Reference

Macros

- #define wxFORCE_LINK_THIS_MODULE(moduleName)

  This macro can be used in conjunction with the wxFORCE_LINK_MODULE() macro to force the linker to include in its output a specific object file.
- #define wxFORCE_LINK_MODULE(moduleName)

  This macro can be used in conjunction with the wxFORCE_LINK_THIS_MODULE() macro to force the linker to include in its output a specific object file.

22.333 interface/wx/list.h File Reference

Classes

- class wxList< T >

  The wxList<T> class provides linked list functionality.
- class wxNode< T >

  wxNode<T> is the node structure used in linked lists (see wxList) and derived classes.

22.334 interface/wx/listbook.h File Reference

Classes

- class wxListbook

  wxListbook is a class similar to wxNotebook but which uses a wxListCtrl to show the labels instead of the tabs.

Macros

- #define wxLB_DEFAULT wxBK_DEFAULT
- #define wxLB_TOP wxBK_TOP
- #define wxLB_BOTTOM wxBK_BOTTOM
- #define wxLB_LEFT wxBK_LEFT
- #define wxLB_RIGHT wxBK_RIGHT
- #define wxLB_ALIGN_MASK wxBK_ALIGN_MASK

Variables

wxEventType wxEVT_LISTBOOK_PAGE_CHANGED

wxEventType wxEVT_LISTBOOK_PAGE_CHANGING

22.335 interface/wx/listbox.h File Reference

Classes

- class wxListBox

  A listbox is used to select one or more of a list of strings.

22.336 interface/wx/longlong.h File Reference

Classes

- class wxLongLong

  This class represents a signed 64 bit long number.
- class wxULongLong

  This class represents an unsigned 64 bit long number.

Macros

- #define wxLongLongFmtSpec

  This macro is defined to contain the `printf()` format specifier using which 64 bit integer numbers (i.e.

Functions

- wxLongLong_t wxLL (number)

  This macro is defined for the platforms with a native 64 bit integer type and allow the use of 64 bit compile time constants:

- wxLongLong_t wxULL (number)

  This macro is defined for the platforms with a native 64 bit integer type and allow the use of 64 bit compile time constants:

22.337 interface/wx/math.h File Reference

Functions

- int wxFinite (double x)

  Returns a non-zero value if x is neither infinite nor NaN (not a number), returns 0 otherwise.
- unsigned int wxGCD (unsigned int u, unsigned int v)

  Returns the greatest common divisor of the two given numbers.
- bool wxIsNaN (double x)

  Returns a non-zero value if x is NaN (not a number), returns 0 otherwise.
- wxFloat64 wxConvertFromIeeeExtended (const wxInt8 *bytes)

  Converts the given array of 10 bytes (corresponding to 80 bits) to a float number according to the IEEE floating point standard format (aka IEEE standard 754).
- void wxConvertToIeeeExtended (wxFloat64 num, wxInt8 *bytes)

  Converts the given floating number num in a sequence of 10 bytes which are stored in the given array bytes (which must be large enough) according to the IEEE floating point standard format (aka IEEE standard 754).
- double wxDegToRad (double deg)

  Convert degrees to radians.
- double wxRadToDeg (double rad)

  Convert radians to degrees.
- int wxRound (double x)

  Small wrapper around round().
- bool wxIsSameDouble (double x, double y)

  Returns true if both double values are identical.
- bool wxIsNullDouble (double x)

  Return true of x is exactly zero.

22.338 interface/wx/mdi.h File Reference

Classes

- class wxMDIClientWindow

  An MDI client window is a child of wxMDIParentFrame, and manages zero or more wxMDIChildFrame objects.
- class wxMDIParentFrame

  An MDI (Multiple Document Interface) parent frame is a window which can contain MDI child frames in its client area which emulates the full desktop.
- class wxMDIChildFrame

  An MDI child frame is a frame that can only exist inside a wxMDIClientWindow, which is itself a child of wxMDI↩ ParentFrame.

22.339 interface/wx/mediactrl.h File Reference

Classes

- class wxMediaEvent

Event wxMediaCtrl uses.

- class wxMediaCtrl

  wxMediaCtrl is a class for displaying types of media, such as videos, audio files, natively through native codecs.

Enumerations

- enum wxMediaState {
  wxMEDIASTATE_STOPPED,
  wxMEDIASTATE_PAUSED,
  wxMEDIASTATE_PLAYING }

  Describes the current state of the media.
- enum wxMediaCtrlPlayerControls {
  wxMEDIACTRLPLAYERCONTROLS_NONE = 0,
  wxMEDIACTRLPLAYERCONTROLS_STEP = 1 << 0,
  wxMEDIACTRLPLAYERCONTROLS_VOLUME = 1 << 1,
  wxMEDIACTRLPLAYERCONTROLS_DEFAULT }

Variables

- wxEventType wxEVT_MEDIA_LOADED
- wxEventType wxEVT_MEDIA_STOP
- wxEventType wxEVT_MEDIA_FINISHED
- wxEventType wxEVT_MEDIA_STATECHANGED
- wxEventType wxEVT_MEDIA_PLAY
- wxEventType wxEVT_MEDIA_PAUSE

22.339.1 Enumeration Type Documentation

enum wxMediaCtrlPlayerControls

Enumerator

wxMEDIACTRLPLAYERCONTROLS_NONE No controls. return wxMediaCtrl to its default state.

wxMEDIACTRLPLAYERCONTROLS_STEP Step controls like fastforward, step one frame etc.

wxMEDIACTRLPLAYERCONTROLS_VOLUME Volume controls like the speaker icon, volume slider, etc.

wxMEDIACTRLPLAYERCONTROLS_DEFAULT Default controls for the toolkit. Currently a combination for `wxMEDIACTRLPLAYERCONTROLS_STEP` and `wxMEDIACTRLPLAYERCONTROLS_VOLUME`.

enum wxMediaState

Describes the current state of the media.

See also

wxMediaCtrl::GetState()

Enumerator

wxMEDIASTATE_STOPPED No media is being currently played.

wxMEDIASTATE_PAUSED Current media is paused.

wxMEDIASTATE_PLAYING There is media currently playing.

22.339.2 Variable Documentation

wxEventType wxEVT_MEDIA_FINISHED

wxEventType wxEVT_MEDIA_LOADED

wxEventType wxEVT_MEDIA_PAUSE

wxEventType wxEVT_MEDIA_PLAY

wxEventType wxEVT_MEDIA_STATECHANGED

wxEventType wxEVT_MEDIA_STOP

22.340 interface/wx/memory.h File Reference

Classes

- class wxDebugContext

  A class for performing various debugging and memory tracing operations.

Macros

- #define WXTRACE(format,...)
- #define WXTRACELEVEL(level, format,...)

Functions

- void wxTrace (const wxString &format,...)
- void wxTraceLevel (int level, const wxString &format,...)

22.341 interface/wx/menu.h File Reference

Classes

- class wxMenuBar

  A menu bar is a series of menus accessible from the top of a frame.

- class wxMenu

  A menu is a popup (or pull down) list of items, one of which may be selected before the menu goes away (clicking elsewhere dismisses the menu).

22.342 interface/wx/menuitem.h File Reference

Classes

- class wxMenuItem

  A menu item represents an item in a menu.

22.343 interface/wx/metafile.h File Reference

Classes

- class wxMetafileDC

  *This is a type of device context that allows a metafile object to be created (Windows only), and has most of the characteristics of a normal **wxDC**.*
- class wxMetafile

  *A **wxMetafile** represents the MS Windows metafile object, so metafile operations have no effect in X.*

Functions

- bool wxMakeMetafilePlaceable (const wxString &filename, int minX, int minY, int maxX, int maxY, float scale=1.0)

  Given a filename for an existing, valid metafile (as constructed using wxMetafileDC) makes it into a placeable metafile by prepending a header containing the given bounding box.

22.344 interface/wx/mimetype.h File Reference

Classes

- class wxMimeTypesManager

  This class allows the application to retrieve information about all known MIME types from a system-specific location and the filename extensions to the MIME types and vice versa.
- class wxFileType

  This class holds information about a given file type.
- class wxFileType::MessageParameters

  Class representing message parameters.
- class wxFileTypeInfo

  Container of information about wxFileType.

Variables

- wxMimeTypesManager * wxTheMimeTypesManager

  The global wxMimeTypesManager instance.

22.344.1 Variable Documentation

wxMimeTypesManager* wxTheMimeTypesManager

The global wxMimeTypesManager instance.

22.345 interface/wx/minifram.h File Reference

Classes

- class wxMiniFrame

  A miniframe is a frame with a small title bar.

22.346 interface/wx/modalhook.h File Reference

Classes

- class wxModalDialogHook

  Allows to intercept all modal dialog calls.

22.347 interface/wx/module.h File Reference

Classes

- class wxModule

  The module system is a very simple mechanism to allow applications (and parts of wxWidgets itself) to define initialization and cleanup functions that are automatically called on wxWidgets startup and exit.

22.348 interface/wx/mousemanager.h File Reference

Classes

- class wxMouseEventsManager

  Helper for handling mouse input events in windows containing multiple items.

22.349 interface/wx/mousestate.h File Reference

Classes

- class wxMouseState

  Represents the mouse state.

Enumerations

- enum wxMouseButton {
  wxMOUSE_BTN_ANY = -1,
  wxMOUSE_BTN_NONE = 0,
  wxMOUSE_BTN_LEFT = 1,
  wxMOUSE_BTN_MIDDLE = 2,
  wxMOUSE_BTN_RIGHT = 3,
  wxMOUSE_BTN_AUX1 = 4,
  wxMOUSE_BTN_AUX2 = 5,
  wxMOUSE_BTN_MAX }

  Symbolic names for the mouse buttons.

22.349.1 Enumeration Type Documentation

enum wxMouseButton

Symbolic names for the mouse buttons.

Enumerator

wxMOUSE_BTN_ANY Any mouse button, means to check for any button being pressed for example.

wxMOUSE_BTN_NONE None of the mouse buttons.

wxMOUSE_BTN_LEFT Left mouse button.

wxMOUSE_BTN_MIDDLE Middle mouse button.

wxMOUSE_BTN_RIGHT Right mouse button.

wxMOUSE_BTN_AUX1 First additional mouse button.

wxMOUSE_BTN_AUX2 Second additional mouse button.

wxMOUSE_BTN_MAX

22.350 interface/wx/msgdlg.h File Reference

Classes

- class wxMessageDialog

  This class represents a dialog that shows a single or multi-line message, with a choice of OK, Yes, No and Cancel buttons.
- class wxMessageDialog::ButtonLabel

  Helper class allowing to use either stock id or string labels.

Functions

- int wxMessageBox (const wxString &message, const wxString &caption=wxMessageBoxCaptionStr, int style=wxOK|wxCENTRE, wxWindow *parent=NULL, int x=wxDefaultCoord, int y=wxDefaultCoord)

  Show a general purpose message dialog.

Variables

- const char wxMessageBoxCaptionStr [] = "Message"

  Default message box caption string.

22.350.1 Variable Documentation

const char wxMessageBoxCaptionStr[ ] = "Message"

Default message box caption string.

22.351 interface/wx/msgout.h File Reference

Classes

- class wxMessageOutput

  Simple class allowing to write strings to various output channels.
- class wxMessageOutputStderr

  Output messages to stderr or another STDIO file stream.
- class wxMessageOutputBest

  Output messages in the best possible way.
- class wxMessageOutputDebug

  Output messages to the system debug output channel.
- class wxMessageOutputMessageBox

  Output messages by showing them in a message box.

Enumerations

- enum wxMessageOutputFlags {
  wxMSGOUT_PREFER_STDERR = 0,
  wxMSGOUT_PREFER_MSGBOX = 1 }
  Flags used with wxMessageOutputBest.

22.351.1 Enumeration Type Documentation

enum wxMessageOutputFlags

Flags used with wxMessageOutputBest.

See wxMessageOutputBest::wxMessageOutputBest().

Enumerator

wxMSGOUT_PREFER_STDERR use stderr if available (this is the default)

wxMSGOUT_PREFER_MSGBOX always use message box if available

22.352 interface/wx/msgqueue.h File Reference

Classes

- class wxMessageQueue< T >
  wxMessageQueue allows passing messages between threads.

Enumerations

- enum wxMessageQueueError {
  wxMSGQUEUE_NO_ERROR = 0,
  wxMSGQUEUE_TIMEOUT,
  wxMSGQUEUE_MISC_ERROR }
  Error codes for wxMessageQueue<> operations.

22.353 interface/wx/mstream.h File Reference

Classes

- class wxMemoryOutputStream
  This class allows to use all methods taking a wxOutputStream reference to write to in-memory data.
- class wxMemoryInputStream
  This class allows to use all methods taking a wxInputStream reference to read in-memory data.

22.354 interface/wx/msw/ole/activex.h File Reference

Classes

- class wxActiveXEvent
  An event class for handling ActiveX events passed from wxActiveXContainer.
- class wxActiveXContainer
  wxActiveXContainer is a host for an ActiveX control on Windows (and as such is a platform-specific class).

22.355 interface/wx/msw/ole/automtn.h File Reference

Classes

- class wxVariantDataCurrency

  This class represents a thin wrapper for Microsoft Windows CURRENCY type.
- class wxVariantDataErrorCode

  This class represents a thin wrapper for Microsoft Windows SCODE type (which is the same as HRESULT).
- class wxVariantDataSafeArray

  This class represents a thin wrapper for Microsoft Windows SAFEARRAY type.
- class wxAutomationObject

  *The **wxAutomationObject** class represents an OLE automation object containing a single data member, an IDispatch pointer.*

Enumerations

- enum wxAutomationInstanceFlags {
  wxAutomationInstance_UseExistingOnly = 0,
  wxAutomationInstance_CreateIfNeeded = 1,
  wxAutomationInstance_SilentIfNone = 2 }

  Automation object creation flags.
- enum wxOleConvertVariantFlags {
  wxOleConvertVariant_Default = 0,
  wxOleConvertVariant_ReturnSafeArrays = 1 }

  Flags used for conversions between wxVariant and OLE VARIANT.

22.355.1 Enumeration Type Documentation

enum wxAutomationInstanceFlags

Automation object creation flags.

These flags can be used with wxAutomationObject::GetInstance().

Since

2.9.2

Enumerator

wxAutomationInstance_UseExistingOnly Only use the existing instance, never create a new one. This flag can be used to forbid the creation of a new instance if none is currently running.

wxAutomationInstance_CreateIfNeeded Create a new instance if there are no existing ones. This flag corresponds to the default behaviour of wxAutomationObject::GetInstance() and means that if getting an existing instance failed, we should call wxAutomationObject::CreateInstance() to create a new one.

wxAutomationInstance_SilentIfNone Do not show an error message if no existing instance is currently running. All other errors will still be reported as usual.

enum wxOleConvertVariantFlags

Flags used for conversions between wxVariant and OLE VARIANT.

These flags are used by wxAutomationObject for its wxConvertOleToVariant() calls. They can be obtained by wxAutomationObject::GetConvertVariantFlags() and set by wxAutomationObject::SetConvertVariantFlags().

Since

3.0

Include file:

```
#include <wx/msw/ole/oleutils.h>
```

Enumerator

wxOleConvertVariant_Default Default value.

wxOleConvertVariant_ReturnSafeArrays If this flag is used, SAFEARRAYs contained in OLE VARIANTs will be returned as wxVariants with wxVariantDataSafeArray type instead of wxVariants with the list type containing the (flattened) SAFEARRAY's elements.

22.356 interface/wx/msw/regconf.h File Reference

Classes

- class wxRegConfig

  wxRegConfig implements the wxConfigBase interface for storing and retrieving configuration information using Windows registry.

22.357 interface/wx/msw/registry.h File Reference

Classes

- class wxRegKey

  wxRegKey is a class representing the Windows registry (it is only available under Windows).

22.358 interface/wx/nonownedwnd.h File Reference

Classes

- class wxNonOwnedWindow

  Common base class for all non-child windows.

Macros

- #define wxFRAME_SHAPED 0x0010

  Styles that can be used with any wxNonOwnedWindow:

22.358.1 Macro Definition Documentation

#define wxFRAME_SHAPED 0x0010

Styles that can be used with any wxNonOwnedWindow:

22.359 interface/wx/notebook.h File Reference

Classes

- class wxNotebook

  This class represents a notebook control, which manages multiple windows with associated tabs.

Macros

- #define wxNB_DEFAULT wxBK_DEFAULT
- #define wxNB_TOP wxBK_TOP
- #define wxNB_BOTTOM wxBK_BOTTOM
- #define wxNB_LEFT wxBK_LEFT
- #define wxNB_RIGHT wxBK_RIGHT
- #define wxNB_FIXEDWIDTH 0x0100
- #define wxNB_MULTILINE 0x0200
- #define wxNB_NOPAGETHEME 0x0400
- #define wxNB_FLAT 0x0800

Enumerations

- enum {
  wxNB_HITTEST_NOWHERE = wxBK_HITTEST_NOWHERE,
  wxNB_HITTEST_ONICON = wxBK_HITTEST_ONICON,
  wxNB_HITTEST_ONLABEL = wxBK_HITTEST_ONLABEL,
  wxNB_HITTEST_ONITEM = wxBK_HITTEST_ONITEM,
  wxNB_HITTEST_ONPAGE = wxBK_HITTEST_ONPAGE }

Variables

- wxEventType wxEVT_NOTEBOOK_PAGE_CHANGED
- wxEventType wxEVT_NOTEBOOK_PAGE_CHANGING

22.359.1 Macro Definition Documentation

#define wxNB_BOTTOM wxBK_BOTTOM

wxNB_HITTEST_ONLABEL

wxNB_HITTEST_ONITEM

wxNB_HITTEST_ONPAGE

22.359.3 Variable Documentation

wxEventType wxEVT_NOTEBOOK_PAGE_CHANGED

wxEventType wxEVT_NOTEBOOK_PAGE_CHANGING

22.360 interface/wx/notifmsg.h File Reference

Classes

- class wxNotificationMessage

  This class allows to show the user a message non intrusively.

22.361 interface/wx/numdlg.h File Reference

Functions

- long wxGetNumberFromUser (const wxString &message, const wxString &prompt, const wxString &caption, long value, long min=0, long max=100, wxWindow *parent=NULL, const wxPoint &pos=wxDefaultPosition)

  Shows a dialog asking the user for numeric input.

22.362 interface/wx/numformatter.h File Reference

Classes

- class wxNumberFormatter

  Helper class for formatting and parsing numbers with thousands separators.

22.363 interface/wx/object.h File Reference

Classes

- class wxRefCounter

  This class is used to manage reference-counting providing a simple interface and a counter.
- class wxObject

  This is the root class of many of the wxWidgets classes.
- class wxClassInfo

This class stores meta-information about classes.

- class wxObjectDataPtr< T >

  This is an helper template class primarily written to avoid memory leaks because of missing calls to wxRefCounter::DecRef() and wxObjectRefData::DecRef().

Macros

- #define wxCLASSINFO(className)

  Returns a pointer to the wxClassInfo object associated with this class.
- #define wxDECLARE_ABSTRACT_CLASS(className)

  Used inside a class declaration to declare that the class should be made known to the class hierarchy, but objects of this class cannot be created dynamically.
- #define wxDECLARE_DYNAMIC_CLASS(className)

  Used inside a class declaration to make the class known to wxWidgets RTTI system and also declare that the objects of this class should be dynamically creatable from run-time type information.
- #define wxDECLARE_CLASS(className)

  Used inside a class declaration to declare that the class should be made known to the class hierarchy, but objects of this class cannot be created dynamically.
- #define wxIMPLEMENT_ABSTRACT_CLASS(className, baseClassName)

  Used in a C++ implementation file to complete the declaration of a class that has run-time type information.
- #define wxIMPLEMENT_ABSTRACT_CLASS2(className, baseClassName1, baseClassName2)

  Used in a C++ implementation file to complete the declaration of a class that has run-time type information and two base classes.
- #define wxIMPLEMENT_DYNAMIC_CLASS(className, baseClassName)

  Used in a C++ implementation file to complete the declaration of a class that has run-time type information, and whose instances can be created dynamically.
- #define wxIMPLEMENT_DYNAMIC_CLASS2(className, baseClassName1, baseClassName2)

  Used in a C++ implementation file to complete the declaration of a class that has run-time type information, and whose instances can be created dynamically.
- #define wxIMPLEMENT_CLASS(className, baseClassName)

  Used in a C++ implementation file to complete the declaration of a class that has run-time type information, and whose instances can be created dynamically.
- #define wxIMPLEMENT_CLASS2(className, baseClassName1, baseClassName2)

  Used in a C++ implementation file to complete the declaration of a class that has run-time type information and two base classes, and whose instances can be created dynamically.
- #define wx_const_cast(T, x)

  Same as `const_cast<T>(x)` if the compiler supports const cast or (T)x for old compilers.
- #define wx_reinterpret_cast(T, x)

  Same as `reinterpret_cast<T>(x)` if the compiler supports reinterpret cast or (T)x for old compilers.
- #define wx_static_cast(T, x)

  Same as `static_cast<T>(x)` if the compiler supports static cast or (T)x for old compilers.
- #define wx_truncate_cast(T, x)

  This case doesn't correspond to any standard cast but exists solely to make casts which possibly result in a truncation of an integer value more readable.
- #define wxConstCast(ptr, classname)

  This macro expands into `const_cast<classname *>(ptr)` if the compiler supports const_cast or into an old, C-style cast, otherwise.
- #define wxDynamicCast(ptr, classname)

  *This macro returns the pointer ptr cast to the type classname * if the pointer is of this type (the check is done during the run-time) or NULL otherwise.*
- #define wxDynamicCastThis(classname)

  This macro is equivalent to `wxDynamicCast(this, classname)` but the latter provokes spurious compilation warnings from some compilers (because it tests whether `this` pointer is non-NULL which is always true), so this macro should be used to avoid them.

- #define wxStaticCast(ptr, classname)

  This macro checks that the cast is valid in debug mode (an assert failure will result if wxDynamicCast(ptr, classname) == NULL) and then returns the result of executing an equivalent of `static_cast<classname *>(ptr)`.

- #define WXDEBUG_NEW(arg)

  This is defined in debug mode to be call the redefined new operator with filename and line number arguments.

Typedefs

- typedef wxRefCounter wxObjectRefData

Functions

- wxObject * wxCreateDynamicObject (const wxString &className)

  Creates and returns an object of the given class, if the class has been registered with the dynamic class system using DECLARE...

22.363.1 Typedef Documentation

typedef wxRefCounter wxObjectRefData

22.364 interface/wx/odcombo.h File Reference

Classes

- class wxOwnerDrawnComboBox

  wxOwnerDrawnComboBox is a combobox with owner-drawn list items.

Enumerations

- enum wxOwnerDrawnComboBoxPaintingFlags {
  wxODCB_PAINTING_CONTROL = 0x0001,
  wxODCB_PAINTING_SELECTED = 0x0002 }
- enum {
  wxODCB_DCLICK_CYCLES = wxCC_SPECIAL_DCLICK,
  wxODCB_STD_CONTROL_PAINT = 0x1000 }

  New window styles for wxOwnerDrawnComboBox.

22.364.1 Enumeration Type Documentation

anonymous enum

New window styles for wxOwnerDrawnComboBox.

Enumerator

wxODCB_DCLICK_CYCLES Double-clicking cycles item if wxCB_READONLY is also used.

wxODCB_STD_CONTROL_PAINT If used, control itself is not custom paint using callback. Even if this is not used, writable combo is never custom paint until SetCustomPaintWidth is called

enum wxOwnerDrawnComboBoxPaintingFlags

Enumerator

wxODCB_PAINTING_CONTROL Combo control is being painted, instead of a list item. Argument item may be `wxNOT_FOUND` in this case.

wxODCB_PAINTING_SELECTED An item with selection background is being painted. DC text colour should already be correct.

22.365 interface/wx/overlay.h File Reference

Classes

- class wxOverlay

  Creates an overlay over an existing window, allowing for manipulations like rubberbanding, etc.
- class wxDCOverlay

  Connects an overlay with a drawing DC.

22.366 interface/wx/palette.h File Reference

Classes

- class wxPalette

  A palette is a table that maps pixel values to RGB colours.

Variables

- wxPalette wxNullPalette

  An empty palette.

22.366.1 Variable Documentation

wxPalette wxNullPalette

An empty palette.

22.367 interface/wx/panel.h File Reference

Classes

- class wxPanel

  A panel is a window on which controls are placed.

22.368 interface/wx/ribbon/panel.h File Reference

Classes

- class wxRibbonPanelEvent

Event used to indicate various actions relating to a wxRibbonPanel.

- class wxRibbonPanel

  Serves as a container for a group of (ribbon) controls.

22.369 interface/wx/pen.h File Reference

Classes

- class wxPen

  A pen is a drawing tool for drawing outlines.

- class wxPenList

  There is only one instance of this class: wxThePenList.

Enumerations

- enum wxPenStyle {
  wxPENSTYLE_INVALID = -1,
  wxPENSTYLE_SOLID,
  wxPENSTYLE_DOT,
  wxPENSTYLE_LONG_DASH,
  wxPENSTYLE_SHORT_DASH,
  wxPENSTYLE_DOT_DASH,
  wxPENSTYLE_USER_DASH,
  wxPENSTYLE_TRANSPARENT,
  wxPENSTYLE_STIPPLE_MASK_OPAQUE,
  wxPENSTYLE_STIPPLE_MASK,
  wxPENSTYLE_STIPPLE,
  wxPENSTYLE_BDIAGONAL_HATCH,
  wxPENSTYLE_CROSSDIAG_HATCH,
  wxPENSTYLE_FDIAGONAL_HATCH,
  wxPENSTYLE_CROSS_HATCH,
  wxPENSTYLE_HORIZONTAL_HATCH,
  wxPENSTYLE_VERTICAL_HATCH,
  wxPENSTYLE_FIRST_HATCH,
  wxPENSTYLE_LAST_HATCH }

  The possible styles for a wxPen.

- enum wxPenJoin {
  wxJOIN_INVALID = -1,
  wxJOIN_BEVEL = 120,
  wxJOIN_MITER,
  wxJOIN_ROUND }

  The possible join values of a wxPen.

- enum wxPenCap {
  wxCAP_INVALID = -1,
  wxCAP_ROUND = 130,
  wxCAP_PROJECTING,
  wxCAP_BUTT }

  The possible cap values of a wxPen.

Variables

- wxPen wxNullPen

  An empty pen.

- wxPen * wxRED_PEN
  Red pen.
- wxPen * wxBLUE_PEN
  Blue pen.
- wxPen * wxCYAN_PEN
  Cyan pen.
- wxPen * wxGREEN_PEN
  Green pen.
- wxPen * wxYELLOW_PEN
  Yellow pen.
- wxPen * wxBLACK_PEN
  Black pen.
- wxPen * wxWHITE_PEN
  White pen.
- wxPen * wxTRANSPARENT_PEN
  Transparent pen.
- wxPen * wxBLACK_DASHED_PEN
  Black dashed pen.
- wxPen * wxGREY_PEN
  Grey pen.
- wxPen * wxMEDIUM_GREY_PEN
  Medium-grey pen.
- wxPen * wxLIGHT_GREY_PEN
  Light-grey pen.
- wxPenList * wxThePenList
  The global list of wxPen objects ready to be re-used (for better performances).

22.369.1 Enumeration Type Documentation

enum wxPenCap

The possible cap values of a wxPen.

Todo use wxPENCAP_ prefix

Enumerator

wxCAP_INVALID
wxCAP_ROUND
wxCAP_PROJECTING
wxCAP_BUTT

enum wxPenJoin

The possible join values of a wxPen.

Todo use wxPENJOIN_ prefix

Enumerator

wxJOIN_INVALID
wxJOIN_BEVEL
wxJOIN_MITER
wxJOIN_ROUND

enum wxPenStyle

The possible styles for a wxPen.

Note that hatched pen styles are not supported by X11-based ports, including wxGTK.

Enumerator

wxPENSTYLE_INVALID

wxPENSTYLE_SOLID Solid style.

wxPENSTYLE_DOT Dotted style.

wxPENSTYLE_LONG_DASH Long dashed style.

wxPENSTYLE_SHORT_DASH Short dashed style.

wxPENSTYLE_DOT_DASH Dot and dash style.

wxPENSTYLE_USER_DASH Use the user dashes: see wxPen::SetDashes.

wxPENSTYLE_TRANSPARENT No pen is used.

wxPENSTYLE_STIPPLE_MASK_OPAQUE **Todo** WHAT's this?

wxPENSTYLE_STIPPLE_MASK **Todo** WHAT's this?

wxPENSTYLE_STIPPLE Use the stipple bitmap.

wxPENSTYLE_BDIAGONAL_HATCH Backward diagonal hatch.

wxPENSTYLE_CROSSDIAG_HATCH Cross-diagonal hatch.

wxPENSTYLE_FDIAGONAL_HATCH Forward diagonal hatch.

wxPENSTYLE_CROSS_HATCH Cross hatch.

wxPENSTYLE_HORIZONTAL_HATCH Horizontal hatch.

wxPENSTYLE_VERTICAL_HATCH Vertical hatch.

wxPENSTYLE_FIRST_HATCH First of the hatch styles (inclusive).

wxPENSTYLE_LAST_HATCH Last of the hatch styles (inclusive).

22.369.2 Variable Documentation

wxPen* wxBLACK_DASHED_PEN

Black dashed pen.

Except for the color and for the `wxPENSTYLE_SHORT_DASH` it has all standard attributes (1-pixel width, `wxCAP_ROUND` style, etc...).

wxPen* wxBLACK_PEN

Black pen.

Except for the color it has all standard attributes (1-pixel width, `wxPENSTYLE_SOLID` and `wxCAP_ROUND` styles, etc...).

wxPen* wxBLUE_PEN

Blue pen.

Except for the color it has all standard attributes (1-pixel width, `wxPENSTYLE_SOLID` and `wxCAP_ROUND` styles, etc...).

wxPen* wxCYAN_PEN

Cyan pen.

Except for the color it has all standard attributes (1-pixel width, `wxPENSTYLE_SOLID` and `wxCAP_ROUND` styles, etc...).

wxPen* wxGREEN_PEN

Green pen.

Except for the color it has all standard attributes (1-pixel width, `wxPENSTYLE_SOLID` and `wxCAP_ROUND` styles, etc...).

wxPen* wxGREY_PEN

Grey pen.

Except for the color it has all standard attributes (1-pixel width, `wxPENSTYLE_SOLID` and `wxCAP_ROUND` styles, etc...).

wxPen* wxLIGHT_GREY_PEN

Light-grey pen.

Except for the color it has all standard attributes (1-pixel width, `wxPENSTYLE_SOLID` and `wxCAP_ROUND` styles, etc...).

wxPen* wxMEDIUM_GREY_PEN

Medium-grey pen.

Except for the color it has all standard attributes (1-pixel width, `wxPENSTYLE_SOLID` and `wxCAP_ROUND` styles, etc...).

wxPen wxNullPen

An empty pen.

wxPen::IsOk() always returns false for this object.

wxPen* wxRED_PEN

Red pen.

Except for the color it has all standard attributes (1-pixel width, `wxPENSTYLE_SOLID` and `wxCAP_ROUND` styles, etc...).

wxPenList* wxThePenList

The global list of wxPen objects ready to be re-used (for better performances).

wxPen* wxTRANSPARENT_PEN

Transparent pen.

Except for the color it has all standard attributes (1-pixel width, `wxPENSTYLE_SOLID` and `wxCAP_ROUND` styles, etc...).

wxPen* wxWHITE_PEN

White pen.

Except for the color it has all standard attributes (1-pixel width, `wxPENSTYLE_SOLID` and `wxCAP_ROUND` styles, etc...).

wxPen* wxYELLOW_PEN

Yellow pen.

Except for the color it has all standard attributes (1-pixel width, `wxPENSTYLE_SOLID` and `wxCAP_ROUND` styles, etc...).

22.370 interface/wx/persist.h File Reference

Classes

- class wxPersistenceManager

  Provides support for automatically saving and restoring object properties to persistent storage.
- class wxPersistentObject

  Base class for persistent object adapters.

Functions

- template<class T >
  wxPersistentObject * wxCreatePersistentObject (T *obj)

  Function used to create the correct persistent adapter for the given type of objects.
- template<class T >
  bool wxPersistentRegisterAndRestore (T *obj, const wxString &name=wxString())

  A shorter synonym for wxPersistenceManager::RegisterAndRestore().

22.370.1 Function Documentation

template<class T > wxPersistentObject* wxCreatePersistentObject (T * *obj*)

Function used to create the correct persistent adapter for the given type of objects.

To be precise, there is no such template function definition but there are overloads of wxCreatePersistentObject() taking different object types for all wxWidgets classes supporting persistence. And you may also define your own overloads to integrate your custom classes with wxWidgets persistence framework.

See also

Defining Custom Persistent Windows

Include file:

```
#include <wx/persist.h>
```

template<class T > bool wxPersistentRegisterAndRestore (T * *obj,* const wxString & *name* = wxString ())

A shorter synonym for wxPersistenceManager::RegisterAndRestore().

This function simply calls wxPersistenceManager::RegisterAndRestore() but using it results in slightly shorter code as it calls wxPersistenceManager::Get() internally. As an additional convenience, this function can also set the window name.

Parameters

obj	wxWindow-derived object to register with persistence manager and to try to restore the settings for.
name	If not empty, *obj* name is changed to the provided value before registering it.

Returns

true if the settings were restored or false otherwise (this will always be the case when the program runs for the first time, for example).

Since

2.9.0, *name* is new in 2.9.1.

Include file:

```
#include <wx/persist.h>
```

22.371 interface/wx/persist/toplevel.h File Reference

Classes

- class wxPersistentTLW

  Persistence adapter for wxTopLevelWindow.

Functions

- wxPersistentObject * wxCreatePersistentObject (wxTopLevelWindow *book)

  Overload allowing persistence adapter creation for wxTopLevelWindow-derived objects.

22.371.1 Function Documentation

wxPersistentObject* wxCreatePersistentObject (wxTopLevelWindow * *book*)

Overload allowing persistence adapter creation for wxTopLevelWindow-derived objects.

22.372 interface/wx/toplevel.h File Reference

Classes

- class wxTopLevelWindow

  wxTopLevelWindow is a common base class for wxDialog and wxFrame.

Macros

- #define wxDEFAULT_FRAME_STYLE

Enumerations

- enum {
  wxUSER_ATTENTION_INFO = 1,
  wxUSER_ATTENTION_ERROR = 2 }

  Styles used with wxTopLevelWindow::RequestUserAttention().
- enum {
  wxFULLSCREEN_NOMENUBAR = 0x0001,
  wxFULLSCREEN_NOTOOLBAR = 0x0002,
  wxFULLSCREEN_NOSTATUSBAR = 0x0004,
  wxFULLSCREEN_NOBORDER = 0x0008,
  wxFULLSCREEN_NOCAPTION = 0x0010,
  wxFULLSCREEN_ALL }

  Styles used with wxTopLevelWindow::ShowFullScreen().

22.372.1 Macro Definition Documentation

#define wxDEFAULT_FRAME_STYLE

Value:

```
(wxSYSTEM_MENU |           \
                           wxRESIZE_BORDER |
      \                    wxMINIMIZE_BOX |
      \                    wxMAXIMIZE_BOX |
      \                    wxCLOSE_BOX |
      \                    wxCAPTION |
      \                    wxCLIP_CHILDREN)
```

22.372.2 Enumeration Type Documentation

anonymous enum

Styles used with wxTopLevelWindow::RequestUserAttention().

Enumerator

wxUSER_ATTENTION_INFO Requests user attention,.

wxUSER_ATTENTION_ERROR Results in a more drastic action.

anonymous enum

Styles used with wxTopLevelWindow::ShowFullScreen().

Enumerator

wxFULLSCREEN_NOMENUBAR Don't display the menu bar.

wxFULLSCREEN_NOTOOLBAR Don't display toolbar bars.

wxFULLSCREEN_NOSTATUSBAR Don't display the status bar.

wxFULLSCREEN_NOBORDER Don't display any border.

wxFULLSCREEN_NOCAPTION Don't display a caption.

wxFULLSCREEN_ALL Combination of all above, will display the least possible.

22.373 interface/wx/persist/treebook.h File Reference

Classes

- class wxPersistentTreeBookCtrl

  Persistence adapter for wxTreebook.

Functions

- wxPersistentObject * wxCreatePersistentObject (wxTreebook *book)

  Overload allowing persistence adapter creation for wxTreebook objects.

22.373.1 Function Documentation

wxPersistentObject* wxCreatePersistentObject (wxTreebook * *book*)

Overload allowing persistence adapter creation for wxTreebook objects.

22.374 interface/wx/treebook.h File Reference

Classes

- class wxTreebook

  This class is an extension of the wxNotebook class that allows a tree structured set of pages to be shown in a control.

Variables

- wxEventType wxEVT_TREEBOOK_PAGE_CHANGED
- wxEventType wxEVT_TREEBOOK_PAGE_CHANGING
- wxEventType wxEVT_TREEBOOK_NODE_COLLAPSED
- wxEventType wxEVT_TREEBOOK_NODE_EXPANDED

22.374.1 Variable Documentation

wxEventType wxEVT_TREEBOOK_NODE_COLLAPSED

wxEventType wxEVT_TREEBOOK_NODE_EXPANDED

wxEventType wxEVT_TREEBOOK_PAGE_CHANGED

wxEventType wxEVT_TREEBOOK_PAGE_CHANGING

22.375 interface/wx/persist/window.h File Reference

Classes

- class wxPersistentWindow< T >

  Base class for persistent windows.

22.376 interface/wx/window.h File Reference

Classes

- struct wxVisualAttributes

  Struct containing all the visual attributes of a control.
- class wxWindow

  wxWindow is the base class for all windows and represents any visible object on screen.
- class wxWindow::ChildrenRepositioningGuard

  Helper for ensuring EndRepositioningChildren() is called correctly.

Enumerations

- enum wxShowEffect {
  wxSHOW_EFFECT_NONE,
  wxSHOW_EFFECT_ROLL_TO_LEFT,
  wxSHOW_EFFECT_ROLL_TO_RIGHT,
  wxSHOW_EFFECT_ROLL_TO_TOP,
  wxSHOW_EFFECT_ROLL_TO_BOTTOM,
  wxSHOW_EFFECT_SLIDE_TO_LEFT,
  wxSHOW_EFFECT_SLIDE_TO_RIGHT,
  wxSHOW_EFFECT_SLIDE_TO_TOP,
  wxSHOW_EFFECT_SLIDE_TO_BOTTOM,
  wxSHOW_EFFECT_BLEND,
  wxSHOW_EFFECT_EXPAND,
  wxSHOW_EFFECT_MAX }

  Valid values for wxWindow::ShowWithEffect() and wxWindow::HideWithEffect().
- enum { wxSEND_EVENT_POST = 1 }

  flags for SendSizeEvent()
- enum wxWindowVariant {
  wxWINDOW_VARIANT_NORMAL,
  wxWINDOW_VARIANT_SMALL,
  wxWINDOW_VARIANT_MINI,
  wxWINDOW_VARIANT_LARGE,
  wxWINDOW_VARIANT_MAX }

  Different window variants, on platforms like eg mac uses different rendering sizes.

Functions

- wxWindow * wxFindWindowAtPointer (wxPoint &pt)

  Find the deepest window at the mouse pointer position, returning the window and current pointer position in screen coordinates.
- wxWindow * wxGetActiveWindow ()

  Gets the currently active window (implemented for MSW and GTK only currently, always returns NULL in the other ports).
- wxWindow * wxGetTopLevelParent (wxWindow *window)

  Returns the first top level parent of the given window, or in other words, the frame or dialog containing it, or NULL.

22.376.1 Enumeration Type Documentation

anonymous enum

flags for SendSizeEvent()

Enumerator

wxSEND_EVENT_POST

enum wxShowEffect

Valid values for wxWindow::ShowWithEffect() and wxWindow::HideWithEffect().

Enumerator

wxSHOW_EFFECT_NONE No effect, equivalent to normal wxWindow::Show() or Hide() call.

Since

2.9.1

wxSHOW_EFFECT_ROLL_TO_LEFT Roll window to the left.

wxSHOW_EFFECT_ROLL_TO_RIGHT Roll window to the right.

wxSHOW_EFFECT_ROLL_TO_TOP Roll window to the top.

wxSHOW_EFFECT_ROLL_TO_BOTTOM Roll window to the bottom.

wxSHOW_EFFECT_SLIDE_TO_LEFT Slide window to the left.

wxSHOW_EFFECT_SLIDE_TO_RIGHT Slide window to the right.

wxSHOW_EFFECT_SLIDE_TO_TOP Slide window to the top.

wxSHOW_EFFECT_SLIDE_TO_BOTTOM Slide window to the bottom.

wxSHOW_EFFECT_BLEND Fade in or out effect.

wxSHOW_EFFECT_EXPAND Expanding or collapsing effect.

wxSHOW_EFFECT_MAX

enum wxWindowVariant

Different window variants, on platforms like eg mac uses different rendering sizes.

Enumerator

wxWINDOW_VARIANT_NORMAL Normal size.

wxWINDOW_VARIANT_SMALL Smaller size (about 25 % smaller than normal)

wxWINDOW_VARIANT_MINI Mini size (about 33 % smaller than normal)

wxWINDOW_VARIANT_LARGE Large size (about 25 % larger than normal)

wxWINDOW_VARIANT_MAX

22.377 interface/wx/pickerbase.h File Reference

Classes

- class wxPickerBase

  Base abstract class for all pickers which support an auxiliary text control.

Macros

- #define wxPB_USE_TEXTCTRL 0x0002
- #define wxPB_SMALL 0x8000

22.377.1 Macro Definition Documentation

#define wxPB_SMALL 0x8000

#define wxPB_USE_TEXTCTRL 0x0002

22.378 interface/wx/platform.h File Reference

Macros

- #define wxCHECK_GCC_VERSION(major, minor)

  Returns true if the compiler being used is GNU C++ and its version is at least major.minor or greater.

- #define wxCHECK_SUNCC_VERSION(major, minor)

  Returns true if the compiler being used is Sun CC Pro and its version is at least major.minor or greater.

- #define wxCHECK_VISUALC_VERSION(major)

  Returns true if the compiler being used is Visual C++ and its version is at least major or greater.

- #define wxCHECK_W32API_VERSION(major, minor)

  Returns true if the version of w32api headers used is major.minor or greater.

22.379 interface/wx/platinfo.h File Reference

Classes

- struct wxLinuxDistributionInfo

  A structure containing information about a Linux distribution as returned by the `lsb_release` utility.

- class wxPlatformInfo

  This class holds information about the operating system, the toolkit and the basic architecture of the machine where the application is currently running.

Enumerations

- enum wxOperatingSystemId {
  wxOS_UNKNOWN = 0,
  wxOS_MAC_OS = 1 << 0,
  wxOS_MAC_OSX_DARWIN = 1 << 1,
  wxOS_MAC = wxOS_MAC_OS|wxOS_MAC_OSX_DARWIN,
  wxOS_WINDOWS_9X = 1 << 2,
  wxOS_WINDOWS_NT = 1 << 3,
  wxOS_WINDOWS_MICRO = 1 << 4,
  wxOS_WINDOWS_CE = 1 << 5,
  wxOS_WINDOWS,
  wxOS_UNIX_LINUX = 1 << 6,
  wxOS_UNIX_FREEBSD = 1 << 7,
  wxOS_UNIX_OPENBSD = 1 << 8,
  wxOS_UNIX_NETBSD = 1 << 9,
  wxOS_UNIX_SOLARIS = 1 << 10,
  wxOS_UNIX_AIX = 1 << 11,
  wxOS_UNIX_HPUX = 1 << 12,
  wxOS_UNIX,
  wxOS_DOS = 1 << 15,
  wxOS_OS2 = 1 << 16 }

  The following are the operating systems which are recognized by wxWidgets and whose version can be detected at run-time.

- enum wxPortId {
  wxPORT_UNKNOWN = 0,
  wxPORT_BASE = 1 << 0,
  wxPORT_MSW = 1 << 1,
  wxPORT_MOTIF = 1 << 2,
  wxPORT_GTK = 1 << 3,
  wxPORT_DFB = 1 << 4,
  wxPORT_X11 = 1 << 5,
  wxPORT_OS2 = 1 << 6,
  wxPORT_MAC = 1 << 7,
  wxPORT_COCOA = 1 << 8,
  wxPORT_WINCE = 1 << 9 }

  The list of wxWidgets ports.

- enum wxArchitecture {
  wxARCH_INVALID = -1,
  wxARCH_32,
  wxARCH_64,
  wxARCH_MAX }

  The architecture of the operating system (regardless of the build environment of wxWidgets library - see wxIs↩ Platform64Bit() documentation for more info).

- enum wxEndianness {
  wxENDIAN_INVALID = -1,
  wxENDIAN_BIG,
  wxENDIAN_LITTLE,
  wxENDIAN_PDP,
  wxENDIAN_MAX }

  The endian-ness of the machine.

22.379.1 Enumeration Type Documentation

enum wxArchitecture

The architecture of the operating system (regardless of the build environment of wxWidgets library - see wxIs↩ Platform64Bit() documentation for more info).

Enumerator

wxARCH_INVALID returned on error

wxARCH_32 32 bit

wxARCH_64 64 bit

wxARCH_MAX

enum wxEndianness

The endian-ness of the machine.

Enumerator

wxENDIAN_INVALID returned on error

wxENDIAN_BIG 4321

wxENDIAN_LITTLE 1234

wxENDIAN_PDP 3412

wxENDIAN_MAX

enum wxOperatingSystemId

The following are the operating systems which are recognized by wxWidgets and whose version can be detected at run-time.

The values of the constants are chosen so that they can be combined as flags; this allows to check for operating system families like e.g. `wxOS_MAC` and `wxOS_UNIX`.

Note that you can obtain more detailed information about the current OS version in use by checking the major and minor version numbers returned by wxGetOsVersion() or by wxPlatformInfo::GetOSMajorVersion(), wxPlatform↩ Info::GetOSMinorVersion().

Enumerator

wxOS_UNKNOWN returned on error

wxOS_MAC_OS Apple Mac OS 8/9/X with Mac paths.

wxOS_MAC_OSX_DARWIN Apple Mac OS X with Unix paths.

wxOS_MAC A combination of all `wxOS_MAC_*` values previously listed.

wxOS_WINDOWS_9X Windows 9x family (95/98/ME)

wxOS_WINDOWS_NT Windows NT family (NT/2000/XP/Vista/7)

wxOS_WINDOWS_MICRO MicroWindows.

wxOS_WINDOWS_CE Windows CE (Window Mobile)

wxOS_WINDOWS A combination of all `wxOS_WINDOWS_*` values previously listed.

wxOS_UNIX_LINUX Linux.

wxOS_UNIX_FREEBSD FreeBSD.

wxOS_UNIX_OPENBSD OpenBSD.

wxOS_UNIX_NETBSD NetBSD.

wxOS_UNIX_SOLARIS SunOS.

wxOS_UNIX_AIX AIX.

wxOS_UNIX_HPUX HP/UX.

wxOS_UNIX A combination of all `wxOS_UNIX_*` values previously listed.

wxOS_DOS Microsoft DOS.

wxOS_OS2 OS/2.

enum wxPortId

The list of wxWidgets ports.

Some of them can be used with more than a single (native) toolkit; e.g. wxWinCE port sources can be used with smartphones, pocket PCs and handheld devices SDKs.

Enumerator

wxPORT_UNKNOWN returned on error

wxPORT_BASE wxBase, no native toolkit used

wxPORT_MSW wxMSW, native toolkit is Windows API

wxPORT_MOTIF wxMotif, using [Open]Motif or Lesstif

wxPORT_GTK wxGTK, using GTK+ 1.x, 2.x, GPE or Maemo

wxPORT_DFB wxDFB, using wxUniversal

wxPORT_X11 wxX11, using wxUniversal

wxPORT_OS2 wxOS2, using OS/2 Presentation Manager

wxPORT_MAC wxMac, using Carbon or Classic Mac API

wxPORT_COCOA wxCocoa, using Cocoa NextStep/Mac API

wxPORT_WINCE wxWinCE, toolkit is WinCE SDK API

22.380 interface/wx/popupwin.h File Reference

Classes

- class wxPopupWindow

  A special kind of top level window used for popup menus, combobox popups and such.

- class wxPopupTransientWindow

  A wxPopupWindow which disappears automatically when the user clicks mouse outside it or if it loses focus in any other way.

22.381 interface/wx/position.h File Reference

Classes

- class wxPosition

  This class represents the position of an item in any kind of grid of rows and columns such as wxGridBagSizer, or wxHVScrolledWindow.

22.382 interface/wx/power.h File Reference

Classes

- class wxPowerEvent

  The power events are generated when the system power state changes, e.g.
- class wxPowerResource

  Helper functions for acquiring and releasing the given power resource.
- class wxPowerResourceBlocker

  Helper RAII class ensuring that power resources are released.

Enumerations

- enum wxPowerType {
  wxPOWER_SOCKET,
  wxPOWER_BATTERY,
  wxPOWER_UNKNOWN }
- enum wxBatteryState {
  wxBATTERY_NORMAL_STATE,
  wxBATTERY_LOW_STATE,
  wxBATTERY_CRITICAL_STATE,
  wxBATTERY_SHUTDOWN_STATE,

Classes

- class wxPreferencesEditor

  Manage preferences dialog.
- class wxPreferencesPage

  One page of preferences dialog.
- class wxStockPreferencesPage

  Specialization of wxPreferencesPage useful for certain commonly used preferences page.

22.384 interface/wx/print.h File Reference

Classes

- class wxPreviewControlBar

  This is the default implementation of the preview control bar, a panel with buttons and a zoom control.
- class wxPreviewCanvas

  A preview canvas is the default canvas used by the print preview system to display the preview.
- class wxPreviewFrame

  This class provides the default method of managing the print preview interface.
- class wxPrintPreview

  Objects of this class manage the print preview process.
- class wxPrinter

This class represents the Windows or PostScript printer, and is the vehicle through which printing may be launched by an application.

- class wxPrintout

  This class encapsulates the functionality of printing out an application document.

- class wxPrintAbortDialog

  The dialog created by default by the print framework that enables aborting the printing process.

Macros

- #define wxPREVIEW_PRINT 1
- #define wxPREVIEW_PREVIOUS 2
- #define wxPREVIEW_NEXT 4
- #define wxPREVIEW_ZOOM 8
- #define wxPREVIEW_FIRST 16
- #define wxPREVIEW_LAST 32

#define wxPREVIEW_PRINT 1

#define wxPREVIEW_ZOOM 8

22.384.2 Enumeration Type Documentation

enum **wxPreviewFrameModalityKind**

Preview frame modality kind.

The elements of this enum can be used with wxPreviewFrame::Initialize() to indicate how should the preview frame be shown.

Since

2.9.2

Enumerator

wxPreviewFrame_AppModal Disable all the other top level windows while the preview frame is shown. This is the default behaviour.

wxPreviewFrame_WindowModal Disable only the parent window while the preview frame is shown.

wxPreviewFrame_NonModal Show the preview frame non-modally and don't disable any other windows.

enum **wxPrinterError**

Enumerator

wxPRINTER_NO_ERROR

wxPRINTER_CANCELLED

wxPRINTER_ERROR

22.385 interface/wx/printdlg.h File Reference

Classes

- class wxPrintDialog

  This class represents the print and print setup common dialogs.
- class wxPageSetupDialog

  This class represents the page setup common dialog.

22.386 interface/wx/process.h File Reference

Classes

- class wxProcess

  The objects of this class are used in conjunction with the wxExecute() function.
- class wxProcessEvent

  A process event is sent to the wxEvtHandler specified to wxProcess when a process is terminated.

Variables

- wxEventType wxEVT_END_PROCESS

22.386.1 Variable Documentation

wxEventType wxEVT_END_PROCESS

22.387 interface/wx/progdlg.h File Reference

Classes

- class wxGenericProgressDialog

  This class represents a dialog that shows a short message and a progress bar.
- class wxProgressDialog

  If supported by the platform this class will provide the platform's native progress dialog, else it will simply be the wxGenericProgressDialog.

Macros

Classes

- class wxPropertySheetDialog

  This class represents a property sheet dialog: a tabbed dialog for showing settings.

Enumerations

- enum wxPropertySheetDialogFlags {
  wxPROPSHEET_DEFAULT = 0x0001,
  wxPROPSHEET_NOTEBOOK = 0x0002,
  wxPROPSHEET_TOOLBOOK = 0x0004,
  wxPROPSHEET_CHOICEBOOK = 0x0008,
  wxPROPSHEET_LISTBOOK = 0x0010,
  wxPROPSHEET_BUTTONTOOLBOOK = 0x0020,
  wxPROPSHEET_TREEBOOK = 0x0040,
  wxPROPSHEET_SHRINKTOFIT = 0x0100 }

  Values used by wxPropertySheetDialog::SetSheetStyle.

22.388.1 Enumeration Type Documentation

enum **wxPropertySheetDialogFlags**

Values used by wxPropertySheetDialog::SetSheetStyle.

Enumerator

wxPROPSHEET_DEFAULT Uses the default look and feel for the controller window, normally a notebook except on Smartphone where a choice control is used.

wxPROPSHEET_NOTEBOOK Uses a notebook for the controller window.

wxPROPSHEET_TOOLBOOK Uses a toolbook for the controller window.

wxPROPSHEET_CHOICEBOOK Uses a choicebook for the controller window.

wxPROPSHEET_LISTBOOK Uses a listbook for the controller window.

wxPROPSHEET_BUTTONTOOLBOOK Uses a button toolbox for the controller window.

wxPROPSHEET_TREEBOOK Uses a treebook for the controller window.

wxPROPSHEET_SHRINKTOFIT Shrinks the dialog window to fit the currently selected page (common behaviour for property sheets on Mac OS X).

22.389 interface/wx/propgrid/editors.h File Reference

Classes

- class wxPGEditor

  Base class for custom wxPropertyGrid editors.
- class wxPGMultiButton

  This class can be used to have multiple buttons in a property editor.

22.390 interface/wx/propgrid/manager.h File Reference

Classes

- class wxPropertyGridPage

  Holder of property grid page information.
- class wxPropertyGridManager

  wxPropertyGridManager is an efficient multi-page version of wxPropertyGrid, which can optionally have toolbar for mode and page selection, a help text box, and a header.

22.391 interface/wx/propgrid/property.h File Reference

- #define wxPG_PROP_MAX wxPG_PROP_AUTO_UNSPECIFIED

  Topmost flag.
- #define wxPG_PROP_PARENTAL_FLAGS

  Property with children must have one of these set, otherwise iterators will not work correctly.
- enum wxPGPropertyFlags {
  wxPG_PROP_MODIFIED = 0x0001,
  wxPG_PROP_DISABLED = 0x0002,
  wxPG_PROP_HIDDEN = 0x0004,

  wxPG_PROP_NOEDITOR = 0x0010,
  wxPG_PROP_COLLAPSED = 0x0020,
  wxPG_PROP_INVALID_VALUE = 0x0040,
  wxPG_PROP_WAS_MODIFIED = 0x0200,
  wxPG_PROP_AGGREGATE = 0x0400,
  wxPG_PROP_CHILDREN_ARE_COPIES = 0x0800,
  wxPG_PROP_PROPERTY = 0x1000,
  wxPG_PROP_CATEGORY = 0x2000,
  wxPG_PROP_MISC_PARENT = 0x4000,
  wxPG_PROP_READONLY = 0x8000,
  wxPG_PROP_COMPOSED_VALUE = 0x00010000,
  wxPG_PROP_USES_COMMON_VALUE = 0x00020000,
  wxPG_PROP_AUTO_UNSPECIFIED = 0x00040000,
  wxPG_PROP_CLASS_SPECIFIC_1 = 0x00080000,
  wxPG_PROP_CLASS_SPECIFIC_2 = 0x00100000,
  wxPG_PROP_BEING_DELETED = 0x00200000 }

Classes

- class wxPGProperty

  wxPGProperty is base class for all wxPropertyGrid properties.
- class wxPGCell

  Base class for wxPropertyGrid cell information.
- class wxPGChoices

  Helper class for managing choices of wxPropertyGrid properties.

Macros

- #define wxNullProperty ((wxPGProperty*)NULL)

- #define wxPG_ATTR_DEFAULT_VALUE wxS("DefaultValue")

  Set default value for property.
- #define wxPG_ATTR_MIN wxS("Min")

  Universal, int or double.
- #define wxPG_ATTR_MAX wxS("Max")

  Universal, int or double.
- #define wxPG_ATTR_UNITS wxS("Units")

  Universal, string.
- #define wxPG_ATTR_HINT wxS("Hint")

  When set, will be shown as 'greyed' text in property's value cell when the actual displayed value is blank.
- #define wxPG_ATTR_INLINE_HELP wxS("InlineHelp")
- #define wxPG_ATTR_AUTOCOMPLETE wxS("AutoComplete")

  Universal, wxArrayString.
- #define wxPG_BOOL_USE_CHECKBOX wxS("UseCheckbox")

  wxBoolProperty and wxFlagsProperty specific.
- #define wxPG_BOOL_USE_DOUBLE_CLICK_CYCLING wxS("UseDClickCycling")

  wxBoolProperty and wxFlagsProperty specific.
- #define wxPG_FLOAT_PRECISION wxS("Precision")

  wxFloatProperty (and similar) specific, int, default -1.
- #define wxPG_STRING_PASSWORD wxS("Password")

  The text will be echoed as asterisks (wxTE_PASSWORD will be passed to textctrl etc).
- #define wxPG_UINT_BASE wxS("Base")

  Define base used by a wxUIntProperty.
- #define wxPG_UINT_PREFIX wxS("Prefix")

  Define prefix rendered to wxUIntProperty.
- #define wxPG_FILE_WILDCARD wxS("Wildcard")

  wxFileProperty/wxImageFileProperty specific, wxChar, default is detected/varies.*
- #define wxPG_FILE_SHOW_FULL_PATH wxS("ShowFullPath")

  wxFileProperty/wxImageFileProperty specific, int, default 1.
- #define wxPG_FILE_SHOW_RELATIVE_PATH wxS("ShowRelativePath")

  Specific to wxFileProperty and derived properties, wxString, default empty.
- #define wxPG_FILE_INITIAL_PATH wxS("InitialPath")

  Specific to wxFileProperty and derived properties, wxString, default is empty.
- #define wxPG_FILE_DIALOG_TITLE wxS("DialogTitle")

  Specific to wxFileProperty and derivatives, wxString, default is empty.
- #define wxPG_FILE_DIALOG_STYLE wxS("DialogStyle")

  Specific to wxFileProperty and derivatives, long, default is 0.
- #define wxPG_DIR_DIALOG_MESSAGE wxS("DialogMessage")

Specific to wxDirProperty, wxString, default is empty.

- #define wxPG_ARRAY_DELIMITER wxS("Delimiter")

  wxArrayStringProperty's string delimiter character.
- #define wxPG_DATE_FORMAT wxS("DateFormat")

  Sets displayed date format for wxDateProperty.
- #define wxPG_DATE_PICKER_STYLE wxS("PickerStyle")

  Sets wxDatePickerCtrl window style used with wxDateProperty.
- #define wxPG_ATTR_SPINCTRL_STEP wxS("Step")

  SpinCtrl editor, int or double.
- #define wxPG_ATTR_SPINCTRL_WRAP wxS("Wrap")

  SpinCtrl editor, bool.
- #define wxPG_ATTR_SPINCTRL_MOTIONSPIN wxS("MotionSpin")

  SpinCtrl editor, bool.
- #define wxPG_ATTR_MULTICHOICE_USERSTRINGMODE wxS("UserStringMode")

  wxMultiChoiceProperty, int.
- #define wxPG_COLOUR_ALLOW_CUSTOM wxS("AllowCustom")

  wxColourProperty and its kind, int, default 1.
- #define wxPG_COLOUR_HAS_ALPHA wxS("HasAlpha")

  wxColourProperty and its kind: Set to True in order to support editing alpha colour component.

22.391.1 Macro Definition Documentation

#define wxNullProperty ((wxPGProperty*)NULL)

#define wxPG_ARRAY_DELIMITER wxS("Delimiter")

wxArrayStringProperty's string delimiter character.

If this is a quotation mark or hyphen, then strings will be quoted instead (with given character).

Default delimiter is quotation mark.

#define wxPG_ATTR_AUTOCOMPLETE wxS("AutoComplete")

Universal, wxArrayString.

Set to enable auto-completion in any wxTextCtrl-based property editor.

#define wxPG_ATTR_DEFAULT_VALUE wxS("DefaultValue")

Set default value for property.

22.391.2 wxPropertyGrid Property Attribute Identifiers

wxPGProperty::SetAttribute() and wxPropertyGridInterface::SetPropertyAttribute() accept one of these as attribute name argument.

You can use strings instead of constants. However, some of these constants are redefined to use cached strings which may reduce your binary size by some amount.

#define wxPG_ATTR_HINT wxS("Hint")

When set, will be shown as 'greyed' text in property's value cell when the actual displayed value is blank.

#define wxPG_ATTR_INLINE_HELP wxS("InlineHelp")

Deprecated Use "Hint" (wxPG_ATTR_HINT) instead.

#define wxPG_ATTR_MAX wxS("Max")

Universal, int or double.

Maximum value for numeric properties.

#define wxPG_ATTR_MIN wxS("Min")

Universal, int or double.

Minimum value for numeric properties.

#define wxPG_ATTR_MULTICHOICE_USERSTRINGMODE wxS("UserStringMode")

wxMultiChoiceProperty, int.

If 0, no user strings allowed. If 1, user strings appear before list strings. If 2, user strings appear after list string.

#define wxPG_ATTR_SPINCTRL_MOTIONSPIN wxS("MotionSpin")

SpinCtrl editor, bool.

If true, value can also by changed by moving mouse when left mouse button is being pressed.

#define wxPG_ATTR_SPINCTRL_STEP wxS("Step")

SpinCtrl editor, int or double.

How much number changes when button is pressed (or up/down on keyboard).

#define wxPG_ATTR_SPINCTRL_WRAP wxS("Wrap")

SpinCtrl editor, bool.

If true, value wraps at Min/Max.

#define wxPG_ATTR_UNITS wxS("Units")

Universal, string.

When set, will be shown as text after the displayed text value. Alternatively, if third column is enabled, text will be shown there (for any type of property).

#define wxPG_BOOL_USE_CHECKBOX wxS("UseCheckbox")

wxBoolProperty and wxFlagsProperty specific.

Value type is bool. Default value is False.

When set to True, bool property will use check box instead of a combo box as its editor control. If you set this attribute for a wxFlagsProperty, it is automatically applied to child bool properties.

#define wxPG_BOOL_USE_DOUBLE_CLICK_CYCLING wxS("UseDClickCycling")

wxBoolProperty and wxFlagsProperty specific.

Value type is bool. Default value is False.

Set to True for the bool property to cycle value on double click (instead of showing the popup listbox). If you set this attribute for a wxFlagsProperty, it is automatically applied to child bool properties.

#define wxPG_COLOUR_ALLOW_CUSTOM wxS("AllowCustom")

wxColourProperty and its kind, int, default 1.

Setting this attribute to 0 hides custom colour from property's list of choices.

#define wxPG_COLOUR_HAS_ALPHA wxS("HasAlpha")

wxColourProperty and its kind: Set to True in order to support editing alpha colour component.

#define wxPG_DATE_FORMAT wxS("DateFormat")

Sets displayed date format for wxDateProperty.

#define wxPG_DATE_PICKER_STYLE wxS("PickerStyle")

Sets wxDatePickerCtrl window style used with wxDateProperty.

Default is wxDP_DEFAULT | wxDP_SHOWCENTURY. Using wxDP_ALLOWNONE will enable better unspecified value support in the editor.

#define wxPG_DIR_DIALOG_MESSAGE wxS("DialogMessage")

Specific to wxDirProperty, wxString, default is empty.

Sets a specific message for the dir dialog.

#define wxPG_FILE_DIALOG_STYLE wxS("DialogStyle")

Specific to wxFileProperty and derivatives, long, default is 0.

Sets a specific wxFileDialog style for the file dialog, e.g. wxFD_SAVE.

Since

2.9.4

#define wxPG_FILE_DIALOG_TITLE wxS("DialogTitle")

Specific to wxFileProperty and derivatives, wxString, default is empty.

Sets a specific title for the dir dialog.

#define wxPG_FILE_INITIAL_PATH wxS("InitialPath")

Specific to wxFileProperty and derived properties, wxString, default is empty.

Sets the initial path of where to look for files.

#define wxPG_FILE_SHOW_FULL_PATH wxS("ShowFullPath")

wxFileProperty/wxImageFileProperty specific, int, default 1.

When 0, only the file name is shown (i.e. drive and directory are hidden).

#define wxPG_FILE_SHOW_RELATIVE_PATH wxS("ShowRelativePath")

Specific to wxFileProperty and derived properties, wxString, default empty.

If set, then the filename is shown relative to the given path string.

#define wxPG_FILE_WILDCARD wxS("Wildcard")

wxFileProperty/wxImageFileProperty specific, wxChar*, default is detected/varies.

Sets the wildcard used in the triggered wxFileDialog. Format is the same.

#define wxPG_FLOAT_PRECISION wxS("Precision")

wxFloatProperty (and similar) specific, int, default -1.

Sets the (max) precision used when floating point value is rendered as text. The default -1 means infinite precision.

#define wxPG_PROP_MAX wxPG_PROP_AUTO_UNSPECIFIED

Topmost flag.

#define wxPG_PROP_PARENTAL_FLAGS

Value:

```
((wxPGPropertyFlags)(wxPG_PROP_AGGREGATE | \
                     wxPG_PROP_CATEGORY | \
                     wxPG_PROP_MISC_PARENT))
```

Property with children must have one of these set, otherwise iterators will not work correctly.

Code should automatically take care of this, however.

#define wxPG_STRING_PASSWORD wxS("Password")

The text will be echoed as asterisks (wxTE_PASSWORD will be passed to textctrl etc).

#define wxPG_UINT_BASE wxS("Base")

Define base used by a wxUIntProperty.

Valid constants are wxPG_BASE_OCT, wxPG_BASE_DEC, wxPG_BASE_HEX and wxPG_BASE_HEXL (lowercase characters).

#define wxPG_UINT_PREFIX wxS("Prefix")

Define prefix rendered to wxUIntProperty.

Accepted constants wxPG_PREFIX_NONE, wxPG_PREFIX_0x, and wxPG_PREFIX_DOLLAR_SIGN. **Note:** Only wxPG_PREFIX_NONE works with Decimal and Octal numbers.

22.391.3 Enumeration Type Documentation

enum wxPGPropertyFlags

22.391.4 wxPGProperty Flags

Enumerator

wxPG_PROP_MODIFIED Indicates bold font.

wxPG_PROP_DISABLED Disables ('greyed' text and editor does not activate) property.

wxPG_PROP_HIDDEN Hider button will hide this property.

wxPG_PROP_CUSTOMIMAGE This property has custom paint image just in front of its value. If property only draws custom images into a popup list, then this flag should not be set.

wxPG_PROP_NOEDITOR Do not create text based editor for this property (but button-triggered dialog and choice are ok).

wxPG_PROP_COLLAPSED Property is collapsed, ie. it's children are hidden.

wxPG_PROP_INVALID_VALUE If property is selected, then indicates that validation failed for pending value. If property is not selected, then indicates that the actual property value has failed validation (NB: this behaviour is not currently supported, but may be used in the future).

wxPG_PROP_WAS_MODIFIED Switched via SetWasModified(). Temporary flag - only used when setting/changing property value.

wxPG_PROP_AGGREGATE If set, then child properties (if any) are private, and should be "invisible" to the application.

wxPG_PROP_CHILDREN_ARE_COPIES If set, then child properties (if any) are copies and should not be deleted in dtor.

wxPG_PROP_PROPERTY Classifies this item as a non-category. Used for faster item type identification.

wxPG_PROP_CATEGORY Classifies this item as a category. Used for faster item type identification.

wxPG_PROP_MISC_PARENT Classifies this item as a property that has children, but is not aggregate (ie children are not private).

wxPG_PROP_READONLY Property is read-only. Editor is still created for wxTextCtrl-based property editors. For others, editor is not usually created because they do implement wxTE_READONLY style or equivalent.

wxPG_PROP_COMPOSED_VALUE Property's value is composed from values of child properties.

Remarks

This flag cannot be used with property iterators.

wxPG_PROP_USES_COMMON_VALUE Common value of property is selectable in editor.

Remarks

This flag cannot be used with property iterators.

wxPG_PROP_AUTO_UNSPECIFIED Property can be set to unspecified value via editor. Currently, this applies to following properties:

- wxIntProperty, wxUIntProperty, wxFloatProperty, wxEditEnumProperty: Clear the text field

Remarks

This flag cannot be used with property iterators.

See also

wxPGProperty::SetAutoUnspecified()

wxPG_PROP_CLASS_SPECIFIC_1 Indicates the bit useable by derived properties.

wxPG_PROP_CLASS_SPECIFIC_2 Indicates the bit useable by derived properties.

wxPG_PROP_BEING_DELETED Indicates that the property is being deleted and should be ignored.

22.392 interface/wx/propgrid/propgridiface.h File Reference

Classes

- class wxPropertyGridInterface

  Most of the shared property manipulation interface shared by wxPropertyGrid, wxPropertyGridPage, and wxPropertyGridManager is defined in this class.

22.393.1 Macro Definition Documentation

#define wxPG_IT_CHILDREN(*A*) (A<<16)

22.393.2 Enumeration Type Documentation

enum wxPG_ITERATOR_FLAGS

22.393.3 wxPropertyGridIterator Flags

NOTES: At lower 16-bits, there are flags to check if item will be included. At higher 16-bits, there are same flags, but to instead check if children will be included.

Enumerator

wxPG_ITERATE_PROPERTIES Iterate through 'normal' property items (does not include children of aggregate or hidden items by default).

wxPG_ITERATE_HIDDEN Iterate children of collapsed parents, and individual items that are hidden.

wxPG_ITERATE_FIXED_CHILDREN Iterate children of parent that is an aggregate property (ie. has fixed children).

wxPG_ITERATE_CATEGORIES Iterate categories. Note that even without this flag, children of categories are still iterated through.

wxPG_ITERATE_ALL_PARENTS

wxPG_ITERATE_ALL_PARENTS_RECURSIVELY

wxPG_ITERATOR_FLAGS_ALL

wxPG_ITERATOR_MASK_OP_ITEM

wxPG_ITERATOR_MASK_OP_PARENT

wxPG_ITERATE_VISIBLE Combines all flags needed to iterate through visible properties (ie. hidden properties and children of collapsed parents are skipped).

wxPG_ITERATE_ALL Iterate all items.

wxPG_ITERATE_NORMAL Iterate through individual properties (ie. categories and children of aggregate properties are skipped).

wxPG_ITERATE_DEFAULT Default iterator flags.

22.394 interface/wx/protocol/ftp.h File Reference

  wxPROTO_ABRT,
  wxPROTO_RCNCT,
  wxPROTO_STREAMING }

  Error values returned by wxProtocol.

22.396.1 Enumeration Type Documentation

enum wxProtocolError

Error values returned by wxProtocol.

Enumerator

wxPROTO_NOERR No error.

wxPROTO_NETERR A generic network error occurred.

wxPROTO_PROTERR An error occurred during negotiation.

wxPROTO_CONNERR The client failed to connect the server.

wxPROTO_INVVAL Invalid value.

wxPROTO_NOHNDLR Not currently used.

wxPROTO_NOFILE The remote file doesn't exist.

wxPROTO_ABRT Last action aborted.

wxPROTO_RCNCT An error occurred during reconnection.

wxPROTO_STREAMING Someone tried to send a command during a transfer.

22.397 interface/wx/quantize.h File Reference

Classes

- class wxQuantize

  Performs quantization, or colour reduction, on a wxImage.

22.398 interface/wx/radiobox.h File Reference

Classes

- class wxRadioBox

  A radio box item is used to select one of number of mutually exclusive choices.

22.399 interface/wx/radiobut.h File Reference

Classes

- class wxRadioButton

  A radio button item is a button which usually denotes one of several mutually exclusive options.

22.400 interface/wx/rawbmp.h File Reference

Classes

- class wxPixelData< Image, PixelFormat >

  A class template with ready to use implementations for getting direct and efficient access to wxBitmap's internal data and wxImage's internal data through a standard interface.
- class wxPixelData< Image, PixelFormat >::Iterator

  The iterator of class wxPixelData.

22.401 interface/wx/rearrangectrl.h File Reference

Classes

- class wxRearrangeList

  A listbox-like control allowing the user to rearrange the items and to enable or disable them.
- class wxRearrangeCtrl

  A composite control containing a wxRearrangeList and the buttons allowing to move the items in it.
- class wxRearrangeDialog

  A dialog allowing the user to rearrange the specified items.

22.402 interface/wx/recguard.h File Reference

Classes

- class wxRecursionGuardFlag

  This is a completely opaque class which exists only to be used with wxRecursionGuard, please see the example in that class' documentation.
- class wxRecursionGuard

  wxRecursionGuard is a very simple class which can be used to prevent reentrancy problems in a function.

22.403 interface/wx/regex.h File Reference

Classes

- class wxRegEx

  wxRegEx represents a regular expression.

Enumerations

- enum {
  wxRE_EXTENDED = 0,
  wxRE_ADVANCED = 1,
  wxRE_BASIC = 2,
  wxRE_ICASE = 4,
  wxRE_NOSUB = 8,
  wxRE_NEWLINE = 16,
  wxRE_DEFAULT = wxRE_EXTENDED }
- enum {
  wxRE_NOTBOL = 32,
  wxRE_NOTEOL = 64 }

22.403.1 Enumeration Type Documentation

anonymous enum

Flags for regex compilation to be used with wxRegEx::Compile().

Enumerator

wxRE_EXTENDED Use extended regex syntax.

wxRE_ADVANCED Use advanced RE syntax (built-in regex only).

wxRE_BASIC Use basic RE syntax.

wxRE_ICASE Ignore case in match.

wxRE_NOSUB Only check match, don't set back references.

wxRE_NEWLINE If not set, treat '
' as an ordinary character, otherwise it is special: it is not matched by '. ' and '^' and '$' always match after/before it regardless of the setting of wxRE_NOT[BE]OL.

wxRE_DEFAULT Default flags.

anonymous enum

Flags for regex matching to be used with wxRegEx::Matches(). These flags are mainly useful when doing several matches in a long string to prevent erroneous matches for '^' and '$':

Enumerator

wxRE_NOTBOL '^' doesn't match at the start of line.

wxRE_NOTEOL '$' doesn't match at the end of line.

22.404 interface/wx/region.h File Reference

Classes

- class wxRegionIterator

This class is used to iterate through the rectangles in a region, typically when examining the damaged regions of a window within an OnPaint call.

- class wxRegion

  A wxRegion represents a simple or complex region on a device context or window.

Enumerations

- enum wxRegionContain {
  wxOutRegion = 0,
  wxPartRegion = 1,
  wxInRegion = 2 }

  Types of results returned from a call to wxRegion::Contains().

Variables

- wxRegion wxNullRegion

  An empty region.

22.404.1 Enumeration Type Documentation

enum wxRegionContain

Types of results returned from a call to wxRegion::Contains().

Enumerator

wxOutRegion The specified value is not contained within this region.

wxPartRegion The specified value is partially contained within this region. On Windows, this result is not supported. wxInRegion will be returned instead.

wxInRegion The specified value is fully contained within this region. On Windows, this result will be returned even if only part of the specified value is contained in this region.

22.404.2 Variable Documentation

wxRegion wxNullRegion

An empty region.

22.405 interface/wx/renderer.h File Reference

Classes

- struct wxSplitterRenderParams

  This is just a simple `struct` used as a return value of wxRendererNative::GetSplitterParams().

- struct wxHeaderButtonParams

  This `struct` can optionally be used with wxRendererNative::DrawHeaderButton() to specify custom values used to draw the text or bitmap label.

- class wxDelegateRendererNative

  wxDelegateRendererNative allows reuse of renderers code by forwarding all the wxRendererNative methods to the given object and thus allowing you to only modify some of its methods – without having to reimplement all of them.

- class wxRendererNative

First, a brief introduction to wxRendererNative and why it is needed.

- struct wxRendererVersion

  This simple struct represents the wxRendererNative interface version and is only used as the return value of wxRendererNative::GetVersion().

Enumerations

- enum {
  wxCONTROL_NONE = 0x00000000,
  wxCONTROL_DISABLED = 0x00000001,
  wxCONTROL_FOCUSED = 0x00000002,
  wxCONTROL_PRESSED = 0x00000004,
  wxCONTROL_SPECIAL = 0x00000008,
  wxCONTROL_ISDEFAULT = wxCONTROL_SPECIAL,
  wxCONTROL_ISSUBMENU = wxCONTROL_SPECIAL,
  wxCONTROL_EXPANDED = wxCONTROL_SPECIAL,
  wxCONTROL_SIZEGRIP = wxCONTROL_SPECIAL,
  wxCONTROL_FLAT = wxCONTROL_SPECIAL,
  wxCONTROL_CURRENT = 0x00000010,
  wxCONTROL_SELECTED = 0x00000020,
  wxCONTROL_CHECKED = 0x00000040,
  wxCONTROL_CHECKABLE = 0x00000080,
  wxCONTROL_UNDETERMINED = wxCONTROL_CHECKABLE }
- enum wxTitleBarButton {
  wxTITLEBAR_BUTTON_CLOSE = 0x01000000,
  wxTITLEBAR_BUTTON_MAXIMIZE = 0x02000000,
  wxTITLEBAR_BUTTON_ICONIZE = 0x04000000,
  wxTITLEBAR_BUTTON_RESTORE = 0x08000000,
  wxTITLEBAR_BUTTON_HELP = 0x10000000 }

  Title bar buttons supported by wxRendererNative::DrawTitleBarBitmap().
- enum wxHeaderSortIconType {
  wxHDR_SORT_ICON_NONE,
  wxHDR_SORT_ICON_UP,
  wxHDR_SORT_ICON_DOWN }

  Used to specify the type of sort arrow used with wxRendererNative::DrawHeaderButton().

22.405.1 Enumeration Type Documentation

anonymous enum

The following rendering flags are defined for wxRendererNative:

Enumerator

wxCONTROL_NONE Default state, no special flags.

Since

3.1.0

wxCONTROL_DISABLED Control is disabled.

wxCONTROL_FOCUSED Currently has keyboard focus.

wxCONTROL_PRESSED (Button) is pressed.

wxCONTROL_SPECIAL Control-specific bit.

wxCONTROL_ISDEFAULT Only for the buttons.

wxCONTROL_ISSUBMENU Only for the menu items.

wxCONTROL_EXPANDED Only for the tree items.

wxCONTROL_SIZEGRIP Only for the status bar panes.

wxCONTROL_FLAT Checkboxes only: flat border.

wxCONTROL_CURRENT Mouse is currently over the control.

wxCONTROL_SELECTED Selected item in e.g. listbox.

wxCONTROL_CHECKED (Check/radio button) is checked.

wxCONTROL_CHECKABLE (Menu) item can be checked.

wxCONTROL_UNDETERMINED (Check) undetermined state.

enum wxHeaderSortIconType

Used to specify the type of sort arrow used with wxRendererNative::DrawHeaderButton().

Enumerator

wxHDR_SORT_ICON_NONE Don't draw a sort arrow.

wxHDR_SORT_ICON_UP Draw a sort arrow icon pointing up.

wxHDR_SORT_ICON_DOWN Draw a sort arrow icon pointing down.

enum wxTitleBarButton

Title bar buttons supported by wxRendererNative::DrawTitleBarBitmap().

Enumerator

wxTITLEBAR_BUTTON_CLOSE

wxTITLEBAR_BUTTON_MAXIMIZE

wxTITLEBAR_BUTTON_ICONIZE

wxTITLEBAR_BUTTON_RESTORE

wxTITLEBAR_BUTTON_HELP

22.406 interface/wx/ribbon/art.h File Reference

Classes

- class wxRibbonArtProvider

  wxRibbonArtProvider is responsible for drawing all the components of the ribbon interface.

Enumerations

- enum wxRibbonArtSetting {

enum wxRibbonButtonKind

Buttons on a ribbon button bar and tools on a ribbon tool bar can each be one of three different kinds.

Enumerator

wxRIBBON_BUTTON_NORMAL Normal button or tool with a clickable area which causes some generic action.

wxRIBBON_BUTTON_DROPDOWN Dropdown button or tool with a clickable area which typically causes a dropdown menu.

wxRIBBON_BUTTON_HYBRID Button or tool with two clickable areas - one which causes a dropdown menu, and one which causes a generic action.

wxRIBBON_BUTTON_TOGGLE Normal button or tool with a clickable area which toggles the button between a pressed and unpressed state.

enum wxRibbonScrollButtonStyle

Flags used to describe the direction, state, and/or purpose of a ribbon-style scroll button.

See also

wxRibbonArtProvider::DrawScrollButton()
wxRibbonArtProvider::GetScrollButtonMinimumSize()

Enumerator

wxRIBBON_SCROLL_BTN_LEFT Button will scroll to the left.

wxRIBBON_SCROLL_BTN_RIGHT Button will scroll to the right.

wxRIBBON_SCROLL_BTN_UP Button will scroll upward.

wxRIBBON_SCROLL_BTN_DOWN Button will scroll downward.

wxRIBBON_SCROLL_BTN_DIRECTION_MASK A mask to extract direction from a combination of flags.

wxRIBBON_SCROLL_BTN_NORMAL Button is not active or hovered.

wxRIBBON_SCROLL_BTN_HOVERED Button has a cursor hovering over it.

wxRIBBON_SCROLL_BTN_ACTIVE Button is being pressed.

wxRIBBON_SCROLL_BTN_STATE_MASK A mask to extract state from a combination of flags.

wxRIBBON_SCROLL_BTN_FOR_OTHER Button is not for scrolling tabs nor pages.

wxRIBBON_SCROLL_BTN_FOR_TABS Button is for scrolling tabs.

wxRIBBON_SCROLL_BTN_FOR_PAGE Button is for scrolling pages.

wxRIBBON_SCROLL_BTN_FOR_MASK A mask to extract purpose from a combination of flags.

22.407 interface/wx/ribbon/bar.h File Reference

Classes

- class wxRibbonBarEvent

  Event used to indicate various actions relating to a wxRibbonBar.
- class wxRibbonBar

  Top-level control in a ribbon user interface.

Enumerations

- enum wxRibbonDisplayMode {
  wxRIBBON_BAR_PINNED,
  wxRIBBON_BAR_MINIMIZED,
  wxRIBBON_BAR_EXPANDED }

  The possible display modes of the panel area of a wxRibbonBar widget.

22.407.1 Enumeration Type Documentation

enum wxRibbonDisplayMode

The possible display modes of the panel area of a wxRibbonBar widget.

See also

wxRibbonBar::ShowPanels()
wxRibbonBar::GetDisplayMode()

Since

2.9.5

Enumerator

wxRIBBON_BAR_PINNED The panel area is visible and pinned: it remains visible when the ribbon bar loses the focus.

wxRIBBON_BAR_MINIMIZED The panel area is hidden: only the pages tabs remain visible.

wxRIBBON_BAR_EXPANDED The panel area is visible, but not pinned: it minimizes as soon as the focus is lost.

22.408 interface/wx/ribbon/buttonbar.h File Reference

Classes

- class wxRibbonButtonBar

  A ribbon button bar is similar to a traditional toolbar.
- class wxRibbonButtonBarEvent

  Event used to indicate various actions relating to a button on a wxRibbonButtonBar.

Enumerations

- enum wxRibbonButtonBarButtonState {
  wxRIBBON_BUTTONBAR_BUTTON_SMALL = 0 << 0,
  wxRIBBON_BUTTONBAR_BUTTON_MEDIUM = 1 << 0,
  wxRIBBON_BUTTONBAR_BUTTON_LARGE = 2 << 0,
  wxRIBBON_BUTTONBAR_BUTTON_SIZE_MASK = 3 << 0,
  wxRIBBON_BUTTONBAR_BUTTON_NORMAL_HOVERED = 1 << 3,
  wxRIBBON_BUTTONBAR_BUTTON_DROPDOWN_HOVERED = 1 << 4,
  wxRIBBON_BUTTONBAR_BUTTON_HOVER_MASK = wxRIBBON_BUTTONBAR_BUTTON_NORMAL_↩
  HOVERED | wxRIBBON_BUTTONBAR_BUTTON_DROPDOWN_HOVERED,
  wxRIBBON_BUTTONBAR_BUTTON_NORMAL_ACTIVE = 1 << 5,
  wxRIBBON_BUTTONBAR_BUTTON_DROPDOWN_ACTIVE = 1 << 6,
  wxRIBBON_BUTTONBAR_BUTTON_DISABLED = 1 << 7,
  wxRIBBON_BUTTONBAR_BUTTON_TOGGLED = 1 << 8,
  wxRIBBON_BUTTONBAR_BUTTON_STATE_MASK = 0x1F8 }

Flags for button bar button size and state.

22.408.1 Enumeration Type Documentation

enum wxRibbonButtonBarButtonState

Flags for button bar button size and state.

Buttons on a ribbon button bar can each come in three sizes: small, medium, and large. In some places this is called the size class, and the term size used for the pixel width and height associated with a particular size class.

A button can also be in zero or more hovered or active states, or in the disabled state.

Enumerator

wxRIBBON_BUTTONBAR_BUTTON_SMALL Button is small (the interpretation of small is dependent upon the art provider, but it will be smaller than medium).

wxRIBBON_BUTTONBAR_BUTTON_MEDIUM Button is medium sized (the interpretation of medium is dependent upon the art provider, but it will be between small and large).

wxRIBBON_BUTTONBAR_BUTTON_LARGE Button is large (the interpretation of large is dependent upon the art provider, but it will be larger than medium).

wxRIBBON_BUTTONBAR_BUTTON_SIZE_MASK A mask to extract button size from a combination of flags.

wxRIBBON_BUTTONBAR_BUTTON_NORMAL_HOVERED The normal (non-dropdown) region of the button is being hovered over by the mouse cursor. Only applicable to normal and hybrid buttons.

wxRIBBON_BUTTONBAR_BUTTON_DROPDOWN_HOVERED The dropdown region of the button is being hovered over by the mouse cursor. Only applicable to dropdown and hybrid buttons.

wxRIBBON_BUTTONBAR_BUTTON_HOVER_MASK A mask to extract button hover state from a combination of flags.

wxRIBBON_BUTTONBAR_BUTTON_NORMAL_ACTIVE The normal (non-dropdown) region of the button is being pressed. Only applicable to normal and hybrid buttons.

wxRIBBON_BUTTONBAR_BUTTON_DROPDOWN_ACTIVE The dropdown region of the button is being pressed. Only applicable to dropdown and hybrid buttons.

wxRIBBON_BUTTONBAR_BUTTON_DISABLED The button is disabled. Hover flags may still be set when a button is disabled, but should be ignored during drawing if the button is disabled.

wxRIBBON_BUTTONBAR_BUTTON_TOGGLED The button is a toggle button which is currently in the toggled state.

wxRIBBON_BUTTONBAR_BUTTON_STATE_MASK A mask to extract button state from a combination of flags.

wxRIBBON_GALLERY_BUTTON_HOVERED

wxRIBBON_GALLERY_BUTTON_ACTIVE

wxRIBBON_GALLERY_BUTTON_DISABLED

22.410 interface/wx/ribbon/page.h File Reference

Classes

- class wxRibbonPage

  Container for related ribbon panels, and a tab within a ribbon bar.

22.411 interface/wx/richmsgdlg.h File Reference

Classes

- class wxRichMessageDialog

  Extension of wxMessageDialog with additional functionality.

22.412 interface/wx/richtext/richtextbuffer.h File Reference

Classes

- class wxTextAttrDimension

  A class representing a rich text dimension, including units and position.
- class wxTextAttrDimensions

  A class for left, right, top and bottom dimensions.
- class wxTextAttrSize

  A class for representing width and height.
- class wxTextAttrDimensionConverter

  A class to make it easier to convert dimensions.
- class wxTextAttrBorder

  A class representing a rich text object border.
- class wxTextAttrBorders

  A class representing a rich text object's borders.
- class wxTextAttrShadow

  A class representing a shadow.
- class wxTextBoxAttr

  A class representing the box attributes of a rich text object.
- class wxRichTextAttr

  A class representing enhanced attributes for rich text objects.
- class wxRichTextProperties

  A simple property class using wxVariants.

- class wxRichTextFontTable

  Manages quick access to a pool of fonts for rendering rich text.
- class wxRichTextRange

  This stores beginning and end positions for a range of data.
- class wxRichTextSelection

  Stores selection information.
- class wxRichTextDrawingContext

  A class for passing information to drawing and measuring functions.
- class wxRichTextObject

  This is the base for drawable rich text objects.
- class wxRichTextCompositeObject

  Objects of this class can contain other objects.
- class wxRichTextParagraphLayoutBox

  This class knows how to lay out paragraphs.
- class wxRichTextBox

  This class implements a floating or inline text box, containing paragraphs.
- class wxRichTextField

  This class implements the general concept of a field, an object that represents additional functionality such as a footnote, a bookmark, a page number, a table of contents, and so on.
- class wxRichTextFieldType

  The base class for custom field types.
- class wxRichTextFieldTypeStandard

  A field type that can handle fields with text or bitmap labels, with a small range of styles for implementing rectangular fields and fields that can be used for start and end tags.
- class wxRichTextLine

  This object represents a line in a paragraph, and stores offsets from the start of the paragraph representing the start and end positions of the line.
- class wxRichTextParagraph

  This object represents a single paragraph containing various objects such as text content, images, and further paragraph layout objects.
- class wxRichTextPlainText

  This object represents a single piece of text.
- class wxRichTextImageBlock

  This class stores information about an image, in binary in-memory form.
- class wxRichTextImage

  This class implements a graphic object.
- class wxRichTextBuffer

  This is a kind of paragraph layout box, used to represent the whole buffer.
- class wxRichTextCell

  wxRichTextCell is the cell in a table, in which the user can type.
- class wxRichTextTable

  wxRichTextTable represents a table with arbitrary columns and rows.
- class wxRichTextTableBlock

  Stores the coordinates for a block of cells.
- class wxRichTextObjectAddress

  A class for specifying an object anywhere in an object hierarchy, without using a pointer, necessary since wxRTC commands may delete and recreate sub-objects so physical object addresses change.
- class wxRichTextCommand

  Implements a command on the undo/redo stack.
- class wxRichTextAction

  Implements a part of a command.
- class wxRichTextFileHandler

The base class for file handlers.

- class wxRichTextPlainTextHandler

  Implements saving a buffer to plain text.
- class wxRichTextDrawingHandler

  The base class for custom drawing handlers.
- class wxRichTextBufferDataObject

  Implements a rich text data object for clipboard transfer.
- class wxRichTextRenderer

  This class isolates some common drawing functionality.
- class wxRichTextStdRenderer

  The standard renderer for drawing bullets.

Macros

- #define wxRICHTEXT_FIXED_WIDTH 0x01

  Flags determining the available space, passed to Layout.
- #define wxRICHTEXT_FIXED_HEIGHT 0x02
- #define wxRICHTEXT_VARIABLE_WIDTH 0x04
- #define wxRICHTEXT_VARIABLE_HEIGHT 0x08
- #define wxRICHTEXT_LAYOUT_SPECIFIED_RECT 0x10
- #define wxRICHTEXT_DRAW_IGNORE_CACHE 0x01

  Flags to pass to Draw.
- #define wxRICHTEXT_DRAW_SELECTED 0x02
- #define wxRICHTEXT_DRAW_PRINT 0x04
- #define wxRICHTEXT_DRAW_GUIDELINES 0x08
- #define wxRICHTEXT_FORMATTED 0x01

  Flags for GetRangeSize.
- #define wxRICHTEXT_UNFORMATTED 0x02
- #define wxRICHTEXT_CACHE_SIZE 0x04
- #define wxRICHTEXT_HEIGHT_ONLY 0x08
- #define wxRICHTEXT_SETSTYLE_NONE 0x00

  Flags for SetStyle/SetListStyle.
- #define wxRICHTEXT_SETSTYLE_WITH_UNDO 0x01
- #define wxRICHTEXT_SETSTYLE_OPTIMIZE 0x02
- #define wxRICHTEXT_SETSTYLE_PARAGRAPHS_ONLY 0x04
- #define wxRICHTEXT_SETSTYLE_CHARACTERS_ONLY 0x08
- #define wxRICHTEXT_SETSTYLE_RENUMBER 0x10
- #define wxRICHTEXT_SETSTYLE_SPECIFY_LEVEL 0x20
- #define wxRICHTEXT_SETSTYLE_RESET 0x40
- #define wxRICHTEXT_SETSTYLE_REMOVE 0x80
- #define wxRICHTEXT_SETPROPERTIES_NONE 0x00

  Flags for SetProperties.
- #define wxRICHTEXT_SETPROPERTIES_WITH_UNDO 0x01
- #define wxRICHTEXT_SETPROPERTIES_PARAGRAPHS_ONLY 0x02
- #define wxRICHTEXT_SETPROPERTIES_CHARACTERS_ONLY 0x04
- #define wxRICHTEXT_SETPROPERTIES_RESET 0x08
- #define wxRICHTEXT_SETPROPERTIES_REMOVE 0x10
- #define wxRICHTEXT_INSERT_NONE 0x00

  Flags for object insertion.
- #define wxRICHTEXT_INSERT_WITH_PREVIOUS_PARAGRAPH_STYLE 0x01
- #define wxRICHTEXT_INSERT_INTERACTIVE 0x02
- #define wxTEXT_ATTR_KEEP_FIRST_PARA_STYLE 0x10000000

- #define wxSCRIPT_MUL_FACTOR 1.5

  Default superscript/subscript font multiplication factor.
- #define wxRICHTEXT_ALL wxRichTextRange(-2, -2)
- #define wxRICHTEXT_NONE wxRichTextRange(-1, -1)
- #define wxRICHTEXT_NO_SELECTION wxRichTextRange(-2, -2)
- #define wxRICHTEXT_HANDLER_INCLUDE_STYLESHEET 0x0001
- #define wxRICHTEXT_HANDLER_SAVE_IMAGES_TO_MEMORY 0x0010
- #define wxRICHTEXT_HANDLER_SAVE_IMAGES_TO_FILES 0x0020
- #define wxRICHTEXT_HANDLER_SAVE_IMAGES_TO_BASE64 0x0040
- #define wxRICHTEXT_HANDLER_NO_HEADER_FOOTER 0x0080
- #define wxRICHTEXT_HANDLER_CONVERT_FACENAMES 0x0100

Typedefs

- typedef unsigned short wxTextAttrDimensionFlags

  The type for wxTextAttrDimension flags.

Enumerations

- enum wxRichTextFileType {
  wxRICHTEXT_TYPE_ANY = 0,
  wxRICHTEXT_TYPE_TEXT,
  wxRICHTEXT_TYPE_XML,
  wxRICHTEXT_TYPE_HTML,
  wxRICHTEXT_TYPE_RTF,
  wxRICHTEXT_TYPE_PDF }

  File types in wxRichText context.
- enum wxRichTextHitTestFlags {
  wxRICHTEXT_HITTEST_NONE = 0x01,
  wxRICHTEXT_HITTEST_BEFORE = 0x02,
  wxRICHTEXT_HITTEST_AFTER = 0x04,
  wxRICHTEXT_HITTEST_ON = 0x08,
  wxRICHTEXT_HITTEST_OUTSIDE = 0x10,
  wxRICHTEXT_HITTEST_NO_NESTED_OBJECTS = 0x20,
  wxRICHTEXT_HITTEST_NO_FLOATING_OBJECTS = 0x40,
  wxRICHTEXT_HITTEST_HONOUR_ATOMIC = 0x80 }

  Flags returned from hit-testing, or passed to hit-test function.
- enum wxTextBoxAttrFlags {
  wxTEXT_BOX_ATTR_FLOAT = 0x00000001,
  wxTEXT_BOX_ATTR_CLEAR = 0x00000002,
  wxTEXT_BOX_ATTR_COLLAPSE_BORDERS = 0x00000004,
  wxTEXT_BOX_ATTR_VERTICAL_ALIGNMENT = 0x00000008,
  wxTEXT_BOX_ATTR_BOX_STYLE_NAME = 0x00000010,
  wxTEXT_BOX_ATTR_WHITESPACE = 0x00000020,
  wxTEXT_BOX_ATTR_CORNER_RADIUS = 0x00000040 }

  Miscellaneous text box flags.
- enum wxTextAttrValueFlags {
  wxTEXT_ATTR_VALUE_VALID = 0x1000,
  wxTEXT_ATTR_VALUE_VALID_MASK = 0x1000 }

  Whether a value is present, used in dimension flags.

- enum wxTextAttrUnits {
  wxTEXT_ATTR_UNITS_TENTHS_MM = 0x0001,
  wxTEXT_ATTR_UNITS_PIXELS = 0x0002,
  wxTEXT_ATTR_UNITS_PERCENTAGE = 0x0004,
  wxTEXT_ATTR_UNITS_POINTS = 0x0008,
  wxTEXT_ATTR_UNITS_HUNDREDTHS_POINT = 0x0100,
  wxTEXT_ATTR_UNITS_MASK = 0x010F }

  Units, included in the dimension value.
- enum wxTextBoxAttrPosition {
  wxTEXT_BOX_ATTR_POSITION_STATIC = 0x0000,
  wxTEXT_BOX_ATTR_POSITION_RELATIVE = 0x0010,
  wxTEXT_BOX_ATTR_POSITION_ABSOLUTE = 0x0020,
  wxTEXT_BOX_ATTR_POSITION_FIXED = 0x0040,
  wxTEXT_BOX_ATTR_POSITION_MASK = 0x00F0 }

  Position alternatives, included in the dimension flags.
- enum wxTextAttrBorderStyle {
  wxTEXT_BOX_ATTR_BORDER_NONE = 0,
  wxTEXT_BOX_ATTR_BORDER_SOLID = 1,
  wxTEXT_BOX_ATTR_BORDER_DOTTED = 2,
  wxTEXT_BOX_ATTR_BORDER_DASHED = 3,
  wxTEXT_BOX_ATTR_BORDER_DOUBLE = 4,
  wxTEXT_BOX_ATTR_BORDER_GROOVE = 5,
  wxTEXT_BOX_ATTR_BORDER_RIDGE = 6,
  wxTEXT_BOX_ATTR_BORDER_INSET = 7,
  wxTEXT_BOX_ATTR_BORDER_OUTSET = 8 }

  Border styles, used with wxTextAttrBorder.
- enum wxTextAttrBorderFlags {
  wxTEXT_BOX_ATTR_BORDER_STYLE = 0x0001,
  wxTEXT_BOX_ATTR_BORDER_COLOUR = 0x0002 }

  Border style presence flags, used with wxTextAttrBorder.
- enum wxTextAttrBorderWidth {
  wxTEXT_BOX_ATTR_BORDER_THIN = -1,
  wxTEXT_BOX_ATTR_BORDER_MEDIUM = -2,
  wxTEXT_BOX_ATTR_BORDER_THICK = -3 }

  Border width symbols for qualitative widths, used with wxTextAttrBorder.
- enum wxTextBoxAttrFloatStyle {
  wxTEXT_BOX_ATTR_FLOAT_NONE = 0,
  wxTEXT_BOX_ATTR_FLOAT_LEFT = 1,
  wxTEXT_BOX_ATTR_FLOAT_RIGHT = 2 }

  Float styles.
- enum wxTextBoxAttrClearStyle {
  wxTEXT_BOX_ATTR_CLEAR_NONE = 0,
  wxTEXT_BOX_ATTR_CLEAR_LEFT = 1,
  wxTEXT_BOX_ATTR_CLEAR_RIGHT = 2,
  wxTEXT_BOX_ATTR_CLEAR_BOTH = 3 }

  Clear styles.
- enum wxTextBoxAttrCollapseMode {
  wxTEXT_BOX_ATTR_COLLAPSE_NONE = 0,
  wxTEXT_BOX_ATTR_COLLAPSE_FULL = 1 }

  Collapse mode styles.
- enum wxTextBoxAttrVerticalAlignment {
  wxTEXT_BOX_ATTR_VERTICAL_ALIGNMENT_NONE = 0,
  wxTEXT_BOX_ATTR_VERTICAL_ALIGNMENT_TOP = 1,
  wxTEXT_BOX_ATTR_VERTICAL_ALIGNMENT_CENTRE = 2,
  wxTEXT_BOX_ATTR_VERTICAL_ALIGNMENT_BOTTOM = 3 }

  Vertical alignment values.

- enum wxTextBoxAttrWhitespaceMode {
  wxTEXT_BOX_ATTR_WHITESPACE_NONE = 0,
  wxTEXT_BOX_ATTR_WHITESPACE_NORMAL = 1,
  wxTEXT_BOX_ATTR_WHITESPACE_NO_WRAP = 2,
  wxTEXT_BOX_ATTR_WHITESPACE_PREFORMATTED = 3,
  wxTEXT_BOX_ATTR_WHITESPACE_PREFORMATTED_LINE = 4,
  wxTEXT_BOX_ATTR_WHITESPACE_PREFORMATTED_WRAP = 5 }

  Whitespace values mirroring the CSS white-space attribute.
- enum wxRichTextCommandId {
  wxRICHTEXT_INSERT,
  wxRICHTEXT_DELETE,
  wxRICHTEXT_CHANGE_ATTRIBUTES,
  wxRICHTEXT_CHANGE_STYLE,
  wxRICHTEXT_CHANGE_OBJECT }

  The command identifiers for Do/Undo.

Functions

- bool wxRichTextHasStyle (int flags, int style)
- bool wxTextAttrEq (const wxRichTextAttr &attr1, const wxRichTextAttr &attr2)

  Compare two attribute objects.
- bool wxRichTextApplyStyle (wxRichTextAttr &destStyle, const wxRichTextAttr &style, wxRichTextAttr *compareWith=NULL)

  Apply one style to another.
- bool wxRichTextRemoveStyle (wxRichTextAttr &destStyle, const wxRichTextAttr &style)
- bool wxRichTextCombineBitlists (int &valueA, int valueB, int &flagsA, int flagsB)

  Combine two bitlists.
- bool wxRichTextBitlistsEqPartial (int valueA, int valueB, int flags)

  Compare two bitlists.
- bool wxRichTextSplitParaCharStyles (const wxRichTextAttr &style, wxRichTextAttr &parStyle, wxRichTextAttr &charStyle)

  Split into paragraph and character styles.
- bool wxRichTextTabsEq (const wxArrayInt &tabs1, const wxArrayInt &tabs2)

  Compare tabs.
- wxString wxRichTextDecimalToRoman (long n)

  Convert a decimal to Roman numerals.
- void wxTextAttrCollectCommonAttributes (wxTextAttr &currentStyle, const wxTextAttr &attr, wxTextAttr &clashingAttr, wxTextAttr &absentAttr)
- void wxRichTextModuleInit ()

Variables

- const wxChar wxRichTextLineBreakChar

  The line break character that can be embedded in content.

22.412.4 Function Documentation

bool wxRichTextApplyStyle (wxRichTextAttr & *destStyle,* const wxRichTextAttr & *style,* wxRichTextAttr * *compareWith* = NULL)

Apply one style to another.

bool wxRichTextBitlistsEqPartial (int *valueA,* int *valueB,* int *flags*)

Compare two bitlists.

bool wxRichTextCombineBitlists (int & *valueA,* int *valueB,* int & *flagsA,* int *flagsB*)

Combine two bitlists.

wxString wxRichTextDecimalToRoman (long *n*)

Convert a decimal to Roman numerals.

bool wxRichTextHasStyle (int *flags,* int *style*) [inline]

Utilities

void wxRichTextModuleInit ( )

bool wxRichTextRemoveStyle (wxRichTextAttr & *destStyle,* const wxRichTextAttr & *style*)

bool wxRichTextSplitParaCharStyles (const wxRichTextAttr & *style,* wxRichTextAttr & *parStyle,* wxRichTextAttr & *charStyle*)

Split into paragraph and character styles.

bool wxRichTextTabsEq (const wxArrayInt & *tabs1,* const wxArrayInt & *tabs2*)

Compare tabs.

void wxTextAttrCollectCommonAttributes (wxTextAttr & *currentStyle,* const wxTextAttr & *attr,* wxTextAttr & *clashingAttr,* wxTextAttr & *absentAttr*)

bool wxTextAttrEq (const wxRichTextAttr & *attr1,* const wxRichTextAttr & *attr2*)

Compare two attribute objects.

22.412.5 Variable Documentation

const wxChar wxRichTextLineBreakChar

The line break character that can be embedded in content.

Classes

- class wxRichTextStyleListCtrl

  This class incorporates a wxRichTextStyleListBox and a choice control that allows the user to select the category of style to view.

- class wxRichTextStyleDefinition

  This is a base class for paragraph and character styles.

- class wxRichTextParagraphStyleDefinition

  This class represents a paragraph style definition, usually added to a wxRichTextStyleSheet.

- class wxRichTextStyleListBox

  This is a listbox that can display the styles in a wxRichTextStyleSheet, and apply the selection to an associated wxRichTextCtrl.

- class wxRichTextStyleComboCtrl

  This is a combo control that can display the styles in a wxRichTextStyleSheet, and apply the selection to an associated wxRichTextCtrl.

- class wxRichTextCharacterStyleDefinition

  This class represents a character style definition, usually added to a wxRichTextStyleSheet.

- class wxRichTextListStyleDefinition

  This class represents a list style definition, usually added to a wxRichTextStyleSheet.

- class wxRichTextStyleSheet

  A style sheet contains named paragraph and character styles that make it easy for a user to apply combinations of attributes to a wxRichTextCtrl.

22.418 interface/wx/richtext/richtextsymboldlg.h File Reference

Classes

- class wxSymbolPickerDialog

  wxSymbolPickerDialog presents the user with a choice of fonts and a grid of available characters.

22.419 interface/wx/richtext/richtextxml.h File Reference

Classes

- class wxRichTextXMLHandler

  A handler for loading and saving content in an XML format specific to wxRichTextBuffer.

22.420 interface/wx/richtooltip.h File Reference

Classes

- class wxRichToolTip

  Allows to show a tool tip with more customizations than wxToolTip.

Enumerations

- enum wxTipKind {
  wxTipKind_None,
  wxTipKind_TopLeft,

  wxTipKind_BottomRight,
  wxTipKind_Auto }

  Support tip kinds for wxRichToolTip.

22.420.1 Enumeration Type Documentation

enum wxTipKind

Support tip kinds for wxRichToolTip.

This enum describes the kind of the tip shown which combines both the tip position and appearance because the two are related (when the tip is positioned asymmetrically, a right handed triangle is used but an equilateral one when it's in the middle of a side).

Automatic selects the tip appearance best suited for the current platform and the position best suited for the window the tooltip is shown for, i.e. chosen in such a way that the tooltip is always fully on screen.

Other values describe the position of the tooltip itself, not the window it relates to. E.g. wxTipKind_Top places the tip on the top of the tooltip and so the tooltip itself is located beneath its associated window.

Enumerator

wxTipKind_None Don't show any tip, the tooltip will be (roughly) rectangular.

wxTipKind_TopLeft Show a right triangle tip in the top left corner of the tooltip.

wxTipKind_Top Show an equilateral triangle tip in the middle of the tooltip top side.

wxTipKind_TopRight Show a right triangle tip in the top right corner of the tooltip.

wxTipKind_BottomLeft Show a right triangle tip in the bottom left corner of the tooltip.

wxTipKind_Bottom Show an equilateral triangle tip in the middle of the tooltip bottom side.

wxTipKind_BottomRight Show a right triangle tip in the bottom right corner of the tooltip.

wxTipKind_Auto Choose the appropriate tip shape and position automatically. This is the default and shouldn't normally need to be changed.

Notice that currently wxTipKind_Top or wxTipKind_Bottom are used under Mac while one of the other four values is selected for the other platforms.

22.421 interface/wx/sashwin.h File Reference

Classes

- class wxSashWindow

  wxSashWindow allows any of its edges to have a sash which can be dragged to resize the window.
- class wxSashEvent

  A sash event is sent when the sash of a wxSashWindow has been dragged by the user.

Macros

- #define wxSW_NOBORDER 0x0000

  wxSashWindow flags
- #define wxSW_BORDER 0x0020
- #define wxSW_3DSASH 0x0040
- #define wxSW_3DBORDER 0x0080

22.423 interface/wx/sckstrm.h File Reference

Classes

- class wxSocketOutputStream

  This class implements an output stream which writes data from a connected socket.
- class wxSocketInputStream

  This class implements an input stream which reads data from a connected socket.

22.424 interface/wx/scopedarray.h File Reference

Classes

- class wxScopedArray< T >

  A scoped array template class.
- class wxScopedArray< T >

  A scoped array template class.

22.425 interface/wx/scopedptr.h File Reference

Classes

- class wxScopedPtr

  This is a simple scoped smart pointer implementation that is similar to the Boost smart pointers (see `http://www.boost.org`*) but rewritten to use macros instead.*
- class wxScopedTiedPtr

  This is a variation on the topic of wxScopedPtr.
- class wxScopedPtr< T >

  A scoped pointer template class.

22.426 interface/wx/scopeguard.h File Reference

Classes

- class wxScopeGuard

  Scope guard is an object which allows executing an action on scope exit.

Macros

- #define wxON_BLOCK_EXIT(function,...)

  Ensure that the global function with a few (up to some implementation-defined limit) is executed on scope exit, whether due to a normal function return or because an exception has been thrown.
- #define wxON_BLOCK_EXIT0(function)
- #define wxON_BLOCK_EXIT1(function, p1)
- #define wxON_BLOCK_EXIT2(function, p1, p2)
- #define wxON_BLOCK_EXIT3(function, p1, p2, p3)
- #define wxON_BLOCK_EXIT_OBJ(object, method,...)

  This family of macros is similar to wxON_BLOCK_EXIT(), but calls a method of the given object instead of a free function.
- #define wxON_BLOCK_EXIT_OBJ0(object, method)
- #define wxON_BLOCK_EXIT_OBJ1(object, method, p1)
- #define wxON_BLOCK_EXIT_OBJ2(object, method, p1, p2)
- #define wxON_BLOCK_EXIT_OBJ3(object, method, p1, p2, p3)
- #define wxON_BLOCK_EXIT_THIS(method,...)

  This family of macros is similar to wxON_BLOCK_OBJ(), but calls a method of `this` *object instead of a method of the specified object.*
- #define wxON_BLOCK_EXIT_THIS0(method)
- #define wxON_BLOCK_EXIT_THIS1(method, p1)
- #define wxON_BLOCK_EXIT_THIS2(method, p1, p2)

- #define wxON_BLOCK_EXIT_THIS3(method, p1, p2, p3)
- #define wxON_BLOCK_EXIT_SET(var, value)

  This macro sets a variable to the specified value on scope exit.
- #define wxON_BLOCK_EXIT_NULL(ptr)

  This macro sets the pointer passed to it as argument to NULL on scope exit.

Functions

- template<typename F , typename P1 , ... , typename PN >
  wxScopeGuard wxMakeGuard (F func, P1 p1,..., PN pN)

  Returns a scope guard object which will call the specified function with the given parameters on scope exit.

22.427 interface/wx/scrolbar.h File Reference

Classes

- class wxScrollBar

  A wxScrollBar is a control that represents a horizontal or vertical scrollbar.

22.428 interface/wx/scrolwin.h File Reference

Classes

- class wxScrolled< T >

  The wxScrolled class manages scrolling for its client area, transforming the coordinates according to the scrollbar positions, and setting the scroll positions, thumb sizes and ranges according to the area in view.

Typedefs

- typedef wxScrolled< wxPanel > wxScrolledWindow

  Scrolled window derived from wxPanel.
- typedef wxScrolled< wxWindow > wxScrolledCanvas

  Alias for wxScrolled<wxWindow>.

Enumerations

- enum wxScrollbarVisibility {
  wxSHOW_SB_NEVER = -1,
  wxSHOW_SB_DEFAULT,
  wxSHOW_SB_ALWAYS }

  Possible values for the second argument of wxScrolled::ShowScrollbars().

22.428.1 Enumeration Type Documentation

enum wxScrollbarVisibility

Possible values for the second argument of wxScrolled::ShowScrollbars().

Enumerator

wxSHOW_SB_NEVER Never show the scrollbar at all.

wxSHOW_SB_DEFAULT Show scrollbar only if it is needed.

wxSHOW_SB_ALWAYS Always show scrollbar, even if not needed.

22.429 interface/wx/settings.h File Reference

Classes

- class wxSystemSettings

  wxSystemSettings allows the application to ask for details about the system.

Enumerations

- enum wxSystemFont {
  wxSYS_OEM_FIXED_FONT = 10,
  wxSYS_ANSI_FIXED_FONT,
  wxSYS_ANSI_VAR_FONT,
  wxSYS_SYSTEM_FONT,
  wxSYS_DEVICE_DEFAULT_FONT,
  wxSYS_DEFAULT_GUI_FONT }

  Possible values for wxSystemSettings::GetFont() parameter.

- enum wxSystemColour {
  wxSYS_COLOUR_SCROLLBAR,
  wxSYS_COLOUR_DESKTOP,
  wxSYS_COLOUR_ACTIVECAPTION,
  wxSYS_COLOUR_INACTIVECAPTION,
  wxSYS_COLOUR_MENU,

  wxSYS_ICONSPACING_X,
  wxSYS_ICONSPACING_Y,
  wxSYS_WINDOWMIN_X,
  wxSYS_WINDOWMIN_Y,
  wxSYS_SCREEN_X,
  wxSYS_SCREEN_Y,
  wxSYS_FRAMESIZE_X,
  wxSYS_FRAMESIZE_Y,
  wxSYS_SMALLICON_X,
  wxSYS_SMALLICON_Y,
  wxSYS_HSCROLL_Y,
  wxSYS_VSCROLL_X,
  wxSYS_VSCROLL_ARROW_X,
  wxSYS_VSCROLL_ARROW_Y,
  wxSYS_VTHUMB_Y,
  wxSYS_CAPTION_Y,
  wxSYS_MENU_Y,
  wxSYS_NETWORK_PRESENT,
  wxSYS_PENWINDOWS_PRESENT,
  wxSYS_SHOW_SOUNDS,
  wxSYS_SWAP_BUTTONS,
  wxSYS_DCLICK_MSEC }

  Possible values for wxSystemSettings::GetMetric() index parameter.

- enum wxSystemFeature {
  wxSYS_CAN_DRAW_FRAME_DECORATIONS = 1,
  wxSYS_CAN_ICONIZE_FRAME,
  wxSYS_TABLET_PRESENT }

  Possible values for wxSystemSettings::HasFeature() parameter.

- enum wxSystemScreenType {
  wxSYS_SCREEN_NONE = 0,
  wxSYS_SCREEN_TINY,
  wxSYS_SCREEN_PDA,
  wxSYS_SCREEN_SMALL,
  wxSYS_SCREEN_DESKTOP }

  Values for different screen designs.

22.429.1 Enumeration Type Documentation

enum wxSystemColour

Possible values for wxSystemSettings::GetColour() parameter.

These values map 1:1 the native values supported by the Windows' `GetSysColor` function. Note that other ports (other than wxMSW) will try to provide meaningful colours but they usually map the same colour to various `wxSYS_COLOUR_*` values.

Enumerator

wxSYS_COLOUR_SCROLLBAR The scrollbar grey area.

wxSYS_COLOUR_DESKTOP The desktop colour.

wxSYS_COLOUR_ACTIVECAPTION Active window caption colour.

wxSYS_COLOUR_INACTIVECAPTION Inactive window caption colour.

wxSYS_COLOUR_MENU Menu background colour.

wxSYS_COLOUR_WINDOW Window background colour.

wxSYS_COLOUR_WINDOWFRAME Window frame colour.

wxSYS_COLOUR_MENUTEXT Colour of the text used in the menus.

wxSYS_COLOUR_WINDOWTEXT Colour of the text used in generic windows.

wxSYS_COLOUR_CAPTIONTEXT Colour of the text used in captions, size boxes and scrollbar arrow boxes.

wxSYS_COLOUR_ACTIVEBORDER Active window border colour.

wxSYS_COLOUR_INACTIVEBORDER Inactive window border colour.

wxSYS_COLOUR_APPWORKSPACE Background colour for MDI applications.

wxSYS_COLOUR_HIGHLIGHT Colour of item(s) selected in a control.

wxSYS_COLOUR_HIGHLIGHTTEXT Colour of the text of item(s) selected in a control.

wxSYS_COLOUR_BTNFACE Face shading colour on push buttons.

wxSYS_COLOUR_BTNSHADOW Edge shading colour on push buttons.

wxSYS_COLOUR_GRAYTEXT Colour of greyed (disabled) text.

wxSYS_COLOUR_BTNTEXT Colour of the text on push buttons.

wxSYS_COLOUR_INACTIVECAPTIONTEXT Colour of the text in active captions.

wxSYS_COLOUR_BTNHIGHLIGHT Highlight colour for buttons.

wxSYS_COLOUR_3DDKSHADOW Dark shadow colour for three-dimensional display elements.

wxSYS_COLOUR_3DLIGHT Light colour for three-dimensional display elements.

wxSYS_COLOUR_INFOTEXT Text colour for tooltip controls.

wxSYS_COLOUR_INFOBK Background colour for tooltip controls.

wxSYS_COLOUR_LISTBOX Background colour for list-like controls.

wxSYS_COLOUR_HOTLIGHT Colour for a hyperlink or hot-tracked item.

wxSYS_COLOUR_GRADIENTACTIVECAPTION Right side colour in the color gradient of an active window's title bar. `wxSYS_COLOUR_ACTIVECAPTION` specifies the left side color.

wxSYS_COLOUR_GRADIENTINACTIVECAPTION Right side colour in the color gradient of an inactive window's title bar. `wxSYS_COLOUR_INACTIVECAPTION` specifies the left side color.

wxSYS_COLOUR_MENUHILIGHT The colour used to highlight menu items when the menu appears as a flat menu. The highlighted menu item is outlined with `wxSYS_COLOUR_HIGHLIGHT`.

wxSYS_COLOUR_MENUBAR The background colour for the menu bar when menus appear as flat menus. However, `wxSYS_COLOUR_MENU` continues to specify the background color of the menu popup.

wxSYS_COLOUR_LISTBOXTEXT Text colour for list-like controls.

Since

2.9.0

wxSYS_COLOUR_LISTBOXHIGHLIGHTTEXT Text colour for the unfocused selection of list-like controls.

Since

2.9.1

wxSYS_COLOUR_BACKGROUND Synonym for `wxSYS_COLOUR_DESKTOP`.

wxSYS_COLOUR_3DFACE Synonym for `wxSYS_COLOUR_BTNFACE`.

wxSYS_COLOUR_3DSHADOW Synonym for `wxSYS_COLOUR_BTNSHADOW`.

wxSYS_COLOUR_BTNHILIGHT Synonym for `wxSYS_COLOUR_BTNHIGHLIGHT`.

wxSYS_COLOUR_3DHIGHLIGHT Synonym for `wxSYS_COLOUR_BTNHIGHLIGHT`.

wxSYS_COLOUR_3DHILIGHT Synonym for `wxSYS_COLOUR_BTNHIGHLIGHT`.

wxSYS_COLOUR_FRAMEBK Synonym for `wxSYS_COLOUR_BTNFACE`. On wxMSW this colour should be used as the background colour of wxFrames which are used as containers of controls; this is in fact the same colour used for the borders of controls like e.g. wxNotebook or for the background of e.g. wxPanel.

Since

2.9.0

enum wxSystemFeature

Possible values for wxSystemSettings::HasFeature() parameter.

Enumerator

wxSYS_CAN_DRAW_FRAME_DECORATIONS

wxSYS_CAN_ICONIZE_FRAME

wxSYS_TABLET_PRESENT

enum wxSystemFont

Possible values for wxSystemSettings::GetFont() parameter.

These values map 1:1 the native values supported by the Windows' `GetStockObject` function. Note that other ports (other than wxMSW) will try to provide meaningful fonts but they usually map the same font to various `wxSYS_*_FONT` values.

Enumerator

wxSYS_OEM_FIXED_FONT Original equipment manufacturer dependent fixed-pitch font.

wxSYS_ANSI_FIXED_FONT Windows fixed-pitch (monospaced) font.

wxSYS_ANSI_VAR_FONT Windows variable-pitch (proportional) font.

wxSYS_SYSTEM_FONT System font. By default, the system uses the system font to draw menus, dialog box controls, and text.

wxSYS_DEVICE_DEFAULT_FONT Device-dependent font (Windows NT and later only).

wxSYS_DEFAULT_GUI_FONT Default font for user interface objects such as menus and dialog boxes. Note that with modern GUIs nothing guarantees that the same font is used for all GUI elements, so some controls might use a different font by default.

enum wxSystemMetric

Possible values for wxSystemSettings::GetMetric() index parameter.

Enumerator

wxSYS_MOUSE_BUTTONS Number of buttons on mouse, or zero if no mouse was installed.

wxSYS_BORDER_X Width of single border.

wxSYS_BORDER_Y Height of single border.

wxSYS_CURSOR_X Width of cursor.

wxSYS_CURSOR_Y Height of cursor.

wxSYS_DCLICK_X Width in pixels of rectangle within which two successive mouse clicks must fall to generate a double-click.

wxSYS_DCLICK_Y Height in pixels of rectangle within which two successive mouse clicks must fall to generate a double-click.

wxSYS_DRAG_X Width in pixels of a rectangle centered on a drag point to allow for limited movement of the mouse pointer before a drag operation begins.

wxSYS_DRAG_Y Height in pixels of a rectangle centered on a drag point to allow for limited movement of the mouse pointer before a drag operation begins.

wxSYS_EDGE_X Width of a 3D border, in pixels.

wxSYS_EDGE_Y Height of a 3D border, in pixels.

wxSYS_HSCROLL_ARROW_X Width of arrow bitmap on horizontal scrollbar.

wxSYS_HSCROLL_ARROW_Y Height of arrow bitmap on horizontal scrollbar.

wxSYS_HTHUMB_X Width of horizontal scrollbar thumb.

wxSYS_ICON_X The default width of an icon.

wxSYS_ICON_Y The default height of an icon.

wxSYS_ICONSPACING_X Width of a grid cell for items in large icon view, in pixels. Each item fits into a rectangle of this size when arranged.

wxSYS_ICONSPACING_Y Height of a grid cell for items in large icon view, in pixels. Each item fits into a rectangle of this size when arranged.

wxSYS_WINDOWMIN_X Minimum width of a window.

wxSYS_WINDOWMIN_Y Minimum height of a window.

wxSYS_SCREEN_X Width of the screen in pixels.

wxSYS_SCREEN_Y Height of the screen in pixels.

wxSYS_FRAMESIZE_X Width of the window frame for a wxTHICK_FRAME window.

wxSYS_FRAMESIZE_Y Height of the window frame for a wxTHICK_FRAME window.

wxSYS_SMALLICON_X Recommended width of a small icon (in window captions, and small icon view).

wxSYS_SMALLICON_Y Recommended height of a small icon (in window captions, and small icon view).

wxSYS_HSCROLL_Y Height of horizontal scrollbar in pixels.

wxSYS_VSCROLL_X Width of vertical scrollbar in pixels.

wxSYS_VSCROLL_ARROW_X Width of arrow bitmap on a vertical scrollbar.

wxSYS_VSCROLL_ARROW_Y Height of arrow bitmap on a vertical scrollbar.

wxSYS_VTHUMB_Y Height of vertical scrollbar thumb.

wxSYS_CAPTION_Y Height of normal caption area.

wxSYS_MENU_Y Height of single-line menu bar.

wxSYS_NETWORK_PRESENT 1 if there is a network present, 0 otherwise.

wxSYS_PENWINDOWS_PRESENT 1 if PenWindows is installed, 0 otherwise.

wxSYS_SHOW_SOUNDS Non-zero if the user requires an application to present information visually in situations where it would otherwise present the information only in audible form; zero otherwise.

wxSYS_SWAP_BUTTONS Non-zero if the meanings of the left and right mouse buttons are swapped; zero otherwise.

wxSYS_DCLICK_MSEC Maximal time, in milliseconds, which may pass between subsequent clicks for a double click to be generated.

enum wxSystemScreenType

Values for different screen designs.

See wxSystemSettings::GetScreenType().

Enumerator

wxSYS_SCREEN_NONE Undefined screen type.

wxSYS_SCREEN_TINY Tiny screen, less than 320x240.

wxSYS_SCREEN_PDA PDA screen, 320x240 or more but less than 640x480.

wxSYS_SCREEN_SMALL Small screen, 640x480 or more but less than 800x600.

wxSYS_SCREEN_DESKTOP Desktop screen, 800x600 or more.

22.430 interface/wx/sharedptr.h File Reference

Classes

- class wxSharedPtr< T >

  A smart pointer with non-intrusive reference counting.

22.431 interface/wx/simplebook.h File Reference

Classes

- class wxSimplebook

  wxSimplebook is a control showing exactly one of its several pages.

22.432 interface/wx/slider.h File Reference

Classes

- class wxSlider

  A slider is a control with a handle which can be pulled back and forth to change the value.

22.433 interface/wx/snglinst.h File Reference

Classes

- class wxSingleInstanceChecker

  wxSingleInstanceChecker class allows to check that only a single instance of a program is running.

22.434 interface/wx/socket.h File Reference

Classes

- class wxIPaddress

  wxIPaddress is an abstract base class for all internet protocol address objects.

- class wxIPV4address

  A class for working with IPv4 network addresses.
- class wxSocketServer
- class wxSocketClient
- class wxSockAddress

  You are unlikely to need to use this class: only wxSocketBase uses it.
- class wxSocketEvent

  This event class contains information about socket events.
- class wxSocketBase

  wxSocketBase is the base class for all socket-related objects, and it defines all basic IO functionality.
- class wxDatagramSocket

Typedefs

- typedef int wxSOCKET_T

  The type of the native socket.

Enumerations

- enum wxSocketError {
  wxSOCKET_NOERROR,
  wxSOCKET_INVOP,
  wxSOCKET_IOERR,
  wxSOCKET_INVADDR,
  wxSOCKET_INVSOCK,
  wxSOCKET_NOHOST,
  wxSOCKET_INVPORT,
  wxSOCKET_WOULDBLOCK,
  wxSOCKET_TIMEDOUT,
  wxSOCKET_MEMERR }

  wxSocket error return values.
- enum wxSocketEventFlags {
  wxSOCKET_INPUT,
  wxSOCKET_OUTPUT,
  wxSOCKET_CONNECTION,
  wxSOCKET_LOST }
- enum {
  wxSOCKET_NONE = 0,

  wxSOCKET_NOWAIT_WRITE = 256,
  wxSOCKET_WAITALL_WRITE = 512 }

22.434.1 Typedef Documentation

typedef int wxSOCKET_T

The type of the native socket.

Notice that the definition below is simplified and this type is not always int, e.g. it is a 64 bit integer type under Win64.

Since

2.9.5

22.434.2 Enumeration Type Documentation

anonymous enum

wxSocket Flags.

A brief overview on how to use these flags follows.

If no flag is specified (this is the same as **wxSOCKET_NONE**), IO calls will return after some data has been read or written, even when the transfer might not be complete. This is the same as issuing exactly one blocking low-level call to **recv()** or **send()**. Note that *blocking* here refers to when the function returns, not to whether the GUI blocks during this time.

If **wxSOCKET_NOWAIT** is specified, IO calls will return immediately. Read operations will retrieve only available data. Write operations will write as much data as possible, depending on how much space is available in the output buffer. This is the same as issuing exactly one nonblocking low-level call to **recv()** or **send()**. Note that *nonblocking* here refers to when the function returns, not to whether the GUI blocks during this time. Also note that this flag impacts both Read and Write operations. If it is desired to control Read independently of Write, for example you want no wait on Read(), but you do want to wait on Write(), then use wxSOCKET_NOWAIT_READ and wxSOCKET_NOWAIT_WRITE.

If **wxSOCKET_NOWAIT_READ** (this flag is new since wxWidgets 2.9.5) is specified, Read operations will return immediately. Read operations will retrieve only available data. This is the same as issuing exactly one nonblocking low-level call to **recv()**. Note that *nonblocking* here refers to when the function returns, not to whether the GUI blocks during this time. This flag should not be enabled if ReadMsg() is going to be used (it will be ignored), if you do then thread-safety may be at risk. Note that wxSOCKET_NOWAIT_READ impacts only Read operations and does not impact Write operations, allowing Read and Write operations to be set differently.

If **wxSOCKET_NOWAIT_WRITE** (this flag is new since wxWidgets 2.9.5) is specified, Write operations will return immediately. Write operations will write as much data as possible, depending on how much space is available in the output buffer. This is the same as issuing exactly one nonblocking low-level call to **send()**. Note that *nonblocking* here refers to when the function returns, not to whether the GUI blocks during this time. This flag should not be enabled if WriteMsg() is going to be used (it will be ignored), if you use it then thread safety may be at risk. Note that wxSOCKET_NOWAIT_WRITE impacts only Write operations and does not impact Read operations, allowing Read and Write operations to be set differently.

If **wxSOCKET_WAITALL** is specified, IO calls won't return until ALL the data has been read or written (or until an error occurs), blocking if necessary, and issuing several low level calls if necessary. This is the same as having a loop which makes as many blocking low-level calls to **recv()** or **send()** as needed so as to transfer all the data. Note that *blocking* here refers to when the function returns, not to whether the GUI blocks during this time. Note that wxSOCKET_WAITALL impacts both Read and Write operations. If you desire to wait for all on just Read operations, but not on Write operations, (or vice versa), use wxSOCKET_WAITALL_READ or wxSOCKET_WAITALL_WRITE.

If **wxSOCKET_WAITALL_READ** (this flag is new since wxWidgets 2.9.5) is specified, Read operations won't return until ALL the data has been read (or until an error occurs), blocking if necessary, and issuing several low level calls if necessary. This is the same as having a loop which makes as many blocking low-level calls to **recv()** as needed so as to transfer all the data. Note that *blocking* here refers to when the function returns, not to whether the GUI blocks during this time. Note that wxSOCKET_WAITALL_READ only has an impact on Read operations, and has no impact on Write operations, allowing Read and Write operations to have different settings.

If **wxSOCKET_WAITALL_WRITE** (this flag is new since wxWidgets 2.9.5) is specified, Write() and WriteMsg() calls won't return until ALL the data has been written (or until an error occurs), blocking if necessary, and issuing several low level calls if necessary. This is the same as having a loop which makes as many blocking low-level calls to **send()** as needed so as to transfer all the data. Note that *blocking* here refers to when the function returns, not to whether the GUI blocks during this time. Note that wxSOCKET_WAITALL_WRITE only has an impact on Write

operations, and has no impact on Read operations, allowing Read and Write operations to have different settings.

The **wxSOCKET_BLOCK** flag controls whether the GUI blocks during IO operations. If this flag is specified, the socket will not yield during IO calls, so the GUI will remain blocked until the operation completes. If it is not used, then the application must take extra care to avoid unwanted reentrance.

The **wxSOCKET_REUSEADDR** flag controls the use of the **SO_REUSEADDR** standard **setsockopt()** flag. This flag allows the socket to bind to a port that is already in use. This is mostly used on UNIX-based systems to allow rapid starting and stopping of a server, otherwise you may have to wait several minutes for the port to become available.

wxSOCKET_REUSEADDR can also be used with socket clients to (re)bind to a particular local port for an outgoing connection. This option can have surprising platform dependent behaviour, so check the documentation for your platform's implementation of setsockopt().

Note that on BSD-based systems(e.g. Mac OS X), use of **wxSOCKET_REUSEADDR** implies **SO_REUSEPORT** in addition to **SO_REUSEADDR** to be consistent with Windows.

The **wxSOCKET_BROADCAST** flag controls the use of the **SO_BROADCAST** standard **setsockopt()** flag. This flag allows the socket to use the broadcast address, and is generally used in conjunction with **wxSOCKET_NOBIND** and wxIPaddress::BroadcastAddress().

So:

- **wxSOCKET_NONE** will try to read at least SOME data, no matter how much.
- **wxSOCKET_NOWAIT** will always return immediately, even if it cannot read or write ANY data.
- **wxSOCKET_WAITALL** will only return when it has read or written ALL the data.
- **wxSOCKET_BLOCK** has nothing to do with the previous flags and it controls whether the GUI blocks.
- **wxSOCKET_REUSEADDR** controls special platform-specific behaviour for reusing local addresses/ports.

Enumerator

wxSOCKET_NONE Normal functionality.

wxSOCKET_NOWAIT Read/write as much data as possible and return immediately.

wxSOCKET_WAITALL Wait for all required data to be read/written unless an error occurs.

wxSOCKET_BLOCK Block the GUI (do not yield) while reading/writing data.

wxSOCKET_REUSEADDR Allows the use of an in-use port.

wxSOCKET_BROADCAST Switches the socket to broadcast mode.

wxSOCKET_NOBIND Stops the socket from being bound to a specific adapter (normally used in conjunction with **wxSOCKET_BROADCAST**)

wxSOCKET_NOWAIT_READ Read as much data as possible and return immediately.

wxSOCKET_WAITALL_READ Wait for all required data to be read unless an error occurs.

wxSOCKET_NOWAIT_WRITE Write as much data as possible and return immediately.

wxSOCKET_WAITALL_WRITE Wait for all required data to be written unless an error occurs.

enum wxSocketError

wxSocket error return values.

Enumerator

wxSOCKET_NOERROR No error happened.

wxSOCKET_INVOP Invalid operation.

wxSOCKET_IOERR Input/Output error.

wxSOCKET_INVADDR Invalid address passed to wxSocket.

wxSOCKET_INVSOCK Invalid socket (uninitialized).

wxSOCKET_NOHOST No corresponding host.

wxSOCKET_INVPORT Invalid port.

wxSOCKET_WOULDBLOCK The socket is non-blocking and the operation would block.

wxSOCKET_TIMEDOUT The timeout for this operation expired.

wxSOCKET_MEMERR Memory exhausted.

enum wxSocketEventFlags

wxSocket Event Flags.

A brief note on how to use these events:

The **wxSOCKET_INPUT** event will be issued whenever there is data available for reading. This will be the case if the input queue was empty and new data arrives, or if the application has read some data yet there is still more data available. This means that the application does not need to read all available data in response to a **wxSOCKET_INPUT** event, as more events will be produced as necessary.

The **wxSOCKET_OUTPUT** event is issued when a socket is first connected with Connect() or accepted with Accept(). After that, new events will be generated only after an output operation fails with **wxSOCKET_WOULDBLOCK** and buffer space becomes available again. This means that the application should assume that it can write data to the socket until an **wxSOCKET_WOULDBLOCK** error occurs; after this, whenever the socket becomes writable again the application will be notified with another **wxSOCKET_OUTPUT** event.

The **wxSOCKET_CONNECTION** event is issued when a delayed connection request completes successfully (client) or when a new connection arrives at the incoming queue (server).

The **wxSOCKET_LOST** event is issued when a close indication is received for the socket. This means that the connection broke down or that it was closed by the peer. Also, this event will be issued if a connection request fails.

Enumerator

wxSOCKET_INPUT There is data available for reading.

wxSOCKET_OUTPUT The socket is ready to be written to.

wxSOCKET_CONNECTION Incoming connection request (server), or successful connection establishment (client).

wxSOCKET_LOST The connection has been closed.

Classes

- class wxSound

  This class represents a short sound (loaded from Windows WAV file), that can be stored in memory and played.

Macros

- #define wxSOUND_SYNC 0
- #define wxSOUND_ASYNC 1
- #define wxSOUND_LOOP 2

22.435.1 Macro Definition Documentation

#define wxSOUND_ASYNC 1

#define wxSOUND_LOOP 2

#define wxSOUND_SYNC 0

22.436 interface/wx/spinbutt.h File Reference

Classes

- class wxSpinEvent

  This event class is used for the events generated by wxSpinButton and wxSpinCtrl.
- class wxSpinButton

  A wxSpinButton has two small up and down (or left and right) arrow buttons.

22.437 interface/wx/spinctrl.h File Reference

Classes

- class wxSpinCtrl

  wxSpinCtrl combines wxTextCtrl and wxSpinButton in one control.
- class wxSpinCtrlDouble

  wxSpinCtrlDouble combines wxTextCtrl and wxSpinButton in one control and displays a real number.
- class wxSpinDoubleEvent

  This event class is used for the events generated by wxSpinCtrlDouble.

Variables

- wxEventType wxEVT_SPINCTRL

- #define wxSTC_VISIBLE_SLOP 0x01

  Constants for use with SetVisiblePolicy, similar to SetCaretPolicy.
- #define wxSTC_VISIBLE_STRICT 0x04
- #define wxSTC_CARET_SLOP 0x01

  Caret policy, used by SetXCaretPolicy and SetYCaretPolicy.
- #define wxSTC_CARET_STRICT 0x04

  If CARET_STRICT is set, the policy is enforced...
- #define wxSTC_CARET_JUMPS 0x10

If CARET_JUMPS is set, the display is moved more energetically so the caret can move in the same direction longer before the policy is applied again.

- #define wxSTC_CARET_EVEN 0x08

  If CARET_EVEN is not set, instead of having symmetrical UZs, the left and bottom UZs are extended up to right and top UZs respectively.

- #define wxSTC_DMAP_WORD 8
- #define wxSTC_DMAP_WORD2 9
- #define wxSTC_DMAP_WORD3 10
- #define wxSTC_CMD_REDO 2011

  Redoes the next action on the undo history.
- #define wxSTC_CMD_SELECTALL 2013

  Select all the text in the document.

- #define wxSTC_CMD_UNDO 2176

  Undo one action in the undo history.
- #define wxSTC_CMD_CUT 2177

  Cut the selection to the clipboard.
- #define wxSTC_CMD_COPY 2178

  Copy the selection to the clipboard.
- #define wxSTC_CMD_PASTE 2179

  Paste the contents of the clipboard into the document replacing the selection.
- #define wxSTC_CMD_CLEAR 2180

  Clear the selection.
- #define wxSTC_CMD_LINEDOWN 2300

  Move caret down one line.
- #define wxSTC_CMD_LINEDOWNEXTEND 2301

  Move caret down one line extending selection to new caret position.
- #define wxSTC_CMD_LINEUP 2302

  Move caret up one line.
- #define wxSTC_CMD_LINEUPEXTEND 2303

  Move caret up one line extending selection to new caret position.
- #define wxSTC_CMD_CHARLEFT 2304

  Move caret left one character.
- #define wxSTC_CMD_CHARLEFTEXTEND 2305

  Move caret left one character extending selection to new caret position.
- #define wxSTC_CMD_CHARRIGHT 2306

  Move caret right one character.
- #define wxSTC_CMD_CHARRIGHTEXTEND 2307

  Move caret right one character extending selection to new caret position.
- #define wxSTC_CMD_WORDLEFT 2308

  Move caret left one word.
- #define wxSTC_CMD_WORDLEFTEXTEND 2309

  Move caret left one word extending selection to new caret position.
- #define wxSTC_CMD_WORDRIGHT 2310

  Move caret right one word.
- #define wxSTC_CMD_WORDRIGHTEXTEND 2311

  Move caret right one word extending selection to new caret position.
- #define wxSTC_CMD_HOME 2312

  Move caret to first position on line.
- #define wxSTC_CMD_HOMEEXTEND 2313

  Move caret to first position on line extending selection to new caret position.
- #define wxSTC_CMD_LINEEND 2314

  Move caret to last position on line.
- #define wxSTC_CMD_LINEENDEXTEND 2315

  Move caret to last position on line extending selection to new caret position.
- #define wxSTC_CMD_DOCUMENTSTART 2316

  Move caret to first position in document.
- #define wxSTC_CMD_DOCUMENTSTARTEXTEND 2317

  Move caret to first position in document extending selection to new caret position.
- #define wxSTC_CMD_DOCUMENTEND 2318

  Move caret to last position in document.
- #define wxSTC_CMD_DOCUMENTENDEXTEND 2319

  Move caret to last position in document extending selection to new caret position.
- #define wxSTC_CMD_PAGEUP 2320

Move caret one page up.

- #define wxSTC_CMD_PAGEUPEXTEND 2321

  Move caret one page up extending selection to new caret position.
- #define wxSTC_CMD_PAGEDOWN 2322

  Move caret one page down.
- #define wxSTC_CMD_PAGEDOWNEXTEND 2323

  Move caret one page down extending selection to new caret position.
- #define wxSTC_CMD_EDITTOGGLEOVERTYPE 2324

  Switch from insert to overtype mode or the reverse.
- #define wxSTC_CMD_CANCEL 2325

  Cancel any modes such as call tip or auto-completion list display.
- #define wxSTC_CMD_DELETEBACK 2326

  Delete the selection or if no selection, the character before the caret.
- #define wxSTC_CMD_TAB 2327

  If selection is empty or all on one line replace the selection with a tab character.
- #define wxSTC_CMD_BACKTAB 2328

  Dedent the selected lines.
- #define wxSTC_CMD_NEWLINE 2329

  Insert a new line, may use a CRLF, CR or LF depending on EOL mode.
- #define wxSTC_CMD_FORMFEED 2330

  Insert a Form Feed character.
- #define wxSTC_CMD_VCHOME 2331

  Move caret to before first visible character on line.
- #define wxSTC_CMD_VCHOMEEXTEND 2332

  Like VCHome but extending selection to new caret position.
- #define wxSTC_CMD_ZOOMIN 2333

  Magnify the displayed text by increasing the sizes by 1 point.
- #define wxSTC_CMD_ZOOMOUT 2334

  Make the displayed text smaller by decreasing the sizes by 1 point.
- #define wxSTC_CMD_DELWORDLEFT 2335

  Delete the word to the left of the caret.
- #define wxSTC_CMD_DELWORDRIGHT 2336

  Delete the word to the right of the caret.
- #define wxSTC_CMD_DELWORDRIGHTEND 2518

  Delete the word to the right of the caret, but not the trailing non-word characters.
- #define wxSTC_CMD_LINECUT 2337

  Cut the line containing the caret.
- #define wxSTC_CMD_LINEDELETE 2338

  Delete the line containing the caret.
- #define wxSTC_CMD_LINETRANSPOSE 2339

  Switch the current line with the previous.
- #define wxSTC_CMD_LINEDUPLICATE 2404

  Duplicate the current line.
- #define wxSTC_CMD_LOWERCASE 2340

  Transform the selection to lower case.
- #define wxSTC_CMD_UPPERCASE 2341

  Transform the selection to upper case.
- #define wxSTC_CMD_LINESCROLLDOWN 2342

  Scroll the document down, keeping the caret visible.
- #define wxSTC_CMD_LINESCROLLUP 2343

  Scroll the document up, keeping the caret visible.

- #define wxSTC_CMD_DELETEBACKNOTLINE 2344

  Delete the selection or if no selection, the character before the caret.
- #define wxSTC_CMD_HOMEDISPLAY 2345

  Move caret to first position on display line.
- #define wxSTC_CMD_HOMEDISPLAYEXTEND 2346

  Move caret to first position on display line extending selection to new caret position.
- #define wxSTC_CMD_LINEENDDISPLAY 2347

  Move caret to last position on display line.
- #define wxSTC_CMD_LINEENDDISPLAYEXTEND 2348

  Move caret to last position on display line extending selection to new caret position.
- #define wxSTC_CMD_HOMEWRAP 2349

  These are like their namesakes Home(Extend)?, LineEnd(Extend)?, VCHome(Extend)? except they behave differently when word-wrap is enabled: They go first to the start / end of the display line, like (Home|LineEnd)Display The difference is that, the cursor is already at the point, it goes on to the start or end of the document line, as appropriate for (Home|LineEnd|VCHome)(Extend)?.
- #define wxSTC_CMD_HOMEWRAPEXTEND 2450
- #define wxSTC_CMD_LINEENDWRAP 2451
- #define wxSTC_CMD_LINEENDWRAPEXTEND 2452
- #define wxSTC_CMD_VCHOMEWRAP 2453
- #define wxSTC_CMD_VCHOMEWRAPEXTEND 2454
- #define wxSTC_CMD_LINECOPY 2455

  Copy the line containing the caret.
- #define wxSTC_CMD_WORDPARTLEFT 2390

  Move to the previous change in capitalisation.
- #define wxSTC_CMD_WORDPARTLEFTEXTEND 2391

  Move to the previous change in capitalisation extending selection to new caret position.
- #define wxSTC_CMD_WORDPARTRIGHT 2392

  Move to the change next in capitalisation.
- #define wxSTC_CMD_WORDPARTRIGHTEXTEND 2393

  Move to the next change in capitalisation extending selection to new caret position.
- #define wxSTC_CMD_DELLINELEFT 2395

  Delete back from the current position to the start of the line.
- #define wxSTC_CMD_DELLINERIGHT 2396

  Delete forwards from the current position to the end of the line.
- #define wxSTC_CMD_PARADOWN 2413

  Move caret between paragraphs (delimited by empty lines).
- #define wxSTC_CMD_PARADOWNEXTEND 2414
- #define wxSTC_CMD_PARAUP 2415
- #define wxSTC_CMD_PARAUPEXTEND 2416
- #define wxSTC_CMD_LINEDOWNRECTEXTEND 2426

  Move caret down one line, extending rectangular selection to new caret position.
- #define wxSTC_CMD_LINEUPRECTEXTEND 2427

  Move caret up one line, extending rectangular selection to new caret position.
- #define wxSTC_CMD_CHARLEFTRECTEXTEND 2428

  Move caret left one character, extending rectangular selection to new caret position.
- #define wxSTC_CMD_CHARRIGHTRECTEXTEND 2429

  Move caret right one character, extending rectangular selection to new caret position.
- #define wxSTC_CMD_HOMERECTEXTEND 2430

  Move caret to first position on line, extending rectangular selection to new caret position.
- #define wxSTC_CMD_VCHOMERECTEXTEND 2431

  Move caret to before first visible character on line.
- #define wxSTC_CMD_LINEENDRECTEXTEND 2432

Move caret to last position on line, extending rectangular selection to new caret position.

- #define wxSTC_CMD_PAGEUPRECTEXTEND 2433

  Move caret one page up, extending rectangular selection to new caret position.
- #define wxSTC_CMD_PAGEDOWNRECTEXTEND 2434

  Move caret one page down, extending rectangular selection to new caret position.
- #define wxSTC_CMD_STUTTEREDPAGEUP 2435

  Move caret to top of page, or one page up if already at top of page.
- #define wxSTC_CMD_STUTTEREDPAGEUPEXTEND 2436

  Move caret to top of page, or one page up if already at top of page, extending selection to new caret position.
- #define wxSTC_CMD_STUTTEREDPAGEDOWN 2437

  Move caret to bottom of page, or one page down if already at bottom of page.
- #define wxSTC_CMD_STUTTEREDPAGEDOWNEXTEND 2438

  Move caret to bottom of page, or one page down if already at bottom of page, extending selection to new caret position.
- #define wxSTC_CMD_WORDLEFTEND 2439

  Move caret left one word, position cursor at end of word.
- #define wxSTC_CMD_WORDLEFTENDEXTEND 2440

  Move caret left one word, position cursor at end of word, extending selection to new caret position.
- #define wxSTC_CMD_WORDRIGHTEND 2441

  Move caret right one word, position cursor at end of word.
- #define wxSTC_CMD_WORDRIGHTENDEXTEND 2442

  Move caret right one word, position cursor at end of word, extending selection to new caret position.
- #define wxSTC_CMD_VERTICALCENTRECARET 2619

  Centre current line in window.
- #define wxSTC_CMD_MOVESELECTEDLINESUP 2620

  Move the selected lines up one line, shifting the line above after the selection.
- #define wxSTC_CMD_MOVESELECTEDLINESDOWN 2621

  Move the selected lines down one line, shifting the line below before the selection.
- #define wxSTC_CMD_SCROLLTOSTART 2628

  Scroll to start of document.
- #define wxSTC_CMD_SCROLLTOEND 2629

  Scroll to end of document.
- #define wxSTC_CMD_VCHOMEDISPLAY 2652

  Move caret to before first visible character on display line.
- #define wxSTC_CMD_VCHOMEDISPLAYEXTEND 2653

  Like VCHomeDisplay but extending selection to new caret position.

#define wxSTC_CAML_TAGNAME 2

#define wxSTC_CAML_WHITE 10

#define wxSTC_CARET_EVEN 0x08

If CARET_EVEN is not set, instead of having symmetrical UZs, the left and bottom UZs are extended up to right and top UZs respectively.

This way, we favour the displaying of useful information: the begining of lines, where most code reside, and the lines after the caret, eg. the body of a function.

#define wxSTC_CARET_JUMPS 0x10

If CARET_JUMPS is set, the display is moved more energetically so the caret can move in the same direction longer before the policy is applied again.

#define wxSTC_CARET_SLOP 0x01

Caret policy, used by SetXCaretPolicy and SetYCaretPolicy.

If CARET_SLOP is set, we can define a slop value: caretSlop. This value defines an unwanted zone (UZ) where the caret is... unwanted. This zone is defined as a number of pixels near the vertical margins, and as a number of lines near the horizontal margins. By keeping the caret away from the edges, it is seen within its context, so it is likely that the identifier that the caret is on can be completely seen, and that the current line is seen with some of the lines following it which are often dependent on that line.

#define wxSTC_CARET_STRICT 0x04

If CARET_STRICT is set, the policy is enforced...

strictly. The caret is centred on the display if slop is not set, and cannot go in the UZ if slop is set.

#define wxSTC_CMAKE_USERDEFINED 8

#define wxSTC_CMAKE_VARIABLE 7

#define wxSTC_CMAKE_WHILEDEF 9

#define wxSTC_CMD_BACKTAB 2328

Dedent the selected lines.

#define wxSTC_CMD_CANCEL 2325

Cancel any modes such as call tip or auto-completion list display.

#define wxSTC_CMD_CHARLEFT 2304

Move caret left one character.

#define wxSTC_CMD_CHARLEFTEXTEND 2305

Move caret left one character extending selection to new caret position.

#define wxSTC_CMD_CHARLEFTRECTEXTEND 2428

Move caret left one character, extending rectangular selection to new caret position.

#define wxSTC_CMD_CHARRIGHT 2306

Move caret right one character.

#define wxSTC_CMD_CHARRIGHTEXTEND 2307

Move caret right one character extending selection to new caret position.

#define wxSTC_CMD_CHARRIGHTRECTEXTEND 2429

Move caret right one character, extending rectangular selection to new caret position.

#define wxSTC_CMD_CLEAR 2180

Clear the selection.

#define wxSTC_CMD_COPY 2178

Copy the selection to the clipboard.

#define wxSTC_CMD_CUT 2177

Cut the selection to the clipboard.

#define wxSTC_CMD_DELETEBACK 2326

Delete the selection or if no selection, the character before the caret.

#define wxSTC_CMD_DELETEBACKNOTLINE 2344

Delete the selection or if no selection, the character before the caret.
Will not delete the character before at the start of a line.

#define wxSTC_CMD_DELLINELEFT 2395

Delete back from the current position to the start of the line.

#define wxSTC_CMD_DELLINERIGHT 2396

Delete forwards from the current position to the end of the line.

#define wxSTC_CMD_DELWORDLEFT 2335

Delete the word to the left of the caret.

#define wxSTC_CMD_DELWORDRIGHT 2336

Delete the word to the right of the caret.

#define wxSTC_CMD_DELWORDRIGHTEND 2518

Delete the word to the right of the caret, but not the trailing non-word characters.

#define wxSTC_CMD_DOCUMENTEND 2318

Move caret to last position in document.

#define wxSTC_CMD_DOCUMENTENDEXTEND 2319

Move caret to last position in document extending selection to new caret position.

#define wxSTC_CMD_DOCUMENTSTART 2316

Move caret to first position in document.

#define wxSTC_CMD_DOCUMENTSTARTEXTEND 2317

Move caret to first position in document extending selection to new caret position.

#define wxSTC_CMD_EDITTOGGLEOVERTYPE 2324

Switch from insert to overtype mode or the reverse.

#define wxSTC_CMD_FORMFEED 2330

Insert a Form Feed character.

#define wxSTC_CMD_HOME 2312

Move caret to first position on line.

#define wxSTC_CMD_HOMEDISPLAY 2345

Move caret to first position on display line.

#define wxSTC_CMD_HOMEDISPLAYEXTEND 2346

Move caret to first position on display line extending selection to new caret position.

#define wxSTC_CMD_HOMEEXTEND 2313

Move caret to first position on line extending selection to new caret position.

#define wxSTC_CMD_HOMERECTEXTEND 2430

Move caret to first position on line, extending rectangular selection to new caret position.

#define wxSTC_CMD_HOMEWRAP 2349

These are like their namesakes Home(Extend)?, LineEnd(Extend)?, VCHome(Extend)? except they behave differently when word-wrap is enabled: They go first to the start / end of the display line, like (Home|LineEnd)Display The difference is that, the cursor is already at the point, it goes on to the start or end of the document line, as appropriate for (Home|LineEnd|VCHome)(Extend)?.

#define wxSTC_CMD_HOMEWRAPEXTEND 2450

#define wxSTC_CMD_LINECOPY 2455

Copy the line containing the caret.

#define wxSTC_CMD_LINECUT 2337

Cut the line containing the caret.

#define wxSTC_CMD_LINEDELETE 2338

Delete the line containing the caret.

#define wxSTC_CMD_LINEDOWN 2300

Move caret down one line.

#define wxSTC_CMD_LINEDOWNEXTEND 2301

Move caret down one line extending selection to new caret position.

#define wxSTC_CMD_LINEDOWNRECTEXTEND 2426

Move caret down one line, extending rectangular selection to new caret position.

#define wxSTC_CMD_LINEDUPLICATE 2404

Duplicate the current line.

#define wxSTC_CMD_LINEEND 2314

Move caret to last position on line.

#define wxSTC_CMD_LINEENDDISPLAY 2347

Move caret to last position on display line.

#define wxSTC_CMD_LINEENDDISPLAYEXTEND 2348

Move caret to last position on display line extending selection to new caret position.

#define wxSTC_CMD_LINEENDEXTEND 2315

Move caret to last position on line extending selection to new caret position.

#define wxSTC_CMD_LINEENDRECTEXTEND 2432

Move caret to last position on line, extending rectangular selection to new caret position.

#define wxSTC_CMD_LINEENDWRAP 2451

#define wxSTC_CMD_LINEENDWRAPEXTEND 2452

#define wxSTC_CMD_LINESCROLLDOWN 2342

Scroll the document down, keeping the caret visible.

#define wxSTC_CMD_LINESCROLLUP 2343

Scroll the document up, keeping the caret visible.

#define wxSTC_CMD_LINETRANSPOSE 2339

Switch the current line with the previous.

#define wxSTC_CMD_LINEUP 2302

Move caret up one line.

#define wxSTC_CMD_LINEUPEXTEND 2303

Move caret up one line extending selection to new caret position.

#define wxSTC_CMD_LINEUPRECTEXTEND 2427

Move caret up one line, extending rectangular selection to new caret position.

#define wxSTC_CMD_LOWERCASE 2340

Transform the selection to lower case.

#define wxSTC_CMD_MOVESELECTEDLINESDOWN 2621

Move the selected lines down one line, shifting the line below before the selection.

#define wxSTC_CMD_MOVESELECTEDLINESUP 2620

Move the selected lines up one line, shifting the line above after the selection.

#define wxSTC_CMD_NEWLINE 2329

Insert a new line, may use a CRLF, CR or LF depending on EOL mode.

#define wxSTC_CMD_PAGEDOWN 2322

Move caret one page down.

#define wxSTC_CMD_PAGEDOWNEXTEND 2323

Move caret one page down extending selection to new caret position.

#define wxSTC_CMD_PAGEDOWNRECTEXTEND 2434

Move caret one page down, extending rectangular selection to new caret position.

#define wxSTC_CMD_PAGEUP 2320

Move caret one page up.

#define wxSTC_CMD_PAGEUPEXTEND 2321

Move caret one page up extending selection to new caret position.

#define wxSTC_CMD_PAGEUPRECTEXTEND 2433

Move caret one page up, extending rectangular selection to new caret position.

#define wxSTC_CMD_PARADOWN 2413

Move caret between paragraphs (delimited by empty lines).

#define wxSTC_CMD_PARADOWNEXTEND 2414

#define wxSTC_CMD_PARAUP 2415

#define wxSTC_CMD_PARAUPEXTEND 2416

#define wxSTC_CMD_PASTE 2179

Paste the contents of the clipboard into the document replacing the selection.

#define wxSTC_CMD_REDO 2011

Redoes the next action on the undo history.

#define wxSTC_CMD_SCROLLTOEND 2629

Scroll to end of document.

#define wxSTC_CMD_SCROLLTOSTART 2628

Scroll to start of document.

#define wxSTC_CMD_SELECTALL 2013

Select all the text in the document.

#define wxSTC_CMD_STUTTEREDPAGEDOWN 2437

Move caret to bottom of page, or one page down if already at bottom of page.

#define wxSTC_CMD_STUTTEREDPAGEDOWNEXTEND 2438

Move caret to bottom of page, or one page down if already at bottom of page, extending selection to new caret position.

#define wxSTC_CMD_STUTTEREDPAGEUP 2435

Move caret to top of page, or one page up if already at top of page.

#define wxSTC_CMD_STUTTEREDPAGEUPEXTEND 2436

Move caret to top of page, or one page up if already at top of page, extending selection to new caret position.

#define wxSTC_CMD_TAB 2327

If selection is empty or all on one line replace the selection with a tab character.

If more than one line selected, indent the lines.

#define wxSTC_CMD_UNDO 2176

Undo one action in the undo history.

#define wxSTC_CMD_UPPERCASE 2341

Transform the selection to upper case.

#define wxSTC_CMD_VCHOME 2331

Move caret to before first visible character on line.

If already there move to first character on line.

#define wxSTC_CMD_VCHOMEDISPLAY 2652

Move caret to before first visible character on display line.

If already there move to first character on display line.

#define wxSTC_CMD_VCHOMEDISPLAYEXTEND 2653

Like VCHomeDisplay but extending selection to new caret position.

#define wxSTC_CMD_VCHOMEEXTEND 2332

Like VCHome but extending selection to new caret position.

#define wxSTC_CMD_VCHOMERECTEXTEND 2431

Move caret to before first visible character on line.

If already there move to first character on line. In either case, extend rectangular selection to new caret position.

#define wxSTC_CMD_VCHOMEWRAP 2453

#define wxSTC_CMD_VCHOMEWRAPEXTEND 2454

#define wxSTC_CMD_VERTICALCENTRECARET 2619

Centre current line in window.

#define wxSTC_CMD_WORDLEFT 2308

Move caret left one word.

#define wxSTC_CMD_WORDLEFTEND 2439

Move caret left one word, position cursor at end of word.

#define wxSTC_CMD_WORDLEFTENDEXTEND 2440

Move caret left one word, position cursor at end of word, extending selection to new caret position.

#define wxSTC_CMD_WORDLEFTEXTEND 2309

Move caret left one word extending selection to new caret position.

#define wxSTC_CMD_WORDPARTLEFT 2390

Move to the previous change in capitalisation.

#define wxSTC_CMD_WORDPARTLEFTEXTEND 2391

Move to the previous change in capitalisation extending selection to new caret position.

#define wxSTC_CMD_WORDPARTRIGHT 2392

Move to the change next in capitalisation.

#define wxSTC_CMD_WORDPARTRIGHTEXTEND 2393

Move to the next change in capitalisation extending selection to new caret position.

#define wxSTC_CMD_WORDRIGHT 2310

Move caret right one word.

#define wxSTC_CMD_WORDRIGHTEND 2441

Move caret right one word, position cursor at end of word.

#define wxSTC_CMD_WORDRIGHTENDEXTEND 2442

Move caret right one word, position cursor at end of word, extending selection to new caret position.

#define wxSTC_CMD_WORDRIGHTEXTEND 2311

Move caret right one word extending selection to new caret position.

#define wxSTC_CMD_ZOOMIN 2333

Magnify the displayed text by increasing the sizes by 1 point.

#define wxSTC_CMD_ZOOMOUT 2334

Make the displayed text smaller by decreasing the sizes by 1 point.

#define wxSTC_COFFEESCRIPT_CHARACTER 7

22.450 interface/wx/stdpaths.h File Reference

Classes

- class wxStandardPaths

  wxStandardPaths returns the standard locations in the file system and should be used by applications to find their data files in a portable way.

22.451 interface/wx/stdstream.h File Reference

Classes

- class wxStdInputStreamBuffer

  wxStdInputStreamBuffer is a std::streambuf derived stream buffer which reads from a wxInputStream.
- class wxStdInputStream

  wxStdInputStream is a std::istream derived stream which reads from a wxInputStream.
- class wxStdOutputStreamBuffer

  wxStdOutputStreamBuffer is a std::streambuf derived stream buffer which writes to a wxOutputStream.
- class wxStdOutputStream

  wxStdOutputStream is a std::ostream derived stream which writes to a wxOutputStream.

22.452 interface/wx/stockitem.h File Reference

Enumerations

- enum wxStockLabelQueryFlag {
  wxSTOCK_NOFLAGS = 0,
  wxSTOCK_WITH_MNEMONIC = 1,
  wxSTOCK_WITH_ACCELERATOR = 2,
  wxSTOCK_WITHOUT_ELLIPSIS = 4,
  wxSTOCK_FOR_BUTTON = wxSTOCK_WITHOUT_ELLIPSIS | wxSTOCK_WITH_MNEMONIC }

  Possible values for flags parameter of wxGetStockLabel().

Functions

- wxString wxGetStockLabel (wxWindowID id, long flags=wxSTOCK_WITH_MNEMONIC)

  Returns label that should be used for given id element.

22.452.1 Enumeration Type Documentation

enum wxStockLabelQueryFlag

Possible values for flags parameter of wxGetStockLabel().

The elements of this enum are bit masks and may be combined with each other (except when specified otherwise).

Enumerator

wxSTOCK_NOFLAGS Indicates absence of wxSTOCK_WITH_MNEMONIC and wxSTOCK_WITH_ACCE↩ LERATOR. Requests just the label (e.g. "Print...").

wxSTOCK_WITH_MNEMONIC Request the label with mnemonics character. E.g. "&Print...".

wxSTOCK_WITH_ACCELERATOR Return the label with accelerator following it after TAB. E.g. "Print...\t↩ Ctrl-P". This can be combined with wxSTOCK_WITH_MNEMONIC to get "&Print...\tCtrl-P".

wxSTOCK_WITHOUT_ELLIPSIS Return the label without any ellipsis at the end. By default, stock items text is returned with ellipsis, if appropriate, this flag allows to avoid having it. So using the same example as above, the returned string would be "Print" or "&Print" if wxSTOCK_WITH_MNEMONIC were also used.

This flag can't be combined with wxSTOCK_WITH_ACCELERATOR.

Since

2.9.1

wxSTOCK_FOR_BUTTON Return the label appropriate for a button and not a menu item. Currently the main difference is that the trailing ellipsis used in some stock labels is never included in the returned label. Also, the mnemonics is included if this flag is used. So the returned value for wxID_PRINT when this flag is used is "&Print".

This flag can't be combined with wxSTOCK_WITH_ACCELERATOR.

Since

2.9.1

22.453 interface/wx/stopwatch.h File Reference

Classes

- class wxStopWatch

  The wxStopWatch class allow you to measure time intervals.

22.454 interface/wx/strconv.h File Reference

Classes

- class wxMBConv

  This class is the base class of a hierarchy of classes capable of converting text strings between multibyte (SBCS or DBCS) encodings and Unicode.
- class wxMBConvUTF7

  This class converts between the UTF-7 encoding and Unicode.
- class wxMBConvUTF8

This class converts between the UTF-8 encoding and Unicode.

- class wxMBConvUTF16

  This class is used to convert between multibyte encodings and UTF-16 Unicode encoding (also known as UCS-2).
- class wxMBConvUTF32

  This class is used to convert between multibyte encodings and UTF-32 Unicode encoding (also known as UCS-4).
- class wxCSConv

  This class converts between any character set supported by the system and Unicode.

Variables

- wxMBConv * wxConvFileName

  Conversion object used for converting file names from their external representation to the one used inside the program.

22.455 interface/wx/sysopt.h File Reference

Classes

- class wxSystemOptions

  wxSystemOptions stores option/value pairs that wxWidgets itself or applications can use to alter behaviour at runtime.

22.456 interface/wx/tarstrm.h File Reference

Classes

- class wxTarInputStream

  Input stream for reading tar files.
- class wxTarClassFactory

  Class factory for the tar archive format.
- class wxTarOutputStream

  Output stream for writing tar files.
- class wxTarEntry

  Holds the meta-data for an entry in a tar.

Enumerations

- enum wxTarType {
  wxTAR_REGTYPE = '0',
  wxTAR_LNKTYPE = '1',
  wxTAR_SYMTYPE = '2',
  wxTAR_CHRTYPE = '3',
  wxTAR_BLKTYPE = '4',
  wxTAR_DIRTYPE = '5',
  wxTAR_FIFOTYPE = '6',
  wxTAR_CONTTYPE = '7' }

  wxTarEntry::GetTypeFlag() values
- enum wxTarFormat {
  wxTAR_USTAR,
  wxTAR_PAX }

  Archive Formats (use wxTAR_PAX, it's backward compatible) used by wxTarEntry.

22.456.1 Enumeration Type Documentation

enum wxTarFormat

Archive Formats (use wxTAR_PAX, it's backward compatible) used by wxTarEntry.

Enumerator

wxTAR_USTAR POSIX.1-1990 tar format.

wxTAR_PAX POSIX.1-2001 tar format.

enum wxTarType

wxTarEntry::GetTypeFlag() values

Enumerator

wxTAR_REGTYPE regular file

wxTAR_LNKTYPE hard link

wxTAR_SYMTYPE symbolic link

wxTAR_CHRTYPE character special

wxTAR_BLKTYPE block special

wxTAR_DIRTYPE directory

wxTAR_FIFOTYPE named pipe

wxTAR_CONTTYPE contiguous file

22.457 interface/wx/taskbar.h File Reference

Classes

- class wxTaskBarIconEvent

  The event class used by wxTaskBarIcon.
- class wxTaskBarIcon

  This class represents a taskbar icon.

Enumerations

- enum wxTaskBarIconType {
  wxTBI_DOCK,
  wxTBI_CUSTOM_STATUSITEM,
  wxTBI_DEFAULT_TYPE }

  On OSX Cocoa the taskbar icon can be in the doc or in the status area.

Variables

- wxEventType wxEVT_TASKBAR_MOVE
- wxEventType wxEVT_TASKBAR_LEFT_DOWN
- wxEventType wxEVT_TASKBAR_LEFT_UP
- wxEventType wxEVT_TASKBAR_RIGHT_DOWN
- wxEventType wxEVT_TASKBAR_RIGHT_UP

wxEventType wxEVT_TASKBAR_LEFT_DOWN

wxEventType wxEVT_TASKBAR_LEFT_UP

wxEventType wxEVT_TASKBAR_MOVE

wxEventType wxEVT_TASKBAR_RIGHT_DCLICK

wxEventType wxEVT_TASKBAR_RIGHT_DOWN

wxEventType wxEVT_TASKBAR_RIGHT_UP

22.458 interface/wx/taskbarbutton.h File Reference

Classes

- class wxThumbBarButton

  A thumbnail toolbar button is a control that displayed in the thumbnail image of a window in a taskbar button flyout.
- class wxTaskBarButton

  A taskbar button that associated with the window under Windows 7 or later.
- class wxTaskBarJumpListItem

  A wxTaskBarJumpListItem represents an item in a jump list category.
- class wxTaskBarJumpListCategory

  This class represents a category of jump list in the taskbar button.
- class wxTaskBarJumpList

  This class is an transparent wrapper around Windows Jump Lists.

Typedefs

- typedef wxVector
  < wxTaskBarJumpListItem * > wxTaskBarJumpListItems

  A vector of wxTaskBarJumpListItem pointers.
- typedef wxVector
  < wxTaskBarJumpListCategory * > wxTaskBarJumpListCategories

  A vector of wxTaskBarJumpListCategory pointers.

Enumerations

- enum wxTaskBarButtonState {
  wxTASKBAR_BUTTON_NO_PROGRESS = 0,
  wxTASKBAR_BUTTON_INDETERMINATE = 1,
  wxTASKBAR_BUTTON_NORMAL = 2,
  wxTASKBAR_BUTTON_ERROR = 4,
  wxTASKBAR_BUTTON_PAUSED = 8 }

  State of the taskbar button.
- enum wxTaskBarJumpListItemType {
  wxTASKBAR_JUMP_LIST_SEPARATOR,
  wxTASKBAR_JUMP_LIST_TASK,
  wxTASKBAR_JUMP_LIST_DESTIONATION }

  Type of jump list item.

22.458.1 Typedef Documentation

typedef wxVector<wxTaskBarJumpListCategory*> wxTaskBarJumpListCategories

A vector of wxTaskBarJumpListCategory pointers.

typedef wxVector<wxTaskBarJumpListItem*> wxTaskBarJumpListItems

A vector of wxTaskBarJumpListItem pointers.

Since

3.1.0

22.458.2 Enumeration Type Documentation

enum wxTaskBarButtonState

State of the taskbar button.

Since

3.1.0

Enumerator

wxTASKBAR_BUTTON_NO_PROGRESS

wxTASKBAR_BUTTON_INDETERMINATE

wxTASKBAR_BUTTON_NORMAL

wxTASKBAR_BUTTON_ERROR

wxTASKBAR_BUTTON_PAUSED

enum wxTaskBarJumpListItemType

Type of jump list item.

Since

3.1.0

Enumerator

wxTASKBAR_JUMP_LIST_SEPARATOR A separator, Only tasks category supports separators.

wxTASKBAR_JUMP_LIST_TASK A task, represents a link to application.

wxTASKBAR_JUMP_LIST_DESTIONATION Item acts as a link to a file that the application can open.

22.459 interface/wx/textcompleter.h File Reference

Classes

- class wxTextCompleter

  Base class for custom text completer objects.
- class wxTextCompleterSimple

  A simpler base class for custom completer objects.

22.460 interface/wx/textctrl.h File Reference

Classes

- class wxTextAttr

  wxTextAttr represents the character and paragraph attributes, or style, for a range of text in a wxTextCtrl or wxRich↩ TextCtrl.
- class wxTextCtrl

  A text control allows text to be displayed and edited.
- class wxTextUrlEvent
- class wxStreamToTextRedirector

  This class can be used to (temporarily) redirect all output sent to a C++ ostream object to a wxTextCtrl instead.

Macros

- #define wxTE_NO_VSCROLL 0x0002

  wxTextCtrl style flags
- #define wxTE_READONLY 0x0010
- #define wxTE_MULTILINE 0x0020
- #define wxTE_PROCESS_TAB 0x0040

typedef long wxTextCoord

wxTextCoord is a line or row number

22.460.3 Enumeration Type Documentation

enum wxTextAttrAlignment

One of the following values can be passed to wxTextAttr::SetAlignment to determine paragraph alignment.

Enumerator

wxTEXT_ALIGNMENT_DEFAULT

wxTEXT_ALIGNMENT_LEFT

wxTEXT_ALIGNMENT_CENTRE

wxTEXT_ALIGNMENT_CENTER

wxTEXT_ALIGNMENT_RIGHT

wxTEXT_ALIGNMENT_JUSTIFIED wxTEXT_ALIGNMENT_JUSTIFIED is unimplemented. In future justification may be supported when printing or previewing, only.

enum wxTextAttrBulletStyle

Styles for wxTextAttr::SetBulletStyle.

They can be combined together as a bitlist.

Enumerator

wxTEXT_ATTR_BULLET_STYLE_NONE

wxTEXT_ATTR_BULLET_STYLE_ARABIC

wxTEXT_ATTR_BULLET_STYLE_LETTERS_UPPER

wxTEXT_ATTR_BULLET_STYLE_LETTERS_LOWER

wxTEXT_ATTR_BULLET_STYLE_ROMAN_UPPER

wxTEXT_ATTR_BULLET_STYLE_ROMAN_LOWER

wxTEXT_ATTR_BULLET_STYLE_SYMBOL

wxTEXT_ATTR_BULLET_STYLE_BITMAP wxTEXT_ATTR_BULLET_STYLE_BITMAP is unimplemented.

wxTEXT_ATTR_BULLET_STYLE_PARENTHESES

wxTEXT_ATTR_BULLET_STYLE_PERIOD

wxTEXT_ATTR_BULLET_STYLE_STANDARD

wxTEXT_ATTR_BULLET_STYLE_RIGHT_PARENTHESIS

wxTEXT_ATTR_BULLET_STYLE_OUTLINE

wxTEXT_ATTR_BULLET_STYLE_ALIGN_LEFT

wxTEXT_ATTR_BULLET_STYLE_ALIGN_RIGHT

wxTEXT_ATTR_BULLET_STYLE_ALIGN_CENTRE

wxTEXT_ATTR_BULLET_STYLE_CONTINUATION

enum wxTextAttrEffects

Styles for wxTextAttr::SetTextEffects().

They can be combined together as a bitlist.

Of these, only wxTEXT_ATTR_EFFECT_CAPITALS, wxTEXT_ATTR_EFFECT_STRIKETHROUGH, wxTEXT_↩ ATTR_EFFECT_SUPERSCRIPT and wxTEXT_ATTR_EFFECT_SUBSCRIPT are implemented.

Enumerator

wxTEXT_ATTR_EFFECT_NONE

wxTEXT_ATTR_EFFECT_CAPITALS

wxTEXT_ATTR_EFFECT_SMALL_CAPITALS

wxTEXT_ATTR_EFFECT_STRIKETHROUGH

wxTEXT_ATTR_EFFECT_DOUBLE_STRIKETHROUGH

wxTEXT_ATTR_EFFECT_SHADOW

wxTEXT_ATTR_EFFECT_EMBOSS

wxTEXT_ATTR_EFFECT_OUTLINE

wxTEXT_ATTR_EFFECT_ENGRAVE

wxTEXT_ATTR_EFFECT_SUPERSCRIPT

wxTEXT_ATTR_EFFECT_SUBSCRIPT

wxTEXT_ATTR_EFFECT_RTL

wxTEXT_ATTR_EFFECT_SUPPRESS_HYPHENATION

enum wxTextAttrFlags

The following values are passed in a bitlist to wxTextAttr::SetFlags() to determine what attributes will be considered when setting the attributes for a text control.

Enumerator

wxTEXT_ATTR_TEXT_COLOUR

wxTEXT_ATTR_BACKGROUND_COLOUR
wxTEXT_ATTR_FONT_FACE
wxTEXT_ATTR_FONT_POINT_SIZE
wxTEXT_ATTR_FONT_PIXEL_SIZE
wxTEXT_ATTR_FONT_WEIGHT
wxTEXT_ATTR_FONT_ITALIC
wxTEXT_ATTR_FONT_UNDERLINE
wxTEXT_ATTR_FONT_STRIKETHROUGH
wxTEXT_ATTR_FONT_ENCODING
wxTEXT_ATTR_FONT_FAMILY
wxTEXT_ATTR_FONT_SIZE
wxTEXT_ATTR_FONT Defined as the combination of all `wxTEXT_ATTR_FONT_*` values above.
wxTEXT_ATTR_ALIGNMENT
wxTEXT_ATTR_LEFT_INDENT
wxTEXT_ATTR_RIGHT_INDENT
wxTEXT_ATTR_TABS
wxTEXT_ATTR_PARA_SPACING_AFTER
wxTEXT_ATTR_PARA_SPACING_BEFORE
wxTEXT_ATTR_LINE_SPACING
wxTEXT_ATTR_CHARACTER_STYLE_NAME
wxTEXT_ATTR_PARAGRAPH_STYLE_NAME
wxTEXT_ATTR_LIST_STYLE_NAME
wxTEXT_ATTR_BULLET_STYLE
wxTEXT_ATTR_BULLET_NUMBER
wxTEXT_ATTR_BULLET_TEXT
wxTEXT_ATTR_BULLET_NAME
wxTEXT_ATTR_BULLET Defined as the combination of all `wxTEXT_ATTR_BULLET_*` values above.
wxTEXT_ATTR_URL
wxTEXT_ATTR_PAGE_BREAK
wxTEXT_ATTR_EFFECTS
wxTEXT_ATTR_OUTLINE_LEVEL
wxTEXT_ATTR_AVOID_PAGE_BREAK_BEFORE
wxTEXT_ATTR_AVOID_PAGE_BREAK_AFTER
wxTEXT_ATTR_CHARACTER Combines the styles `wxTEXT_ATTR_FONT`, `wxTEXT_ATTR_EFFECTS`, `wxTEXT_ATTR_BACKGROUND_COLOUR`, `wxTEXT_ATTR_TEXT_COLOUR`, `wxTEXT_ATTR_CHARACTER_STYLE_NAME`, `wxTEXT_ATTR_URL`.
wxTEXT_ATTR_PARAGRAPH Combines all the styles regarding text paragraphs.
wxTEXT_ATTR_ALL Combines all previous values.

enum wxTextAttrLineSpacing

Convenience line spacing values; see wxTextAttr::SetLineSpacing().

Enumerator

wxTEXT_ATTR_LINE_SPACING_NORMAL
wxTEXT_ATTR_LINE_SPACING_HALF
wxTEXT_ATTR_LINE_SPACING_TWICE

enum wxTextCtrlHitTestResult

Describes the possible return values of wxTextCtrl::HitTest().

The element names correspond to the relationship between the point asked for and the character returned, e.g. `wxTE_HT_BEFORE` means that the point is before (leftward or upward) it and so on.

Enumerator

wxTE_HT_UNKNOWN Indicates that wxTextCtrl::HitTest() is not implemented on this platform.

wxTE_HT_BEFORE The point is before the character returned.

wxTE_HT_ON_TEXT The point is directly on the character returned.

wxTE_HT_BELOW The point is below the last line of the control.

wxTE_HT_BEYOND The point is beyond the end of line containing the character returned.

Classes

- class wxPasswordEntryDialog

  This class represents a dialog that requests a one-line password string from the user.
- class wxTextEntryDialog

  This class represents a dialog that requests a one-line text string from the user.

Macros

- #define wxTextEntryDialogStyle (wxOK | wxCANCEL | wxCENTRE | wxWS_EX_VALIDATE_RECURSIVELY)

  Default text dialog style.

Functions

- wxString wxGetTextFromUser (const wxString &message, const wxString &caption=wxGetTextFromUserPromptStr, const wxString &default_value=wxEmptyString, wxWindow *parent=NULL, int x=wxDefaultCoord, int y=wxDefaultCoord, bool centre=true)

  Pop up a dialog box with title set to caption, `message`, and a `default_value`.
- wxString wxGetPasswordFromUser (const wxString &message, const wxString &caption=wxGetPasswordFromUserPromptStr, const wxString &default_value=wxEmptyString, wxWindow *parent=NULL, int x=wxDefaultCoord, int y=wxDefaultCoord, bool centre=true)

  Similar to wxGetTextFromUser() but the text entered in the dialog is not shown on screen but replaced with stars.

Variables

- const char wxGetTextFromUserPromptStr [] = "Input Text"

  Default text dialog caption.
- const char wxGetPasswordFromUserPromptStr [] = "Enter Password"

  Default password dialog caption.

22.461.1 Macro Definition Documentation

#define wxTextEntryDialogStyle (wxOK | wxCANCEL | wxCENTRE | wxWS_EX_VALIDATE_RECURSIVELY)

Default text dialog style.

22.461.2 Variable Documentation

const char wxGetPasswordFromUserPromptStr[ ] = "Enter Password"

Default password dialog caption.

const char wxGetTextFromUserPromptStr[ ] = "Input Text"

Default text dialog caption.

22.462 interface/wx/textentry.h File Reference

Classes

- class wxTextEntry

  Common base class for single line text entry fields.

Typedefs

- typedef long wxTextPos

  wxTextPos is a position in the text

22.462.1 Typedef Documentation

typedef long wxTextPos

wxTextPos is a position in the text

22.463 interface/wx/textfile.h File Reference

Classes

- class wxTextFile

  The wxTextFile is a simple class which allows to work with text files on line by line basis.

Enumerations

- enum wxTextFileType {
  wxTextFileType_None,
  wxTextFileType_Unix,
  wxTextFileType_Dos,
  wxTextFileType_Mac,
  wxTextFileType_Os2 }

  The line termination type.

22.463.1 Enumeration Type Documentation

enum wxTextFileType

The line termination type.

Enumerator

wxTextFileType_None incomplete (the last line of the file only)

wxTextFileType_Unix line is terminated with 'LF' = 0xA = 10 = '\n'

wxTextFileType_Dos line is terminated with 'CR' 'LF'

wxTextFileType_Mac line is terminated with 'CR' = 0xD = 13 = '\r'

wxTextFileType_Os2 line is terminated with 'CR' 'LF'

22.464 interface/wx/textwrapper.h File Reference

Classes

- class wxTextWrapper

  Helps wrap lines of text to given width.

22.465 interface/wx/tglbtn.h File Reference

Classes

- class wxToggleButton

  wxToggleButton is a button that stays pressed when clicked by the user.
- class wxBitmapToggleButton

  wxBitmapToggleButton is a wxToggleButton that contains a bitmap instead of text.

Variables

22.465.1 Variable Documentation

wxEventType wxEVT_TOGGLEBUTTON

22.466 interface/wx/time.h File Reference

Functions

- int wxGetTimeZone ()

  Returns the difference between UTC and local time in seconds.
- long wxGetLocalTime ()

  Returns the number of seconds since local time 00:00:00 Jan 1st 1970.
- wxLongLong wxGetLocalTimeMillis ()

  Returns the number of milliseconds since local time 00:00:00 Jan 1st 1970.
- long wxGetUTCTime ()

  Returns the number of seconds since GMT 00:00:00 Jan 1st 1970.
- wxLongLong wxGetUTCTimeMillis ()

  Returns the number of milliseconds since GMT 00:00:00 Jan 1st 1970.
- wxLongLong wxGetUTCTimeUSec ()

  Returns the number of microseconds since GMT 00:00:00 Jan 1st 1970.

22.467 interface/wx/timectrl.h File Reference

Classes

- class wxTimePickerCtrl

  This control allows the user to enter time.

Enumerations

- enum { wxTP_DEFAULT = 0 }

  Styles used with wxTimePickerCtrl.

22.468 interface/wx/timer.h File Reference

Classes

- class wxTimer

  The wxTimer class allows you to execute code at specified intervals.
- class wxTimerRunner

  Starts the timer in its ctor, stops in the dtor.
- class wxTimerEvent

  wxTimerEvent object is passed to the event handler of timer events (see wxTimer::SetOwner).

Macros

- #define wxTIMER_CONTINUOUS false
- #define wxTIMER_ONE_SHOT true

Variables

- wxEventType wxEVT_TIMER

22.468.1 Macro Definition Documentation

#define wxTIMER_CONTINUOUS false

#define wxTIMER_ONE_SHOT true

22.468.2 Variable Documentation

wxEventType wxEVT_TIMER

22.469 interface/wx/tipdlg.h File Reference

Classes

- class wxTipProvider
  This is the class used together with wxShowTip() function.

Functions

- wxTipProvider * wxCreateFileTipProvider (const wxString &filename, size_t currentTip)
  This function creates a wxTipProvider which may be used with wxShowTip().
- bool wxShowTip (wxWindow *parent, wxTipProvider *tipProvider, bool showAtStartup=true)
  This function shows a "startup tip" to the user.

22.470 interface/wx/tipwin.h File Reference

Classes

- class wxTipWindow
  Shows simple text in a popup tip window on creation.

22.471 interface/wx/tls.h File Reference

Macros

- #define wxTLS_TYPE(type) compiler-dependent-implementation
  Macro to be used for thread-specific variables declarations.
- #define wxTLS_VALUE(var)
  Macro to access thread-specific variables.
- #define wxTLS_PTR(var)
  Macro to return address of a thread-specific variables.

22.471.1 Macro Definition Documentation

#define wxTLS_PTR(*var*)

Macro to return address of a thread-specific variables.

This macro is similar to wxTLS_VALUE() except that it always returns a pointer to the type of thread-specific variable.

Notice that this is not a constant expression even if the macro is defined simply as `&var` – the value returned is still different for every thread.

#define wxTLS_TYPE(*type*) compiler-dependent-implementation

Macro to be used for thread-specific variables declarations.

This macro can be used to define thread-specific variables of the specified *type*. Such variables must be global or static and must be POD, i.e. not have any constructors or destructor (even implicitly generated by the compiler due to use of base classes or members which are not POD in a struct).

Example of use:

```
1 struct PerThreadData
2 {
3     ... data which will be different for every thread ...
4 };
5
6 static wxTLS_TYPE(PerThreadData) s_threadDataVar;
7 #define s_threadData (wxTLS_VALUE(s_threadDataVar))
8
9 ... use s_threadData as a variable of type PerThreadData ...
```

Notice that the use of the ugly wxTLS_VALUE() macro is unfortunately required if you need to support platforms without native compiler support for thread-specific variables. If you compile your code only on platforms which do have such support (recent versions of GNU C++ compiler, Microsoft Visual C++ and Sun C++ compiler are known to have it), you can avoid it and use the variable directly.

#define wxTLS_VALUE(*var*)

Macro to access thread-specific variables.

This macro is used to hide the difference in implementation of thread-specific variables under different platforms: they can be of type T used in wxTLS_TYPE() if they are directly supported by the compiler or of type emulating `T *`, i.e. a pointer to this type otherwise. This macro always returns an expression of type `T` itself.

As shown in wxTLS_TYPE() example, you may want to `#define` a symbol wrapping a thread-specific variable with this macro. And, as also explained in wxTLS_TYPE() documentation, you may avoid using it entirely if you target only recent compilers.

See also

wxTLS_PTR()

22.472 interface/wx/tokenzr.h File Reference

Classes

- class wxStringTokenizer

  wxStringTokenizer helps you to break a string up into a number of tokens.

Macros

- #define wxDEFAULT_DELIMITERS " \t\r\n"

  Default wxStringTokenizer delimiters are the usual white space characters.

Enumerations

- enum wxStringTokenizerMode {
  wxTOKEN_INVALID = -1,
  wxTOKEN_DEFAULT,
  wxTOKEN_RET_EMPTY,
  wxTOKEN_RET_EMPTY_ALL,
  wxTOKEN_RET_DELIMS,
  wxTOKEN_STRTOK }

  The behaviour of wxStringTokenizer is governed by the wxStringTokenizer::wxStringTokenizer() or wxStringTokenizer::SetString() with the parameter mode, which may be one of the following:

Functions

- wxArrayString wxStringTokenize (const wxString &str, const wxString &delims=wxDEFAULT_DELIMITERS, wxStringTokenizerMode mode=wxTOKEN_DEFAULT)

  This is a convenience function wrapping wxStringTokenizer which simply returns all tokens found in the given str as an array.

22.472.1 Macro Definition Documentation

#define wxDEFAULT_DELIMITERS " \t\r\n"

Default wxStringTokenizer delimiters are the usual white space characters.

22.472.2 Enumeration Type Documentation

enum wxStringTokenizerMode

The behaviour of wxStringTokenizer is governed by the wxStringTokenizer::wxStringTokenizer() or wxStringTokenizer::SetString() with the parameter *mode*, which may be one of the following:

Enumerator

wxTOKEN_INVALID Invalid tokenizer mode.

wxTOKEN_DEFAULT Default behaviour: wxStringTokenizer will behave in the same way as `strtok()` (wxTOKEN_STRTOK) if the delimiters string only contains white space characters but, unlike the standard function, it will behave like wxTOKEN_RET_EMPTY, returning empty tokens if this is not the case. This is helpful for parsing strictly formatted data where the number of fields is fixed but some of them may be empty (i.e. `TAB` or comma delimited text files).

wxTOKEN_RET_EMPTY In this mode, the empty tokens in the middle of the string will be returned, i.e. `"a::b:"` will be tokenized in three tokens `'a'`, `''` and `'b'`. Notice that all trailing delimiters are ignored in this mode, not just the last one, i.e. a string `"a::b::"` would still result in the same set of tokens.

wxTOKEN_RET_EMPTY_ALL In this mode, empty trailing tokens (including the one after the last delimiter character) will be returned as well. The string `"a::b:"` will be tokenized in four tokens: the already mentioned ones and another empty one as the last one and a string `"a::b::"` will have five tokens.

wxTOKEN_RET_DELIMS In this mode, the delimiter character after the end of the current token (there may be none if this is the last token) is returned appended to the token. Otherwise, it is the same mode as wxTOKEN_RET_EMPTY. Notice that there is no mode like this one but behaving like wxTOKEN_RET_EMPTY_ALL instead of wxTOKEN_RET_EMPTY, use wxTOKEN_RET_EMPTY_ALL and wxStringTokenizer::GetLastDelimiter() to emulate it.

wxTOKEN_STRTOK In this mode the class behaves exactly like the standard `strtok()` function: the empty tokens are never returned.

22.473 interface/wx/toolbook.h File Reference

Classes

- class wxToolbook

  wxToolbook is a class similar to wxNotebook but which uses a wxToolBar to show the labels instead of the tabs.

Macros

- #define wxTBK_BUTTONBAR 0x0100
- #define wxTBK_HORZ_LAYOUT 0x8000

Variables

- wxEventType wxEVT_TOOLBOOK_PAGE_CHANGED
- wxEventType wxEVT_TOOLBOOK_PAGE_CHANGING

22.473.1 Macro Definition Documentation

#define wxTBK_BUTTONBAR 0x0100

#define wxTBK_HORZ_LAYOUT 0x8000

22.473.2 Variable Documentation

wxEventType wxEVT_TOOLBOOK_PAGE_CHANGED

wxEventType wxEVT_TOOLBOOK_PAGE_CHANGING

22.474 interface/wx/tooltip.h File Reference

Classes

- class wxToolTip

  This class holds information about a tooltip associated with a window (see wxWindow::SetToolTip()).

22.475 interface/wx/tracker.h File Reference

Classes

- class wxTrackable

  Add-on base class for a trackable object.

22.476 interface/wx/translation.h File Reference

Classes

- class wxTranslations

  This class allows to get translations for strings.

- class wxTranslationsLoader

  Abstraction of translations discovery and loading.
- class wxFileTranslationsLoader

  Standard wxTranslationsLoader implementation.
- class wxResourceTranslationsLoader

  This loader makes it possible to load translations from Windows resources.
- class wxMsgCatalog

  Represents a loaded translations message catalog.

Macros

- #define wxPLURAL(string, plural, n)

  This macro is identical to _() but for the plural variant of wxGetTranslation().
- #define wxTRANSLATE(string)

  This macro doesn't do anything in the program code – it simply expands to the value of its argument.

Functions

- const wxString & wxGetTranslation (const wxString &string, const wxString &domain=wxEmptyString)

  This function returns the translation of string in the current `locale()`.
- const wxString & wxGetTranslation (const wxString &string, const wxString &plural, unsigned n, const wxString &domain=wxEmptyString)

  This is an overloaded version of wxGetTranslation(const wxString&, const wxString&), please see its documentation for general information.
- const wxString & _ (const wxString &string)

  Macro to be used around all literal strings that should be translated.

22.477 interface/wx/treebase.h File Reference

Classes

- class wxTreeItemId

  An opaque reference to a tree item.
- class wxTreeItemData

  wxTreeItemData is some (arbitrary) user class associated with some item.

Macros

- #define wxTR_NO_BUTTONS 0x0000
- #define wxTR_HAS_BUTTONS 0x0001
- #define wxTR_NO_LINES 0x0004
- #define wxTR_LINES_AT_ROOT 0x0008
- #define wxTR_TWIST_BUTTONS 0x0010
- #define wxTR_SINGLE 0x0000
- #define wxTR_MULTIPLE 0x0020
- #define wxTR_HAS_VARIABLE_ROW_HEIGHT 0x0080
- #define wxTR_EDIT_LABELS 0x0200
- #define wxTR_ROW_LINES 0x0400
- #define wxTR_HIDE_ROOT 0x0800
- #define wxTR_FULL_ROW_HIGHLIGHT 0x2000
- #define wxTR_DEFAULT_STYLE (wxTR_HAS_BUTTONS | wxTR_LINES_AT_ROOT)

Enumerations

- enum wxTreeItemIcon {
  wxTreeItemIcon_Normal,
  wxTreeItemIcon_Selected,
  wxTreeItemIcon_Expanded,
  wxTreeItemIcon_SelectedExpanded,
  wxTreeItemIcon_Max }

  Indicates which type to associate an image with a wxTreeCtrl item.

Functions

- bool operator== (const wxTreeItemId &left, const wxTreeItemId &right)
- bool operator!= (const wxTreeItemId &left, const wxTreeItemId &right)

Variables

- static const int wxTREE_ITEMSTATE_NONE = -1

  special values for the 'state' parameter of wxTreeCtrl::SetItemState()
- static const int wxTREE_ITEMSTATE_NEXT = -2
- static const int wxTREE_ITEMSTATE_PREV = -3
- static const int wxTREE_HITTEST_ABOVE = 0x0001
- static const int wxTREE_HITTEST_BELOW = 0x0002
- static const int wxTREE_HITTEST_NOWHERE = 0x0004
- static const int wxTREE_HITTEST_ONITEMBUTTON = 0x0008
- static const int wxTREE_HITTEST_ONITEMICON = 0x0010
- static const int wxTREE_HITTEST_ONITEMINDENT = 0x0020
- static const int wxTREE_HITTEST_ONITEMLABEL = 0x0040
- static const int wxTREE_HITTEST_ONITEMRIGHT = 0x0080
- static const int wxTREE_HITTEST_ONITEMSTATEICON = 0x0100
- static const int wxTREE_HITTEST_TOLEFT = 0x0200
- static const int wxTREE_HITTEST_TORIGHT = 0x0400
- static const int wxTREE_HITTEST_ONITEMUPPERPART = 0x0800
- static const int wxTREE_HITTEST_ONITEMLOWERPART = 0x1000
- static const int wxTREE_HITTEST_ONITEM

22.477.1 Macro Definition Documentation

#define wxTR_DEFAULT_STYLE (wxTR_HAS_BUTTONS | wxTR_LINES_AT_ROOT)

#define wxTR_EDIT_LABELS 0x0200

#define wxTR_FULL_ROW_HIGHLIGHT 0x2000

#define wxTR_NO_LINES 0x0004

#define wxTR_ROW_LINES 0x0400

#define wxTR_SINGLE 0x0000

#define wxTR_TWIST_BUTTONS 0x0010

22.477.2 Enumeration Type Documentation

enum **wxTreeItemIcon**

Indicates which type to associate an image with a wxTreeCtrl item.

See also

wxTreeCtrl::GetItemImage(), wxTreeCtrl::SetItemImage()

Enumerator

wxTreeItemIcon_Normal To get/set the item image for when the item is **not** selected and **not** expanded.

wxTreeItemIcon_Selected To get/set the item image for when the item is **selected** and **not** expanded.

wxTreeItemIcon_Expanded To get/set the item image for when the item is **not** selected and **expanded**.

wxTreeItemIcon_SelectedExpanded To get/set the item image for when the item is **selected** and **expanded**.

wxTreeItemIcon_Max

22.477.3 Function Documentation

bool operator!= (const **wxTreeItemId** & *left,* const **wxTreeItemId** & *right*)

bool operator== (const **wxTreeItemId** & *left,* const **wxTreeItemId** & *right*)

special values for the 'state' parameter of wxTreeCtrl::SetItemState()

const int wxTREE_ITEMSTATE_PREV = -3 [static]

22.478 interface/wx/treelist.h File Reference

Classes

- class wxTreeListItem

  Unique identifier of an item in wxTreeListCtrl.
- class wxTreeListItemComparator

  Class defining sort order for the items in wxTreeListCtrl.
- class wxTreeListCtrl

  A control combining wxTreeCtrl and wxListCtrl features.
- class wxTreeListEvent

  Event generated by wxTreeListCtrl.

Macros

- #define wxTreeListEventHandler(func) wxEVENT_HANDLER_CAST(wxTreeListEventFunction, func)

  Type of wxTreeListEvent event handlers.

Typedefs

- typedef wxVector< wxTreeListItem > wxTreeListItems

  Container of multiple items.

Enumerations

- enum {
  wxTL_SINGLE = 0x0000,
  wxTL_MULTIPLE = 0x0001,
  wxTL_CHECKBOX = 0x0002,
  wxTL_3STATE = 0x0004,
  wxTL_USER_3STATE = 0x0008,
  wxTL_NO_HEADER = 0x0010,
  wxTL_DEFAULT_STYLE = wxTL_SINGLE,
  wxTL_STYLE_MASK }

  wxTreeListCtrl styles.

Variables

- const wxTreeListItem wxTLI_FIRST

  Special wxTreeListItem value meaning "insert before the first item".
- const wxTreeListItem wxTLI_LAST

  Special wxTreeListItem value meaning "insert after the last item".
- wxEventType wxEVT_TREELIST_SELECTION_CHANGED
- wxEventType wxEVT_TREELIST_ITEM_EXPANDING
- wxEventType wxEVT_TREELIST_ITEM_EXPANDED
- wxEventType wxEVT_TREELIST_ITEM_CHECKED
- wxEventType wxEVT_TREELIST_ITEM_ACTIVATED
- wxEventType wxEVT_TREELIST_ITEM_CONTEXT_MENU
- wxEventType wxEVT_TREELIST_COLUMN_SORTED

22.478.1 Macro Definition Documentation

#define wxTreeListEventHandler(*func*) wxEVENT_HANDLER_CAST(wxTreeListEventFunction, func)

Type of wxTreeListEvent event handlers.

This macro should be used with wxEvtHandler::Connect() when connecting to wxTreeListCtrl events.

22.478.2 Typedef Documentation

typedef wxVector<wxTreeListItem> wxTreeListItems

Container of multiple items.

22.478.3 Enumeration Type Documentation

anonymous enum

wxTreeListCtrl styles.

Notice that using wxTL_USER_3STATE implies wxTL_3STATE and wxTL_3STATE in turn implies wxTL_CHEC↩
KBOX.

Enumerator

wxTL_SINGLE

wxTL_MULTIPLE This is the default anyhow.

wxTL_CHECKBOX Allow multiple selection.

wxTL_3STATE Show checkboxes in the first column.

wxTL_USER_3STATE Allow 3rd state in checkboxes.

wxTL_NO_HEADER Allow user to set 3rd state. Don't show the column headers.

By default this control shows the column headers, using this class allows to avoid this and show only the data.

Since

2.9.5

wxTL_DEFAULT_STYLE

wxTL_STYLE_MASK

const wxTreeListItem wxTLI_FIRST

Special wxTreeListItem value meaning "insert before the first item".

This value can be passed to wxTreeListCtrl::InsertItem() to achieve the same effect as calling wxTreeListCtrl::↩ PrependItem().

const wxTreeListItem wxTLI_LAST

Special wxTreeListItem value meaning "insert after the last item".

This value can be passed to wxTreeListCtrl::InsertItem() to achieve the same effect as calling wxTreeListCtrl::↩ AppendItem().

22.479 interface/wx/txtstrm.h File Reference

Classes

- class wxTextInputStream

  This class provides functions that reads text data using an input stream, allowing you to read text, floats, and integers.
- class wxTextOutputStream

  This class provides functions that write text data using an output stream, allowing you to write text, floats, and integers.

Enumerations

- enum wxEOL {
  wxEOL_NATIVE,
  wxEOL_UNIX,
  wxEOL_MAC,
  wxEOL_DOS }

  Specifies the end-of-line characters to use with wxTextOutputStream.

22.479.1 Enumeration Type Documentation

enum wxEOL

Specifies the end-of-line characters to use with wxTextOutputStream.

Enumerator

wxEOL_NATIVE Specifies wxTextOutputStream to use the native end-of-line characters.

wxEOL_UNIX Specifies wxTextOutputStream to use Unix end-of-line characters.

wxEOL_MAC Specifies wxTextOutputStream to use Mac end-of-line characters.

wxEOL_DOS Specifies wxTextOutputStream to use DOS end-of-line characters.

22.480 interface/wx/uiaction.h File Reference

Classes

- class wxUIActionSimulator

  wxUIActionSimulator is a class used to simulate user interface actions such as a mouse click or a key press.

22.481 interface/wx/unichar.h File Reference

Classes

- class wxUniChar

  This class represents a single Unicode character.
- class wxUniCharRef

  Writeable reference to a character in wxString.

22.482 interface/wx/uri.h File Reference

Classes

- class wxURI

  wxURI is used to extract information from a URI (Uniform Resource Identifier).

Enumerations

- enum wxURIHostType {
  wxURI_REGNAME,
  wxURI_IPV4ADDRESS,
  wxURI_IPV6ADDRESS,
  wxURI_IPVFUTURE }

  Host type of URI returned from wxURI::GetHostType().

22.482.1 Enumeration Type Documentation

enum wxURIHostType

Host type of URI returned from wxURI::GetHostType().

Enumerator

wxURI_REGNAME Host is a normal register name (`"www.mysite.com"`).

wxURI_IPV4ADDRESS Host is a version 4 ip address (`"192.168.1.100"`).

wxURI_IPV6ADDRESS Host is a version 6 ip address (`"[aa:aa:aa:aa::aa:aa]:5050"`).

wxURI_IPVFUTURE Host is a future ip address, wxURI is unsure what kind.

22.483 interface/wx/url.h File Reference

Classes

- class wxURL

  wxURL is a specialization of wxURI for parsing URLs.

Enumerations

- enum wxURLError {
  wxURL_NOERR = 0,
  wxURL_SNTXERR,
  wxURL_NOPROTO,
  wxURL_NOHOST,
  wxURL_NOPATH,
  wxURL_CONNERR,
  wxURL_PROTOERR }

  Error types returned from wxURL::GetError().

22.483.1 Enumeration Type Documentation

enum wxURLError

Error types returned from wxURL::GetError().

Enumerator

wxURL_NOERR No error.

wxURL_SNTXERR Syntax error in the URL string.

wxURL_NOPROTO Found no protocol which can get this URL.

wxURL_NOHOST A host name is required for this protocol.

wxURL_NOPATH A path is required for this protocol.

wxURL_CONNERR Connection error.

wxURL_PROTOERR An error occurred during negotiation.

22.484 interface/wx/ustring.h File Reference

Classes

- class wxUString

  wxUString is a class representing a Unicode character string where each character is stored using a 32-bit value.

Functions

- wxUString operator+ (const wxUString &s1, const wxUString &s2)

  Concatenation operator.
- bool operator== (const wxUString &s1, const wxUString &s2)

  Equality operator.
- bool operator!= (const wxUString &s1, const wxUString &s2)

  Inequality operator.
- bool operator< (const wxUString &s1, const wxUString &s2)

  Comparison operator.
- bool operator> (const wxUString &s1, const wxUString &s2)

  Comparison operator.
- bool operator<= (const wxUString &s1, const wxUString &s2)

  Comparison operator.
- bool operator>= (const wxUString &s1, const wxUString &s2)

  Comparison operator.

22.484.1 Function Documentation

bool operator!= (const wxUString & *s1*, const wxUString & *s2*) `[inline]`

Inequality operator.

wxUString additionally provides overloads for wxString, C string, UTF-16 strings, 32-bit strings, char buffers, single characters etc.

wxUString operator+ (const wxUString & *s1*, const wxUString & *s2*) `[inline]`

Concatenation operator.

wxUString additionally provides overloads for wxString, C string, UTF-16 strings, 32-bit strings, char buffers, single characters etc.

bool operator< (const wxUString & *s1*, const wxUString & *s2*) `[inline]`

Comparison operator.

wxUString additionally provides overloads for wxString, C string, UTF-16 strings, 32-bit strings, char buffers, single characters etc.

bool operator<= (const wxUString & *s1,* const wxUString & *s2*) `[inline]`

Comparison operator.

wxUString additionally provides overloads for wxString, C string, UTF-16 strings, 32-bit strings, char buffers, single characters etc.

bool operator== (const wxUString & *s1,* const wxUString & *s2*) `[inline]`

Equality operator.

wxUString additionally provides overloads for wxString, C string, UTF-16 strings, 32-bit strings, char buffers, single characters etc.

bool operator> (const wxUString & *s1,* const wxUString & *s2*) `[inline]`

Comparison operator.

wxUString additionally provides overloads for wxString, C string, UTF-16 strings, 32-bit strings, char buffers, single characters etc.

bool operator>= (const wxUString & *s1,* const wxUString & *s2*) `[inline]`

Comparison operator.

wxUString additionally provides overloads for wxString, C string, UTF-16 strings, 32-bit strings, char buffers, single characters etc.

22.485 interface/wx/utils.h File Reference

Classes

- class wxWindowDisabler

  This class disables all windows of the application (may be with the exception of one of them) in its constructor and enables them back in its destructor.

- class wxBusyCursor

  This class makes it easy to tell your user that the program is temporarily busy.

- struct wxExecuteEnv

  This structure can optionally be passed to wxExecute() to specify additional options to use for the child process.

Typedefs

- typedef wxStringToStringHashMap wxEnvVariableHashMap

  A map type containing environment variables names and values.

- typedef int(∗ wxSortCallback)(const void ∗pItem1, const void ∗pItem2, const void ∗user_data)

  Compare function type for use with wxQsort()

Enumerations

- enum wxSignal {
  wxSIGNONE = 0,
  wxSIGHUP,
  wxSIGINT,
  wxSIGQUIT,
  wxSIGILL,
  wxSIGTRAP,
  wxSIGABRT,
  wxSIGEMT,
  wxSIGFPE,
  wxSIGKILL,
  wxSIGBUS,
  wxSIGSEGV,
  wxSIGSYS,
  wxSIGPIPE,
  wxSIGALRM,
  wxSIGTERM }

  Signal constants used by wxProcess.
- enum wxKillError {
  wxKILL_OK,
  wxKILL_BAD_SIGNAL,
  wxKILL_ACCESS_DENIED,
  wxKILL_NO_PROCESS,
  wxKILL_ERROR }

  Return values for wxProcess::Kill.
- enum wxKillFlags {
  wxKILL_NOCHILDREN = 0,
  wxKILL_CHILDREN = 1 }
- enum wxShutdownFlags {
  wxSHUTDOWN_FORCE = 1,
  wxSHUTDOWN_POWEROFF = 2,
  wxSHUTDOWN_REBOOT = 4,
  wxSHUTDOWN_LOGOFF = 8 }
- enum {
  wxStrip_Mnemonics = 1,
  wxStrip_Accel = 2,
  wxStrip_All = wxStrip_Mnemonics | wxStrip_Accel }

  flags for wxStripMenuCodes
- enum {
  wxEXEC_ASYNC = 0,
  wxEXEC_SYNC = 1,
  wxEXEC_SHOW_CONSOLE = 2,
  wxEXEC_MAKE_GROUP_LEADER = 4,
  wxEXEC_NODISABLE = 8,
  wxEXEC_NOEVENTS = 16,
  wxEXEC_HIDE_CONSOLE = 32,
  wxEXEC_BLOCK = wxEXEC_SYNC | wxEXEC_NOEVENTS }

  Bit flags that can be used with wxExecute().

Functions

- void wxBeginBusyCursor (const wxCursor *cursor=wxHOURGLASS_CURSOR)

  Changes the cursor to the given cursor for all windows in the application.
- void wxEndBusyCursor ()

Changes the cursor back to the original cursor, for all windows in the application.

- bool wxIsBusy ()

  Returns true if between two wxBeginBusyCursor() and wxEndBusyCursor() calls.

- void wxBell ()

  Ring the system bell.

- void wxInfoMessageBox (wxWindow *parent)

  Shows a message box with the information about the wxWidgets build used, including its version, most important build parameters and the version of the underlying GUI toolkit.

- wxVersionInfo wxGetLibraryVersionInfo ()

  Get wxWidgets version information.

- wxChar * wxGetenv (const wxString &var)

  This is a macro defined as `getenv()` or its wide char version in Unicode mode.

- bool wxGetEnv (const wxString &var, wxString *value)

  Returns the current value of the environment variable var in value.

- bool wxSetEnv (const wxString &var, const wxString &value)

  Sets the value of the environment variable var (adding it if necessary) to value.

- bool wxUnsetEnv (const wxString &var)

  Removes the variable var from the environment.

- bool wxGetEnvMap (wxEnvVariableHashMap *map)

  Fill a map with the complete content of current environment.

- wxBatteryState wxGetBatteryState ()

  Returns battery state as one of `wxBATTERY_NORMAL_STATE`, `wxBATTERY_LOW_STATE`, `wxBATTERY_CRITICAL_STATE`, `wxBATTERY_SHUTDOWN_STATE` or `wxBATTERY_UNKNOWN_STATE`.

- wxPowerType wxGetPowerType ()

  Returns the type of power source as one of `wxPOWER_SOCKET`, `wxPOWER_BATTERY` or `wxPOWER_UNKNOWN`.

- wxString wxGetDisplayName ()

  Under X only, returns the current display name.

- bool wxGetKeyState (wxKeyCode key)

  For normal keys, returns true if the specified key is currently down.

- wxPoint wxGetMousePosition ()

  Returns the mouse position in screen coordinates.

- wxMouseState wxGetMouseState ()

  Returns the current state of the mouse.

- void wxEnableTopLevelWindows (bool enable=true)

  This function enables or disables all top level windows.

- wxWindow * wxFindWindowAtPoint (const wxPoint &pt)

  Find the deepest window at the given mouse position in screen coordinates, returning the window if found, or NULL if not.

- wxWindow * wxFindWindowByLabel (const wxString &label, wxWindow *parent=NULL)
- wxWindow * wxFindWindowByName (const wxString &name, wxWindow *parent=NULL)
- int wxFindMenuItemId (wxFrame *frame, const wxString &menuString, const wxString &itemString)

  Find a menu item identifier associated with the given frame's menu bar.

- int wxNewId ()
- void wxRegisterId (int id)

  Ensures that Ids subsequently generated by wxNewId() do not clash with the given id.

- bool wxLaunchDefaultApplication (const wxString &document, int flags=0)

  Opens the document in the application associated with the files of this type.

- bool wxLaunchDefaultBrowser (const wxString &url, int flags=0)

  Opens the url in user's default browser.

- bool wxLoadUserResource (const void **outData, size_t *outLen, const wxString &resourceName, const wxChar *resourceType="TEXT", WXHINSTANCE module=0)

  Loads an object from Windows resource file.

- char * wxLoadUserResource (const wxString &resourceName, const wxChar *resourceType="TEXT", int *pLen=NULL, WXHINSTANCE module=0)

  Loads a user-defined Windows resource as a string.
- void wxPostDelete (wxObject *object)
- void wxQsort (void *pbase, size_t total_elems, size_t size, wxSortCallback cmp, const void *user_data)

  Function implementing quick sort algorithm.
- void wxSetDisplayName (const wxString &displayName)

  Under X only, sets the current display name.
- wxString wxStripMenuCodes (const wxString &str, int flags=wxStrip_All)

  Strips any menu codes from str and returns the result.
- wxString wxGetEmailAddress ()

  Copies the user's email address into the supplied buffer, by concatenating the values returned by wxGetFullHostName() and wxGetUserId().
- bool wxGetEmailAddress (char *buf, int sz)
- wxMemorySize wxGetFreeMemory ()

  Returns the amount of free memory in bytes under environments which support it, and -1 if not supported or failed to perform measurement.
- wxString wxGetHomeDir ()

  Return the (current) user's home directory.
- wxString wxGetHostName ()

  Copies the current host machine's name into the supplied buffer.
- bool wxGetHostName (char *buf, int sz)
- wxString wxGetFullHostName ()

  Returns the FQDN (fully qualified domain host name) or an empty string on error.
- wxString wxGetUserHome (const wxString &user=wxEmptyString)

  Returns the home directory for the given user.
- wxString wxGetUserId ()

  This function returns the "user id" also known as "login name" under Unix (i.e.
- bool wxGetUserId (char *buf, int sz)
- wxString wxGetUserName ()

  This function returns the full user name (something like "Mr. John Smith").
- bool wxGetUserName (char *buf, int sz)
- wxString wxGetOsDescription ()

  Returns the string containing the description of the current platform in a user-readable form.
- wxOperatingSystemId wxGetOsVersion (int *major=NULL, int *minor=NULL)

  Gets the version and the operating system ID for currently running OS.
- bool wxIsPlatform64Bit ()

  Returns true if the operating system the program is running under is 64 bit.
- bool wxIsPlatformLittleEndian ()

  Returns true if the current platform is little endian (instead of big endian).
- wxLinuxDistributionInfo wxGetLinuxDistributionInfo ()

  Returns a structure containing information about the currently running Linux distribution.
- long wxExecute (const wxString &command, int flags=wxEXEC_ASYNC, wxProcess *callback=NULL, const wxExecuteEnv *env=NULL)

  Executes another program in Unix or Windows.
- long wxExecute (char **argv, int flags=wxEXEC_ASYNC, wxProcess *callback=NULL, const wxExecuteEnv *env=NULL)

  This is an overloaded version of wxExecute(const wxString&,int,wxProcess), please see its documentation for general information.*
- long wxExecute (wchar_t **argv, int flags=wxEXEC_ASYNC, wxProcess *callback=NULL, const wxExecuteEnv *env=NULL)
- long wxExecute (const wxString &command, wxArrayString &output, int flags=0, const wxExecuteEnv *env=NULL)

This is an overloaded version of wxExecute(const wxString&,int,wxProcess∗), please see its documentation for general information.

- long wxExecute (const wxString &command, wxArrayString &output, wxArrayString &errors, int flags=0, const wxExecuteEnv ∗env=NULL)

  This is an overloaded version of wxExecute(const wxString&,int,wxProcess∗), please see its documentation for general information.
- unsigned long wxGetProcessId ()

  Returns the number uniquely identifying the current process in the system.
- int wxKill (long pid, wxSignal sig=wxSIGTERM, wxKillError ∗rc=NULL, int flags=wxKILL_NOCHILDREN)

  Equivalent to the Unix kill function: send the given signal sig to the process with PID pid.
- bool wxShell (const wxString &command=wxEmptyString)

  Executes a command in an interactive shell window.
- bool wxShutdown (int flags=wxSHUTDOWN_POWEROFF)

  This function shuts down or reboots the computer depending on the value of the flags.
- void wxMicroSleep (unsigned long microseconds)

  Sleeps for the specified number of microseconds.
- void wxMilliSleep (unsigned long milliseconds)

  Sleeps for the specified number of milliseconds.
- wxString wxNow ()

  Returns a string representing the current date and time.
- void wxSleep (int secs)

  Sleeps for the specified number of seconds.
- void wxUsleep (unsigned long milliseconds)

22.485.1 Enumeration Type Documentation

enum wxKillError

Return values for wxProcess::Kill.

Enumerator

wxKILL_OK no error
wxKILL_BAD_SIGNAL no such signal
wxKILL_ACCESS_DENIED permission denied
wxKILL_NO_PROCESS no such process
wxKILL_ERROR another, unspecified error

enum wxKillFlags

Enumerator

wxKILL_NOCHILDREN don't kill children
wxKILL_CHILDREN kill children

enum wxShutdownFlags

Enumerator

wxSHUTDOWN_FORCE can be combined with other flags (MSW-only)
wxSHUTDOWN_POWEROFF power off the computer
wxSHUTDOWN_REBOOT shutdown and reboot
wxSHUTDOWN_LOGOFF close session (currently MSW-only)

enum wxSignal

Signal constants used by wxProcess.

Enumerator

wxSIGNONE verify if the process exists under Unix

wxSIGHUP

wxSIGINT

wxSIGQUIT

wxSIGILL

wxSIGTRAP

wxSIGABRT

wxSIGEMT

wxSIGFPE

wxSIGKILL forcefully kill, dangerous!

wxSIGBUS

wxSIGSEGV

wxSIGSYS

wxSIGPIPE

wxSIGALRM

wxSIGTERM terminate the process gently

22.486 interface/wx/valgen.h File Reference

Classes

- class wxGenericValidator

  wxGenericValidator performs data transfer (but not validation or filtering) for many type of controls.

22.487 interface/wx/validate.h File Reference

Classes

- class wxValidator

  wxValidator is the base class for a family of validator classes that mediate between a class of control, and application data.

Variables

- const wxValidator wxDefaultValidator

  An empty, "null" wxValidator instance.

22.487.1 Variable Documentation

const wxValidator wxDefaultValidator

An empty, "null" wxValidator instance.

22.488 interface/wx/valnum.h File Reference

Classes

- class wxNumValidator< T >

  wxNumValidator is the common base class for numeric validator classes.
- class wxIntegerValidator< T >

  Validator for text entries used for integer entry.
- class wxFloatingPointValidator< T >

  Validator for text entries used for floating point numbers entry.

Enumerations

- enum wxNumValidatorStyle {
  wxNUM_VAL_DEFAULT = 0,
  wxNUM_VAL_THOUSANDS_SEPARATOR = 1,
  wxNUM_VAL_ZERO_AS_BLANK = 2,
  wxNUM_VAL_NO_TRAILING_ZEROES }

  Bit masks used for numeric validator styles.

Functions

- template<typename T >
  wxIntegerValidator< T > wxMakeIntegerValidator (T *value, int style=wxNUM_VAL_DEFAULT)

  Creates a wxIntegerValidator object with automatic type deduction.

- template<typename T >
  wxFloatingPointValidator< T > wxMakeFloatingPointValidator (T *value, int style=wxNUM_VAL_DEFAULT)

  Creates a wxFloatingPointValidator object with automatic type deduction.
- template<typename T >
  wxFloatingPointValidator< T > wxMakeFloatingPointValidator (int precision, T *value, int style=wxNUM_V↩
  AL_DEFAULT)

  Creates a wxFloatingPointValidator object with automatic type deduction.

22.488.1 Function Documentation

template<typename T > wxFloatingPointValidator<T> wxMakeFloatingPointValidator (T * *value,* int *style =* wxNUM_VAL_DEFAULT) [inline]

Creates a wxFloatingPointValidator object with automatic type deduction.

Similarly to wxMakeIntegerValidator(), this function allows to avoid explicitly specifying the validator type.

Since

2.9.2

template<typename T > wxFloatingPointValidator<T> wxMakeFloatingPointValidator (int *precision,* T * *value,* int *style* = wxNUM_VAL_DEFAULT) [inline]

Creates a wxFloatingPointValidator object with automatic type deduction.

Similarly to wxMakeIntegerValidator(), this function allows to avoid explicitly specifying the validator type.

Since

2.9.2

template<typename T > wxIntegerValidator<T> wxMakeIntegerValidator (T * *value*, int *style* = wxNUM_VAL_DEFAULT)

Creates a wxIntegerValidator object with automatic type deduction.

This function can be used to create wxIntegerValidator object without explicitly specifying its type, e.g. write just:

```
1 new wxTextCtrl(..., wxMakeIntegerValidator(&m_var));
```

instead of more verbose

```
1 new wxTextCtrl(..., wxIntegerValidator<unsigned long>(&m_var));
```

Since

2.9.2

22.489 interface/wx/valtext.h File Reference

Classes

- class wxTextValidator

  wxTextValidator validates text controls, providing a variety of filtering behaviours.

Enumerations

- enum wxTextValidatorStyle {
  wxFILTER_NONE,
  wxFILTER_EMPTY,
  wxFILTER_ASCII,
  wxFILTER_ALPHA,
  wxFILTER_ALPHANUMERIC,
  wxFILTER_DIGITS,
  wxFILTER_NUMERIC,
  wxFILTER_INCLUDE_LIST,
  wxFILTER_INCLUDE_CHAR_LIST,
  wxFILTER_EXCLUDE_LIST,
  wxFILTER_EXCLUDE_CHAR_LIST }

  Styles used by wxTextValidator.

22.489.1 Enumeration Type Documentation

enum wxTextValidatorStyle

Styles used by wxTextValidator.

Note that when you specify more styles in wxTextValidator the validation checks are performed in the order in which the styles of this enumeration are defined.

Enumerator

wxFILTER_NONE No filtering takes place.

wxFILTER_EMPTY Empty strings are filtered out. If this style is not specified then empty strings are accepted only if they pass the other checks (if you use more than one wxTextValidatorStyle).

wxFILTER_ASCII Non-ASCII characters are filtered out. See wxString::IsAscii.

wxFILTER_ALPHA Non-alpha characters are filtered out. Uses the wxWidgets wrapper for the standard CRT function `isalpha` (which is locale-dependent) on all characters of the string.

wxFILTER_ALPHANUMERIC Non-alphanumeric characters are filtered out. Uses the wxWidgets wrapper for the standard CRT function `isalnum` (which is locale-dependent) on all characters of the string.

wxFILTER_DIGITS Non-numeric characters are filtered out. Uses the wxWidgets wrapper for the standard CRT function `isdigit` (which is locale-dependent) on all characters of the string.

wxFILTER_NUMERIC Non-numeric characters are filtered out. Works like `wxFILTER_DIGITS` but allows also decimal points, minus/plus signs and the 'e' or 'E' character to input exponents. Note that this is not the same behaviour of wxString::IsNumber().

wxFILTER_INCLUDE_LIST Use an include list. The validator checks if the user input is on the list, complaining if not. See wxTextValidator::SetIncludes().

wxFILTER_INCLUDE_CHAR_LIST Use an include list. The validator checks if each input character is in the list (one character per list element), complaining if not. See wxTextValidator::SetCharIncludes().

wxFILTER_EXCLUDE_LIST Use an exclude list. The validator checks if the user input is on the list, complaining if it is. See wxTextValidator::SetExcludes().

wxFILTER_EXCLUDE_CHAR_LIST Use an exclude list. The validator checks if each input character is in the list (one character per list element), complaining if it is. See wxTextValidator::SetCharExcludes().

22.490 interface/wx/variant.h File Reference

Classes

- class wxVariant

  The wxVariant class represents a container for any type.
- class wxVariantData

  The wxVariantData class is used to implement a new type for wxVariant.

Macros

- #define wxGetVariantCast(var, classname)

  This macro returns a pointer to the data stored in var (wxVariant) cast to the type classname if the data is of this type (the check is done during the run-time) or NULL otherwise.

22.491 interface/wx/vector.h File Reference

Classes

- class wxVector< T >

  wxVector<T> is a template class which implements most of the `std::vector` class and can be used like it.

Functions

- template<typename T >
  void wxVectorSort (wxVector< T > &v)

  Sort the contents of a `wxVector<T>`.

22.491.1 Function Documentation

template<typename T > void wxVectorSort (wxVector< T > & *v*)

Sort the contents of a wxVector<T>.

In a STL build this function will be defined as a thin wrapper around std::sort. To be sortable the contained type must support the less-than operator.

```
1 wxVector<SomeClass> v;
2 ... // items are added to the vector v...
3 wxVectorSort(v);
```

See also

wxVector<T>

22.492 interface/wx/version.h File Reference

Macros

- #define wxCHECK_VERSION(major, minor, release)

  This is a macro which evaluates to true if the current wxWidgets version is at least major.minor.release.
- #define wxCHECK_VERSION_FULL(major, minor, release, subrel)

  Same as wxCHECK_VERSION() but also checks that wxSUBRELEASE_NUMBER is at least subrel.

22.493 interface/wx/versioninfo.h File Reference

Classes

- class wxVersionInfo

  wxVersionInfo contains version information.

22.494 interface/wx/vidmode.h File Reference

Classes

- struct wxVideoMode

  Determines the sizes and locations of displays connected to the system.

Variables

- const wxVideoMode wxDefaultVideoMode

  A global wxVideoMode instance used by wxDisplay.

22.494.1 Variable Documentation

const wxVideoMode wxDefaultVideoMode

A global wxVideoMode instance used by wxDisplay.

22.495 interface/wx/vlbox.h File Reference

Classes

- class wxVListBox

  wxVListBox is a wxListBox-like control with the following two main differences from a regular wxListBox: it can have an arbitrarily huge number of items because it doesn't store them itself but uses the OnDrawItem() callback to draw them (so it is a virtual listbox) and its items can have variable height as determined by OnMeasureItem() (so it is also a listbox with the lines of variable height).

22.496 interface/wx/volume.h File Reference

Classes

- class wxFSVolume

  wxFSVolume represents a volume (also known as 'drive') in a file system under wxMSW.

Enumerations

- enum wxFSVolumeFlags {
  wxFS_VOL_MOUNTED = 0x0001,
  wxFS_VOL_REMOVABLE = 0x0002,
  wxFS_VOL_READONLY = 0x0004,
  wxFS_VOL_REMOTE = 0x0008 }

  The volume flags.
- enum wxFSVolumeKind {
  wxFS_VOL_FLOPPY,
  wxFS_VOL_DISK,
  wxFS_VOL_CDROM,
  wxFS_VOL_DVDROM,
  wxFS_VOL_NETWORK,
  wxFS_VOL_OTHER,
  wxFS_VOL_MAX }

  The volume types.
- enum wxFSIconType {
  wxFS_VOL_ICO_SMALL = 0,
  wxFS_VOL_ICO_LARGE,
  wxFS_VOL_ICO_SEL_SMALL,
  wxFS_VOL_ICO_SEL_LARGE,
  wxFS_VOL_ICO_MAX }

  Icon types used by wxFSVolume.

22.496.1 Enumeration Type Documentation

enum wxFSIconType

Icon types used by wxFSVolume.

Enumerator

wxFS_VOL_ICO_SMALL

wxFS_VOL_ICO_LARGE

wxFS_VOL_ICO_SEL_SMALL

wxFS_VOL_ICO_SEL_LARGE
wxFS_VOL_ICO_MAX

enum wxFSVolumeFlags

The volume flags.

Enumerator

wxFS_VOL_MOUNTED Is the volume mounted?
wxFS_VOL_REMOVABLE Is the volume removable (floppy, CD, ...)?
wxFS_VOL_READONLY Read only? (otherwise read write).
wxFS_VOL_REMOTE Network resources.

enum wxFSVolumeKind

The volume types.

Enumerator

wxFS_VOL_FLOPPY
wxFS_VOL_DISK
wxFS_VOL_CDROM
wxFS_VOL_DVDROM
wxFS_VOL_NETWORK
wxFS_VOL_OTHER
wxFS_VOL_MAX

22.497 interface/wx/vscroll.h File Reference

Classes

- class wxVarScrollHelperBase

  This class provides all common base functionality for scroll calculations shared among all variable scrolled window implementations as well as automatic scrollbar functionality, saved scroll positions, controlling target windows to be scrolled, as well as defining all required virtual functions that need to be implemented for any orientation specific work.
- class wxVarVScrollHelper

  This class provides functions wrapping the wxVarScrollHelperBase class, targeted for vertical-specific scrolling.
- class wxVarHScrollHelper

  This class provides functions wrapping the wxVarScrollHelperBase class, targeted for horizontal-specific scrolling.
- class wxVarHVScrollHelper

  This class provides functions wrapping the wxVarHScrollHelper and wxVarVScrollHelper classes, targeted for scrolling a window in both axis.
- class wxVScrolledWindow

  In the name of this class, "V" may stand for "variable" because it can be used for scrolling rows of variable heights; "virtual", because it is not necessary to know the heights of all rows in advance – only those which are shown on the screen need to be measured; or even "vertical", because this class only supports scrolling vertically.
- class wxHScrolledWindow

  In the name of this class, "H" stands for "horizontal" because it can be used for scrolling columns of variable widths.
- class wxHVScrolledWindow

  This window inherits all functionality of both vertical and horizontal, variable scrolled windows.

22.498 interface/wx/weakref.h File Reference

Classes

- class wxWeakRefDynamic< T >

  wxWeakRefDynamic<T> is a template class for weak references that is used in the same way as wxWeakRef<T>.
- class wxWeakRef< T >

  wxWeakRef<T> is a template class for weak references to wxWidgets objects, such as wxEvtHandler, wxWindow and wxObject.

22.499 interface/wx/webview.h File Reference

Classes

- class wxWebViewHistoryItem

  A simple class that contains the URL and title of an element of the history of a wxWebView.
- class wxWebViewFactory

  An abstract factory class for creating wxWebView backends.
- class wxWebViewHandler

  The base class for handling custom schemes in wxWebView, for example to allow virtual file system support.
- class wxWebView

  This control may be used to render web (HTML / CSS / javascript) documents.
- class wxWebViewEvent

  A navigation event holds information about events associated with wxWebView objects.

Enumerations

- enum wxWebViewZoom {
  wxWEBVIEW_ZOOM_TINY,
  wxWEBVIEW_ZOOM_SMALL,
  wxWEBVIEW_ZOOM_MEDIUM,
  wxWEBVIEW_ZOOM_LARGE,
  wxWEBVIEW_ZOOM_LARGEST }

  Zoom levels available in wxWebView.
- enum wxWebViewZoomType {
  wxWEBVIEW_ZOOM_TYPE_LAYOUT,
  wxWEBVIEW_ZOOM_TYPE_TEXT }

  The type of zooming that the web view control can perform.
- enum wxWebViewNavigationError {
  wxWEBVIEW_NAV_ERR_CONNECTION,
  wxWEBVIEW_NAV_ERR_CERTIFICATE,
  wxWEBVIEW_NAV_ERR_AUTH,
  wxWEBVIEW_NAV_ERR_SECURITY,
  wxWEBVIEW_NAV_ERR_NOT_FOUND,
  wxWEBVIEW_NAV_ERR_REQUEST,
  wxWEBVIEW_NAV_ERR_USER_CANCELLED,
  wxWEBVIEW_NAV_ERR_OTHER }

  Types of errors that can cause navigation to fail.
- enum wxWebViewReloadFlags {
  wxWEBVIEW_RELOAD_DEFAULT,
  wxWEBVIEW_RELOAD_NO_CACHE }

  Type of refresh.

- enum wxWebViewFindFlags {
  wxWEBVIEW_FIND_WRAP = 0x0001,
  wxWEBVIEW_FIND_ENTIRE_WORD = 0x0002,
  wxWEBVIEW_FIND_MATCH_CASE = 0x0004,
  wxWEBVIEW_FIND_HIGHLIGHT_RESULT = 0x0008,
  wxWEBVIEW_FIND_BACKWARDS = 0x0010,
  wxWEBVIEW_FIND_DEFAULT = 0 }

  Find flags used when searching for text on page.

Variables

- wxEventType wxEVT_WEBVIEW_NAVIGATING
- wxEventType wxEVT_WEBVIEW_NAVIGATED
- wxEventType wxEVT_WEBVIEW_LOADED
- wxEventType wxEVT_WEBVIEW_ERROR
- wxEventType wxEVT_WEBVIEW_NEWWINDOW
- wxEventType wxEVT_WEBVIEW_TITLE_CHANGED

22.499.1 Enumeration Type Documentation

enum wxWebViewFindFlags

Find flags used when searching for text on page.

Enumerator

wxWEBVIEW_FIND_WRAP Causes the search to restart when end or beginning reached.

wxWEBVIEW_FIND_ENTIRE_WORD Matches an entire word when searching.

wxWEBVIEW_FIND_MATCH_CASE Match case, i.e. case sensitive searching

wxWEBVIEW_FIND_HIGHLIGHT_RESULT Highlights the search results.

wxWEBVIEW_FIND_BACKWARDS Searches for phrase in backward direction.

wxWEBVIEW_FIND_DEFAULT The default flag, which is simple searching.

enum wxWebViewNavigationError

Types of errors that can cause navigation to fail.

Enumerator

wxWEBVIEW_NAV_ERR_CONNECTION Connection error (timeout, etc.)

wxWEBVIEW_NAV_ERR_CERTIFICATE Invalid certificate.

wxWEBVIEW_NAV_ERR_AUTH Authentication required.

wxWEBVIEW_NAV_ERR_SECURITY Other security error.

wxWEBVIEW_NAV_ERR_NOT_FOUND Requested resource not found.

wxWEBVIEW_NAV_ERR_REQUEST Invalid request/parameters (e.g. bad URL, bad protocol, unsupported resource type)

wxWEBVIEW_NAV_ERR_USER_CANCELLED The user cancelled (e.g. in a dialog)

wxWEBVIEW_NAV_ERR_OTHER Another (exotic) type of error that didn't fit in other categories.

enum wxWebViewReloadFlags

Type of refresh.

Enumerator

wxWEBVIEW_RELOAD_DEFAULT Default reload, will access cache.

wxWEBVIEW_RELOAD_NO_CACHE Reload the current view without accessing the cache.

enum wxWebViewZoom

Zoom levels available in wxWebView.

Enumerator

wxWEBVIEW_ZOOM_TINY

wxWEBVIEW_ZOOM_SMALL

wxWEBVIEW_ZOOM_MEDIUM default size

wxWEBVIEW_ZOOM_LARGE

wxWEBVIEW_ZOOM_LARGEST

enum wxWebViewZoomType

The type of zooming that the web view control can perform.

Enumerator

wxWEBVIEW_ZOOM_TYPE_LAYOUT The entire layout scales when zooming, including images.

wxWEBVIEW_ZOOM_TYPE_TEXT Only the text changes in size when zooming, images and other layout elements retain their initial size.

22.499.2 Variable Documentation

wxEventType wxEVT_WEBVIEW_ERROR

wxEventType wxEVT_WEBVIEW_LOADED

wxEventType wxEVT_WEBVIEW_NAVIGATED

wxEventType wxEVT_WEBVIEW_NAVIGATING

wxEventType wxEVT_WEBVIEW_NEWWINDOW

wxEventType wxEVT_WEBVIEW_TITLE_CHANGED

22.500 interface/wx/webviewarchivehandler.h File Reference

Classes

- class wxWebViewArchiveHandler

  A custom handler for the file scheme which also supports loading from archives.

22.501 interface/wx/webviewfshandler.h File Reference

Classes

- class wxWebViewFSHandler

  A wxWebView file system handler to support standard wxFileSystem protocols of the form `example:page.htm` *The handler allows wxWebView to use wxFileSystem in a similar fashion to its use with wxHtml.*

22.502 interface/wx/wfstream.h File Reference

Classes

- class wxTempFileOutputStream

  wxTempFileOutputStream is an output stream based on wxTempFile.
- class wxFFileOutputStream

  This class represents data written to a file.
- class wxFileOutputStream

  This class represents data written to a file.
- class wxFileInputStream

  This class represents data read in from a file.
- class wxFFileInputStream

  This class represents data read in from a file.
- class wxFFileStream

  This stream allows to both read from and write to a file using buffered STDIO functions.
- class wxFileStream

  This class represents data that can be both read from and written to a file.

22.503 interface/wx/windowid.h File Reference

Classes

- class wxIdManager

  wxIdManager is responsible for allocating and releasing window IDs.

Typedefs

- typedef int wxWindowID

  The type of unique identifiers (ID) used for wxWindow-derived classes.

22.503.1 Typedef Documentation

typedef int wxWindowID

The type of unique identifiers (ID) used for wxWindow-derived classes.

22.504 interface/wx/windowptr.h File Reference

Classes

- class wxWindowPtr< T >

  A reference-counted smart pointer for holding wxWindow instances.

22.505 interface/wx/withimages.h File Reference

Classes

- class wxWithImages

  A mixin class to be used with other classes that use a wxImageList.

22.506 interface/wx/wizard.h File Reference

Classes

- class wxWizardPage

  wxWizardPage is one of the screens in wxWizard: it must know what are the following and preceding pages (which may be NULL for the first/last page).
- class wxWizardEvent

  wxWizardEvent class represents an event generated by the wxWizard: this event is first sent to the page itself and, if not processed there, goes up the window hierarchy as usual.
- class wxWizardPageSimple

  wxWizardPageSimple is the simplest possible wxWizardPage implementation: it just returns the pointers given to its constructor from wxWizardPage::GetNext() and wxWizardPage::GetPrev() functions.
- class wxWizard

  wxWizard is the central class for implementing 'wizard-like' dialogs.

Macros

- #define wxWIZARD_EX_HELPBUTTON 0x00000010

22.507 interface/wx/wrapsizer.h File Reference

Classes

- class wxWrapSizer

  A wrap sizer lays out its items in a single line, like a box sizer – as long as there is space available in that direction.

Enumerations

- enum {
  wxEXTEND_LAST_ON_EACH_LINE,
  wxREMOVE_LEADING_SPACES,
  wxWRAPSIZER_DEFAULT_FLAGS }

22.507.1 Enumeration Type Documentation

anonymous enum

Enumerator

wxEXTEND_LAST_ON_EACH_LINE

wxREMOVE_LEADING_SPACES

wxWRAPSIZER_DEFAULT_FLAGS

22.508 interface/wx/wupdlock.h File Reference

Classes

- class wxWindowUpdateLocker

  This tiny class prevents redrawing of a wxWindow during its lifetime by using wxWindow::Freeze() and wxWindow::Thaw() methods.

22.509 interface/wx/wxcrt.h File Reference

Functions

- bool wxIsEmpty (const char ∗s)
- bool wxIsEmpty (const wchar_t ∗s)
- bool wxIsEmpty (const wxCharBuffer &s)
- bool wxIsEmpty (const wxWCharBuffer &s)
- bool wxIsEmpty (const wxString &s)
- bool wxIsEmpty (const wxCStrData &s)
- wxChar ∗ wxTmemchr (const wxChar ∗s, wxChar c, size_t l)
- int wxTmemcmp (const wxChar ∗sz1, const wxChar ∗sz2, size_t len)
- wxChar ∗ wxTmemcpy (wxChar ∗szOut, const wxChar ∗szIn, size_t len)
- wxChar ∗ wxTmemmove (wxChar ∗szOut, const wxChar ∗szIn, size_t len)
- wxChar ∗ wxTmemset (wxChar ∗szOut, const wxChar cIn, size_t len)
- char ∗ wxTmemchr (const char ∗s, char c, size_t len)
- int wxTmemcmp (const char ∗sz1, const char ∗sz2, size_t len)
- char ∗ wxTmemcpy (char ∗szOut, const char ∗szIn, size_t len)
- char ∗ wxTmemmove (char ∗szOut, const char ∗szIn, size_t len)
- char ∗ wxTmemset (char ∗szOut, const char cIn, size_t len)
- char ∗ wxSetlocale (int category, const wxCharBuffer &locale)
- char ∗ wxSetlocale (int category, const wxString &locale)
- char ∗ wxSetlocale (int category, const wxCStrData &locale)
- size_t wxStrlen (const wxCharBuffer &s)
- size_t wxStrlen (const wxWCharBuffer &s)
- size_t wxStrlen (const wxString &s)
- size_t wxStrlen (const wxCStrData &s)
- size_t wxStrnlen (const char ∗str, size_t maxlen)
- size_t wxStrnlen (const wchar_t ∗str, size_t maxlen)
- char ∗ wxStrdup (const wxCharBuffer &s)
- wchar_t ∗ wxStrdup (const wxWCharBuffer &s)
- char ∗ wxStrdup (const wxString &s)
- char ∗ wxStrdup (const wxCStrData &s)
- char ∗ wxStrcpy (char ∗dest, const char ∗src)
- wchar_t ∗ wxStrcpy (wchar_t ∗dest, const wchar_t ∗src)
- char ∗ wxStrcpy (char ∗dest, const wxString &src)
- char ∗ wxStrcpy (char ∗dest, const wxCStrData &src)
- char ∗ wxStrcpy (char ∗dest, const wxCharBuffer &src)
- wchar_t ∗ wxStrcpy (wchar_t ∗dest, const wxString &src)
- wchar_t ∗ wxStrcpy (wchar_t ∗dest, const wxCStrData &src)
- wchar_t ∗ wxStrcpy (wchar_t ∗dest, const wxWCharBuffer &src)

- char * wxStrcpy (char *dest, const wchar_t *src)
- wchar_t * wxStrcpy (wchar_t *dest, const char *src)
- char * wxStrncpy (char *dest, const char *src, size_t n)
- wchar_t * wxStrncpy (wchar_t *dest, const wchar_t *src, size_t n)
- char * wxStrncpy (char *dest, const wxString &src, size_t n)
- char * wxStrncpy (char *dest, const wxCStrData &src, size_t n)
- char * wxStrncpy (char *dest, const wxCharBuffer &src, size_t n)
- wchar_t * wxStrncpy (wchar_t *dest, const wxString &src, size_t n)
- wchar_t * wxStrncpy (wchar_t *dest, const wxCStrData &src, size_t n)
- wchar_t * wxStrncpy (wchar_t *dest, const wxWCharBuffer &src, size_t n)
- char * wxStrncpy (char *dest, const wchar_t *src, size_t n)
- wchar_t * wxStrncpy (wchar_t *dest, const char *src, size_t n)

Classes

- class wxXLocale

  This class represents a locale object used by so-called xlocale API.

Functions

- int wxIsalnum_l (wchar_t c, const wxXLocale &loc)
- int wxIsalpha_l (wchar_t c, const wxXLocale &loc)
- int wxIscntrl_l (wchar_t c, const wxXLocale &loc)
- int wxIsdigit_l (wchar_t c, const wxXLocale &loc)
- int wxIsgraph_l (wchar_t c, const wxXLocale &loc)
- int wxIslower_l (wchar_t c, const wxXLocale &loc)
- int wxIsprint_l (wchar_t c, const wxXLocale &loc)
- int wxIspunct_l (wchar_t c, const wxXLocale &loc)
- int wxIsspace_l (wchar_t c, const wxXLocale &loc)
- int wxIsupper_l (wchar_t c, const wxXLocale &loc)
- int wxIsxdigit_l (wchar_t c, const wxXLocale &loc)
- wchar_t wxTolower_l (wchar_t c, const wxXLocale &loc)
- wchar_t wxToupper_l (wchar_t c, const wxXLocale &loc)
- double wxStrtod_l (const wchar_t *c, wchar_t **endptr, const wxXLocale &loc)
- long wxStrtol_l (const wchar_t *c, wchar_t **endptr, int base, const wxXLocale &loc)
- unsigned long wxStrtoul_l (const wchar_t *c, wchar_t **endptr, int base, const wxXLocale &loc)

Variables

- wxXLocale wxNullXLocale

  An empty and invalid wxXLocale object.

22.510.1 Variable Documentation

wxXLocale wxNullXLocale

An empty and invalid wxXLocale object.

22.511 interface/wx/xml/xml.h File Reference

Classes

- class wxXmlNode

  Represents a node in an XML document.
- class wxXmlAttribute

  Represents a node attribute.
- class wxXmlDocument

  This class holds XML data/document as parsed by XML parser in the root node.

Macros

- #define wxXML_NO_INDENTATION (-1)

Enumerations

- enum wxXmlNodeType {
  wxXML_ELEMENT_NODE = 1,
  wxXML_ATTRIBUTE_NODE = 2,
  wxXML_TEXT_NODE = 3,
  wxXML_CDATA_SECTION_NODE = 4,
  wxXML_ENTITY_REF_NODE = 5,
  wxXML_ENTITY_NODE = 6,
  wxXML_PI_NODE = 7,
  wxXML_COMMENT_NODE = 8,
  wxXML_DOCUMENT_NODE = 9,
  wxXML_DOCUMENT_TYPE_NODE = 10,
  wxXML_DOCUMENT_FRAG_NODE = 11,
  wxXML_NOTATION_NODE = 12,
  wxXML_HTML_DOCUMENT_NODE = 13 }

  Represents XML node type.
- enum wxXmlDocumentLoadFlag {
  wxXMLDOC_NONE,
  wxXMLDOC_KEEP_WHITESPACE_NODES }

22.511.1 Macro Definition Documentation

#define wxXML_NO_INDENTATION (-1)

22.511.2 Enumeration Type Documentation

enum wxXmlDocumentLoadFlag

Enumerator

wxXMLDOC_NONE

wxXMLDOC_KEEP_WHITESPACE_NODES

enum wxXmlNodeType

Represents XML node type.

Enumerator

wxXML_ELEMENT_NODE

wxXML_ATTRIBUTE_NODE

wxXML_TEXT_NODE

wxXML_CDATA_SECTION_NODE

wxXML_ENTITY_REF_NODE

wxXML_ENTITY_NODE

wxXML_PI_NODE

wxXML_COMMENT_NODE

wxXML_DOCUMENT_NODE

wxXML_HTML_DOCUMENT_NODE

22.512 interface/wx/xrc/xh_sizer.h File Reference

Classes

- class wxSizerXmlHandler

22.513 interface/wx/xrc/xmlres.h File Reference

Classes

- class wxXmlResource

  This is the main class for interacting with the XML-based resource system.
- class wxXmlResourceHandler

  wxSizerXmlHandler is a class for resource handlers capable of creating a wxSizer object from an XML node.

Enumerations

- enum wxXmlResourceFlags {
  wxXRC_USE_LOCALE = 1,
  wxXRC_NO_SUBCLASSING = 2,
  wxXRC_NO_RELOADING = 4 }

  Flags which can be used with wxXmlResource::wxXmlResource.

22.513.1 Enumeration Type Documentation

enum wxXmlResourceFlags

Flags which can be used with wxXmlResource::wxXmlResource.

Enumerator

wxXRC_USE_LOCALE Translatable strings will be translated via _().

wxXRC_NO_SUBCLASSING Subclass property of object nodes will be ignored (useful for previews in XRC editors).

wxXRC_NO_RELOADING Prevent the XRC files from being reloaded from disk in case they have been modified there since being last loaded (may slightly speed up loading them).

22.514 interface/wx/zipstrm.h File Reference

Classes

- class wxZipNotifier

  If you need to know when a wxZipInputStream updates a wxZipEntry, you can create a notifier by deriving from this abstract base class, overriding wxZipNotifier::OnEntryUpdated().
- class wxZipEntry

  Holds the meta-data for an entry in a zip.
- class wxZipInputStream

  Input stream for reading zip files.
- class wxZipClassFactory

  Class factory for the zip archive format.
- class wxZipOutputStream

  Output stream for writing zip files.

Enumerations

- enum wxZipMethod {
  wxZIP_METHOD_STORE,
  wxZIP_METHOD_SHRINK,
  wxZIP_METHOD_REDUCE1,
  wxZIP_METHOD_REDUCE2,
  wxZIP_METHOD_REDUCE3,
